**AVERAGE MEAN TEMPERATURE** for the ensuing week deduced from observations during the last fifty years at Greenwich, 37.9.

**ACTUAL TEMPERATURE:—**

*Gardeners' Chronicle* Office, 5, Tavistock Street, Covent Garden, London, Wednesday, January 4, 10 a.m.: Bar. 30; temp. 41°. Weather—Sunny.

The year 1921 will be memorable in the annals of horticulture on account of the prolonged drought, which was the severest within living memory. Extremes of weather, either of wet or drought, heat or cold are the most serious problems the gardener has to contend with, and it is not surprising that the drought was reflected in a general failure of many plants and crops in the south, while numerous subjects were killed outright; it was also responsible for some interesting happenings, such as the general flowering of plants that are natives of hot, dry districts. We do not propose to refer further to the drought here, as on another page we are publishing the first instalment of a series of notes from well-known gardeners in different parts of the country on the effects of the drought in their particular districts, in the belief that they will constitute a useful record of the behaviour of garden plants in a season of abnormal dryness.

The year 1921 opened auspiciously, for vegetation was healthy and the weather of early spring reasonable without much frost; moreover, the crops had wintered well. Trees and shrubs made good progress, and early flowering subjects, such as the Almond and Forsythias, were never more beautiful in flower. Fruit trees gave promise of bountiful yields, for fruit buds were plentiful and the wood well ripened. Later, however, the nights turned very cold, with bright sun by day, causing wide fluctuations of day and night temperatures that imposed a severe check upon developing vegetation. Actual frost held off until the fruit blossom was well expanded, but at the end of April and the

beginning of May the fruit blossom of nearly all kinds of fruits was ruined by frost, Apples alone escaping injury. The bountiful Apple crop compensated, in some measure, for the scarcity of nearly all other hardy fruits, and the Imperial Fruit Show at the Crystal Palace in October was an exhibition almost entirely of Apples. As this show was held mainly in the interests of commercial fruit growers, whose principal crop is this fruit, the shortage of other kinds did not affect it, and with plenty of Apples success was assured. This great exhibition doubtless had its inception in the efforts made by growers in such centres of the fruit-growing industry as Maidstone, Cambridge and Hereford, to stimulate the consumption of home-grown fruits, and rather than hold an Imperial Fruit Show annually we think it would be wiser to allow these several organisations to continue their shows, with a big exhibition, say, once in every four or five years. The interest taken in the exhibition by the Ministry of Agriculture proves the great value of the special horticultural department of the Ministry to the gardening industry, and with the Chamber of Horticulture, the Horticultural Trades' Association, and the British Florists' Federation actively engaged in looking after the business interests of the craft, horticulture has ceased to be merely the Cinderella of farming.

The Royal Horticultural Society and the special horticultural associations accomplished much useful work during the past year, and the support all received proves that public interest in gardening is as keen as ever. The progress made by the National Rose Society in the past few years has been phenomenal and the holding of some of its shows in association with the R.H.S. is in the best interests of both societies and of horticulture generally. The National Chrysanthemum Society is to be congratulated on the success of its show, which was entirely of Chrysanthemums and not, as in the past few years, held in conjunction with an R.H.S. fortnightly meeting. The show was held on two days and the hall was thronged with visitors on both dates. We are glad to know that the National Dahlia Society will hold its annual exhibition this year entirely on its own. All these floral societies should continue to look to the Royal Horticultural Society for help in every direction and especially in the matter of providing accommodation for their annual shows. Although, as has been mooted, it might be possible for these special societies to arrange for their exhibitions to be held in a common hall of their own, the centre of horticultural activities in the metropolis should be Vincent Square. The R.H.S. exhibition at Chelsea was as successful as ever, and the Holland House show was one of the best held in Lady Ilchester's beautiful London estate. As it is unlikely that this latter place will be again available for the holding of flower shows, the Council has made arrangements for a great exhibition under cover at Holland Park Rink in October next. The provincial exhibitions, including those at Shrewsbury, York and Birmingham, were well attended and showed a steady return to their pre-war importance. Most of the smaller societies, however, found it difficult to hold their annual shows, as expenses have increased, but not so receipts, and there is the Entertainment Tax to pay in addition. Those responsible for horticultural exhibitions may, of course, drop all additional attractions, such as bands, and thus obtain freedom from the tax, but this would not prove profitable in all cases. Agitation is on foot to form a special society in the interest of Daffodil growers under the

title of the National Daffodil Society, but the latest suggestion is to create a National Bulb Society to embrace all bulbous flowers. The reason may be a wish to force the hands of the R.H.S. to do more for the Daffodil cult, and especially in the matter of literature on the subject, such as the continuation of the *Daffodil Year Book*.

After a period of 134 years the publication of the *Botanical Magazine* was suspended, much to the regret of all lovers of plants, for this work affords easy reference for identification purposes and is to be relied on for its accuracy. The abnormal costs entailed in colour printing nowadays renders such a work as this unprofitable as a commercial proposition and its continuance could only be undertaken by some body with funds at its disposal for the purpose. We are glad to know that the R.H.S. has accepted this responsibility and will continue the publication of the *Botanical Magazine* in 1922.

Our gardens have been enriched during the past year by many new plants and the awards to novelties by the R.H.S. have been as numerous as ever. Plant collectors in China continue to send home large consignments from the flora of that vast country and great hopes are entertained that several useful alpines and Rhododendrons will be forthcoming from the seeds collected by members of the Mount Everest Expedition. One of the saddest events of the year was the death of Mr. Reginald Farrer, in Asia, just as he was terminating his second plant-collecting expedition; it is regrettable, too, that most of the results of his recent labours were lost, as there was no one on the spot to look after his latest packages. We were fortunate in receiving a large amount of MS. from this intrepid collector and brilliant writer a few weeks before his decease, so that we are able to put on record his more recent discoveries. Mr. Kingdon Ward is at present engaged in plant collecting in Asia and we shall continue to publish the series of his articles commenced in these pages last year.

Horticulture has lost by death several other prominent members, notably the veteran Mr. George Paul, whose knowledge of gardening, and especially of Roses and shrubs, was profound—a man loved by his friends and esteemed by all who knew him—Mr. Robert Ballantyne, Mr. Joseph Godseff, Mr. R. A. Rolfe, Mr. James Coey, Mr. Archibald Findlay, Mr. Edwin Molyneux and Mr. William Purdom, all men of ability and whose loss to gardening is great. Altogether the year 1921 was not kind to horticulture, so, with our readers, we look forward to happier conditions and better results in 1922.

**Coloured Supplementary Illustration.**—With the present issue we publish a coloured supplementary illustration of Apple Norfolk Beauty, a description of which is given on p. 11.

**The Sweet Pea Annual, 1922.**—Sweet Pea enthusiasts cannot fail to be interested in the National Sweet Pea Society's Year Book just issued under the title of the *Sweet Pea Annual*. Although the new issue lacks the substantial binding of former years, it is well filled with interesting and instructive matter. Mr. S. B. Dicks adds something to his already numerous discoveries concerning "The Early History of the Sweet Pea," and it appears that Ceylon is now ruled out of court as a possible source of the original Sweet Pea. In the "History of the National Sweet Pea Society" Mr. Charles H. Curtis reviews the work carried out by the Society during the twenty-one years of its existence and makes a special point of the wonderful improvement made in the flower between the years 1900 and 1921. The institution of the Henry Eckford Memorial Medal is recorded, and an appreciation is published of

Mr. R. Bolton, the first holder of this important award. Mr. Andrew Ireland discusses "The Cultivation of Sweet Peas under Glass," and Mr. G. H. Burt contributes an interesting study of "The Life of a Sweet Pea Plant." The interest shown in Sweet Peas by Colonial members is reflected in two contributions from British Columbia and one from New Zealand, and the former are accompanied by illustrations of Sweet Pea seed crops in the far West. The Annual Report and Financial Statement for 1921 are included, as well as an Audit of the first prize exhibits at the show held in July, 1921, the prize-winners at the same exhibition, and an alphabetical list of members and their addresses, but the most important item from the point of view of seedsmen and exhibitors is the report of the Floral Committee upon the trials held at Reading and the up-to-date Classification and Too-much alike Lists. Humour is not wanting, and it is found chiefly in Press cuttings on "Sweet Pea Topics in the Year 1941."

**Trial of Violas at Wisley.**—The Royal Horticultural Society has arranged to carry out a trial of Violas in their gardens at Wisley during the coming year, and growers are invited to send three plants of each of the varieties they desire tried to reach the Director, R.H.S. Gardens, Wisley, Ripley, Surrey (Goods via Horsley Station, L. and S. W. Ry.) on or before February 28, 1922. Entry forms may be obtained from the Director on application.

**War Memorial at the Ministry of Agriculture.**—On the 21st ult. Sir Arthur Griffith Boscawen unveiled, at the Ministry's new offices, 10, Whitehall Place, London, a war memorial to the 38 members of the staff of the Ministry who died on active service in the war. The memorial, which is fixed in the entrance hall, consists of a marble of cartouche form, surmounted by a bronze roundel bearing a replica of the old seal of the Board of Agriculture and Fisheries within a wreath supported by emblems. It was designed by Mr. H. Duncan Hendry, A.R.I.B.A., a member of the Ministry's staff. The names on the tablet include Lord Lucas, a former president of the Board, who was killed near Bapaume in 1916 whilst serving with the Royal Flying Corps.

**French Iris Conference.**—The French National Horticultural Society is organising a Conference, to take place at its own offices in the Rue de Grenelle, Paris, of which the subject will be the Genus Iris, to celebrate the centenary of the raising of the first garden varieties in France by M. de Bures, about the year 1822. The Iris Committee will assemble on the ordinary meeting days of the Society, i.e., the second and fourth Thursdays of each month, from April 1 to July 30 at 2 p.m.. At the height of the flowering season, if there are sufficient exhibits to warrant it, the committee may also meet on the remaining Thursdays, at the same time. Plants and cut flowers should arrive at the Society's office at latest in the morning of Thursday. The Society will undertake to stage any plants the senders of which cannot attend themselves; but the Committee should be informed at least eight days in advance of any exhibits being sent. Cut flowers should be gathered in bud, with the whole of the stem and a few of the lower leaves. They should be carefully packed in such manner as to ensure their being in the best condition on the Committee day. The Conference provides an excellent opportunity to growers of Irises, whether amateurs or professionals, to have their plants examined and doubtful names verified. Exhibits may be awarded prizes, and certificates of merit may be given to new plants of value. Papers sent on the subjects given below will be examined beforehand by the Committee, and will be discussed at the plenary session of the Conference, which will take place on May 27, 1922, at the same time as the horticultural Congress. Papers must be sent to the Iris Committee at least a month in advance. (1) The history of the raising of varieties of garden Irises, groups Pogoniris, germanica, pumila. (2) The history of the introduction, hybridisation, and varieties of *Oncocylus*, *Regelia*, *Regelocylus*, and *Evansia*. (3) The history of the introduction, hybridisation, and varieties of bulbous

Irises of the group *Xyphion*, *Juno*, etc. (4) The history of the introduction, hybridisation, and classification of the varieties of Iris in the group *Apogon* (*Kaempferi*, *sibirica*, *ochroleuca*, etc.). (5) Hybridisation in the genus Iris. (6) Classification of varieties among garden Irises (group *germanica*). (7) Cultivation and multiplication of Irises in the four above-named groups (each group may be treated separately). (8) Utilisation of Irises in the ornamentation of gardens and cool greenhouses, for the production of cut flowers, etc. (9) Pests and diseases of the Iris. (10) Studies of the Iris from the point of view of the perfumer and chemist. (11) Elementary study of the genus Iris from the amateur's point of view. (12) The Iris in decorative arts. Papers treating of the Iris from other points of view will also receive consideration.

**Mr. Frank Ladds.**—Although still a young man, Mr. Frank W. Ladds has been for many years the head of the firm of Philip Ladds, growers for market, of Swanley Junction, Meopham and Bexley Heath. It was at Bexley that his father, the late Mr. Philip Ladds, commenced business as a plant and flower grower about the year 1860, and laid the foundation of

MR. FRANK W. LADDS.

a business which now considers the disposal of 25,000 *Erica hyemalis* just before Christmas to be an ordinary routine item. Bedding plants of most kinds, but especially *Pelargoniums*, are grown in enormous quantities and in fine quality by Mr. Ladds, and other big crops grown in the ten acres of glasshouses or the sixty acres of open ground include several sorts of *Heaths*, *Palms*, *Fuchsias*, *Cyclamen*, *Genistas*, *Solanums*, *Marguerites*, *Ferns*, *Hyacinths*, *Hydrangeas*, *Chrysanthemums* and *Tomatos*. Before taking charge of the business, Mr. Frank Ladds spent about three years with Mr. Sweet, of Whetstone, and he was a very young man to take over so great a responsibility. Nevertheless, he accepted it, and the fame and increasing business of his firm is the measure of his success as plantsman and organiser. In this latter connection Mr. Ladds was extremely useful to his fellow-craftsmen in many ways during the war period, and is still a valuable asset to the plant and flower growing trade by virtue of his official association with the Kent Growers' Association, British Florists' Federation, Horticultural Trades' Association, and last, but not least, the Chamber of Horticulture. Mr. Ladds is a born fighter, but his obvious honesty of purpose and overflowing good humour are probably equally as helpful in winning over his opponents as are his cogent arguments fired off with machine-gun rapidity, but no matter how keen the fight at a Government office, the Railway Clearing House, the Committee Room or the

Council Chamber, or what the result of the fight, Mr. Ladds will shake hands equally heartily with victim or victor, as the case may be, and it is because of this characteristic that he is held in such high esteem by all who have business relations with him. It should be added that Mr. Ladds is a high authority on *Chrysanthemums* and a prominent member of the Floral and Executive Committees of the National Chrysanthemum Society.

**Thefts at a Nursery.**—Two men were sentenced to three months' imprisonment at Enfield Police Court on the 2nd inst, for stealing Carnation blooms from the nurseries of Messrs. Stuart Low and Co., Enfield. Their capture is the sequel to more than a score of similar robberies at the same nurseries during the past two years. The thefts usually occurred just before a flower show, and the choicest blooms were always stolen. Carnations that had been grown especially for exhibiting at the British Carnation Society's show on November 30, 1921, mysteriously disappeared, and the police were called in. The thieves were detected on Christmas Eve leaving a greenhouse with blooms in their possession, and, although they pleaded guilty to the charge on that occasion, they would not admit responsibility for the long series of previous thefts.

**Sweet Potatoes in Queensland.**—The Queensland Department of Agriculture is experimenting in the culture of Sweet Potatoes with a view to improving the type and yield. These excellent tubers have been grown for over fifty years by Queensland farmers, and when Kanakas were employed on the Sugar plantations, it was no uncommon thing for 10,000 acres to be under this crop for the use of the "boys." Lately, smaller quantities have been grown for market and home consumption. Growers have been content with six to eight tons of Sweet Potatoes to the acre, but recent intensive experiments have yielded 30 to 35 tons an acre. Data are now being collected with a view to correct the classification and nomenclature of the many varieties grown in the State. In addition to tubers grown for human consumption or as food for cattle and pigs, attention is being given to those which yield most starch for manufacturing purposes. Should it be possible, as is hoped, to produce and manufacture starch, glucose, power alcohol, and other commercial products from Sweet Potatoes, there will be a great expansion of the cultivation of this crop in Queensland.

**Appointments for the Ensuing Week.**—Monday, January 9, United Horticultural Benefit and Provident Society meet. Wednesday, January 11.—East Anglian Horticultural Society's meeting; lecture by Mr. J. E. Fitt on "Berried Shrubs"; Royal Caledonian Horticultural Society's meeting; Newport and District Gardeners' Association's lecture by Mr. E. Brown on "Winter Flowering Plants in the Greenhouse." Thursday, January 12.—Bristol and District Gardeners' Association's meeting. Friday, January 13.—Paisley Florists Society's meeting.

**"Gardeners' Chronicle" Seventy-five Years Ago.**—*Funkia grandiflora*.—This is one of the greatest conquests made by Dr. Siebold upon the barbarity of the Japanese, and at the same time one of the most precious things introduced into our gardens. It is the most beautiful of all the known species—equally remarkable for the size of its gay foliage as for the profusion and delicious fragrance of its flowers. The leaves are very large, lanceolate, and rather long-vennated, with hardly heart-shaped and little elevated lobes standing on the base. They are of a lively green colour, with distinct swellings between their nerves. The plant bears multitudes of very long, funnel-shaped flowers, which are white as snow, and very sweet. Its calinary bracts are very large, foliaceous, sessile, and bearing flowers. The hardly inflated and campaniform limb is divided into six rather narrow, long, revolute, and blunt segments. The exerted and ascending stamina, reclinate, according to the curvature of the perianth. The style is robust and green, and bears a capitate stigma.—*Ch. L.* (We believe that the sole possessor of this plant is Mr. Van Houtte, of Ghent). *Gard. Chron.*, January 2, 1847.

**ORCHID NOTES AND GLEANINGS.**

**ORCHIDS OF 1921.**

PROGRESS among Orchids was admirably demonstrated during the past year, both in private gardens and trade establishments, and the Orchid displays at the meetings of the Royal Horticultural Society, the Manchester and North of England Orchid Society, and at the provincial shows were better and more numerous than usual.

The Orchid Committee of the Royal Horticultural Society granted thirty-one First-Class Certificates and seventy Awards of Merit, beside a number of Preliminary Commendations to seedlings flowering for the first time.

**AMATEURS.**

Lt.-Col. Sir Geo. L. Holford, K.C.V.O., Westonbirt, Tetbury (gr. Mr. H. G. Alexander), whose grand display of Cypripediums at the last show of the year will be long remembered, received four First-Class Certificates and a number of Awards of Merit, the higher award being secured for *Sopbro-Laelio-Cattleya Falcon* (*S. grandiflora* × *L.-C. Aureole*), the best rich scarlet of the year, and an interesting instance of successful scientific methods; *Laelio-Cattleya Orange Blossom*, a grand, rich yellow; *Cymbidium Landrail*, and *C. Dragonfly*. Among Sir Geo. L. Holford's other awards were those to *Cattleya Mary Sander* with a fine head of white flowers; *C. Fabia*, Westonbirt variety, the richest in colour of the set evolved at Westonbirt; the pretty *Odontoglossum Lady Avice Menzies*; some pretty new Cypripediums and *Cymbidium Martin*.

Baron Bruno Schröder, The Dell Park, Englefield Green (gr. Mr. J. E. Shill), received First-Class Certificates for the fine, white-petalled *Laelio-Cattleya Schröderae* var. *The Conqueror*; *L.-C. Ivanhoe*, The Dell variety; *L.-C. Mrs. Willoughby Pemberton*; *L.-C. Golden Glow*; the clear yellow *Brasso-Cattleya Mrs. J. Leemann*, The Dell variety; the rich yellow *Brasso-Laelio-Cattleya maculata aurea*, and for the large and handsome *Dendrobium Model*, The Dell variety; the best of the other plants to gain awards were *Laelio-Cattleya Victrix*, which shows evidence of *Cattleya Trianae Backhousiana* in its petals in a marked degree.

Sir Jeremiah Colman, Bart., Gatton Park (gr. Mr. J. Collier), the largest amateur exhibitor of the year, added to his noted collection of white *Brassavola* hybrids, raised at Gatton, the charming *Brasso-Cattleya speciosa* var. *Lady Colman*, a clear white flower, of fine size, for which a First-Class Certificate was secured; and *Brasso-Cattleya Gatton Snowflake*; two other very remarkable hybrids being *Laelio-Cattleya Copper King*, unique in colour; and *Dendrobium Gatton Sunray*, a clear yellow *D. Dalhousieanum* cross.

W. R. Fasey, Esq., Holly Bush Hill, Snaresbrook (gr. Mr. E. J. Seymont), one of the most constant exhibitors, especially of fine *Odontoglossums*, received a First-Class Certificate for the very richly coloured *Odontonia W. R. Fasey* (*M. Venus* × *Odm. Louise*), and Awards of Merit for *Odontoglossum Rufus*, *O. Barnaby Rudge*, *O. Sandow*, *O. Faustina*, *O. Chu Chin Chow*, curious *O. aspersum* cross; *O. Desdemona*, *O. Gloriette*, *Odontidea Nubia Fasey's* variety, and *Miltonia vexillaria Purple Emperor*, a remarkable dark rose-purple flower.

H. T. Pitt, Esq., Rossllyn, Stamford Hill (gr. Mr. Thurgood), exhibited regularly, his groups being always of special interest by reason of the selections of rare species included. Fine *Miltonias* were a feature with him last season. *M. Venus* var. *Fascinator* securing a First-Class Certificate, whilst the fine golden yellow *Brasso-Laelio-Cattleya Golden Crown*, the richly coloured *Odontoglossum Bullecourt*, and *Laelio-Cattleya General Maude* var. *Rubens* gained Awards of Merit.

Pantia Ralli, Esq., Ashtead Park (Orchid grower Mr. Farnes), received Awards for *Laelio-Cattleya Sargon Ralli's* var., *L.-C. Canary II.*, a very pretty yellow, and *Odontoglossum Phillipsianum*.

Other remarkable exhibits shown by amateurs and receiving recognition were the beautiful *Vanda coerulea* *Bodnant Rose* of Lady Aberconway; the showy *Brasso-Cattleya Heatherwood*

var. *Prince of Wales* of J. J. Joicey, Esq., both F.C.C. plants; the large and handsome *Cymbidium Alexanderi giganteum* of Mrs. Bischoffsheim; *Cattleya Pittportia* var. *Lady Leon*, and *Cypripedium Lady Leon*, of Sir H. S. Leon; the very fine *Cypripedium Bedfordiae*, shown by Dr. Bedford, and some showy novelties shown by the Duke of Marlborough on various occasions.

(To be concluded.)

**THE BULB GARDEN.**

**LILIUM TESTACEUM.**

I AM somewhat surprised that Mr. Arnett (see p. 309, vol. LXX) should recommend planting bulbs of this Lily at a depth from six to nine inches. That may succeed in very sandy soil; but as it is not a stem-rooting species, in ordinary garden soil I find that three or four

**FUNKIAS.**

FUNKIAS hold a very high place among hardy herbaceous plants with bold, handsome foliage, and they are eminently suited for planting in a variety of positions in the garden. The several species and varieties vary considerably in their flowers and foliage. The handsome *F. Sieboldiana* (see Fig. 1) makes a fine marginal line for a shrubbery border, and may be used with good effect as a permanent edging to large beds that are filled either with hardy or tender summer subjects to produce a sub-tropical effect. They are also useful for grouping in front of the herbaceous border where bold foliage groups are required. Funkias are accommodating plants, and strong clumps may safely be divided and replanted at almost any time from autumn until spring. They grow best in a deep, rich, free soil, and, like most strong-growing herbaceous plants, enjoy liberal supplies of well-decayed

FIG. 1.—FUNKIA SIEBOLDIANA.

inches is ample. It seems to share with one of its reputed parents, the *Madonna Lily*, a preference for shallow planting, and all the sun it can get. It may be noted that *L. chalcedonicum*, its other reputed parent, is not a stem-rooting species.

It is a pity that the older specific name for the *Nankin Lily*, *isabellinum*, has been dropped in favour of *testaceum*, which means "brick-coloured," an epithet which is far from appropriate to the flushed-apricot hue of this Lily's corolla. "*Isabellinum*" is the Latinised version of the French *isabelle*, meaning "dove-coloured"—the hue of a turtle-dove's breast, which pretty closely matches the flower. The origin of "*isabelle*," however, has no connection with turtle doves though it is not devoid of romance. When Archduke Albert caused Spinola to lay siege to Ostend on July 5, 1601, his wife Archduchess Isabel, vowed that she would not change her chemise till the city was taken. The siege lasted three years and ten weeks. Not until September 14, 1604, was the Archduchess released from her vow. When at last she doffed her chemise, it was of a hue which the French dyers exerted themselves to match, and Parisian milliners, with an eye to court patronage, romantically named it "*isabelle*!" *Herbert Maxwell, Monceith.*

farmyard manure. The largest growing species are *Funkia Sieboldiana*, *F. Fortunei* and *F. ovata*, of which there is a variety with variegated leaves. The smaller growing *F. lancifolia* has a number of forms including several variegated sorts as well as a white-flowered form. A very beautiful, but less well known species is *F. subcordata* (syn. *F. grandiflora*). Towards the end of August and September this plant produces its large, pure white, sweet-scented flowers, but it requires a warm and sunny position in a well-drained, sandy loam, or it may prove uncertain in flowering. In colder districts it is well worth growing in pots for the autumn decoration of the greenhouse. For some reason *F. tardiflora* is not well known in gardens; botanically it is regarded as a variety of *F. lancifolia*, but for garden purposes it is quite distinct, especially in its flowering period. It blooms from the end of September until November, whereas *F. lancifolia* flowers during July. Whatever its specific rank it is a very beautiful plant, and, like *F. subcordata*, makes a good pot plant for the cool greenhouse. Some of the Funkias make good dwelling-room plants and they are effective either in or out of bloom, for the foliage is exceedingly handsome. *J. Coultis.*

## The Week's Work.

### THE HARDY FRUIT GARDEN.

By H. MARKHAM, Gardener to the EARL OF STRAFFORD, Wrotham Park, Barnet.

**Planting Apples.**—Arrears of planting Apple trees should be done while the weather remains open and the ground in a suitable condition.

Do not plant the roots too deeply; if the stems are covered with soil to the depth of two or three inches this will be sufficient in most cases. On heavy land I prefer to plant on mounds raised a few inches above the ground level. In planting shake a few shovelful

of fine, light soil amongst the roots. Standard trees in orchards and paddocks should have a clear stem of 6 ft. to 7 ft., so that the future heads are kept well above the reach of sheep and cattle. Plant only good, useful varieties for the different purposes, and those that will maintain a supply of good sound fruits over a long period. Bramley's Seedling, Newtown Wonder, Lane's Prince Albert, Chelmsford Wonder, Dumelow's Seedling, and Crawley Beauty, are excellent and late keeping cooking varieties. All young standards should be securely staked to prevent swaying by high winds, which break many of the finer roots. Correctly label the trees and protect them against injury by hares and rabbits.

**Pruning.**—In pruning young trees take care to select from three to five shoots at equal distances apart and shorten these more or less, always cutting just above a bud pointing outwards. As a rule from 10 in. to 15 in. of growth will be sufficient to retain. Very careful pruning is necessary when the trees are young to form an evenly balanced, fruitful head. As the trees increase in size less pruning will be needed.

### THE ORCHID HOUSES.

By J. T. BARKER, Gardener to His Grace the DUKE OF MARLBOROUGH, K.G., Blenheim Palace, Woodstock, Oxon.

**Forewords.**—In the cultivation of all plants under glass, it is essential that the conditions should be as near as possible

of those the different species enjoy in their native habitats. Success depends entirely upon the conditions provided for the different plants which go to make up a collection, yet (even when the best possible conditions are provided) certain districts are more favourable for certain plants than others. Cleanliness being one of the greatest aids to good cultivation, the

annual cleansing of the houses should be completed as soon as possible. Whilst this operation is in progress, a favourable opportunity presents itself to thoroughly cleanse the plants, even if they are not infested with insect pests.

**Temperatures.**—At this season it is advisable to keep the temperatures of the different houses at those figures given so many times in these pages for the winter months. No effort should be made to hasten the plants into growth, but those which have developed secondary growth during the winter should be placed where they may receive the maximum amount of sunlight and heat, according to their respective genera. Plants grown in high temperatures in winter are more liable to receive a check through a temporary fall in the temperature during a very cold night than plants accustomed to less warmth. The plants will not suffer from the temperature dropping a few degrees during severe weather provided the atmosphere and the plants are in a dry condition. Another important detail to observe is that the lowest temperature in the houses during the twenty-four hours should be in the early morning, with a gradual rise until mid-day, and then a gradual falling-off till the night temperatures are reached. The two extremes of a very warm, dry atmosphere and a low, cold, damp one should at all times be avoided, as much harm may accrue from either.

### THE KITCHEN GARDEN.

By JAMES E. HATHAWAY, Gardener to JOHN BRENNAN, Esq., Baldersby Park, Thirsk, Yorkshire.

**Trenching.**—Advantage should be taken of dry weather to complete the work of trenching land. It is not necessary to trench all the

ground of the kitchen garden every year; not everyone has sufficient labour to do this, but effort should be made to trench the plots which are to be cropped with Peas, Onions and Beans. Take out a trench 3 ft. wide, removing the first and second spits to the opposite end of the plot to be dug; the bottom spit should then be broken up and covered with a layer of half-decayed leaves. The top spit of the next trench should then be thrown on top, with a coating of manure added, and this in turn have the second spit thrown over it. The next trench will now be ready for breaking up the bottom. If the ground is not of a very heavy texture, the bottom spit may be brought to the top, and this method in a few years' time will ensure a depth of 3 ft. of rich soil, which is essential to good vegetable cultivation. The rougher the ground is dug the better, and no effort should be made to break up the soil finely. Heavy lands should receive liberal dressings of river sand, old mortar rubble, road scrapings and burnt refuse, in fact, anything that would have a tendency to keep the soil open. On no account should trenching be done when the soil is wet.

**General Remarks.**—Celery should be protected from severe weather by Bracken Fern or any light material of a similar nature. Frames containing vegetables should be attended to carefully and, whenever possible, freely ventilated. The glass should be well protected in frosty weather. All decaying leaves should be kept picked off from such crops as Lettuces and Cauliflowers in frames, otherwise loss from damp will follow.

### PLANTS UNDER GLASS

By T. PATEMAN, Gardener to Sir C. NALL-CAIN, Bart., The Nod, Codicote, Welwyn, Hertfordshire.

**Forewords.**—As cleanliness in the plants and houses is probably the greatest aid to success in indoor plant cultivation the plant houses should receive a thorough cleansing during the early weeks of the present month.

The glass, wood work and walls should be thoroughly washed with strong soapy water, and the walls afterwards limewashed. An important thing to guard

against is crowding the plants on the stages; many attempt to grow too many plants, a mistake which is as fatal to success as any other error in cultivation. With the advent of the New Year, no time should be lost in making the selection of seeds for the year's requirements. Obtain the best strains of the various kinds of flowers needed for indoor cultivation, and, whilst it is desirable to rely mainly on old and tried varieties, a few novelties should be included.

**Carnations.**—The propagating of these most valuable flowers should receive attention whenever suitable shoots for cuttings are available. Cuttings inserted now should produce good flowering plants that will bloom early in autumn. In selecting the cuttings, choose them from the healthiest and most vigorous plants, an important item in maintaining a healthy stock; a weakly cutting taken from an unhealthy plant will often result in failure. The cuttings should be made about 3 inches long, with a "heel," and inserted in a small pot filled with about equal parts of good loam, leaf-mould and sand; the cuttings should be inserted around the edge of the receptacle. They should be watered with a fine-rose can and stood in a propagating frame where a temperature of 55° is maintained. Very little air is needed until roots develop, beyond removing the glass every morning and wiping it with a sponge to clear it of condensed moisture.

### THE FLOWER GARDEN.

By EDWIN BECKETT, Gardener to the Hon. VICAR GENERAL, Aldenham House, Hertfordshire.

**The Mild Winter.**—Following a summer of exceptional drought, with, as yet, little rain, few opportunities have occurred for proper root

action, and the plants are consequently not in the happiest of conditions. This must be borne in mind where it is contemplated breaking up herbaceous borders for replanting. It is as well to do this work every two or three years in order to reduce the size

of strong growing subjects, but replanting may not be necessary this year, and it will be better to allow most of the subjects to remain undisturbed, merely furnishing them with a dressing of manure that should be forked into the soil.

**The Borders.**—Where herbaceous borders have not been trimmed and tidied this work

IT IS THE STANDARD FOOD FOR PLANTS.

should be done forthwith; old growths and stakes should be removed, and the border forked over carefully. Fern borders should be left for the present, for, though it is often advised that the dead fronds should be cut away, this is a mistake, as the fronds of the previous season are Nature's own and efficient means of protecting the crowns from frost. A light forking or rousing of the Fern borders may, however, be done.

**The Shrubberies.**—Whilst the weather remains open every advantage should be taken to rearrange shrubberies and plant subjects afresh, generally clearing and tidying up the ground prior to forking it over to move and aerate the soil. Where small shrubs are being moved this does not call for special precautions, but where larger specimens are being placed into fresh quarters, care should be taken to retain as large a ball of soil around the roots as possible. This prevents too much root movement, and the plants will greatly benefit from such care and become established more readily. Where plants have been sent by rail from a distance the roots may have become exposed and possibly damaged; if this has occurred they should be trimmed carefully and replanted in good soil. Standards and subjects with large heads should be staked at the time of planting, to prevent root damage from the tree swaying in rough winds. Holes for the reception of the plants should be prepared carefully, and the soil at the bottom forked deeply. This is of special importance in heavy, clayey soils, where, if the holes are dug in advance, the sides and bottom may set hard and form a basin holding water about the roots, a condition that is harmful to most vegetation. The moving of shrubs occasionally is very essential; too often one sees what might be otherwise very beautiful portions of a well-kept garden spoiled by allowing the plants so to grow into one another that all beauty of shape and appearance is lost, the shrubs becoming drawn in growth, and the whole presenting an untidy tangle. Every shrub should be allowed ample space for development, and the choicer the subject the more important this is, for whereas proper trimming and pruning will materially assist in keeping the plants shapely, yet the moving of some and the retention of others is certainly the best way to obtain good specimens.

**FRUITS UNDER GLASS.**

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

**Melons.**—Where efficiently heated pits will soon be available for these plants, a few seeds of an early maturing variety may be sown this month.

Melon seeds being plentiful, they may be sown singly or in pairs in small pots, plunging the latter in a bottom heat of 75°, with full exposure to light. Sow rather more seeds than are required, discarding, in the case of two growing

in the same pot, the weaker seedling when the seed leaves have developed. A good body of fermenting materials, consisting of Oak or Beech leaves and stable litter, should be secured, so that everything will be ready by the time the plants are large enough for planting finally. This early batch should be grown in 11 or 12 inch pots. The pots may be plunged where they are to remain, or, better still, set them on other inverted pots to prevent sinking and possible strangling of the plants later, placing the fermenting material

around them. Drain the pots well, using the roughest of the compost, which should consist of fairly heavy loam and lime rubble, to which a little bone meal has been added, at the bottom. Make the soil fairly firm. If planting out is more convenient, the same compost, placed on turf, grass side downwards, in the form of a ridge, will answer equally well; but, unless the hot-water pipes are equal to maintaining a bottom heat of 75°, the pot plants will ripen their fruits first. A night temperature of 65° to 68°, 75° to 85° by day, with sun heat, and a moderately moist, growing atmosphere secured by frequent sprinklings according to the weather, should be maintained. See that the pits are made sweet and clean for the reception of the plants, thoroughly cleansing the glass and woodwork.

ments or lobes. The basal part of the leaflet is the broadest, being sometimes 1½ in. broad, but mostly less and cut down to the midrib. The tree can be multiplied by grafting on seedlings of the ordinary Walnut, and there seems to be no reason why it should not be more common.

The word Walnut means the foreign nut, as indicated by the names Welsch Nutz in High Dutch, Walsch Noten in Low Dutch, and by Walsch Nut, used by John Gerard.

**CASTANEA SATIVA HETEROPHYLLA.**

In the early part of the present century I found four small trees of the above variety on Esher Common; and now that the Pine trees have mostly been cut down, for the purposes of the late war, I found it again during the

FIG. 2.—CHRYSANTHEMUM MRS. D. ANDREWS; A WHITE JAPANESE VARIETY. F.C.C. NATIONAL CHRYSANTHEMUM SOCIETY, NOVEMBER 23, 1921. SHOWN BY MESSRS. KEITH LUXFORD AND CO., SHEERING, HARLOW.

**TREES AND SHRUBS.**

**THE FERN-LEAVED WALNUT.**

The above is the only distinctly ornamental of the many varieties of Walnut which have originated under cultivation. It is the *Juglans regia laciniata* of modern botanists; the *J. filicifolia*, of Loddiges' Catalogue, ed. 1836; and the *Nux Juglans foliis laciniatis* of Renealm, who published a book in 1611. This would indicate that a cut-leaved Walnut existed 310 years ago, whether the same form or not. It is strange that a distinct and beautiful variety could have existed so long and yet be so uncommon in gardens. There are small trees at Syon House and Holland House, or at least there were a few years ago. I saw it last autumn in the nursery of Messrs. L. R. Russell, Richmond. The leaves are twice as broad as those of the common Walnut, with leaflets 3½ in. to 6½ in. long, and stalks up to three-eighths of an inch long. The leaflets are greatly elongated and very irregularly cut into long, pointed seg-

ments or lobes. The basal part of the leaflet is the broadest, being sometimes 1½ in. broad, but mostly less and cut down to the midrib. The tree can be multiplied by grafting on seedlings of the ordinary Walnut, and there seems to be no reason why it should not be more common.

These narrow leaves gave rise to one of the old names, *C. salicifolia*, or Willow-leaved; but as many forms of leaves occur on the same shoot, the name at the above heading best expresses the variation. This, as well as other names, are sometimes listed in catalogues of trees and suggest variations. I have not seen a fruiting tree of the variety in the wild state, and the question arises whether or not it occurs from seeds of the type, which is a common tree on the Bagshot sand formation. J. F.

## EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, W.C.2.

Editors and Publisher.—Our correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the Editors. The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.

## MR. KINGDON WARD'S SIXTH EXPEDITION IN ASIA.\*

## 8.—INTO THE WILD COUNTRY.

I HAVE said that the Pine clad hills round Yung-pei, starved of flowers as they are, nevertheless are richer than similar country yet passed through. Besides the violet *Dracocephalum* everywhere met with, and a blue *Beraginaceous* flower also widely distributed, there is a *Euphorbia* with bright scarlet bracts (a striking plant, this) and a *Hemerocallis*, with large blooms for its size, tawny orange in colour—there are also the bright orange-flowered *Stellaria* and several *Labiatae*. One feature all these plants have in common: they all have enormously developed root-stocks, hard, woody, often tuberous, and as large as a small Potato, in which case (e.g., the *Euphorbia* and *Stellaria* referred to above) they probably serve as water reservoirs. From these growths the roots descend far into the inhospitable soil. On May 22 we started northwards again, and, crossing the mountains which run immediately east of the city, entered the wild country. All provisions, both for men and animals, had to be carried, as we could get nothing on the road for several days at least.

All this country east of the great bend of the Yang-tze is very dry, and we found the mountains covered with shrubs instead of trees. The streams, however, where they flowed in deep, narrow valleys, were fringed with forest, tangled up with climbing plants, which abound.

As if to emphasise the fact that we really were in the dry country, it began to pour with rain, and by the time we reached a camping ground we were soaked through and had the disagreeable task of putting up tents in the rain. However, as it was practically the first rain we had had since leaving Lashia, five weeks previously, we really couldn't grumble. Moreover, there were many fine plants abroad. A *Roscoea*, with ivory white flowers, was a delight. There is little grace about these perky *Monocots*, but their colours are beyond cavil; even the purple-flowered species, very common along this route, is a splendid thing.

An *Azalea*, with very pale pinkish-purple flowers, mottled the slopes with colour, and a white *Rhododendron*, already met with far away to the south-west, was still in bloom. The corollas of this latter are eaten in Ta-li and elsewhere as a vegetable, under the illuminating name of "white flowered vegetable."

*Clematis montana* was also in flower—the first of the genus we had seen, and a couple of days later a second species with rich velvet-purple flowers was found. This, however, is widely distributed in the dry parts of Yunnan. *Deutzia*, yellow *Jasmine*, *Privet*, and other shrubs, were in flower. There was a much greater variety of trees and shrubs here than we had yet come across in the dry mountains. *Barberry*, *Cotoneaster*, *Oaks*, *Maples*, *Willow*, *Poplar*, and many *Leguminosae* may be mentioned, in addition to those referred to: a small tree of the order *Rosaceae*, crowded with blossom, scented the air with Meadowsweet. Amongst several lianas, was a species of *Actinidia*, and on a bare limestone cliff matted tangles of a *Vitis* quite new to me grew in profusion.

We crossed a pass of 9,612 feet, and, descending a narrow ravine, camped at 8,984 feet in a valley which promised quite a lot of surprises,

\* The previous articles by Mr. Kingdon Ward were published in our issues of May 14, June 18, July 23, August 20, September 3, October 8, and October 29, 1921.

considering that the mountains did not rise much above 10,000 feet here.

I am talking about camp already, and have said nothing about the field of the cloth of fine purple, where we had lunch, a meadow of pinky-crimson *Candelabra Primula*. It really was a fine sight, notwithstanding the obtrusive colour. The plant, which is a sort of giant *Primula burmanica*, grows 20 inches high under the shady hedges, with a few (generally only two or three) crowded whorls of large flowers which vary in colour from almost pink to a nearly Tyrian purple, with orange eye. There is a very light powdering of meai on the calyces and pedicels, and only a suspicion of scent. But the flowers are phenomenally large for a *Candelabra Primula*, though they are of the colour most frequently met with in the section.

Curiously enough, we did not meet with the plant again till we reached Yung-ning, when it turned up again in the meadows. *Primula Poisonii* also grows here abundantly, but always on wetter ground, in actual bogs; this vile coloured species stayed with us all the way to Yung-ning. If one could only find a blue or a red *Candelabra*! But they grow too far from heaven for that, I fear; there are no *Candelabras* at much over 12,000 feet.

Marching down the valley next day, we found the hillsides dabbled with purple *Roscoea*, and with white *Salvia*. There is a variety of this latter, speckled with purple, having darkly pigmented calyces, whereas, in the white-flowered form they are green. *Deutzia*, *Clematis*, a small-flowered *Akebia*, *Philadelphus* and *Azalea*, all blossomed profusely in the ravines, but above the stream, the slopes were thinly covered with *Pines*, which, however, managed to stand up straight and not resemble corkscrews. Here and there a *Tsuga* grew on the rock.

We crossed a pass of nearly 10,000 feet and found true *Rhododendron Delavayii*, the crimson flowers having the almost black honey glands which are a feature of that species; these the *Shui-ning* plant previously referred to lacked.

Over the pass we came on masses of a blood-orange *Candelabra Primula*—a fine plant. The buds are distinctly brick red, but they are more orange when open. A slight powdering of meal whitens the calyces as an early snowstorm might whiten the trees; and there is a fugitive scent of *Cowslips*, for which the exile sniffs desperately. We saw this plant henceforth every day till we reached Yung-ning on May 28; sometimes in the open meadow, sometimes in deep shade, or by streams, scattered, or in masses. Good plants were as much as twenty inches high, the flower whorls tightly jammed with blossom. After travelling through wooded ravines and Pine forest all day, we emerged into broad, open, grassy valleys, and camped while it was still quite light, the weather having turned fine again.

This country to the east of the great bend of the Yang-tze is one enormous block of limestone, sliced into by streams, which, at first flowing north and south more or less parallel to the trend of the mountain axes, eventually turn east or west, and break through the ranges. There is a tendency for the water to disappear underground, and even at this season, not a few of the streams were dry. The whole region is very dry, and where the valleys are wide, only a thin covering of Pine and Oak is seen below 10,000 feet. Variety is added to the scenery and to the vegetation by deep ravines, filled with trees, giving shade and shelter to a number of other plants; and in places are grassy meadows, delightful spots in which to camp.

On May 24 we crossed a fair-sized river, climbed to a pass, and descended into a typical valley. That is to say, being wide and open at the summit it was dry and bare; but presently we came to Pine woods, where the slopes were carpeted with two species of dwarf *Rhododendron*, both of them over, though I secured lingering flowers. With them grew *Barberry*, *Corylus* and *Holly-leaved Oak*. Presently the valley narrowed and we came to groves of Oak and Alder by the stream, and halted on such a wooded lawn for lunch.

A most odd little *Aristolochia* grew in the Pine woods here, on the dry, rocky slopes; and a series of scarps displayed a number of *Primula* capsules, suggesting *muscaroides* or something

near to it. There was not a sign of a new plant coming up, but by collecting every capsule I could find, we managed to coax a few clinging seeds from a living death, in the hope that they would open their eyes in a new land.

It may be remarked here that more or less bare scarps are of frequent occurrence throughout this limestone region, both down in the valleys and high up in the mountains. Some of these cliffs are very conspicuous objects, visible from a great distance. For the most part they are as bare as they look, but in chimneys and crevices plants often lurk, especially at high altitudes. Of these cliffs mons anon.

That afternoon we ascended another valley, and crossed several beautiful grassy meadows, rather marshy, and crowded with flowers of a somewhat tame appearance. At the head of this valley was a high rocky range, which had been in sight all day; unfortunately the pass to be crossed left it well to a flank, and next day it dropped out of sight behind. We camped by the stream at 8,000 feet, the country still being almost uninhabited. F. Kingdon Ward.

## FLORISTS' FLOWERS.

## THE CARNATION.

WHAT one generation of florists or lovers of flowers may esteem perfect in a *Carnation* may by another and a later generation be set aside as unworthy of attention. This has been the case for as long as anything is known of the plant. The old English *Carnation* was eclipsed by the yellow or "orange-tawny" strain introduced by the merchant Lete in the 16th century, that again, in the 17th century, by Dutch varieties, conspicuous by the enormous proportions of their flowers, and these in turn by a more refined strain about 1740 from France, and its progeny served to keep florists employed in improving its characteristics and that of the *Picotée* for a very long time. In 1820 we read of more Continental varieties being dispersed.

Up to the end of the 'eighties of last century the florist confined his attention to, and bestowed his homage on, *Carnations* and *Picotées* of a rigidly florist type—*Picotées* with pure grounds and the edges of their petals neatly margined in colour. *Carnations* also with pure grounds striped with various colours. But there were always a few varieties with self colours grown in gardens, though in the one in which I served my time none but show flowers was admitted.

When the *Carnation Manual* was published in 1892 there was already a fair selection of border varieties, and in it a selection of selfs for borders is given. However, they all belonged to a type or strain that has been superseded by another, the characteristics of which I propose to notice. Briefly the first-named were wanting in stamina, flowered but sparsely, and the "grass" grew in a cluster close to the ground, an example of which is seen in Sam Weller. On reference to notes I find that a new type was in existence in 1893-4. The plants were very robust, upright in habit, with flowers non-drooping, but upstanding and a proportion producing shoots on the stems, and showing a partially perpetual tendency. Of British cultivators, Mr. Martin Smith, if not the originator, was certainly the first who worked up this strain. His first plants were obtained from Mr. Matthew Campbell, of High Blantyre, who once told me he had obtained plants from America quite distinct in growth from ours, particularly in their rigid stems. Mr. Smith also, though later, procured plants from Benary, the German florist, and he informed me that Germania had been one of his stud plants for many years. This old variety has exactly the general habit though not the robustness of the novelties Mr. Smith produced annually. It was introduced about 1890. In 1892 I cut over 300 dozen of its blooms and had about 2,000 plants in the autumn, while in the ensuing spring I struck as many more from stem cuttings. Against all the rules Mr. Smith set about producing varieties with colours

so remarkable that new sections had to be found for them by the names of Fancies and Yellow Fancies. Such flowers may have been produced before, but, if they were, no doubt the earlier florists would dispose of them as monstrosities. However, no one need be told how popular they were and are and how useful to the mere gardener who has ladies to provide with flowers. Their productiveness is remarkable, and has been increased in the later varieties, strong layers of which will throw as many as ten flowering stems, and if grown in pots will continue producing odd flowering stems all the winter. I recollect one of the earlier varieties grown in pots never having been without flowers or buds for the space of three years.

Perpetuals are obviously similar in diversity of production to other Carnations, and we seem to be within reasonable distance of varieties as remarkable for colouring as in the border section. Out of a small number of seedlings which have flowered or are now flowering a large proportion are Fancies, one, a true yellow ground. Some are pink striped with red, some flushed, and one at present in course of expansion reminds me of the variety Sir D. Haig. A single is a true bizarre, and in the hope of F<sub>2</sub> throwing doubles of the same type, it was allowed to bear seed, which, however was completely devoured by voles. Another single of these seedling Carnations is marked exactly like a Pink with a ringed eye of deep rose, the other parts of the petals being blush, spotted. What I esteem the most remarkable break is one of the Painted Lady type with the stone-white reverse of the petals curling over on the crimson front. There is no apparent reason why any of the breaks, as well as a true apricot self, should have occurred, as the seeds were derived from selfs and from Alma Ward. It seems to demonstrate the wonderful variability of the Carnation, and also leads one to conclude that Perpetuals have inherited "blood," which one would never have anticipated to be possible.

For the encouragement of others who might like to try raising seedlings I may add that all ours are grown in 4-in. pots, potted on from thumbs, the seedlings being transferred from cutting boxes to these. The seeds are sown as soon as ripe and this year's seedlings are now in thumbs, singly. *R. P. Brotherston.*

## INDOOR PLANTS.

### GLOXINIAS.

A GLASSHOUSE filled with choice varieties of Gloxinias with their masses of richly coloured flowers is a most beautiful object. When the erect-flowered varieties made their appearance the older type with drooping blooms gradually disappeared from cultivation. At first there were only a few colours, and these without any brilliancy, but by continual fertilisation and selection a remarkable change has been accomplished, and there are now strains of the finest quality, the plants free flowering, of compact habit, and with flowers of perfect form and great substance. The colours include scarlet, violet, pink, purple, crimson-scarlet, and pure white while others are beautifully marked with distinct shades in great variety. A fine plant of the erect-flowered type is illustrated in Fig. 3. There is also a strain with extra large flowers delicately spotted and marked in an infinite variety of colours which are extremely interesting and unique, these making a pretty contrast to the self and other shades of colour.

The Gloxinia has not proved itself to be very amenable to hybridising with other genera. An interesting hybrid was raised from *Gesnera pyramidalis* fertilised with the pollen of a brilliant scarlet Gloxinia; it was put into commerce under the name of *Gloxinia Brilliant* (see Fig. 4). The flowers were as large as those of a medium-size Gloxinia, horizontal in position, and of a brilliant carmine-crimson. Many other crosses were made both ways between Gloxinias in variety and *Gesnera* in variety, but the result was practically the same, the *Gesnera* predominating in each case. All bore drooping flowers of different shades of mauve, but none was equal to the Gloxinia.

The Gloxinia is easy of culture provided it is grown in a moist atmosphere and a temperature of 65°. If grown in cooler conditions the plants flower later, and do not grow so vigorously, or give such good results. The first batch of seed should be sown at the beginning of January in a temperature from 65° to 70°. Well-drained pots or seed pans should be filled with clean crocks to within two to three inches of the top, and over these should be placed a thin layer of some of the rougher parts of the prepared soil, filling the receptacle to within half an inch of the rim. The surface should be made perfectly level and firm by pressing it lightly. The seed should be just covered with fine, sandy soil, and watered with a fine rose pot. Shade the soil from the bright sun, and never allow it to become dry.

may be easily examined. Place them under a dry stage or in a cellar with a temperature about 55°. The corms should on no account be allowed to get dry enough to shrivel nor should they be kept damp, as this would cause rotting. The corms may be started again in the beginning of January or February in shallow boxes, or potted singly in small pots placed in a genial, moist atmosphere with a temperature of from 65° to 70°. Pot moderately firmly in soil consisting of two-thirds turfy loam, one-third good leaf-mould or fibrous peat, and a little decayed cow manure with silver-sand added. Water the soil sparingly at first; shift the plants into larger pots as required, but be careful not to over-pot them.

When the flower buds begin to appear and the plants are well rooted a little liquid manure

FIG. 3.—A FINE PLANT OF THE ERECT FLOWERING TYPE OF GLOXINIA; EXHIBITED BY MESSRS. E. WEBB AND SONS.

Cover the pot or pan with a piece of glass, tilted at the back about an inch, until germination takes place.

When the seedlings appear they should be gradually exposed to the light and air to prevent them becoming drawn or weak. As soon as they are large enough to handle prick them off, about an inch apart, in shallow boxes or pans, and when sufficiently strong repot them singly in small pots. When the roots of the plants reach the pots, and before they become pot bound, give them another shift as required. Be careful not to over-pot the plants.

Gloxinia seedlings will flower, under normal conditions, in about eight months from the time of sowing; when in bloom select the best varieties for next season's flowering. After they have done flowering gradually ripen the plants by withholding water, and when they are fully ripened and have lost their foliage shake the soil from them and store the tubers in boxes or pans in a little nearly dry coconut fibre or sandy soil, in which condition they

is beneficial to growth. Shade the plants from bright sunshine, and, until they are in flower, keep the atmosphere always moist by damping the stage and floor in order to prevent that troublesome pest, the mite, attacking them. The mites are so small they can scarcely be detected by the naked eye, and if not dealt with in time the plants will be ruined for the season. Avoid draughts and a dry atmosphere, which encourage the spread of mite and thrip. The latter pest may be guarded against by fumigating the house from time to time when the plant commences to make fresh growth.

To increase the stock of any special variety, take well ripened leaves and make them into cuttings below the principal veins, about three inches in length, and put the leaf cuttings in small pots. The stock may also be increased from leaves laid on sandy soil with the principal veins cut across, and placed in heat under a hand-light or frame. These will form small corms for flowering the following season. *John Heal, F.M.H.*

## THE GREAT DROUGHT OF 1921 AND ITS EFFECT ON GARDEN PLANTS.

S.W. SCOTLAND.

THE northern frontier of the great drought of 1921 has been the Caledonian Canal. All the Scottish counties south of that line shared the shortage of rainfall which prevailed in England. Conditions in the Northern Highlands may be best illustrated by quoting from a letter received on November 9 from Mr. Osgood Mackenzie, whose fine collection of shrubs and herbs is grown on the west coast of

vapour suspended in the air protects vegetation from scorching, and plenty of stones in the soil check both evaporation and radiation.

No genus is more liable to suffer from drought than *Rhododendron*, whereof upwards of ninety species are grown here, chiefly Asiatic. Not one plant has been lost, but the season's growth has been normal, with plenty of bloom set for 1922; the result might have been different had not all young *Rhododendrons*, and those older ones, whose upright or sparse habit exposes the soil over their shallow roots to sun heat, received as usual a heavy mulch of withered leaves during the winter.

was not so good as usual, and *Trienspidaria lanceolata* resented the cold and wet summer of 1920 by a deficiency of bloom, the flower-buds being set in the summer preceding that in which they open. *Mitraria coccinea* suffered from the heat and flowered poorly, while *Abutilon vitifolium* and *Desfontainia spinosa* were as free as usual.

In the Australasian flora all species of *Olearia* and *Senecio* revelled in the sunshine; but not one out of about forty *Cordyline australis* bore flowers, though several of them did so in 1920. *Herbert Maxwell, Monreith.*

SUSSEX.

I am afraid it is rather difficult to send any definite particulars as to the effects of the drought of 1921 in my garden. So far the effects are not very marked, but I feel sure another six months will reveal a certain amount of serious damage to flowering shrubs. Certain plants have suffered, but shrubs will recover if the winter is normal and the spring of 1922 favourable.

Fruit trees on the whole seem to have got through very well. There is a good deal of weak growth. The most noticeable feature was the late fall of the leaf on many Apples. There is a fair show of fruit buds on Apples, Pears and Plums.

Vegetables were damaged, and in many cases winter greens had to be planted two or three times before a crop was established.

Potatoes were a light crop, and "growing out" was very marked. Carrots were completely checked in growth, and when rain came growth recommenced. The result is that most of the roots contain a hard core, and are useless for cooking. On the whole I should prefer to give an account of the effects of the drought about April or May, 1922. *Charles G. A. Nix, Tilgate Forest Lodge, Crawley.*

WARWICKSHIRE.

The outstanding feature of the abnormally hot summer at Ward End Park, Birmingham, was the remarkable recovery of grass. Situated on the top of rising land, the ground is practically a bank of sand and gravel, therefore grass showed the effect of the hot sun more than that on heavier land. The grass was burnt completely off, yet it recovered, and looks better than it ever did before by reason of the fact that one half was not cut and the plants seeded all over the place. Patches that have never had grass on before are now thickly covered with grass. The only trees or shrubs we have lost through the drought are those transplanted last season. *Rhododendrons*, although at one time they looked dead, broke into growth, and one of *Cunningham's White* was in full flower in August. Self-sown seedlings of various flowers have been common. *Collerette Dahlias* which came up in the border last spring flowered well, but what surprised me most were two beds of *Golden Verona Pelargonium*—hundreds of seedlings came up at the end of July, and 90 per cent. were true to type, with golden foliage. *Chrysanthemums* were very dwarf, and varieties which in normal seasons grow 6 feet tall, were only 2 feet 6 inches high. I left a few rows of *Majestic Potatoes* in the ground until the first week in November, and found the secondary tubers were of suitable size for seed, and there were plenty of them. *A. J. Elgar, West End Park, Birmingham.*

NORFOLK.

In answer to your inquiries concerning the effect of the drought of 1921 in my garden I must begin by stating that it is situated on the top of a hill, that the soil is very poor and sandy, and that I had no water to use for the garden, as I was fearful of my well (my only water supply) failing. Under these circumstances it will be understood that my list of plants which have done well is a very small one.

On the whole the fruit crop was wonderful. Pears, Apples and all small fruit, except Raspberries, were really good, and there was a half crop of Plums. Vegetables were very poor and dried up.

FIG. 4.—GLOXINIA X BRILLIANT (SEE P. 7).

Ross-shire:—"What we have suffered from perpetual rain all this summer and autumn, I cannot describe; never a dry day north of the Caledonian Canal." In 1920 the conditions were just reversed. During the summer months when all in the south were shivering and soaked, the summer north of the Caledonian Canal was exceptionally warm and sunny.

In the extreme south-west of Scotland (this garden lies actually further south than Durham) no rain fell between April 27 and July 22, a drought unprecedented in my recollection. Owing, however, to a cool subsoil—boulder clay underlying sharp loam full of stones of all sizes—and to the humidity of the atmosphere near the sea, we really have no losses to complain of, except an occasional plant of the *Kabschia* section of *Saxifrage*. The invisible

Lilies and Roses flourished exceptionally; there has been a total absence of *Botrytis* on the former; but *L. giganteum* was far below its average height of flowering stem. There was practically no green fly on Roses; but this has been the case during the last four years, which I attribute to the industry of the tits that occupy nesting boxes in the garden. Before these were put up, we used to suffer badly from green fly.

*Amaryllis Belladonna* flowered most profusely, more so than usual. On the other hand, *Lycoris squamigera*, which flowered freely in 1920, produced nothing but leaves in 1921.

Among Chilean shrubs, *Euryphia pinnatifolia* and *E. cordifolia* were sheeted with blossom; *Berberidopsis corallina* (on a wall)

# "Bull's"

THE FOOD FOR PLANTS

Plants which have withstood the drought are *Roses*, *Fremontia californica*, *Romneya Coulteri*, all the Chinese species of *Berberis*, *Lilium Henryi*, *Zauschneria californica*, *Oxalis valdiviana*, *O. lobata*, *O. purpurata*, *Saxifraga cochlearis major*, *S. pyrenaica*, *S. Cotyledon*, *S. pyramidalis*, *S. longifolia*, *Androsace sarmentosa*, *A. Chumbyi*, and all the *Cotoneasters*.

Plants that died from the effects of the drought in this garden include almost all the mossy *Saxifrages*, *S. Aizoon*, *S. Aizoon rosea*, *S. oppositifolia*, and *S. Elizabethae*; *Potentilla nitida*, *Desfontainea spinosa*, all the *Pernettyas*, *Paeonia lutea*, and many *Thuya Lobbii*, 8 ft. high, in a hedge.

Practically the whole of the plants in the large herbaceous borders were reduced to dried sticks with shrivelled flowers (if any). All the different varieties of *Ericas* except *E. stricta* and *mediterranea*, *Daphne Cneorum*, *D. Blagayana*, *Saxifraga apiculata*, *S. sancta*, and *Androsace lamuginosa* all suffered badly. *Montbretias* (a speciality here) had their leaves all dried up and smothered with red spider. All *Primulas* and *Gladioli* suffered. *Sydney Morris, Earham Hall, Norwich.*

(To be continued.)

## MESEMBRYANTHEMUM AND SOME NEW GENERA SEPARATED FROM IT.

(Continued from page 336, Vol. LXX.)

10. *G. LONGUM*, N. E. Br.—Leaves 2-ranked, tongue or strap-shaped, 3-5 in. long and about  $\frac{3}{4}$  in. broad, ascending or spreading, moderately straight, variably obtuse or more or less hooked at the apex. Pedicels up to 2 in. or more long. Flower 2.2½ in. in diameter. Capsule 6-7 lines in diameter, slightly domed at the top.

*M. longum*, Haw. *Obs.*, p. 177 (1794), founded upon *M. foliis linguiformi longiore*, Dillen., *Hort. Elth.*, p. 238, t. 185, f. 227; N. E. Br. in *Journ. Linn. Soc. Bot.*, v. 45, p. 70.

*M. linguiforme*, D. C., *Pl. Grasses*, t. 71, not of Linné.

*M. lucidum*, Haw., *Suppl.*, p. 89 (1819), and *Rev.*, p. 96.

*M. ascendens*, Haw., *Synop.*, p. 220 (1812), not of Salm. Dyck.

This species is distinguished from the others that have 2-ranked leaves, by the ascending leaves and long pedicels. But in his *Revisions*, p. 96, Haworth seems to have substituted a different plant, with several varieties to it, having sessile or subsessile flowers. With the exception of the variety *uncatum* quoted under *G. uncatum* (p. 336, 1921), I can find no clue to what plants these may have been, but think it quite possible they may have been hybrid forms raised from seeds produced in Europe, and I feel sure that several of the forms now cultivated under this and various other names are also of hybrid origin.

The plant figured as *M. heterophyllum*, Jackson in *Andrews Bot. Rep.*, v. 8, t. 540 (not of Haworth), I suspect to have been one of these seminal forms. It has very long leaves irregularly incurved-hooked at the apex, pressed to the ground and flowers about 2½ in. in diameter on pedicels an inch or more long. Haworth (*Rev.*, p. 102) names this plant *M. angustum* var. *heterophyllum*, but according to his original description of *M. angustum*, it has nothing in common with that species. It may be the same as *M. longum* var. *flaccidum*, Haw., *Synop.*, p. 22.

A. A.—Leaves not in two regular ranks, but pointing in various directions, the pairs crossing one another obliquely or rarely at right angles.

\* Leaves usually broader than thick, flat above, without a hump or teeth on the flat face.

11. *G. TAURINUM*, N. E. Br. Leaves obliquely cruciate, half-cylindric, obtuse, very thick, incurved, "less cruciate than *M. cruciatum*, usually somewhat finger-like and nearly the size

of a finger, the younger incurved like the horns of a bull." Flowers sessile; stigmas 8.

*M. taurinum*, Haw., *Synop.*, p. 224 (1834). I think it probable that to this species should be referred *M. angustum*, Salm. Dyck, *Hort. Dyck.*, 1818, p. 17, and *Mes.*, §7, f. 6 and 6B (not of Haworth, but named by the latter *M. angustum* var. *pallidum*, *Rev.*, p. 101, with the statement that it is "perhaps a distinct species or variety of another species"). Its flowers are 2½-2¾ in. in diameter.

12. *G. PRAEPINGUE*, N. E. Br. Leaves obliquely cruciate, not depressed, up to 3 in. long, some tongue-shaped with the points obliquely incurving, others narrower without any oblique curve or ridge near the point, others with subulate triangular or broad compressed points, bent and ending in a soft white bristle, whitish or shining near their bases, or as if frosted over with exceedingly minute papillae, when young minutely ciliate. Flower about 2 in. in diameter, nearly sessile, or according to Salm. Dyck with a pedicel 9-10 lines long. Stigmas 8.

*M. praepingue*, Haw., *Obs.*, p. 179 (1794); Salm. Dyck, *Mes.*, §7, f. 5.

13. *G. CRUCIATUM*, N. E. Br. Leaves exactly cruciate (but the pair as figured by Salm. Dyck

that of the capsule, is made from Salm. Dyck's figure, as Haworth's original description is rather vague, and does not agree very well with Salm. Dyck's figure and description. But I think there can be no doubt that both descriptions refer to the same plant, the difference being caused by Haworth having described from a young plant that had not assumed the adult form. In his *Revisions*, p. 100, he describes three varieties besides the type, all of which he states were received from Salm. Dyck. Original drawings of some of these varieties made in 1823 and 1826 are preserved at Kew, and merely represent young plants not arrived at maturity, and as they seem better to agree with Haworth's description, support my above expressed view that he described from immature plants.

\*\* Leaves nearly cylindric, ascending, without teeth on the face.

15. *G. ARRECTUM*, N. E. Br. (new species, Fig. 5). Leaves 2-3 (rarely 4) pair to each branch or growth, suberect or ascending-spreading, usually more or less curved, and the pairs set obliquely to one another, 2-3 inches long, 3½-5 lines broad near the base and 3-4 lines thick.

FIG. 5.—GLOTTIPHYLLUM ARRECTUM, N. E. BR. (NATURAL SIZE).

are obliquely crossing each other), 3-in. long, 1 in. broad at the base; all old leaves appear swollen (? convex) on the upper side, particularly near the somewhat dilated base. Pedicels stout, 1-2 in. long, of equal thickness to the very calyx. Flowers large. Petals not so long as those of *M. difforme*, but broader. Stigmas 8-9.

*M. cruciatum*, Haw., *Obs.*, p. 173 (1794), and *Misc.*, p. 35; Salm. Dyck, *Mes.*, §7, f. 7.

If Salm. Dyck's figure correctly represents Haworth's species, the leaves are unequal, much curved, 2-4 in. long and 6-9 lines broad, semi-terete, flat above nearly to the obtuse tip. Pedicels 2 in. long. Flower 2½ in. in diameter.

14. *G. SALMII*, N. E. Br. Leaf-pairs crossing one another, variously curved, 3-4 in. long, 7-9 lines broad at the base, thence tapering to an acute point, flat above, convex beneath, with the apical part sometimes obliquely prolonged beyond the flat surface and laterally compressed or keeled. Flowers sessile, 2-2½ in. in diameter. Capsule depressed, half included.

*M. Salmii*, Haw., *Suppl.*, p. 89 (1819); Link and Oto, *Icon. Pl. Sel.*, p. 95, t. 44; Salm. Dyck *Mes.*, §7, f. 8.

The above description, with the exception of

somewhat cylindric, but with the inner face more or less flattened, not at all keeled on the back, acute or subobtuse, smooth, glabrous, light green, not at all glaucous nor dotted. Flowers subsessile or on pedicels 1-2 lines long and 1½ line thick. Calyx 4-lobed; lobes 3-4½ lines long and as much in breadth, broadly ovate, obtuse, green, all with membranous margins. Corolla 2-3 inches in diameter, cup-shaped, expanding in sunshine, scentless; petals about 50, in 1 series, lax, 12-16 lines long and about 1 line broad, linear, very obtuse or subtruncate and notched at the apex, bright yellow on both sides. Stamens numerous, erectly spreading in a ring around the stigmas; filaments pale yellow; anthers darker yellow. Stigmas 7-8, widely spreading, about 2 lines long, lanceolate, acute, plumose, pale yellowish-green. Capsule subglobose, with a high dome-like top, 3-5 lines in diameter, 7-8 valved.

Sent to me from Sevenfontein in Swellendam Division, by Dr. I. B. Pole Evans, 6922. It flowered in September, 1921.

This species is easily distinguished from all the others by its ascending, nearly cylindric leaves. *N. E. Brown.*

(To be continued.)

## SCARLET TOMATO-FRUITED EGG PLANT.

PERHAPS a few further notes on this ornamental plant (see p. 269, vol. LXX.) may be of interest. It is not an Egg Plant, though related to the Egg Plant. The fruits are quite different, both externally and internally. Nor is it a Tomato, though the fruits externally resemble an early form of the Tomato. The confusion of the name with *Solanum ovigerum*, which is an Egg Plant, doubtless arose because by accident a Continental firm appears to have distributed seed of this plant under the name *S. ovigerum*. Dunal (1852) distinguished a plant which was growing in a garden under the name *S. texanum*, and said it was distinct, but not very dissimilar from *S. integrifolium*, Poir., which he places next to it. Some botanists since his time (Kew apparently among them) have placed the two species, as he considered them, together, as not so distinct from one another as to be regarded as more than forms of one species, which would then have the older name of *S. integrifolium*. Dunal's plant was figured in *Le pict. fac. sc. Monsp.*, vol. 9, t. 857, and he states, "*Habitus S. esculenti*," i.e., the Egg Plant. The seed from which it was grown was sent from Texas, but not directly.

*S. integrifolium* is native in Mauritius, and was figured by Jacquin in *Herbarium Botanicum Vindobonensis*, t. 12, and elsewhere under the name of *S. aethiopicum*, but it was known long before his time. Apparently the same thing appeared in Robert Morison's *Plantarum Historiae Universalis Ozoniensis* (1715), sect. 13, t. 2, vol. 3, p. 525, under the name *S. pomiferum*, fructu rotundo, striato, duro, and Caspar Bauhin mentions it in his *Pinax* (1623), and J. Bauhin in his *Historia* (3, p. 920), while Dodoens refers to it as *Mala aethiopica* in *Stirpium Historiae Pemptades Sex* (1616) 459. It is thus an old plant well known to early botanists. *F. J. Chittenden, Wisley.*

## CHINESE RHODODENDRON SEEDLINGS AND LIME.

IN 1920 Professor C. S. Sargent, Director of the Arnold Arboretum, very kindly sent me some Chinese Rhododendron seeds collected in 1919 by Forest, in Yunnan. The soil in this district of Vancouver Island has very little, if any, lime in it; the ground for miles is covered with such plants as *Gaultheria*, *Vaccinium*, *Kalmia*, *Ledum*, *Blechnum*, *Linnaea*, and other subjects known to prefer soil of a peaty nature, and the only Rhododendron that ever failed with me as regards soil was a batch of either *R. hirsutum* or *R. ferrugineum*. I don't remember which now, but it was the want of lime that killed them.

I divided each packet of the seeds sent me by the Arnold Arboretum, and on June 4, 1920, sowed one half in a box with the ordinary soil, the other in a compost of one ounce of air-slaked lime—that had been exposed to sun and rain for years—to each pound of soil. The seeds, placed in a cool, half-shaded situation, germinated at about the same time and at the same rate in both boxes, but the seedlings in the lime mixture soon turned brown, and to-day not one of them is alive, and the box now has a covering of green moss, in which over a dozen different species of flowering plants, including a Mountain Oak (sometimes associated with Rhododendrons in the Himalayas) is growing, showing that there could have been nothing poisonous in the soil and that the percentage of lime could not be considered excessive. Owing, no doubt, to the long distance they had travelled, the Yunnan seeds germinated very poorly compared with a sample of home-saved *R. californicum*, sown as a test in the lime mixture, but now also dead. Those alive, in the box with the ordinary soil, are numbered F. No. 15745, F. No. 17827, F. No. 13769. *R. detonum*: F. No. 15667, *R. Scottianum*; F. No. 17828, and F. No. 15736. The last two numbers had very fine seeds, and the seedlings look as if they might be deciduous. *George Fraser, Ucluellet, Vancouver Island, B.C.*

## HOME CORRESPONDENCE.

[The Editors do not hold themselves responsible for the opinions expressed by correspondents.]

**Freeing a Pond from Weeds.**—From my note recommending swans for the extermination of Potamogetons (see p. 304, vol. LXX.) it might be inferred that some other weeds would also be exterminated. This, I daresay, may be expected, but swans are far from being indiscriminate feeders, and they will not touch perhaps the majority of those weeds that are the least desirable. After the extermination of several kinds of Potamogeton, I have found them of little use. The only way of dealing effectively with a weedy pond is to drain it and dig out the weeds that root in the mud. This I have had to do a number of times. Loose floating vegetation like *Limnanthemum* can be dealt with quite effectively in summer by a man with a punt and a rake, it might be with assistants, one on each side of the pond, with a rope end each to keep the punt in position. I have found that very little good can be done with scythe blades strung together. If the pond is not too deep, it is possible for a man to wade into it and pull out the young growths of Typha, which often extend very inconveniently. For the cleaning out of a pond, by which is meant the removal of weeds, some years ago I got an estimate of 6d. per square yard from a firm of drainage contractors, but at that time it was possible to do the work for much less by hiring one's own men. I have never adopted the scheme, but I have often thought I should like to try the plan of diverting the water supply and cultivating the bed of the pond until all the water plants were dead. It would then be possible to plant only the choicest and most desirable sorts, exercising a very careful *Index Expurgatorius*. First on this list I would place Nuphar luteum, which seeds freely and quickly becomes a nuisance. Very carefully I would keep out *Polygonum amphibium*, which I have known to grow in the deepest water of the pond, and also apparently from the same stock on the driest ground of the whole garden. Water-fowl are not now in question, but they may cause a considerable amount of work and trouble by pulling down the banks and making very ugly breaks in the curves determined upon. I have never seen the plan referred to, but at Cambridge, whereof I write, the difficulty was effectively and easily overcome by laying wire netting on the turf. It was soon hidden by the grass, and few, I believe, ever knew of its presence. To meet the turf margin from the water it is of great value to have the bank lined with old bricks, unless some more expensive method to accomplish the same end is preferred. *R. Irwin Lynch, V.M.H.*

**Exocorda Albertii** (Regel).—Doubtless as the result of the past abnormal summer and mild autumn, *Exocorda Albertii* is flowering (December 13) sparingly on the bare shoots of this year's growth. The racemes are shorter, flowers smaller and more compact, suggesting at a little distance the white variety of *Daphne Mezereum*, an impression enhanced by the leafless branches, though naturally the habit of growth is not the same. I would like to know if plants elsewhere have behaved in a similar manner. There are no flowers on *E. macrantha* or *E. grandiflora*. *A. B. H., Smeaton, East Lothian.*

**Iris unguicularis.**—This Iris, established in a row at the foot of a south wall, continues to produce its fragrant blue flowers. During December the border has been most beautiful—a mass of blue colour. It has been flowering since the middle of October in very poor soil, and flowers have been cut almost daily. They are best cut in the bud state and opened in water, and when cut down as low as possible they last longer than those with a comparatively short length of stem. I attribute the early flowering of this Iris to the unusually long dry, warm season. *James A. Paice, Aldenham Vicarage Garden.*

**Begonia Gloire de Lorraine.**—Referring to your recent reference to the measurements of plants of *Begonia Gloire de Lorraine* grown at Tindhead Court, it may be of interest to give the dimensions of those grown at King's Walden

Bury. Several houses are occupied by Winter-flowering Begonias, one house being wholly given up to *B. Optima*, in 5-inch and 6-inch pots. Of *Begonia Gloire de Lorraine*, several in 10-inch pots have a circumference of 7 ft. 6 in., diameter 3 ft. and height 2 ft. 9 in. Some twenty plants, including the white Turnford Hall form in 6-inch pots, measure 6 ft. 6 in. in circumference, 2 ft. 4 in. in diameter, and 2 ft. high. The sticks which support these plants are practically hidden by the foliage and the masses of flower. *A. J. Hartless, King's Walden Bury Gardens.*

**Wilt in Melons.**—In answer to the inquiry by "Ardtara" (page 316, vol. LXX.), regarding the application of sulphate of copper, I dust the powder freely on the Melon stem from base upwards, at frequent intervals. One tablespoonful of sulphate to a gallon of water, syringed over the foliage, leaves a deposit which is also beneficial. This remedy was kindly suggested to me in answer to an inquiry in *Gard. Chron.* last spring. Sulphate of copper does not prevent the disease, but prolongs the life of the plant attacked and allows it to finish good fruit. Without its use, my plants have always collapsed when the fruit begins to net. One of our leading mycologists is studying the disease from plants I have sent him. Melons were a success here until 1914; since then, I have had "Wilt," even in houses in which Melons have never been grown before. *Anxious.*

**Doubling in Stocks.**—I have been, and still am, very much interested in the articles and correspondence relating to the doubling of Stocks. Personally, as a young student of Mendelian Law, I support Miss Saunders in her statements; incidentally my experience also coincides with hers. As someone seeking the light where it is not (for does not the mature experiences of these competent gardeners, Messrs. Brotherston and Taylor, shut out the vista which Mendel had opened before us), I ask why do these two gentlemen not proceed to enlighten us upon their method of defying fundamental laws. I would far rather believe that the much derided scientist is right and that the Lothian methods are, after all, only a perpetuation of the abnormal. I also observe Mr. Brotherston's remarks (page 97, vol. LXX.) relative to the history of Malmaison Carnations, which remarks apply equally to other subjects, vegetable or floral. A strong constitution is only to be got when based upon a good pedigree, and in starting new stocks it is often only possible to work upon tradition, the results of which are only known in all their several details to the breeder himself, and sometimes, maybe, his superiors. I do not think that Messrs. Brotherston and Taylor would really wish to contradict Miss Saunders, who merely states a scientific fact supported by practical demonstration and general experience, so that I have no doubt they will willingly elucidate any mystery (if there is one) surrounding their statements. *G. R. Sargeant, Kelso.*

**Oncidium ornithorhynchum.**—This pretty species has recently passed out of flower. As soon as new roots are observed at the base of the new growths, the plant should receive attention. If the pots are of a suitable size and the compost in good condition, the latter need only to be resurfaced with fresh material. Some may, however, require repotting, and such should be attended to at this stage. The plants succeed best in a position near the roof glass in an intermediate house. *J. C.*

**Rare British Orchids.**—If Mr. G. Claridge Druce will refer to that delightful book on natural history, *A Hundred Years in the Highlands*, by Osgood Mackenzie (Arnold, 1920), he will there find a record of the discovery of that rare Orchid—*Cephalanthera rubra*—at the Gairloch. The late Lord Avebury pointed out with pride to several naturalists, including the late Professor Marshall Ward, quite a little colony of this Orchid, growing by the margin of the racecourse at High Elms. Since that time I have again seen it, where long may it remain undisturbed. A lengthy description of *Orchis maculata praecox* will be found in the second edition of my *British Orchids*, and more fully in the *Transactions of the Botanical Society of Edinburgh*. *A. D. Webster.*

**FRUIT REGISTER.**

**APPLE NORFOLK BEAUTY.**

In the coloured plate accompanying this issue we present our readers with an illustration of Apple Norfolk Beauty, a variety first exhibited by Mr. W. Allan (gr. to Lord Suffield), Gunton Park, Norwich, at a meeting of the Royal Horticultural Society held on October 15, 1901, when it was granted an Award of Merit. He exhibited it again on December 9, 1902, when a First Class Certificate was awarded. Norfolk Beauty appears to have resulted from a cross between Warner's King and Waltham Abbey Seedling, as these two varieties were growing closely together where the seedling appeared and the fruits bear some resemblance to both. The Apple is a culinary variety in use from October to December. The fruits are large, round, slightly flattened, lemon yellow in colour, with a faint red flush; the closed eye is set in a moderately deep and plaited basin round which are more or less prominent knobs. The long and thin stem is set in an even, narrow and russet cavity. It is an excellent culinary variety, of good flavour and crops well. Apple Norfolk Beauty was introduced to commerce in 1902 and is already regarded as one of the standard early sorts.

**APPLE CALVILLE BLANC.**

To the aged or toothless, this Apple is most commendable, as it has flesh of remarkable tenderness, not unlike that of James Grieve when in first-rate condition, the texture being soft and Pear-like, with a sugary juice, sub-acid and refreshing. The tree requires a warm situation, and does well only as a cordon, espalier or bush.

It is also suitable for growing as a pot tree in cold orchard houses, and is very productive if stood in proximity to Bismarck or Worcester Pearmain. The keeping qualities extend to March, if properly stored. It is a very old French variety, and was known in the 16th century. *J. L.*

**DAMSONS.**

WHILST planting Damsons in the hedgerows in Herefordshire and Shropshire—from which prolific crops are obtained—the thought often occurred to me that the majority of gardeners plant Damson trees in too rich a soil, thus accounting for the trees being unproductive. My contention is, this particular member of the Prunus family should have a restrictive root run consisting of soil well charged with lime and lime phosphates, such as is provided in mortar rubble, bone-meal and basic slag.

I have particularly noticed how well certain varieties do in one place compared with their comparative failure in another. Large crops of fine, luscious fruits may be obtained from bush-formed trees, especially of the Merryweather and Ring's Early Damson.

For standard planting, I prefer Bradley's King, which makes a tree of medium size, with oval-shaped, deep black fruits having a beautiful bloom and of brisk, sweet flavour. The growth of this variety is moderate, and the tree most fertile.

Farleigh or Cluster Damson is a late keeping variety. The fruits are oval, small, and of good flavour. The growth is compact, and the tree of great fertility.

The variety Frogmore is the sweetest of all the Damsons, and when the fruits are perfectly finished and ripe they are suitable for dessert. They are roundish-oval in shape and coloured purplish-black with a thick bloom. The tree grows vigorously and is most productive. *Pomona.*

**SOME GOOD LATE PEARS.**

GLOU MORCEAU is one of the best late Pears, but the fruit should be allowed to hang on the tree until they are thoroughly ripe. I have gathered this variety on November 20, having covered the tree with a double layer of fish netting to ward off frost. It is a good sized fruit, and when put on the table in good condition is very refreshing and buttery.

Beurré d'Artemberg is another very good late Pear.

Marie Benoist is a large Pear, and is in

season through December. Its flavour is not, perhaps, so luscious as some, but it is acceptable as a large and handsome fruit at the present season.

Princess is another late variety of good flavour.

Winter Nelis, from trees on a N.W. wall, is a fine flavoured Pear, and may be kept until Christmas. I consider this one of the best of all late Pears.

For cooking purposes, no variety is superior to Catillac or Pound Pear. Moreover, the tree is a free grower and good cropper, and it seldom fails to fruit on any kind of soil.

Uvedale's St. Germain is also very good from now onwards till April.

I have grown upwards of 80 varieties of Pears, and consider these the best for use at the end of December. *W. A. Cook.*

**PEAR CONFERENCE.**

A WELL-KNOWN pomologist declared in our hearing that if he were restricted to a single Pear for his garden he would chose the variety

**SOCIETIES.**

**MANCHESTER AND NORTH OF ENGLAND ORCHID.**

DECEMBER 15.—Committee present: The Rev. J. Crombleholme (in the chair), Mrs. Slingsby, Messrs. R. Ashworth, Dr. F. Bedford, B. J. Beckton, J. Birchenall, A. Burns, A. Coningsby, J. Cypher, A. G. Ellwood, J. Evans, W. Giles, Dr. R. N. Hartley, J. Howes, A. Keeling, J. Lupton, D. McLeod, F. K. Sander, E. W. Thompson, and H. Arthur.

**Awards.**

**FIRST-CLASS CERTIFICATES.**

*Cypripedium Dalmatian*: The large, white, dorsal sepal has a green base spotted with purple; the petals and pouch are reddish-brown. *C. Elise* var. *Grand Monarch* (Hermes × Lady Dillon): A variety with very large, flat, dorsal sepal that has a white-green base, and heavy purple spots; the petals and pouch are light brown. *Odontoglossum Princess Mary*: An exceptionally

FIG. 6.—A WELL-CROPPED ESPALIER TREE OF PEAR CONFERENCE.

Conference. This high praise is certainly merited by the variety, for, in addition to its prolific and consistent fruiting qualities, it possesses the merit of hardiness and grows well in most kinds of soil. The variety is named from the National Pear Conference held in 1885 at Chiswick, when it was shown by Messrs. T. S. Rivers and Son.

The fruits have a very characteristic appearance and may be easily recognised. They are pyriform in shape with a dark green skin that fades to pale yellow when ripe, with much russet spotting. The flesh is pale yellow, very juicy, melting and of good flavour. Because of its hardiness and fine cropping qualities this Pear is extensively cultivated by market growers, and those with small gardens will find it one of the most suitable for their purpose, as it succeeds splendidly trained as a cordon. Fruits from trees on warm walls are of exceptionally fine quality; an espalier tree trained on a south wall at the Node, Welwyn, is illustrated in Fig. 6, but the fruits shown represent only a portion of the crop, as some had been gathered before the photograph was taken.

fine, white flower heavily blotched with deep reddish-brown. From S. GRATRIX, Esq.

*Cypripedium Eurybiades Bedfordiae*: The large, white dorsal sepal has a green base and deep purple spots; the petals and lip are greenish-brown. *C. Sanacderae Bedfordiae*: The dorsal sepal is clear white, green base, petals and pouch greenish-yellow. From Dr. F. BEDFORD.

*Odontoglossum St. Edmund* (Jasper × spectabile): A fine flower of good shape with bluish-purple markings. *O. Ithone Edgemoor* var.: A large flower with a white ground, blotched with intensely deep claret-brown. From A. HANMER, Esq.

*Cypripedium Grey Friar* (Grovesianum var. Richard Ashworth × Traceyanum var. Lady Evelyn James): The dorsal sepal is white with a green base and small purple spots; the petals are yellowish-green with a brown line in the centre; the lip is yellowish-green. From Dr. R. N. HARTLEY.

*Calanthe Harrisii*: A beautiful large white flower. From the Hon. ROBERT JAMES.

## AWARDS OF MERIT.

*Cypripedium amberleyense* (Lady Dillon × Mrs. Mostyn), *Piccaninii* (majesticum × Leander superba), *C. Brilliantissimum*, *C. Birk-dalense* var. *Chanticleer*, from H. Y. GREEN, Esq.  
*C. Trebizona*, *C. Monte* (Farrieanum × nitens), *Odontoglossum crispum Medusae*, from S. GRATIUX, Esq.

*Cymbidium Mastersii* *Cusson's* var., from A. T. CUSSENS, Esq.

*Cypripedium Challenger* (Curtmanii × Beryl West Point var.), from A. HANMER, Esq.

*C. Roy Hartley* (Earl Tankerville × alportense), from Dr. R. N. HARTLEY.

## GROUPS.

Lt.-Col. Sir GEORGE HOLFORD, K.C.V.O., Westonbirt, Tetbury (gr. Mr. H. G. Alexander), staged a group of *Cypripediums*, for which a Gold Medal was awarded. Mrs. BRUCE and Miss WRIGLEY, Bury (gr. Mr. A. Burns), were awarded a Silver-Gilt Medal for a group of *Cypripediums*. S. GRATIUX, Esq., West Point (gr. Mr. J. Howes) was also awarded a Silver-Gilt Medal for a group of *Cypripediums*. H. GREEN, Esq., Birmingham (gr. Mr. G. W. Marsh), was awarded a Large Silver Medal for a group of *Cypripediums*. A. HANMER, Esq., Buxton (gr. Mr. G. Giles), was also awarded a Large Silver Medal for *Cypripediums*. A. T. CUSSENS, Esq., Kersal (gr. Mr. F. Cookson), staged a group for which a Silver Medal was awarded. Silver Medals were also awarded to Messrs. CYPHER AND SONS, Cheltenham, and Messrs. SANDEES, St. Albans, for collections.

## Obituary.

**George Baxter Sharpe.**—It is with great regret we have to record the death of Mr. George Baxter Sharpe, which occurred on the 24th ult., following an operation. Mr. Sharpe served his apprenticeship with Messrs. William Paul and Son, of Waltham Cross, and afterwards spent some time with Messrs. William Bull and Son, of Chelsea, but for the past 45 years he was propagator and grower at Hollamby's Nurseries, Groombridge, where he was held in the highest esteem by employer, fellow-employees and all who knew him. The funeral took place at Eridge Green on Wednesday, the 28th ult.

**William Edward Bisset.**—It is with deep regret we announce the death of Mr. Wm. E. Bisset, Show Superintendent of the Royal Horticultural Society. Mr. Bisset, who was 55 years of age, passed away at a nursing home on Thursday, the 29th ult., the cause of death being cancer, and was buried at West Norwood Cemetery on Monday last. During the eight years Mr. Bisset had been in the service of the R.H.S. he made many friends in the horticultural world, and with ready courtesy was always eager to give every assistance to exhibitors and to promote the interests of the Society and of horticulturists generally. He was formerly in the service of Messrs. Milner, Son and White, and we understand that for a time he was also engaged in farming at Brighton. He rendered valuable assistance in connection with the International Horticultural Exhibition of 1912, and it was in the following year that he was engaged by the R.H.S. to assist in the organisation of their exhibitions. The shows at Chelsea and Holland House involve a large amount of work, and it is notoriously no light task to satisfy all the exhibitors' requirements; yet Mr. Bisset did his part in the organisation of these great exhibitions to the satisfaction of everyone. We understand that a fund is being raised in aid of Mr. Bisset's widow and that Mr. Frank Reader of the R.H.S., who is acting as treasurer, is prepared to receive subscriptions from all who desire to show their appreciation of Mr. Bisset's services to horticulture.

**Dr. John Harley.**—We regret to announce the death, at Beedings, Pulborough, on the 9th ult., of Dr. John Harley, aged 88. Dr. Harley was a prominent geologist, but he was also interested in botany, and his memoir on the parasitism of the Mistletoe was published by the Linnean Society in 1863.

## TRADE NOTE.

At a recent meeting of the Transport Subcommittee of the Chamber of Horticulture, the Secretary submitted a memorandum from the railway companies setting forth modifications to their proposed classification in respect of the nursery side of horticulture, which have already been published in detail. The Committee briefly discussed these modifications, and with the exception of evergreens, they were considered very satisfactory, giving a lasting benefit to traders.

A message was received from the Railway Clearing House, that the companies had considered the formulæ with respect to shrubs and plants, submitted the previous week, and they could not see their way to modify their proposed classification in these commodities, on the grounds that the formulæ were not sufficiently distinctive and would be liable to abuse. This Committee was of opinion that they should stand or fall by their previous decisions in this respect, and agreed to recommend that the Chamber carry this matter to the Rates Advisory Committee, whose decision in matters of re-classification is final and binding. The meeting agreed to recommend that cases pressing for lower classification as to bulbs and evergreens also be prepared, and it was resolved to draw up a full report to the Parliamentary and Transport Committee, outlining:—(1) What modifications have been conceded by the railways; (2) Objections that have been lodged and rejected; (3) Request for permission to proceed before the Rates Advisory Committee. The question of expenses in this matter was brought forward by the Secretary, and it was generally thought that each association concerned should contribute equal proportions thereto.

## NEW HORTICULTURAL INVENTIONS.

## LATEST PATENT APPLICATIONS.

- 31,277.—Deutsche Gold and Silber-Scheideanstalt.—Treatment of seeds for agricultural purposes.—November 22.  
31,165.—Holmes, R.—Plant fertiliser.—November 22.  
31,268.—Savage, A. J.—Hand tool for cultivating and scarifying land.—November 22.  
32,310.—Llewellyn, G. E.—Combined shovel and fork, etc.—December 2.  
32,116.—Rasmussen, R.—Material for fumigating plants, and process of using it.—November 30.  
30,280.—Ballantyne, J. B.—Beehives.—November 14.

## SPECIFICATIONS PUBLISHED LAST MONTH.

- 171,155.—Broadbridge, W.—Production of fertiliser.  
171,744.—Edmonds, J.—Machine for spraying fruit and other trees or plants and crops generally.  
171,784.—Western, C. J.—Construction of hand grabber or hoe.

## ABSTRACT PUBLISHED LAST MONTH.

*Teaching Gardening.*—An apparatus for teaching gardening has been invented by Mr. C. H. Jones, of 14, Custom House Street, Aberystwyth. It consists of an oblong frame having flanges along adjacent sides, and a series of oblong troughs of wood or light material, whose length is less than the width of the frame and which represent garden plots. The uncovered parts of the frame represent an alley and a path respectively. Grooves are provided to carry off drainage water. The device is used to illustrate the series of crops or plants, and plants so raised may be transferred to the garden. For those who desire further particulars of the invention, the patent number is 170,198.

This list is specially compiled for *The Gardeners' Chronicle* by Messrs. Rayner and Co., registered patent agents, of 5, Chancery Lane, London, from whom all information relating to patents, trade-marks, and designs can be obtained gratuitously.

Messrs. Rayner and Co. will obtain printed copies of the published specifications, and will forward them, post free, for the sum of 1s. each.

## ANSWERS TO CORRESPONDENTS.

**DWARF SHRUBS TO FLOWER FROM JULY TO DECEMBER:** *E. D.* The Heaths which would be in flower during the period named would include *Daboecia polifolia*, *Erica ciliaris*, *E. ciliaris* *Mawiana*, *E. Mackaii*, *E. Tetralix* and its varieties *alba*, *mollis* and *Williamsii*; *E. vagans* and the varieties *alba*, *grandiflora*, *St. Keverne* and *rubra*, and probably *E. carnea* and *E. c. alba*. Other shrubs which, no doubt, would be suitable for your purpose are *Ceanothus americanus*, *C. azureus*, *Clethra alnifolia*, *Escallonia montevidensis*, *E. Philippiana*, *Hydrangea paniculata grandiflora*, *Indigofera Gerardiana*, *Daphne Mezereum grandiflora* and *D. Cneorum*.

**ESTIMATE FOR MAKING LAWNS:** *A. C.* It is impossible to suggest any but very approximate costs of garden work without a personal knowledge of the nature of the ground and local conditions as regards labour. If you have reasonable doubts as to the fairness of any estimates submitted, it may probably be worth while, before coming to any decision, to call in a consultant who, after viewing the ground, would be able to advise you on the point; but as rough guides, we may say that we should consider a fair price for making and sowing the lawn with best grass seed and protecting the latter, from birds would be, on a level site and ordinary soil, about £30. For the cricket pitch, as stated, probably the cost would be about £55. But it should be clearly understood that these figures must only be considered as rough estimates.

**NAMES OF FRUIT:** *J. S.* 1, Blenheim Pippin; 2, Gascoyne's Scarlet; 3, Barnack Beauty.—*C. T.* 1, Hambleton Deux Ans; 2, Bess Pool; 3, American Mother; 4, Reine de Caux; 5, Mannington's Pearmain; 6, Calville St. Sauveur; 7, Benoni; 8, Scarlet Nonpareil; 9, Duke of Devonshire; 10, Tyler's Kernel; 11, Fondante du Panisel; 12, Autumn Nelis; 13, Glou Morceau.

**NAMES OF PLANTS:** *H. B. M.* *Cymbidium giganteum*.—*E. B.* *Schizostylis coccinea*.

**MARKET BUNCHES OF FLOWERS:** *H. L.* It is usual to place from twelve to eighteen stems of Sweet Peas in a market bunch, the number varying according to the amount of flowers on each stem. Nine to twelve stems go to form a bunch of early-flowering *Chrysanthemums*, while six to twelve stems of Stocks are placed in a bunch according to their size; side shoots are usually bunched in dozens, and main shoots in sixes. Twelve Asters constitute a market bunch.

**RATING OF COMMERCIAL GLASSHOUSES:** *H. L.* The rateable value of glasshouses is assessed by the owner, or whether they are removable as they learn that they have been constructed, just as with other buildings. There are no fixed rules to guide them in arriving at the value, except in such districts as Worthing, where the glasshouse industry is of considerable importance. It makes no difference whether the glasshouses are rented or used by the owner, or whether they are removable or not.

**SUNK GARDEN.** *B. A. J.*—We have no plans or illustrations of sunk gardens other than those which have appeared at various times in our pages.

**WALL SHRUBS:** *A. H.* In addition to the Roses and Ivies, the following is a list of plants suitable for clothing the wall. *Actinidia chinensis*, *Ceanothus Veitchianus*, *Clematis montana*, *C. montana rubens*, *C. Beauty of Worcester*, *C. Countess of Lovelace*, *C. Duchess of Edinburgh*, *C. Jackmanii superba*, *C. Lady Northcliffe*, *C. Marcel Moser*, *C. Nelly Moser*, *C. Ville de Lyon*, *Elaeagnus glabra variegata*, *Jasminum officinale*, *Lonicera Late Dutch*, *Polygonum Baldschuanicum*, *Wistaria sinensis*, *Vitis Cointetiae* *V. Thunbergii* and *Berberis stenophylla*. All of the above may be obtained from a nurseryman dealing in trees and shrubs.

**Communications Received.**—*W. B. W.*, *A. M.*, *W. J. M.*, *H. L.*, *Y. G.*, *W. A.*, *C. D.*, *A.*, *Begun*, *T. H.*, *M. R.*, *W. J. B.*, *A. C. B.*

Presented to the Gardeners' Club

APPLE NORFOLK BEAUTY

to which Mr. Cox draws attention is known as a silver thaw and is due to the temperature at a short distance above the ground being higher than that on the ground itself. Such abnormal conditions obtain when the ground and the lower air have been rendered excessively cold from some cause, such as a warm, moist upper current in advance of an approaching cyclone bringing clouds and rain. Silver thaws are sometimes seen in the south of England, and one occurred in London on January 22, 1867. The phenomenon is stated to be common on Ben Nevis in Scotland.

**National Rose Society.**—The forty-fifth Annual General Meeting of the National Rose Society will be held at Caxton Hall, Victoria Street, Westminster, on Tuesday, January 17, at 2.30 p.m. Members attending are invited to remain to tea at the conclusion of the business proceedings, and after tea the President, Mr. E. J. Holland, will exhibit a set of the latest lantern slides acquired by the Society.

**The Late Mr. William Purdom.**—Mr. William Purdom, whose death at Peking on November 7th, 1921, was announced in our issue of December 31, 1921, was a native of Heversham, Westmorland, and was forty-one years of age. We learn from the *Kew Bulletin* that he chose the profession of a gardener and gained experience at Brathay Hall Gardens, Messrs. Low and Sons' nurseries, Eufield, Messrs. J. Veitch and Sons' nursery, Coombe Wood, and at Kew Gardens, which he entered in August, 1902, and where he remained until December, 1903. His association with Mr. Reginald Farrer as travelling companion in his first exploration in China is recorded in Farrer's works, *Eaves of the World* and *The Rainbow Bridge*, and the esteem and affection with which Farrer regarded Purdom is expressed in his dedication of the first book to Purdom, whom he refers to as "an absolutely perfect friend and helper." In 1917 Purdom was appointed head of one of the five departments of forestry maintained by the Chinese Government, and during his term of office he established nurseries in various parts of Honan in furtherance of large schemes of re-afforestation in the north of China.

**Legacy to a Gardener.**—The late Mr. Thomas Embleton, of the Cedars, Methley, and Layton Manor, Yorkshire, bequeathed the sum of £1,500 to his gardener, Mr. John Lee. Mr. Embleton bequeathed substantial sums to several other servants, including £1,500 to his coachman, Mr. J. Bell; £1,500 to his estate foreman, Mr. Marshall Hardy; £2,500 to his nurse, Annie Robinson, and, to his servants not mentioned in his will, the sum of £30 in the case of males and £20 in the case of females for each year's service.

**Dry Season at Shinfield in 1921.**—The rainfall at the Reading University College Gardens, Shinfield, during 1921 was much below the average, and the total of 14.41 inches indicates the trying conditions under which Mr. A. J. Cobb and his staff carried out their duties, including the conduct of a large trial of Sweet Peas on behalf of the National Sweet Pea Society. The rainfall during the year was as follows: January, 2.24 inches; February, .58; March, 1.18; April, .55; May, 1.75; June, .37; July, .2; August, 1.4; September, 1.91; October, 1.07; November, 2.14; and December, 1.22 inches.

**"Flowering Plants of South Africa."**—The fifth part of this work, being issue No. 5, Vol. II, January, 1922, contains illustrations and descriptions of ten South African plants. The work is almost a replica of the *Botanical Magazine* save that the pages are a little larger, which is rather an advantage, for it permits of easy disposition and grouping of the various details of the flowers. Plate 41 is of *Aloe Wickensii*, which is described as one of the most beautiful and showy of the South African Aloes; at first glance the inflorescence might be mistaken for that of a *Kniphofia*. *Watsonia Galpinii*, plate 45, has the appearance of a good garden plant. The leaves are up to 35 cm. long and over 1 cm. broad; the inflorescence is

simple or branched, and bears reddish pink blossoms. *Kniphofia alooides*, plate 47, is an old garden plant, well known in this country as *Tritoma Uvaria* and also as *Kniphofia Uvaria*. It is stated that two varieties of the plant are found in the coastal districts of Natal, known as *nobilis* and *maxima*. It is the most robust and valuable species of the genus. A curious climbing Crucifer, *Heliophila scandens*, is illustrated in plate 48. The plant is said to be growing in the succulent house at Kew, where it flowers about mid-winter. *Holmskioldia speciosa*, plate 49, forms a large bush, ten to twenty feet high, and when in full bloom is one of the most conspicuous objects in the veld. The inflorescence is very pretty, the flowers having a large pink calyx and violet corolla; the blossoms are arranged in axillary cymes about 4 cm. long. Other plants illustrated are *Commelina benghalensis*, *Hessea Zeyheri*, *Ceropegia tristis*, *Massonia latifolia*, and *Rhamphicarpa tubulosa*.

**Mr. Alexander Dickson.**—We congratulate Mr. Alex. Dickson, head of the firm of Messrs. Alex. Dickson and Sons, Ltd., of Belfast, Newtownards, and Dublin, upon the honour which

MR. ALEXANDER DICKSON.

the French Government have conferred upon him in granting him the rank of Chevalier of the Order of the Mérite Agricole, for services rendered by him to horticulture in France. Although the head of a firm which does not confine its attention to Roses, it is not too much to state that Mr. Alex. Dickson has devoted the larger part of his life to the development of the new Roses for which his firm is famous throughout the world, and he has been very largely instrumental in beautifying our gardens with Roses of such colours as were hardly imagined to be possible in these flowers twenty-five years ago. Mr. Dickson has been a frequent visitor to France, sometimes at the request of the French Minister of Agriculture, and he has sat upon Government juries at Paris and Lyons on some seven occasions, and, of course, he has made frequent visits to the trials of Roses at Bagatelle. Evidence of the high position of his firm is shown by the fact that it holds a warrant from His Majesty King George V. and has held similar appointments under King Edward and Queen Victoria. Mr. A. Dickson has for many years been a member on the Council of the National Rose Society, and he is also a member of the Council of the Horticultural Trades' Association, while as a kind of recreation from ordinary business he finds time to represent his native town on the County Council of Down.

**Carriage of Orchids by Passenger Train.**—On behalf of Orchid growers, the Chamber of Horticulture recently approached the Railway Clearing House with reference to the excessive rates charged for the conveyance of Orchids by passenger train. To the representations then made, the railway authorities have made concessions which, in addition to affording relief from the previous special rates charged for these plants, will remove the absurd anomaly of denying Orchids in bud or flower the benefits of the owner's risk rate. On and after February 1, Orchids in less than truck loads, in soil, or in soil in pots, packed in substantial crates or wooden boxes, so constructed as to admit of other traffic being loaded on top thereof, will be conveyed by company's risk at the general parcels scale, and at owner's risk at the usual owner's risk scale. If not so packed, and the plants are one foot or less in height, a general parcels scale plus 50 per cent. will be charged (C.R.) and the general parcels scale (O.R.). If above one foot in height, the general parcels scale, plus 25 per cent. will apply (C.R.), and the ordinary owners' risk scale, plus 25 per cent. (O.R.). If packed other than in soil, or in soil in pots, the C.R. rate will be the general parcels scale, and the O.R. rate the ordinary owners' risk scale. In all these cases the company's risk rates include collection and delivery and the owner's risk rates include delivery where arrangements for these services are in operation. If Orchids are packed in owner's risk vans, maximum weight 50 cwt. per truck, the scale will be the same as for carriages. If packed in truck-loads in company's vans, the loaded-van scale plus 25 per cent., station to station, will be applied (C.R.), and the ordinary loaded van scale will apply O.R. One prominent firm of Orchid growers has informed the Chamber that these concessions are of considerable benefit, especially in connection with the dispatch of plants to exhibitions.

**Appointments for the Ensuing Week.**—Tuesday, January 17: Royal Horticultural Society's Committee meetings; Cardiff Gardeners' Society's meeting.—Wednesday, January 18: British Florists' Federation annual meeting and dinner; Hertford Horticultural Society's meeting.—Thursday, January 19: Manchester and North of England Orchid Society's meeting.—Friday, January 20: Eastbourne Horticultural Society's meeting.—Saturday, January 21: British Mycological Society's meeting at University College, London.

**"The Gardeners' Chronicle" Seventy-five Years Ago.**—*The Victoria regia.*—*Curtis's Botanical Magazine* for the present month is wholly occupied by a history of *Victoria regia*, the most noble of all aquatics, and of which living plants exist in the Royal Botanical Garden, at Kew. We need not say that Sir William Hooker has done justice to his subject. In addition to a sketch of the royal plant reposing on the surface of the quiet waters in which it loves to dwell, we are presented with many details of its structure, never before published. The living plants to which we have alluded were raised from Bolivian seeds, brought home by Mr. Bridges, one of the most indefatigable and successful investigators of the Natural History of South America. We must refer to this interesting monograph for full information respecting the plant, our limited space not permitting us to extract more than the following memorandum supplied by Mr. Bridges: "During my stay at the Indian town of Santa Anna, in the province of Moxos, Republic of Bolivia, during the months of June and July, 1845, I made daily shooting excursions in the vicinity. In one of these I had the good fortune (whilst riding along the woody banks of the river Yacuma, one of the tributary rivers of the Mamoré) to come suddenly on a beautiful pond, or rather small lake, embosomed in the forest, where, to my delight and astonishment, I discovered, for the first time, 'the Queen of Aquatics,' the *Victoria regia*! There were at least fifty flowers in view, and Belzoni could not have felt more rapture at his Egyptian discoveries than I did in beholding the beautiful and novel sight before me, such as it has fallen to the lot of few Englishmen to witness." *Gard. Chron.*, Jan. 9, 1847.

## NOTICES OF BOOKS.

## Notes on Edible Plants.

FROM a memoir of the compiler of these notes,\* which follows the brief preface by Dr. Hedrick, we learn that Dr. E. Lewis Sturtevant was born in Boston, Massachusetts, on January 23, 1842. His school-days finished, he entered Bowdoin College in 1859, and left in 1861 to enlist in the Union Army, which was then engaged in civil strife. Subsequent to his army career, he studied medicine, and later he became a successful farmer at South Framingham, Massachusetts, where he carried out important breeding and cultural experiments, and published the results of his researches in the periodical literature of his time. In 1882 he was appointed first Director of the Experiment Station at Geneva, a post he held until 1887, when he was retired. Taking as his motto, "discover, verify and disseminate," Sturtevant was one of the pioneer builders of the Agricultural Experiment Stations in the United States of America, whose researches and publications have now a world-wide reputation. He died on July 30, 1898, at Waushakum Farm, where so many of his early experiments had been made.

After remaining untouched for twenty years, the notes left by Sturtevant were edited and arranged for publication by Dr. U. P. Hedrick, Horticulturist at the Geneva Station. They comprise the work under notice, a sumptuous volume of nearly 700 pages, containing useful historical information relating to the food-plants capable of being utilised for human sustenance. Probably few besides students of economic botany realise that nearly 2,900 species of plants, exclusive of Fungi, are in use throughout the world as human food, most of which are cultivated for that purpose.

Numerous sources of information have been drawn upon for the notes, as a glance at the list of authors and titles appended to the volume shows. The plan of arrangement adopted is to give the botanical names of the plants in alphabetical order, thereby securing easy reference. The common names and synonyms are given in indices at the end. The first entry, a short one, may be quoted as an illustration of the form the notes take—

*Aberia caffra* Harv. and Sond. Bixinae.  
*Kai Apple, Kau Apple, Kei Apple.*

South Africa. The fruits are of a golden yellow color, about the size of a small apple. They are used by the natives for making a preserve, and are so exceedingly acid when fresh that the Dutch settlers prepare them for their table, as a pickle, without vinegar.†

It will be seen that the work is of the nature of a dictionary of edible plants, and in most instances it gives authorities and references to original sources of information. It is rather remarkable in this connection that Watt's *Dictionary of Economic Products of India*, the standard work of reference for information regarding the uses of plants found in India, and the East generally, is omitted from the list of works to which reference is made.

Although now conveniently arranged for reference in one volume, much of the information has been published previously, but it is claimed for the work that new knowledge may be found in the following directions: (1) The original home of many esculents is given for the first time. (2) New land-marks in the histories of edible plants are pointed out. (3) An effort has been made to mention all cultivated esculents. (4) Though much new information is given regarding the history of food plants of the Old World, it is especially full and accurate in the discussion of esculents of the New World. (5) It presents much new information on the varieties that have been

\* *Sturtevant's Notes on Edible Plants.* Edited by U. P. Hedrick. Report of the New York Experiment Station for the year 1919, 27th Annual Report, Vol. 2, pt. II. (Albany U.S.A., J. B. Lyon and Co.), 1919, pp. 686, with portrait.

† Jackson, J. R., *Treas. Bot.* 2; 1255, 1876.

produced in plants by cultivation. (6) It adds much to geographical botany. (7) It contributes much data for the study of acclimatisation.

The home of the Cacao plant (*Theobroma Cacao*) is South America, and the history and uses of the plant in that country are mentioned, but the note gives no information regarding the acclimatisation of the plant in the Gold Coast, which is now the leading Cacao-exporting country. The remarkable development of the industry in the Gold Coast is illustrated by the fact that the export has grown from 80 lb., of the value of £4, in 1891 to an export of 176,000 tons, valued at £8,278,000, in 1919. It is to be regretted,

## A NEW SWEET PEA.

AMONG the several novelties in Sweet Peas which arrested the attention of the Floral Committee of the National Sweet Pea Society at the trials held at Reading last year, the one which was subsequently to bear the name of Mascotts Ingman received sufficient votes to secure it an Award of Merit. But another variety, which was eventually found to carry the name of Renown, was considered to be identical with the former, and the Committee agreed that the award should be conditional upon both senders agreeing to distribute the variety under the same name. Messrs. Ireland

FIG. 7.—SWEET PEA MASCOTTS INGMAN; CONSIDERED IDENTICAL WITH RENOWN.

therefore, that the notes were not brought more up to date before they were published, as this would have greatly increased their present usefulness, but this defect may, we hope, be remedied in a future edition.

It will be evident from what has been said that the book presents in a concise and convenient form a mass of useful information regarding the esculent plants of the world, and as a work of reference for the gardener, the colonist, the student of economic botany, and all interested in plants, it should prove of great value. The type, printing and paper are all excellent, and the generous margins to the pages would admit of lengthy additional manuscript notes. In these days of costly book production it is a pleasure to see and handle such a work.

and Hitchcock, of Mark's Tey, are responsible for Mascotts Ingman, which is a very fine carmine variety (Fig. 7), while Renown is one of Messrs. Dobbie and Co.'s novelties. Unfortunately, these firms could not agree to distribute the variety under one name, consequently, to quote from the report of the Floral Committee, "as neither firm could see their way clear to alter the names already given, the Award of Merit is struck off." It will be readily understood that failure to secure the award under these conditions does not affect the merit of the variety, which has flowers of fine, rich carmine colour, of large size and of first-rate form. The flowers illustrated in Fig. 7 represent a spike exhibited by Messrs. Ireland and Hitchcock under the name of Mascotts Ingman during the past season.

## The Week's Work.

### THE HARDY FRUIT GARDEN.

By H. MARKHAM, Gardener to the EARL OF STRAFFORD, Wrotham Park, BARNET.

**Damsons.**—These trees, when suitably planted, form a capital screen to the more tender kinds of fruits. There are many good varieties to select from, which will yield excellent crops of fruit, where other kinds may not succeed. Bradley's King, Prune Damson, Farleigh Prolific, and the Merryweather are varieties to be recommended.

**Morello Cherries.**—The pruning and training of Morello Cherries should be done as soon as the leaves have fallen, so that the work is completed before very cold weather sets in. If, however, the work has not yet been done, it should be carried out in favourable weather. It is not necessary to remove all the shoots and branches from the walls annually, but the trees should be carefully gone over, and the old shreds examined with a view to removing any that are compressing the bark. Train in sturdy, fruitful shoots at intervals all over the trees, but guard against crowding the wall with useless wood. Young Morello Cherry trees should, if not equally balanced in growth, be removed from the wall and the shoots regulated. The main branches should be trained at equal distances and suitable angles to build up an evenly balanced head. Allow room in the ties for the shoots to swell, and take care that no old twine ties are overlooked, for these would cut into the bark.

**General Remarks.**—Keep a watch on the doings of birds, especially bullfinches. Syringing the trees with soap-suds or Quassia extract, and thoroughly dusting them with lime and wood ashes, will sometimes prevent birds from destroying fruit buds. Feeding the roots should not be overlooked, especially on light, shallow land; soakings of liquid farmyard manure, not too strong, will prove very helpful; or a good mulching of decayed manure may be given in time for the rain to wash its fertilising properties down to the roots.

### PLANTS UNDER GLASS

By T. PATEMAN, Gardener to Sir C. NALL-CAIN, Bart., The Node, Codicote, Welwyn, Hertfordshire.

**Souvenir de la Malmaison Carnations.**—Perhaps the best results are obtained with these charming flowers when the plants are kept in a somewhat dormant state during the winter, and this may be done by keeping them on the dry side and in a comparatively cool house, admitting plenty of fresh air whenever the outside conditions are favourable for ventilating. Very little fire heat is needed, only sufficient should be used to keep the atmosphere from becoming too damp or to exclude frost.

**Chrysanthemums.**—Cuttings of Chrysanthemums that were inserted in early December, with a view to producing large flowers, should be removed from their propagating quarters as soon as they have rooted. Place them in a cool house or frame as near the roof-glass as possible to prevent them becoming drawn. They may remain in this position for a week or ten days, when they should be placed singly in small 60-sized pots; if three or four cuttings have been rooted in a small pot it is not advisable to allow them to remain in the receptacle until the roots have become matted together. The soil for this potting may consist of three parts good loam and one part leaf-mould mixed with a little bone meal and just sufficient silver sand and burnt garden refuse to keep the compost porous. Cuttings of the single and decorative varieties may now be inserted. These will strike readily in a temperature of 45° to 50°; while it is not advisable to propagate these Chrysanthemums in a high temperature, a lower temperature than 45° to 50° is not to be recommended. After the cuttings have been procured many of the old stools may be thrown away, retaining

only sufficient plants to ensure a few more cuttings if the others fail or it is desired to propagate again in early April to produce small plants for growing in 6-in. pots for decorating purposes.

**Winter Flowering Begonias.**—Winter flowering Begonias of the Mrs. Heal, Optima, and Exquisite type will, in most cases, have passed out of flower by this date. These plants need careful attention with regard to watering. It is not wise to withhold water altogether, but just sufficient should be given to keep the plants from drying off completely. The plants should be rested in a temperature of 50° to 55°. Begonias of the Gloire de Lorraine type that have passed out of flower should be cut back and watered sparingly for a few weeks, with a view to starting them into new growth to obtain cuttings for next season's stock.

FIG. 3.—GLADIOLUS CAMEO (SEE P. 17).

### THE KITCHEN GARDEN.

By JAMES E. HATHAWAY, Gardener to JOHN BRENNAND, Esq., Baldersby Park, Thirsk, Yorkshire.

**Peas.**—Peas raised from a sowing made in November should be carefully watched and protected from birds and slugs. Wire netting, one foot wide, arched over the plants and pegged down on both sides of the rows, provides the best protection from birds, but if wire is not available, small Spruce branches stuck on either side of the rows will help to keep birds away. A dressing of soot and wood ash will act as a deterrent to slugs. A further sowing should be made in a sheltered situation when the ground is in a favourable condition. Peas should also be sown in pots, boxes, or turves, the last for preference. The turves should be cut about 9 in. wide and about 4 in. thick and placed turf side downwards on boards about 4 ft. long. Afterwards scoop out about an inch of the loam and substitute a mixture of loam, leaf-soil, sand and wood ash, sifted through a half-inch sieve. Carter's Eight Weeks and Sutton's

Pioneer are suitable varieties for sowing now and there are many other sorts which may be used. After sowing, germinate the seeds in a cool house or frame.

**The Seed Order.**—The greatest care should be taken in making the selection of seeds for the coming season. If notes were taken during the past season of varieties which did well, reference to them will help to simplify matters. It is not always an easy matter to select the most suitable varieties for particular districts, for those that may succeed in one part may not do so well in others. If extra fine vegetables are required, such as for exhibitions, do not rely on old seeds.

**Cucumbers.**—A sowing of Cucumbers should now be made in 60-sized pots, placing one seed in each receptacle. Germinate the seeds on a slight hot-bed in the Cucumber house; the seedlings will appear very quickly, and need plenty of light and warmth; a temperature of 70° is suitable, but in very severe weather they will take no harm if it drops to 65°. Remove all decaying foliage from winter fruiting Cucumbers. Keep the shoots thinned.

**Tomatos.**—A sowing of Tomato seed should be made to raise plants for early fruiting. Sow thinly in well-drained 6-inch pots, filled with good, sifted soil composed of two parts loam, one part leaf-soil, one part spent horse droppings, and enough sand to render it porous. Place the seed pans in a Cucumber house, and as soon as the seedlings appear stand them near to the roof-glass. As soon as the plants are big enough to handle pot them singly in thumb pots.

### FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

**Figs.**—Pot Figs in houses that were closed for forcing last month may have the fermenting material replenished. This may not be absolutely necessary, but it plays a prominent part in the successful cultivation of these early fruits, not only in affording warmth, but also in maintaining suitable atmospheric conditions, and helps in preventing early attacks of red spider. A steady bottom heat of about 75°, with a night temperature of 60° to 65° on mild nights, and 70° to 80° by day, with a very small amount of fresh air admitted on all favourable occasions, will be found suitable conditions for Fig trees started early last month. The second house, containing permanent trees, may now be closed. This is, in many cases, the earliest house, while late houses should be kept as cool as possible. As these trees are grown in restricted borders, it is often possible to place fermenting materials over the roots. This will not only help to maintain the requisite temperature, but give off the necessary atmospheric moisture for starting the trees.

**Strawberries.**—The present is a suitable time to house the first batch of Strawberries, as much care is necessary to be successful with plants started last month. Place the plants on a bed of fermenting leaves, as the gentle warmth will stimulate the roots before the crowns make much progress. Clear the pots of weeds and make the soil firm when it is moderately dry. Sufficient moisture will be obtained from the leaves for the first few weeks, and water should only be given the roots after careful examination. The same remarks apply to plants stood on shelves in the Strawberry house proper, during their early stages of forcing. A night temperature of 40° to 45° will be sufficient for the first few weeks.

**Propagating Vine Eyes.**—Where young vines are required for growing in pots or planting out as "green" vines now is a suitable time to raise them from "eyes." The young vines will then be in readiness for potting or planting out any time from March to June. The "eyes" may be inserted in small pots or in squares of turf and placed on the bed in a Melon or Cucumber house where plenty of bottom heat and moisture are available.

**THE FLOWER GARDEN.**

By EDWIN BECKETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Hertfordshire.

**Frost Protection.**—After the very mild season prior to the turn of the year, there is great probability of the old saw, "As the days lengthen, so the cold strengthens," being realised, and steps should be taken to protect any subjects that are likely to be adversely affected on the borders and shrubberies. One of the most efficient means, for such plants as Kniphofias and Moutbretias is a good layer of cinder ash placed around and over the plant where this is possible, whilst dwarf shrubs likely to be adversely affected should be enclosed in "wigwams" formed of Spruce boughs, or similar growths thrust into the soil around the plant, and tied together at the top; stems of taller subjects may be protected by wrapping hay bands around them from the ground level.

**The Rockery and Alpines.**—Many subjects dislike overhead damp, and such as Androsaces, Marrubiuns, Asperulas, and other woolly-leaved subjects repay for overhead covering during the winter season; a piece of glass of sufficient size to cover the plant from above, and fixed into position in some way or other, will easily accomplish this. At this season especially close watch must be kept against slugs, which are fond of Dianthi, Campanulas, Silenes, Omphalodes, and rare Saxifragas, whilst the short-tailed vole is another depredator in similar directions. Measures should be taken against both as soon as discovered. Look over the spring bedding occasionally, and stir the soil around the plants; also, after a spell of frost, see that they have not broken loose from the soil, a remark that also applies to any Alpine plants that may have been planted in late autumn.

**Plants in Pots.**—Where Alpine and other hardy plants are being grown in pots, the soil should be stirred frequently, and watch kept for slugs. Alpines in pots and pans should not be coddled too much, for they can stand many degrees of frost, but where pots are a consideration, the frames may be covered during severe weather.

**THE ORCHID HOUSES.**

By J. T. BARKER, Gardener to His Grace the DUKE OF MARLBOROUGH, K.G., Blenheim Palace, Woodstock, Oxon.

**Ventilating.**—Owing to the amount of fire heat required to maintain the necessary warmth, especially in the hotter divisions, it is quite easy for any house to acquire a stuffy condition, unless fresh air is admitted daily. At this season discretion must be used in admitting air, but it must be done by some means every day, as a dry, stagnant atmosphere is most injurious to the plants. The observant cultivator will soon find the difference between a badly ventilated and a judiciously ventilated house, not only by his own personal comfort, but in the health and vigour of his plants. Houses vary considerably in their requirements, according to the plants grown in them, their position and proximity to the heating apparatus. Orchids need fresh air, but should not be exposed to cold draughts. To those who do not succeed with Orchids exactly as they would like, I urge a closer study of the atmospheric conditions of the houses.

**Dendrobium.**—The flower buds of many of the deciduous and semi-deciduous varieties of Dendrobium are developing, and the roots will require more water than they have received since the past season's growth was completed, but the plants should be allowed to become dry before being watered. When the outside temperature does not fall below 40°, maintain a minimum temperature of about 60°, but during colder weather the temperature of the house may be allowed to drop slightly without harm accruing, provided a dry atmosphere is maintained. Any check given to these plants during the development of the flowers, either from an excess or deficiency of water, or from too low a tempera-

ture, will reduce the size and quality of the flowers to a considerable extent. When the flowering season is over the plants should be kept growing very slowly until the days get longer and the weather conditions are more conducive to the plants making satisfactory growth. The flowering period may be prolonged by placing some of the more forward specimens in gentle warmth. The change from the cool resting quarters to that of a warm house should be gradual, as should any forcing of the plants be attempted there is the danger

of them making premature growth, instead of flowering. Plants which were forced in previous years readily respond to this treatment, and some varieties respond readily to gentle forcing, but this should only be attempted with strong, well-rooted, vigorous plants, which have been well ripened and matured.

FIG. 9.—GLADIOLUS DUNLAPS.

**THE GLADIOLUS IN AMERICA.**

JACK LONDON, referred to in my notes on p. 157, Vol. LXX., was raised in California, and until last year represented the only variety from that land of sunshine which grew with any degree of success with me. The flowers of the majority of the varieties I have tried have been too heavy for the epike. Several

of a new race of Kunderii Gladiolus, a cross between a Kunderii variety and the species Quartinianns. They are said to come into bloom about one month later than other flowering kinds planted at the same time. I grow Indian Summer a year or two ago and it did not flower until the first week in October, although planted in March. It produced a fine spike. In 1921 I planted four other varieties at the same time (9.4) as Fire Ribbon. The latter flowered on 17.7, Dunlaps (Fig. 9) on 4.9, Arcadia on 10.9, Arcola on 12.9, and the fourth, Storm King, much after that date. The three that bloomed first are quite distinct, and Arcola has a feature which I have never noticed in any other Gladiolus. The flowers that have not fully developed during the day, partially close at night and open out again in the following morning. G. C.

### EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, W.C.2.

Editors and Publisher.—Our correspondents would oblige by delaying in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the Editors. The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.

### THIRTEEN GOOD BORDER PLANTS.

OLD things need not be therefore true, O, brother men, nor yet the new.

Thus spake A. H. Clough from his viewpoint of human circumstance, and the amateur gardener, reviewing the good and ill of the memorable summer of 1921, may thus paraphrase the couplet to fit his own case—

Many old plants are very good;  
Some new ones don't please as they should.

It may be of some use to those who have blanks to fill in their borders, and care to do so with herbs that are not met with in every garden, if leaving out Lilies and Roses, I jot down some notes on things that have contributed to the gaiety of the past season. I shall restrict the list to a baker's dozen, well knowing how prone one is to prose about his pastime.

**PAEONIA CAMBESSEDESII**, the gift of an Irish lady who collected it in the Balearic Islands. In my opinion it is the loveliest of the genus and the earliest to flower. Before the New Year it had pushed up shoots a couple of inches long, intensely scarlet, and, as experience in former winters goes to prove, immune to any ordinary degree of cold. These shoots will lengthen out to the height of a foot, and in April, when clad with leaves with a silvery lustre on the upper side, rich red on the lower, will bear cup-shaped blossoms of tender rose, enclosing a bunch of golden anthers whence protrude the scarlet stigmata. The habit of this plant is neat and compact, and it relishes lime in the soil.

**GEUM BORISII**.—I bless the day when I first met this—the choicest of its kind—at the R.H.S. show. It is quite free from the sprawling habit which mars the merit of the varieties Mrs. Bradshaw, Gibson's Scarlet, Heldreichii, etc. It carries its flowers, the colour of red lead, with golden anthers, erect on wiry stems, and is lavish of them throughout summer and autumn. It began to flower on April 30 last, and is still starred with a few blooms on this New Year's Day.

**DRACOCEPHALUM FORRESTII**.—A recent introduction from Western China, with bright green Heath-like foliage and rich purplish-blue spikes of blossom continuously produced. It grows about one foot high and is well suited for the front of a border.

**GLADIOLUS TRISTIS**.—This plant is not included in the *Kew Hand List*, but it has been established in this country for several years, and deserves to be more generally grown. Had I been asked to name this species I should have called it *gracilis*; the epithet *tristis* is far from appropriate to the delicate sulphur hue of the vase-shaped blossoms. It sends up its rush-like leaves in autumn, which remain green all the winter, till it flowers in June. This plant prefers a sunny exposure.

**INULA ROYLEANA**.—A Himalayan species, the handsomest of a comely family. Grows two feet high and is of the easiest culture.

**LOBELIA CAVANILLESII**.—A Chilean plant, bearing plenty of gay scarlet flowers lined with yellow, in July. Perhaps tender in cold districts, but revels under a south wall.

**NERINE BOWDENII**.—Exquisite is the right epithet for this plant, which is not usually named in lists of hardy subjects, but which seems quite happy here under similar conditions to those that agree with *Amaryllis Belladonna*.

**SALVIA HIANS**.—The blue and white blossoms of this Himalayan species are so charming as to warrant its place in the select number; but here, at least, it is somewhat niggardly in producing them. Probably in sunnier districts it would be more liberal in display.

**PHYGELIUS CAENSIS**, the Cape Figwort.—I never realised the full merit of this plant until several years ago I received from the Edinburgh Botanic Garden one that bore scarlet blossoms. That which had been in the garden here for half a century produced flowers of dull brick-red. A free and showy herb; but to get the best of it let it be trained against a south wall. It is hardy in the open border in the south and west, but straggles over too much space to be effective, and smothers weaker neighbours.

**CRASPEDIA UNIFLORA**.—This New Zealand Composite also I owe to my good friends in Edinburgh. In 1920 I received a plant with a single flower-head thereon. Seed ripened and was sown, and the numerous offspring flowered freely in 1921. It is a very neat plant, nine inches or a foot high, producing many solitary, globular, rayless yellow heads.

**SAXIFRAGA AIZOON ROSEA**.—This is one of the very best of the encrusted section. It makes a pretty edging, and thrives better in the open border than on the dry retaining wall where I first grew it. The plant increases fast.

**ROSCOEIA CAPITATA**.—A purple Ginger-wort from the Himalayas which I got from Bees', Ltd. It is a rich-coloured counterpart of the sulphureous *R. cautioides*, eighteen inches high, but flowering a month later. Another species or variety obtained from Bees' under the unsatisfactory name of August Beauty, closely resembles *R. cautioides* in form, height and colour, but does not flower till August. All species of *Roscoeia* require careful labelling, because none of them show above ground till a few days before they come into flower. They spread satisfactorily by underground runners, so the ground should not be disturbed round the parent plant. A very desirable family.

**POTERIUM OBTUSUM**.—An aristocratic kinsman of our native Salad Burnet, and a notable addition to our border in July and August. It grows three feet high, and its elegant foliage flames, blushes or pales into attractive tints in the autumn. *Herbert Maxwell, Monreith, January 1, 1922.*

### THE GREAT DROUGHT OF 1921 AND ITS EFFECT ON GARDEN PLANTS.

(Continued from page 9.)

HERTFORDSHIRE.

THE drought of 1921 punished this garden severely from the beginning of June until the welcome fall of two inches of rain on the 12th of September. The soil is ill adapted to withstand a period of more than a week without rain in the summer months. It is for the most part very shallow, and the subsoil, a coarse and hungry gravel, makes for rapid drainage. Old trees have filled most of it with such a network of roots that they take first toll of any moisture in the ground, therefore in such a season as we experienced it was inevitable that the damage should be great, that the benefit of extra sunshine and dryness of atmosphere should be noticeable in certain plants, and also that others should add to our knowledge by behaving in an unexpected manner.

In the first class, namely, those one would expect to suffer first and most must be placed almost all shallow rooting plants and those that demand a great amount of moisture in the atmosphere.

Ferns and Mossy Saxifrages showed signs of distress by the end of May. Many of both are dead, most of those still alive are ruined for a season or two. Even in the most favoured nooks *Polystichum* and Hart's Tongue fronds were short—mostly scorched at the tips. In situations that drained out more the season's growths was no more than an inch or two of living green. An old plant of *Adiantum*

*pedatum* among *Primula Bulleyana* was scorched up in mid July, but a younger one planted partly under the north side of a fair-sized boulder, in imitation of the successful clumps at Wisley, has remained green.

*Asarum europaeum*, normally an evergreen, lost every leaf. They dried up to a tea-leaf consistency, broke to pieces, and were blown away by the persistent N.E. winds. Deciduous species such as *A. caudense* and *A. caudatum* suffered almost as badly. At one time the rhizomes appeared dead, but recovered and filled out with sap after rain fell. *Epimediums*, especially those with thin and deciduous leaves, such as *E. alpinum* and *E. Muscianum*, were badly scorched. *Rodgersia podophylla*, *R. tabularis*, *R. aesculifolia* and *R. pinnata* lost the undersized leaves they had managed to make. On the contrary *Saxifraga peltata* showed its Californian origin by developing and lasting as well as usual. *Primulas* such as *P. japonica*, *P. Bulleyana* and its hybrids; *P. pulverulenta*, *P. chionantha*, *P. Beesiana* and its hybrids, and other moisture lovers, even though well watered failed to make satisfactory roots after flowering, and have mostly died. *P. Juliana* and its hybrids, though losing their leaves, seem to have been saved by the storage in the fleshy rhizomes.

Heaths suffered severely. Several old stretches of *Erica carnea* and *E. darleyensis* being killed. *E. vagans* and *E. stricta* stood the best of the family. *Rhododendrons* and *Azaleas* are sad sights. Many late flowering varieties failed to open their flower buds. Young growths were either scorched up altogether, or the edges of the very undersized leaves burnt brown; only the earliest flowering varieties formed any flower buds for the coming season. *Zingiber Mioga*, the hardy Ginger from Japan, made growths of four inches instead of a yard high, and failed to flower. *Anemone vitifolia*, Farrer's pink flowered variety, never opened a bud; all were scorched brown. *Bamboos* suffered terribly. *B. palmata*, even where old growths had been thinned out and some good soakings supplied to the vigorous young shoots, became a buff coloured eyesore. A few young shoots replaced the dead ones since the September rain, and look as though they will withstand the frosts. *Arundinaria anceps* lost every green leaf, and the young canes started too late to ripen. *A. nitida*, though looking brown and ugly for months, has clothed itself in greenery, and looks none the worse; even two large clumps moved in May have not suffered seriously. It was too dry for *Alstroemerias* even. The stems were short, and the flowers small and soon over. *Anemone japonica*, too, when it flowered a month later than usual, looked more like *A. sylvestris* than its tall self. *Eucryphia pinnatifolia*, such a wonderful picture for several weeks in 1920, was in beauty for but a few days in 1921, and the flowers that first opened were small, and later ones were scorched and browned.

Early *Chrysanthemums* were markedly delayed in their period of flowering, but owing to the glorious weather of October they have seldom been finer. *Amicia Zygomeris* grew well, but flowered later than usual, as also did *Parochetus communis*, where established for stock in a cold frame as well as where newly planted in what in most years is a moist bed. In contrast with the retarded flowering of *Acemone japonica* and late appearance of *Bamboo* shoots mentioned above, the earliness of flowers from certain bulbous plants or those with storage corms such as *Cyclamen* and *Colchicum* was very noticeable. *Merendera Bulbocodium* appeared early in July, a fortnight sooner than in most seasons. *Leucojum autumnale* was not far behind, and *Colchicum autumnale* in a damp meadow broke all previous records by flowering a week before *C. variegatum* and *C. Bornmuelleri* usually the two earliest. *C. byzantinum* followed after *C. autumnale*, before the end of July; by that time *Cyclamen neapolitanum* made a good show under a Cedar.

After a wet summer it has frequently happened that *Amaryllis Belladonna* has sent

Webbs' "King George" Pea.  
Award of Merit, R.H.S., Wisley Trials.

"'King George Pea' did very well. I grew it for exhibition, and it was the finest that we had. The pods measured 7½ inches in length and were well filled. It is a grand variety for exhibition."—  
Mr. A. R. SEARLE, Head Gardener to THE MARQUIS OF NORTHAMPTON.

## Pea Progress.

By scientific cross-breeding and selection we have secured remarkable improvements in Garden Peas during recent years, and it is now possible, under suitable cultural conditions, to obtain a successive supply of Delicious Marrowfat Pea for a period extending from early Summer to late Autumn.

By Appointment.

# WEBB'S GARDEN PEAS

*The Finest Breeds in Cultivation.*

	Per Pint	Per Quart
<b>First Early</b>		
Webbs' "New Surprise," 15 to 18 in.	2/3	4/-
Webbs' "Little Marvel" 12 to 18 in.	2/3	4/-
Webbs' "New Pioneer," 3 to 3½ ft.	2/-	3/6
<b>Second Early</b>		
Webbs' "Stourbridge Marrow," 5 ft.	2/6	4/6
Webbs' "Rival Marrowfat," 3½ ft.	2/-	3/6
Webbs' "Defiance Marrowfat," 4 ft.	2/6	4/6
<b>Main Crop</b>		
Webbs' New "King George," 5 ft. In sealed packets only, at 1/6 & 2/6 each		
Webbs' "Senator," 2½ to 3ft. (The most Prolific Pea ever raised.)	2/3	4/-
Webbs' "Reliance" Marrowfat, 5 ft.	2/3	4/-
<b>Late Main Crop</b>		
Webbs' "New Masterpiece," 4 ft.	2/3	4/-
Webbs' "Distinction," 3½ to 4 ft.	2/6	4/6
Webbs' "Selected Gladstone," 3½ ft.	2/3	4/-

"'Senator' Pea carried a splendid crop of pods and hanging on each side so thick that one could hardly see any leaves, pods produced in pairs, simply grand as it fills with the pod."—Mr. A. W. TAYLOR, Head Gardener to LORD INCHCAPE, G.C.M.G., K.C.I.E., K.C.S.I.

Heating Apparatus,  
Rustic Work, Rustic Houses,  
Garden Requisites and  
Furniture,  
Portable Buildings and Huts,  
Motor and Cycle Houses,  
Bungalows and Pavilions,  
Poultry Houses, Appliances,  
etc., etc.

Estimates for every description of Horticultural Wood, Iron and Asbestos Buildings FREE.

SEND FOR ILLUSTRATED CATALOGUE No 16 POST FREE

**GLASS** Horticultural, 15 oz. to 21 oz. Every Size in stock.

**TIMBER** Best Quality Imported Timber. Sash Bars, Cills, Wall Plates, Matching, Boards. Large stocks.

SPECIAL QUOTATIONS ON RECEIPT OF REQUIREMENTS

**BULBS** Hyacinths, Daffodils, Crocuses, Early and Darwin Tulips, Irises, Anemones, etc. Bulbs, finest quality and lowest prices. Also Bulb bowls, bulb fibre, manures, potting materials, and insecticides, etc. Send for illustrated Bulb Catalogue No. 4, post free, which describes our bargains and gives full particulars of Bulb Culture.

**GARDEN TOOLS** Lawn Mowers, Rollers, Rubber Hose and Hose Reels, Galvanised Water and Wheel Barrows, Galvanised Corn Bins, Wire and Tinned Netting, Sprayng Machines and Syringes, Wood Trellis, Garden Arches, Water Cans, Stakes, Bamboo Canes, Forks, Spades, Rakes, etc. Send for illustrated Tool Catalogue No. 6, post free.

## WILLIS BROS.' Garden Fertiliser

A REAL MANURE

NOT A SUBSTITUTE.

NO STABLE MANURE REQUIRED.

For digging in or as a top dressing. For Kitchen Garden and Herbaceous Borders. We are constantly receiving orders and testimonials from satisfied users both on heavy and light soils.

1 cwt. 17/6; ½ cwt. 10/-; 28 lbs. 8/-; per ton £16 10. All Carriage Paid.

### VINE MANURE.

27 6 per cwt., 15/- half cwt., carriage paid.

Mr. KIDD, NEW BERRIES GARDENS, RADLETT, has won 3 firsts and 3 seconds in Grape class at R.H.S. Fruit Show and writes us that he has only used our manure on his vines for years with above results.

### LAWN MANURE

For renovating Lawns after dry season. 20/- per cwt., £19 10 per ton carriage paid.

### LAWN SAND and DAISY KILLER.

For destroying daisies and other weeds on Lawns and encouraging the grasses. 27/6 per cwt., 56 lbs 16/-, £26 per ton, carriage paid.

### WILLIS BROS.' WINTER WASH

For Fruit Trees.

Safe, reliable spray for winter use. Kills Hens, mussel scale, and other fruit-tree pests. This is not a caustic soda wash, but a lime sulphur mixed with sterilising and other ingredients. Does not injure the bark of fruit trees.

1 gallon 10/-; 5 gallons 45/-; carriage paid. Tins included.

**BONE MEALS. SUPERPHOSPHATE. NITRATE OF SODA. SULPHATE OF AMMONIA. KAINIT. SULPHATE OF POTASH. BASIC SLAG. etc.. SUPPLIED.**

Send for our list of Garden Manures and Horticultural Sundries. Free on application.

**WILLIS Bros. and Garden Sundries.**  
(HARPEN DEN) LTD. HARPEN DEN, HERTS.

# Wallace's Novelties in Rhododendrons and Azaleas

Rhododendron Hugo De Vries, A.M., R.H.S., Chelsea, 1921, possessing all the fine qualities of Pink Pearl but of better habit, flowering more freely, with broader and more massive foliage. Flower trusses large, well filled, and of splendid shape. 35s. each.

The Rhododendron Walk in "The Old Gardens," Tunbridge Wells.

(From a photograph taken in late May, 1921.)

Rhododendron Britannia, A.M., R.H.S., April, 1921, one of the most telling crimson varieties in cultivation. Bold trusses of flowers of rich flaming colour. A few well-budded plants, 63s. each.

## Three New Azaleas.

**Dr. Oosthoek, A.M., R.H.S., May, 1920, the deepest red yet raised. 10s. 6d.**

**King Albert.**—Pure bright yellow. Unsurpassed for colour effect. 7s. 6d.

**Rhespierre, A.M., R.H.S., April, 1921, immense trusses of rich clear salmon. 15s.**

We have a grand stock of AZALEAS of unsurpassed quality for FORCING OR PLANTING, including the finest forms as Coccinea Speciosa (flaming orange), Anthony Koster (yellow), J. C. Van Thol (scarlet), and Unique, (nankeen and orange), and others.

**NOW READY!** Our New Catalogue of TREES and SHRUBS for Garden and Woodland, containing descriptions of Rhododendrons and Azaleas, and such grand novelties as Pyrus Sargentii, Viburnum Carlesii V. fragrans, Osmanthus Delavayi, New Berberis Philadelphus, etc., also special list of Shrubs for Forcing, post free on application.

**R. WALLACE & CO., LTD., "The Old Gardens," TUNBRIDGE WELLS.**

up its flower spikes so late in November that they failed to open. This season they appeared early in August, and continued in succession until the end of September, many clumps blooming freely that had never done so before. *A. Parkesi* (the Kew Belladonna) blossomed in the open here for the first time in ten years. *Zephyranthes candida* in the var. major were in time to ripen seeds in October, and young plants from those of the latter were two inches high at the end of November. *Sternbergia lutea* var. *angustifolia* was an astonishing sight. A long edging of it in an Iris border was a solid band of yellow, as gay as yellow Crocuses in spring. *Lilium Henryi* gained a fresh value by growing as tall as usual and flowering well, but unlike its behaviour in 1911, when it seeded abundantly, only six pods were formed and ripened. *Lilium testaceum* ripened seed, as did also the old garden form of *L. candidum*.

Crocuses were delayed, and save for one clump of *C. cancellatus*, which bore a few flowers in August, none appeared before the

its admirers and practical jokes for many small boys for two months. Hitherto there have been but three or four ripe fruits at a time; last season it was hard to gather the first half dozen any day without being shot by an equal number of the yellowish-green Gherkins ready to discharge their juice and pips. Here, as in all other gardens I visited during the year, I learnt two facts new to me. No established Rose of any species or variety suffered in the vigour of its young growth, but apparently rejoiced in the drought. Blue forms of Conifers were uninjured alongside green forms that are to all appearance dead. This is very marked with forms of Lawson's Cypress, and it would seem that the waxy coating that gives these their glaucous appearance is able to check transpiration sufficiently to save their lives under conditions that prove fatal to green varieties.

Another lesson was the vindication of the Arab proverb, "Dig for a hundred days, irrigate for one." Deeply trenched ground where trees were felled last winter, though planted rather

*mollis* is just beginning to flower, and Hellebores are to be seen on the banks of the ditches. Whereas in some other gardens there was an unprecedented flowering of *Iris unguicularis* (*styiosa*) in the autumn of 1921, there are at present at Wisley very few blooms showing. A good baking is conducive to the free flowering of this plant, but it is possible that as the position occupied at Wisley is exceptionally dry, it found the past summer too severe and is consequently backward.

*Primula Winteri* (see Fig. 10) is flowering freely at the top of the rock garden, in spite of the attacks of mice, four of which have been caught in traps close by. This beautiful plant does well at Wisley because its roots obtain a plentiful supply of water, and the crowns are protected from wet by overhanging rocks. The flowers are all thrum-eyed and set no seed; this might be rectified if some pin-eyed forms were introduced. Propagation can be effected, however, by separating and replanting the new crowns formed.

Protection from wet by means of glass sheets

FIG. 10.—PRIMULA WINTERI : FLOWERS PALE PURPLE.

September rain fell. Even then *C. zonatus* and *C. speciosus* made no show for fully a week, but when they did appear, favoured by the continuance of sunny days, they were finer than usual, the latter forming a sea of blue in certain borders where it has colonised freely and stretches many yards wide.

All Californian plants were better than usual, and notably so Romneyas and *Zauschneria californica* var. *mexicana*, always satisfactory here, but this year a flare of scarlet from July till the November frosts. *Solanum Torreyi*, with its flat heads of immense Potato-like flowers almost as fine as those of *S. Wendlandii* is another drought lover, and was in great beauty for many weeks. *Oxalis purpurata* (Bowiei) was a lovely sight mingled with *Verbena venosa*, where both have lived for some dozen or more seasons in a south border. *Nerine Bowdeni* was in good form under a wall, and some spikes cut in early October have ripened apparently good seed in water with a pinch of sugar added to it. *Ecballium Elaterium*, the Squinting Cucumber, had an unusually large crop of its explosive fruits, providing daily amusement for

late in the spring, helped *Berberis* of many species, some really too old for moving, not only to live but to make fair growth. In it, too, some small portions pulled off an old clump of *Polygonum cymesum* grew into a mass seven feet high, covered with white flowers, whereas the parent clump wilted badly and failed to flower ornamentally until after the rain fell. *E. A. Bowles, Myddelton House, Waltham Cross.*  
(To be continued.)

### NOTES FROM WISLEY.

AUTHENTIC accounts of Primroses picked in Scotland so long ago as three weeks encouraged expectations of finding a very early show of spring flowers at Wisley. It is a little surprising, therefore, to find so few signs of bloom in early January. But the gardens do not lack interesting features, for many of the berried shrubs are still beautiful. Some of the *Pyracanthas* have had their fruits spoiled by frost, especially those with berries unripened, such as *Pyracantha angustifolia*.

The insufficiently appreciated *Hamamelis*

has been given to such plants as *Androsace primuloides*, *A. Chumbyi*, *Lewisia Cotyledon* and *Campanula mirabilis*, which are apt to rot if water is continually dripping on them. The only plant in flower in the alpine house is *Saxifraga burseriana tridentata*, which alone is worth a visit. The bog garden in the lower part of the rock garden has been dug out and the *Mimulus* removed, as it was becoming too assertive.

Phloxes will be much in evidence at Wisley this year, since, in addition to the trial of 350 varieties, a large border is devoted to them. This border has been established for a year, and is now being dressed with leaf-mould and material from the ditch-bottoms, which is now easily obtained owing to the absence of water. This border also contains varieties of *Chrysanthemum maximum* and some good *Tradescantias*.

The drought of 1921 has been too severe for many plants of *Primula japonica* and *P. pulverulenta* which carpeted the wood last year, but the Azaleas and *Rhododendrons* should make a good show this season, and *Lilium giganteum* should not disappoint visitors during 1922.  
T. E. G. White.

ORCHID NOTES AND GLEANINGS.

ORCHIDS OF 1921.  
(Concluded from p. 3.)  
NURSERYMEN.

MESSRS. J. and A. McBean, Cooksbridge, have been deservedly successful, their exhibits always showing excellence and good taste. The firm started the year at the first meeting in January by securing a First-Class Certificate for the handsome *Odontioda Hypatia*, McBean's variety, and an Award of Merit for *Odontioda Madeline* McBean's variety. Other awards obtained during the year were *Cattleya Enid alba* var. *Kathleen*, and *Laelio-Cattleya Eunice alba* var. *Constance*, both fine white varieties, receiving Awards of Merit on February 22; and F.C.C. for *Odontoglossum crispum* R. Felton; *O. Diamond* var. *Perfection*; *O. Rosina* var. *Invincible*; the famous *O. crispum* Solon *Carminetta*, and the richly-coloured *Odontioda Joiceyi splendens*. The remaining eight Awards of Merit were for *Odontoglossum Radiant* McBean's variety, *O. crispum* Ada Evans, *O. St. George* var. *Vulpus*, *Odontioda Enchantress*, *Oda. Cilleham* var. *Ada Evans*, *Cymbidium Excelsior*, *Cattleya Falco*, and the clear yellow *Laelio-Cattleya Allananda*, the best of its class.

Messrs. Charlesworth and Co., Haywards Heath, were well represented at nearly every meeting of the Royal Horticultural Society during the year, showing the most novelties.

Large-flowered *Sophro-Laelio-Cattleyas* were always a speciality, and in 1921 their First-Class Certificate plants included those of the best, viz., S.-L.-C. Joseph Charlesworth, S.-L.-C. Prince Hirohito, and S.-L.-C. His Majesty, all large and of indescribably rich shades of colour; and *Odontoglossum Britannia*. The Awards of Merit were for *Odontonia Ceres*, *O. Melia*, *O. Thais*, new departures which have yet to be shown in the mature stage. Others receiving awards were *Charlesworthiana nobilis*, a curious cross of *Oncidium macranthum*; *Brasso-Cattleya Soifano* var. *Prince of Orange*; *Laelio-Cattleya Athene*, and *Oncidium Papilio* Charlesworthii, the very distinct representative of the only species to secure recognition, the entries for species before the R.H.S. Orchid Committee being unfortunately very few.

Messrs. Armstrong and Brown, Orchidhurst, Tunbridge Wells, have been amongst the largest exhibitors of distinct strains of those favourite hybrids, *Odontioda* and *Odontoglossum*, the range in colour being very remarkable. Among their First-Class Certificate plants were the large scarlet *Odontioda Marion* Worsley, shown at Chelsea; the deep red *O. Dauntless* Orchidhurst variety; the ruby-red *O. Magna rubra*, shown at Chelsea; and the superb white and yellow *Odontoglossum Armstrongii*. Awards of Merit were for *Odontoglossum crispum*, *Victor Newton*, *O. eximium* var. *Rex*, and *Dendrobium nobile* Sir F. W. Moore, a great advance on the famous *Dendrobium nobile nobilium* from which it was raised.

Messrs. Stuart Low and Co., Jarvisbrook, Sussex, made good displays during the past year, *Sophronitis* crosses being prominent, and several of their fine novelties flowering for the first time were recorded. Awards were secured for *Sophro-Cattleya Dorea*, Low's variety, one of the best large scarlet forms; *Brasso-Cattleya Admiral Jellicoe* var. *Rosita*, large and rich purplish mauve, and the rich yellow *Dendrobium Butterfly* Low's var.

Messrs. Flory and Black, Slough, have shown many novelties and secured awards for several, the best of which are *Cattleya Prince Shimadzu*, *Laelio-Cattleya Vivid* and *Odontoglossum Trident*.

Great improvement in high colours in *Brassavola* hybrids has been shown during the year, the *Brasso-Laelio-Cattleya Jupiter* var. *Majestica*, for which Messrs. Hassall and Co., Southgate, obtained a First-Class Certificate last June, being one of the best. Unmistakable evidence of the activity of the hybridists is given in our list of new hybrid Orchids, periodically published during the past year, three hundred and twenty novelties having been recorded in brief, besides descriptive notes of the best.

The following Orchids were illustrated in *The Gardener's Chronicle* in 1921:—*Brasso-Laelio-Cattleya Imogen*, November 5, p. 233; *Cymbidium Dragonfly*, February 26, p. 101; *Cypripedium Dixon* Thorpe, June 11, p. 285; *C. Penelope*, coloured supplement, January 1; *Dendrobium Model*, The Dell variety, March 5, p. 116; *Laelio-Cattleya Allananda*, September 3, p. 121; *L.-C. Golden Glow*, August 20, p. 99; *L.-C. Orange Blossom*, April 23, p. 201; *Miltonia Venus* var. *Rascinator*, May 14, p. 235; *Odontioda Joiceyi splendens*, May 21, p. 245; *O. W. R. Fasey*, April 16, p. 183; *Odontoglossum Armstrongii*, October 29, p. 221; *O. crispum* Solon *Carminetta*, June 25, p. 309; *O. Desdemona II.*, May 14, p. 234; *O. Pescatorei* Lady Holford, December 10, p. 295; *Sophro-Laelio-Cattleya Falcon*, February 19, p. 91; *S.-L.-O. Prince Hirohito*, May 23, p. 259; *S.-L.-C. Rex* Orchidhurst variety, November 19, p. 259.

Vuystekeara Nora	Miltoniada Harwoodii x Oda. Cooksoniae ...	Charlesworth.
Vuystekeara Ruby	Miltoniada Harwoodii x O. Ashworthianum	Charlesworth.

ODONTOGLOSSUM ITHONE VAR. PAPPILLON.

A FLOWER of this handsome new cross between *O. Aglaon* (eximium x Vuylstekeae) and *O. Dusky Monarch* (unrecorded) is sent by Ernest R. Ashton, Esq., Broadlands, Camden Park, Tunbridge Wells (gr. Mr. Kent). It is a fine flower in every respect, the ground colour, white, heavily blotched with reddish-purple. A very remarkable feature in the flower is that each segment bears in the middle two ovate-oblong, whitish opaque patches, like some of the markings on a tropical butterfly. The labellum has a large purple blotch, the front and margin being white.

Mr. Ashton also sends flowers of *O. xanthos* var. Mrs. F. M. Ogilvie, snow white with some pale yellow markings; *O. Black Prince*; *O. Mrs. Harold King*, and *O. Camden* (Lambardeanum x regale), a new cross of large size, white, finely blotched with bright mauve.

ODONTIODA LOUISA.

A FLOWER of this new hybrid raised between *Odontoglossum Louise* (Ossulstonii x Pescatorei) and *Odontioda Chantecler* (Oda Cooksoniae x C. Nozliana), raised by Messrs. Charlesworth and Co., is sent by Pantia Ralli, Esq., Ashted Park, Surrey (Orchid grower Mr. Farnes). It is a very beautiful hybrid of model form and closely adhering to *Odontoglossum* in size and shape, the *O. Pescatorei* in all its parents predominating in its almost circular flower with equally broad sepals and petals, and finely expanded lip.

The ground colour of this fine hybrid is white, but the greater part of the surface is taken up by large confluent blotches of ruby-purple colour, the white showing on the margins and bases of the petals. The lip has one large purple blotch in front of the prominent yellow crest, and some smaller blotches inside the white margin. There is little evidence of *Cochlioda Nozliana* except a slight vermilion shade in the purple blotching.

**TREES AND SHRUBS.**

**MAGNOLIAS.**

THE Magnolias are amongst the most beautiful of trees and shrubs, suitable for the embellishment of gardens and pleasure-grounds. In spite of their beauty they are by no means so common in good gardens as one would expect. This probably is due to the fact that they are by no means the easiest of subjects to transplant successfully; intending planters should insist on having trees that have been regularly shifted, for plants that have not been disturbed develop large, fleshy roots, which are apt to die back when they are injured. If planting cannot be done early in the autumn, it is wise to wait until the spring, just before the trees start into growth.

The ground for planting should be carefully prepared; it should be enriched with a compost consisting of good mellow loam, with the addition of good fibrous peat and well-decayed leaf-mould. When the trees are well established in the soil they are quite capable of taking care of themselves in soils of average quality. Many of the species flower so early that the blossoms are liable to injury by spring frosts, but such handsome sorts as *M. stellata* and *M. Soulangeana* (see Fig. 11) open their flowers in succession over a fairly long period; thus it seldom happens that the entire crop of flowers of these species is entirely destroyed. It is also advisable to plant in sheltered positions, as rough winds damage and discolour the flowers.

*M. grandiflora*, the evergreen Magnolia from the Southern States of America, is usually seen planted and trained on walls. Although in sheltered positions in the south and western counties it is frequently seen growing quite well in the open, this species varies considerably in its freedom of flowering—the so-called Exmouth variety usually being the best in this respect.

Other species of Magnolia native of the Southern United States are *M. acuminata* (Cucumber Tree) with handsome foliage and yellow tinted, slightly fragrant flowers (this species makes a fine, large tree); *M. Fraseri*, which attains a height of 30 to 50 feet, and bears white flowers and leaves which are often a foot in length; *M. tripetala*, with large, white flowers, and leaves from 1 to 3 feet in length; *M. macrophylla*, another large-leaved species bearing large, white flowers with a purple blotch at the base; the blooms often measure 8 to 10 inches across; and *M. glauca*, with small very fragrant flowers.

*M. conspicua* (the Yulan) is a native of China, and flowers from February to May, its beautiful white flowers being often in part injured by frost. Many fine specimens of this species are met with in old gardens; there are numbers of varieties, or hybrids of this species with the Japanese *M. obovata*, such as *M. Soulangeana* and its var. *nigra*, also *M. Lennei*, both beautiful plants, their large flowers being white inside and purple on the outer side of the petals. Other varieties are *Alexandrina*, *spectabilis* and *speciosa*.

Among the Japanese species are *M. stellata*, a very fine and early flowering tree, with starry-shaped and deliciously scented white flowers, which are borne in succession over a long period; *M. obovata*, of which there are several varieties; *M. Kobus*, with creamy white flowers, this in its native state forms a tree some 80 feet in height; and *M. salicifolia*, a small, slender tree with white flowers, somewhat resembling *M. Kobus*; this species has only recently flowered in this country. Other beautiful and distinct species are *M. parviflora*, *M. Watsonii* and *M. hypoleuca*.

The beautiful *M. Campbellii*, from the Himalayas, is not hardy except in favoured positions in Ireland and in the south and western counties of England.

More recent introductions from China are *M. Delavayi*, a species with very large, evergreen leaves and creamy white flowers (except in the west this handsome Magnolia requires the shelter of a wall), and *M. Wilsonii*. *J. C.*

**THE WESTERN PLANE; PLATANUS OCCIDENTALIS.**

WITH regard to the inquiry by Mr. J. D. Colledge about the existence of this tree in England (see *Gard. Chron.*, December 31, 1921, p. 335) and the reply by Mr. A. D. Webster, it is quite true that the latter gentleman sent me in August, 1919, fruit-bearing twigs of a Plane at Westcombe Park, Blackheath, which he considers to be true *Platanus occidentalis*. They did not appear to me to belong to that species, but more likely to one of the several forms of the "London" Plane (*P. acerifolia*). But as Prof. Henry had just then concluded an exhaustive study of cultivated Planes and published the results in Vol. XXXV. of the *Proceedings of the Royal Irish Academy*, I forwarded the twigs to him for his opinion. He knows more about the subject probably than any-

men ceased to offer *P. occidentalis* in their catalogues in large quantities when all they have to supply is the common "London" Plane or some of its progeny. *W. J. Bean.*

**ÆSCULUS INDICA.**

READERS contemplating the planting of ornamental flowering trees of the largest size, in pleasure grounds and parks, should not omit to include *Æsculus indica*, the Indian Horse-Chestnut, a subject also for a wide, imposing avenue. Towards the end of May, most arboriculturists regard the Common Horse-Chestnut (*Æsculus Hippocastanum*) as our most beautiful flowering tree. A month to six weeks later, no one who has seen the Indian Horse-Chestnut flowering at Barton, Suffolk; Tortworth, Gloucester; or Kew will dispute the claim that the Himalayan species is equally attractive, and, if possible,

FIG. 11.—MAGNOLIA SOULANGEANA; FLOWER NATURAL SIZE, WHITE FLUSHED RICH PURPLE.

one else. His reply to me was as follows: "You are quite right about the specimen of Plane from Westcombe Park. It is not *P. occidentalis*, and is identical in leaves and fruit with a branch from the large tree of *P. acerifolia* at Ranelagh."

The mere fact of a Plane producing solitary fruit-balls does not prove it to be *P. occidentalis*, although that is an almost invariable characteristic of the species. The Plane known as *P. hispanica* (doubtless a seedling from *P. acerifolia*) very frequently bears solitary fruit-balls.

*P. occidentalis* has been raised frequently at Kew from American seed, but none of the plants have ever succeeded well. One young tree grew to about 12 feet high, but became much cankered on the stem and eventually died. Personally, I have never seen other than small plants of *P. occidentalis* in this country, and no satisfactory evidence has yet been produced of the existence of even moderate-sized trees in England. It is time, at any rate, that nursery-

more valuable, because at the later date the galaxy of trees and shrubs in flower is past. Before the flowers open, and again after they fade, trees of *Æsculus indica* attract attention because of their luxuriant leafage. The tree is hardy, except perhaps in the coldest parts of the British Isles; probably the difficulty of importing the seeds, which soon lose their vitality, explains why this Horse-Chestnut is so little grown. Now, however, that the home-grown trees ripen fruits in most seasons, plenty of young trees should be available for planters. The fruits are darker skinned than those of the common Horse-Chestnut; when they are ripe the seed collector at Kew has to be about early in the morning before the gardens open, as small boys have discovered there are dark "cankers." *Æsculus indica* is also known as *Pavia indica*; a full-sized figure of the inflorescence and foliage formed the subject of the supplementary illustration in *Gard. Chron.*, February 28, 1905, and the plant is also illustrated in *Bot. Mag.*, tab. 5117. *A. O.*

## MESEMBRYANTHEMUM AND SOME NEW GENERA SEPARATED FROM IT.

(Continued from page 9.)

\*.\* Leaves with a hump or food teeth on the flattened base.

16. *G. DIFFORME*, N. E. Br. Leaves as described by Haworth obliquely cruciate, 1-6 in. long and  $\frac{1}{2}$  in. broad, some semicylindric from the base upward with a kind of half-twist at about the middle, with a sort of lobe-like tooth near the compressed-triquetrous or somewhat dolabriform tip, which often ends in a straight curved or hooked harmless bristle; other leaves without either a tooth or lobe-like rising, but hooked or gibbous near the point, or with a concavity above, one side of which forms a ridge. Some leaves microscopically ciliate towards the tip. Peduncle of plants flowering in the open air very short or scarcely any except the quadrangular base of the calyx. Flower 2-2 $\frac{1}{2}$  in. in diameter with fewer, longer and more lax petals than in *G. semicylindricum*, according to a drawing at Kew.

*M. difforme*, Linn., *Sp. Pl.*, ed. 1, p. 487 partly, as to *M. foliis difformibus*, Dillen., *Hort. Elth.*, p. 252, t. 194, f. 242 (not 241), and Haw., *Obs.*, p. 169 (1795) not of other authors.

The two figures of Dillenius were considered to represent one species by Linné, but Haworth retained the name *M. difforme* for the plant represented by Fig. 242, and separated that figured at 241 under the name of *M. semicylindricum*, and he was probably right, for I have not seen any among the plants I have raised of the latter species at all like the Dillenian figure 242, which represents the pedicel as being about  $\frac{3}{4}$  in. long and distinctly angular, and there is drawing at Kew, made in 1826, of what was doubtless the plant Haworth described, which has the pedicel about an inch long, much thickened upwards and almost winged-angular (Haworth states under *M. cruciatum*, *Obs.*, p. 175, that it is "not of equal thickness"). But probably both these figures were made from plants grown under glass, causing the pedicel to elongate. The plant figured by Salm. Dyck as *M. difforme* is a totally different species, represented with long cylindrical pedicels that are not thickened upwards, nor at all angular.

17. *G. SEMICYLINDRICUM*, N. E. Br. Leaf-pairs obliquely crossing each other, variable in size, 2-4 in. long and 3-4 lines broad and nearly as thick, half-cylindric, but the flat face not nearly extending to the variably formed compressed tip, with two blunt teeth on the upper side beyond the middle. The leaves are sometimes tipped or hooked with a short soft bristle. Pedicel 6-8 lines long, very slightly thickened at the apex and slightly angular. Corolla  $1\frac{1}{2}$ - $1\frac{3}{4}$  in. in diameter; petals more numerous and more crowded than those of *G. difforme*, according to the Kew drawings of these species.

*M. semicylindricum*, Haw., *Obs.*, p. 238 (1794), founded upon *M. foliis difformibus*, Dillen *Hort. Elth.*, p. 252, t. 194, f. 241, which is a much reduced figure of the plant.

*M. bidentatum*, Haw., *Suppl.*, p. 89 (1819); Salm. Dyck, *Mes.*, §7, f. 1; N. E. Br. in *Journ. Linn. Soc. Bot.*, v. 45, p. 125.

*M. bigibberatum* Haw., in *Phil Mag.*, v. 63, p. 338 (1826) not of Salm. Dyck.

I have this plant in cultivation, raised from seeds from Mount Stewart, Jansenville Division, sent to me by Dr. I. B. Pole Evans, 5579, and find that it varies very much in size and appearance. Haworth seems not to have realised that Dillenius' fig. 241 is a much reduced representation of the plant, and considered size of specific value. There is no difference whatever between his three supposed species.

N.B.—*M. semicylindricum*, Salm. Dyck, *Mes.*, §7, f. 2, not of Haworth; *M. difforme*, Salm. Dyck, *Mes.*, §7, f. 3, not of Linné nor Haworth; and *M. bigibberatum*, Salm. Dyck, *Mes.*, §7, f. 4, not of Haworth are three differently named plates all representing the same species, and might even have been drawn from the same individual in different years. All the names given to the plant represented are wrong, but

I have not seen any plant like it, so refrain from giving it a name.

18. *G. OCHRACEUM*, N. E. Br. Leaves 3-4 in. long, triangular or semiterete, obtusely pointed, slightly thickened upwards, one of each pair broader than the other towards the apex and slightly recurved, the other narrower and straight, flat above, one side convex, the other flat or even concave; the younger leaves finely ciliate. Pedicels 3-4 in. long, slightly compressed, thickened above. Calyx compressed top-shaped, 2-edged, 5-lobed, two of the lobes much elongated, leaf-like, 3-angled, ciliate. Corolla  $1\frac{1}{2}$  in. or more in diameter; petals 8 lines long, in two series, recurved-spreading and oblique, brownish-yellow, paler on the back. Stamens numerous, erect, scarcely half as long as the petals; filaments, white. Ovary flattish on the top. Stigmas 5, lanceolate, acute, plumose, greenish-yellow.

*M. ochraceum*, Berger, *Mesemb. and Portul.*, p. 234.

### DOUBTFUL SPECIES.

*M. HETEROPHYLLUM*, Haw., *Obs.*, p. 420 (1794). This is quite an unknown plant whose position is doubtful. It is not at all the same as *M. angustum* var. *heterophyllum*, Haw., with which it has been confused by Sonder. It is described by Haworth as a singular and very distinct species having robust green leaves that are not dotted, the lower being somewhat like those of *M. canum*, Haw. (not of Berger), and the upper somewhat like, but not quite so large as those of *M. difforme*, Linn. Nothing more is known of this species. Haworth (*Misc.*, p. 36) states "I once saw two plants of this fine species alive in the collection of Messrs. Malcolm, nurserymen, at Kennington." Although placed under the *Difformia* group by Haworth, I do not think it can be a species of *Glottiphyllum*.

*M. SURRECTUM*, Haw., *Rev.*, p. 101 (1821). This species also does not appear to be a *Glottiphyllum*, although placed in the same group by Haworth. According to a drawing of it at Kew it was raised in 1817 from seeds collected by Bowie. It is a very distinct species, with three pairs of ascending-spreading semiterete or nearly terete obtuse leaves about 2-2 $\frac{1}{2}$  in. long,  $\frac{1}{2}$  in. broad, and nearly as thick, placed at right-angles to each other, and not at all tongue-shaped, of a dark green colour and not dotted. I have not seen anything like it. *N. E. Brown.*

(To be continued.)

## THE MARKET FRUIT GARDEN.

DECEMBER, 1921, did its best to make up the deficiency in the year's rainfall. With 3.04 in. of rain it was the wettest month of 1921, and the heaviest rainfall for any single day in the year occurred on the 14th, though that was only 0.66 in. However, the total rainfall for the year was brought up only to 15.23 in., which, it is to be hoped, will long stand as a record. It is only 0.39 in. more than half the average for the previous twenty years in my district. In other words, the total rainfall for 1921 was 14.45 in. short of the average. Moreover, the number of days on which rain fell, 106, was 46 below the average. January and December were the only two months with over 2 in. of rain, whilst February, July, and September had less than 1 in., and June no rain at all.

### WHEN ARE FRUIT BUDS FORMED?

It is wonderful how much knowledge some of the old gardeners gained about the plants they grew, apparently simply by observation and thought. I am delighted with one of the seventy-five observations concerning the culture of fruit trees quoted in *The Gardeners' Chronicle*, p. 300. Vol. LXX., from Bradley's *Treatise of Husbandry and Gardening*. He says: "Blossom buds are formed by the first sap between April and June, and filled for bearing between July and October." The reason why this pleases me so much is that it appears to reconcile the apparently conflicting results of two modern investigations, both of which have

been referred to in these notes more than once. Some elaborate American experiments established the fact that Apples form their fruit buds for the following year quite early in the season, within about a month, in fact, of the trees coming into life in spring. Then came the late Mr. H. E. P. Hodson's theory that the biennial bearing habit of Apples could be overcome by manuring, the unique feature of his system being a dressing of soluble fertilisers early in August to feed the fruit buds for the following season, the trees by that time having practically completed their growth and the hanging crop, and therefore being obliged to store the food material in the buds and other parts. This theory appealed to me as being well worthy of further trial, but I could not quite see why the trees should be fed in early autumn for fruit bud development if the buds were actually formed several months before, as the American investigations seemed to prove beyond reasonable doubt. Bradley's "observation" seems to supply the solution of the problem. The blossom buds are formed between April and June, but are "filled for bearing" between July and October. Early autumn, therefore, should be the right time to manure the trees, in order to feed the buds for the next year's crop. Incidentally this manuring should also help the trees in the following spring, when the new buds are being formed, since at that time, root action hardly having started, the trees are drawing on reserve food material stored in their system during the previous autumn. Later on, when root action and sap flow are in full swing, they can utilise the manures given in the ordinary way in winter.

### BLACK CURRANT CUTTINGS.

I am much obliged to Mr. H. E. Durham (p. 327, Vol. LXX) for giving me another method of treating Black Currant cuttings, with the idea of getting them to throw up plenty of shoots from below the ground level. The idea appears to be excellent, and will be given a trial. But to carry it through to the end involves leaving the bushes three years in the nursery quarters. Probably, however, they could be transplanted to their permanent positions as two-year-olds, and planted deep, in place of hilling in the trench and leaving them for another year. I have generally transplanted my bushes as yearlings, planting deep, so as to get the base of the shoots well under the soil. There is no doubt that deep planting is very important. Bushes that are planted shallow seldom make large specimens.

### EFFECT OF SPRAYING ON THE SOIL.

When orchards are sprayed year after year with the same washes, the soil must receive a considerable amount of the chemicals employed. In some cases this is beneficial, as when the trees are sprayed with limewash, but in others the result in time might be injurious, for all that is known to the contrary at present. It has been suggested, for instance, that the continued use of lead arsenate might in time affect the soil, rendering it unhealthy for plant growth.

I propose to use a solution of copper sulphate every winter, or rather early spring, on such varieties of Apples as are liable to scab, having found this to be a partial preventive of this disease, and I wondered if this might in time injure the trees through the soil. Apparently, however, there is no fear of this. Some French investigators have found that the soil of vineyards which are repeatedly sprayed with copper sulphate for many years does become very rich in copper, even up to 100 lb. or more per acre in the surface soil. The metal is retained by the fine particles of the soil, owing to their absorbent properties, and also by the chemical reactions in which it may be involved, so that the drainage water is able to remove only an infinitesimal amount. Vineyard soils thus become constantly richer in copper; but their quality does not vary, as they fix it with such energy that the plants are not able to assimilate too much. As a matter of fact, copper has been found in varying amounts in all soils and in all plants. It is evidently soluble in the cell sap, as it travels

about the plant at the same time and in the same manner as the nutritive principle, without in any way harming the tissues through which it passes. It is suggested that it may even be of use to them.

DUAL-PURPOSE APPLES.

In some official notes on the Imperial Fruit Show, published in the *Journal of the Ministry of Agriculture*, it is pointed out that most of the varieties of Apples exhibited by overseas growers are suitable for both dessert and cooking. It is suggested that, as these Apples have been successful in the home markets, it may be necessary for growers to consider seriously whether the great degree of specialisation which in the British section was manifest by the very large fruits of Bramley's Seedling and the small ones of Cox's Orange Pippin is either necessary or wise. In my opinion we should be making a mistake if we introduced more dual-purpose varieties. The public certainly prefer big Apples for cooking. Again and again market reports state that good large cookers are in demand, whilst smaller samples are cheap. In times of glut the latter are almost unsaleable. It is difficult to sell cooking Apples which have the size and colour of dessert fruit. It is true that we have two excellent dual-purpose Apples in Newton Wonder and Blenheim Pippin, but in these cases the large fruits are sold for cooking and the small for dessert. At present we have the finest dessert and the finest cooking Apples in the world. If we went in for dual-purpose varieties, we could make neither claim with truth. After all, are not our dessert varieties quite as suitable for cooking as any of the imported dual-purpose Apples? Worcester Pearmain is about the only market variety I know that does not cook well. There is nothing to prevent people from cooking Cox's Orange if they like. It is certainly excellent for the purpose, but it is difficult to make people believe that a dessert Apple will cook well. *Market Grower.*

CULTURAL MEMORANDA.

MELONS.

I HAVE read with much interest the recent notes in the *Gard. Chron.* regarding "wilt" in Melons and how to cure it, but all Melon growers should bear in mind the old adage "Prevention is better than cure." I venture to suggest that under proper cultivation there should be no wilting. I have grown Melons for the past twenty years, and have had little or no trouble with damping or canker at the collar.

The soil best suited to Melons is a yellow loam, somewhat consistent. The object is to provide a rich holding medium which will encourage the young plants to make an abundance of roots. To two parts of such loam add one part of well-rotted farmyard manure, rubbed through a half-inch riddle and enough coarse, sharp sand to keep the whole porous. I sow my earliest batch in February, preferably one seed in a thumb pot, as this prevents disturbance of the roots when potting. Plunge the pots over a bottom heat of 70°, allowing the temperature to rise to 80° in the daytime. My aim is to get plants with as strong a constitution as possible right from the very beginning, as soft, drawn stems always lead to disappointment. When the seedlings show their third or rough leaf, pot them moderately firmly in 3-inch pots, using a similar mixture. Before potting, the soil used should be warmed to the temperature of the house, and when watering always use tepid water. A week before the plants are ready for their fruiting quarters—which will be ascertained by turning a plant out of the pot to see if it is well rooted—make up a bed in ridge form, 2½ feet wide, 9 inches deep at the sides, and rising to 18 inches in the centre. By this method the soil will become warmed to the same temperature as that of the house in which the Melons are to be grown.

For the Melon bed, chop up good fibrous turf into pieces about 3 inches square. To each barrow-load of soil add half a barrow-load of

decayed farmyard manure, and one 6-inch pot of crushed bones, mixing the whole well together. Set the plants 18 inches apart in the centre of the ridge (some may think this rather close). Beat the bed firmly all over, and cover it with an inch of loose soil to leave a rough surface. Give the plants a good soaking with tepid water and be sure that the whole bed is well moistened.

The leader should be allowed to run up without being stopped until all the fruits have formed, then stop it two joints above the last side shoot carrying fruit. Stop the side shoots one joint beyond each fruit, and tie the growth upright about 6 inches from the leader; thin out the leaves as the plant develops, but do not remove a leaf where there is a fruit near its base. Maintain a buoyant atmosphere in the house by damping the floor twice a day until the time for pollinating, when the house should be kept dry. When pollinating it is most essential that three to four fruits on each plant should be set on the same day so that they swell in unison. Syringe the foliage once a day after bright sunshine, taking care not to wet the base of the plant, as in nine cases out of ten this is the main cause of canker or wilt. Give air on all favourable occasions, but guard against draughts. All through the growing season the collars of the plants must be exposed to the light, and this can be done by cutting away with a sharp knife the cluster of leaves which form at the base of the plant. Care must be taken in doing this, as a ragged cut may mean decay. When the plants are in full growth, with the fruit swelling freely, afford an occasional watering with liquid manure, always bearing in mind that one good soaking is better than six sprinklings. When netting commences the waterings should be gradually reduced as the fruit ripens. This treatment should procure a good crop of Melons, each weighing from 6 to 7 lb. *Donald Allan, Marks Tey.*

HOME CORRESPONDENCE.

[The Editors do not hold themselves responsible for the opinions expressed by correspondents.]

**Mistletoe.**—Our experience here tends to confirm Mr. Dallimore's observation on the result of resistance on the part of a tree to invasion by Mistletoe (see p. 390, December 24, 1921), namely, that more swelling is caused by successful than by unsuccessful resistance. Mistletoe, if it ever was indigenous in Scotland, disappeared with the primeval forest; but it grows and fruits freely when sown north of the Tweed. About forty years ago I sowed a quantity of berries on young Apple and Hawthorn trees. The Apple trees now carry huge clumps of Mistletoe, four and five feet in diameter, but the swelling on the branches is hardly noticeable. Of the Hawthorns so treated, only one remains, the rest having been removed to relieve choice Rhododendrons. The survivor is Paul's Scarlet variety; there is a large swelling on one of its branches, from which protrude a few twigs of the parasite, none of them more than two inches long. When another Hawthorn of the same variety was removed two years ago, I noted similar swellings, and even shorter twigs of Mistletoe. Both Apple trees and Thorns were slender saplings when the berries were applied in March, to their previous year's growth. This seems to indicate greater power of resistance in the Hawthorn than in the Apple tree; but whereas I have seen Hawthorns in the south of France crowded with Mistletoe, it may be that Paul's variety keeps the parasite better at bay owing to superior vigour. *Herbert Maxwell, Monreith.*

**Apple Orleans Reinette.**—With regard to your interesting report in the *Gard. Chron.*, of December 17, 1921, page 317, concerning Apple Orleans Reinette, submitted to the R.H.S. Fruit and Vegetable Committee, by Mr. Bunyard, I find that Scott in his *Orchardist*, second edition, published in 1873, states, "I received it under

the name of Court Pendu de Tournay, 1st size, 1st equal, December to March, introduced here in 1872, and has not yet fruited." It would be interesting to know if the variety is grown by anyone under this name. *G. J. Warren, The Gables, Balcombe, Sussex.*

**The late Mr. Andrew Henderson.**—I would like, through your columns, to thank Mr. C. Orchard for his kindly remarks (p. 337, Dec. 31, 1921) concerning my father, the late Mr. Andrew Henderson. Although only seven years old at the time, I well remember my mother making the pork pies for the gardeners who came to the meetings at Wimbledon House, though I may remind Mr. Orchard sometimes mutton was substituted for pork. My sisters also join with me in thanks for your own and Mr. Orchard's appreciation of my father's work and goodness. *Thomas Henderson, 14, Wickham Road, Beckenham.*

—I failed to notice the announcement of the death of Mr. Henderson on p. 337 of Vol. LXX. This clever craftsman was all that Mr. Orchard writes of him, but of too retiring a disposition to have had justice done to his abilities as a gardener. At Wimbledon House, "intensive" cultivation was in full swing long before the expression was invented. And his Orchids, Grapes, Pineapples, etc., were first-class. I kept up a correspondence with him till the infirmities of old age came upon him. I think it was George Turner who introduced me to the club, and Mr. Bentley, who I believe is still living, was another member. The first communication I sent to *The Gardeners' Chronicle* was an account of one of the meetings. It appeared in the number for February 14, 1874, but they had been noted long before that. The late William Tait, of Downie's Edinburgh, so well known in Scotland, was a nephew of Mr. Henderson's. His father, and later, his brother, carried on a successful joinery business in Tynninghame for many years. *R. P. Brotherton.*

Second Flowering of *Cheiranthus mutabilis*.

—Among the many floral freaks of 1921, I may mention the profuse flowering for the second time of *Cheiranthus mutabilis*, L'Herit. It flowered freely in May, as usual, and at Christmas I had two plants with at least 30 flower spikes each, in an exposed situation on the top of a rockery. I have had this species (which is a native of Madeira) in cultivation for about 50 years, having had it originally from my old friend, the Rev. H. Harpur Crewe, and have never known it bloom a second time in the same year before. No doubt the deficiency of rain in 1921 has been the cause. Every month of 1921 has been below the 20-year average rainfall here; in the last few days of December we needed 1.78 in. of rain to reach the average of 2.87 in. *Alfred O. Walker, Ulcombe Place, near Maidstone.*

"Isabelle."—I have long been familiar with this word as a colour name and also with the story that gave rise to it. But when Sir Herbert Maxwell (see p. 3) states that it is a French word meaning dove-coloured, I am more than perplexed. Dove-colour, Plum-colour, mouse-colour, and many similar quasi-coloured names seldom convey the same idea to the reader or hearer, as is intended by the person using them. Dove-colour here in the south of England is usually intended to describe a distinct shade of soft pale grey. Isabelle, on the contrary, is a proper colour name used in French to describe a light brown shade. For synonyms in French, there are *fauve, bai, peau de buffle*, and certainly none of these is what we know as dove-colour. Buff or pale buff may be considered the best English translation, or even tan. These shades are certainly more applicable to soiled linen than dove-colour! *C. H. P.*

**Lardizabala biternata.**—This climber grew in the garden I had charge of in Killarney, on a south wall, but did not seem so happy as at Monreith, for although it flowered fairly well, it did not make any appreciable growth. In spite of this, I always felt proud of the flowers that did appear. *Mandevilla suaveolens* in a similar

position was rampant and flowered quite freely, and in 1911 several of its peculiar seed pods developed and ripened. Sir H. Maxwell's hesitation to have his plant torn down reminds me of a case when a mansion was at the time a blazing furnace, and an individual looking on asked a man directing a fire hose to play on to the creepers and try to save them! *A. Elgar, Ward End Park, Birmingham.*

## SOCIETIES.

### WATFORD HORTICULTURAL.

MISS BRADFORD, J.P., presided over the December (1921) meeting of this society, at the Council Chamber, Watford. Miss Bradford in her opening remarks paid tribute to the fine power for good which the society exercised in a large, populous and growing district such as Watford, and said that the hard-working committee of this organisation had done magnificent work during the war period in maintaining and improving local food supplies. The subject for the evening, "Pruning Fruit Trees," was ably dealt with by the lecturer for the evening, Mr. F. W. Miles, and the interest of an audience numbering well over 100, was fully held for considerably over an hour.

### PERTHSHIRE AND FORFARSHIRE FRUIT GROWERS.

A MOVEMENT which has been on foot for some time to establish a fruit growers' association for Perthshire and Forfarshire was brought to a successful issue on January 7, when a meeting of fruit growers was held in Blairgowrie to consider the matter. There was a good and representative attendance presided over by Mr. Wm. G. Macpherson, Blairgowrie. It was resolved to form a fruit growers' association for the two counties, and office bearers and a committee were appointed, with Mr. Macpherson as Chairman and Mr. McDonald, Walton, Blairgowrie, as Vice-Chairman.

## THE WEATHER.

### THE WEATHER IN DECEMBER.

THE month of December, 1921, opened with a five days' continuation of the cold, easterly weather experienced in November; but a very mild, westerly wind afterwards set in, and this continued with scarcely any interruption to the month's close, the latter half of December being very stormy and at times wet, at Southport. The earlier weeks had been quieter, with a damp atmosphere, but only small amounts of rain fell. The mean temperature of the complete month was so high as 44.40, or 4.79 above the normal for December. Frost in the shade was restricted to a couple of days, and even ground frost to seven days. Of bright sunshine, 42.7 hours were experienced, or 8 hours more than the average. The total rainfall, however, amounted to 3.87 inches, implying an excess of 0.70 inch. Wind movement was so much as 491 miles per day, or 74 miles per day above the normal. There were no fewer than 511 hours of wind from westerly points (i.e., off the sea). Gales occupied 68 hours, distributed over eight days; but really destructive force was not attained (except in a few momentary gusts, and even these were not severe). There was no snow, and very little fog. Hail fell on three days. A notable smooth, glazed frost was produced on the morning of December 5.—*Joseph Borendell, The Fernley Observatory, Southport.*

### THE WEATHER IN SCOTLAND.

DECEMBER, 1921, was another month of mild, dry, bright weather with slight falls of snow on two days. The mean temperature was nearly 3.5°, and the rainfall fully 1 inch, below the normal. Rain fell on 16 days to a total of 1.55 inch, the 21st being the wettest day with a fall of 0.38 inch. Bright sunshine was recorded for 49.8 hours, being an average of 1.6 hour per day and a percentage of 23. With a mean of 29.79 inch, the barometer varied from a highest of 30.38 inches on the 4th to a lowest of 29.15 inches on the 20th and 28th. The mean temperature was 41°, with a mean maximum of 47° and a mean minimum of 35°. The highest maximum of 55° was registered on the 8th and 31st, and the lowest minimum of 27° on the 5th, while the lowest maximum of 36° occurred on the 4th and the highest minimum of 43° on the 8th and 17th. On 9 nights the temperature fell below the freezing point. On the grass the mean minimum was 30°, with a lowest of 20° on the 5th; there were 17 nights of ground frost. At 1 foot deep the soil temperature with a mean of 40° fluctuated between 41° and 36°. The prevailing winds were from the west, with gales towards the end of the month.—*John Davidson, Director of Studies, St. Andrews Provincial Committee at the Training College Gardens, Kirkton-of-Mains, near Dundee.*

## ANSWERS TO CORRESPONDENTS.

"There are few gardeners, and still fewer amateurs, who do not on occasion require immediate information upon various points of practice. But either from an unwillingness to inquire, or from not knowing of whom to make the inquiry, they too often fail to obtain the information they are in want of. And let no one be alarmed lest his questions should appear trifling, or those of a person ignorant of that which he ought to know. He is the wisest man who is conscious of his ignorance; for how little do the wisest really know!—except that they know little. If one man is unacquainted with a fact, however common, it is probable that hundreds of others in the same position as himself are equally in want of similar information. To ask a question, then, is to consult the good of others as well as of one's self.—*Gardeners' Chronicle, No. 1, Vol. 1, January 2, 1841.*

**HEDGE OF THUYA LOBBII:** *J. M. W.* As the young plants are only two feet apart and they have already met, it will not be necessary to stop them until they are within six inches of the desired height. The tops of vigorous young examples of this evergreen are nearly always whip-like in character, and they stiffen with age. We note with satisfaction the good preparations that were made previous to planting the Thuyas. The well-being of the hedge will be all the greater secured if attention is paid to after cultivation in such matters as keeping the surface regularly hoed in order to prevent the growth of weeds and to aerate the soil.

**HORTI-PLOUGH:** *H. L.* Information about the Horti-Plough could be obtained from the makers, Messrs. Mote and Boland, Somerset Road, Teddington, Middlesex. The cable is wound on to a drum by moving a lever backwards and forwards, and this draws the plough along.

**HORTICULTURAL TRADE PAPERS:** *Japonica.* The *Horticultural Advertiser* is published at Lowdham, Notts, and communications should be addressed to Mr. C. E. Pearson; the *Nurseryman and Seedsman* is published at Hatton House, Great Queen Street, W.C.; and the *Horticultural Trades' Journal*, by the Hortus Printing Co., Junction Road, Burnley, Lancs.

**HYACINTH BLOOMS DROPPING OFF:** *Constant Reader.* The trouble is probably due to the action of cockroaches (see *Gard. Chron.*, December 31, p. 332).

**HYBRIDS:** *B.* A hybrid is the progeny resulting from the crossing of two distinct species; i.e., the pollen from one species is used to fertilise the second species, and the seeds resulting from such a combination will produce plants showing some of the characteristics of each parent. For instance, *Begonia Gloire de Lorraine* is the result of crossing the South African *Begonia Dregei* with *B. socotrana*, which is a native of the island of Socotra. Of course, you will understand that the seed parent must be so treated that neither its own pollen or the pollen of any other species than the one desired to be used as the male parent is allowed to fertilise the flower.

**KEROSENE SPRAY:** *Anxious.* Six pounds of copper sulphate, 85 pounds of lime water, and 1½ gallon of paraffin are sufficient to make 100 gallons of the wash. The copper sulphate is first dissolved in a little of the water and the clear lime water run into it. The paraffin is then added, and the whole churned up with water to make 100 gallons. If a lesser quantity than 100 gallons is required, you can easily work out the proportions.

**MAGNOLIA GRANDIFLORA NOT FLOWERING:** *Constant Reader.* The type species rarely flowers before it attains considerable size, but the flowering may, at times, be hastened by growing the plant in very firm and rather poor soil until it has formed the habit of flowering, after which, under the conditions stated, top-dressing would be necessary. Root-pruning would not be advisable unless the growth is very rampant, and even then it should be practised with caution. The pruning of this evergreen *Magnolia* should consist

in removing, during the winter or early spring all the side shoots that were formed during the previous year. This may be done by giving them a sharp, downward jerk, or by cutting them off close to the leading shoot from which they spring. The Exmouth variety of *Magnolia grandiflora* blooms in a much younger state, and this we have seen, in the West of England, as young bushes not more than 4 feet high, bearing four and five flowers each.

**MANURES FOR CORDON APPLE TREES:** *G. B.* If your recently planted cordon apple trees are growing satisfactorily, the use of animal manure is not to be recommended, as this would cause them to make too much wood growth at the expense of fruiting. Seeing that the soil was formerly rich pasture-land and that the turves have been dug well under the surface and the subsoil loosened, the trees should fruit satisfactorily, but a little basic slag applied in the autumn, with a dressing of potash in the spring, will favour the production of fruit rather than of wood. When the trees are cropping heavily, it would be an advantage in hot, dry summers to apply a mulch of stable manure, as this would help to conserve the soil moisture, and, by feeding the roots, enable the trees to mature their crop.

**NAMES OF PLANTS:** *J. P.* *Drimys Winteri*.—*Dendron*: 1, *Sequoia sempervirens* 2, *Cryptomeria japonica*.—*W. J. M.* 1, *Eranthemum pulchellum*; 2, *Ficus repens variegata*.—*L. C.* *Danae Laurus* (*Ruscus racemosus*); 2, *Solanum aculeatissimum*.

**NICOTIANAS FOR SUMMER BEDDING:** *Constant Reader.* The seed should be sown in moderate heat towards the end of the present month, and as soon as the seedlings are large enough to be handled they should be pricked off at 2 inches apart in boxes containing leafy, sandy soil and placed in a warm house. After a few weeks a further transplanting will be necessary, and if this can be done in 3-inch flower-pots, the plants will be best for planting out in the flower-beds, but many gardeners obtain good results from plants which have been grown in boxes. The soil at this stage should contain more loam than before. After having been potted or transplanted into boxes, the plants should be replaced in the same temperature as that in which they were growing. Ten days later they may be gradually hardened off and be planted out in their flowering quarters at the end of May or early in June. The sorts which give the best floral display are the hybrids of *N. affinis* and *N. Sanderae* while *N. sylvestris* and *N. grandiflora* are robust species which bear handsome foliage surmounted by smaller flowers.

**PRIMULA OBCONICA:** *G. F.* The flower of *Primula obconica* submitted is rather more blue in the colouring than usual.

**SOIL ON AN ANTS' HILL:** *H. W.* The soil which you describe as being obtainable from an ants' hill would probably be suitable for use in potting plants, but it would have to be mixed with plenty of sand, as, being in a fine state of division, it would probably set so closely when watered as to exclude the air from entering freely. Mixed with such materials as bone meal, wood ash, crushed mortar, and well-rotted stable dung, it should be suitable for a variety of garden purposes.

**VIOLETS FAILING:** *H. L.* We have made a careful examination of the soil in which your Violets are growing, and can find no pest that would be likely to cause the damage you describe. Send an affected plant and some of the white worms you refer to. The grubs should be enclosed in a tin box separate from the plant, which should also be packed in a tin box, if possible.

**AVERAGE MEAN TEMPERATURE** for the ensuing week deduced from observations during the last fifty years at Greenwich, 39.1.

**ACTUAL TEMPERATURE:—**

*Gardeners' Chronicle* Office, 5, Tavistock Street, Covent Garden, London, Wednesday, January 18, 10 a.m.; Bar. 29.8; temp. 41°. Weather—Bright.

**Sleepy Disease of Tomatos.**

The aptly-named Sleepy Disease which not infrequently affects Tomato plants and causes loss of crop has been the subject of thorough and able investigation\* by Mr. W. F. Bewley, Mycologist to the Research Station of the Nursery and Market Garden Industries Development Society. The conclusions reached by Mr. Bewley are of great importance and point the way to the prevention, if not to the absolute cure, of this disease. The agent producing the disease is almost invariably the fungus *Verticillium albo-atrum*, but in some cases it is another and altogether distinct fungus, *Fusarium lycopersici*. It is easy for a grower to ascertain which of the two fungi is the cause of an outbreak, for *Verticillium* is a fungus which grows best and therefore does most damage at a relatively low temperature—70-72°F., whereas the *Fusarium* is a high-temperature fungus and thrives best at 82-84°F. The symptoms of Sleepy Disease are well known; a generally stunted plant with leaves on which yellow blotches occur. When conditions are favourable to the spread of the disease, the plants suddenly succumb to it without any previous sign of infection. In this state the limpness of the leaves is a sure sign of the impending death of the plants. A certain means of identification of the disease is afforded by the post-mortem dissection; for in any plant affected with sleepy disease, a brown stain running along the wood from the point of infection in the root and up the stem may be seen. The fungus, *Verticillium albo-atrum* is able to gain entrance to the root of the Tomato

plant either by way of a wound or through the intact surface, and inasmuch as it has been shown by Mr. Bewley to thrive vigorously when it gains access to soil which has been partially sterilised, soil-sterilisation is of little value in preventing the disease if means are not also taken to prevent the re-infection of the soil. That such means must be thorough may be judged by the facts, first, that the fungus continues to grow and may pass into a resting stage on the remains of the roots of diseased and dead plants left in the soil, and second, that as has been shown by careful inoculations and re-infections, numerous plants beside the Tomato may serve as hosts (or nurses) of the disease-producing fungus. Among such plants are the Potato which, when infected, also shows yellowing and wilting, the Egg Plant, *Antirrhinum*, Cucumber, and sundry others, such as seedling Sycamore and Elm. From experimental inoculations made in Tomatos growing at different temperatures and at different times of the year, Mr. Bewley has shown that owing to the temperature requirements of the fungus, the disease is worst in spring when the temperature is relatively low, is checked in summer with a rising and higher temperature and reappears again in autumn as the temperature falls. Following the line pointed to by this evidence, Mr. Bewley has shown that it is possible to check the disease and obtain a crop by increasing the temperature of the houses in which the Tomatos are growing. Additional boiler heat sufficient to produce a temperature just above 77°F. has proved successful—especially if at the same time the house can be shaded; for with a lowered rate of transpiration of the plants, the progress of the disease is less rapid. In one experiment of this kind, of 68 per cent. of plants showing sleepy disease 58 per cent. recovered and no longer showed wilting. Other points of great interest to growers are that "soft" grown plants are less liable to Sleepy Disease than are "hard" grown plants, and that the practice sometimes adopted of giving plants a check at an early stage is calculated to render them more prone to the disease; also that plants grown in a soil rich in humus are more apt to exhibit Sleepy Disease than are those which are grown in poorer soil. One variety only, *Manx Marvel*, appears to be highly resistant, and the investigators at the Experimental Station are at present engaged in endeavouring to raise varieties immune to this serious disease.

**British Mycological Society.**—The programme for the meeting of this society, to be held on Saturday, January 21, in the Botany Lecture Theatre, University College, Gower Street, W.C., at 11 a.m., includes lectures as follows:—Dr. W. Brown, "On the Germination and Growth of Fungi at Various Temperatures and in Various Atmospheres"; Miss D. M. Cayley, on "Die Back of Stone Fruits due to *Diaporthe perniciosa* and the Behaviour of Monospore Cultures in Artificial Media"; Mr. W. B. Crow, on "The Morphology and Affinities of *Leucostoea mesenteroides*"; Dr. H. Wormald, "Notes on Crown-gall"; Dr. M. C. Rayner, on "Obliged Symbiosis in Calluna"; Mr. W. J. Dowson, "Michaelmas Daisy Wilt."

**Handsome Bequest for Musselburgh Public Park.**—A handsome bequest for the maintenance of Lewisvale Public Park, Musselburgh, was intimated at the last meeting of the Town Council of that Burgh. It was announced that the late Mr. Douglas Brown, formerly of California, native of Musselburgh, and a son of a former magistrate, had bequeathed, subject to a life rent, one-seventh of his estate, to be devoted to the maintenance of the Park and also to defray the salary of the park-keeper. The Lewisvale Park

was presented to the Burgh by Mr. Douglas Brown and his brothers as a memorial of their late father. The Provost expressed the gratification of the Council and inhabitants at this intimation, and the Burgh treasurer said that the income would be quite sufficient to maintain the Park and pay the park-keeper's salary.

**La Societe Lyonnaise d'Horticulture.**—After seventy-eight years' existence and active work in Lyons, the *Societe d'Horticulture Pratique du Rhone* has amalgamated with the *Association Horticole Lyonnaise*, adopting the above-named title. It is interesting to record that this amalgamation is, in fact, a reunion, for the *Association Horticole* broke away from the parent society some years ago. Other societies that have emanated from the *Societe d'Horticulture Pratique du Rhone* are the *Societe Pomologique de France*, the *Societe Francaise des Rosieristes*, and the *Societe Francaise des Chrysanthemistes*, all prosperous and progressive organisations engaged in a special branch of horticultural work in their own particular spheres. The official organ of the newly constituted society will be issued during January of this year, and will be known as the *Lyon Horticole et Horticulture Nouvelle Reunis*.

**Early Snowdrops.**—Mr. S. Arnott, of Maxwelltown, writes: I was agreeably surprised on January 2 to be informed that a clump of Snowdrops was in full bloom that morning, and evidences of this were brought to me, as I was confined to bed through illness. The clump was composed of bulbs of one of the hybrid Snowdrops raised by the late Mr. William Thomson, High Blantyre, Lanarkshire. These were derived from *Galanthus nivalis* and *G. plicatus*, but the raiser kept no record of which was the pollen and which the seed parent. These hybrids are mostly of exceptional size and beauty. Other clumps, including one of *G. Elwesii*, flowered in quick succession, and during the week ending January 9 a goodly number of Snowdrops were in bloom. This is remarkably early for our neighbourhood, although at St. Mary's Isle, Monreith and other places in the seaboard counties of Kirkeudbrightshire and Wigtownshire, Snowdrops in December are quite common.

**Munificent Gifts to Colchester.**—Lord Cowdray has presented the town of Colchester with the sum of £10,000 for the purchase of the Holly Trees Mansion for the extension of the public park. This makes the second gift of £10,000 to the town, the other being for the purchase of Colchester Castle and other property for the town's use. Lord Cowdray has announced his intention, in connection with Lady Cowdray, of contributing a further £3,000 to provide new entrance gates and railings in connection with the extension of the public park.

**"Index Kewensis."**—A further Supplement, making the fifth, to the *Index Kewensis*, brings up the list of known plants to the year 1915. It is a large volume, containing 277 pages, and the geographical distribution of new species is given in greater detail than in previous parts of this monumental work. Numerous names accidentally omitted from previous Supplements are included, and others are reinserted in cases where the reference originally given was not the earliest.

**Association of Economic Biologists.**—A general meeting will be held at 2.30 p.m. on Friday, January 27, in the Botanical Lecture Theatre of the Imperial College of Science, South Kensington, London, S.W.7. The chair will be taken by the President, Sir David Praeger, F.R.S., and Professor E. P. Stebbing, Professor of Forestry in the University of Edinburgh, will open a discussion upon "The Importance of Scientific Research in Forestry and its Position in the Empire."

**Hopetoun House Gardens.**—Much to the regret of all who know Hopetoun House, the seat of the Marquis of Linlithgow, in West Lothian, the Marquis has intimated his decision to close the establishment on account of the burden of taxation. This decision will probably mean some changes in the gardens, which have for so many years been among the finest in Scotland,

\* Sixth Annual Report (1920) of the Experimental and Research Station, Turner's Hill, Cheshunt.

and have been maintained in splendid condition under the care of a succession of able gardeners, such as the late Mr. Smith, Mr. T. Hay, now of Regent's Park, London, and latterly of Mr. Highgate, who has worthily maintained the traditions of Hopetoun. Where all departments of gardening have received due attention, it is impossible to discriminate, but it is well known that hardy flowers have been a conspicuous feature of these noble Gardens. In an interview with a Press correspondent Lord Linlithgow stated that he was extremely sorry to have to close down the gardens at Hopetoun House, as these were of great interest to himself and his family. It was a satisfaction to him to know that his head gardener, Mr. Highgate, was a moving spirit in the allotment movement and in the encouragement of Scottish gardening, and it had always been a pleasure to send Mr. Highgate to various places to lecture on horticultural subjects and to judge at local shows.

**Rock and Formal Gardens at Chelsea Show.**—We are asked to state that all exhibitors who propose to arrange Rock Gardens or Formal Gardens at the Chelsea Show to be held on May 23 to 25, and who have not already received a communication from the Royal Horticultural Society, should communicate with the Secretary, Mr. W. R. Dykes, at once.

**American Rose Society.**—We learn from an American contemporary that this society now has a membership roll of 2,000, of which there are some in sixteen different foreign countries. Evidently the Rose is a popular flower in the United States, and there is probably no other special floricultural society there with so large a list of members.

**Sir John Kirk.**—The death of Sir John Kirk, in his 90th year, is a great loss to British science. Born at Barry, near Arbroath, Forfarshire, on December 19, 1832, Kirk devoted himself at an early age to the study of botany. He followed the profession of medicine, and his proclivities and profession determined his career. He organised a party of medical men as a volunteer corps to aid the British wounded in the Crimean War, and his great chance came when, in 1858, he was selected to accompany Livingstone in his Zanzibar expedition. For five years he acted as second to that great explorer and was with him in the discovery of Lake Nyasa. Returning to England in 1863, he spent much time at Kew in working out his botanical collections. From 1866 he held various offices at Zanzibar, and there he remained with increasing influence until 1886. Thanks to him, German designs on Zanzibar were in a large measure frustrated, and it was through him that negotiations, which led to the foundation of British East Africa, were set on foot. After his retirement, Sir John settled at Sevenoaks, and during the years spent in retirement he devoted himself with never-failing energy to the advancement of science.

**Horticultural Club for Farmers.**—Steps have already been taken to form a club for the newly-organised horticultural section of the Young Farmers' Club at the Model Village, Welwyn Garden City. At the opening meeting, Mr. W. Jenkins, of the Ministry of Agriculture, was able to state that twelve young people had undertaken to cultivate the fruit-belt, which it is hoped will be a distinct and attractive feature of the village. Mr. H. Etchers and Captain J. G. Simpson have volunteered to superintend the future work of the new club.

**National Institute of Agricultural Botany.**—In connection with the proposal to create a fellowship of the Institute of Agricultural Botany, the Prime Minister has shown his interest in the work of the Council in a letter sent by him to Sir Lawrence Weaver, the Chairman. The letter is as follows: "Dear Sir Lawrence, I have been following with great interest the rapid progress of the National Institute of Agricultural Botany, and congratulate you and your colleagues on the serious and useful work the Institute is already doing for the farming community. You are wise to broaden the basis of your organisation by creating a Fellowship of the Institute, which will enable every one con-

cerned with the improvement of crops to help forward the good work. I gladly show my appreciation of what you are doing by asking to be enrolled as one of the first Life Fellows of the Institute. With all good wishes for its continued progress, both in successful work and in wide support from everyone interested in agriculture.—Believe me, Yours sincerely, D. Lloyd George."

**The Hon. Vicary Gibbs.**—The Hon. Vicary Gibbs' garden at Aldenham, Elstree, is famous throughout the world of horticulture, not only for its general beauty, but particularly for the wealth of flowering trees and shrubs which it contains, and, moreover, those who have lacked the good fortune to see Aldenham in its growing glory are yet able to enjoy the reflex of its beauty by reading the descriptions of choice plants which the Hon. Vicary Gibbs and his gifted head gardener, Mr. Beckett, contribute with such generous and skilled hands to the horticultural Press. The Hon. Vicary Gibbs has the versatility of the cultured Englishman, and when his garden is fallow in winter he devotes his leisure to genealogical research—results of

HON. VICARY GIBBS.

which have appeared in the *Complete Peerage*, the fifth volume of which has recently been published. The trees and shrubs at Aldenham represent much devoted labour, both in their acquisition and cultivation, and among them are to be found many of the best plants, both from North America and from China. During the period of the war the Hon. Vicary Gibbs set a fine example in patriotism by devoting a large acreage at Aldenham to the cultivation of vegetables. The energies of the staff were diverted from the pleasure grounds to the Potato fields, and the crops which were raised were not only a real contribution towards an increased food supply, but showed what high yields may be obtained when the pleasure gardener turns his skill to market gardening. The Hon. Vicary Gibbs, whose knowledge of horticulture is no less than his devotion thereto, has had a busy life—a partner in Antony Gibbs and Sons, merchants and bankers, he occupied a seat in the House of Commons for the St. Albans Division of Herts from 1892-1904. Born in 1853, he is the second surviving son of the first Baron Aldenham, was educated at Eton and Christ Church, Oxford, and was called to the Bar in 1880. It is well for horticulture that in spite of the difficulties of the present time, men like the Hon. Vicary Gibbs continue to follow Candide's advice: "Let us cultivate our gardens; alike in the pleasure which they derive and give they are happy."

**Retirement of Sir David Prain.**—Sir David Prain, C.M.G., F.R.S., who has occupied the

post of Director of the Royal Botanic Gardens, Kew, since 1905, will retire under the age limit at the end of February of this year. It will be remembered that Sir David Prain was formerly director of the Royal Botanic Gardens at Calcutta, and came to Kew as successor to Sir W. Thiselton Dyer. Sir David's work as a botanist is very widely known, while his capabilities as an organiser and a horticulturist are reflected in the admirable condition of the famous national gardens which have been under his care for seventeen years. The First Lord of the Treasury has appointed Mr. A. W. Hill, F.R.S., D.Sc., as successor to Sir David Prain. Mr. Hill has been Assistant Director at the Gardens for fourteen years and was previously Fellow and Dean of King's College, Cambridge, and University Lecturer in botany. Mr. Hill will take up his new duties on March 1.

**Rainfall at Tirley Garth Gardens.**—Mr. J. B. Allan, Tirley Garth Gardens, Tarporley, Cheshire, informs us that the rainfall there during 1921 amounted to 21.31 inches, or 14.32 inches less than in 1920. The heaviest rainfall occurred on October 3, when 1.22 inch was registered. February was the driest month with .35 of an inch of rain. In August, the rainfall amounted to 4.48 inches, and this was the wettest month in the year, with 22 rainy days. January had the most rainy days, with a total of 24. There were 170 days in which .01 of an inch or more of rain was registered and 118 days in which .04 of an inch or more was recorded. The driest spell of weather was from June 26 to July 22, when there were 25 dry days. The hottest days were July 8 and 9, when the temperature rose to 95° in the shade. The coldest day was on November 6, when 11° of frost was registered.

**Appointments for the Ensuing Week.**—Wednesday, January 25.—Irish Gardeners' Association meeting; Wimbledon and District Gardeners' Society's meeting; Newport and District Gardeners' Association's lecture by Mr. G. E. Davies on "Propagation." Thursday, January 26.—Gardeners' Royal Benevolent Institution annual general meeting and election of annuitants at Simpson's, 101, Strand, W.C.; Bristol and District Gardeners' Association meeting; Royal Botanic Society's meeting; Hornsey and District Chrysanthemum Society's annual general meeting. Friday, January 27.—Association of Economic Biologists meeting; Paisley Florists' Society's meeting. Saturday, January 28.—National Auricula Society's annual meeting.

**"The Gardeners' Chronicle" Seventy-five Years Ago.**—*Birmingham and Edgbaston Horticultural Society.*—We understand the donations which have been so liberally contributed for the purpose of improving and embellishing the Botanic Garden at Edgbaston now amount to little short of £400, the whole of which has been raised within the last few weeks, and it is highly probable that a considerable addition thereto will soon be realised. We learn that it is intended, as soon as the state of the funds will admit, to erect a Geranium house, in addition to the present buildings, to be devoted exclusively to the culture of the numerous varieties of that beautiful and favourite plant. A Garden Committee has been appointed, to whom will be confided the direction and superintendence of improvements which it is decided to carry into effect in the forthcoming spring. The Committee, it is said, will direct their attention to the floral department of the gardens (irrespective of the present botanical arrangement), with a view to render them more generally attractive than they have hitherto proved, by means of a regular and unbroken succession of flowers. *Birmingham Advertiser*, Dec. 31. *Gard. Chron.*, Jan. 16, 1847.

**Publications Received.**—*On Forms of the Hop (Humulus lupulus L.) Resistant to Mildew (Sphaerotheca humuli (DC) Burr).* By E. S. Salmon. Reprinted from the *Annals of Applied Biology*, Vol. VIII, Nos. 3 and 4, November, 1921. University Press, Cambridge.—*Seed Trade Buyer's Guide for 1922.* Published by the *Seed World*, Chicago, Illinois. Price \$1.00.

**FLORISTS' FLOWERS.**

**ANTIRRHINUMS.**

ALTHOUGH the Antirrhinum is a hardy perennial it may be treated as an annual, and grown as such it forms one of the most showy of summer bedding subjects. The habit of growth is admirably adapted for bedding purposes; there are dwarf, intermediate, and tall forms, and in many instances the effect is greatly enhanced by a combination of the three types, especially in the case of large numbers in beds or wide borders.

The colours of the flowers include a wide variation of hues, those enjoying the greatest popularity are the selfs, or at least those in which only one shade predominates. Seeds of many distinct colour forms may be had from seedsmen, and the plants may be relied on to give good results.

To secure stock for a summer display a sowing of seed should be made at the end of January; use small, shallow boxes filled with light, sandy soil made moderately firm, and scatter the seeds thinly over the surface. Cover the seeds lightly with fine soil, in which a little old mortar rubble has been mixed, and place the seed pans in a moderately warm house or frame.

As soon as the seedlings appear, place them in a light, airy position to prevent damping, and when large enough to handle prick them out into boxes. Afford the plants a little warmth until early in April, when they may be planted out into a cold frame or any position where protection can be given during cold, wet weather. By pinching out the tip of the leading shoots side growths are induced to develop, and bushy plants thus obtained, which, by the time the borders and beds are cleared of the spring flowering plants, should be in excellent condition for planting permanently.

Antirrhinums will grow well in most kinds of soils, but well drained ground is most suitable. Any attempt to winter the plants on stiff, cold ground, with a view to obtaining a spring and early summer display of flowers is sure to end in failure. On a friable soil plants raised from seeds sown at the latter end of July in the open ground, and transplanted early in the autumn to allow them time to become established before winter, will give a wealth of flower in the spring.

In suitable soils Antirrhinums sometimes grow to a height of 4 to 5 feet, and assume quite a shrubby appearance; such plants when in flower are most beautiful objects. When preparing the sites for Antirrhinums it is better to exclude manure unless the soil is exceptionally poor, especially for autumn planting, as excessively rich soil is productive of rank, sappy growth at the expense of flowers. To prolong the flowering season, all seed vessels and dead flowers should be kept removed. Good colour varieties are:—Coral Red, Orange King, Rich Apricot, Pale Apricot, Bright Pink, Maave Queen, Yellow King, White and Crimson Gold—suffused. *James A. Paice.*

**SEEDLING PHLOXES.**

I DOUBT if there is a more pleasant phase of gardening than that of raising new varieties of popular kinds of flowering plants with a view to obtaining improvements on existing varieties; with many kinds of florists' flowers this enterprise proves interesting and exciting. The accompanying illustration (Fig. 12) of a bed of seedling Phloxes at Aldenham in 1921 conveys some idea of the contrasts in colour found in such a display.

At Aldenham we carry out a considerable amount of this class of work, dealing with such subjects as Pentstemons, Polyanthus, Streptocarpus and Asters, but I never recollect anything to be compared with these seedling Phloxes. They were seen by many folk, and gave great pleasure to all; in fact, it was a difficult task in some instances to draw attention to other points of interest at Aldenham, once the visitor had reached the Phloxes. One gentleman, who has done very much good work among Phloxes expressed the opinion that he had never seen anything to equal ours.

There were about 1,400 seedlings, and of these nearly 500 were selected as worthy of a second

season's trial, inasmuch as they showed prospect of advance in comparison with existing varieties. My sole reason for setting out these details is to endeavour to emphasise the great pleasure that this sort of enterprise can afford to those who will undertake it. Unfortunately, the illustration does not show the wonderful range of colour tones and tints that the flowers displayed.

The seeds were sown at the end of October, 1920, in a light, sandy compost, and placed in a temperature of about 50° to 55°; when the young seedlings were sufficiently large enough to handle comfortably, they were pricked off into boxes. After they had become established, they were gradually hardened off, and were planted out into the bed in rows, 1 foot apart, with 6 inches between the plants in the rows. They were carefully supported by Spiraea sticks, each plant being tied to its support, and, to further help them to resist the effects of any rough winds, the sticks were in turn tied to lines of tarred twine run along the rows and attached to stout stakes inserted at the ends of the rows. Until flowering took place, the Dutch hoe was kept busy along the rows to keep down weeds, and aerate the soil, while the plants' requirements in the way of water were carefully

to remember that the photograph was taken early in March. Since then I have searched the regular channels for an advertisement of this variety, and am still searching, though with the conviction now that it must be paying the raisers better to sell the flowers than the cuttings, although I note that this Chrysanthemum was exhibited at the last R.H.S. fortnightly meeting in the old year. In the meantime the alternative for the majority of us is to make use of the sorts that are available, and fortunately there is a fair choice. As a flower, Cheshunt White leaves little to be desired, but the plant has a poor habit. I grow this sort four together in a 9-inch pot, and stop the plants once in April. In an average season this stopping results in January flowers, but last year Christmas saw them at their best.

The Favourite is a later introduction, with a habit as near perfection as one could wish in a bush Chrysanthemum. The blooms are of the incurving type, and each plant will develop a dozen or more flowers each, some 4 or 5 inches across. Christmas White is useful, but hardly so serviceable as the other two for late work, the flowers being at their best about

FIG. 12.—SEEDLING PHLOXES AT ALDENHAM HOUSE GARDENS.

attended to. After they commenced to flower many happy hours spent in examining and comparing the varieties gave us our reward; the comparisons have been made with named varieties in our big Phlox borders, near at hand, and which in their turn contain somewhere between 150 and 200 of the best-named sorts obtained in Great Britain, and from France, Germany, Holland and the United States.

The selected 500 will be subjected to a further strict examination this year, with a view to eliminating all that are not up to the desired standard, for there is neither pleasure nor utility in saving a seedling that is only equal to or inferior to one already in cultivation.

One of the great advantages derived from growing seedling Phloxes is that they commence to flower when the permanent plants are on the wane, and will continue blooming to quite late autumn. *E. Beckett, Aldenham Gardens.*

**LATE-FLOWERING CHRYSANTHEMUMS.**

LATE-FLOWERING Chrysanthemums are amongst the most useful plants in gardens and well worth growing. Whilst in camp in the spring of 1919 I received a copy of *The Gardeners' Chronicle*, which contained an illustration of a houseful of Chrysanthemums of the variety Autocrat. I lost the paper, but seem

mid-December. Western King is a free-blooming variety, but rather on the small side. The plants, however, lift well, and are grown with but little trouble.

Baldock's Crimson seem to be about the best variety of its colour, and the plant has a nice, stocky habit. The bronze sport from it is also worth a place in collections. Edith Cavell, a famous exhibition variety, makes a good late bush, blooming at the end of the year, when the shoots are restricted to a dozen disbudbed blooms; the colour is rich under artificial light. Lient. H. Peto is, however, an improvement upon it, being a dwarfer grower, while the blooms are more refined.

W. H. Lincoln has disappeared from most catalogues, but as it was well exhibited in late December it is evident that its period of usefulness is not yet over. In its day it was the best yellow variety of its type. Nagoya is useful in this colour, but it has a poor habit.

December Gold is a variety which varies with the seasons, and is not to be relied on after the middle of December. Framfield Pink retains its vigour wonderfully well, and Pink Pearl can hardly be overlooked. My favourite is, however, Bertha Lachaux. The blooms are of substantial build, the florets reflexing beautifully and the colour a rich, clear pink. *F. G.*

## The Week's Work.

### THE ORCHID HOUSES.

By J. T. BARKER, Gardener to His Grace the DUKE OF MARGBOROUGH, K.G., Blenheim Palace, Woodstock, Oxon.

**Laelia anceps.**—The varieties of this beautiful Orchid take a prominent place in supplying choice blooms during the winter. The white varieties are specially valuable in what is probably the duldest season of the Orchid year. When the flowering period is over the plants should be allowed to rest until new roots are observed to be pushing from the rhizome, when any necessary repotting should be done. Where the plants are grown in quantity, it is not desirable to disturb the whole stock in one season, unless the plants are in a bad condition, as in many cases they take some considerable time to recover after being disturbed. In repotting large specimens it is advisable to take them carefully to pieces, each having two or three pseudo-bulbs. The back pseudo-bulbs may, if the eyes are good, be potted separately, or with the leading ones, as they will generally break, and make new growths, unless they are very old. *Osmunda fibre*, of a coarse nature, thoroughly pulled to pieces and mixed with a small quantity of Sphagnum-moss provides a suitable compost, which will last a considerable time. The white varieties, especially, should be induced to rest for so long as possible, as they then break into growth more freely, and produce flowers more abundantly. The coloured varieties are free in the production of flowers, and bloom in advance of the white ones, therefore they should receive attention first. Newly potted plants will not require much water for some time to come provided the material is neither wet nor dry when it is used. This small detail is often overlooked, especially by amateur growers. No recently potted plant should have water applied to the compost until the new roots have grown freely in the fresh material.

**Watering.**—The greatest care and attention must be given in the application of water at this season. Many plants are at rest, and these only require sufficient moisture to keep them plump, and prevent them from shrivelling; others will be growing actively, and require water whenever they become dry. A recognition of this difference is one of the secrets of successful cultivation. Too much water is as bad as too little, the effect being the same in both cases, namely, the loss of roots and the general deterioration of the plant.

### THE HARDY FRUIT GARDEN.

By H. MARKHAM, Gardener to the EARL OF STRAFFORD, Wrotham Park, Barnet.

**Pruning Older Fruit Trees.**—Much has been written in favour of pruning and keeping the heads of old fruit trees well thinned. Yet we not infrequently meet with trees quite thickets of useless wood that rarely bear satisfactory crops. In suitable weather these should be thinned out so that the remaining branches may have ample light and a better chance to develop strong, fruitful buds and fruits.

**Root Pruning.**—Trees that are not yielding satisfactory crops of fruit should have their roots thoroughly examined, and, if found necessary, pruned and replanted in a sweet, fertile compost. Although this work is best undertaken early in autumn, when the ground is still sufficiently warm to enable fresh fibrous roots to develop, it may be successfully carried out at any time when the weather is suitable during winter. When operating on large trees it is prudent to extend the work over two seasons so as not to give the trees too severe a check. In commencing the work dig out a trench 2 ft. deep from 4 ft. to 6 ft. away from the stems, a little more or less according to the age and size of the trees. Gradually remove the soil from amongst the roots with a garden fork, taking

every possible precaution not to injure them more than can be helped. Thick tap roots which have penetrated the subsoil should be severed, fit being of the greatest importance not to miss a single root of this character, for which reason undermine the trees thoroughly. In cases where the roots have taken a downward direction near the main stems, it will be advisable to place a piece of tile or slate under the roots that are severed in order to prevent them growing downward again. When the roots have been lifted, see that the drainage is made good. Prune the tips of any roots which have been injured, and replant at different angles, working plenty of fine soil amongst them, and after making the whole firm, finishing with a mulch of strong manure. In some cases the whole of the roots may be lifted at one time, but one-half the roots of larger trees should be pruned one season and the rest early the following autumn.

**Younger Trees.**—Any of the younger trees that are growing so strongly as to be unfruitful should have their roots lifted entirely and relaid afresh in moderately firm soil. This will at once check the exuberant growth and cause the tree to make sturdy fruiting wood.

### PLANTS UNDER GLASS

By T. PATEMAN, Gardener to Sir C. NALL-CAIN, Bart., The Node, Codicote, Welwyn, Hertfordshire.

**Begonia Gloire de Sceaux.**—This useful *Begonia* is coming into flower, and the roots may be stimulated with a concentrated fertiliser about every ten days. They will also benefit by having a little of the soil carefully removed and a light compost containing a little artificial manure substituted.

**Violets in Frames.**—These plants will need constant attention during the next few weeks with regard to removing decaying foliage to prevent damping and consequent loss of many flowers. Slightly stirring of the soil between the plants will be very beneficial, and will tend to maintain a sweeter atmosphere. Violets require an abundance of fresh air, and the lights should be removed entirely whenever the weather permits.

**Forcing Flowering Shrubs.**—For grouping in the decorative plant houses and for cutting purposes forced flowering shrubs are indispensable during the early spring months, especially where decorations are required on a large scale. When forcing these plants into flower it is not advisable to bring them direct from the open and place them in a high temperature forthwith, as this would tend to result in spindly growth, which is not to be recommended. Perhaps there is no better place in which to place them direct from the open than a fruit house that has just been closed for forcing. In such a house, with a gradual rise in the temperature, the plants will form strong sturdy growth, which is essential to produce good flowers. At this stage a double quantity of the plants may be brought under cover, and stood closely together until growth commences, when they may be divided into two batches, the one to remain in the lower temperature to form a succession, and the other transferred to the forcing house. When the flowers have almost developed, the plants should be removed to cooler quarters, but they must not be exposed to cold draughts. Plants of a shrubby nature suitable for forcing include *Azalea indica* in standard and bush forms, *Azalea sinensis* hybrids, Lilacs, *Wistarias*, *Laburnums* and *Viburnum Opulus*. *Rhododendron* may be forced, but instead of being subjected to hard forcing, they should be allowed to develop in a medium temperature.

**Calceolaria Clibranii.**—This useful plant is beginning to grow freely, and attention should be given to the proper staking and tying of the shoots, otherwise the growths, which are very brittle, may be broken when tying them in position. Two-year-old plants will benefit from occasional applications of plant food. This *Calceolaria* makes fine specimens when grown on the second year provided attention is given to feeding the roots.

### THE FLOWER GARDEN.

By EDWIN BRACKET, Gardener to the Hon. VICARY GIBBS, Aldenham House, Hertfordshire.

**Preparation of New Borders.**—Where new borders are to be made, this work should be proceeded with without loss of time in suitable weather, and there are one or two important points to remember. A deep, free root run is as essential to herbaceous and similar flowering subjects as to vegetables, and therefore in making a new bed or border see that the soil is thoroughly and deeply worked. Further, make sure that the drainage is in good condition, and where beds are made in positions that are not of easy access to land drains, then some form of drain, such as a good layer of broken bricks or large stones, should be put well down to form a place to which surplus water can soak until such time as it can get away into the surrounding ground. Old beds that are being got ready for bedding purposes should receive some form of plant food, either in the way of animal manure, well decayed, or a dressing of a reliable artificial manure, for it must be borne in mind that exhaustion of such food is constantly taking place in those beds that are occupied year after year with such plants. Where it can be done, it is as well to remove some of the soil, say, to a depth of from two to three feet, and replace it with good stuff, such as decayed turves well chopped up. Where heavier material only is available, mix with it a good proportion of gritty material such as road sand.

**Summer Bedding.**—There are many extra subjects which are used nowadays to enhance greatly the beauty of summer bedding. The modern style of flower bedding is not of such a formal character as at one time, and a great variety of half-tender plants may be used for the purpose that are at the present season of the year being sheltered in pits and frames. Most of these are presumably young plants raised from cuttings that were struck towards the end of last season, or when the summer bedding was removed to make way for the spring bedding. As the very best results can be attained only from really well-grown specimens, these young plants should now be re-potted into suitable-sized pots, and grown on in a warm temperature to develop healthy growth, so that by the time they are ready to be hardened off they will be shapely specimens of full beauty. This work may be carried out as opportunity presents during the next month, and will be found to well repay for careful attention. Where stock of the nature referred to was not propagated during the fall of the year the work should be undertaken forthwith. Many growers pot the best of the bedding plants as they are lifted, with a view to propagating from them now, and if the larger specimens devoted to this purpose are brought into growth in a house having a genial temperature, and fairly moist atmosphere, they will soon provide ample material for use as cuttings. The latter should, when ready, be inserted without further delay in sandy compost, and potted on as soon as they are suitably rooted. *Fuchsias*, *Pelargoniums*, *Heliotropes*, *Swainsonias*, *Calceolarias*, *Iresines*, *Plumbagos*, and many other bedding plants may thus be dealt with now.

### FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

**Cucumbers.**—Make a further sowing of *Cucumber* seeds, as young plants raised now will make rapid progress as the days increase in length, provided they are grown in plenty of heat and moisture. A night temperature of 65° to 68°, with a corresponding rise during the day, will be suitable for the next few weeks. Plants already fruiting require extra care and attention during this month; encourage the young growths to develop as much as possible by affording the roots light top dressings of rich compost, and watering them occasionally with warm, diluted liquid manure. Admit a little fresh air, if only for a short time, on bright days to prevent a stagnant atmosphere. Damp

the beds and paths lightly, according to the weather, in order to maintain a moderately moist atmosphere.

**Ventilation and Temperatures.**—The ventilation of fruit houses requires to be done with great care and needs constant attention during the early stages of forcing. Guard against cold draughts and checks from sudden changes in the outside temperatures. Nothing will be gained by attempting to force the plants unduly during very cold weather; slow progress now is soon made up later when more genial weather and longer days prevail.

**General Remarks.**—The pruning of vines or Peaches should be completed without further delay. The houses should be washed and painted if possible, especially if mealy bug or red spider has been troublesome. Place a sheet on the border and carefully rub the loose bark off vines; carefully collect up all the rubbish and burn it. Wash the vine rods with Gishurst Compound to destroy any insects that may be harbouring on them, and also as a preventive against further attacks.

**Permanent Trees in Borders.**—The house containing trees planted in borders should be closed, if this has not been done already. Examine the borders carefully and supply the necessary moisture down to the drainage, using tepid water. Promote atmospheric moisture by dampening the walls and paths, and not so much by direct syringing of the trees, especially in dull or damp weather. Keeping the trees constantly moist is detrimental to their progress.

### THE KITCHEN GARDEN.

By JAMES E. HATHAWAY, Gardener to JOHN BRENNAN, Esq., Ralderby Park, Thirsk, Yorkshire.

**Onions.**—Where large Onions are required for exhibition the seed should be sown now in pots or boxes. Where plenty of room is available 60-sized pots are the best receptacles as seed pans, but Onion seed may be sown in well-drained boxes, about 3 to 4 in. deep. Cover the drainage material with rough fibre from turves, and fill the box with a mixture of rich fibrous loam, leaf-mould, decayed horse droppings, wood ash, and, if the soil is of a heavy texture, sand to lighten it. The whole of the materials should be passed through a half-inch sieve. The soil should not be too wet nor too dry, and should be made firm, and the boxes should be filled nearly to the top. Press the surface perfectly flat, and sow the seeds thinly, shaking soil over them through a very fine sieve to cover them. The seed pans or boxes should be placed near to the roof-glass in a house having a temperature of about 55° to 60°. If the seedlings are grown in an excessive amount of fire-heat they will become drawn and spindly. In gardens where Onions sown out-of-doors do badly this is the best method of growing the plants forming the main crop.

**Leeks.**—A sowing of Leeks should be made now. The general treatment should be similar to that advised for Onions, but the seed is best sown in 60-sized pots, and the soil should not be made too firm.

**Hot Beds.**—As fast as materials are available continue to make hot-beds. Stable litter and leaves in equal proportions make good hot-beds. Beds on which it is intended to place portable frames should be made 3 ft. wider all round than the size of the frame. Tread the litter and leaves firmly. Soil which has been sifted through a half-inch sieve should be placed in the frames to a depth of about 8 inches. As soon as the soil is in a suitable condition (which may be ascertained by means of a thermometer or a stick pushed into the fermenting materials) early types of Carrots may be sown in rows 10 to 12 in. apart, and Radishes sown thinly between them as an intercrop. Early Snowball and Milan Turnips may also be sown in these frames. Turnip seeds germinate very quickly, and so soon as the seedlings appear air should be admitted when the weather is favourable to prevent the plants becoming drawn.

**Shallots.**—Shallots should be forthwith planted if not already done. Level the ground with a rake and plant in rows made 1 foot apart, allow-

ing 9 inches between the bulbs in the rows. Shallots should be planted practically on the top of the soil, and only just pressed into the ground. Afterwards draw the soil to them, leaving only just the tip of the bulb showing. Garlic may also be planted now, but this herb should be planted deeper than Shallots.

### PALMS OF THE RIVIERA.

*JUBAEA CHILENSIS*, Mol. (*J. spectabilis*, H. B. and Kunt) is a Palm which resembles *Butia* very much, but is a much larger size. Though this Palm is not rare in the Riviera gardens, still it is not met with frequently, though it was introduced many years ago, and before several other Palms which are now met with everywhere, such as *Phoenix canariensis* and *Washingtonia*. The reason is that *Jubaea chilensis* is slow growing, and that it commences to flower only at the age of fifty or sixty years, while *Phoenix canariensis*, which is quick-growing, flowers and fruits at the age of eight or ten years. Apart from this, *Jubaea chilensis* is a much less ornamental Palm than *Phoenix canariensis*. Its trunk is even thicker and its leaves shorter and more stiff, also less gracefully arched. The fact of it being less orna-

mental than *Phoenix canariensis* and that, though it was introduced much earlier, it did not produce seeds, when *Phoenix canariensis* already did so, accounts for its relative rarity in the Riviera. Still, like all Palms, it has a great ornamental value, and is well worth planting, especially as it is very hardy, much more so than *Phoenix canariensis*, and is, with its tall, straight, smooth trunk, always an imposing Palm when of a certain age. As stated, the trunk is smooth, the bases of the dead leaves, though remaining for many years, finally falling off. The folioles are bent, like the folioles of *Butia* and all Palms of the tribe *Coccoloba*, so that each half is turned downwards, while in the *Phoenix* the halves are turned upwards, forming a rim in both cases. Unlike the *Butia*, to which *Jubaea chilensis* bears a great resemblance, the petioles are spineless. This slow-growing Palm reaches in time, probably in the space of centuries only, a height of twenty to twenty-eight metres, but such very large individuals, which exist only in the wild state in a few parts of its native country, Chili, are becoming exceedingly scarce, since this Palm is frequently cut down to obtain the sap from the trunk, this sap being boiled until it acquires the consistency of syrup or sugar, which it replaces in its native country. After the plant has been felled, the top is cut off, and from this cut continues to flow for months a quantity of sap, which fills the enormous trunk. It is rather unfortunate

that such a stately Palm, the only native Palm of the Chilean mainland, should be thus exterminated without adequate means being taken to replace the felled trees or some way found to tap the sap without cutting down and thus destroying the Palm outright. It is so much more regrettable, as the sap is not the only useful part of the plant, for the kernels of the fruits are edible, as, indeed, are probably those of all Palms belonging to the tribe *Coccoloba*. The kernels of the fruits of *Jubaea chilensis* are single in the fruits, which vary according to varieties, from the size of Walnuts to that of a middle-sized Apricot. While the flesh of the fruit is full of fibre and of no value for eating, the kernels have a very fine flavour, like that of the well-known Coco-nuts, but superior. The kernels are much appreciated in Chili and used for all purposes, for which Coco-nuts, Almonds and such nuts are used, that is either eaten raw or boiled with sugar, in cakes or in other ways. The fact of the kernels of *Jubaea chilensis* being so valuable may, perhaps, prevent the utter destruction in the wild state of this interesting Palm and eventually lead to its cultivation, especially as it is not exacting as to the kind of soil in which it will grow and resists great drought.

To those who like to combine the useful with the ornamental, I could not give better advice

FIG. 13.—*SALVIA LEUCANTHA* FLOWERING A SECOND TIME IN THE SAME YEAR.

mental than *Phoenix canariensis* and that, though it was introduced much earlier, it did not produce seeds, when *Phoenix canariensis* already did so, accounts for its relative rarity in the Riviera.

Still, like all Palms, it has a great ornamental value, and is well worth planting, especially as it is very hardy, much more so than *Phoenix canariensis*, and is, with its tall, straight, smooth trunk, always an imposing Palm when of a certain age. As stated, the trunk is smooth, the bases of the dead leaves, though remaining for many years, finally falling off. The folioles are bent, like the folioles of *Butia* and all Palms of the tribe *Coccoloba*, so that each half is turned downwards, while in the *Phoenix* the halves are turned upwards, forming a rim in both cases. Unlike the *Butia*, to which *Jubaea chilensis* bears a great resemblance, the petioles are spineless. This slow-growing Palm reaches in time, probably in the space of centuries only, a height of twenty to twenty-eight metres, but such very large individuals, which exist only in the wild state in a few parts of its native country, Chili, are becoming exceedingly scarce, since this Palm is frequently cut down to obtain the sap from the trunk, this sap being boiled until it acquires the consistency of syrup or sugar, which it replaces in its native country. After the plant has been felled, the top is cut off, and from this cut continues to flow for months a quantity of sap, which fills the enormous trunk. It is rather unfortunate

than to plant a few specimens of *Jubaea chilensis*, and where the temperature of the district is favourable to the tree, that is where frosts as low as 15° C. occur occasionally, but do not last more than a short time, this hardy Palm will exist, though, of course, like all plants, it will do better in climates where its vitality is not put to such a severe trial. Dr. A. Robertson Proschowsky, *Jardin d'Acclimatation, Les Tropiques, Nice, France.*

### SALVIA LEUCANTHA.

This very pretty Labiate comes from Mexico, and is usually treated as a greenhouse shrub, though in the West of England we grow it out of doors. It usually flowers profusely during July and August, but in 1921, owing no doubt to the extraordinarily fine summer, we had two crops of flowers, the second of which was unusually good. The photograph (Fig. 13) was taken here at Tolvean, Redruth, on November 7. The corolla is white and densely woolly, while the rachis is equally woolly, but it is violet or amethyst, and the whole looks uncommonly pretty. It is a splendid companion for *Leonotus Leonurus* or *Salvia Pride of Zurich*. A stock plant gives numerous cuttings in the autumn, and they in their turn, when rooted and planted out in April, make a handsome show during the following summer. H. W. Redruth.

**EDITORIAL NOTICE.**

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, W.C.2.

Editors and Publisher.—Our correspondents would oblige by delaying in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the EDITORS. The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.

Local News.—Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

## MR. KINGDON WARD'S SIXTH EXPEDITION IN ASIA.\*

9.—IN THE LIMESTONE COUNTRY.

WE were now deep in the limestone country, and as we went northwards the country grew drier. Many of the streams disappeared underground, and I imagine that at certain seasons there would be difficulty in finding water. In such a region the only permanent water supply would be that derived from melting snow, and the snow line could not be expected to be much below 19,000 feet. So far we had not glimpsed a snow peak, nor so much as a lurking patch of snow. The passes we crossed were not above 9,000 feet, the highest peaks some four or five thousand feet higher, grim and bare looking. Nevertheless we found new flowers every day, and the flora was clearly growing richer in spite of the disabilities under which it laboured. Clearly we were travelling towards the source of supply, in the direction from which the flora had originally come. Also the mountains were growing higher, so that we found more species for the same altitude than hitherto. So far east of the Yangtze we had found but seven species of *Rhododendron* below 10,000 feet altitude, including *R. Delavayi* and two white flowered species already found far to the south of Ta-li, the purplish-pink *Azalea*, and three dwarfs. At least six species of *Oak* occurred commonly, and the *Conifers* were becoming more varied, though *Pines* were still by far the commonest trees. A shocking purple *Pleione* was plentiful in the Pine woods, though scattered; it vied with the *Roscoea* in outrage. On May 25 we got down into more populated country—open valleys of hard, red earth, where there was cultivation. *Amphicome arguta* warned us not to expect flowers here. In the evening we came down to a considerable stream, the La-pa-ho, which I mention by name because it is not marked on any map. A pretty *Cornus* was in flower here, with large and cream-coloured bracts, and masses of fragrant white *Jasmine* grew everywhere; it was the sixth species of that genus we had met with.

On the arid, shrub-clad slopes the pale blue *Iris kumaonensis*, funny little dwarf that it is, alone cheered our hearts, though *Primula Poissonii* glared balefully at us from the bogs, which were not numerous.

All next day, till late in the afternoon, we were marching through cultivated valleys, where surprising quantities of Paddy are raised. The flora in the wayside ditches and on the gentle slopes was astonishingly unromantic; in fact we were back to civilisation—or in what goes by that name in China. We even passed

through a village where a five-days market was being held, and saw the finest assortment of Mosses, Lisus, Lao-pang, and other picturesque hill tribes to be met with in a day's march.

However, in the evening we turned off from the valley and climbed up amongst broken limestone crags, where we found a few flowers. A *Thalictrum* with purple blossoms just opening out was probably *T. Delavayi*; a fine, hairy-leaved *Geranium* grew on the rocks, and an orange-eyed *Aster* with brilliant violet ray. Dwarf blue *Irises* dotted the slope, and a *Vetch* with yellow flowers was rampant in the gullies. The country here was very much broken up, and the going correspondingly hard. Our route lay practically north, behind a range of limestone hills, which separated us from the valley we had been following earlier in the day; but streams from the west broke through this range, and had to be crossed. It was the same next day, but we crossed a pass and returned to the other side of the range, only to find ourselves in a valley where the stream flowed south instead of north, so that these main streams also flowed eastwards to the Litang river, instead of west to the Yangtze, whose gorge here must be very narrow. It was not a little surprising to find a *Ficus* growing on the bare limestone crags up here. A maroon-red *Paeony* was coming into flower—it looks a fine colour with the sun shining through the blooms. This species, in favourable situations, forms a small bush up to four feet high, springing from a large woody rootstock. We did not come across the yellow *P. Delavayi*. The country was still very bare, not even *Pines* growing on these south-facing slopes under 10,000 or 11,000 feet.

In the afternoon we ascended another wide valley where there was some cultivation; then, leaving that behind, where the stream issued from a ravine, we camped at an altitude of 9,167 feet. In the stream bed here grew *Tamarisk* bushes, their pale, sea-green foliage looking fresh and pleasing. A *Lycyteria* was in flower, and a charming little *Picea*, laden with cones, young and old, growing in honourable isolation, made a delightful picture.

Tremendous cliffs rose steeply on either side, up one of which we had to climb next day. The other, facing north, had rolled down a long scree of big boulders, and here grew thickets of shrubs, conspicuous amongst which was a *Dipelta*, with tender, white flowers, orange spotted, and a *Schizandra*. There was also a lot of *Bamboo*, but no trees save a few gaunt and scattered *Tsuga*, waving streamers of green lichen.

We started early for the big climb on May 28. Up through the steep Pine woods, till we could see over the heads of the mountains we had recently crossed, and still up. It grew perceptibly cooler, and still we mounted. The ground was purple with *Roscoea* which, however, varies widely in depth of colour. One might suspect it to be stained with the variation of each soil, only there is an absolute monotony of soil; we never were off limestone during the week's march.

A purple *Morina* grew here too—possibly *M. betonicoides*—and all the familiar Pine-wood flowers already referred to. Then we left the *Pines* and came out on to the open ridge covered with shrubs such as we had already seen in abundance. Only the white *Rhododendron*, a shrub of four or five feet, mottled the slope. The *Azalea* was also still in flower, with *Pieris*, *Desmodium*, etc. *P. Kingdon Ward*.

## "THE FLOWER GARDEN."

IN the year when Queen Victoria ascended the throne, Messrs. Orr and Co. commenced to issue a series of books on gardening, which are interesting as showing the stage that horticulture had reached at that period. The first of these dainty volumes was that whose title stands above this article. The other two were respectively *The Greenhouse* and *The Orchard*, written by Charles McIntosh, of Claremont and Dalkeith Palace, and illustrated, as was *The Flower Garden*, with Baxter colour prints and engravings. They were published in numbers at 1s. each. I have been unable to identify the writer, or rather, editor, of this, the first volume, but there is internal evidence that he was a Scot, and, obviously, well educated. The remarks on landscape gardening, with which the volume opens, did not please Loudon, who slated the writer unmercifully in *The Gardeners' Magazine*. Notwithstanding, we are obliged to the writer for information, and for designs of then existing flower gardens, which Loudon failed to supply, and not impossible he may have incurred the displeasure of that gentleman by ridiculing some of his designs. The author's point of view as opposed to the striving after "irregularities"—sometimes grotesque, instances, of which are mentioned, is summed up in the remark that "it is a narrow, partial and incorrect principle to represent nature as irregular. At the same time, it seems to be quite forgotten that gardens are not natural." It is stated that the style of flower gardening—which has continued till the present time—was introduced about 1790. A plate of a geometrical flower garden shows the method of arranging and the plants to be used. For spring, there were *Hyacinths*, *Tulips*, *Narcissus*, *Violas* of sorts (an old name revived later) *Ranunculus*, *Anemones*, and *Stocks*. For summer and autumn there were choice *Dahlias*, *Verbena chamaedrifolia*, *Calceolarias*, *Fuchsias*, *Heliotrope*, *Scarlet Geraniums*, *Lobelia*, *Stocks*, *Viola*, *Campanula pyramidalis*, intermixed with *Lobelia fulgens*, and *Lobelia splendens* with *Campanula persicifolia*, and two beds of *Roses* and herbaceous plants.

Though many of these names represent beautiful plants, yet I am afraid that the choice in 1837 was at best a poor one, and the lists are interesting chiefly as showing that the foundation was laid ready for the superior class of plants that succeeded them shortly thereafter.

The chapters on florists' flowers are not lengthy, but extended enough to contain all that is needed to obtain a clear conception of their status. The lists of varieties are very long and the prices usually are attached. Thus, of *Tulips*, there are about 400 names, the prices ranging from 2s. 6d. each to £50 for *Parmegiano*, a *Bybloemen*. There were, however, varieties still higher priced, but these were never catalogued. A *Tulip* bed in full bloom, fully protected by a shed-like construction and with a sheet of calico stretched over the plants to prevent drip, affords a good idea of the care taken to perfect the blooms of *Tulips*. Some 150 *Hyacinths* are named and priced, among which are a few still appearing in bulb catalogues. The *Ranunculus* was still popular, though approaching decline, and of this, some 500 varieties appear. Prices were mostly one shilling, and none reached a pound. They are divided into no fewer than 18 colour sections. *Anemones*, if the number of varieties named affords a criterion for judging, were less popular, only 146 being listed at prices as low as 6d. each. The *Dahlia*, however, was as popular then as now, more than 900 varieties being named. These are distinguished by colour only, and the height of each is given; heights ranging from 2 to 7 feet. The beginnings of the Show and Fancy sections are clearly indicated.

About 130 *Auriculas* are named and priced. Some, as Lee's *Bright Venus* and Taylor's *Glory*, have no price attached, but *Conqueror* of Europe is as much as £3, while *Booth's Freedom* is 15s., and *Lovely Ann* 5s. Many are as low as 4s. each. An *Auricula* stage, a frame, an implement for flattening unuly

\* The previous articles by Mr. Kingdon Ward were published in our issues of May 14, June 18, July 23, August 20, September 3, October 8, October 29, 1921, and January 7, 1922.

petals and other engravings are included in this chapter.

A fine print of the beautiful old double crimson Primrose appears in the chapter on Polyanthus; I wonder the plant still exists, being a difficult client to please.

A fine example of a scarlet Bizarre illustrates the chapter on the Carnation, of which about 270 are named, of Picotees 120, and yellow grounds 40. These are all comparatively cheap, 4s. to 5s. the pair being the price generally. All but an insignificant minority have their raisers names prefixed, but alas! as little is known of the identity of these folk as of the particular flowers. Hogg, of course, we know, and Turner, Glenny, Tyso and Willmer are not unfamiliar, but of Crook and Snook and the rest, we are oblivious. In those days, Carnations had as many troubles to contend against as now. Our author has his doubts as to who or what was responsible for the eating down to the very "stumps" of the leaves of Carnations. He laughs at the suspicion of rats, but is not so sure about cats, for do not cats eat grass? Of the guilt of sparrows, he has no doubt. A little less than 200 Pinks are named, mostly at 2s. per pair. Hogg and Turner are largely represented as raisers, but the Pink men, as a rule, are different from Carnation growers. About 350 Pansies are named, the varieties shown in a plate giving one to wonder how such things could be named at all. From this time, however, the Pansy made great progress. A different account of the origin of the Pansy is given here from that generally accepted. Lee, of Hammersmith, was attracted by some seedlings he saw in a garden at Walton, and added to these some he imported from Holland, among which was the large blue, and from these all the varieties then cultivated had been raised! So difficult is it to get at facts.

The list of Chrysanthemums is that published earlier in *The Gardeners' Magazine*. In addition to these, there were others raised by one or two persons. Mr. Freestone, gardener to W. Brereton, Holt, not only raised new varieties, but had succeeded in flowering them the same year from seed.

The number of Roses exceeded any other flower by many hundreds, and an epitome of the history of many kinds is given, not quite complete however. There are, too, very large selections of plants and shrubs, that devoted to hardy Heaths having a plate of greenhouse kinds beautifully executed. The botanical names of species are translated into English, and some curious examples are among these. "Alpine," for instance, is "kin," but the greatest attempt of all is "Canadian Shepherd" for *Shepherdia canadensis*! Vulgar names I have not met with elsewhere are Primrose rose for *Rosa hamaespherica*, and Aaron's Rod for *Phlox paniculata*. Among the large number of plants treated in brief fashion, the Hollyhock is absent. Like so many others, its time was coming speedily. R. P. Brotherton.

## HOW ARE PLANTS AWARE OF TIME ?

THE majority of people would, perhaps, reply off-hand to this query that it is a question of season, which plants are compelled to know by force of physical circumstances, such as conditions of temperature and moisture; but very little reflection will show that this answer is incomplete. In my garden, as a weed, I have a Cape Oxalis, much like *O. versicolor*, and now, in spite of being chilled and discouraged by the worst weather of the year, it insists on growing, evidently with all the vigour it can bring to bear, while in much more favourable weather it is perfectly quiescent. It has no encouragement whatever, and it is growing apparently only because it is the time of growth in South Africa. Many would say "of course," and pass the matter over, but I think there is here a mystery that no one has attempted to explain—so far as I remember. It is notorious that plants do flower at the right time according to the calendar rather than at the right season according to physical conditions, so much so that none marvel; indeed, it is the sole explanation why we have various plants in flower when they are the most

valuable, and growth, too, at a fixed time is often one of the great difficulties of cultivation.

There are, however, various things to observe which require some explanation. It would be thought, for instance, that there would be forgetfulness in the dormant seed, so that a seedling raised in this country would readily accommodate itself to seasons of the English climate, corresponding with those of its natural home. If it does this in some cases, it does not in numerous instances I have in mind. I believe I am correct in stating that seedlings of Aloe raised from an imported packet of seed, which may have been sown at any time of the year, would in every case flower when the plant flowers in South Africa, *i.e.*, according to calendar, paying no regard whatever to corresponding seasons in this country. Moreover, I believe that English-grown seed would result in

then may not be induced in the habit of a plant if ages of repeating seasons take the place of the klimostat? I am aware, of course, that there are instances of accommodation to climate, as, for instance, I believe, the change of the flowering season in the case of Australian *Acacias* planted in India. R. Irwin Lynch, *V.M.H., Chelston, Torquay.*

## PRIMULA LIMNOICA, CRAIB.

*PRIMULA limnoica*, which is illustrated in Fig. 14, belongs to the denticulata section of the genus. The chief difference between it and *P. denticulata* lies in its somewhat narrower leaves, which are closely set with short, pilose hairs, while the peduncles are clothed on the upper part near the capitate head of flowers

FIG. 14.—PRIMULA LIMNOICA.

the same way. I have had various experiences of this kind, but, obviously, it is not the kind of thing that one could carry very far in experiment. For many years I have had my mind upon this subject, but I cannot say that I have any fixed theory, though, as shown by Sir Francis Darwin, rhythmic action can sometimes be very wonderful in plant life. As an example the case of Dandelion stalk just now occurs to me. If laid horizontally it naturally turns up, if, however, it is turned the other way after a sufficient interval of time by a klimostat it reverses, and if then the klimostat is made to turn at the same interval of time, the turning first one way and then the other by this Dandelion stem becomes automatic, and if the klimostat is finally stopped, nevertheless the Dandelion stem continues to turn first one way and then the other at the correct interval of time. What

with a yellow farina. So far the plant has not proved so hardy as its better-known ally, but it will evidently succeed under the same conditions, that is, in rich, moist soil in half shady situations. The lavender-blue flowers are produced in heads, on stems from 6 inches to 15 inches high, during April or May.

This species was found by Forrest in the Taping Valley, Upper Burma, at an altitude of 3,500 feet in April, 1917. He states that it grows in boggy situations by the sides of streams. Farrer came across it in 1919 growing on the Iipimaw Hill at an altitude of from 7,000 feet to 9,000 feet. He describes it as abundant on the Brackened slopes, making drifts of blue when in flower. These flowers have little or no scent. The plant figured was shown by Mr. Lionel de Rothschild at a meeting of the Royal Horticultural Society on March 3, 1921. W. F.

## THE GREAT DROUGHT OF 1921 AND ITS EFFECT ON GARDEN PLANTS.

(Continued from page 19.)

### HAMPSHIRE.

The drought at Exbury was even more severe than in other parts of England, only about 60 per cent. of the rainfall at Kew being registered.

All the newly planted shrubs and the Rhododendrons in the woods had to be watered from the beginning of May to the middle of October, with the exception of two weeks. There was, however, an adequate water supply, and as a result very few plants suffered. Some newly planted Austrian and Scotch Firs outside the watered area succumbed, whereas the evergreen Oaks and *Picea orientalis* seemed to relish the drought and heat; in fact, some 7-ft. evergreen Oaks acquired in 1921 have done remarkably well.

The ponticum Rhododendrons in the woods looked very sorry for themselves, made hardly any growth, and hung their leaves straight down, but the later rains revived them, and there seems to be practically no casualties.

*Cobaea scandens*, which survived the winter on the verandah of the house, fruited freely in the open, and the large green fruits have been quite attractive; ripe seed has been gathered. *Buddleia alternifolia* seeded for the first time. *Viburnum Henryi* was particularly attractive, covered with its red berries. *Cerastigma Willmottiana* flowered freely and was very attractive at the end of October. Rhododendrons set flower-buds more freely than I ever remember, every plant being covered with some hundreds of buds, and they should be a glorious sight in 1922.

Altogether the season appears to have been one eminently suitable to Chinese plants. *Lionel de Rothschild, Exbury, Hampshire.*

### LANCASHIRE.

The year 1921 will be long remembered by gardeners in Manchester and its immediate neighbourhood as one of the most productive and successful seasons for many years past. Gardeners and allotment holders who gave ordinary attention to the culture of their vegetable plots were rewarded in most instances with abundant crops. Flowers in private gardens and in public parks were never seen in greater profusion, in better colour, or in the aggregate blooming over a longer period than during the past year. Two factors were mainly responsible for these effects, viz., the long spell of bright, dry weather and the abnormal absence of smoke in the atmosphere brought about by the coal strike. The following are a few details regarding the effect of the drought upon various vegetable and fruit crops, trees and shrubs:—All Brassica crops were exceptionally good. There was a marked absence of the Cabbage fly, which is the more remarkable as this pest has been extremely destructive in this district during late years. The only failures were with Turnips and Kohl Rabi. Where the ground was deeply tilled and manured Peas gave magnificent crops, both in quantity and quality, the pods being thoroughly well filled. Early and second early varieties matured rather quickly, and only in the case of deep cultivation did they produce a second crop. Beans of all kinds were good. Kidney and Runner Beans gave heavy crops, and it was a very poor allotment or garden where the owners did not secure Beans to salt in sufficient quantities for use through the winter.

Although Celery is generally regarded as a moisture-loving plant the crops last year were exceptionally fine.

Beet, Silver Beet, and Jerusalem Artichokes produced very heavy and fine, clean crops.

Leeks produced very fine, well-matured stems.

Potatoes were about the average, although in some instances the drought seemed to suit this crop exceptionally well. Witch Hill and Edzell Blue were two of the best early immune varieties grown. King George, as a second-early, yielded a fairly heavy crop. Great Scot

and Kerr's Pink in some gardens produced close on sixteen tons to the acre. Kerr's Pink is about the only variety which has shown any tendency to produce second growth.

Summing up one may safely say that the vegetable crops on the whole were very abundant in 1921, of excellent quality, but of short duration. It must be borne in mind, however, that the rains which came in August in the northern part of the country saved many garden crops which were on the verge of ruin, and helped them on wonderfully.

With regard to fruit, Pears suffered from frost and bitter winds when in bloom, and consequently a meagre crop of fruits set. The fruits, however, which did set on the whole developed well. In some cases trees which lost all their first crop of blossom, flowered a second time shortly afterwards; the fruits set well and in some instances were a heavy crop.

Apple trees were later coming into flower and these fruits set magnificently. Owing to the drought and the impossibility of spraying and watering the trees in June the fruits dropped all too freely. Notwithstanding this the crops on many trees had to be thinned, and on the whole the fruits developed well and were of good quality and colour. Generally speaking, neither Apples nor Pears kept as well as usual. One unusual experience was the splitting of the fruits of Warner's King and Bramley's Seedlings after they had been safely stored. This is a condition that has not previously been observed in this district, and one is apt to put it down to the effects of the drought.

Pears and Apple shoots have ripened most satisfactorily, and the trees are packed with well-developed fruit buds, which thus show encouraging prospects for next year.

Plum trees were badly caught by frost when in bloom, the crop being an absolute failure.

Raspberries, Blackberries and Loganberries all suffered from the frosts and cold winds early in the season, when the terminals, the young foliage and the flower buds were considerably damaged. The result was short crops of rather poor quality.

A few of the earliest blooms of Strawberries opened with blackened centres, but in spite of this the plants produced the heaviest crop that has been known in the district for many years past, and the fruit was really magnificent, being of excellent quality.

Black Currants produced a heavy crop of exceptional quality and of large-sized berries.

Red and White Currants did well and produced very satisfactory crops.

Gooseberries were a light crop, but this was not due to the drought as most of the bushes were damaged by late frosts. It was found that in the case of all fruit-bearing plants where the ground had been well mulched the ill effects of the drought were not noticeable.

On the whole herbaceous flowering plants flowered very abundantly during 1921, although in many instances they were over very early, but produced second crops of blooms.

Dahlias made a great show and produced an abundance of fine blooms until the frost destroyed them in November.

Roses suffered rather from frosts and winds in their first growth and blooming. The blooms were not very good and had no lasting power. On the contrary, the second crop was magnificent, and the plants bloomed on until the first days of November, and when cut lasted exceptionally well. Although the first growths of Sweet Peas were browned by the frost the plants did well, but the crop was produced on the secondary growths.

After such a small rainfall it was naturally expected that the leaves of most deciduous trees and shrubs would fall very early in the year. This proved quite a false expectation as the trees were clothed with luxuriant foliage later into the season than has been the case for a great number of years past. Beech, Ash, Oak, Thorn and Elm retained their leaves until the sharp frost which was experienced about the last week in November. Shrubs also made new growths late in the season, and in some instances—Rhododendrons for example—bloomed a second time. *W. W. Pettigrew, Manchester.*

### OXFORDSHIRE.

*Eryobotrya* has flowered in these gardens this year for the first time. The tree is growing on a wall facing south, but sheltered by shrubs and tall *Cupressus macrocarpa*. It has made good growth and fine foliage each year, but has never flowered until this year. The soil here is a stiff loam over very stiff clay.

*Iris stylosa* has also flowered much more freely than usual. The first blooms were fully three weeks in advance of other years. *Y. Gammon, Eynsham Hall Gardens, Witney, Oxon.*

(To be continued.)

## NOTES FROM IRELAND.

The rainfall registered at the Royal Botanic Gardens, Glasnevin, for the 11 months ending November 30, 1921, totalled 22.41 inches; the annual average rainfall for ten years at Glasnevin is 27.15 inches.

*Rhodostachys andina*, a conspicuously charming Bromeliad, recently flowered at Glasnevin, planted at the foot of a greenhouse wall; it is furnished with a soft rose-pink inflorescence. Near at hand was a little colony of *Polyanthus Narcissus*, sent to Sir Frederick Moore from Crete, in full flower; it is a pretty, refined plant in flower, and the earliest of its family.

The dying year was remarkable for a wealth of blossom on such winter-flowering subjects as *Chimonanthus fragrans*, *Lonicera fragrantissima*, and *Iris stylosa*, which yielded a rare crop of blossom, in both the white and typical colour, for some three months previously, while the ubiquitous winter Jasmine is cheery everywhere around Dublin, but rarely are its full possibilities revealed as seen in one garden in the Monkstown district, where an old plant is pruned annually after flowering, and fed liberally, resulting in a pendant shower of strong, arched sprays five feet, or more long, row one mass of golden glory.

At the 92nd annual general meeting of the Royal Horticultural Society of Ireland held at the offices, 5, Molesworth Street, Dublin, on December 16, visitors were much interested in a remarkable display of *Calanthe Veitchii*, shown in arched sprays four feet long with up to three dozen flowers on a spike. The exhibit further included some handsome *Cypripediums* in such kinds as *Sanderac*, *Lecanum giganteum*, *Lady Moore*, *violaceum* and *Portia*, and was from the gardens of B. H. Barton, Esq., D.L., Straffan House, Co. Kildare (gr. Mr. F. Streeter), to whom a First-Class Cultural Certificate was unanimously awarded.

At the previous Council meeting of the above Society, a First-Class Certificate was awarded to Messrs. Wm Cotter and Co., Corporation Fruit and Vegetable Markets, Dublin, for the new Irish seedling Potato named Mahon's Fingallian. This fine Potato was raised by Mr. Mahon, gardener to the Earl of Fingal, Killeen Castle, Dunsany, Co. Meath, and has been under control trial for several seasons; it is a very prolific main-crop, round, rough-skinned variety, with shallow eyes, and the haulm remained green, sturdy, and unaffected by late blight when that of Arran Chief and similar main-crop sorts had quite died down.

At the last monthly meeting of the Irish Gardeners' Association, at which a Potato competition was held amongst the members, Mr. Wm. Cotter handed in a cheque for £25, as prizes during the coming year for Mahon's Fingallian Potato and has further presented ten guineas to the R.H.S.I. for the same object.

The 24th annual meeting of the Drummond Benefit Association for land stewards and gardeners was held at 58, Dawson, Dublin, December 20, Mr. P. J. Reid, St. Anne's Gardens, Clontarf, presiding. The balance-sheet disclosed assets, chiefly invested in trust securities, on bank deposit, and cash on hand, £3,189 5s. 2d. Since the Association's inception the amount disbursed in assisting members and the widows and orphans of deceased members, exceeds three thousand pounds.

Here, as elsewhere, Apples are keeping badly and the Potato crop generally, which was plentiful and fairly good, is inclined to be troublesome under storage. *K., Dublin.*

**WOOLLY APHIS, OR AMERICAN BLIGHT.**

WOOLLY Aphis, or American Blight, is one of several species of aphides that feed on the sap of trees, and it does much damage to Apple trees.

Schizoneura lanigera, to give it its scientific name, can be readily detected along the stems of young, infested branches and about the bole of the tree, by its white, tufty, woolly masses.

Its size, when fully grown, is about 1/4 inch long and about 1-8 inch across, and as it multiplies in various forms during growth, having winged females producing live young, wingless females also viviparous, and males without wings that pair with egg-laying, wingless females, its numbers are rapidly augmented.

It is a dark purplish-brown colour, oval in shape, with very small eyes, legs and antennae very short, a body covered with a cottony coat most markedly developed towards the tail. The legs, when contracted under the body, are quite hidden, allowing dense masses of the pests to lie close together.

As the aphides are wholly suctorial in their habits, depending upon the sap for their nourishment, they are provided with a rostrum or haustellum, which is grooved on one side along the entire length, and in this groove lie the three setae, or piercers, used in puncturing the bark. The rostrum is divided into three separate members, or joints, the first, arising from the lower portion of the head, being much the longest; the second is more dilated and

fine hooked hairs, and others can be seen near the tip, employed probably for tentative purposes. The setae (Fig. 17) are very fine and very elastic, and will return to their former position when bent in a medium such as glycerine or Canada Balsam; they possess no barbs or other serrations, are finely furrowed along their length and possess a central canal.

While members of some genera of aphides

and the blue tit is especially useful in ridding infested trees of the pests. *J. W. Plaskitt, Rickmansworth.*

**JERUSALEM ARTICHOKE.**

It may be of interest to describe the excellent collection of Jerusalem Artichokes exhibited by Messrs. Vilmorin, Andrieux et Cie. at the last meeting of the French National Horticultural Society, comprising no fewer than 26 different varieties. Some were old, others—some named and some unnamed—had been raised at Verrières.

Among the older varieties were the common Artichoke, widely known for a long time, with large, red irregularly shaped tubers; the Egyptian variety, received from that country in 1895, and probably a seedling from the common kind, which it much resembles, except that the tubers are smaller and more irregular in outline; the Improved White variety, received from England in 1892, with very white and "warted" tubers, producing a large yield; the Pink, with piriform tubers, regularly shaped, and of a coppery-pink colour.

The varieties raised as seedlings by Messrs. Vilmorin included the Long Red variety, introduced more than half a century ago, with long, fairly large tubers, very deeply coloured, almost violet; the Patate, a well-known variety, raised in 1839, with long yellow tubers, but little "warted"; the Piriform variety, raised in 1903,

FIG. 16.--WOOLLY APHIS, FROM THE UNDERSIDE; SHOWING THE ROSTRUM.

are furnished with exceedingly short rostra, others have this organ produced to an extraordinary length. Normally, the rostrum of the Woolly Aphis is short, reaching to about the second pair of legs (Fig. 16), but when first born it appears disproportionately long and stout, protruding far beyond the tail. It soon ceases to grow, however, whilst the rest of the body rapidly develops.

Living in dense companies and, by the incessant probing and pricking of the bark by their setae, setting up warty and spongy swellings caused by the increased flow of sap to the wounds, it follows that the small twigs attacked produce stunted leaves and fruit, and often die. Closely packed as they are with heads towards the bark and woolly tails or backs uppermost, the Woolly Aphis is capable of withstanding great cold, and an instance is recorded where some of the insects were taken alive in the month of December while the thermometer registered 20 deg. F., and snow was on the ground. Moisture, too, does not readily penetrate between the waxy threads, and provided as the pests are with plenty of fat globules throughout their body, they are practically weatherproof.

The woolly fibres are given off from a series of four longitudinally arranged pores down the back, and form a means of protection and concealment.

Various kinds of applications have been used and suggested for the eradication of these insects, such as tars, fish-oils, ammoniacal gas liquors, tobacco water, lime and soot, soap-washes, and others, but whichever is used a thorough and careful hand-brushing is necessary, as mere spraying is insufficient. A strong solution of soft soap, with paraffin added, is very good, used as suggested, so long as no crevice is left untouched. It should be remembered also that these woolly aphides come up from the roots, so the soil should be disinfected. The little ladybird insects (Coccinellidae) will devour American Blight,

FIG. 17.--ROSTRUM OF WOOLLY APHIS WITH THE THREE SETAE EXTENDED.

with purplish-red tubers of long shape—larger and more shapely than the common kind, but less prolific in yield; the Spindle, raised at Verrières in 1913, a very interesting production, with pinkish-yellow, fusiform tubers, very shapely and smooth. This variety has been sold lately, especially in England, under the name of "Topinckel," and stated to be a hybrid,

FIG. 15.--ROSTRUM OF WOOLLY APHIS; SHOWING THE OPEN CANAL ALONG THE ENTIRE LENGTH OF SHEATH.

formerly was thought to be perforated and not channelled like the others, but, as may be seen from the illustration (Fig. 15), also is grooved; the third or tip portion is obtusely pointed, can sweep round in a circular manner, and has a stout ring at the point through which the piercers may be seen occasionally to protrude. The edges of the channel are armed with

viz., a cross between *Helianthus tuberosus* and *H. doricoides* or *H. decapetalus*.

Besides those already described, seventeen recent varieties were shown, which have not yet been named. Most of them produce tubers with a yellow skin, more or less dark, oval or long-shaped; several appeared decidedly interesting.

The percentage of sugar in the tubers according to analyses taken in 1920 (*i.e.*, the quantities of reducible sugar obtained after hydrolysis) varied between 14.5 per cent. for the common Artichoke with red tubers, 16.6 per cent. for the white variety, and 21.2 per cent. for the Spindle. Among the unnamed varieties, several contained 18 per cent. and 19 per cent. of sugar; the tubers were large, rounded and regular in shape.

It is now more than a century since Messrs. Vilmorin turned their attention to the improvement of the Artichoke. At the meeting of April 13, 1809, of the Société d'Agriculture du Département de la Seine, Philippe-André de Vilmorin gave a report of the results he had obtained in his experiments in raising these plants from seed\*. He believed he had found "a means of regenerating the race, if that were necessary, and perhaps of obtaining interesting varieties, as had been found possible in the case of the Potato." Already he had obtained forms with tubers variously coloured red, yellow or whitish.

On April 20, 1831, Louis de Vilmorin, his son, presented to the same society a paper on the number of sowings he had made the previous year, which had resulted in plants exhibiting numerous variations in the size, number and positions in the ground of the tubers produced. He had come to the conclusion that the Artichoke was an exceedingly variable plant when multiplied from seed, and therefore capable of improvement. This opinion was confirmed shortly afterwards by a letter† which he sent to Tessier, the editor of the *Annales de l'Agriculture Française*, in which he remarked, however, that there would always, or at any rate for a long time, be a difficulty in the way of raisers who wished to make numerous and repeated sowings—viz., that the plant does not seed, or scarcely at all, in the north, and very little in the centre, of France. In this letter Louis de Vilmorin also stated, in reference to the colouring of the tubers: "The colour is also very variable, about a third of the plants raised from seed having produced yellow or yellowish-white tubers, instead of red, as in the cultivated species."

At the meeting held on March 4, 1857, of the Imperial and Central Agricultural Society, Louis de Vilmorin presented a collection of 28 varieties of Artichokes, in which No. 1 represented the old kind, and the 27 others the results of sowings made by his father and himself.

Henry de Vilmorin (1843-1899) went on with the experiments. He procured some seeds from Corsica, with the assistance of Dr. Joseph Michon, and made a number of sowings. Towards 1890 he reported several times to the various societies on the subject of his work. From the point of view of appearance and colour the tubers showed great variation; about a third were yellow, the rest varying from pink to purplish red.

In 1895 the variety Patate was placed on the market. It had yellow tubers, of a long shape which made it easy to pull them out of the ground.

Philippe de Vilmorin continued the experiments of his predecessors on a very large scale, and obtained several varieties of merit, notably the Spindle, which has been already mentioned. It may easily be seen that the development of the Jerusalem Artichoke, introduced into Europe from North America about 1607 (according to the opinion of M. C. C. Lacaïta—see his interesting article in *Kew Bulletin*, 1919) has been very slow. It may, however, be hoped

that if its cultivation is undertaken in earnest in the countries where the plant attains normal development, if the seed is sown on a large scale, and judicious selection is made among the resulting plants, progress may become very rapid. The Artichoke is important from an industrial point of view as being a source of alcohol, and if the abundant yield of the white variety could be combined with the regularity of shape found in the Patate variety, and the richness in sugar of the Spindle, it might be said that genuine progress had been made. A. M.

## HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

**Funkias for Shady Positions.**—Funkias are very accommodating plants, as instanced by Mr. Coult's in his interesting article in your issue of January 7th (p. 3). In addition to the positions mentioned, it may not be generally known what excellent plants Funkias are for shady and partially shady places. Even under trees, in good soil, they thrive well. I have seen them used for covering the ground under Pines, where the stems were bare; also under Oaks. Considering what handsome plants they are, and the many and varied positions they are able to fill so well, it is surprising they are not more largely grown. *Arthur J. Cobb, University College, Reading.*

**Lilium testaceum.**—I am glad that the difference of opinion regarding the depth at which to plant this beautiful Lily has been the means of inducing Sir Herbert Maxwell to write such an interesting note as that which appeared on page 3. My own experience has been in favour of deep planting; but it is only fair to say that Mr. A. Grove, one of our best authorities on the culture of Lilies, recommends that *L. testaceum* should be planted at the same depth as *L. candidum*, for which he advises one of 4 inches. I can only state that in most cases in which I have observed this Lily doing exceptionally well, it was at a greater depth than 4 inches—at least 6 or more. Of course, much depends on the nature of the soil and the exposure of the position, and I am not disposed to be dogmatic on the point. *S. Arnott.*

**Wilt in Melons.**—Your correspondent "Anxious" recommends the use of sulphate of copper for the above disease, and not only advises sprinkling it on the base of the stem, but also syringing the foliage with a solution of the salt. Surely there is some mistake in this; a solution of copper sulphate would burn up every piece of foliage, as it is a strong corrosive, and, as is well known, is used for this purpose to destroy Charlock, and algae in ponds, though, certainly, at a greater strength than is recommended by your correspondent. Can it be that a Bordeaux mixture or Burgundy mixture in powder form is meant, as these are very often referred to as sulphate of copper? I think this matter should be made clear, as I have seen disastrous results to foliage from the use of copper sulphate dissolved in water without the addition of a base to neutralise the acid present in the salt. *C. G.*

**Damage to Fruit Trees in Pots by Voles.**—During the recent cold weather, early in the present month, I had occasion to examine the protecting material around and over our orchard house trees, which were standing in the open on a bed of coal ashes. I was astonished to find many of the trees completely ringed by voles. The Cherry trees had suffered most, for every tree had been eaten for several inches in a complete circle from the pot upwards. The Pears and Apples had also suffered, but not to the extent of the Cherries. It was singular that the Plum trees were not touched. The trees in question were standing in a fully open position in front of the fruit range, which position they have occupied during their resting period for several seasons, and no damage had been done by voles before. I have never known pot trees to be attacked by voles previously; although I have seen trees in grass orchards and shrubs, notably Laurels, badly eaten during severe

weather. The damage to our pot trees was all done in a few days, when bitter, cold winds were prevalent in this district. This may possibly account for the voles being driven into the protecting material, hence the damage. Those having pot trees covered with protecting material, either litter and leaves, still in the open, will be well advised to examine their trees frequently, and so possibly avoid damage being done by these destructive pests. *J. Hawkes, Cliveden Gardens, Shenfield, Essex.*

**Sowing Lawn Grass Seed.**—The hot and dry season experienced during 1921 was disastrous to lawns in many parts of the country, and the small amount of rain that has fallen since has failed to bring them into good condition. It will therefore be desirable, especially in the absence of good turf, to sow the lawn areas with grass seed. There is no better time for this work than the latter half of March or the early part of April, as the showery weather usually experienced then is favourable to rapid germination. The ground should first be thoroughly prepared as for turfing, made solid by treading, and worked to a perfect level by means of a finely toothed rake. Quantities and kinds of grass seeds found suitable per acre for producing a fine sward on most soils are as follows:—*Lolium perenne tenue*, 20 lb.; *Cynosurus cristatus*, 5 lb.; *Festuca duriuscula*, 3 lb.; *F. ovina tenuifolia*, 2 lb.; *Poa nemoralis*, 2 lb.; *P. semper-virens*, 2 lb.; *P. trivialis*, 2 lb.; *Triticum flavescens*, 1 lb.; *Trifolium repens*, 6 lb.; and *T. minus*, 2 lb. *Thos. Glover, Benfleet Hall.*

**Grape Gros Colman at Nymans, Handcross.**—Mr. James Comber, gardener to Colonel Messel, O.B.E., has grown some remarkably fine bunches of this well known and often despised Grape. The berries were as large as Czar Plums and beautifully finished, when I saw them hanging on the vines on January 2. When grown to perfection, it is certainly the best late black Grape. The skin is thin, the flesh melting, and the flavour delicious. The viney is a lean-facing due south, rather higher than generally seen. I gathered from conversation with Mr. Comber that this variety needs generous treatment, free circulation of air, and gentle warmth from the heating apparatus. I noticed the branches were further away from the glass than usual, and no shading had been given. *R. H. Holton, Crawley.*

**Winter Flowering Begonias at Steep Park, Jarvis Brook, Crowborough.**—Mr. C. Milner, gardener to W. B. Woodrow, Esq., is an enthusiastic and successful cultivator of the increasingly popular winter flowering Begonias, and he has a brilliant display of them at Steep Park. *B. Gloire de Lorraine* var. Mrs. Rothschild, and the variety Turnford Hall are both grown in quantity. The large conservatory is practically filled with glorious plants in about 7-in. pots averaging 2½ feet to 3 feet in diameter, and 2½ feet high. The colour of the pink variety is extremely rich, and each plant is a specimen with clean, healthy foliage and fine long sprays of bloom. I noticed suspended from the roof three grand baskets of the pink variety, each 3½ feet in diameter and a perfect mass of bloom, associated with *Cobaea scandens variegata* growing luxuriantly from the pillars and rafters of the house, and forming a charmingly effective combination. Mr. Woodrow is evidently a plant lover, and has given every encouragement to his gardener. I understood from Mr. Milner he found April the best time to propagate these Begonias, the cuttings being then in the right condition to produce healthy and vigorous plants. About equal parts leaf-mould and loam, with a good addition of coarse sand are used for the cuttings; and one part leaf-mould and three parts loam, with sand, is the compost used for potting on. For the final potting one part leaf-mould, three parts fibrous loam, with most of the fine soil removed, and sand forms the compost. Mr. Milner does not mix organic manure in the compost, preferring to top dress the roots with decomposed cow manure and fibrous loam. Careful watering is practised at all times and the plants are never allowed to become dry. It was on January 7th I saw the Begonias at Steep Park, and the display was well worth the journey to Crowborough. *R. H. Holton.*

## SOCIETIES.

### ROYAL HORTICULTURAL.

JANUARY 17.—The first meeting of the year was held on this date and there was a fairly good attendance. The exhibits were good but not so numerous as usual, although they combined to make up an interesting display, consisting chiefly of capital groups of vegetables, fruits, Carnations, and early hardy flowers. The Orchid Committee granted four Awards of Merit and the Floral Committee one only.

#### Orchid Committee.

*Present:* Sir Jeremiah Colman, Bart. (in the chair), Messrs. Jas. O'Brien (hon. secretary), Arthur Dye, Gurney Wilson, C. J. Lucas, Fred. K. Sanders, R. Brooman White, Frederick J. Hanbury, C. H. Curtis, W. J. Kaye, Pantia Ralli, A. McBean, H. T. Pitt, J. E. Shill and S. W. Flory.

#### AWARDS.

##### AWARD OF MERIT.

*Brasso-Cattleya Rutherfordii* The Dell variety (B.-C. Digbyano-Mossiae Queen Alexandra × C. Gaskelliana alba), from BARON BRUNO SCHRÖDER (gr. Mr. Shill), The Dell Park, Englefield Green. A superb white *Brasso-Cattleya*, of model form, the petals and lip being effectively crimped and fringed. The only colour is the pale lemon yellow tinge on the disc of the lip.

*Cypripedium Nellie Pitt* (*Idina* × *Pyramus* var. *Black Prince*), from H. T. PITT, Esq., Rosslyn, Stamford Hill (gr. Mr. Thurgood). Dorsal sepal broad and flatly expanded, pure white, with large claret-red blotches ascending from the yellowish base. Petals very broad, honey-yellow with dark blotches; lip tinged with purple.

*Lycaste Lucianii* (*Skinneri* × *lasioglossa*), from W. R. FASEY, Esq., Holly Bush Hill, Snaresbrook (gr. Mr. E. J. Seymour). This Orchid was imported as a natural hybrid some years ago, and has been shown on several occasions since. The plant now shown had fifteen flowers and buds. Sepals light mauve, petals white, the hairy lip having rose spotting on white ground.

*Odontioda Thalia* (*Schröderiana* × *Lambeaiana*), from Messrs. CHARLESWORTH AND Co., Haywards Heath. The plant bore four large and finely formed flowers of ruby-purple colour with a gold shade. Lip rosy-mauve with dark blotch in front of the yellow crest.

#### PRELIMINARY COMMENDATION.

To *Odontoglossum crispum Veeroy*, a grand home-raised seedling of model shape with pure white flowers, from Messrs. CHARLESWORTH AND Co., Haywards Heath.

#### CULTURAL COMMENDATION.

To Messrs. SANDERS, St. Albans, for a very fine plant of the pure white *Vanda Watsonii* with many flowers.

#### GROUPS.

Messrs. SANDERS, St. Albans, were awarded a Silver Flora Medal for a very effective group—tastefully arranged on a base of green Moss, and including fine *Odontoglossums*, *Odontiodas* and *Cypripediums*, with a very interesting selection of species, including the rare *Coelia bella*, with white flowers tipped with violet; *Epidendrum polybulbon* luteo-album, and various *Lycastes*, both species and hybrids. Novelties in the group were *Odontioda Jupiter* (O. Magali Sander × Oda. Joan), with a branched spike of nineteen flowers of large size and bright chestnut-red colour, the lip being bluish white in front; and *Odontoglossum Mosaic* (*formosum* × *ardentissimum*), with large white flowers evenly blotched with rose-purple.

Messrs. STUART LOW AND Co., Jarvisbrook, Sussex, were awarded a Silver Flora Medal for a pretty group in which the varieties of *Laelia anceps*, both white and coloured, were well represented, the coloured forms containing a good specimen of the rare var. *Roeblingianum*, with petals marked like the lip. Good scarlet *Sophranitis* crosses, including the new S.-L.-C. Nestor with salmon-red flowers, were also shown with *Odontoglossum cordatum* Low's variety. O.

*Uro-Skinneri splendens* and var. *album*, and various other species of *Odontoglossums*.

Messrs. FLORY AND BLACK, Slough, were awarded a Silver Banksian Medal for a small group of specially good hybrids raised at Langley, and including the new *Sophranitis* *Phyllis* (C. Tityus × S. grandiflora), with good red flowers. Messrs. J. AND A. McBEAN, Cooksbridge, showed a set of their superb *Odontoglossums*.

#### OTHER EXHIBITS.

Mrs. FARRER, Ingleborough, sent *Cypripedium Virginia* Farrer's variety (*Fairricanum* × *aureum* Oedippe), raised by the late Reginald Farrer, whose death under lamentable circumstances we recorded last year. The plant bore three very pretty flowers, with white dorsal sepal tinged with mauve, and bearing fine dark-feathered lines. R. GERRISH, Esq., Milford Manor, Salisbury, showed *Odontoglossum Gorizia* (*Jasper* × *President Poincaré*), with fine flowers of an unusually clear violet tint. PANTIA RALLI, Esq., Ashtead Park, Surrey (Orchid grower, Mr. Farnes), sent *Odontoglossum Violetta* (*Armstrongiae* × *Doris*), a perfect flower with rich violet-purple blotching. W. R. FASEY, Esq., sent probably the finest form of the large pure white *Lycaste Skinneri alba magnifica* yet shown. Messrs. SANDERS showed *Odontoglossum Cræsus* (*harvengtense* × *Fascination*), a distinct yellow-ground hybrid with dark purple blotches.

#### Floral Committee.

*Present:* Messrs. H. B. May (in the chair), W. J. Bean, W. B. Cranfield, James Hudson, John Green, G. Reuthe, John Heal, Donald Allan, F. McLeod, J. Jennings, C. R. Fielder, T. Stevenson, W. B. Gingell, Charles Dixon, H. J. Jones, R. W. Wallace, Chas. E. Pearson, E. F. Hazelton, W. P. Thomson, Clarence Elliott, W. R. Dykes, and R. C. Notcutt.

#### AWARD OF MERIT.

*Erica carnea King George V.*—This is one of the varieties of *Erica carnea* collected in Switzerland some years ago by Mr. Potter for Messrs. Backhouse, of York. It differs from the species in having a more compact habit and in flowering much earlier. We were informed that the floriferous little bush on view had been in bloom continuously since last September. Shown by Messrs. R. WALLACE AND Co.

#### GROUPS.

Carnations were represented by really good blooms. Lord LAMBOURNE, C.V.O. (gr. Mr. H. Cunningham), Bishop's Hall, Romford, contributed a tastefully arranged collection of such sorts as *Carola Snowstorm*, *Wivelsfield White*, *Edward Allwood* and *Mrs. C. F. Raphael* (Silver Flora Medal). A collection from Messrs. ALLWOOD BROS. was noteworthy for the bright colours and general freshness of the blooms. The most prominent varieties were *Edward Allwood*, *Mary Allwood*, *Wivelsfield Pink*, *Wivelsfield Claret*, *Laddie*, and *Benora* (Silver Flora Medal).

Many varieties of Carnations were displayed by Mr. C. ENGELMANN, who had particularly good blooms of *Topsy*, *Laddie*, *Benora*, *Cupid*, *Saffron and Triumph* (Silver Flora Medal). Associated with a praise-worthy collection of Carnations Messrs. STUART LOW AND Co. displayed a batch of freely flowered plants of the fragrant *Daphne indica rubra*, and also of well flowered *Azalea indica* varieties and *Acacia platyptera*. Amongst the Carnations a vase of *Laddie* was prominent (Silver Flora Medal).

Plants of *Azalea indica* in variety were shown by Messrs. L. R. RUSSELL, LTD., amongst which were displayed such uncommon *Bronchiads* as *Tillandsia Zahni*, *T. Lindenii* and *Vriesia splendens major* (Silver Grenfell Medal).

*Chrysanthemums* of unusually good quality for so late in the season were shown by Mr. S. ARSI. The chief varieties were *Winter Cheer*, *Nagoya* and *The Favourite* (Silver Banksian Medal). An exceptionally artistic arrangement of *Iris tingitana* was made by Messrs. CARTER AND Co., and the many flowers were of much more than average merit (Silver Banksian Medal).

A selection of *Erica carnea* varieties, with the type of *E. præcox*, were shown by Messrs.

R. WALLACE AND Co., who also displayed *Hamamelis mollis* and *H. japonica rubra* (Silver Grenfell Medal). A capital rock garden was made by Messrs. WM. CUTBUSH AND SON, who planted it with various dwarf shrubs and such alpinas as *Sedums*, *Saxifrages*, *Sempervivums* and *Arenaria balearica* (Silver Banksian Medal). A small model rock garden and sunken garden was exhibited by Mr. C. DIXON (Bronze Flora Medal).

Messrs. SKELTON AND KIRBY made a small rock garden in which *Ericas* and *Nandina domestica* predominated (Bronze Banksian Medal). An interesting collection of sprays of Conifers was shown by Mr. G. REITHE, who also had Christmas Roses and *Iris histrioides* (Bronze Flora Medal), while Mrs. HOPKINS showed miniature succulents and a few alpinas.

#### Fruit and Vegetable Committee.

*Present:* Messrs. C. A. Nix (in the chair), Wm. Poupart, Owen Thomas, E. A. Bunyard, F. Jordan, Wm. Pope, E. A. Merryweather, E. Beckett, T. Pateman, James Kelly, W. Bates, A. Bullock, S. B. Dicks, W. H. Divers, G. P. Berry, A. W. Metcalfe, G. Reynolds, and J. G. Weston.

#### GROUPS.

A particularly noteworthy collection of Apples was contributed by Messrs. G. BUNYARD AND Co. There were no fewer than 75 varieties, and each was represented by a goodly dish of firm and shapely fruits. High colour predominated, and in this respect the collection was even better than at the Autumn Fruit Show. The following varieties were perhaps the most prominent—*Wealthy*, *Newton Wonder*, *Wm. Crump*, *Forster's Seedling*, *Rongemont*, *Scarlet Hollandbury*, *Baumann's Red Winter Reinette* and *Mother* (Gold Medal).

An excellent exhibit of Apples and Pears was made by Sir CHARLES NALL-CAIN (gr. Mr. T. Pateman), The Node, Welwyn. The dessert varieties of Apple were excellent in their medium size, good form and typical colouring. These included *Cox's Orange Pippin*, *Cox's Pomona*, *Rival*, *Paroquet*, *Adam's Pearmain* and *Claygate Pearmain*. The culinary sorts were also admirable, and of these *Lane's Prince Albert*, *Newton Wonder*, *Lord Derby* and *Royal Jubilee* were fine examples (Silver-Gilt Knightian Medal).

The only collection of vegetables was from Messrs. SUTTON AND SONS, who staged splendid Leeks in such varieties as *The Lyon*, *Sutton's A.I.*, *Improved Musselburgh* and *Royal Favourite*. *Sutton's A1 Kale* and *Couve Tronchuda* were also particularly good. *Forced Dandelion* and *Chicory*, *Potatoes* and *Onions* were also well shown (Silver Knightian Medal).

#### NATIONAL ROSE.

JANUARY 17.—There was a larger attendance than usual at the Annual General Meeting of this Society, which was held at Caxton Hall, Westminster, under the presidency of Mr. E. J. Holland.

In moving the adoption of the Report for the year, the President remarked that from the many appreciative letters that had been received, it was evident the publications of the Society met with the approval of the general body of members. When discussing the financial state of the Society, Mr. Holland remarked that for a long time it had been the custom of the Society to pay all debts during the year in which they were incurred, but this year it had not been found possible to continue this desirable custom. It would be seen from the Statement of Accounts that while there was a balance in hand of just over £14, there was an unpaid account of £1,058 18s. 6d. due to the printers. This sum was incurred for the issue of the various publications, and a great proportion was for the *Enemies of the Rose* and the *Selected List of Roses*, which would be issued to new members during the present year, and it was confidently anticipated that the deficit would be cleared off before the end of the year.

There had been a record increase in membership during the past year, when no fewer than 1,604 new members joined the Society.

Feeling reference was made by the President to the great loss that had been sustained by the deaths of Mr. George Paul and Mr. John Hart. Mr. Paul was one of the oldest members and was closely associated with the work of the Society almost to the day of his death. Mr. John Hart, who was well known as a successful amateur Rosarian, was also an active and valuable member of the council.

The proposal was seconded by Mr. H. R. Darlington, who also paid a tribute to the memories of Mr. George Paul and Mr. John Hart. There was no discussion, and the report was unanimously adopted.

The Dean Hole Memorial Medal for the past year was awarded to Mr. Samuel McGredy, who was unfortunately unable to come across from Ireland to receive it personally. In making the announcement, Mr. Holland referred to Mr. McGredy's well-known genial disposition and enthusiastic love of Roses. He was a particularly successful raiser of new varieties of merit, of which he had raised a record number and had been awarded fifty Gold Medals of the National Rose Society.

In formally presenting the financial statement the Hon. Treasurer, Mr. Preston-Hillary, reminded the meeting that it had already received an admirably lucid explanation of the reasons for the adverse financial position, and in view of the general increase in costs of all descriptions this was unavoidable. He pointed out that on the receipt side the income from subscriptions was £500 more than ever before, and the income from advertisements and sales of publications had also increased.

An enthusiastic vote of thanks was accorded to Mr. Courtney Page, the Hon. Secretary, in appreciation of his great work for the Society, and in reply he referred to the extraordinary efforts made by members in proposing new members. The trade had assisted greatly in this direction, and Mr. H. R. Botwright, an amateur, had proposed over seventy members. Of the 7,386 members of the Society there were, Mr. Page stated, only 31 whose subscriptions were unpaid, and he felt sure that this small number would soon be further reduced. In giving interesting particulars of the office work done during the past year he said that 1,500 technical questions were answered.

On the close of the meeting the members attending adjourned for tea, which was followed by an exhibition of the latest lantern slides acquired by the Society.

#### UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

The monthly meeting of this society was held in the R.H.S. Hall on Monday, January 9, Mr. Arthur Bedford in the chair. Seven new members were elected, and four members were allowed to withdraw double the amount of the interest on their deposit account, amounting to £13 17s. One member withdrew the sum of £10 from his deposit. The sum of £5 8s. 5d. was passed for payment to one lapsed member, and £55 14s. 4d. was passed for payment to the nominee of one deceased member.

The sick pay for the month on the ordinary side amounted to £89 15s. 3d., and on the State side to £33 11s., while maternity benefits came to £6. Three members were assisted in regard to the cost of dental treatment, and one in regard to optical treatment, from the extra benefits provided by the State section. The sum of £800 was invested in Funding Loan by the State section, and the trustees were instructed to invest £1,000 on the private side.

#### Obituary.

R. Murrell.—We are informed that Mr. R. Murrell, Rose Acre, Shepperton, died somewhat suddenly a few days ago from a severe attack of influenza. He was an expert Rosarian and cultivated a large collection of Roses. Only two years ago he added several acres to his nursery at Halliford, and in this addition he took a very keen interest during the past season. His death, in the prime of life, is a great loss to the world of floriculture.

William Carter.—We regret to announce the death, on December 18 last, of Mr. William Carter, at the age of 76 years. The deceased entered the employ of Messrs. Nutting and Sons, Ltd., 106, Southwark Street, London, in 1874, and he represented this firm for many years on Romford and other markets, where he made many friends amongst market growers. Owing to failing health, Mr. Carter was compelled to retire a few months ago after 47 years of loyal service with the same firm.

#### INQUIRY.

CAN any reader give me the names of Begonias that produce tubers or "bulbils" at the tips of their growth, or in the axils of their leaves, and, if so, whether such tubers are formed before or after the plants have flowered? *Coombe.*

#### TRADE NOTE.

TRADERS are no doubt acquainted with the scheme which the Government have initiated, whereby traders and others can obtain facilities from their bankers to enable them to finance their export trade. Briefly, the Government are prepared, under certain conditions, to guarantee drafts against shipments of goods exported from this country, and the scheme has quite recently been extended, now covering general credits and credits in respect of specific transactions. Explanatory leaflets can be obtained from the Department of Overseas Trade, 35, Old Queen Street, S.W.1.

Horticultural traders having an export business, which at the time may be of diminishing value on account of the existing depreciated exchanges, could with advantage apply for Government guarantees under this scheme, but in this case difficulties might be experienced by reason of horticultural commodities, such as fruit and forest trees, plants, insecticides, fertilisers, etc., not being listed with the Department. Therefore, any horticultural trader wishing to avail himself of the facilities offered by the Government, and, after acquainting himself with the conditions of these credits, is invited to communicate with the Secretary of the Chamber, 18, Bedford Square, W.C.1, as the Chamber has received official notification that special commodities can be listed with the Export Credits Department.

#### ANSWERS TO CORRESPONDENTS.

BOOKS: A. S. R. *Cactus Culture*, by W. Watson, price 2s. 3d., and *Orchids for Everyone*, by C. H. Curtis, price 27s. free by post, would be suitable for your purpose, and can be obtained from our Publishing Department.

BOOK ON FRUITS: *Eastnor. Fruit and its Cultivation*, by T. W. Sanders, obtainable from our Publishing Department, price 8s. 3d. post free, would be suitable for your purpose.

GREENHOUSE ERICAS: F. M. K. The type of Ericas used for pot cultivation may be propagated by means of cuttings inserted during the spring, selecting small, twiggy shoots, about 1½ to 2 inches in length, and young growth that is just sufficiently firm to prevent damping. August is also a suitable month for propagating these plants, but on the whole spring is the best time, as the rooted cuttings may be potted, and become nicely established in thumb pots before the winter. The receptacles in which the cuttings are rooted should be clean—48-sized pots are very suitable, and should be filled with crocks to at least half their depth, the crocks being covered with coarse peat to keep the drainage clear. Fill the pots with fine sandy peat, which should be rammed very firmly, finishing with clean silver sand on the surface. The cuttings should be

carefully dibbled into the soil. The specimen you enclose is *Erica hymenalis*.

MOSSY LAWNS: *Mere Grass*. The use of lime on lawns is good practice, as the grasses, in common with so many other plants, require lime for their well being, and its application will also assist in checking the spread of the moss. For this purpose it may be applied as freshly slacked lime at the rate of 5 lb. per square yard as soon as this may be conveniently done. As suggested, a short-handled domestic fire shovel would be useful in spreading the lime evenly. If the lawn is in otherwise good order it would not be necessary to rake it over before applying the lime; but the dead moss should be raked out later on. The dressing of lime may well be followed by soot during the early spring; this will give a very dark green colour to the grasses. Superphosphate is an excellent moss destroyer, and, at the same time, is a good fertiliser. This may be applied towards the end of February at the rate of 4 lb. per square rod, or an even stronger application made without fear of injury to the grasses.

NAMES OF PLANTS: W. S. Wickham. *Viburnum rhytidophyllum*.—A. M. D. *Cryptomeria japonica*; an old introduction to English gardens, and not at all rare.

PRUNING NEWLY PLANTED PEACHES AND NECTARINES: G. C. When pruning newly planted Peaches and Nectarines great care is necessary in keeping the basal and lower branches well furnished with fruit-bearing shoots. We recommend in your case that each young shoot be cut back two-thirds its length, and the weaker shoots half their length, and any unnecessary shoots removed altogether. This will cause growths from buds near the stem and an ample supply of shoots at the base of the tree for future years. In disbudding a basal shoot must be preserved, so also must the terminal shoot on the same branch, and any necessary shoots in between required for shaping the tree must be kept on the upper side of the branch. The same remarks apply to the Cherry, but much depends on the size of the tree. As a rule, the growth a young Cherry tree makes the first year is small, and shoots must be corrected in the same way as for the Peach; later prunings will be confined to the extreme ends of the branches, and in cutting back the current year's shoots to a couple of buds to form fruit spurs. The treatment for Apricots the first year is similar to that recommended for Peaches; later, the trees will be composed of main branches, and the small shoots which issue from the latter must be shortened back to three buds to form fruit-bearing spurs along the whole of these main branches.

RHODODENDRON HYBRID: J. C. W. You will probably be able to obtain the hybrid mentioned from Messrs. R. Veitch and Sons, Exeter.

TO SKELETONISE LEAVES: P. Put 6 oz. of washing soda into two quarts of boiling water. Slack 3 oz. of quicklime, and add to the soda solution. Boil the whole for 15 minutes, let it settle, and then pour off the clear fluid. Put this on the fire and boil; while it is boiling put in the leaves and boil them for one hour or so. Take out a leaf, and if the epidermis comes away easily when rubbed between the finger and thumb (under clean water), the leaves are ready. After the epidermis is removed, put the skeletons into a solution of a wineglassful of chloride of lime to a quart of water, in order to bleach them; some will be finished in about 10 minutes others in about an hour; when white, throw them into pure water to clean out the bleach, and float out on to slips of paper. The best leaves to commence with are Holly, Poplar, Ivy and Laurel, and they should have no signs of decay in them.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 39.6.

### ACTUAL TEMPERATURE:—

Gardeners' Chronicle Office, 5, Tavistock street, Covent Garden, London, Wednesday, January 25, 10 a.m.: Bar. 29.6; temp. 40°. Weather—Dull.

### The Origin of the Potato.

Students of horticultural history will find much of interest in Professor Hindrick's sumptuous volume of *Sturtevant's Notes on Edible Plants*, a review of which appeared in our issue of January 14, and they will be grateful to the Editor for having accomplished an onerous and important task with such skill and thoroughness. Although much has been written on the origin of the Potato, there are few contributions to this much-debated subject which provide so many facts as are contained in Sturtevant's notes. The difficulties of elucidating the origin of anything are illustrated strikingly by the case of the Potato. Men are late in realising that any new thing they do may have historical interest, and hence, when interest is quickened and later generations cast about to discover the origin of this or that, the records, if they ever existed at all, are found to be too meagre for certainty. Humboldt's observations recorded by Sturtevant (p. 545 *op. cit.*) that the Potato was in cultivation at the time of the discovery of America, in all the temperate regions of Chili to New Grenada seems to be borne out amply by subsequent researches. Thus in the vocabulary of a now extinct S. American tribe (the Chibcha) the names of ten distinct varieties of Potato are to be identified. The earlier records, such as those of Peter Martyr which refer to the time of Columbus, are rendered doubtful by the references they make to "betatas" which may refer not to Solanum tuberosum, but to the Sweet Potato. The "papas" referred to by Peter Cieca as being used by the inhabitants of Peru would seem without doubt to be true Potatos, and date from about the same time as another record by Cieza de Leon from the region of the Collao to the effect that the inhabitants'

principal food are "Potatos" which when dried are called chunus—it is to be observed that chunus or frozen Potatos are still the ordinary food in the Collao. That the diseases of Potatos are no new infliction is apparent from the observation of Garcilasso de la Vega that the "papas" of the Collao, round and moist, are inclined to rot soon. Hawkins appears, according to Sturtevant, to have been the first Englishman to interest himself in Potatos, and in 1564, speaking of the tubers growing in Margarita Island off the coast of Venezuela, says that "they are the most delicate rootes that may be eaten and doe far exceede parsnips or carets." Sturtevant suggests that Hawkins carried the Potato to N. America in 1565 when he relieved the famine among the French on the banks of the river May, Florida, in 1584. Hawkins' appreciation is all the more curious in that for a long time after its introduction the Potato was held in but light esteem in Europe. Already, in 1597, Gerarde had the Potato growing in his garden. Mortimer, whom Sturtevant quotes, wrote in his *Gardeners' Kalendar* for 1708 that the root is very near the nature of the Jerusalem Artichoke, although not so good and wholesome, but it may prove good to swine. The prejudice continued for long, and in 1754 Mißler says of Potatos that "they are despised by rich and deemed only proper food for the meaner sort of persons." An amusing confirmation of the aphorism "what Lancashire thinks to-day, England thinks to-morrow," is supplied by the fact that when the Potato was introduced to Lancashire in 1728, its cultivation became general in the county and gradually spread to other parts of the county. Sturtevant is of opinion that the history of the Potato seems to imply that at first its tuber was of such poor quality as not to obtain general liking. We are, for our part, inclined to believe that cultivation and not the tuber was at fault. In the sixteenth century the standard of cultivation, as judged by the average yield of Wheat, was not high—not exceeding ten bushels to the acre. Much land was undrained or imperfectly drained and in these circumstances the Potato which finds its best flavour, although not its great yields, in light, sandy soils, might well have produced tubers of generally unpleasant flavour. On the other hand, and in support of Sturtevant's view, Europe was for a long time no more well-disposed than was England to the new food plant, and the ruse said to have been resorted to by Parmentier—whether it be true or not, serves to illustrate this fact. As recorded in this journal,\* the story goes that it was only by withdrawing at night the military guards set by day to protect his experimental plots that he succeeded in getting Potatos into the category of "stolen fruit" which appears sweetest to the pilferer. In the present state of knowledge it is, perhaps, useless to speculate on the origin of the Potato. It would seem probable, however, that in the case of this plant as in that of other edible plants, the numerous varieties point to a hybrid origin, although in the case of the Potato the hybridity would appear to be between races and not, as in the case of Wheat and Maize, between species.

**National Dahlia Society.**—The annual general meeting of the members of the National Dahlia Society will be held on Tuesday, January 31, at 4 p.m., in the Lecture Room at the Royal Horticultural Hall, Vincent Square, Westminster.

**Estate Nursery and Plantation Competitions in Scotland.**—In the year 1912, the Royal Scottish Arboricultural Society started a series of competitions open to estate nurseries and plantations,

\* *Gard. Chron.*, February 21, 1914.

and these competitions have been conducted in connection with the Society's Forestry Exhibition at the Highland and Agricultural Society's show. During 1921 the show district included the counties of Clackmannan, Dumbarton, Perth and Stirling. Two of the estates entered were also in the 1912 competition, consequently it will be seen that the competitions have completed their first circuit or rotation. In the Nursery Section, Class I. is for estate nurseries not exceeding two acres in extent, and Class II. for those of more than two acres. In the Plantations Section, there are seven classes in all. The first three classes are for plantations of not less than two acres, consisting mainly of Conifers (I.) under ten years of age; (II.) exceeding ten years and not exceeding twenty years; (III.) exceeding twenty years and not exceeding forty years. These are confined to estates having less than 300 acres of woods. Classes IV., V. and VI. are open to estates having more than 300 acres of woods, and the plantations are similarly specified, with the exception that they must be not less than five acres in extent. Class VII. is for plantations mainly of hardwoods not exceeding 35 years of age and not less than two acres in extent. The nurseries and plantations entered in 1921 were of a high order of merit and the majority of the plantations were under twenty years of age. In the Nursery Section a Gold Medal was awarded to the Dunkeld Estate and a Silver Medal to the Keir Estate, while in the Plantation Section Silver Medals were awarded to the estates of Keir, Dunkeld, Doune, Ardochullary, and Tullichewan. According to the report published in the recent issue of the *Transactions of the Royal Scottish Arboricultural Society*, the judges found a tendency in most places to increase the planting distance, especially so far as the more rapidly growing Conifers are concerned.

**Florists' Tulips.**—The members of the London School-Gardening Association and their friends are to be favoured by a lecture on "Florists' Tulips" by their president, Sir A. Daniel Hall. The lecture will be delivered at the London Day Training College, Southampton Row, at 7.50 p.m., on Friday, January 27.

**Commercial Fruit Show at Hereford in 1922.**—The Imperial Fruit Show of 1921 was discussed at considerable length, and its management was subjected to considerable adverse criticism at a meeting of the West Midland Commercial Fruit Show Association held at the Shirehall, Hereford, on Monday, the 9th inst. The members of the Association decided to hold a commercial fruit show at Hereford this year (date to be fixed), but expressed themselves ready to consider the possibility of joining in an Imperial Fruit Show if it were held in the north of England during the present season.

**Exterminating Rats.**—In connection with the crusade for the extermination of rats in this country, it is interesting to observe that in different countries different methods are employed to destroy these rodents. An interesting method is described in the *Queensland Agricultural Journal*, which is as follows: "Put down a tempting bait and surround it with a ring of caustic soda. Outside the ring of soda place a ring of wet rags or bags. The rat, to reach the bait, must walk over the wet bags, and so wet its feet. He then walks over the caustic soda, which, of course, burns him. He will next lick off the irritating substance, and becomes a dead rat. The same procedure may be adopted at the main entrance to a rat's tunnel. Close up all the holes possible, and put wet rags at the entrance, and soda outside, and then the bait."

**A New Park for Chicago.**—The authorities at Chicago have already commenced the construction and lay-out of Lake Front Park, which is to connect Grant Park with Jackson Park, and will cost approximately 50,000,000 dollars. This park will be six miles long and about half a mile wide, and will contain a series of island-dotted lagoons 400 to 700 feet wide, extending through its centre. These lagoons will be spanned by seven artistic concrete bridges, so as to give ready access to

streets converging on the outer drive. The construction of this new park will necessitate the filling in of two square miles at present occupied by water averaging 15 feet deep, and it is estimated that this undertaking alone will require about 40,000,000 cubic yards of soil. About twenty miles of main drive way will be constructed, in addition to subways and five long viaducts over the Illinois Central Railway. When finished, the park will provide six miles of lake frontage, which will include extensive beaches for bathing.

**A Large Addition to Box Hill.**—We learn with great pleasure that Miss Warburg has presented seventy acres of land (purchased from Lord Francis Hope's trustees) to the nation as an addition to Box Hill. This magnificent gift is Miss Warburg's thankoffering for the conclusion of the war, and the area occupies a site on the right side of the Happy Valley, and runs with the boundary of land held by the National Trust, above the zig-zag. Beech and Larch woods and the Round Tower are included in these seventy acres of beautifully situated and charmingly wooded land.

**The Rainfall of 1921.**—Although time has not permitted a comprehensive summary of the rainfall records for 1921, a selection from the 3,000 returns made to the Meteorological Office has sufficed to give a preliminary idea of the distribution of rain in relation to the average fall in the British Isles. Probably every gardener will agree that in the year 1921 there was a very unusual shortage of rainfall, but we gather from a recent review of the year\* that the area affected in an extreme degree was not very large. During the months of January, March, and December the total rainfall was above the average at all meteorological stations in the western half of Scotland, and over a considerable part of the Western Highlands there was an excess of more than 10 per cent. In a small area in the northern Pennines and some isolated spots in Ireland there was more than an average rainfall, but with these exceptions there was a deficiency throughout the British Isles, and this deficiency increased in a marked degree towards the east and south of England. Around Aberdeen the deficiency was 40 per cent. below the average, and in Ireland to the east of Cork, the deficiency was more than 70 per cent. South-east of a line drawn roughly from the Bristol Channel to Yorkshire, the deficiency was more than 30 per cent., and throughout almost the whole of the district below a line from Plymouth to Yarmouth the deficiency was more than 40 per cent., while in the east of Kent there was less than half the average rainfall. The driest years hitherto recorded were probably 1854, 1864, 1870, and 1887, and in each of these years considerable areas experienced less than 70 per cent. of the average rainfall, while in 1887 almost the whole of England and Wales, as well as more than half the area of Scotland and Ireland, had less than 80 per cent. The general percentage of the average rainfall in the dry years of 1864, 1870, 1887, and 1921 respectively were as follows:—England and Wales, 76, 82, 74, 71; Scotland, 94, 80, 80, 99; Ireland, 36, 95, 77, 83; British Isles, 85, 84, 77, 82. Throughout the greater part of the Thames Estuary, the rainfall was unprecedentedly low during 1921. The highest rainfall record in this district was barely 20 inches, and over the whole of the valley it was less than 17.5 inches, while in the area below Lechlade the rainfall was less than 15 inches. From the review referred to we learn that the most remarkable totals were observed in the Thames Estuary and the southern Fen districts, where considerable areas had less than 12 inches of rain; these were undoubtedly the driest places in England during 1921. The review concludes with the observation that most of the water supplies of the south-east of England are drawn from underground sources, and it may be that well-supplies are being used up in a manner analogous to

living on capital. It is known that the underground water in the chalk formations depends intimately upon the rainfall for its maintenance, and in particular the winter rains percolate freely into the fissures of chalk and compensate for the draft made during the summer. It is an ominous fact that percolation records made during 1921 in the south of England show that no water had reached the chalk since May, and that the quantity between February 1 and December 31 was not more than the equivalent of 1.75 inch of rain. Unless, therefore, an unusually rainy period intervenes between this and the early summer, the outlook for the summer of 1922, from the point of view of water supply, is not very promising.

**Mr. John Cairns.**—Mr. John Cairns is almost as well known in the south of England and on the Continent as in Scotland, for he is no stay-at-home Scot. Mr. Cairns received his early training with the firm of Messrs. W. Drummond and Sons, Stirling, and after five years spent in their establishment he obtained employment with Messrs. Austin and McAslan, of Mitchell Street, Glasgow, and he has remained with this firm of seedsmen and nur-

MR. JOHN CAIRNS.

seriesmen ever since, and is now one of the partners. Mr. Cairns possesses a wide knowledge of plants and is thoroughly well acquainted with all that pertains to the seed trade, and to his wide knowledge and experience he adds a charming personality which must be a fine asset to the firm with which he has been associated for so many years. Eleven years ago Mr. Cairns was appointed a director of the Glasgow and West of Scotland Horticultural Society, and the present year is his third period of office as Chairman of the Directors of that Society. He is taking an especially keen interest in the International Horticultural Exhibition which is to open at Glasgow on August 30, and he is sparing no efforts to ensure its success. We have had the opportunity of inspecting a draft of the schedule which is to appear shortly, and we feel sure that the wide range of subjects dealt with and the handsome prizes offered will attract exhibitors from all parts of the United Kingdom. Both Mr. Cairns, the Chairman, and Mr. Hugh M. Mackie, 124, St Vincent Street, Glasgow, the Secretary, will readily answer any communications sent to them with reference to the forthcoming great exhibition.

**The Flora of Jan Mayen Island.**—One of the most interesting items in the programme of the general meeting of the Linnean Society, held

on the 19th inst., was an exhibition of lantern slides, together with an account of the Flora of Jan Mayen Island, communicated by Dr. W. Rushton Parker. Dr. Parker considers that the Flora of Jan Mayen may be divided into four main groups—the floras of the sea-shore, of the bird-cliffs, of sheltered places in the "tundra," and the mountain flora. The most luxuriant flora, which consists of *Taraxacum* or *Oxyria*, grows either under the bird-cliffs or in places where tuff has been reasserted by water. The limit of flowering plants seems to be about 3,000 feet. The total phanerogamic vegetation consists of about 43 species, all of which are common to both Norway and East Greenland. The origin of the flora presents a very complicated problem. Seeds have probably been brought there on the feet of wading birds which migrate to and from their breeding-grounds in East Greenland. It is highly improbable that Jan Mayen has ever been connected with either Iceland or Greenland. Many plants have probably reached Jan Mayen during very recent years.

**Disease-proof Cabbages.**—At the request of the National Kraut Growers' Association, the authorities at the Wisconsin College of Agriculture have developed a strain of Cabbages immune to the "Yellows" disease, which has been a scourge for some years throughout the Cabbage-growing districts of the United States. Tests conducted on disease-infected soil show that the new Cabbages are immune to the disease, while old varieties growing in parallel rows have been almost all killed. That the Wisconsin authorities consider the new strain to be quite immune may be gathered from the fact that the Association already referred to will distribute 5,000 pounds weight of the new Cabbage seed throughout the United States at an early date. This will be sufficient to plant 40,000 acres, and the amount has been obtained from stock grown from the disease-resistant strains supplied by the experts at the Wisconsin Experiment Station.

**Appointments for the Ensuing Week**—Tuesday, January 31: Royal Horticultural Society's Committee meeting; Lecture by Captain A. W. Hill on "Botanical Stations in the Cameroons and Nigeria"; National Dahlia Society's Annual meeting at R.H.S. Hall; Bath and West and Southern Counties Society's Council meeting; Cardiff Gardeners' Society's meeting.—Wednesday, February 1: Royal Agricultural Society's Council meeting; National Viola and Pansy Society's meeting.—Thursday, February 2: Manchester and North of England Orchid Society's meeting; Linnean Society's meeting at 5 p.m.; Wargrave and District Gardeners' Society's meeting.

**"The Gardeners' Chronicle" Seventy-five Years Ago.**—*Substitute for the Potato.*—Considering what a cottager may grow at least expense to supply the loss of the Potato, it occurred to me that the Scarlet Runner may be grown in large quantities, for the sake of the seed, with great advantage. I, therefore, had some dressed to fry, and when scalded, they readily slip out of the skin, and soon boil tender, and either with a little pepper and salt only, or the addition of a very small piece of bacon stewed with them, make a most excellent dish. The expense attending the growth of the plant would be the sticking, which might be obviated by putting the seed into the earth close to the hedge or fence of the cottager's garden or allotment, which would form a support without further trouble, and the space thus occupied would be very trifling. Peas they may certainly grow more extensively in their allotments than they have hitherto done, to preserve dry instead of eating them green, but they would be more open to the attack of birds than the Scarlet Runner.—*Polypodium*, Jan. 7. (These have been often recommended.) *Gard. Chron.*, Jan. 23, 1847.

**Publication Received.**—*Fungi*. By Dame Helen Gwynne-Vaughan. Cambridge University Press, Fetter Lane, E.C. Price 35s. net.

**FLORISTS' FLOWERS.**

**SOME OF THE NEWER CHRYSANTHEMUMS.**

JUDGING by the results of the past season, the introductions of three and four years ago do not include so many reliable exhibition sorts as was anticipated, Wm. Rigby, Mrs. Algernon Davis, Princess Mary, and Edith Cavell being the chief exceptions from a list of about thirty. High hopes were entertained in some quarters that such varieties as Golden Champion, Undaunted, Mr. Lloyd George, Mrs. H. Tysoe and Louisa Pockett would replace with advantage Lady Talbot, F. S. Vallis, and other of the old sorts; but they have not done so, with the consequence that older varieties were very much in evidence in the season 1921. This latter year's introductions and those of 1920, however, promise better, and the following amongst them should supply blooms of high quality for some years to come.

**PRINCE ALBERT.**—This is a deep yellow sport from Princess Mary, and needs no recommendation. But, as is essential with the parent, the plants need to be well cultivated to secure an early first crown bud, otherwise the blooms show an eye.

**MAJESTIC.**—This variety has already won its spurs, being shown at practically every exhibition of note last season. Dwarf plants are not generally associated with monster blooms, but this variety is a remarkable exception, a fact which will insure its popularity. Early propagation and a natural break are points to observe with this choice Chrysanthemum.

**Mrs. H. E. DIXON.**—This variety was better in 1920 than last year. In an attempt to obtain natural second crowns our plants grew over 6 feet tall, and the buds were rather late. It appears to be necessary to root the cuttings in December to obtain second crowns, or to anticipate the second break by stopping about the third week in June.

**Mrs. SPENCER CHICHESTER.**—This is a primrose yellow incurving Japanese variety of fine form. Our plants did not show any signs of breaking in the middle of June, and were stopped, which brought the development of the buds to the third week in August. In an ordinary season early propagated plants should break naturally.

**Mrs. GEO. MONRO.**—This magnificent velvety crimson does not appear to be of much use if first crown buds are chosen, and yet it is rather slow growing, so needs rooting very early.

**SHIRLEY GOLDEN.**—The blooms of this Chrysanthemum are something after the form of Lady Talbot, and the colour of James Fraser, when the variety was grown on the early bud. In its early stages the plant is one to persevere with, for it is rather delicate, but when it is growing freely in 6-inch pots, it soon puts on as robust a look as the average variety, and runs on to the second crown bud.

**Mrs. PETER MURRAY.**—A fine habited Chrysanthemum producing a solid bloom of rich purple colour. Buds of the natural break and first crown buds open perfectly.

**ROSEMARY SIMMONS.**—Another of the Lady Talbot "build," but a variety that requires growing well to obtain good blooms. Plants stopped at the end of May were late by a fortnight, and this in a hot summer.

**Mrs. T. J. FLEMING.**—This is of the colour of Sir E. Letchworth when that variety is grown on the early crown bud, but it is a much larger bloom, and will doubtless be more heard of in the future. Of medium height, the plant has a strong habit, and requires a long growing season, so a stopping early in April is essential.

**HELEN MARGERISON.**—This is another pink Chrysanthemum of good quality. Grown to a natural first crown, the buds are somewhat late unless the break occurs early in June.

**VISCOUNT CHINIA.**—An erratic grower, which takes after Mrs. Algernon Davis in that it is a persistent bud thrower. This failing has appeared in districts widely apart, and from root

cuttings, so the fault does not rest alone with stem cuttings, which are often said to be the source of this trouble. Late rooted plants have done best, second crown buds being easily secured.

**Mrs. CHAS. H. CURTIS.**—This reminds me of the variety Mrs. H. J. Stratton in colour, but it should last longer than that variety, as the blooms are more solid, and better formed. Natural crown buds seem to finish the best.

**A. S. WATT.**—This may be described as a glorified Princess Mary. The blooms are certainly a little deeper coloured, otherwise there does not appear to be much between the two, excepting there is no need to stop the plants.

**VICTORY.**—For a good white of proved merit it is necessary to go back to the season of 1919 for this variety. It is a monster bloom,

**NEW OR NOTEWORTHY PLANTS.**

**PHYTOLACCA CLAVIGERA.**

THE Phytolaccas are mostly coarse-growing perennials, with succulent stems and large, fleshy rootstocks, suitable for the wild garden or shrubby borders. The species generally met with in cultivation are the North American *P. americana* (syn. *P. decandra*), the Virginian Pokeweed, and *P. acinosa* (syn. *P. edulis*), a common plant in the Himalayas and Western China. These two plants are distinguished by the former having the carpels composing the black fruits entirely enclosed in a skin, giving it the appearance of a berry. In *P. acinosa* the carpels are all separate.

An arborescent member of the genus occurs in

FIG. 18.—PHYTOLACCA CLAVIGERA; A NEW SPECIES OF POKEWEEED.

with long, drooping florets which incurve at the tips. The plant is of medium height, and in an average season stopping at the end of April seems necessary to produce blooms early in November.

**Mrs. CHAS. DAVIS.**—This is the latest white sort and, judging by the fine blooms, it will become popular. I have it from one of the specialists that it is the best white sort he has handled, better than Queen Mary, W. Turner, and Mrs. A. T. Miller, while the plant is a much better grower than the two first named. Next November I hope to have verified these statements.

The following are still in the front rank of exhibition varieties:—A. F. Tofield, Wm. Rigby, Mrs. G. Drabble, Dawn of Day, Francis Jolliffe, Mrs. R. C. Pulling, Princess Mary, and Mrs. Algernon Davis. Y. G.

South America; this is *P. dioica*, which has stems from 20 ft. to 30 ft. high.

A fourth species, *P. clavigera*, is illustrated in Fig. 18. This is a robust-growing perennial, about 4 ft. high, with rounded, terminal spikes of small rose-pink flowers that are succeeded by black fruits packed into a dense, club-shaped mass. The individual fruits have their carpels enclosed in a skin, as in the American *P. americana*. This species is a native of Yunnan, where it was found by Mr. G. Forrest, who sent seeds to the Royal Botanic Garden, Edinburgh. There it flowered and fruited freely, growing from 3 ft. to 4 ft. high. Specimens in fruit were exhibited by Mr. Amos Perry at the meeting of the Royal Horticultural Society on June 21, 1921, when the plant obtained an Award of Merit. W. I.

## The Week's Work.

### THE FLOWER GARDEN.

By EDWIN BECKETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Hertfordshire.

**The Rose Garden.**—Work in the Rose garden occasionally falls into arrears in winter, and where this has occurred labour should be diverted to it. New beds should be well and properly prepared, and when ready the plants carefully and firmly planted. Where planting is already finished, attention should be given, after periods of heavy winds such as we have experienced this season, to ascertain if the plants have become loosened in the soil, and where this is found to be the case they should at once be made firm again. Renovations to old beds should also be carried out, and when all these operations are completed a winter wash formed of one ounce of blue vitriol (copper sulphate) to two gallons of water should be well sprayed over the plants and beds, to act as a preventive against fungous diseases and a deterrent to insect pests. Do not apply the wash when the weather is frosty.

FIG. 19.—*ARBCTUS MENZIESII* IN CALIFORNIA; SHOWING LARGE BRANCHES STARTING FROM NEAR THE BASE OF THE TREE. (SEE PAGE 41.)

**Rockery and Rock Edges.**—Where rockeries are to be formed, advantage should be taken of open weather to commence this work so that the mass of stone and soil may have the fullest opportunity of settling firmly in position before the time arrives for spring planting. Rock edges, which are nowadays superseding the old grass verges and Box-edgings along the fronts of herbaceous borders, should also be put in position. For either purpose it should be borne in mind that the rocks are only provided for the benefit of the plants, whereby a cool, moist rooting medium is secured, and not, as many seem to think, the prime feature of the whole. Another point to be remembered is that alpine plants benefit greatly, when grown under artificial conditions, if they are provided with a good, deep compost of a suitable nature, either in pockets or crevices, for many of the dwarf-growing alpines send out roots a yard long in search of food, coolness and moisture. Rockeries and stone edges already in existence should be examined, and, where the plants are found to be lifting themselves out of the soil, a top dressing of suitable compost should be applied. The composts suited to the various subjects differ considerably, and it is of great benefit alike to the cultivator and to his plants to make a careful study of particular plant requirements in this respect.

### THE ORCHID HOUSES.

By J. T. BARRER, Gardener to His Grace the DUKE OF MARLBOROUGH, K.G., Blenheim Palace, Woodstock, Oxon.

**Coclogyne.**—*C. cristata* and its varieties have their flower spikes well advanced, and should be carefully watered, as an excess of moisture at the roots or overhead may cause them to turn black and decay. The rare *C. Mooreana* is a most lovely Orchid that produces its blooms at this season. It is easy to grow if treated much in the same manner as *C. cristata*, but prefers slightly more heat, hence the necessity for placing it at the warmest end of the intermediate house. This beautiful, if somewhat neglected, genus of plants must not be exposed to much sunlight at any season, as their rather thin leaves readily scorch, especially if the plants are at all dry. *C. elata* and *C. ochracea* are also pushing up their flower spikes, and require water whenever they become dry at the roots. Plants of *C. pandurata*, *C. Massangeana*, and other varieties of this rather large family that have not as yet commenced to grow must be kept on the dry side. There is a great diversity, both in style and season of growth of these plants, also in their treatment, some growing in cool and others under tropical conditions. Many require a long season of rest to induce them

back portions having no roots are best removed. The whole of these Brazilian *Miltonias* succeed in a shady part of the intermediate house, and delight in ample drainage with a small depth of compost made up of A1 fibre and Sphagnum-moss, cut up moderately fine and placed somewhat firmly around the rhizomes.

### THE HARDY FRUIT GARDEN.

By H. MARKHAM, Gardener to the EARL OF STRAFFORD, Wrotham Park, Barnet.

**Gooseberries.**—The pruning and thinning of Gooseberry bushes should receive careful attention, especially where large fruits are desired. Overcrowding of the branches is one of the principal causes of failure, and should be prevented. When thinning the bushes, cut out some of the oldest branches and leave plenty of the younger wood, not forgetting that the Gooseberry crops all along the previous season's growth. Side shoots should be spurred back to two or three eyes, and the leaders and other parts required for filling up open spaces be left almost at their full length. As a guide to the pruner, the branches should be far enough apart to allow the hand to pass between them without coming into contact with the spines. Gooseberry bushes delight in plenty of air and light about their stems. Old, scraggy bushes are never profitable, the fruits being small and flavourless; they should be grubbed up. After pruning is completed, rake a little of the old soil from under the bushes, apply a good dusting of lime and soot, and top-dress with suitable soil and manure.

**Young Gooseberry Bushes.**—These are easily raised from cuttings, and a sufficient quantity should be rooted annually for either new plantations or filling up gaps as required. Firm, short-jointed shoots should be selected, those with little pith, from 15 to 18 inches long. Remove the eyes along the cutting, with the exception of five or six at the top, to form the head. Insert the cuttings firmly in the soil, 3 inches apart, in lines 12 inches apart, and see that they are kept free from weeds and firmly pressed back into the soil when loosened by frost.

**Black Currants.**—Keep the bushes well thinned, and encourage strong, young growth from the base, as it is from this young wood the fruits are produced. Feed the roots more or less according to the nature and condition of the soil. Very old trees, when cut almost down to the ground level, sometimes throw up strong, fruitful wood, and continue, with feeding, to produce good crops for several years.

### PLANTS UNDER GLASS

By T. PATEMAN, Gardener to Sir C. NALL-CAIN, Bart The Node, Codicote, Welwyn, Hertfordshire.

**Euphorbia (Poinsettia) pulcherrima.**—After the inflorescences of these plants have been cut for decorating purposes, or as the plants pass out of flower, they should be cut back, leaving about 15 inches to 18 inches of stem. They should then be stood under the stage in a moderately warm house until they are required for starting into growth to produce cuttings for next season's stock. *Euphorbia jacquiniæflora* requires practically the same treatment as that advised for the *Poinsettia*.

**Plant Cleaning.**—During the present month special efforts should be made to sponge and clean such plants as *Codiaeum* (*Crotons*), *Cordylines*, *Dracaenas*, *Palms* and climbing plants in the houses. If the cleaning of such plants is completed this month it will relieve pressure of other work that comes with the lengthening days, and, moreover, the plants will be in a clean state for propagating next month.

**Bouvardia.**—Where *Bouvardias* are grown in quantity, and it is found necessary to increase the stock, old stock plants should be placed in a warm house after being cut back, to in-

to produce flowers; others produce flowers in the greatest profusion.

**Miltonias of the Brazilian Section.**—These should be examined to see if any of the plants are in need of more root room or new material. It is necessary, perhaps, to point out that a plant may want repotting without being in need of a larger receptacle. In some instances a plant will deteriorate from causes not always apparent, and it will then be advisable to place the plants in smaller receptacles so that they may become well rooted. Roots being the chief feeding medium of plants, and as no plant can survive long if root action is not thoroughly healthy, the necessity for paying close attention to the condition of the compost will be obvious. To the close observer plants will teach the cultivator their requirements. *Miltonias* of the Brazilian section, being dwarf growers, do best in shallow pans suspended from the roof. All old and useless pseudo-bulbs should be cut away and the growing parts made up afresh, giving each leading growth room to develop. Those portions which have few roots to hold them in position should be pegged down firmly to the compost. Should it be desirable to increase the stock, the back portions, if the eyes are good, may be placed in small receptacles, where many will make new growths and eventually new plants. Those

duce them to break into new growth. Given a moist atmosphere, young growths will soon be available for propagating purposes, and when they are about 3 inches in length they may be removed and inserted, several together, in small 60-sized pots, using a good, open compost, with a sprinkling of silver sand on the surface. When making a hole with a small dibber to receive the cutting, the sand will fall to the bottom for the cutting to rest upon and prevent it from rotting at the heel. *Bouvardias* may also be increased by means of root cuttings. These may be obtained by shaking out some of the old plants and cutting the strongest roots into pieces about 3 inches in length; dibble these into pans or boxes, in sandy soil, and place them in a warm propagating case, where they will soon commence to grow. To be successful with *Bouvardias*, frequent fumigating is necessary during their early period of growth.

**FRUITS UNDER GLASS.**

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

**Pot Vines.**—If the earliest vinery was closed in December the buds of the vines will now be swelling freely, and the temperature may be increased from 3° to 5° at night, and from 5° to 10° during the day, as forcing should be done as much as possible during the day for the next few weeks. Renovate the fermenting material if the pots are plunged in litter, as this softens the fire heat and helps to supply the necessary moisture with light syringings on bright days. Disbud the vines as soon as it can be seen which shoots show the best bunches, and discontinue the use of the syringe direct on the vines, supplying the necessary moisture by damping all bare spaces. Let the temperature at this stage range from 55° to 58°, according to the outside weather, or until the vines are approaching the flowering stage, when the night temperature may be increased to 65° with 10° higher by day. Water the roots only after a careful examination of the soil, and give sufficient tepid water to penetrate the whole ball of roots.

**Early Permanent Vines.**—In many cases these vines are the earliest from which ripe Grapes are expected to be cut in May or June, and the vinery should be closed early this month. Vines which have been forced annually will quickly respond to a temperature of 48° to 53°. Little or no ventilation is necessary for the first few weeks. Thoroughly soak the border with tepid water, giving sufficient to reach the drainage, and supply the necessary atmospheric moisture by syringing the vines and other available spaces on fine days. Later vinerias should be kept as cool as possible for so long as the pipes are secure from frost.

**THE KITCHEN GARDEN.**

By JAMES E. HATHAWAY, Gardener to JOHN BRENNAND, Esq., Balderby Park, Thirsk, Yorkshire.

**French Beans.**—Successional batches of French Beans should be sown at intervals of three weeks for the purpose of maintaining a regular supply. They should be sown in eight-inch pots, well drained and half filled with a compost of good loam and Mushroom-bed manure; place the seeds evenly, about six to eight in a pot, and stand the pots in a house with a temperature of 60° to 65°. As soon as the seedlings reach the top of the pot afford a top dressing, and place the pots near to the roof glass. French Beans are very susceptible to red spider, therefore the atmosphere of the house should be kept moist and the plants syringed at least twice a day in bright weather. Where heated pits are available French Beans may be sown in them, but the bed should be raised well up to the glass. Plants raised earlier will now require plenty of weak liquid manure.

**Mushrooms.**—Horse droppings should be collected, and the larger the quantity that can be got together at once the better; the droppings should be spread out in a shed as gathered, and when sufficient have been

collected they should be thrown into a heap about 2 ft. thick, and turned over about every second morning for ten days. Afterwards the manure will not need so much turning, and as soon as it is in a suitable condition and the heat begins to decline it should be made into beds, the size of which must depend on the amount of material at hand. It is better to make smaller beds than to wait till enough manure is gathered ready to make a large one. A Mushroom bed should be made as firm as possible by beating the manure with a wooden mallet. When the bed is made a thermometer should be placed in it to test the temperature. Do not spawn the bed until the temperature is at about 80°. An eighteen-inch depth of material will suffice, but the deeper it is the better as it will retain heat longer. Three or four days after spawning cover the bed with a two-inch layer of finely chopped loam which has been stacked for a season; make this firm with the back of a spade. Mushrooms resent an excess of fire heat; a temperature of 60° is ample, but the house should be kept well damped. I do not advise covering the bed with litter or hay, as this has a tendency to encourage wood lice.

The species is hardy in most parts of Great Britain, though I have always failed with it in my cold climate at Dawyck in Tweed-dale. I have seen a fine plant at Castle Menzies in Perthshire, and I believe there is a good specimen at Fife. It bears fruit in this country; I have myself gathered good seed from Mr. Clinton Baker's tree at Bayfordbury in Hertfordshire. The fine specimen at Kew is well known. Elwes and Henry report a tree at Bassetwood, near Southampton, which was not less than fifty feet high, with a girth of 3 ft. 2 in., in 1903. *Arbutus Menziesii* bears transplanting badly, and therefore it ought to be grown in pots until it is put in its permanent quarters.

Nurserymen in this country do not seem to stock it, and yet there is not the least difficulty in getting seed from California. *P. R. S. Balfour, Dawyck.*

**THE SEA BUCKTHORN.**

THE beauty of *Hippophaë rhamnoides* is so great when densely laden with berries that many people would plant it in their gardens if they were aware that male and female plants are necessary in order to get fruit; or if they could get plants

FIG. 20.—HUGE TRUNK OF AN *ARBUTUS MENZIESII* IN MARIN COUNTY, CALIFORNIA.

**TREES AND SHRUBS.**

**THE MADRONA: *ARBUTUS MENZIESII* (PURSH).**

It is curious that this finest evergreen tree of the Pacific Coast is still comparatively so rare in cultivation, though introduced by David Douglas in 1827. It is, of course, named after Archibald Menzies, who thirty years earlier than Douglas explored Puget Sound and the adjacent bays, inlets and islands when he accompanied Vancouver to the N.W. Pacific Coast in 1793.

I have seen a tree, when drawn up among tall Conifers, reach a height of about 100 feet in the forests of British Columbia, Washington and Oregon, but never there of any considerable girth. Its smooth stems of rich, reddish-brown, and crown of shining foliage, are most conspicuous, and only rivalled in beauty by *Cornus Nuttallii* when in full flower—that finest and largest of Dogwoods. The two are often seen together in the more Northern range of the *Arbutus*. The latter extends south so far as the Santa Lucia Mountains, 100 miles south of San Francisco. In California I never saw it as a very tall tree; but in Marin County, immediately north of the bay of San Francisco, there are growing several specimens which reach the immense girth of over twenty feet.

I saw these trees about nineteen years ago in company with that excellent botanist, Mr. R. W. Menzies of San Francisco, who is seen beside the trunk in the photographs (Figs. 19 and 20) of them taken last September.

from the nurseries so labelled. The berries are variously described as orange-yellow, bright orange and yellow.

Loudon describes the Sea Buckthorn as growing wild from Kent to Yorkshire, on cliffs above sea-level, and as plentiful on the sandy flats between Yarmouth and Cromer. Philip Miller described the berries as yellow, and stated that he had seen the species growing naturally on the sea banks in Lincolnshire. He states he had seen a red-berried variety on the sea banks of Holland.

I have recently seen a broad belt of this shrub about three miles long, stretching from Skegness to Gibraltar Point, Lincolnshire, and have no doubt about its being a native there. The berries are orange-yellow, though a few bushes with yellow berries have been seen. All become yellow after a sharp frost. This seems to correct their acidity sufficiently for the birds to attack them. A frost occurred in November and the berries had mostly disappeared by the end of the year, the birds eating them being the missel-thrush and possibly the fieldfare, for both are very abundant there just now. The growing town of Skegness is actually encroaching upon the Buckthorn, and bushes of it can be seen between some of the houses. The sea is receding along this coast, and the first plant to take possession of a heap of sand is *Ammophila arenaria* (the Maram Grass). Then comes the Buckthorn, binding the sand just above high-water mark. Ridge and valley succeed one another landward, the innermost series being used as extensive golf links. *J. F.*

**EDITORIAL NOTICE.**

**ADVERTISEMENTS** should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, W.C.2.

**Editors and Publisher.**—Our correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the EDITORS. The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.

**Local News.**—Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturalists.

**Illustrations.**—The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.

**RHODODENDRONS.**

MR. COWLEY'S interesting little letter on *Rhododendron Alice* (see p. 301, Vol. LXX) has made me wish that Mr.

Mangles was still among us; for though at this time of day pioneer work ought not to be necessary, there seem to be left a large number of people for whom the term *Rhododendron* means the section known as "hardy hybrids" and that alone.

Mr. Mangles took a broader view, and constantly reiterated his praises of the species and the direct hybrids therefrom; and no one who has grown these would willingly confine himself to the so-called hardy hybrids, which they so far surpass in beauty of flower and foliage, in the length of their season of flowering, and in their intrinsic interest.

Mr. Euan Cox not long ago wrote an article to *The Gardeners' Chronicle*, in which he lamented the deadly monotony of the hardy hybrids at the Chelsea Show; and he might have added that their period of bloom was confined to the six hottest weeks of the year, when the sun may do as much damage to the flowers as the frost sometimes does to those which are produced earlier.

I am completely in accord with Mr. Cowley in his remarks on the use of peat. Not only is it unnecessary, but in heavy soil, and if the right sort is not obtained, it may be absolutely deadly. In my early gardening days I used to send a wagon to the moors and bring in peat—quite oblivious of the lesson before my eyes provided by the presence in this garden of bushes of that old plant known as *Smith's Scarlet*, in perfect health and over 20 feet high, which must long ago have outgrown any peat which may have been supplied to them when they were planted—and many a *Rhododendron* I lost thereby. Also, I find that, when a nurseryman sends me a plant which has been grown in peat, it is as likely as not to die in this heavy soil, accompanied as it is by a wet climate. But should an untoward fate confine me to but six varieties, they would not be hardy hybrids—not even the handsome *Alice*, nor our opulent friend *Pink Pearl*.

Leaving out the tender species and hybrids, and choosing only those of medium size, I think they would be the pale yellow *R. campylocarpum*, the best lavender blue form of *R. Augustinii*, the brilliant scarlet *R. neriiflorum*, *R. Roylei* or *R. cinnabarinum*, the lovely pink seven-lobed *R. Fargesii* (Fig. 21), and *R. Thomsonii* with its waxy, crimson bells. Yet the last

is unwillingly substituted for the blood-red *R. arboreum*, excluded only because it is not absolutely hardy. But among so large a number of glorious species and their hybrids it is almost impossible to make so limited a choice.

*Rhododendron Mrs. Kingsmill*, which is derived from *R. campylocarpum* × *R. Aucklandii*, and was originally raised by Mr. Mangles, is perhaps the first of all in my estimation, for it has eight or nine large and delicate flowers of the palest possible shade of cream, and appeals to some of us even more than most of its more showy compeers; but since it is a first cross from *R. Aucklandii*, it would not be hardy everywhere. Hardiness is, of course, the crux, though a lot may be done by putting the plants in a place absolutely protected from the morning sun. Still, this puts out of court *R. Nuttallii*, the largest of all in flower; the incomparable *R. Lindleyi*, with its ally *R. Dalhousiae*; *R. Scottianum*, *R.*

After these come *Glory of Leonardslee*, *Gill's Triumph*, *Glory of Penjerriek*, and the others of the same cross, *i.e.*, blood-red *R. arboreum* × *R. Aucklandii*, raised by Sir Edmund Loder and others. *R. Loderi* and *R. Cornnbia* in its best varieties can hardly be omitted, and they may be a shade hardier than those just enumerated.

So much for the hybrids; and, so far as my small experience goes, I am inclined to agree with Siedel's dictum that to make a good hybrid one at least of the parents should be a pure species, rather than that both should be unmitigated mongrels.

What a wonderful variety there is, too, among the species! They range from trees 80 feet high, such as *R. giganteum*, recently discovered by Forrest in China, and its near ally *R. protistum*, down to absolute carpet plants like *R. prostratum*, found from 16,000 feet altitude upwards; whilst *R. Forrestii* and

FIG. 21.—RHODODENDRON FARGESII; FLOWERS ROSY-LILAC WITH RED SPOTS.

*Maddenii*, and *R. crassum*; the deliciously sweet-scented *R. Edgeworthii* and *R. bullatum*; the beautiful, frilled *R. Veitchii*, and some few others.

Whilst I am on the subject of the hybrids of the doubtfully hardy sorts, one or two more of the best may be mentioned. The finest scarlet I have ever seen is blood-red *R. arboreum* × *R. Thomsonii*, raised by a friend, and, I believe, still unnamed; and hailing from the same place is the finest white, *R. arboreum album* × *R. Aucklandii*. Almost on a par with these is an exceedingly beautiful hybrid, *R. campylocarpum* × *R. Aucklandii*, raised here, of a wonderful shade of yellowish pink, on which, unfortunately, a tree of *Pinus insignis*, 8 feet in diameter, fell and almost destroyed after its first flowering; also, a plant of doubtful parentage, which I have named *R. Gilian*, again raised here, with fine foliage and flowers, the shape and colour of those of *R. Thomsonii*, but twice the size.

its allies climb like ivy, rooting along the stem as they grow. And the foliage varies immensely, from the enormous leaves of *R. sinogrande*—I have just been out and measured one 1 foot 9 inches by 10 inches—to the minute ones of *R. serpyllifolium*; some are dark green and bullate above, others smooth and pale or glaucous, and beneath there is every kind of tomentum, from bright red brown to grey, and in some cases a white waxy covering.

The inflorescence is of many shapes, colours, and sizes, *R. Nuttallii* being some 7 inches across, and *R. Tschonoskii* so small that it is apt to escape detection altogether. Sometimes the flowers are flat and salver-shaped, and from this range through every variation to the cylindrical tubes of *R. spinuliferum* and *R. Keysii*, which scarcely open at the mouth.

The colours found in the flowers are of almost every shade, except blue, and even this is approached in the lavender tints of 4238

Wilson—Augustinii forma, in *R. fastigiatum*, *R. intricatum*, *R. hippophaeoides*, *R. scintillans*, etc.

Among the most remarkable are the black-crimson of *R. haemaleum*, the orange of *R. dichroanthum* and *R. apodectum*, and the yellows of *R. campylocarpum*, *R. Wardii*, *R. Boothii*, *R. aureum*, *R. sulfureum*, and others.

The habit of growth is also very diverse, in some cases tree-like, with lofty trunks, bare of branches in their maturity, in others in the form of large bushes, or in that of tall, slender shrubs with fine, attenuated branches, or, again, dwarf, spreading, sturdy little plants, as exemplified in the *R. haematodes* and *R. dichroanthum* series, and so down to the minute alpine carpet plants.

In the Azaleoid section there is much charm also, and what a pity it is that one so seldom sees the Apple-blossom flowers of *R. Vaseyi* or those of the peerless *R. Schlippenbachii*, broad in the limb, pale clear pink, and delicately spotted with green. Whilst for the gardens of the curious there are *R. Przewalskii*, *R. chrysanthum*, and *R. Championae*, which may be said never, or hardly ever, to flower at all!

Whence it may be gathered that there are *Rhododendrons* to suit every garden, from the largest park to the tiniest rock-work; and a representative collection can produce a flower or two out-of-doors all through the year, except during severe frost.

What more lovely sight can be imagined than a big bush of the blood-red *R. barbatum* in full flower in January or February? True, it is sometimes spoilt by frost, but when once the wind veers to the west or south more flowers come out to replace those which have been destroyed. Much the same may be said of *R. Nobleanum*, but that begins to bloom earlier, sometimes in September, and goes on at intervals throughout the winter. Why is it, I wonder, that its white variety is so seldom seen? It is at least as beautiful as the type, but seems rare, and the plant here, a gift from Sir Isaac Bayley-Balfour, is one of my greatest treasures.

Many species are, as regards their flowers, only known to us so far from dried specimens and the collectors' descriptions, but yearly more are declaring themselves for the first time; especially is there a wonderful promise for next spring, and among others I hear that 6778 Forrest, the true lacteum of Franchet, with canary-yellow sweet-scented flowers, has buds in one garden.

One word as to the pestilent practice of grafting. It is to be feared that it is always with us, but seed, cuttings, and layers are the most satisfactory methods of propagation from the point of view of the planter, and many of us would welcome a nurseryman who would raise them in these ways; nor would we grudge paying more for plants on their own roots than for those now sent out, often troubled as they are with suckers, and frequently grafted on unsuitable stocks.

Finally, let these in search of beauty, who are anxious to improve their minds and their gardens, make an effort to attend the *Rhododendron* show, which, I hear, is to be held under the auspices of the R.H.S. on April 25, and I think they will come away with their eyes opened to the possibilities of this genus, albeit cut flowers cannot be expected to compare with those on the plant *in situ*.

With the view of disarming criticism, I may say that many, very many of the species and their hybrids I have omitted to mention, and possibly the initiated will find their favourites or their most-prized hybrids—if they are raisers of such things—left out. But I must plead ignorance in some cases and lack of space in others, and will end by expressing the hope that this somewhat discursive letter may be the means of introducing new plants to some few, or, better still, encouraging them to try seed-raising and hybridisation for themselves. *B. J. P. Major, Lamellen, St. Tudy, Cornwall.*

### THE GRAPE ROOM AT TEWIN WATER.

As so many gardeners are interested in maintaining a supply of Grapes over as long a season as possible, no doubt many of your readers will be interested in the method which obtains at *Tewin Water*. I had the pleasure of designing

washed, and the ceiling is lined with stained match-boarding. In front there is a two-inch air cavity, and in the roof there are six inch-and-a-half ventilators equally and triangularly placed in the outer and centre walls at the ground level, and there are somewhat similar ventilators at the roof. By this means a continuous current of air passes round the two rows

FIG. 22.—THE GRAPE ROOM AT TEWIN WATER, WELWYN.

the Grape room illustrated in Fig. 22, which is a lean-to brick structure with slated roof. It is built on a northern aspect, is 21 feet long and 5 feet 4 inches wide. The height to the ceiling in front is 7 feet 5 inches, and the back wall is 9 feet high to the ceiling. There are five sky-lights in the roof and two windows in front, which provide sufficient light for all the necessary work that has to be done in the Grape room, but the lights and windows are easily closed by means of sliding shutters. The floor is of solid concrete with a smoothly finished surface. All the walls are plastered and cement-

of inch-and-a-quarter hot water pipes and then cut through the three gauze wire ventilators into the roof's highest point. The stained lattice shelves are designed to hold the Copped Hall bottles, and are fixtures on the back wall and gable end, but removable in the front, where they can be arranged right and left as required. The equableness of the temperature is splendidly maintained, and there is no difficulty in keeping Grapes in splendid condition until the end of April. The capacity of the Grape room is 300 bunches. *H. Lloyd, The Gardens, Tewin Water, Welwyn, Herts.*

## THE DISCOVERY OF SOME OF JACQUES LE MOYNE'S BOTANICAL DRAWINGS.

A DISCOVERY of considerable interest to the student of botanical illustration has come to light in connection with an album of drawings in the Victoria and Albert Museum, South Kensington. This album had been exhibited as a specimen of early bookbinding, but the drawings it contained were brought to the notice of Mr. R. T. Gunther, M.A., F.L.S., the librarian of Magdalen College, Oxford, who very kindly directed my attention to them. Both the album, of small folio size, and the paper it contains belong to the sixteenth century: and the very beautiful water-colour drawings, fifty-nine in number, are without doubt the work of a French artist, Jacques (or Jaques) Le Moyne, dit de Morgues (or de Morogues), who accompanied one of the French expeditions to America as an artist, and who settled in London after his return, dying in 1588.

In 1586 Le Moyne published in London a quaint little book of woodcuts of animals, birds, and plants, entitled *La Clef des Champs*, which is now exceedingly scarce. I am convinced that some of the woodcuts of plants in this book were made from these drawings of Le Moyne which have now come to light, but only a careful comparison would determine how many. That such a set of plant drawings by Le Moyne existed has been pointed out by Prof. Platten in his *Craftsman's Plant-Book*.

These water-colour drawings are highly finished and show great artistic skill. Some are ornamented with very life-like drawings of butterflies and insects. The colouring is strikingly fresh, and looks almost too fresh for the date at which they were executed, which must have been prior to 1586. Their fine preservation is no doubt partly due to their having been kept in book form and in a fine binding. Seventeen of the drawings have names added by the artist, in Latin or French, and the first drawing has what looks like a signature of the artist—Demorogues. It is this name, considered in connection with the date of the binding and paper, and also from the fact that some at least of the originals of the *La Clef des Champs* woodcuts are amongst the drawings, that convinces me that this very beautiful and probably unique set of sixteenth-century plant drawings is the work of Le Moyne.

The plants depicted include many which were commonly found in the gardens of the period. The Daffodil, Violet, Snowdrop, Lily of the Valley, Roses, Stocks, the Daisy, Carnations, Marigolds, Lavender, Poppies, both wild and cultivated, and a fine Iris are among the garden flowers depicted. The fruits include the Pear, Apple, Pomegranate, Lemon, Grapes, Walnut, Cherries, Medlar, Fig and Damson. Other plants are the Artichoke, Millet, the Cucumber, etc.

The exquisite colouring and finish of these drawings is most remarkable. The woodcuts of *La Clef des Champs* did but scant justice to the fine drawings of Le Moyne, but his worth as a plant artist is now substantiated. These drawings of his show a keen love and perception of the delicate beauties of plants, and were undoubtedly painted direct from nature. They bear out his own words in the preface to his book, where, in speaking of the purpose of his drawings, he says they "*pourront servir à ceux qui ayment et desirant d'apprendre choses bonnes et honnêtes.*"

These drawings have been removed from the album in which they have remained so long, and are to be placed in the Prints and Drawings Department at the Victoria and Albert Museum. It is hoped that the authorities will see their way to allow these unique specimens to be exhibited for a time in the galleries of the Victoria and Albert Museum, South Kensington. *S. Savage.*

## MESEMBRYANTHEMUM AND SOME NEW GENERA SEPARATED FROM IT.

(Continued from page 22.)  
LITHOPS, N. E. BROWN.

VERY dwarf succulent plants, in nature growing buried in the ground with their tops scarcely, or not at all, rising above the level of the surface, consisting of a single growth or of two to many growths in a clump. Each growth a more or less obconic or rarely compressed-cylindric body with a transverse fissure across the top dividing it into two short lobes, flat or convex on the top when adult, but in a juvenile state with only a central orifice at the top, as in the genus *Conophytum*. Flower solitary, from or partly included in the fissure, more or less compressed, without a tube above the ovary, 4-7 (usually 5-6) lobed. Corolla without a tube; petals numerous, widely spreading. Stamens numerous, collected into an erect column. Style short, sometimes almost absent; stigmas 4-7, filiform.

The above generic name which I give to the plants I now separate from *Mesembryanthemum* is formed from the Greek words *lithos*, a stone, and *ops*, the face, on account of their resemblance in colour and appearance to the stones and pebbles they grow among. The remarkable resemblance of these plants to pebbles is well demonstrated by an account given by Dr. R. Marloth in the *Transactions of the South African Philosophical Society*, Vol. 15, p. 100, in an interesting description of the manner in which plants imitate the ground and stones they grow among. Dr. Marloth states that Mr. Hammond Hook (? W. Hammond Tooke), "During a stay in the Karroo had often used a certain footpath which passed for some distance over bare ground merely covered with pebbles. One day, however, he saw some of these pebbles bearing bright yellow flowers, one on the top of each stonelet. The number of these flowering pebbles increased every day until there were hundreds of them on the otherwise bare veld. It was *Mesembryanthemum truncatellum*, Haw., which occurred rather plentifully in this locality." The resemblance to pebbles must be very great for anyone to frequently walk over the ground on which they grow without discovering that they were not stones until flowers appeared. But Dr. Marloth is quite wrong in his identification of the plant, which I have no doubt whatever is a species of *Lithops* unknown to me at present. For *M. truncatellum* grows in tufts, does not resemble pebbles, but is glaucous-green and dotted, and has light straw-yellow flowers that only open in the evening. I have given an account of the resemblance of these plants to stones on p. 250 of Volume LXX., and have also there stated and explained that they all belong to the small group known as "windowed plants." The window, however, is sometimes quite obscured by coloured pigment, which acts as a screen to soften the light, yet does not prevent it from penetrating into the interior of the plant and reaching the chlorophyll layer (see Fig. 112, p. 251, Vol. LXX).

When these plants are very young and have only a central orifice, there is nothing in their external appearance to distinguish any of them from the genus *Conophytum*; compare, for example, Fig. 84, R, with 84, O, on p. 207, and with Fig. 97 on p. 223, Vol. LXX. But when the adult condition with a fissure all across the top is assumed, or the plant flowers, the distinction between the two genera is very obvious. While, in any of its stages, if a longitudinal section through a plant is made, the peculiar disposition of the chlorophyll layer, as shown in Fig. 112, p. 251, Vol. LXX., will at once serve to distinguish this genus from *Conophytum*, in which the chlorophyll layer covers the whole surface.

Although in nature these plants grow buried in the soil with the top level with or just rising above the surface, they often refuse to grow in that way in this country. For if planted with their tops just above or level with the soil, I have found that the first new growth that is made in most cases rises far above the

ground level, doubtless due to the absence of such intense light as they get in their own country. On the contrary, I have one plant of *L. Lesbeii* that I planted over two years ago, with its top level with the earth in the pot, that has in no way changed or made any attempt to develop a new growth since it was planted, but has remained plump and healthy all that time, and has not flowered. But planting them level with the earth in this country is to risk their loss by rot, as I have found from experiment, for it is very difficult to know when the moisture in the soil is greater than the plant will endure at any particular season. For, as I have previously stated, the watering of these plants is an art requiring special knowledge. If insufficiently watered at the proper season they do not flower, and if overwatered they rot. The thermometer and dryness of the atmosphere should also be consulted as guides to the amount of water that should be given and how often it should be applied; for a tablespoonful may be enough for three weeks in June or December, yet not more than enough for two or three days in August. I have found *L. fulviceps* and *L. optica* to be especially sensitive to a little too much water at the wrong season.

The plant I described in the *Journal of the Linnean Society*, Vol. 45, p. 68, as *Mesembryanthemum locale*, and associated with species of this genus, may belong here, but it is only known from an imperfect, dried specimen, and cannot be properly placed until the living plant from near the Gamka River is obtained, for after re-examining the specimen I am now inclined to think that what I supposed to be a transverse fissure may be only a furrow due to shrivelling. *N. E. Brown.*

(To be continued.)

## THE GREAT DROUGHT OF 1921 AND ITS EFFECT ON GARDEN PLANTS.

(Continued from page 32.)

CUMBERLAND.

THE summer of 1921 was remarkable in north-west England for its abundant sunshine, and also for the drought in the early summer months, which was not so prolonged here as in the south. August provided many refreshing showers, and we enjoyed an exceedingly fine autumn. This combination had a very marked effect on vegetation, many plants flowering a second time. The common Holly was in some instances literally covered with its flowers, and wild Roses were abundant late in the season.

During the middle of October the writer gathered 126 sorts of wild flowers and 21 grasses. When walking through Holker Hall Gardens, the home of many interesting plants, I found some plants anticipating early spring, such as the lovely Chilean *Crinodendron Hookerii*, with its dark green, glistening, linear leaves and lovely crimson, campanulate flowers. Another Chilean plant, *Berberidopsis corallina* did well, and *Osmanthus myrtilifolius* produced its small white flowers. *Spiraea confusa* had even finer flowers than in May. A noble plant of *Yucca recurva* bore its pyramidal spikes of creamy white flowers, and near by a small reservoir a fine group of *Pborium tenax* bore spikes carrying black seeds. *Laurus nobilis*, with a perfume not unlike that of Lemons, carried plenty of its oval, yellow or green seed-pods. *T. R. Cuckney, Arnside, Carnforth.*

HADDINGTONSHIRE.

The year 1921 was remarkable for its weather and for the manner in which vegetation adapted itself to the changes, good and bad. The autumn was glorious, and there was no winter—if the occurrence of frost and snow make winter. Bitter weather in late spring was followed by lengthened summer's drought and a high temperature; in August there was abundance of rain, which, unhappily, left some localities unrefreshed. The effects and results of the drought have demonstrated once more how little we know of Nature's ways, and how what were deemed unshakable facts were mere opinions. How is one to account for the non-flowering of a num-

ber of large specimens of *Agapanthus*, white as well as blue, in tubs and planted out, while small plants of both have flowered? My own opinion is that the former had received no check to growth owing to the previous abnormal autumn and winter.

Serious inflictions of insect pests were not unexpected, yet vegetation was singularly free from them. Violets were seriously weakened by red spider in 1920, but in 1921 there was no difficulty in controlling that pest. So with Grape vines; not a leaf was attacked by any insect during the whole period of intense heat and excessive drought, while sometimes in seasons of alternate dryness and wet red spider has appeared. The reason would seem to be that a period of dull and wet weather predisposes the foliage to attack, when a spell of hot sunshine follows—a condition that had softened the leaves. Another point regarding Grapes is that White Muscats here had reached the flowering stage when fuel ran out, and knowing from experience that Muscats set more perfectly in a high temperature than a low one, a deficient set and clusters of diminished proportions were anticipated. Nevertheless, I do not remember a better

quite so fine. More fruit dropped during August, however, than usually is the case. The promise for another year, if clean and perfect foliage may be taken as an indication, is good indeed. Up to the beginning of August the expectation of securing Strawberry runners was low, yet new plantings were made as usual of healthy, nicely rooted plants.

The transformation in vegetables was equally remarkable. Cauliflowers were expected to button, and lo! fine heads were abundant for weeks. But the excitement was not beneficial in every instance. Seedling Cabbages grew so fast they had to be planted a fortnight earlier than usual, which necessitated a later planting to make sure of a crop.

A disturbing element of the great heat was the early maturing of crops. Plums were from three to five weeks earlier than usual, and so with Figs, while Apples matured and were gathered two to three weeks before the normal time.

A curious circumstance in relation to Potatoes was brought to my notice. On lifting there was nothing but mops of fibrous roots and tiny tubers, the size of Peas, just commencing to grow. This was doubtless due to very imperfect

piece of Fig or a Grape impaled on a "Nipper" trap proved a certain bait. It is probable the open winter of 1920-21 was responsible for such a plague as these proved. It is fortunate they eat only a few select things, otherwise nothing would escape their voracity. *R. P. Brotherton, Tynningham Gardens, Prestonkirk.*  
(To be continued.)

### NURSERY NOTES.

#### A KENTISH FRUIT NURSERY.

No Kentish Man or Man of Kent entertains the slightest doubt that his county is the premier fruit district of Great Britain, a corner of England so specially favoured by nature in climate, soil and situation as to be called "The Garden of England." With rich scenery goes a fertile soil, so that rural industries flourish, and, in the higher branches, such as market-gardening, flower-gardening and fruit-growing, Kent growers—who are luckily favoured with a near market in the metropolis with its teeming population—are pre-eminent.

Some of the finest fruit-growing land is met

FIG. 23.—GOLD MEDAL COLLECTION OF HARDY FRUITS EXHIBITED BY MESSRS. G. BUNYARD AND CO. AT THE ROYAL HORTICULTURAL SOCIETY'S FRUIT SHOW OF 1921. (See page 46.)

set, due no doubt to the heated external atmosphere at the time of flowering. It was only at the end of the coal strike when rain came and the berries began to crack that heating had to be resorted to in order to stop cracking. One hears of splendid Grapes produced without applied heat, and even the presumption that every particle of sun heat needs to be conserved in order to meet the requirements of the vines has been proved to be erroneous. One, indeed, hears of failures, due probably to a system of over damping and under ventilating.

Plum trees on walls facing west cropped very lightly, or not at all, but on an east aspect, where as a rule the trees are less fruitful, seven out of nine carried much larger crops than usual. This was very marked in the case of a Greengage, a Washington, and a White Magnum Bonum.

The rain caused an extraordinary transformation in the appearance of Apples. From undersized fruit for the time of year, Apples, in the course of a few weeks, attained proportions rarely seen. Cox's Orange Pippin, Ribston Pippin and James Grieve were, perhaps, never

cultivation. It is impossible to make people with small gardens comprehend the importance of deep cultivation. Year after year the Potatoes are planted in the same ground, a few inches of the surface soil alone being turned over, with results always poor, and, in the present instance, yielding nothing. The crop here turned out well. Many Potatoes were as large as those of 1920, when it was thought the season was responsible for overgrown tubers. Some growers lifted up to 14 tons to the acre. Such results I am certain are due to deep cultivation, deep planting and getting the crop planted in February, so that the drought had only a slightly deterrent effect on growth. In half a ton lifted here there was only half a cwt. of small size.

An unusual amount of damage was done by voles assisted by two species of mice. The former commenced early in 1921 by eating through the stems of young Brussels Sprouts, and by an attack on young Perpetual-flowering Carnations. They destroyed also whole beds of Picotees. No bait either in trap or as poison tempted them, and it was not until fruit began to ripen that they were reduced in numbers. A

with in the valley of the Medway, and the centre of the fruit-growing industry may be regarded as Maidstone, with Sittingbourne for Cherries.

Maidstone is at once associated in the gardener's mind with one of the most famous fruit nurseries in the kingdom, for various circumstances have contributed to make the name of Bunyard, of Maidstone, a household word in horticultural circles. Bunyard's nursery has been known to successive generations of gardeners, for it was in the closing years of the eighteenth century that it was established by Mr. James Bunyard, who, like many other successful pioneers in the nursery business, was a private gardener. James Bunyard was succeeded in the business by his son Thomas, but it was the latter's youngest son George—one of the greatest of English pomologists, and the author of valuable works on fruit-growing—who raised this famous fruit-growing establishment to the very forefront of its prosperity.

It was during Mr. George Bunyard's proprietorship that the first three acres of land were acquired at Allington, a village just outside the

town of Maidstone, and these three acres formed the nucleus of the celebrated Allington nursery, which has since been enlarged to 165 acres. The two sons of Mr. George Bunyard—Mr. E. A. Bunyard and Mr. G. Norman Bunyard—worthily carry on the traditions of the firm, and in September last we accepted an invitation from them to visit the Allington nursery. Although still a young man, Mr. E. A. Bunyard has a wide reputation as a pomologist, and he has placed fruit growers under a debt by publishing at considerable expense, out of his own pocket, *The Journal of Pomology*, a monthly periodical dealing with their special interests, besides giving them the useful *Handbook of Fruits*, which is as reliable as Hogg's *Fruit Manual*. Mr. Norman Bunyard is as interested in plants and flowers as his brother is in fruit, and under his special care this branch of the business has become second in importance to that of tree growing.

The first thought that arises in the mind of the visitor to a fruit nursery of this extent is the vast number of young fruit trees that must be planted annually in gardens of this county, for quarter after quarter is filled with young Apple, Pear, Plum, Cherry, Peach, Nectarine, Apricot, and other kinds of fruit trees, in all styles of training, and how well the soil suits them is evidenced by their splendid condition. In one part are seen four or five acres of standard Pears, in another equally large areas planted with bush Apples, in another, flat-trained Peaches and Nectarines, and so on. Thirty-thousand standard trees in one batch of such popular Apples as Lane's Prince Albert, Bramley's Seedling, Newton Wonder, and Allington Pippin, show the extent to which fruit trees are propagated at Allington. In addition there are large stocks of Gooseberries, Currants, Raspberries, Loganberries, Almonds, Walnuts, Medlars, Mulberries, hardy Grapes, and other kinds, together with everything else such a nursery is called upon to supply.

The older Apple trees in fruit were the feature of the place at the time of our visit, for the Apple crop in every part of Kent during the past season was the greatest within living memory, and Allington had its full share. The most remarkable trees were large, bush-trained specimens, that were almost replicas of those in the upper orchard at Wisley. This is certainly a profitable method of training the Apple, and may be likened to a series of cordons radiating from a main stem, for the side shoots are pruned closely to obtain spur growths the whole length of the branches. Trees of this type were to be seen at the Node, Welwyn, where Mr. Pateman had to use props to support the weight of fruit, and this notwithstanding the crop had been thinned drastically.

A few remarks on certain varieties of Apples that specially appealed to us may be of interest to readers. Royal Jubilee, a comparatively modern variety, is a most reliable cropper, whilst the large, conical, golden fruits are of beautiful appearance and splendid for cooking. The tree has a characteristic flat-headed habit of growth, the shoots forming a drooping canopy supported by the stem. It is amongst the latest of Apples to flower, from which fact it frequently escapes injury by frost. Hector McDonald, one of the numerous Apples raised by the late Mr. Chas. Rose, is of the Lane's Prince Albert type. The trees were bearing a profusion of exceedingly handsome fruits. Sanspareil is useful for either culinary or dessert purposes, and keeps until April without shrivelling. The yellow fruits with red stripes are very pleasing in appearance. James Grieve is a good September dessert Apple with a Cox's Orange Pippin flavour; it is a reliable bearer and last season cropped profusely. Transparent de Croncels is a French Apple of merit, not much grown in this country, but the tree is said to be of great hardiness. The fruits are quite distinct, the colour being almost white with a little dark flushing in places.

Cutler Grieve is a handsome Apple of the Worcester Pearmain type, but keeps much later. It is a vigorous grower and fertile, indeed it has all the necessary qualities looked for in a dessert Apple except rich flavour;

still it is juicy and very sweet, and is worth growing for market.

By their splendid exhibits of hardy fruits displayed at the principal London and provincial shows (see Fig. 23), the Maidstone firm has done much to encourage fruit growing and to provide the public with opportunities for comparing varieties of Apples and Pears, as well as of ascertaining the correct names of the varieties.

In addition, it should be remembered that Messrs. G. Bunyard and Co. have introduced several fine new fruits, as recorded in our pages at various times. Besides fruit trees, large areas are devoted to Roses, flowering trees and shrubs and herbaceous and alpine plants, so that most subjects required in a garden can be supplied from stock in this extensive and finely kept nursery.

## RUSSET APPLES.

In dealing with Russet Apples (Vol. LXX., p. 337), *Pomona* has omitted to include one of the choicest and finest of the type in his list of varieties. The variety in question is St. Edmund's Pippin. I do not know why it is called a Pippin, for it is actually a russet in character. It received a First-Class Certificate from the Royal Horticultural Society in 1875, and it is really worthy of that high award. For some reason it has never made much headway in popularity, and it appears to be unknown to the average writer when recommending a list of high-grade Apples to prospective planters.

This general lack of appreciation is certainly not founded upon lack of quality nor yet upon any difficulty in the way of fertility, for it is a good grower and an almost certain annual cropper.

I have to thank Mr. Charles E. Pearson, of Lowdham, for my introduction to this fine Apple. I was on the hunt for varieties of really outstanding merit in regard to quality when Mr. Pearson kindly sent me a couple of trees of St. Edmund's Pippin, with the remark that the variety would certainly have to be included in a half-dozen of the best flavoured Apples in cultivation. I entirely agree with Mr. Pearson, and I go a great deal further in my own appreciation of this variety. I have a fairly large collection of Apples—over a hundred varieties in all—and I put St. Edmund's at the top of the list for quality. It is in season in October and November. I cannot understand why this Apple is not more popular.

There is another Apple of a decided russet type, and which is very finely flavoured. It is Reinette de Canada. It is in season from November to March, and a reliable cropper. It like St. Edmund's Pippin, is a favourite where it is known.

These two varieties, with the addition of Gravenstein and Roundway Magnum Bonum, are the finest flavoured Apples in my collection. All four are superior to Cox's Orange Pippin in my experience. It may be heresy to write thus of what is regarded as the finest British Apple, but the point is this: Have Apple growers in general tested any of the four sorts which I have named as fully as they have done Cox's Orange Pippin? The latter is so often written about as the finest Apple in cultivation that I am afraid prospective growers accept it on that valuation only. It is, of course, a remarkably fine variety, but I prefer my St. Edmund's Pippin and my Roundway Magnum Bonum season after season. It is not a question of soil, for I do not confine my criticism to the locally grown Cox's Orange Pippins. I have sampled fruits from several English counties.

Tastes differ, undoubtedly, but I find that several worshippers at the shrine of Cox's Orange Pippin have become converts to St. Edmund's, whilst several doughty champions of Cox's Orange Pippin whom I have met—and who call it the finest British Apple—had never heard of St. Edmund's Pippin! *George M. Taylor, Edinburgh.*

## HOME CORRESPONDENCE.

[The Editors do not hold themselves responsible for the opinions expressed by correspondents.]

**Doubling in Stocks.**—Mr. G. R. Sargeant states (p. 10) that he is a young student of Mendel, and as such he ventures to express the opinion that the Lothian methods of saving Stock seeds in order to produce a maximum number of seedlings possessed of double flowers are a perpetuation of the abnormal. My reply is simply this. The Lothian methods are founded upon years of practical experience and give, undoubtedly, the best results. If Miss Saunders, or any other scientist, can demonstrate a method which will give equal results in regard to a high percentage of doubles in the seedlings, without the ageing of the mother plants, then Mr. Sargeant may condemn the Lothian methods and deservedly so. The doubling of the Stock has always been a puzzle to the Mendelian student. I have a great admiration for the research work already done by Miss Saunders, but I believe she has a long way to go before she finally puts the fact of doubling upon a valid basis. The fact of single Stocks producing double-flowered seedlings from the first saving of seed is nothing new. Miss Saunders gets an average of about 56 per cent. Horticultural literature of three quarters of a century ago shows that growers got seed from one-year-old plants that produced practically cent. per cent. doubles, and the question of the perpetuation of the strain became an acute difficulty. But what was the type of those old Stocks? They were not, and could not possibly have been, East Lothians—the robust and hardiest of the race. Mr. William Cuthbertson, Chairman of the Wisley Garden Development Committee, has interested himself in this matter, and at his request I have sent seeds of what I regard as the true form of the East Lothian Stock to Wisley for trial and experiment. I am not aware that there is any mystery in any statement I have made in my contributions to the debate on this subject, but if Mr. Sargeant is under that impression and will inform me upon what point he has any difficulty, I shall do my best to enlighten him. *George M. Taylor, Edinburgh.*

**What is Fragrance?**—Not many botanists go into details concerning the scents of the plants they describe; but, when they do, they are sometimes at great variance with the modern idea of fragrance, especially the older botanists. In the case of the Mints, *Sole* nearly always gives his idea of their particular odour. Concerning his *Mentha villosa*, he says, the whole plant has a disagreeable goatish, minty smell; and of *M. v. secunda*, that it smells much like Spearmint. Both these are forms of *M. sylvestris*, concerning which Babington says, scent sweet. *Sole's M. sylvestris* is really *M. rotundifolia*, and he describes it as having a strong, volatile mixed smell of amber, camphor, and Mint. Babington states it is acrid. It is the Apple-scented Mint of modern writers, and was everywhere grown in our grandmothers' gardens for mixing with cut flowers for the sake of the scent. *Sole's M. rotundifolia* was *M. alopecuroides*, and he stated the smell resembled Spearmint, but not so strong. Under Spearmint (*M. viridis*) he states, "The whole plant has a most fragrant and refreshing smell." Most people whom I have consulted consider it has an acrid smell; and the *Students' Flora* records, "It may be distinguished by its pungent smell." *Sole* describes his *M. palustris* as having a goatish, minty smell. He says that Peppermint has a most agreeable odour of pepper, and speaks similarly of *M. odorata*, *M. gracilis*, *M. pratensis*, *M. rubra*, *M. gentilis variegata*, *M. cardinea*, *M. paludosa* and *M. arvensis agrestis*, adding the word aromatic to several of them. He seems to contradict himself somewhat when he states that *M. rivalis* has a heavy, mixed, goatish smell of Peppermint; while *M. piperita sylvestris* has a disagreeable goatish smell of Peppermint. His *M. aquatica major* had a "smell like a rosy chimney in a wet summer,

where wood fires have been kept in winter-time"; while *M. arvensis* had "a strong, full-some, mixed smell of mellow Apples and ginger-bread." This author may be compared with Harvey, who wrote some volumes of the *Flora capensis*. The last eight of his species of Pelargonium he describes as foetid, although they are reckoned amongst the sweetest-scented of the species by modern cultivators. *J. F.*

**Apple Calville Blanc.**—A correspondent mentions this Apple on p. 11. I have often wondered why Calville is masculine, and not feminine. According to the rules for the determination of French genders, this name ought to be Calville Blanche. *Le Jardinier Solitaire* gives that form. The Pomological Section of the National Horticultural Society of France gives the masculine, with the feminine form as a synonym. But, surely, grammatically it ought to be feminine. *C. H. P.*

**"Isabelle."**—I agree with C. H. P. (page 23, that the term "dove colour" in English parlance indicates soft, pearly grey. But if he will look up "isabelle" in a French-English dictionary he will find it translated "dove colour," the reference, as I mentioned in my note, being to the fawn-coloured breast of the turtle dove, not to the blue-grey plumage of our rock doves and cushats. The French have named another colour from the rock dove, namely, *gorge-de-pigeon*, from the iridescent plumage on the neck of the rock dove. *Herbert Maxwell, Monreith.*

**Damage to Fruit Trees by Voles.**—Mr. Hawkes (page 34) does well to draw attention to the damage done to his fruit trees by voles. I recollect a similar occurrence taking place at Pencarrow during the time the late Mr. H. Jones was in charge of the gardens. Vines had been planted in an outside border, and the borders covered with leaves and stable litter. During the vines resting period an unobserved colony of voles took possession of this covering, and wrought destruction by severing each vine stem near the surface of the border. This reminds me of damage done to vines by frost, which I may here be allowed to refer to. Soon after taking charge of the Hendre Gardens, and in the early days of the phylloxera scare, I paid a visit to Mr. J. Roberts, at that time in charge of the gardens at Gunnersbury Park, who showed me vines attacked by this troublesome pest, and pointed out its effects. I noticed that the unsatisfactory symptoms were similar to those in the Hendre vines, which were perplexing me at that time, and on reaching home I had no difficulty in finding that we also had attacks of the phylloxera to contend with. At that time it was generally considered that this insect was harmless in this country to vines planted in outside borders, and so we replanted the vineries in this manner. In the late spring of the second year after the vines were planted and had made considerable growth, a severe frost occurred, followed by bright sunshine in the early morning, and upon entering a Muscat vinery I found the vine leaves hanging down—the result of the vine stems having been frozen through. The young growths were killed. Had the freezing of the stems been discovered, and had they been thawed, the sap might have been liberated before the sun gained power, and probably no damage would have been done. This points to the advisability of protecting the stems of vines planted in outside borders, particularly in low situations similar to that of the Hendre Gardens. *Thos. Coomber, F.M.H., Lansdowne House, Lydney.*

**Are Plants Aware of Time?**—The article by Mr. Lynch (on p. 31) is extremely interesting to all lovers of Nature. May I ask him to kindly explain what a "klimostat" is? I have searched all my dictionaries without obtaining any information, and I want to test a Dandelion. There are many interesting facts connected with plants which one does not find in books, and all interested in plants will welcome any more notes on similar unusual subjects. *W. H. Divers, Westdean, Hook, near Surbiton.*

**Exochorda Albertii.**—In reply to A. B. H. (page 10) I beg to state that I have a fine plant of this beautiful shrub growing in the sunniest exposed corner I can afford it in a garden in East Lothian, not far from his own. It has been established for six years, but has not yet borne flowers. As a result, however, of the fine summer of 1921, I am pleased to note that its branches are set with a fine crop of bloom buds, which should give a good display later on in the season. Fortunately, my plant has not behaved like his, and its buds are still dormant and in proper seasonal condition. *George M. Taylor, Edinburgh.*

**Gentiana lutea.**—A yellow Gentian seems to appeal to some lovers of this exquisite race as it is represented by the numerous blue species, some of which are of almost transcendent beauty. But those who know it need not expect to find in *Gentiana lutea* a yellow-flowered companion to our *Gentianella*, *G. acaulis*, or to that newer and delightful introduction, *G. Farreri*. On the contrary, it finds its claims upon the gardener by its nobility of mien and the boldness of its corrugated foliage rather than the brightness of its yellow flowers, which some call "golden," but do not always come up to that description, being duller in hue. In the garden it is possible that we have not made enough of *G. lutea*. It would appear to be a flower which ought to be planted in bold masses, with the plants not too close together, so as to show their true attractions. A wild garden would seem to afford scope for a plant like this, especially if planted in good, strong, rich soil, where it might reach its full stature of 3 to 4 feet and carry its clusters of starchy, yellow flowers. In cultivation in the border it is not always so free-flowering as it should be. *S. Arnett.*

## SOCIETIES.

### ROYAL SCOTTISH ARBORICULTURAL.

THE annual business meeting of this society was held at 5, St. Andrew Square, Edinburgh, on January 20th. His Grace the Duke of Atholl, K.T., president, occupied the chair, and among others present were Lord Lovat, chairman of the Forestry Commission; Viscount Novar, honorary secretary of the society; Sir John Stirling Maxwell, one of the Forestry Commissioners; and Mr. John Sutherland, Assistant Forestry Commissioner for Scotland.

The report by the council stated that the net increase of membership for the year was 42, and that the total membership was now 1,724. The statement of accounts showed a balance of £152 8s. 2d. over expenditure, making, with a balance of £45 7s. 3d. at the credit of the capital account (of uninvested funds), and £175 2s. 4d. at the credit of the Education Fund, a total balance at the close of the accounts of £372 17s. 9d. The total invested funds amounted to £2,212 2s. 3d.

The following office-bearers were elected:—President, Duke of Atholl, K.T. (re-elected); Vice-President, Mr. A. Spiers, Edinburgh; Councillors, Messrs. J. H. Milne-Home, Jas. F. Hardie, David Keir, Wm. Leven, and Peter Leslie, B.Sc. Mr. Robert Galloway, S.S.C., was re-elected Secretary and Treasurer, and the various honorary officials were also re-elected.

Various topics were discussed, including the adverse influence of high railway rates on home-grown timber; the society's essay competition by pupils in rural schools on forestry subjects, in which no fewer than 1,359 essays were sent in, and for which 26 prizes and 307 certificates were awarded; and the Government grants for forestry in connection with the relief of unemployment.

At the close of the business a discussion was initiated by Mr. G. U. Macdonald, Haystack, Peebles, on "Economic Planting," in which Lord Lovat stated that investigation had showed that 4½ ft. seemed to be a reasonable planting

distance for Scotch Pine, while this might be extended to 5½ ft. in the case of Larch and 6 ft. in the case of Douglas Fir.

### ROYAL CALEDONIAN HORTICULTURAL.

THE annual general meeting of this society (with which is now incorporated the Scottish Horticultural Association) was held at Dowell's Rooms, George Street, Edinburgh, on January 11th. Mr. David King, the president, occupied the chair.

The report by the council stated that the first year's working of the combined societies had been successful, and that the monthly meetings were well attended. The scheme for the institution of Certificates in Horticulture for practical gardeners had been completed and the first examination fixed for April next.

The financial statement showed that the balance of revenue over expenditure was £6 10s. 9d., and that the increase in the funds for the year was £242 12s. 8d.

The Duke of Atholl, K.T., was elected honorary president; Mr. David King was re-elected president, and the following were elected to the other vacancies:—Vice-president, Mr. W. J. Thomson; Councillors, Messrs. W. Lamont, J. H. Alexander, and Robert Fife.

### BRITISH FLORISTS' FEDERATION.

THE plague of influenza was responsible in some measure for the comparatively small attendance at the fifth Annual General Meeting of the British Florists' Federation, held at the Connaught Rooms, Great Queen Street, W.C., on Wednesday, the 18th inst. Fortunately, the room in which the meeting was held was an extremely pleasant one.

The minutes of the previous Annual General Meeting having been read and signed, correspondence was read, which was chiefly in the nature of regrets from members unable to be present.

The Report of the Committee for the year 1921 and the Financial Statement were then presented. In the former, reference was made to the new offices of the Federation at the offices of *The Gardeners' Chronicle*; to the opening of the new home of the Chamber of Horticulture at Bedford Square, in which event the Federation took a notable part; to co-operative advertising, in which, apparently, retail florists are not willing to join with the growers and salesmen; to growers' difficulties, especially with reference to *Lygus pratensis*, a pest that does a great deal of harm to *Chrysanthemums*, and which is being investigated on behalf of the members; to salesmen's problems, with special reference to the French flower trade; and to traders' troubles, notably the disabilities under which members suffer in connection with the transport of pot plants by passenger train, and concerning which Mr. F. W. Ladds and other members are working continuously to secure better terms. The Statement of Accounts showed a turnover of £337 16s. 11d., with an income from subscriptions of just over £250, and £43 derived from advertisements in the *Florists' Bulletin*. A cash balance of £6 17s. 1d. is carried forward.

Mr. Alfred W. White, the president, who occupied the chair, moved the adoption of the Report and Financial Statement, and referred briefly to the principal items therein, pointing out that there had been some slight falling off in membership during the year, owing, probably, to the fact that no great difficulties had arisen, but he expected that, as soon as a difficulty arose, wherein the assistance of the Federation was needed, there would be an increase of members. The Federation was working in close and happy relationship with other bodies of similar character, and a large amount of useful work was being done in a quiet way. The motion was seconded by Mr. John Collingridge and carried.

A vote of thanks to the Officers and Committee for their services during the past year was accorded on the motion of Messrs. R. Coryton and Mr. A. Bird. Mr. W. E. Wallace

proposed the re-election of Mr. A. W. White as President. This was seconded by Mr. W. A. Cull; both proposer and seconder paid high tribute to the services Mr. White had rendered to the Federation. Mr. White was unanimously re-elected, and suitably acknowledged the honour conferred upon him. All the retiring members of committee were re-elected on the proposal of Mr. G. Shawyer, seconded by Mr. W. Robins, and on the motion of Mr. D. Ingamells and Mr. George Shawyer, Messrs. Cobley, Kay and Co were re-elected honorary auditors.

At the close of the formal business several members referred to the rumours concerning the proposal of the Covent Garden Estate Company to raise the rents of the stands in the Flower Market. At the invitation of Mr. White, the Secretary, Mr. C. H. Curtis, referred to this matter, and stated that it was already being dealt with, and that a meeting of all the stand-holders would be called to consider the proposal and, if desirable, to consider counter proposals. Mr. G. Shawyer referred to the inspection restrictions upon bulbs imported from Holland, and thought that bulbs for forcing might be exempted from the conditions now imposed. This matter was referred to the Bulb Committee.

Later in the evening, members and friends, including ladies, dined together at the Connaught Rooms under the presidency of Mr. Alfred W. White. The tables were pleasingly decorated with Carnations, Tulips, and Narcissus, provided by several of the members, and a capital programme of music was carried out under the direction of Mr. A. Bird, who also contributed several items. Speeches were few and brief, the only toasts being those of "The King," "Success to the British Florists' Federation," "The Ladies," and "Flowers and Florists." In addition to the President, the chief speakers were Mrs. A. W. White, Mr. George Monro, Mr. J. Collingridge, Mr. W. G. Innes, and Mr. D. Ingamells.

#### ROYAL HORTICULTURAL Scientific Committee.

JANUARY 17, 1922.—*Arbutus Unedo* in Flower.—MR. MARSDEN JONES showed a flowering branch of *Arbutus Unedo* and a variety (?) with very narrow leaves.

*Begonia Gloire de Lorraine Damaged*.—Plants of this *Begonia* were received with the foliage badly disfigured through the attacks of thrips, especially evident along the veins.

*Winged Seeds of Lilies*.—Seeds of *Lilium* × sulphurgale were exhibited to show the wing which is not found in *L. regale* itself.

#### Obituary.

W. H. Bavin.—Many gardeners in the southern counties will regret to learn of the death of Mr. W. H. Bavin, who passed away on Sunday, the 15th inst., after a prolonged illness. Mr. Bavin had represented Messrs. William Cutbush and Son for a long number of years, and was well known in the horticultural world, and especially at Tonbridge, where he lived. He was held in high esteem by all who knew him, and the deepest sympathy is being extended to Mrs. Bavin and her two sons in the great loss they have sustained.

#### REPLY.

##### BULBIL PRODUCING BEGONIAS.

IN reply to *Coombe*, bulbils are produced in the axils of the leaves of *Begonia discolor*, preferably called *B. Evansiana*. These bulbils are produced at, or soon after, the time of flowering, that is, when growth is checked. As a bud-producing *Begonia*, the most extraordinary species is *B. phyllomanica*, which at all seasons produces buds on the stem, leaf stalk and leaf surface. *Coombe* would probably be

interested in the root stock of *Begonia socotrana*, which is quite unique, although it does not perhaps come under the terms of his inquiry; trusting to recollection, I think it may best be described as a cluster of scaly buds—bubils, in a broad sense of the word. R. I. L.

##### ABSTRACT PUBLISHED LAST MONTH

- Sterilising Soil.—Patent No. 163710.  
A process and apparatus for sterilising soil by steam pressure has been invented by Mr. T. R. Bean, of Northland Vale, Guernsey.

Soil and other substances are sterilised by subjecting them to a temperature above 212° F. by means of steam exerting a pressure above atmospheric pressure. The apparatus comprises a tapered receptacle mounted on trunnions and adapted to be tipped to discharge the contents; the lower end of the receptacle is provided with a fire-box and a water container having a steam space communicating with the soil container by one or more perforated pipes. The cover of the receptacle rests on a rubber band, and is secured by screw clamps. It may be lifted by means of a winding drum and a chain. The apparatus is mounted on a wheeled frame and is provided with a mud-hole and chimney, and means for preventing it from swinging in such a way as to tip the fire out. In a stationary form of the apparatus, steam is supplied to the soil-container from a detached boiler.

This list is specially compiled for *The Gardeners' Chronicle* by Messrs. Rayner and Co., Registered Patent Agents, of 5, Chancery Lane, London, from whom all information relating to Patents, Trade Marks, and Designs, can be obtained gratuitously.

Messrs. Rayner and Co. will obtain printed copies of the published specifications and forward them post free for the sum of 1s each.

#### ANSWERS TO CORRESPONDENTS.

CORRECTION: Mr. P. R. Murton writes asking us to state that his new appointment (see p. XIII. January 21) is at Carclew and not Carslew, as printed.

CHRYSANTHEMUM RAYONNANTE AND ITS SPORTS: A. II. There is already one sport of *Chrysanthemum Rayonnante* on the market, and apparently it is very similar to, if not identical with, the one you have obtained. The sport referred to goes under the two slightly dissimilar names of Mrs. Guy Harewood and Miss Gina Harewood, and it is described as light rosy fawn, which is evidently much the same shade of colour as the pinkish orange of your description. Of this sport there is plenty of stock in this country.

EARLY-FLOWERING CHRYSANTHEMUMS: T. II. Six first-rate early-flowering varieties of *Chrysanthemums* for disbudding, including two white sorts, for cultivation for market, are Sanctity, white; Framfield Early White, white; Cranfordia, yellow; Admirante, bronze;

Betty Spark, pink (September); and Cranford Pink, pink (October). The formula you suggest for use for top dressing *Chrysanthemums* in pots would no doubt be suitable for that purpose, but we strongly recommend you to use a well compounded organic manure unless you are in a very large way of business.

LAPAGERIA ROSEA: H. S., India. A correspondent kindly informs us that you can obtain seeds of *Lapageria rosea* from Mr. S. P. Chatterji, nurseryman, 78, Marcaledanga, Main Road, Calcutta.

NAMES OF PLANTS: A. N. 1. *Abies concolor*; 2. *Quercus Turneri*; 3. *Quercus acuta* var. *bambusaeifolia*; 4. *Osmanthus rotundifolius*; 5. *Osmanthus ilicifolius*.—W. M. B. 1. *Stantonia hexaphylla*; 2. *Vitis striata*; 3. *Escalonia illipita*; 4. *Genista hispanica*; 5. *Viburnum rhytidophyllum*; 6. *Elaeagnus macrophylla*.—W. L. *Billbergia nutans* (Brazil).—G. R. 1. *Cordyline australis lentiginosa*; 2. *Nephrolepis exaltata superba*; 3. *Pteris serrulata cristata*; 4. *Adiantum scutum*; 5. *Pteris cretica albo-lineata*; 6. *Pteris serrulata maxima*; 7. *Adiantum Pacottii*; 8. *Cordyline australis*; 9. *Kentia belmoreana*.—A. J. S. The *Begonia* is *B. President Carnot*. The Orchids are: 1. *Cypripedium Leeanum*; 2. *C. chrysotoxum*; 3. *C. Boxalbi*; 4. *C. Calypso*; 5. *C. venustum*; 6. *C. calophyllum*; 7. *C. insignis*.—F. S., *Gaussenworth*. *Chimonanthus fragrans*.—Lenton Sands. *Pteroma macrantha*.

PLANTS FOR TUFFA OR STONE POCKETS: G. S.

It is rather difficult to state what plants would succeed in the dry corner of your fernery. The moist atmosphere of a fernery would hardly suit Cacti, or any class of succulent plants, as they must have dry atmospheric conditions, especially during the winter. Among Ferns, those most likely to succeed are *Nephrolepis exaltata*, of which there are many fine forms, and they are really not very particular where they grow. You might also try some of the strong-growing forms of *Begonia Rex*. If you have water laid on, you might connect the supply pipe to a perforated pipe at the top of your rockery and thus provide a ready means of watering your plants, more or less, according to the weather and their needs.

RABBITS EATING FRUIT TREE STEMS: S. W. II.

The only satisfactory way of preventing rabbits from "barking" the stems of young fruit trees is to erect a rabbit-proof fence round the orchard. At least 6 inches of the netting should be laid flat on the bottom of a shallow trench all round the orchard, while the fence proper should be a little over 3½ feet high. Wire netting 4 feet wide will serve the purpose, and should be attached to stout posts set not more than 3 yards apart. A point of the utmost importance is that the buried portion of the wire netting should be turned outwards to prevent rabbits from burrowing under the fence. A detailed description of this method of fencing was given in our issue of January 31, 1920 (Vol. LXVII., page 55).

ROMAN CYPRESS: G. The Cypress that is such a great feature of many South European gardens is the Upright Roman Cypress (*Cupressus sempervirens*), and from the description we suspect that this is the species meant. Although it is not commonly met with in this country, there are good examples in certain of the older gardens of the home counties and elsewhere.

SECOND-HAND BOOK: A. C. W. You would most likely be able to procure the work you mention from either Messrs. Wheldon and Wesley, Great Queen Street, W.C., or Messrs. H. Sotheran and Co., 140, Strand, W.C.

WINTER-FLOWERING BEGONIAS: W. W. W. We believe you will be able to obtain plants of the various winter-flowering *Begonias* from Messrs. Stuart Low and Co., Enfield, Middlesex, or Messrs. Clibrans, Altrincham.

**The Fellowship of the National Institute of Agricultural Botany.**

The Council of the National Institute of Agricultural Botany has taken a wise step in establishing a system of Fellowship whereby all who are in sympathy with the aims of the Institute may, on certain conditions, become Fellows and take a part in

promoting its work. The conditions of Fellowship are set forth in a brochure issued by the N.I.A.B., containing a brief summary of the aims and activities of the Institute. The aims are, succinctly stated, the improvement of yield and quality of farm crops and the present work of the N.I.A.B. consists of three branches. One, devoted to crop improvement, provides facilities for the introduction and field-testing of new varieties of agricultural plants. Another consists in the official seed Testing Station, and the third is concerned with the carrying out on behalf of the Ministry of Agriculture of the Potato immunity trials at Ormskirk, the object of which is to ascertain which varieties, and particularly which new varieties of Potato, are resistant to Wart Disease. This immunity-testing work, long conducted with marked benefit to Potato growers by the Ministry, has now been extended and includes maturity trials and the investigation of synonyms. Horticulturists need no convincing as to the importance of all these branches of the Institute's work. They are aware that there is no finality to the improvement of varieties, and they are also aware that, of new varieties put on the market, many are called but few are chosen. In the case of Potatoes, it is well that new varieties should be ex-

amined by drastic tests at the time of their introduction as to their immunity from or susceptibility to Wart Disease, and it is no less important that the place of each new variety in the Potato world—whether early, mid-season or late—should be determined, for in the case of "earlies," at all events, a difference of days in the time of maturing is of decisive importance in determining the use of a variety for market purposes. The National Institute proposes to keep its Fellows in touch with the work which it is doing at Cambridge and at Ormskirk, both by means of periodical meetings, at which the work of the Institute will be described and discussed, and by appointing to the Council representatives of the Fellows. Although the Fellowship scheme has but recently been launched it has already met with a wide response. The first Fellow to be enrolled was the Prime Minister, who, in a letter to the Chairman of Council, Sir Lawrence Weaver (see p. 26), expressed his whole-hearted sympathy with the objects of the Institute and his earnest hope for the full attainment of those objects. The terms of Fellowship are such as should, and, we are sure, will secure a large membership. The annual Fellow's subscription is one guinea—with an entrance fee of one guinea—and candidates may either become annual Fellows, or by a limited composition of seven guineas may enjoy ten years of Fellowship or become life Fellows by payment of a subscription of fifteen guineas. The excellence of the work already done by the Institute is an earnest of the success which will attend its efforts, and that success, needless to say, will be hastened and enhanced if, as is to be hoped, a numerous body of Fellows comes into being. The help which they will give is both moral and financial. Every guinea subscribed by a Fellow will be the means of ensuring the Institute a larger measure of financial aid from the Development Commission and, moreover, every Fellow, by taking an active interest in the work done by the Institute, helps in a very real manner to make that work more effective, for a science remote from the general life and affairs of a people is a sterile science, but one which is part of their life and enters into their affairs is fertile and twice blessed—blessing him that gives and him that takes.

**Imperial Fruit Show.**—An Imperial Fruit Show will be held this year at the Crystal Palace on approximately the same dates as last year's show. There will be a United Kingdom section, an Overseas section, and a British Empire section, and it is expected that tropical and sub-tropical fruits will be displayed, in addition to Apples and Pears. Matters relating to finance and organisation will be left entirely to the staff of the *Daily Mail*, while technical matters will be decided by a Trades' Committee. The decision to hold this show was made at a meeting of the Imperial Fruit Show Advisory Committee held at the Ministry of Agriculture.

**National Chrysanthemum Society.**—The annual general meeting of the members of the National Chrysanthemum Society will be held in the Floral Committee Room of the Royal Horticultural Hall, Vincent Square, Westminster, S.W., at 6.30 p.m. on Monday, February 6, when the report of the committee and the statement of accounts for 1921 will be presented and officers elected.

**A New *Gladiolus* from S. Africa.**—Mr. A. E. Kunderd, the well-known American *Gladiolus* specialist and former President of the American *Gladiolus* Society, in a paper on the *Gladiolus* read to the Wisconsin State Horticultural Society, on December 15, referred to a new species of *Gladiolus* received from his brother-in-law, Dr. Hall, in South Africa. He did not

disclose the name, but described the plant as having tall, slender and graceful foliage and stems. It bore on the main stem upwards of forty blossoms, and four of its branches developed more than thirty blossoms each, so that the plant produced about 175 individual flowers. Mr. Kunderd described the work of the Canadian raiser Groff as monumental, and he paid a tribute to such pioneers as Lemoine, Childs and Max Leichtlin. Mr. Kunderd is himself a successful raiser of *Gladioli*, and commenced hybridising this flower about 35 years ago.

**The Royal Gardeners' Orphan Fund.**—The annual general meeting of the subscribers to this Fund will be held at "Simpson's," 100, Strand, London, W.C., on Thursday, February 9, 1922, for the purpose of receiving the report of the Committee and Statement of Accounts for the past year; to elect officers for the ensuing year; to elect four children to the benefits of the Fund; and to transact such other business as may arise. The chair will be taken at four p.m.

**Food Exhibition at Olympia.**—The International Trade Exhibitions, Ltd., and The Trades Markets and Exhibitions, Ltd., are combining to organise a great food exhibition, to be held at Olympia from September 6 to 26 this year. This exhibition should provide a most fascinating object-lesson with regard to the sources from which our principal food supplies are derived. We understand that many foreign Governments propose to make large displays at the exhibition. Vegetable products will occupy a large area, but all other kinds of food materials will be exhibited.

**Spraying Trees from an Aeroplane.**—The *American Florist* records the spraying of fruit trees in America from an aeroplane. The experiment was conducted by the Ohio Department of Agriculture in co-operation with an airman of the United States Army, who fastened a container filled with arsenate of lead to the side of his machine, and, arising to the proper altitude on the windward side of a badly infected orchard, released the powder with such effect that the insects were all killed. The operation from the time of releasing the powder until landing lasted only 51 seconds. In America, where Apple orchards are of very great extent, it is anticipated that an extensive use of this method of spraying will be adopted by growers.

**Temporary War Buildings in London's Parks and Open Spaces.**—We are very pleased to notice that at last a decided clearance is being made of some of the war-time huts in the London parks and open spaces. The beautiful Embankment Gardens were almost entirely covered with temporary buildings, which are now in process of removal, and the site will probably be cleared in about three weeks time. The huts in Tower Gardens, Millbank, have also been taken down, and it is expected that the ground there will be completely cleared at the end of next week. The Admiralty huts in St. James's Park will take about four or five weeks to remove, and the demolition of the Passport Office, in that Park, commenced on Tuesday last. Several of the store huts in Regent's Park have also been demolished, and the ground cleared. It is to be hoped that all these eyesores in London's most beautiful spots will be removed at the earliest opportunity, and the grounds restored to their legitimate purpose of pleasure and recreation.

**A Canadian Impression of the Imperial Fruit Show.**—The *Canadian Horticulturist* makes adverse observations on the judging at the Imperial Fruit Show, held at the Crystal Palace in October, 1921, and published an illustration of three of the twenty boxes of Newton Wonder Apples staged by the Spalding and District Bulb Growers' and Market Gardeners' Association, that won the first prize in the culinary class of the British Empire section. Our Canadian contemporary states that the fruits were not graded uniformly, there being Apples on the faces of the boxes ranging in diameter from 5 1/2 to 5 3/4 inches. "The packing was decidedly amateur-

ish, rather than commercial, many boxes having a solid layer of three rows across on the faces and four rows in the tiers beneath." It is recognised by the critic that the judges had a difficult task on account of the high standard of excellence of the exhibits in general, and he excuses them because they were not familiar with the ideal box pack, but states that some of their decisions would be impossible at an Apple show in Canada or in the United States. The writer claims that the boxes were not of the standard required and that the twenty boxes that won the principal awards were 20 by 11 by 10 inches and not 18 by 11½ by 10½, as required. The criticism is further made that by the system of packing adopted, the Apples would not "carry safely." The critic, however, was much impressed with the good quality of the Newton Wonder Apples, and with their well-grown appearance. Remarkings on the exhibits in the overseas section, he states that the second prize exhibit for King of the Pippins lost the first place because the quality was "too good" that is, too highly coloured, and blames the judges for misinterpreting the Canadian Fruit Marks Act, both in regard to this and other varieties. The criticisms are made by a well-known Canadian expert who, it is stated, on three occasions won the sweepstake prize at the New York State's show for the best box of Apples grown in America.

**A Late-fruiting Blackberry.**—Mr. W. Crisp, of 22, Pretoria Road, Halstead, records in a letter to *The Field* the discovery of a late-fruiting Blackberry during a country walk on November 15. He was enabled to gather 10½ lbs. of fruit, and could have obtained more had he the time to gather them. To quote from the letter, the berries "were red, like a Raspberry, and they make quite excellent jam, the flavour being like that of the Loganberry. It is a great bearer of fruit in long bunches and a strong grower. It comes in about six weeks after the ordinary Blackberries, and when all soft fruits are over. It would pay to plant in woods both for fruit and for game cover. It also produces abundant food for pheasants, and will keep them in the wood at a time when they are given to wander far afield for acorns." It is to be hoped that Mr. Crisp will take measures to secure suckers from such a valuable wilding in order that the plant may be propagated and distributed; it should prove specially valuable for purposes of hybridising and raising a race of late-fruiting Brambles. There is just a possibility, however, that the fruits were a second crop that found the season exceptionally favourable for them to ripen, for it is well known that the early blossoms of Brambles are sometimes all sterile and that the plants are then enabled to develop secondary growths which flower later in the same season.

**Allotments.**—The report of the Departmental Committee appointed by the Ministry of Agriculture and Fisheries and the Secretary for Scotland, to investigate the present position as regards provision by local authorities of allotments in Great Britain has been issued, and may be obtained at His Majesty's Stationery Office, Imperial House, Kingsway, W.C., price 7d. post free. The report has been compiled on the evidence of various societies, organisations, and authorities connected with the allotment movement, which apparently originated in the nineteenth century at the time of the development of the industrial system and the growth of towns. The greatest number of allotments under cultivation was in 1918, when they totalled 42,277, representing an acreage of 2,551, but the 41,756 allotments in 1919 represented a slightly larger acreage, namely, 2,641 acres. The chief recommendations of the Committee are that local authorities should purchase land for allotments wherever practicable; that schemes under the housing and town planning acts should provide for the preservation of sites for allotments; that loans for the purchase of lands for allotments should be excluded from the debt of local authorities; that county councils should be empowered to let land direct for allotments; that co-operative allotment associations should be empowered to obtain loans for

the purchase of land from the Public Works Loan Commissioners; that the principle of State assistance in the encouragement and development of the provisions of allotments already conceded in Scotland should be extended to England and Wales; that six months' notice should be required to terminate a vacancy, and that where less than six months' notice is given, the tenant should be compensated for his crops and unexhausted manures. We hope to refer in more detail to the report in a subsequent issue.

**Mr. H. Markham.**—The genial head over the Earl of Strathford's gardens at Wrotham Park, Barnet, has had a wide and varied experience, consequently he is well known to gardeners in many parts of England and Wales, while his eminently practical gardening notes, which have appeared in our pages over a long period of years, have extended his reputation. In his earlier years he was employed in the gardens at Hornsea House, Hull; Ivy Bank, Burnley; Bodrhyddan, North Wales; Burgbley House, Stamford; and Longford Castle, Salisbury. After serving several years under the late Mr. Richard Gilbert, at Burghley, Mr. Markham was sent by that famous gardener to Longford Castle, where he remained three years under the late Mr. H. W. Ward. It was on the recommendation of Mr. Gilbert and Mr. Ward

MR. H. MARKHAM.

that Mr. Markham took over the charge of Mereworth Castle Gardens, where Lord Falmonth at that time took a great interest in choice fruits, especially Peaches and Nectarines, and gave Mr. Markham every encouragement to acquire a collection and produce large crops of fine fruits. Thirteen years later, there was a general agreement among those best qualified to give it that the Peach and Nectarine trees at Mereworth were among the finest trained specimens to be found in this country. From Mereworth Mr. Markham went to Wrotham Park, Barnet, where he makes a special feature of fruit culture, but also keeps the other departments of the garden in first-rate condition. He is proud to have charge of the old vines planted at Wrotham by the late Mr. William Thompson in 1848-9, as well as the ancient specimen of Black Hamburgh planted in 1785, said to have been from a stock originally received from Holland in 1710, and from which Mr. Markham cut and exhibited fine bunches in September, 1921 (see p. 141, *Gard. Chron.*, September 10, 1921). Mr. Markham has for many years been a member of the Royal Horticultural Society's Fruit and Vegetable Committee. Apart from business matters, Mr.

Markham is a musician of no mean order and a delightful raconteur.

**Potato K. of K.**—In view of the fact that other Potatoes have been sold under the name of this variety, the Ministry of Agriculture directs the attention of sellers of seed Potatoes to the description of the variety of late or main crop Potato known as "K. of K.," which is as follows:—"Shape, oval; eyes, shallow; skin, white, splashed crimson, more pronounced round eyes, especially at rose end; flesh, pale yellow; colour of sprout, rose; haulm, upright; foliage, light green with small corrugated leaves; flowers, mauve in colour, tipped with white. The variety does not flower freely." This description has been approved and recognised by the Ministry. The variety is immune to Wart Disease. Growers and dealers who sell Potatoes of a different variety under the name "K. of K." are liable to a penalty under the Seeds Act, 1920.

**New Secretary of the National Dahlia Society.**—At the annual meeting of the National Dahlia Society, held in the Royal Horticultural Hall on Tuesday last, Mr. A. C. Bartlett was appointed hon. secretary in succession to Mr. Gerald Hillier, who was accorded a hearty vote of thanks for his services during the past year. Mr. Bartlett is well known in the horticultural world both as a writer on gardening and a skilful cultivator of plants.

**Accident to Mr. E. M. Holmes.**—The numerous gardening friends of Mr. Edward Morell Holmes, for many years Curator to the Pharmaceutical Society's Museums, Bloomsbury Square, will be sorry to learn that he has met with a serious accident, necessitating the amputation of a leg. The injuries were received as the result of a motor accident, and, following an action in the King's Bench Division, Mr. Justice Salter has awarded Mr. Holmes £1,000 damages, with costs. Mr. Holmes is a recognised authority on medicinal plants, and the results of his experiments in their cultural requirements have been published in *The Gardeners' Chronicle* and other journals from time to time. In 1915 Mr. Holmes was awarded the Hanbury Medal, which was first struck in 1881 to perpetuate the memory of Daniel Hanbury, the eminent pharmacognosist.

**Appointments for the Ensuing Week.**—Monday, February 6: National Chrysanthemum Society's annual meeting at R.H.S. Hall. Tuesday, February 7: Royal Caledonian Horticultural Society's meeting; Bournemouth Gardeners' Mutual Improvement Association's meeting. Wednesday, February 8: East Anglian Horticultural Society's Meeting; Sheffield Chrysanthemum Society's meeting; Wimbledon and District Gardeners' Society's meeting. Thursday, February 9: Bristol and District Gardeners' Association's meeting; Hornsey and District Chrysanthemum Society's meeting; Royal Gardeners' Orphan Fund annual meeting and election at Simpsons, 100, Strand, W.C., at 4 p.m. Friday, February 10: Paisley Florists' Society's meeting; Royal Horticultural and Arboricultural Society's Council meeting. Saturday, February 11.—Ringswood Society's meeting.

**"Gardeners' Chronicle" Seventy-five Years Ago.**—*Double Stocks.*—The cause of the production of double flowers in Stocks seems to be a disputed point. I gave a friend part of some seed of 1843, of my own saving, and I sowed from the same parcel, both in the autumn of 1844 and the spring of 1845; in both seasons the produce was double; but my friend informed me that his flowers were nearly, if not all, single. The soil on which the plants producing single flowers grew was warm, gravelly material; the other was a stiff loam, well worked; this, I imagine, clearly proves that the nature of the soil has great influence in the production of double flowers. In saving the seed, I paid no regard to the parts of the flower, but merely saved some of the single from among double flowers.—*J. L., Deptford, Gard. Chron., January 31, 1846.*

**THE BULB GARDEN.**

**CROCUS AERIUS AND C. VITELLINUS.**

**CROCUS AERIUS** (see Fig. 24) is one of the most lovely of spring-flowering Crocuses and a flower of much beauty in every respect. It is a native of Asia Minor. It often blooms in March, but sometimes earlier, and is one of the species which has secured for itself high favour in the eyes of specialists in these flowers. The bald description that it has "medium-sized flowers of bright lilac or lavender-blue with a yellow throat" fails to convey the lovely shades and gradations of the interior of the flower. It varies a great deal in size and shade, and selected varieties are occasionally offered; the variety *C. aerijs major* is a charming sort. I have heard of a white variety, *C. aerijs albus*, but have never met with it. In my experience *C. aerijs* requires a warm, sheltered, sunny place in light soil, and the corms should be planted from 1½ to 2 inches deep.

In *Crocus vitellinus*, which has for a synonym *Crocus syriacus*, we have a pleasing little *Crocus* which, unfortunately for some of us, blooms from November to March, and is, consequently, liable to fall an easy prey to the vagaries of our winter season. Those who are fortunate enough to possess a garden in an exceptionally mild and equable district may succeed well with it in the open, and the writer can recall flowers of *C. vitellinus* sent him to name which were growing in a garden in an exceptionally mild part of the north-west of England and near the sea. These were blooms culled from large quantities of this *Crocus* planted in the grass and giving great pleasure almost every year in the dead of winter. But to most of us this gratification is denied, and we must content ourselves with sheltering our clumps of *C. vitellinus* which are planted in the garden under a hand-light, cloche, or frame, or, better still, grow them in pots in a cool greenhouse or alpine house, where, screened from the weather, the flowers may expand without fear of untimely destruction. Small though they are, they are very pretty, being bright orange-yellow, with scarlet stigmata to add to their attractions.

The variety *graveolens* is not so acceptable. Its flowers are smaller, and the strong and rather offensive odour, which has given rise to its varietal name of *graveolens*, lessens its value. Its flowers are striped or flushed with black.

*C. vitellinus*, so far as culture is concerned, is as easily grown as any other *Crocus*. Its protection from rough weather is only called for in order that its beauty may be revealed and retained under favourable conditions. *S. Arnott*.

**BRODIAEA HOWELLII.**

ALTHOUGH I greatly prefer September and October for planting the *Brodiaeas*, the work may be done as late as February and March, if the weather is open. The corms, however, require to be kept properly, lest they become partially shrivelled and therefore weakened by being too long out of the soil.

*Brodiaea howellii* is one of the best garden species, and it has been more appreciated through its variety, *B. howellii lilacina*. Both the type and the variety have long leaves and scapes about 12 to 18 inches tall, and carrying umbels of funnelled flowers, each about half an inch in diameter. Those of the variety *lilacina* are more numerous than those of the type, and often exceed 18 or 20 in number. The flowers of *B. howellii* are of a pretty porcelain white streaked or flushed with blue. Those of *B. howellii lilacina* are delightful in their colouring of delicate lavender-blue or lilac, with the segments of white.

In order to succeed with *B. howellii*, it must have an open, light, well-drained soil, that should be made fertile by the addition of decayed manure. A sunny place should be selected for planting, and the surface be kept rather loose, in order to allow the heat of the sun to penetrate the ground. Two to three inches is a suitable depth at which to plant. *A*

**ORCHID NOTES AND GLEANINGS.**

**NEW CYPRIPEDIUMS.**

**CLIVE COOKSON, Esq., Nether Warden, Hexham** (gr. Mr. W. J. Stables) sends flowers of four handsome *Cypripediums*, two of which are new crosses.

*C. Carina* (*Leeaunum Clinkaberryanum* × *Villma*) is a large flower with white dorsal sepal having a broad claret band up the middle and some small rose lines, the petals and lip being pale yellow tinged with red-brown.

*C. Griqua* (*Graceae* var. *J. W. H. Page* × *Lawrenceanum*) has a white dorsal sepal tinged with rose, the large lip being light brownish rose.

*C. Bantam*, *Cookson's* variety (*Hera Emyades* New Hall Hey var. × *C. nitens* *Drewett's* variety) is a model flower with white dorsal sepal bearing large claret-crimson blotches ascending from a small, emerald-green base, the broad petals and lip, with shining surface, being dark chestnut red.

*C. Georgius Rex* var. (*Minos Youngii* × *Alciades illustre*) resembles a large form of *C. Minos Youngii* in a great degree.

**SOPHRO-LAELIO-CATTELEYA EILEEN.**

**MESSRS. STUART LOW AND CO., Bush Hill Park, Enfield, and Jarvisbrook, Sussex**, send the first flower of a finely formed and brightly coloured cross between *Cattleya Moira* (*Fabia* × *Mantini*) and *Sophro-Laelio heatonensis* (*L. purpurata* × *S. grandiflora*). All the segments are broad, of firm substance, and flatly arranged, the petals especially being broader than long.

The sepals of *S.-L.-C. Eileen* are purplish rose; the petals tinged with violet on white ground on the inner halves, the outer parts dark red with a gold shade, the blending of the colours having a glowing effect. The lip is ruby-crimson with a reddish orange base; the column fleshy, pure white. The flower, it is said, was taken from a very small plant, which, when matured, will probably give a still more remarkable bloom.

FIG. 24.—CROCUS AERIUS; FLOWERS LILAC-PURPLE.

## The Week's Work.

### THE ORCHID HOUSES.

By J. T. BARBER, Gardener to His Grace the DUKE OF MARLBOROUGH, K.G., Blenheim Palace, Woodstock, Oxon.

**Odontoglossum.**—The various members of the genus *Odontoglossum* will now be in all stages of growth; some just starting, others in full growth, whilst many are sending up their flower spikes. The latter should be carefully and neatly staked as they attain sufficient length. Flowering plants are best placed by themselves in the lightest position in the house, where they may be examined from time to time for the presence of slugs, which devour the spikes and do irreparable harm. Full exposure to the light, combined with moderate heat, is a great assistance in the development of flowers. Small or weakly plants should have their spikes removed as soon as they are observed, as the production of flowers may mean the death of the plant.

FIG. 25.—POTATO KATIE GLOVER (SEE P. 53).

Weakly, unhealthy plants are very precocious in the production of flower spikes, which, if allowed to develop, never produce satisfactory flowers. Should any plant be in need of fresh rooting material, and its new growth in the desired condition, that is some few inches long, and about to send out fresh roots, it may be repotted. The condition of all Orchids that need repotting should be closely studied, for if the work is done when the plants are about to make roots, they will receive only a very slight check. It is much easier to keep a healthy plant growing than it is to nurse an unhealthy plant back to a vigorous condition again. Most plants appreciate fresh material, especially at the season when they are developing fresh roots. A compost consisting of equal portions of peat fibre, and A1 fibre of a soft nature, with *Sphagnum*-moss, to which some broken leaves may be added, will be found suitable for *Odontoglossum*. Newly-potted plants need to be watered with extreme care at this season, as the plants will not produce fresh roots in a saturated compost.

### HARDY FRUIT GARDEN.

By H. MARSHAM, Gardener to the EARL OF STRAFFORD, Wrotham Park, Barnet.

**Apricots.**—As Apricot trees bloom early, the pruning and regulating of the branches should be done before the buds are far advanced. If the trees were given proper cultural attention last summer very little pruning will now be required, beyond shortening fore-right shoots and stopping young branches that are needed to fill bare spaces or to replace unsuitable branches, etc. Examine the ties and remove any that are faulty, using fresh ones where needed, allowing ample space for the swelling of the bark during the coming season. Young trees that made rather strong growths last year will need to have these shortened to ripened wood, and the suitable shoots for filling bare spaces and building up a goodly shaped tree carefully secured to the wall or trellis, as desired. Top dress the roots of older, fruiting trees, after removing a portion of the top soil, with a mixture of fibrous loam, old brick mortar, and a little well-rotted manure.

**Cordon Apples.**—As cordon Apples are useful for a variety of purposes, such as covering fences, walls, and arches, and usually bear good crops of fruits early, they should be planted

### PLANTS UNDER GLASS

By T. PATEMAN, Gardener to Sir C. NALL-CAIN, Bart The Node, Codicote, Welwyn, Hertfordshire.

**Cineraria.**—A batch of the earliest plants may be brought in from the frames and placed in an intermediate house; by treating the plants in this way a long succession of bloom may be obtained. The leaf-mining maggot is sometimes troublesome, but occasional spraying with a nicotine emulsion will do much to prevent the appearance of this pest and also keep green fly in check. A little soluble plant food mixed in the water about every tenth day will be found very beneficial for feeding the roots at this stage of growth.

**Allamanda.**—These climbing plants should be cut hard back without further delay. Where they are grown in pots, they should be re-potted into larger receptacles if this appears desirable, or a portion of the surface soil may be removed and new material added. Allamandas may be trained on wires, and will be found to make fine specimen plants during the summer months. Cuttings may be inserted now in sandy soil in a fairly high temperature, when they will soon root.

**The Conservatory.**—Every effort should be made to keep the conservatory as bright as possible. Fresh batches of various kinds of bulbs and Azaleas should be brought on in the forcing quarters, so as to maintain the display. These subjects, with *Cyclamen* and *Primula*, will give a pleasing effect. Watering must be done carefully at this period.

**Ferns.**—At this season of the year Ferns are generally in a dormant state, and may safely be potted into larger receptacles. Where good turfy loam is available for this work, a mixture of equal parts loam and peat, with clean, finely broken crocks, and silver sand added to assist good drainage, will form a very suitable compost for most kinds and varieties of Ferns.

### THE FLOWER GARDEN.

By EDWIN BECKETT, Gardener to the Hon. VEARY GRASS, Aldenham House, Hertfordshire.

**Lawns and Drives.**—As they form important adjuncts to the pleasure grounds and gardens lawns and carriage drives should be kept thoroughly clean and tidy, and rolled on all suitable occasions. New walks should be prepared at this time of the year, and grass verges trimmed where necessary. Clean, well-rolled drives and walks add greatly to the appearance of a well-kept garden.

**East Lothian Stocks.**—To provide beds of these lovely, sweet-scented, early flowering plants, the seeds should now be sown in heat and the young plants pricked off into boxes. Great care should be exercised when watering these plants, and they should not be sprinkled overhead, as this would cause the plants to rot off at the base. Autumn-sown plants that are being wintered in cold frames should also be protected from an excess of moisture for the same reason. They are fairly hardy subjects, and it will not harm them if a little frost delays their progress. Sharp frost may harm them, but a few degrees will be beneficial.

**Sweet Peas.**—Modern practice tends to the raising of Sweet Peas in pots during the autumn and wintering them in cold frames. This is not, however, practicable everywhere, and where plants are required for early flowering seedlings should be raised in gentle heat, so that they will be ready for planting out in April. Sixty-sized pots should be employed, and filled with a good, sandy compost. Sow three seeds in each pot, and thrust the seeds down into the soil to a depth of about  $\frac{1}{2}$  to  $\frac{3}{4}$  inch. A temperature of about 60° will secure rapid germination. When the seedlings are well through, place them in cold frames, after hardening off, and protect them from frost during severe weather. At a later stage, when they have become well hardened, afford ample ventilation when the weather is suitable, but steps should be taken to protect the young plants by means of netting, when the frames are open, as birds are very partial to them. Guard also against damage by mice.

freely. The borders should be thoroughly prepared and the drainage made good, especially where the soil is of a heavy nature and resting on a great depth of clay. Either single or double upright cordons will quickly make useful fruiting trees, and may be used for filling bare spaces on walls or fences. Plant at a sufficient distance from the wall to allow ample space for the thickening of the stems as the trees increase in size. The following is a select list of useful dessert Apples that will give a supply of excellent fruits over a long period: Ellison's Orange, Cox's Orange Pippin, Egremont Russet, Allington Pippin, Maidstone Favourite, Ribston Pippin, Wyken Pippin, Duke of Devonshire, May Queen, and Adams's Pearmain.

**Espalier Pears.**—When pruning these trees thin out the old spurs where they are crowded in order to encourage strong and fruitful buds to develop all along the branches. Timely attention in this respect will greatly improve both the fruitfulness of the trees and the size and quality of the fruits.

## FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

**The Orchard House.**—A few trees of such varieties as Cardinal and Early Rivers' Nectarines, with Duke of York, James Walker, and Duchess of Cornwall Peaches, will have been started. Another batch of these trees should now be introduced to gentle warmth, with a few Peregrine Peaches in addition. Select well-rooted trees in moderate-sized pots, trees with short-jointed wood, full of buds. Allow plenty of time for the plants to develop slowly in a moderate temperature of 43° to 48°. Encourage the trees to grow as much as possible during the daytime when sun heat is available, as little or no fire heat will be necessary, except in severe weather. Plunge the pots, where this is possible, and renovate the fermenting material in the earlier houses, as recommended for pot vines.

**Cucumbers.**—Plants raised from seed sown as recommended in a previous calendar will now be ready for planting out. See that the pits are clean, and make up a bed of leaves and litter, on which place small mounds of soil, about four feet apart, composed of two parts loam and one part each of old Mushroom-bed manure and leaf-mould. Set out the plants as soon as ready, when the mounds have become warmed through. Maintain a humid atmosphere by lightly syringing the plants and damping the paths and other surfaces. Let the temperature remain at present similar to that recommended on p. 28 in the issue of January 21.

**Melons.**—Although the weather has been fairly mild, it has been almost sunless, and young plants are consequently weak, no matter how suitable the houses or pits. A few more seeds should be sown to raise a batch of plants that may have to take the places of those which persist in remaining weak. These new plants, when once they root freely, make rapid progress as the days lengthen.

## THE KITCHEN GARDEN.

By JAMES E. HATHAWAY, Gardener to JOHN BRENNAN, Esq., Baldersby Park, Thirsk, Yorkshire.

**Mustard and Cress.**—Sowings of these salad plants should be made once a fortnight in shallow boxes. The seed should be sown on a flat soil surface without any covering. When a crop has been cut it is not necessary to empty the box; if the surface is skimmed off and a little fresh soil added another sowing may be made at once. Young Onions for salad use may be raised in a similar manner.

**Mint.**—Roots should be lifted and placed in boxes eight to ten inches deep; the roots can be cut out in squares the size of the box, dropped in and slightly covered with soil; if placed in a temperature of 60° a supply of fresh Mint will be forthcoming.

**Seakale.**—To obtain supplies of Seakale over a long period, roots should be introduced into warmth every fortnight. A Mushroom house is a suitable place for forcing Seakale, also underneath plant stages where the light can be excluded. The roots should be well moistened with the syringe twice a day. A temperature of 50° to 55° is sufficient, for in a higher temperature the growth develops weakly. In taking up the crowns save the smaller roots for propagating; these should be cut in lengths of 6 inches and placed in boxes filled with soil just sufficient to cover them, and placed in a cold frame. These prepared roots will be ready for planting in the open in April.

**Seakale in the Open.**—Plants in beds in the open may have pots placed over them, and if the pots are covered with fermenting material good blanched stems will soon be available for use.

**Rhubarb.**—Roots of this vegetable should be regularly introduced to a warm dark place and treated very similarly to Seakale. A stock of crowns should be lifted when the weather is open, so that in frosty weather there will be no difficulty in maintaining a constant supply of leaf stalks.

## POTATOS.

For a number of years past I have presumed to offer, in your columns, some advice regarding the new varieties of Potatos as they were put on the market. To-day there is a slump in Potatos, nevertheless several new varieties are before the public, and are being taken up by keen growers, if not in large quantities yet sufficient to carry out experimental trials. Messrs. Sutton and Sons are offering their new early Dunvegan, which is a white round, immune to wart disease. I was privileged to see it lifted at the Ormskirk trials in July, and its appearance and crop then delighted every one. One of the largest growers present asked Mr. Lasham (Messrs. Sutton's Potato expert): "What price 10 tons, Mr. Lasham?"

Katie Glover (see Fig. 25) is one of Findlay's introductions, and received an Award of Merit at Ormskirk. It is a second early round, of a pinkish colour, and may have a future before it. It will be in the running at Ormskirk this season for a higher award. K. of K. is also one of Findlay's; the tubers somewhat resemble those of Katie Glover, but with a most distinct haulm, producing very many stems of a

Edward and Arran Chief, which are not immune to wart disease, is bound to bring about a new condition of things, and tend to the spread of wart disease, I think. It is up to the growers to help in suppressing any outbreak of wart disease that may occur as a result of this concession.

The Board of Agriculture for Scotland has just published the acreage under each variety of Potato in Scotland in 1921, and it is interesting to note that among earlies Epicure heads the list with over 9,000 acres; Eclipse (including Sir John Llewellyn) is next, and Duke of York (including Midlothian Early) is third, but both these are under 2,000 acres. Sharpe's Express has 887 acres. These are all susceptible to wart disease. Edzell Blue, Dargill Early, and Witch Hill are the immunes, and of these the last is the Potato for the connoisseur. In the second early group Great Scot is easily at the top with 13,196 acres. Mr. Chittenden, Director of the R.H.S. Gardens, at the International Potato Conference in 1921, stated that he considered this the "best all-round Potato." Arran Comrade comes next with 5,607 acres. For garden culture and for exhibi-

FIG. 26.—POTATO DI-VERNON.

rather thin, wiry growth, Katie Glover, on the contrary, having an ideal "top."

Di-Vernon (Findlay) (see Fig. 26) is a thick kidney in shape, splashed with purple at the eyes. My experience of it two years ago was as follows:—I paid Mr. Findlay five guineas for 1 lb. of tubers, which I cut up into single eyes and planted in my private garden. The yield was 56 lb. I was doubtful of its being popular on the early market on account of its colour, but Sir Matthew Wallace and Mr. T. Scarlett assure me if it is early enough the colour splashes will not be prejudicial.

Crusader (the late Dr. Wilson) is a late kidney variety, not unlike a refined Golden Wonder in appearance, which is being distributed widely for the first time this season. Unlike the first two preceding sorts, which cost the purchaser some eight or ten shillings a pound, Crusader may be had for seven or eight shillings a stone—quite a reasonable price for a new Potato.

Rhoderick Dhu (S. T. Farish) is a late round variety that obtained Lord Derby's Gold Medal at Ormskirk in 1920, but the season of 1921 did not suit it so well as previous ones. Given a normal season, it will yield a great crop of tubers which cook splendidly and keep well. The changed policy of the Ministry of Agriculture, which will again allow varieties like King

Edward and Great Scot are both immune. British Queen is represented by 5,592 acres. King George and The Ally have both decreased acreage, King George from 5,540 in 1920 to 2,327 acres in 1921. I am not surprised at this, as it always, in my estimation, lacked quality and is apt to go black when cooked. Arran Chief has a great place. It is at the top of the main-crops, with 28,298 acres; King Edward is next with 14,038 acres; Kerr's Pink, 11,809; Golden Wonder, 5,505; Up to Date types, 4,665; Tinwald Perfection, 4,179; Majestic, Abundance types, Langworthy, and the old Champion, which is still grown in the north of Scotland, have each a record of over 2,000 acres.

Among the immune varieties Tinwald Perfection and Majestic are in very good demand. Kerr's Pink has lost some of its popularity on account of developing much second growth last season, but where weight of crop is wanted it must be considered. My friend, Mr. G. W. Leak, Managing Director of Messrs. R. H. Bath, Wishech, tells me he raised 46 tons of Kerr's Pink from 2½ acres of ground last season! Where Golden Wonder will grow, and it will succeed in most places if it has very generous treatment, my advice is to plant some ground with it, as there is no late Potato that has ever been raised to equal it in quality on the table. H. Cuthbertson, Duddington, N.B.

## EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, W.C.2

Editors and Publisher.—Our correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the EDITORS. The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.

Local News.—Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

## A SEEDSMAN'S BROADSIDE.

THE earlier history of most great industrial concerns is largely made up of odds and ends, many of which, lightly regarded at the time, have been destroyed. These which, by some curious accident, still exist, have become of the highest documentary value. Buckle, in his *History of Civilisation in England*, and Macaulay in his *History and Essays* found much of their most valuable data in the flotsam and jetsam of literature; and no branch of commercial activity is more dependent for its history on what may be regarded as *ephemerides* than that which deals with the history of the dealer in seeds and plants. Carlyle has declared that "ten histories of kings and courtiers were well exchanged against the tenth part of one good History of Booksellers"; and the same, I think, might be said of the seedsmen and nurseryman.

The history of botany has been told many times, but little credit has been given to these who have done so much to import and distribute garden plants of all kinds. Unfortunately, those who have had the knowledge and some of the material have not had the time to compile an adequate history of the nursery and seed trade. It would not be an easy task, but it would be its own reward.

Meanwhile, it is interesting to deal with some of the many points in its history, and one of these seems to suggest itself in a very curious and unusual broadside which I have had the good luck to add to my modest collection—an advertisement in the shape of a broadside issued by the historic and world-esteemed house of MM. Vilmorin et Cie., of Paris. The most ancient British firm of seedsmen is, I think, that of Dickson and Co., of Edinburgh, which has had an uninterrupted existence since 1729—nearly two centuries; I have one of their catalogues dated 1794. But that firm no longer includes among its partners anyone of the name of Dickson.

MM. Vilmorin, however, continue to direct the firm which has been in their family for over two centuries, and which, in a sense, goes back much farther, for they absorbed in the 18th century the business of one Le Febvre\*, which existed prior to 1692 on the Quai de la Mégisserie, Paris. This, as its name indicates, was a very important centre when distribution of merchandise was solely confined to road coaches. The founder of the Vilmorin-Andrieux branch of the business, so far as can be definitely ascertained, was one Pierre Geoffroy, who died on June 2, 1728, and whose widow, Jeanne Diffetot, continued it after her husband's death, and she was succeeded by her daughter Claude Geoffroy. The business was then, as now, on the Quai de la Mégisserie, formerly called Quai de la Ferraille. In 1745,

\* "Le Sieur Le Febvre, sur le quay de la Mégisserie, a un grand assortiment de graines et vignons de Jardins," recorded A. de Pradel in *Le Livre Composé des adresses de Paris pour 1692*; and Dr Martin Lister, who accompanied the Earl of Portland on his Embassy to Paris, of which he published an account in 1698, speaks of this same Le Febvre as a seedsmen, of his nursery and of his particularly fine Tulips.

Mlle. Geoffroy married Pierre Andrieux, whose knowledge of plants procured him the appointment of Botanist to the King, Louis XV.—*le bien aimé*; and M. M. Vilmorin still possess the actual orders to Pierre Andrieux from the King for seeds and trees to be supplied for the gardens of the Tuileries.

Pierre Andrieux and his wife had one daughter, Adelaïde, who, on July 14, 1774, married Philippe Victoire Lévêque de Vilmorin. M. de Vilmorin was born on September 22, 1746, at Landrecourt, near Verdun of imperishable memory; he was the youngest of ten children of a nobleman greatly reduced in circumstances by the wars, and, an orphan at 13, he went to Paris at an early age, intending to take up the medical profession. He became acquainted with Antoine Nicholas Duchesne (1747—1816), the eminent botanist, and, among others, also with Pierre Andrieux, whose daughter, as already stated, he married; he then became a partner in his father-in-law's business, which changed its title to Andrieux et Vilmorin, and afterwards to that of Vilmorin-Andrieux; and as such it has always remained. In common with other business houses, the establishment had its sign, which was originally *Au Coq de la bonne Foy*, which was altered in 1747 to *Au Roi des Oiseaux*. But during the

how to make it. The broadside concludes with the following: *Les curieux qui voudront choisir eux-mêmes leurs arbres, plantes et arbustes, pourront aller au jardin du sieur Vilmorin Andrieux*. One wonders where in Paris M. de Vilmorin's nursery garden was at that time situated.

The broadside derives a special interest from the little account which is written on the back, evidently by a clerk, but signed by the head of the firm himself. The account is as follows:—

	Du 1er decembre, 1769	liv.	sols.	den

Ci-devant AU COQ DE LA BONNE-FOY,  
Quai de la Mégisserie.  
(N<sup>o</sup> 45.)  
(Vous êtes prié de faire attention à ne pas confondre l'Enseigne : )  
la véritable est le ROI DES OISEAUX.

FIG. 27.—TITLE HEADING OF MESSRS. VILMORIN'S BROADSIDE OF 1769.

Revolution, when anything with the name *roi* was anathema, M. de Vilmorin discreetly changed his sign to *A L'Oiseau National*, and thus probably escaped molestation.

It would appear from our broadside that the partnership with Pierre Andrieux was entered into by M. de Vilmorin before his marriage to the daughter, if the year given, 1774, is correct, for the interesting bill written on the back and signed by the head of the firm as Vilmorin-Andrieux, is dated 1769. In this broadside M. de Vilmorin describes himself as *Gendre et unique successeur du feu Sr. [Sieur] Andrieux, précédemment au coin de l'Arche Marion, Marchand Grainier Fleuriste et Botaniste ordinaire du Roi*. From this it is clear that Pierre Andrieux died before 1769, and that his son-in-law had succeeded him in his royal appointment. The broadside, of which the upper portion, serving as a title, is here reproduced (Fig. 27), is a kind of handbill or catalogue of the seeds and plants in which the firm dealt. It offers all kinds of seeds, bulbs and shrubs, particularly *graines et plantes servant à la médecine, à la pharmacie, aux distillateurs et aux teinturiers*.

One notes, among other things, *Ray-Grass d'Irlande* and *gros navets d'Angleterre*. But special emphasis is placed on the *semences nouvelles, propres à la composition du Rutafat des sept graines*, and then follow directions

on November 19, 1776, and who, elected to the French Académie des Sciences in 1844, died at Barvies (Loiret), March 21, 1860, who raised his firm from a comparatively small affair into one of world-wide renown. He is described by J. C. Loudon (*Gardeners' Magazine*, February, 1831, p. 16) as "an accomplished gentleman and scholar." "We are proud," Loudon goes on to say, "to reckon him among the number of our friends," and most happy to have an opportunity of acknowledging the hospitality and kindness which the British author received at his hands. M. de Vilmorin was a great agriculturist, Editor of the long-lived *Bon Jardinier*, and a prolific author of books on gardening and allied subjects. "M. Vilmorin, the celebrated French seedsmen," Peter Lawson and Son tell us in their *Synopsis of the Vegetable Products of Scotland*, 1851 (p. 12), "introduced St. John's day or mid-summer rye into France from Tuscan." His name is commemorated in Vilmorinia, introduced from Domingo in 1826.

Probably our broadside, with its interesting personal touch in the way of an account, is the only surviving relic of its kind issued by this firm in the earlier years of its existence as Vilmorin-Andrieux; of how and when it crossed the Channel no one can tell, and its very preservation was probably a mere accident. W. Roberts,

**THE DROOPING-FLOWERED GLOXINIA.**

The figure of the hybrid Gloxinia, on page 8, recalls a strain of Gloxinia that was grown at Chiswick in the gardens of the Royal Horticultural Society in the early 'eighties of last century. The flowers were tubular, drooping, and of an unattractive shade of blue purple. They appeared at a time when the transition from the drooping and irregular to the erect and regular flower was not complete; and formed a marked contrast to the fine strains with erect flowers in those days.

The small and almost invisible mite mentioned by Mr. Heal was destructive even then. One large batch was ruined. The next year the Gloxinias were placed under the care of the late Mr. A. Hemsley, and he found the plants going wrong just as they were coming to their best. He brought a plant to me to see if I could tell him what was the matter. I soon showed him the mite. He then thoroughly syringed each plant with soft soap and water, kept the house close and steamy for two or three days, and the plants completely recovered. *J. F.*

**CULTURAL MEMORANDA.**

**RAISING PERENNIALS FROM SEED.**

MANY perennial flowering plants may be raised from seed sown at this time of the year, and this work forms a most useful occupation on days that are unsuitable for operations in the open. Seeds of such plants as hybrid Pentstemons, Michaelmas Daisies, Phloxes and Delphiniums may be sown, and the seedlings raised in gentle heat; when large enough to handle comfortably, the plants should be pricked off into well-drained boxes containing a suitable compost, and grown on for a short time in a warm temperature until established, after which they may be hardened off and placed in cold frames where they can be protected during adverse weather until such time as they may safely be stood out of doors prior to planting time.

One great advantage of this system of raising seedlings is that over and above having plants to replace old ones, and possibly worn-out plants on the borders, the seedlings will in all probability flower at a later period than the permanent plants, thus maintaining a longer season. *Ed. Beckett.*

**MESEMBRYANTHEMUM AND SOME NEW GENERA SEPARATED FROM IT.**

(Continued from page 44.)

The following are all the species at present known to me, of which I have all but two in cultivation. For brevity in the synonymy the generic name *Mesembryanthemum* is indicated by the letter M.

A.—Surface minutely puberulous, smooth and velvety to the touch.

(1) *Lithops Friedrichiae*, N. E. Br.—Growths up to 1 in. high, 10 lines broad, and 8 lines thick, dull red, or brownish-green, with the convex top of the lobes greener, without spots, and reflecting light like a looking-glass, although puberulous. Flower not seen, stated to be yellow.—*Friedrichiae*, Dinter, *Neue und werig bekannte Pfl. Deutsch-Südwest Afr.*, p. 41. Great Namaqualand, near Warmbad.

AA.—Surface glabrous, opaque, not reflecting light (to the end).

B.—Flowers yellow.

C.—Top of the lobes tuberculate or with a more or less evident network of slight furrows or with slightly raised dots.

(2) *L. turbiniformis*, N. E. Br. (Fig. 28).—Growths solitary or 2-4 in a clump, up to about 1 in. high, 1½ in. broad, and 1 in. thick, flat at the top, which is either distinctly tuberculate or marked with a sort of network of slight furrows varying from light rusty-ochreous to a dark ironstone colour, with the furrows of

a darker tint, not spotted. Calyx unequally 8-lobed, stout, compressed; lobes 8-10 mm. long, 4-5 mm. broad, oblong or ovate-oblong, obtuse, green with reddish tips. Corolla about 1¼ in. in diameter; petals 50-60 in about 2 closely overlapping series, widely spreading, 6-8 lines long, about 1 line broad, linear, tapering towards the base, bright yellow on the inner face, whitish on the back. Stamens collected into a column about 4 lines long; filaments yellow, fading into white at the base; anthers orange-yellow. Ovary slightly convex at the top. Stigmas usually 6-7 (sometimes 5), finally 6-7 lines long and exceeding and curving over the stamens, filiform, yellowish. Capsule somewhat compressed, 4½-6 lines in diameter, 6-7-valved. Seeds smooth, brown.—*M. turbiniforme*, Haw. *Rev.* p. 84 (1821); Burchell, *Travels*, Vol. 1, p. 310; D. C., *Prodr.*, Vol. 3, p. 417; Don, *Gen. Syst.*, Vol. 3, p. 126; Berger, *Mesemb.*, p. 291; M. Hookeri, Berger, *Mesemb.*, p. 283 and

been misled by Sonder's union of these two species in the *Flora Capensis*. For not only are they two utterly different species, but one is a *Lithops* and the other a *Conophytum*, and grow about two hundred miles away from each other.

(3) *L. fulviceps*, N. E. Br.—Growths solitary or 2-4 in a clump, up to 1 in. high, 1½ in. broad, and 1 in. thick, nearly flat or slightly convex at the top, which varies from bright fulvous to dingy pinkish-rust colour, thickly sprinkled with rather large, round, dark green dots, which are usually slightly raised, but sometimes almost even with the surface, and scattered among the dots are few or several inconspicuous slender dark orange-red irregular lines or dots, usually placed in slight depressions of the surface, so that the latter is usually very slightly tuberculate-rugulose to the touch. Calyx 4-6-lobed; lobes 2½-5 lines long, 1½-3 lines broad, linear-oblong, obtuse, brownish or brownish-fulvous, sometimes tinted with pale violaceous, dotted.

FIG. 28.—LITHOPS TURBINIFORMIS (SYN. MESEMBRYANTHEMUM HOOKERI AND M. TURBINIFORME). NATURAL SIZE.

284, f. 64, copied from *Bot. Mag.* (1908). *M. truncatellum*, Hook, f. *Bot. Mag.*, t. 6077, not of Haworth.

Prieska Division, at Zand Vlei, Burchell, Pole Evans. This species was the first that was discovered of these very remarkable "mimicry" and "windowed" plants, but as I have already given some account of its discovery and rediscovery on p. 250, Vol. LXX., I need only add here that the abovedescription was made from the living plants that were so generously sent to me by Dr. I. B. Pole Evans, and the figure is reproduced from a photograph kindly sent to me by Mr. T. N. Leslie. This figure represents the tuberculate form, but I also have other forms that are very much smoother with only a coarse meshwork of slightly impressed lines upon the top of the plant.

In his very interesting account of plant-mimicry, Dr. Marloth (*Trans. S. Afr. Phil. Soc.*, Vol. 15, p. 99), remarks that Burchell, "in his travels through the Karroo found a species of *Mesembryanthemum* which he named *M. turbiniforme*, thinking it to be undescribed. As a matter of fact it had been found by Thunberg, who had named it *M. truncatum* from the shape of its leaves." Dr. Marloth has in this

Corolla 10-14 lines in diameter, expanding between 3 and 4 p.m. (Greenwich time), and closing at night, lasting about a week, odourless; petals 40-45, in about 2 series, 4.5 lines long, and less than 1 line broad, linear, subacute, the inner bright yellow on both sides, the outer whitish with a faint pink tinge on the back, with the tips often becoming more or less red on both sides. Stamens about 3 lines long; filaments deep yellow or ochreous fading to pale yellow at the base; anthers yellow. Style short, up to 1 line long, stigmas 4-6, about 3 lines long, slightly exceeding the stamens, filiform, rich ochreous yellow.—*M. fulviceps*, N. E. Br., in *Kew Bull.*, 1914, p. 167; *Bot. Mag.* t. 8776a, an extremely bad figure of the plant. Great Namaqualand, Great Karasberg Range, on sandy plains at South Narudas, 4,300 ft. above sea level, Pearson 7812!

Described from living plants sent to England by Prof. H. H. W. Pearson. In my original description I stated that this plant is smooth on the top; that statement was based upon a single specimen which probably was nearly smooth, but numbers of others examined since were as above described. *N. E. Brown.*

(To be continued.)

## THE GREAT DROUGHT OF 1921 AND ITS EFFECT ON GARDEN PLANTS.

(Continued from p. 45.)

SURREY.

FROST, as well as the abnormally dry season, caused much damage to plants. On December 13, 1920, we registered 27° of frost, and this frost had a very serious effect on many plants, some of which were recovering nicely when they had a further set-back by more frost and snow, for all the young growths were expanding in a most promising manner. This was on April 15 and 16, 1921. The previous days had been warm and sunny and the temperature as much as 70°. Many beautiful Azaleas, Acers and Magnolias (notably *M. parviflora* and *M. Watsonii*) were badly damaged, and these and the choice Acers never really recovered all the summer, as the frozen young leaves and points were visible all the season. The choicer forms of Azalea amoena were showing flower, and these were all spoilt. They looked as if they had been baked—or hoiled—but these recovered splendidly during the summer. Roses were breaking, and many of these were badly injured, and the first flowers ruined, but they recovered splendidly and we had a fine display later. Many Primulas were killed outright; Spiraeas were showing bloom, and these were partially spoilt, as also were some of the Himalayan Rhododendrons and Abutilon vitifolia. These shrubs recovered partially, but were again harmed by the severe drought, which has lasted up till the time of writing.

Laurel hedges and Arbor vitæ suffered very much in this district and even Pine trees, Raspberries, Strawberries and Black Currants were among the fruits that suffered most, for many bushes were killed outright, and it was difficult to replace the Strawberries. Apples were small generally—King of Tomkin's County, Bismarck, Ribston Pippin, Lane's Prince Albert, Sturmer Pippin, Lady Sudeley were among the best. A good deal of the Pear blossom was killed by frost and snow. Violas were killed (scorched) by hundreds during August. Peas suffered after the first and second earlies were over; the late varieties were roasted and watering was no use. Brussels Sprouts were all but a failure, in fact, all Brassicas were difficult to arrange for successions. Scarlet Runner Beans were excellent indeed. I never had better pods. Carniflowers were bad—turning in in the open before they were any size. Potatoes looked well, but the tubers were very small. Lettuces in partial shade were excellent, two outstanding varieties being Carter's Holborn Standard and Continuity. These did remarkably well where others failed.

In the rock garden, Saxifragas were the worst sufferers, and perhaps Primulas next. Small Rhododendrons and Azaleas needed water every day to keep them alive in shallow quarters. Our soil is sandy and only nine inches to a foot in depth. *W. A. Cook, Dryham Gardens, Walton-on-Thames.*

SUSSEX.

It will be interesting to see what influence the abnormal drought will have on the fruit season of 1922. Most growers seem to expect that Apples will be a very light crop, and there certainly appears to be every reason to anticipate that the biennial bearing habit to which Apples are liable will be even more pronounced than usual. Carrying a heavy crop in such a dry season must have been an exceptional strain on the trees, and it hardly seems possible that they can have had food material to spare for the development of fruit buds. They appear to be full of buds, it is true, but it is probable that these buds are weak, and that much of the bloom will not set. But this should not apply to many of the younger trees which bore only a light crop last year. I shall certainly look to these to give a good account of themselves this season, particularly as they have managed somehow to make a fair amount of growth and appear to be in excellent health. The leaves hung on them till very late in the autumn, which I fancy is a favour-

able sign. Plums and Pears, which yielded very little last year, should certainly do well if they escape frost at blooming time. Some of my oldest Plums have quite refurnished themselves with growth in the absence of fruit.

One thing is certain—whatever after-effects of the drought may show themselves in the coming season, it can hardly fail to be an improvement on the last, the passing of which was regretted by very few growers. Financially 1921 was by far the worst year I have had since the war. There was practically nothing to sell but Apples, and those were mostly cheap, owing to the heavy crop throughout the country and the frequent glutting of markets by windfalls, which were exceptionally plentiful, as a result of the drought and high winds. At the same time expenses were higher than ever. I look forward very hopefully to a much more successful season in 1922. Most of the grower's requirements, including labour, are at last becoming cheaper, and there is the prospect that a general improvement in trade conditions will produce a better demand for fruit. A substantial reduction in railway rates would be more helpful than almost anything else. *E. M. Bear, Magham Down, Hailsham.*

(To be continued.)

## RAISING CONSERVATORY PLANTS FROM SEED.

WHEN making the seed order in spring, one realises how much the conservatory depends for its brightness, the year round, on plants which may be raised from seeds. At this season of the year especially, excepting for bulbs, practically all the dwarf plants in flower were raised from seed included in last year's order. Cyclamen, for instance, although they are generally classed amongst those to be raised in autumn, are no less satisfactory if raised from seed sown in a brisk heat very early in February, since the plants have no dull days to contend with, like those raised in autumn, and it is surprising the difference this makes. In fact, in July, when both are ready for their flowering pots, there is little, if any, difference between the two batches. I have also had occasion to purchase young plants from boxes in March, and where there is not sufficient heat to warrant sowing now, it is a plan to be commended.

Primulas of the sinensis type will shortly be at their best from seed sown in April and May, 1921. Simple as is the raising of these flowers, December tries them, unless there is a free circulation of warm air in the growing house, and extra care is taken, when watering, not to wet the collar of the plant. Primulas should not be taken into the conservatory until they are nearly in full bloom, otherwise the trusses will not develop evenly. *P. stellata* will do with much cooler conditions than the ordinary type of *P. sinensis*, as the plants are not so subject to damping as are the older varieties. *P. obconica* is the least fastidious of all greenhouse Primulas, and it is worth going to a little trouble to obtain seeds from those who have exceptional strains. *P. malacoides* and *P. kewensis*, amongst the smaller types, are useful. All these may be sown at the same time. Likewise Cinerarias, which from January to May are indispensable to any show house. In addition to the large-flowered and Stellata types, Sutton's Feltham Beauty, with a habit much similar to the last-mentioned varieties, but with large flowers, is worth including.

Herbaceous Calceolarias merit attention, and few plants are more showy. June is early enough for sowing the seed. *C. Clibrani* bears the same relation to the herbaceous type as the Star Cineraria does to the large-flowered form. The flowers are clear golden yellow. A variety, however, is assured if the hybrids are sown. Amongst these the John Innes strain is very rich in mauve and cream shades. Although

the foregoing plants will keep the house gay to the end of June, autumn-sown annuals come in early in May, and add considerably to the effect. Some of the strains of Schizanthus are exceptionally fine, while Clarkias, in orange shades particularly, combine to make a most effective group. *Y. G.*

(To be concluded.)

## HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

**Isabelle** (see pp. 3, 23, 47).—The correct use of the word is evidently desirable. The following information is taken from Littré's *Dictionnaire*, than which there can be perhaps no higher authority: (1) Originally noun, signifying a kind of stuff in colour midway between white and yellow; "les isabelles pâles et dorées seront teintées avec un peu de raucourt (roucou)" (1669). Rocou, Rocourt, Raucourt or Rancourt (Mod. Brazilian-mucil) being a dyeing material obtained from *Bixa Orellana*, and used to produce a yellow or golden yellow on silk, etc. (2) Adjectival use, whence, for instance, "cheval isabelle," a pale yellow, self-coloured horse became simply an isabelle or cream, as we should say. Littré does not regard the ascribed derivation from the archduchess as having any foundation. The tint given by the well-known vegetable dye should fix the matter. *H. B. Durham.*

**Prevention of Wilt in Melons.**—Wilt or canker in Melon plants may be due to several causes, including bad ventilation, the use of the knife, and by a too frequent use of the syringe. From the seedling stage to ripening of the fruit, the plants need an adequate and continuous circulation of fresh air, without creating a draught or reducing the temperature; this will prevent moisture from condensing, and the plants will develop strong, leathery leaves, capable of resisting red spider, and so do away with the necessity for the syringe. Continuous and timely attention to stopping and pinching with the thumb and finger-nail will prevent the production of superfluous leaves and largely obviate the use—and consequent wounds—of the knife. *John Bates, Meaford Gardens, Stone, Staffs.*

**Cedrus Libani.**—We have a group of four magnificent trees of *Cedrus Libani*, the largest of which is 25 feet in circumference, at 3 feet from the ground. These Cedars are reputed the largest in England and the age variously computed at from 450 to 1,000 years. They almost strip themselves of "needles" every third or fourth year, and are very slow growing. *Cedrus atlantica glauca* is also very fine here. Could any reader kindly give me information respecting *Cedrus Libani*, the introduction of the tree to this country, and the reputed ages of specimens. *G. W. Stacy, The Gardens, Chorleywood Cedars.*

**Begonias Forming Bulbils at the Axils of Leaves** (see pp. 36, 48).—Having grown *Begonia martiana* for the past five seasons, my experience of it is that bulbils are formed in the axils of leaves and flower stalks at the time the flowers commence to open, and are ready to drop when the flowers fade, as a slight shaking then will practically clear the plant of them. I believe that *B. martiana* is a variety of *B. gracilis*. It is a very fine subject for the conservatory during August and September. The plant requires a warm temperature and a peaty soil, with a liberal quantity of silver sand. I find that the tubers decay at the end of the second season, but as the plant is easily raised from the bulbils, if sown the same as seed, at the end of April, there is no difficulty in keeping up the stock. This beautiful *Begonia* should be more widely grown for indoor decoration. Four plants in an eight-inch pot make a fine bush about 3 ft. high and 18 in. through, as laterals develop from every joint. *G. Horne, Craigavad House, Co. Down.*

## SOME EXPERIMENTS WITH STRAWBERRIES.

It is fate, but none the less unfortunate, that the origin of the garden Strawberry is quite unknown. It is a descendant of the Pine variety, which may or may not be *Fragaria grandiflora*. This Pine came from Holland to England, but where it was found in the first place history apparently fails to relate. There is an old romance that it came from Surinam, which is about as probable as the somewhat older story that there were unicorns in Florida, and, in consequence, lions, as animals were supposed to be found next to their natural enemies. A more probable suggestion is that the Pine is a sport from *F. illinoensis*, but it is past belief that the Americans should have failed to reproduce it, for a native fruit with "some" flavour would have had volumes written about it.

Eight or nine years ago I self-fertilised a Pine obtained from Cambridge Botanical Gardens. It produced too mixed a progeny to be ranked as pure. A cross with *F. chiloensis*, which I self-fertilised, gave various forms of foliage and many sterile degenerates. One of these degenerates was quite new to me; it started as a monophylla and gradually developed more leaflets till at one time it had young leaves with one, two, three, four and five leaflets, all of about the same age, and distributed just anyhow about the plant. My Pine may not be a warranted genuine article, but I doubt if a letter could be found; there are many forms of Pine to-day, including a fluctuating variegated form, which is sometimes green, sometimes mottled or splashed with white.

In all the crosses I made with the Pine variety I found nothing in the nature of the Mendelian equality ratio, in any simple character. My work on simple characters has been limited to such things as white and red fruits, white and pink flowers, double and single flowers, runner making and bush, hairy leaf-stalks and hairless, with a few other experiments of an obvious type, so it is quite possible some cross of Pine  $\times$  *F. chiloensis* may have produced a simple 1:1 ratio which I neglected, but I do not think this likely.

The fact that there are probably multitudes of characters in foliage was very clearly demonstrated in a cross, *F. chiloensis  $\times$  *F. elatior* (Hautbois); the first generation was uniform in all respects, except sex and structures dependent upon sex. Unfortunately, the degree of female sterility has been so great that I have failed to raise a plant from a self-fertilised or brother-fertilised female, but the cross-back *F. chiloensis  $\times$  (*chiloensis*  $\times$  *elatior*) has produced a family with no two plants alike in foliage, and, further, it is impossible to grade the leaves, starting at one end with *F. chiloensis* and ending at the other with *F. elatior*.**

Whilst endeavouring to obtain some light on the Pine by analysis, I have carried on parallel work of reconstruction, based on the supposition that the garden Strawberry is the outcome of a series of crossings between species well known in England and Holland in the eighteenth century and earlier. Here I have wasted much time through ignorance on the subject of fertility and sterility, a subject which I can but say I consider has been grossly neglected in the past. With the gleam of light I have very recently obtained on this subject I hope to make better progress in future.

The value of unfinished work is frequently less than that placed on it by its originator, but the storing of facts in inaccessible places is not a habit to be encouraged, accordingly, I trust the following may be acceptable:—

On a large scale I crossed *F. vesca* and *F. virginiana*, using both plants as male and female parents. The results were two families of plants alike in character and uniform in all respects except sex. The majority of these plants were female sterile, and no well-developed fruit has been obtained from them, either by hand pollination or by chance. From hermaphrodites, which set occasional seeds, I have grown nine plants, all rather closely resembling one another and

their parents. From this I suggest that the female, containing all the *F. virginiana* and *F. vesca* factors, when crossed with pollen containing all the *virginiana* and *vesca* factors, can only produce seed when certain combinations of factors are formed, the same as, or similar to, the original cross. That the chances of pure *F. virginiana* ovules meeting pure *F. virginiana* pollen are so remote that the appearance of a pure *F. virginiana* grand-child is not to be expected (the same also applies to a pure *F. vesca* grand-child). That, as above stated, the problems of sterility and fertility have been neglected too long. The foliage of this cross resembled that of *F. virginiana* in colour, and was intermediate in shape and texture, many plants producing multi-foliolate leaves.

Continuing, I crossed *F. chiloensis* with a (*virginiana*  $\times$  *vesca*) grand-child. The progeny flowered in the summer of 1921, and fruited to some extent, though the prolonged drought seriously affected the crop. The size of fruit was too dependent on the amount of seed set to grade the fruit, but there were distinct indications that some plants, under favourable pollination, would produce fruits about the size of those of *F. chiloensis*, whilst a majority would be about midway between *F. vesca* and *F.*

FIG. 23.—FIRST PRIZE EXHIBIT OF HARDY FRUIT AT WORCESTER SHOW.

*virginiana*. The *F. vesca* flavour appeared both in the large and small fruit in about half the plants that fruited. The leaves are nearly always multifoliolate and vary greatly in shape, colour and texture. The plants resisted the drought exceedingly well. A sample of these plants will be tested for fertility this year. A batch of seedlings is being raised from self-fertilised plants in the meantime.

The *F. chiloensis  $\times$  *F. elatior* cross, mentioned above, has been used as pollen parent to *F. virginiana* and the plants grown have scarcely developed sufficiently to enable any conclusions to be drawn. My hope is to unite a plant with fair-sized and *F. elatior* flavoured fruit to a plant of the *F. vesca  $\times$  (*virginiana*  $\times$  *chiloensis*) cross, with fair-sized and *F. vesca*-flavoured fruit; then, if all goes well, I should have a reconstructed Pine variety, with a pedigree of a kind to rely upon. Even supposing the Pine does not appear (it is long odds against it doing so) there will be a flavour or flavours ready to pass to the race of modern giants, which, like all giants, seems to be docile and, from the hybridist's point of view, obliging.**

All this experimental work has been conducted by me at the John Innes Horticultural Institution, Merton, under the kind supervision of Professor Bateson, and with the assistance of his able staff, to whom I owe a deep debt of gratitude. C. W. Richardson.

## GOLD MEDAL EXHIBIT OF HARDY FRUIT AT WORCESTER.

The display of fruits on the occasion of the Worcestershire Root, Fruit, Grain and Flower Society's exhibition held in November last, at the County Hall, Worcester, was certainly the finest of its kind ever seen in that old City. In all the classes entries were numerous and filled with excellent produce, the competition being exceptionally keen in the sections for Apples and Potatoes. In the fruit section the principal class was for a display of hardy fruit arranged on a table 8 feet by 4 feet, and decorated with hardy foliage. The first prize in this class was a Challenge Cup, value forty guineas, together with a Gold Medal. W. J. Gresson, Esq. (gr. Mr. T. Parry), Stoke House, Severn Stoke, Worcester, won the premier prize with a superb exhibit (Fig. 29) decorated with great taste. Most of the better known varieties of Apples and Pears were represented and the specimens were of good size and bright colour. Quinces, Medlars, Walnuts and Red Currants were also exhibited, the whole making a grand display of nearly sixty dishes. Mr. Gresson had to compete against

four other exhibitors. It may be added that Mr. Gresson was also successful in the leading class for a display of Potatoes arranged on a table space 5 feet by 4 feet, and here he won a Silver Cup, value fifteen guineas, and a Silver Medal. Exhibits from Stoke House Gardens also won many prizes at the National Potato Show held in Birmingham in 1920. *Visitor*.

## FRUIT REGISTER.

### APPLE ISLE OF WIGHT PIPPIN.

In mid-December a gentleman sent me a box of specimen Apples for naming, and I was delighted to handle a sort well known to me in my boyhood days, Isle of Wight Pippin.

Trees of this old, useful sort are, I believe, prevalent on the island after which it is named. The fruits are useful both for dessert and cooking purposes. The tree is most productive, and by keeping the fruits in a cool atmosphere its season may be extended to the end of December. The fruits are of second or medium size; the skin is coloured rich yellow and covered with a russet shading on the shaded side, giving the whole a luscious appearance. Trees of this useful pippin may be obtained from nurserymen in the South of England, and if only grown for productiveness would be well worth planting. *Pomona*.

**SOCIETIES.**

**MANCHESTER AND NORTH OF ENGLAND ORCHID.**

JANUARY 5.—Committee present: The Rev. J. Crombleholme (in the chair), Messrs. R. Ashworth, B. J. Beckton, J. Birchenall, A. Burns, D. A. Cowan, J. C. Cowan, J. Cypher, A. G. Ellwood, A. Haumer, Dr. R. N. Hartley, J. Howes, A. Keeling, D. McLeod, F. K. Sander, E. W. Thompson and H. Arthur (Secretary).

**AWARDS.**

**FIRST-CLASS CERTIFICATES.**

*Cypripedium Gratrixiae*.—The large, flat, dorsal sepal is white suffused with rose and heavily spotted with dark red; the petals and pouch are bright reddish brown. *C. Cyclops Weston-birt var.* A beautiful flower of large size, and perfect shape. From Mrs. GRATRIX.

*C. Bourtonense* (Harefield Hall × Blanche Moore).—A well-shaped flower; the dorsal sepal is green with deep white margin, the green covered with brown spots; the petals and pouch are light brown.

*C. Hestra var. Empress of India*.—The dorsal sepal is heavily spotted with deep purple; the petals and pouch are dark brown. All from S. GRATRIX, Esq.

*C. Merlene* (Lord Wolmer × Silene).—The dorsal sepal is white with small green base and a few black spots; the petals and pouch are light green; *Laelo-Cattleya Elystian var. Solaris* (L.-C. Myrrha × L.-C. Smilax). A large flower; the sepals are deep orange and the petals orange-crimson; the lip is deep crimson, and throat veined with orange. From D. SMITH, Esq.

*Odontonia Charlesworthii Bedford's var.* from Dr. F. BEDFORD.

**AWARDS OF MERIT.**

*Cypripedium Dulciora splendens* (Helen II. × Wellesleyae) and *C. Lord Wolmer var. Aranea*, from the Rev. J. CROMBLEHOLME.

*C. Conquest var. compactum*, and *Odontoglossum crispum Noel* from S. GRATRIX, Esq. *Cypripedium San-Actaeus var. giganteum*, *C. Zsmanii* (*Zsion giganteum* × *Beckmanii*), from P. SMITH, Esq.

*C. Alma var. Hildegarde*, from Mrs. GRATRIX. *C. Argo var. March Along*, from B. J. BECKTON, Esq.

*Odontoglossum leightmense* (Rossii × promerens), from Dr. R. N. HARTLEY.

**GROUPS.**

S. GRATRIX, Esq., West Point (gr. Mr. J. Howes), staged a group for which a Gold Medal was awarded. It included *Cypripediums* in great variety. Silver Medals were awarded to Mrs. BRUCE and Miss WRIGLEY, Bury (gr. Mr. A. Burns, the Rev. J. CROMBLEHOLME, Clayton-le-Moors (gr. Mr. E. Marshall), and Messrs. CYPHER AND SONS, Cheltenham, for collections.

**NORFOLK AND NORWICH HORTICULTURAL SOCIETY.**

This old society (dating back to 1829) held its annual meeting on the 28th ult. The report was not such a favourable one as could be wished. Owing to financial loss, the committee has decided not to hold a spring show this year. The Rose Show will be held on the last Thursday in June in the grounds of Bracondale Woods, Norwich, and the Chrysanthemum and Fruit Show in the latter part of November.

J. E. T. Pollard, Esq., who was hon. secretary for many years, was elected president, and Mrs. Hoffman, Blickling Hall, kindly consented to accept the vice-presidency. As the hon. secretary, Mr. R. J. Preston had notified his wish to retire, it was agreed, upon the suggestion of Mr. H. Perry, that a paid secretary should be engaged. For this position, Captain Sandys Winsch was elected. He is Parks Superintendent of Norwich, and his office is at St. Peters Street, Norwich.

**GARDENERS' ROYAL BENEVOLENT INSTITUTION.**

JANUARY 26.—We were glad to notice a very considerable increase in the attendance at the annual meeting of this excellent horticultural charity over that of recent years, although there is every truth in the frequent contention that a small meeting betokens great confidence in the management. Regret was voiced by all present that the chairman and hon. treasurer, Sir Harry J. Veitch, was absent on the advice of his doctor, thus breaking the long sequence of his presidency at these annual gatherings of friends and supporters of the Institution. We are happy to state, however, that Sir Harry is not seriously indisposed, but keeping to his room as a precaution, in view of the unsettled weather and prevalence of illness. Amongst those who attended we noticed Messrs. P. C. M. Veitch, John White, H. G. Cox, A. Bullock, Owen Thomas, John Heal, H. M. Veitch, Leonard Sutton, R. Frogbrook, George Monro, C. H. Curtis, P. R. Barr, Geo. F. Tinley, J. F. McLeod, E. Monro, Donald McDonald, J. Linford, W. O. Hieble, J. R. Pulham, D. Ingamells, A. R. Lake, R. W. Wallace, C. R. Fielder, T. Passmore, and Percival Etheridge.

On the motion of Mr. P. C. M. Veitch, Mr. Leonard Sutton was appointed chairman, and after the secretary had read the minutes of the previous annual meeting, the annual report of the committee for 1921 was presented, of which the following are extracts:—

**EXTRACTS FROM THE REPORT OF THE COMMITTEE FOR 1921.**

In presenting their 82nd Annual Statement, together with the Accounts (as audited) for 1921, the Committee are pleased and thankful to report that, owing to the means so kindly placed at their disposal by the friends of the Institution, they have been enabled to maintain the work during the year without any curtailment of efficiency or benefits, although they cannot conceal their great anxiety for the future, in view of the unsettled financial state of the country, which must necessarily affect the income of all charities, and they therefore very earnestly appeal to their friends and well-wishers to do their utmost to continue their support and interest in this National Horticultural charity.

At the beginning of the year there were 250 annuitants on the list—men and widows receiving £20 and £16 a year respectively. During the year several have passed away, three of whom, having left widows whose circumstances being in every way deserving, were placed on the funds in succession to their late husbands in accordance with Rule III, 13; and to-day the Committee recommend that 29 applicants from an approved list of 48 candidates be added by election to receive the "Arthur W. Sutton Pension." The Annual Festival Dinner in aid of the funds, which was held on May 27 of the Hotel Victoria,

under the Presidency of His Royal Highness the Duke of York, K.G., proved very successful, and the eloquent advocacy of the Royal President on behalf of the claims of the charity resulted in a much valued addition to the amount required towards carrying on the work.

The Committee have the great pleasure to announce the following very generous gifts: one of War Loan from Arthur W. Sutton, Esq., F.L.S., J.P., V.M.H., to found an "Arthur W. Sutton Pension"; and another from Mrs. Monro, J.P., Major E. G. Monro, (Geo. Monro, Esq., and Bert J. Monro, Esq., to found a "Geo. Monro Trust" in memory of the late Geo. Monro, Esq., V.M.H., who was a member of the Committee for 45 years. It is needless to say how welcome these gifts are and how much they are appreciated.

The Committee desire to offer their thanks to the ladies and gentlemen who have again so kindly allowed their beautiful gardens to be opened to the public on behalf of the funds.

Reference is also made to the kindness of Sir Harry J. Veitch (treasurer), Mrs. Monro, J.P., Geo. Monro, Esq., and Bert J. Monro, Esq., in providing an allowance of £10 each to four unsuccessful candidates at the last election.

The Auxiliaries still prove very valuable adjuncts to the Institution, each having materially added to the funds yearly, the Worcester Auxiliary having raised the largest amount during the past year since it was established.

The Committee have the sad duty to announce the loss by death of many valued friends and supporters, whose passing away will be deeply felt. Amongst them may be mentioned: The Earl of Ducie, P.C.; The Lord Balfour of Burleigh, K.T.; The Lord Mount Stephen, Major-General Sir Edward Cortes; The Rt. Hon. Sir Ernest Cassel, P.C.; Lady Veitch; Mrs. Adair; W. L. A. Burdett-Coutts, Esq., M.P.; C. S. Hunting, Esq.; J. C. Geiselbrecht, Esq.; and Walter Speed, Esq., V.M.H.; also Geo. Paul, Esq., J.P., V.M.H., for 50 years a warm friend of the Institution; and R. G. Waterman, Esq., Hon. Secretary to the Liverpool Auxiliary, a devoted worker for the cause.

HARRY J. VEITCH, Treasurer & Chairman of Committee  
GEO. J. INGRAM, Secretary.

The Chairman moved the adoption of the report and statement of accounts and proceeded to offer a few remarks on the Fund. He congratulated the committee on a satisfactory year's work and considered that much of the success was due to the efforts of their hard-working Secretary, Mr. Geo. Ingram, and their Hon. Treasurer, Sir Harry Veitch. No fewer than 250 homes were benefiting through the Institution, and although the amount allotted to each individual was small, it made all the difference in the world to those people who received it, and was especially valuable to poor people in their declining years. The Fund was to be congratulated on having for its President the Prince of Wales, and the Institution was honoured by having the Duke of York as Chairman at the Annual Festival Dinner last year, and he hoped that His Royal Highness's presence was an inspiration to all the younger members of the company present on that

\*£1208 is required to meet the quarterly payments due on December 31, 1921.

occasion. The paragraph referring to the deaths of prominent supporters of the charity included many distinguished horticulturists, and their loss showed the need for fresh supporters to carry on the useful work that had extended over eighty years. Mr. Etheridge, in seconding the adoption of the report, stated that nothing gave him greater pleasure than to help institutions of this kind. Although not attached to horticulture in a commercial sense, he loved his garden, and knew the strain and stress gardening involved and the worry all are experiencing in these times of reduced finance. The Institution was doing most laudable work, but he considered that funds should be forthcoming to support not 250 annuitants, but 500. He paid high tribute to the committee, to Sir Harry Veitch and the excellent Secretary, whose work had been second to none. Mr. Etheridge advocated obtaining many more small subscriptions, and he would like the committee to accept them as low as 5s., so that means of help would be within the reach of all. We were living in most strenuous times and he considered that the financial strain was far greater now than at any time during the war; we must retrench, not with regard to these poor pensioners, but rather go forward and build up a much larger subscription list.

At this stage of the proceedings, the Chairman read a telegram from Sir Harry Veitch as follows: "Very sorry not to be with you. Cordial greetings to all friends." It was decided to send a telegram to Sir Harry thanking him for his message and wishing him a speedy recovery.

The election of officers was next proceeded with. Sir Harry Veitch was re-elected Treasurer on the proposition of Mr. Owen Thomas, seconded by Mr. George Monro. Mr. Geo. Ingram was reappointed Secretary, and the retiring members of the committee were all re-elected. The Hon. Auditors and Arbitrators were also re-elected and the Scrutineers of the ballot appointed. The meeting was then adjourned until the declaration of the poll. The successful twenty candidates were as follows:—Thomas Jones, 5,276; Henry J. Godfrey, 4,943; Aaron Rawle, 4,858; Thomas East, 4,447; John G. Bristol, 4,311; Thomas Leslie, 4,172; William R. Baker, 3,681; Martha Chudleigh, 3,489; James Dongall, 3,453; William Hunter, 3,286; Thomas Cranham, 3,219; John Dey, 3,197; James Taverner, 3,103; Emily S. Whiting, 2,923; Elizabeth A. Wilson, 2,834; Elizabeth A. Trussler, 2,653; Selina A. Martin, 2,651; Emma Woodhatch, 2,615; Elizabeth Rye, 2,658; and William Hill, 2,602. In addition to the above, Mr. Joseph Mallard was awarded the Arthur W. Sutton Annuity, and sums of £10 each, being one year's allowances, were given by Sir Harry J. Veitch, Mrs. Geo. Monro, Mr. Geo. Monro, Mr. Bert Monro, and Mr. Leonard Sutton to five unsuccessful candidates.

## ROYAL HORTICULTURAL.

JANUARY 31.—A bright and attractive exhibition was held in connection with the meeting of this date, and although it was not such an extensive display as many Fellows anticipated, it was a most interesting one, consisting chiefly of Orchids, Carnations, Primulas and early hardy flowers, the latter including numerous Daffodils, Hyacinths and Crocuses gently forced into bloom. Novelties were few in number and the Floral Committee made no awards at all to new plants.

### Orchid Committee.

Present: Frederick J. Hanbury, Esq., in the chair, Messrs. Jas. O'Brien (Hon. Secretary), R. Brooman White, Walter Cobb, Arthur Dye, S. W. Flory, J. T. Barker, Chas. H. Curtis, J. E. Shill, H. T. Pitt, T. Armstrong, E. R. Ashton, Richard G. Thwaites, C. Cookson, Gurney Wilson, and C. J. Lucas.

### AWARDS.

#### FIRST-CLASS CERTIFICATE.

*Odontioda Cordor* (*Oda Coronation* × *Odm. Doris*), from Messrs. ARMSTRONG AND

BROWN, Orchidhurst, Tunbridge Wells. A grand variety, with a fine spike of ten flowers, equal in size, and form to a good *Odm. crispum*. Sepals and petals rich red, tinged with mauve. Lip with a dark red blotch in front of the yellow crest, and white front, spotted with red.

### AWARDS OF MERIT.

*Odontioda Antinous* (*Oda Coronation* × *Odm. exultans*), from Messrs. ARMSTRONG AND BROWN. Flowers perfectly formed, deep violet, tinged with red. Lip, lilac colour, with violet blotch in front of the well-defined yellow crest. The plant bore three flowers.

*Odontoglossum crispum Hero*, from Messrs. CHARLESWORTH, Hayward's Heath. Probably the finest of the grand strain of *Odm. crispum* raised true by Messrs. Charlesworth. The plant bore a noble spike of large and finely-formed pure white flowers, the sepals having each one reddish blotch.

*Brasso-Cattleya Ruby var. Rosetti* (*B.-C. Mrs. J. Leemann* × *C. labiata*), from Messrs. STUART LOW AND CO., Jarvisbrook. One of the brightest and most richly coloured of the section. Flowers deep rosy-mauve. Crest of the lip chrome-yellow with gold lines from the base. The spike bore three finely-formed flowers.

### GROUPS.

MESSRS. SANDERS, St. Albans, were awarded a Silver Flora Medal for a pretty group, most effectively arranged in green moss, each plant standing out distinctly. The back was of *Cymbidiums*, including *Alexanderi*, *Pauwelsii* and *Butterfly*, the novelty being *C. Tracyanum leopardinum* with a fine spike of large flowers evenly spotted with chocolate red. *Cattleyas*, *Laelio-Cattleyas*, *Odontoglossums* and *Cypripediums*, were well displayed, with several very rare species, including the delicate *Otocilus fuscus*, with a spray of pretty white flowers, the peculiarity in which is the globular gland at the base of the upper sepal, which possibly acts as a nectary. Scarlet *Sophrontis*, with many flowers, and species of *Masdevallia* and allied genera were arranged in the front.

MESSRS. CHARLESWORTH AND CO., Hayward's Heath, were awarded a Silver Banksian Medal for a select group, in which the richly-coloured *Odontoglossum Tityus*, violet with white margin, the snow white *Odm. eximium Virginiae*, and the yellow *Odm. Phillipsianum aureum* with the new *Odm. eximatum* were attractive features.

MESSRS. FLORY AND BLACK, Slough, were awarded a Silver Banksian Medal for a group including some *Sophrontis* crosses; the very fine *Odontioda St. Quentin var. rotundum* with white flowers marked on the inner part of the segments with light red; *Laelio-Cattleya H. T. Pitt* and *Brasso-Cattleya Floryi*, attractive plants of unusually good colour.

### OTHER EXHIBITS.

G. W. BIRD, Esq., Manor House, West Wickham (gr. Mr. H. Redden), showed a fine specimen of his deep purple-tinted *Odontioda Trebizond* (*Odm. Fascinator* × *Oda. Charlesworthii*), which secured an Award of Merit in 1918.

MESSRS. ARMSTRONG AND BROWN showed the handsome *Cypripedium Satyr* (*Beryl* × *Hera Euryades*) with a fine white dorsal sepal, richly blotched with deep maroon.

MESSRS. HASSALL AND CO., Southgate, showed a fine plant of the rich red *Oncidioda Cooksonii* with over 100 flowers.

### Floral Committee.

Present: Messrs. H. B. May (in the chair), W. J. Bean, G. Reuthe, Reginald Cory, Jas. Hudson, R. C. Notcutt, Hugh Dickson, John Heal, George Harrow, C. R. Fielder, Andrew Ireland, Donald Allan, W. Howe, Charles Dixon, W. B. Gingell, Arthur Turner, H. J. Jones, Chas. E. Shea, Chas. E. Pearson, W. H. Page, W. B. Cranfield, and E. A. Bowles.

### AWARD.

A card of Cultural Commendation was awarded to Mrs. A. M. ROBINSON, Eastgate Manor, Chichester, for exceptionally large blooms of *Violets Princess of Wales*, Marie Louise, and Mrs. D. Lloyd George.

### GROUPS.

On a floor space, just inside the entrance of the hall, Messrs. SUTTON AND SONS arranged an exceedingly attractive collection of their noted Primulas. The large exhibit was arranged very skilfully and included particularly well-grown plants, as well as admirable strains. The *stellata* strain, which included Improved Giant White, bearing large, pure flowers of good texture, and Coral Pink, were especially graceful, and served also to draw attention to the solid value of the *sinensis* section. Of the latter, Giant Crimson, Reading Pink, and Coral Pink, amongst the single-flowered varieties, were admirable, whilst the double-flowered variety Queen of Pinks bore a profusion of charming flowers. On a table space Messrs. Sutton and Sons had a second exhibit and this was a graceful display of spring bulbs growing in delightful bowls of fibre. Besides many Hyacinths and Narcissus there were bowls of *Lachenalias*, *Anemone blanda*, *Crocuses* and *Lily-of-the-Valley* (Silver-Gilt Flora Medal).

Carnations were of especially good quality. Messrs. ALLWOOD BROS. had an interesting collection of their recently raised Perpetual-Border varieties at the end of a display of Perpetuals and Perpetual-Malmaisons. Of the latter, Mrs. C. F. Raphael, which seems to be always in season, was particularly attractive. The newer Jessie Allwood was also of merit; the yellow flowers were very bright and harmonise well with those of pink shades (Silver Grenfell Medal).

Although good Carnations formed a large part of the contribution by Messrs. STUART LOW AND CO., it was the small plants of the fragrant *Daphne indica rubra* and the various *Mimosas* that attracted most attention. Besides these there were equally well-flowered examples of *Camellias* and *Azalea indica* in variety (Silver Banksian Medal). The varieties of pink shades of colour were very prominent in a collection of Carnations shown by Mr. C. ENGELMANN. Of these the most prominent were Laddie, Delice, Boadicea and Cupid (Silver Banksian Medal).

Several informal little rock gardens added greatly to the variety and interest of the show. Messrs. WM. CUTBUSH AND SON planted theirs with shapely, dwarf Conifers and Ericas, and such alpine as Saxifrages and Sedums. Adjoining the rock garden they had a group of decorative pot plants of *Eucalyptus Gunnii* (Silver Grenfell Medal). Messrs. WATERER, SONS AND CRISP displayed good batches of Irises in their rock garden. The principal sorts were *I. stylosa* lilacina, *I. reticulata* and *I. scindjarensis*. They also had pretty patches of *Sedillas* and *Crocus versicolor Cloth of Silver* (Silver Grenfell Medal).

Besides a pleasant little rockery surmounted with dwarf Conifers, *Skimmia japonica*, freely berried, and the like, and planted with *Iris reticulata*, Saxifrages and Sedums, Messrs. J. CHEAL AND SONS showed various Conifers and branches of *Hamamelis* bearing quantities of attractive flowers (Bronze Flora Medal). Mr. DIXON again made a little model sunken garden backed by a low rockery (Silver Banksian Medal).

Amongst a small collection of Conifer branches, Mr. G. REUTHE included several species of *Athrotaxis* and *Pinus*. He also showed other trees and shrubs, alpine, *Iris histrioides*, Christmas Roses and *Eranthis hyemalis* (Bronze Flora Medal).

A beautiful patch of *Saxifraga Burseriana magna* was conspicuous in the low rockery built by Messrs. SKELTON AND HARDY, who also displayed *Saxifraga Elizabethae*, various Ericas and Conifers (Silver Banksian Medal).

Many plants of *Azalea indica* were shown by Messrs. L. R. RUSSELL, LTD., and these were interspersed by several *Bromeliads* and *Begonia manicata*, with a smaller collection of small *Camellias* in full bloom, and sprays of *Prunus triloba* (Silver Banksian Medal). Mr. S. ASH continued his exhibits of unusually late *Chrysanthemum* blooms by showing good examples of such varieties as Heston White, Percy A. Dove and Enfield White.

## Fruit and Vegetable Committee.

Present: Messrs. C. G. A. Nix (in the chair), W. Poupart, H. S. Rivers, G. Berry, A. H. Pearson, E. A. Merryweather, Geo. F. Tinley, Ed. Beckett, E. Neal, W. Bates, S. B. Dicks, W. H. Divers, W. Wilks, and S. T. Wright.

There were no groups on this occasion, but several interesting seedling Apples were submitted for awards.

## AWARD OF MERIT.

*Apple Laxton's Pearmain.*—This variety was raised from Wyken Pippin crossed with Cox's Orange Pippin, the same parentage that resulted in another excellent variety, namely, Laxton's Superb. The fruits greatly resemble Cox's Orange Pippin in appearance, but are of a duller red and have a longer stalk; the eye is very much like Cox's. The quality is excellent, although the specimens were about a fortnight past their best condition. The flavour partakes of the Cox's Orange Pippin type and the flesh is a very pale green and not pure white. The raisers inform us that the tree is of very vigorous growth, upright in habit and a very free cropper. Exhibited by Messrs. LAXTON BROS., Bedford.

## OTHER EXHIBITS.

An excellent Apple, without a name, supposed to be a seedling raised from a pip of Newtown Pippin, was shown by Mrs. Alice G. HARRISON, Haltondale, Wellingborough. It is probable that the pip was taken from a fruit of Northern Spy, which the Committee considered it so nearly resembled as to be almost identical. The quality of this rather upright, ribbed fruit, with a bright crimson flush at the base, is excellent, and it may prove a more fertile type in this country than the old Northern Spy, which is a very shy bearer in British gardens.

Mr. E. A. BUNYARD brought from the Allington Nurseries specimens of Apples; Ananas Reinette, often known as Pineapple Reinette, is a very highly flavoured variety like a smooth Cockle's Pippin or Coe's Golden Drop; the Pineapple flavour is very pronounced; Reinette Grise de Saintonge is a large russet Apple with firm, solid, juicy flesh, of excellent flavour, and the fruits had the appearance of keeping until much longer. The third variety was William Crump, an excellent late Apple for quality, but said to be so shy in bearing as to be unprofitable for planting.

An Apple named Good's Bushy Grove was submitted on October 5, 1920, and a deputation was appointed to inspect the tree; the report received was favourable, and the Committee recommended an Award of Merit, but the grower will be asked to substitute another name, under which it will be recorded.

## Obituary.

**Thomas Nutting.**—We learn with regret of the death of Mr. Thomas Nutting, gardener at Childwickbury, St. Albans, Hertfordshire, for 36 years. He died on January 24 at Childwickbury Gardens, aged 71 years. The late Mr. Nutting commenced his gardening career at the early age of twelve years in Messrs. Osborne's Nurseries, Fulham, where he remained for five years. From there he went to Danesfield Gardens, where he remained for nearly two years, proceeding thence to Sherborne Castle for a similar period, under the late Mr. Pragnell; he was also at Canford Manor for a year, and subsequently at Wotton Gardens, near Aylesbury. From the last-named gardens he proceeded to Chirk Castle as foreman. His first appointment as head gardener was to Richard Naylor, Esq., Kilmarsh Hall, Northampton, which post he held for a period of three and a half years, when he left to take a similar appointment to Henry Hall, Esq., Alton, Hants, where he remained for a further three and a half years. In 1886 he was appointed gardener at Childwickbury, near St. Albans, to the late Sir J. Blundell Maple, and he remained at Childwickbury until his death, in the service of

J. B. Joel, Esq. Mr. Nutting was a clever gardener, and won many awards as an exhibitor. All who came in contact with him found him of a genial and kindly nature, and were impressed by his fine character and remarkable keenness in all matters appertaining to his profession. No doubt the sad bereavements he suffered in recent days in the death, first of his beloved daughter, and shortly afterwards of his devoted wife, tended to shorten his span of life.

**George V. Nash.**—A correspondent sends us some interesting particulars of the late Mr. G. V. Nash, who was curator, under the official title of head gardener, of the New York Botanic Garden since 1896. Mr. Nash, who died in the summer of 1921, visited Kew in 1891 for the purpose of examining the collections there, and made a selection of over 1,000 species from duplicates of the indoor plants for the gardens at Bronx Park. He was a most lovable man and took a prominent part in the development of horticultural interests in New York City, for, apart from his connection with the Botanic Gardens, he was intimately associated with the many horticultural associations and the numerous floricultural shows held in that city. He was secretary of the Horticultural Society of New York for 10 years, and held that office at the time of his death. He is described in the American Horticultural Press as "A striking figure; his presence, his practical and systematic knowledge, and his helpfulness will be greatly missed."

**Dr. Cecil A. P. Osburne.**—We regret to announce that Dr. Osburne passed away on Tuesday, the 24th ult. The funeral took place in the churchyard of Old Catton, on Friday, the 27th ult. Apart from his profession, the doctor was a keen horticulturist, his leanings being towards floriculture. He was always ready to purchase the best varieties of any subject that appealed to him. Perhaps his great interest in his beautiful garden was the collection of Irises he had got together. He had over a quarter of an acre devoted to the Germanica section, and these he attended to personally, trying all the time to find out their likes and dislikes and making experiments to impart vigour and combat disease. He was president for the past two years of the Norfolk and Norwich Horticultural Society, and always exhibited largely at its shows.

## TRADE NOTES.

THE Parliamentary Committee of the Chamber of Horticulture has considered a Report from the Transport Sub-Committee, summarising the work done during the past year, the concessions already obtained by direct conference with the railway companies, and the points upon which the Sub-Committee asked for instructions to proceed before the Rates Advisory Committee. The chairman, Mr. G. W. Leak, remarked that the Report was very satisfactory as regards the Chamber's particular case for nursery commodities. The report was adopted and the Sub-Committee given instructions to proceed. The question of the expenses incurred to date, also the cost of briefing counsel to plead the case before the Rates Advisory Committee was then discussed, and it was agreed that Associations concerned should unite in defraying the same.

Major Matthews submitted a letter from the private secretary to the President of the Board of Trade stating that the Board was prepared to receive a statement of a case for horticulture, and also to receive a deputation thereon. This refers to efforts being made with a view to the possible inclusion of horticultural produce in a Bill, which the Board of Trade have stated in the House of Commons, they propose to introduce to amend the present Merchandise Marks Acts. Extended powers of prosecution and compulsory labelling of foreign produce are points likely to be pressed for, and it was agreed that a conference of associations was necessary in order to decide on and draft the various points entailed, also to elect delegates.

## ANSWERS TO CORRESPONDENTS.

**ADIANTUM FERNS ATTACKED BY GRUBS:** *A. E. P.* The insects you sent are the larvae of weevils, and these are exceedingly destructive to Ferns. Turn the plants out of the pots and remove as many of the larvae as can be seen by means of a pointed stick. Place the plant in the pot again and make four holes in the soil with a piece of stiff wire and pour a little carbon bi-sulphide in each. This material is very inflammable and due precautions should be taken in using it. If these methods fail, wash all the soil from the roots and repot the plants in soil free from the grubs.

**CANKERED APPLE TREE:** *T. E. H.* The plan you propose of cutting the main stem down below the seat of the disease and grafting afresh may be adopted, but such an unhealthy tree is best destroyed and a fresh one planted in the ground it occupies. If you decide to re-graft, adopt the rind or

FIG. 30.—CROWN OR RIND GRAFTING.

crown method, as shown in the accompanying illustration, Fig. 30. Of the sorts you mention, choose either Warner's King, Annie Elizabeth, or Allington Pippin, all of which are vigorously growing varieties.

**NAMES OF FRUITS:** *F. W.* Duke of Devonshire.—*N. G.*: 1, Annie Elizabeth; 2, American Mother; 3, Lane's Prince Albert; 4, Colonel Vaughan.—*Rosamund*: Norfolk Beefing.

**NAMES OF PLANTS:** *H. B. M.* Both the Orchids are forms of *Dendrobium nobile*, No. 2 approaching *D. n. nobilium* in colour.

**TREATMENT OF SOIL:** *F. H.* You do not state the area of land, kind of soil, or number of men available. When first working the land, it was a bad plan to remove the turf, as you took away the most fertile portion. It should have been ploughed in, cross-ploughed, rolled, ploughed again if necessary, and harrowed down fine, after being left exposed to the weather. Probably the best thing to do now is to trench as much as possible, say to 3 feet depth, putting in a good layer of manure at the bottom of each trench, after breaking up the bottom. A portion of the area done properly will prove more profitable than the whole only half done. If the soil is heavy, make sure the drainage is efficient. Potatoes form an ideal crop for growing on newly broken pasture land.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 39.2.

### ACTUAL TEMPERATURE:—

Gardeners' Chronicle Office, 5, Tavistock Street, Covent Garden, London, Wednesday, February 8, 10 a.m. Bar. 30.3; temp. 43°. Weather—Sunny.

**Royal Horticultural Society.**

The most gratifying statement in the Annual Report of the Council of the Royal Horticultural Society for 1921, which will be presented officially at the annual meeting on Tuesday next, is the one referring to membership, which records an increase of no fewer than 1,214 Fellows—a reminder that horticulture is as popular as ever with the inhabitants of this country. The total membership on November 15, 1921, was 16,494—compared with 15,280 on December 31, 1920—the largest total in the history of the Society. The number of fellows elected in 1921 was 2,160 and, seeing that losses by death amounted to so many as 150, the number of Fellows who resigned is much smaller than might be expected in such times of adverse financial circumstances. We understand that 360 Fellows have been already elected this year. With such a large membership it is not surprising to find that the amount received from subscriptions reached the fine total of £23,099 and, in addition, nearly £400 was contributed as entrance fees. Receipts of all kinds, including dividends and interest, income from shows, hall lettings, advertisements, sale of publications, etc., made a grand total of £37,664. With regard to the Society's shows, there was a considerable profit on the one held at Chelsea, but, as usual, the Holland House exhibition resulted in a loss; and there was a deficiency on the exhibitions as a whole, for the cost of the various meetings, conferences, etc., was £6,187 4s. 11d., compared with receipts amounting to £5,925 14s. 3d. The Vincent Square balance-sheet shows a profit of £12,262 os. 10d., but of that sum £7,979 5s. 6d. was required to meet the excess of expenditure over revenue

in connection with the Wisley Gardens, so that the total available balance for the year amounted to £4,282 15s. 4d. The work at Wisley probably represents the most valuable of all the activities of this important Society, and no one will grudge the necessary funds for its efficient maintenance, but the Society may not always be in the happy financial position in which it finds itself at present, and we commend to the Fellows the appeal of the Council for an endowment fund for the gardens and the founding of permanent or the increasing of existing temporary scholarships for the investigation of definite problems, for, as the Council truly states, the future progress of horticulture depends upon the scientific investigation both of plant life and the soil, and their reactions upon one another. We are glad to see that the Society is in negotiation with the National Rose Society for making a Rose trial garden on a part of the new land recently acquired at Wisley, but we are not sure that the soil of these gardens is best suited for Roses, although doubtless the skilful cultivation and great care which all plants receive at Wisley may compensate largely for any deficiency in this respect. The experiment of holding a great exhibition in the autumn of 1922 at the Holland Park Skating Rink will, we trust, be justified; and as the show will be held entirely under cover, there will be little risk of failure owing to inclement weather, which has sometimes spoiled the shows at Holland Park. There are plenty of challenge cups from supporters of the Society, and at the October show in the Holland Park Skating Rink the Gordon-Lennox Cup will be offered for fruit; two Orchid challenge cups presented by trade growers for Orchids; the George Monro Memorial Challenge Cup for the best exhibit of Grapes by an amateur, and one of the Allwood Carnation Bowls for amateur growers of Carnations. In addition to all these trophies the Council is offering silver cups in the various sections of the schedule as well as the Coronation Cup for the best exhibit in the show. A new award has been created by the Society to be known as the Award of Garden Merit, and this will be recommended by the Wisley Garden Committee to plants that are either well known to the Council, Committees and garden staff, or which have been tested at Wisley and proved to be excellent for garden or greenhouse use. Apparently the two days' meetings, instituted for the first time last year, have proved a success, for the Council has decided to extend the period to include March in 1922, and lectures will be held at 5 p.m. during the summer months from April to September inclusive. Nothing is said in the Report as to the publication of Pritzel, but we notice that there is a sum of £859 2s. 2d. invested in India 2½ per cent. stock, representing the amount of the fund on December 31, 1920. As the estimated cost of publication is a very much larger amount than this, the Society will find itself committed to a considerable expenditure from its funds, unless those who have pressed so urgently for the revision contribute in a larger degree than they have done. The Lindley Library received an addition of 129 books during the year and a considerable number of volumes were bound. Although the increase of the library is not so rapid as some could wish, the steady accretion of books from year to year has rendered it necessary to place certain works not in frequent use in a store, and thus relieve congestion in the library. One of the most interesting paragraphs in the Report to professional horticulturists is that dealing with the appointment of new holders of the Victoria Medal of Honour to fill vacancies

caused by five deaths during 1921. The new members selected are the President (Lord Lambourne), Mr. W. A. Bilney, the Rev. Arthur Boscawen, Mr. John Fraser and Mr. William Poupart, and, we believe, the choice will be confirmed by horticulturists generally, for these are all worthy of this high honour. We notice that the name of the late Mr. J. Seden has not been removed from the list of present holders, and we find no one nominated in his place. This is doubtless an oversight. Altogether the R.H.S. has had a very successful year: we look to it to lead in horticultural progress and to lend its powerful aid to those kindred floricultural societies which are actuated by similar motives—the furthering of the interests of British horticulture.

**Prof. Henry and Czecho-Slovakia.**—We learn that Prof. Augustine Henry has been elected a corresponding member of the Czecho-Slovakian Botanical Society "in recognition of the inestimable services rendered to botanical science in the course of his studies." In August last, Prof. Henry visited the localities of Czecho-Slovakia and Poland in which the Larch occurs as a wild tree. The European Larch, as is well known, is widely distributed in the Alps, but it has besides three out-lying stations, little known to British foresters:—One in the Sudeten Mountains in Silesia, another in the Tatra range of the Carpathians, and a third in the so called plateau of Poland, a hilly district situated to the north of Krakow. In the wild forests of these three regions, it grows mixed with Spruce, in each case over a limited area. The Silesian Larch is scarcely known in cultivation, though a small quantity of seed is reputed to have been imported a few years ago. The Carpathian and Polish Larches have never been introduced into this country. It is possible seed may be obtained this season from all three localities, but the crop of cones has been very meagre, and there are great difficulties in obtaining a supply. The Larch is of splendid growth and the timber in all these forests of fine quality; and in Poland and Silesia descends to a much lower altitude than in Switzerland or the Tyrol. Indeed, in Poland, it descends to the zone of the Oak and Hornbeam, which fringes the Spruce forest. Its natural regeneration is very good. It may interest our readers if, at this point, we record the fact that a copy of *Trees of Great Britain and Ireland*, the well-known work by Mr. H. J. Elwes and Prof. Henry, was sold at an auction of books in Dublin on February 2, for £37.

**Silloth Turf for Wimbledon Tennis Courts.**—The committee of the All-English Lawn Tennis Club have laid their new courts at Wimbledon with Silloth turf brought from the Solway Firth. This Cumberland turf, which is so highly prized for bowling-greens, is rarely used on tennis lawns on account of its high cost and the expense of carriage. Altogether 12,000 square yards of this Silloth turf have been laid. The turves were cut in foot squares, one inch and a half thick.

**The Biology of Waterworks.**—This was the title of a lecture delivered to the members of the Gilbert White Fellowship at 6, Queen Square, London, last Saturday, by Sir Sidney Harper, F.R.S. He reminded his audience that in the 'eighties the people of Hamburg had their water taps stopped, and in some cases eels and other animals came through when a tap was turned on. But such were not the only troubles experienced by the waterworks engineers in their endeavours to provide a healthy supply of water. Investigations at Hamburg showed that there was "an El Dorado of animal life" in the water pipes there. The greater part of this water population consisted of polyzoa, which formed gelatinous masses as large as cricket balls; there were also fresh-water sponges, worms, leeches, molluscs and crustacea, as well as the eels aforementioned. The polyzoa flourish during the summer and die in winter, but before doing so throw off "buds," which develop in the next spring. These egg-shaped little "buds," technically known as

"statoblasts," break away from the parent body, and often become attached to birds and are conveyed to other waters, there to start fresh colonies. Fresh-water algae carried into water pipes is also at times a fertile source of worry. At Manchester 700 tons of "pipemoss" were removed, with much labour, from the pipes. As Sir Sidney pointed out, the remedy is efficient filtration, and in this respect it is interesting to know that the sand filter, invented by James Simpson in 1829, has been but little improved on. By forming a film over the surface of the sand minute living things like diatoms, on which the statoblasts feed, give valuable assistance in the filtration.

**Legacy to a Gardener.**—The late Colonel Walter Morrison, V.D., of Malham Tarn, Yorkshire, and Moor Court, Sidmouth, Devonshire, who left estate provisionally sworn at £2,000,000, bequeathed the sum of £1,000 to his garden, Mr. George Petty. He left a similar sum to his steward, housekeeper and groom.

**Wart Disease Attacking the Tomato.**—Investigations carried out by the United States Department of Agriculture have proved that Tomatos are susceptible to wart disease of Potatos. Out of twenty-eight varieties of Tomatos planted in a wart-infested garden in Eastern Pennsylvania, twenty-six sorts were found to be susceptible to the disease. The fungus attacks only the stems and roots of the Tomato plants, causing the formation of small warts, and the disease does not appear to reduce the yield of fruit. The investigators state that there is a danger of affected Tomato plants serving to carry over the disease from year to year in the absence of Potatos, and the complaint may be introduced into localities free of wart disease through transplanting Tomato seedlings that have been in infested soil. Other plants belonging to the Solanaceae were tested as to their susceptibility to wart disease, but, so far, with inconclusive results.

**International Commercial Horticultural Conference.**—We learn that the Annual Conference of representatives of the Fédération Horticole Professionnelle Internationale will be held this year in Holland, at the Hague, on April 20. Mr. Krelage is the President for 1922, and the Conference is always held in the country of which the President is a national.

**A Bill Relating to Allotments.**—We are glad to notice from the King's speech at the opening of Parliament on Tuesday last, that the Government intends to bring forward a new Bill relating to allotments. The situation with regard to allotments has been thoroughly considered by a Departmental Committee appointed by the Ministry of Agriculture, and doubtless the chief recommendations of that Committee, to which we referred on p. 50, will form the basis of the new Bill. Under the present conditions, with practically no security of tenure, the majority of allotment holders are unwilling to continue the cultivation of their plots, knowing that their efforts would be wasted, although most of them are as enthusiastic cultivators as ever. Local authorities have the power to provide allotments, yet many are unwilling to move in the matter, and in most places the provision of permanent allotments is regarded as an impossibility.

**The Royal Botanic Society's Gardens.**—We are glad to notice from the *Quarterly Summary* issued by the Royal Botanic Society, London, that several improvements are to be undertaken in the Society's gardens at Regent's Park, and especially in the provision of new greenhouses. Some of the smaller greenhouses are in a dilapidated condition, and it is proposed to spend the sum of £2,000 on new ones, of which amount £1,300 has already been promised. The large conservatory has been cleared of its former occupants, and is being replanted with beautiful, rare, and interesting plants. Ornamental climbers have been planted at the bases of the iron columns supporting the roof, and the Palms, of which there are many fine specimens, will have more room to develop, and be seen to greater advantage than hitherto. In the out-door garden, the trees and shrubs have been pruned, and

many worn-out specimens removed. The flower beds and borders have been trenched and replanted with choice herbaceous plants, and with bulbs for a spring display. Several new beds have been laid out on the lawn to the left of the Broad Walk. The lake has been cleared of superfluous reeds and flags, and most of the accumulated silt used for enriching the soil of the shrubberies near by. The beds containing representatives of Natural Orders have also been replanted. Large numbers of plants have been contributed to the gardens by the authorities at Kew, Cambridge Botanic Garden, Chelsea Physic Garden, Miss Ellen Willmott, Mr. T. Hay, Superintendent of Regent's Park, and others.

**Mr. B. H. MacLaren.**—The superintendent of the public parks and gardens of Brighton, Mr. B. H. MacLaren, was educated at Christ's College, London. He studied agriculture, forestry and estate management at Tamworth Agricultural College, and, later, gained practical experience on some of the largest farms in Warwickshire and Wiltshire. But horticulture proved a stronger attraction than agriculture, consequently, Mr. MacLaren served for a considerable period with Messrs. J. Backhouse and Son, of York, where he eventually

MR. B. H. MACLAREN.

became foreman in the landscape department. Having gained a wide experience in the north of England, he came south and joined the landscape department of Messrs. J. Cheal and Sons, Crawley, and while in the service of this firm he obtained the position of Assistant Superintendent of the Brighton public parks and open spaces in 1913. In 1915, Mr. MacLaren joined the Army, and, passing through the School of Military Engineering, obtained a commission in the Royal Engineers and went to France, where he eventually became Company Commander. The excellence of his work secured the appreciation of his superiors, and, finally, Captain MacLaren was mentioned in Lord (then Sir Douglas) Haig's dispatches. Shortly after returning to his old position at Brighton, his former chief retired, and he was appointed Superintendent, a position he now occupies, to the great satisfaction of the Town Council and inhabitants of Brighton. Mr. MacLaren has greatly improved the attractions of the famous sea-side resort, and he has been especially successful in reconstructing the whole of the Valley Gardens, forming boulevards, and improving the surroundings of the Royal Pavilion. Mr. MacLaren's department is a large and busy one, as he has under his control small holdings, allotments, woods, street trees, parks, gardens, sports' grounds, nurseries, open-air markets and the winter gardens. Fortunately, Mr. MacLaren is a young man, and the suc-

cess he has achieved encourages the hope that Brighton may become as famous horticulturally as it is socially.

**Guildford and District Chrysanthemum Society.**—We are glad to learn that the Guildford and District Chrysanthemum Society, which ceased its activities during the war, has been reconstituted, and will hold an exhibition in the Borough Hall, Guildford, on November 1st and 2nd next. The Secretary is Mr. Walter Miles, Ashbrook, Cadogan Road, Surbiton.

**The British Carnation Society.**—The Spring Show of this flourishing society will be held in the Royal Horticultural Hall, Westminster, on March 21. In addition to numerous increased money prizes, valuable challenge trophies are presented by Lord Howard de Walden, Reginald Cory, Esq., George Monro, Esq., and others. There are special classes for florists, notably one for a decorative exhibit of Carnations on a table space 15 feet by 6 feet, the first prize in which is the Covent Garden Challenge Trophy valued at £20. Schedules may be obtained post free from the Honorary Secretary, Mr. P. F. Bunyard, 57, Kidderminster Road, Croydon.

**Appointments for the Ensuing Week.**—Monday, February 13.—United Horticultural Benefit and Provident Society's meeting; Bath Gardeners' Society's meeting; Purley Horticultural Society's meeting. Tuesday, February 14.—Royal Horticultural Society's Committees' meeting and annual general meeting, at 3 p.m.; Cardiff Gardeners' Society's meeting. Wednesday, February 15.—National Dahlia Society's Schedule Committee's meeting, at R.H.S. Hall, at 4 p.m.; Hertford Horticultural Society's meeting. Thursday, February 16.—Manchester and North of England Orchid Society's meeting; Linnean Society's meeting, at 5 p.m.; Wargrave and District Gardeners' Society's meeting. Friday, February 17.—Eastbourne Horticultural Society's meeting.

**"Gardeners' Chronicle" Seventy-five Years Ago.**—*Carrot Bread.*—The Belgian Carrot mixed with flour makes capital bread, as does also the red Carrot; but the colour is somewhat against the latter, although the bread is superior to that made with the white Carrot, being pleasanter in flavour, moister, and yet firmer, as you will see from the enclosed specimen. Instead of equal quantities of Carrots and flour, only one-fourth of the former is used, a half being found to render the loaf too close in texture. A peck of flour by itself yields three good-sized loaves, but mixed with 7 lb. of Carrots produces four, and of excellent quality. As regards the preparation, I followed the instructions in the *Chronicle* to the letter. Carrots grown on sandy soil are better than those from clayey land, as, when boiled, you may pass a fork with the greatest ease through the former; but those from the clay are hard at the heart, therefore much more difficulty is found in breaking them up. They should be mixed with the flour while warm, a point, as I understand, of considerable importance. In beating the Carrots up, use a wooden bowl and spoon, the wood affording hold which other vessels do not. *F. Nash, Ludlow, February 2.* (The bread was good, but it tasted too much of the Carrot for a fastidious palate).—*Gard. Chron., Feb. 6, 1847.*

**Publications Received.**—*Roses for Market.* By F. J. Fletcher. Vol. III. and IV., Market Nursery Work Series. Benn Bros., Ltd., 8, Bouverie Street, E.C.4. Price 4s. 6d. each net. *The Genetic Relations of Plant Colours in Maize.* By R. A. Emerson; *Resistance of the Roots of Some Fruit Species to Low Temperature.* By D. B. Carrick; *The Crane Flies of New York.* By C. P. Alexander; *Raising Colts.* By M. W. Harper. *A Modified Babcock Method for Determining Fat in Butter.* By Nelson W. Hepburn. *Working Plan for a Communal Forest for the Town of Ithaca, New York.* By John S. Everitt. *An Economic Study of Farm Layout.* By W. I. ## MICHAELMAS DAISY WILT.

A PAPER on this disease was read by Mr. W. J. Dowson at the meeting of the British Mycological Society on the 21st ult. He dealt with it as it occurs at the R.H.S. Gardens at Wisley. The disease was first noted by growers in the early summer of 1920, and is very widely spread. So far, it has only been recorded in the groups *Novae Belgii* and *Novae Angliae*. The obvious symptom to the horticulturist is a wilting of shoots soon after they have reached a foot in height in early summer, *i.e.*, the leaves of an entire shoot are noticed to have turned yellow; they rapidly dry, shrivel and turn brown. Shoots coming up from the ground as suckers behave in the same way. In some instances a variety is soon killed, *e.g.*, Climax; others, *e.g.*, Gladys Donellan, are resistant, as they also are to mildew (*Erysiphe cichoracearum*) and to drought. Examination of shoots with yellow foliage does not reveal mycelium in the tissues in the early stages of the disease. A plentiful mycelium is found, however, at the base of older stems; and on shoots long dead mycelium can be traced all the way up; it is also present in the rootstock. The mycelium, which is very fine, is confined for the most part to the larger vessels of the xylem, and is particularly found in those of the protoxylem. Careful staining shows that the hyphae invade tracheids and medullary rays. Very small microconidia are also seen in the vessels.

At first a *Fusarium* was isolated, but this proved to be non-pathogenic. Finally, a species of *Cephalosporium* was obtained which, when inoculated into healthy plants raised by transplanting rooted suckers, by introducing mycelium or conidia into incisions, caused the characteristic wilt. The fungus produces myriads of microconidia in culture. The fungus apparently differs somewhat from that isolated by Wiltshire at Long Ashton. The inoculations enabled the first symptoms of the disease to be accurately described. In all cases of inoculation at or about ground level, some of the lower leaves became mottled after about three weeks time, and a few days later became yellow. The mottled leaves appeared in no particular order, and the yellowing often started on one side of the midrib and later spread to the other side. It was impossible to find mycelium in the neighbourhood of the mottled and yellowing leaves, and thus it appeared unlikely that the symptoms can be explained by the actual blocking of the water-conducting elements by hyphae. A toxin was therefore looked for. It seemed probable that if the fungus excreted a toxin it would do so in water cultures, and thus the trouble of extracting it artificially would be avoided. The liquid from some of these cultures was filtered through a Berkfeld filter into sterilised flasks, and into these vigorous green shoots of various Michaelmas Daisies were placed. The results obtained were that shoots in the filtered liquid turned mottled in three days and yellow in six, while controls remained green for ten days.

In a dialyser of goldbeaters' skin the active principle passed through the membrane into surrounding sterilised water in three days, and shoots in this acted as in the previous experiment. Mesophyll cells of *Aster* leaves were set up in suspension in hanging drops of water from the cultures. After twenty-four hours the chloroplasts were seen to migrate slowly to one or both ends of the cells, become clumped together in a mass, and in from three to six days slowly disintegrate, after which the cells were plasmolyzed. It seems, therefore, that a definite substance secreted by the hyphae of *Cephalosporium* at the base of shoots becomes sucked up in the transpiration current, and acts as a poison to the chlorophyll-cells, bringing about the symptoms of wilt noticed in the field.

The research is still in progress, but it is thought that it will be possible to eliminate the disease by striking cuttings from the ends of vigorous suckers so as to avoid the slightest chance of including mycelium.

## TREES AND SHRUBS.

## A NEW VALUE OF CYDONIA MAULEI.

I WOULD like to put in a good word for *Cydonia Maulei*. In a distant sort of way it reminds me in its garden position of the Lovo Apple, and the more ancient inhabitant the Scarlet-Runner Bean. No one gives us a better idea of an up-to-date border of annuals in the last half of the eighteenth century than Swinden in *The Beauties of Flora Displayed*. Among the tender ones, which grow from 2½ to 3 feet high, we find "No. 157, Love Apple, Solanum; Yellow; and Red Fruit." With the colon after yellow it must mean yellow flowers and red fruit. It would be easy to multiply instances, but there is very little doubt but that Love Apples were once regarded, like Scarlet Runners before them, as suitable and proper inhabitants of the flower garden. Today, when we regard their uses as culinary herbs as giving them their chief, if not their only, value, they have been transferred to the kitchen garden. I do not exactly suggest that the same thing will happen with regard to

years ago Henry Bright's son Allan, a successful Liverpool shipowner, sold the old home at Knotty Ash, on the outskirts of Liverpool, and now lives somewhere under the shadow of the Malvern Hills. *Joseph Jacob*.

## CEDRUS LIBANI.

In answer to Mr. Stacey's inquiry on p. 56, this tree was probably introduced about 250 years ago. It is not mentioned in Evelyn's *Sylva*, which was written in 1664, and, according to Veitch's *Manual of Coniferae*, one of the oldest Cedars in England was that in Bretby Park, Derbyshire, which tree was known to have been planted in 1676. *Cedrus Deodara* and *C. atlantica* are comparative newcomers, both having been introduced during the last 100 years. The Chorleywood Cedars cannot, therefore, be as old as Mr. Stacey says they are estimated to be. Perhaps Mr. Stacey has noticed the Cedar in the grounds of St. Albans Abbey, which people say Queen Elizabeth planted.

It would be interesting if some correspondent could tell us whether the Bretby Park specimen is still alive. *A. Simmonds, Maidstone*.

FIG. 31.—CHIMONANTHUS FRAGANS LUTEUS GRANDIFLORUS.

*Cydonia Maulei*, but it is quite on the cards that it might. It is no great stretch of imagination, especially after reading on page 241 of *My Garden in Autumn and Winter*, what Mr. E. A. Bowles has to say about its fruits making a good jelly to "eat with roast mutton as a change from the orthodox Red Currant," to find on my next visit to Myddelton House that he had taken some of the plants from the little hillock on the rock garden and transferred them to a place in the kitchen garden, where their object would be to produce an abundance of those deliciously coloured, scented and tasty pale-orange, tiny, Quince-like fruits which provide a jelly of—so, at least, I think—far higher value than to be classed among condiments. Well-made "Maulei" jelly is every bit as good as any Guava jelly from the East or West Indies. So far as I know, most varieties of *Cydonia* make good jelly. One year, thanks to the kindness of Mr. Bean, of Kew, we had a grand trial of some of them at a tea party given for the express purpose of picking the best. Henceforth, "Maulei" jelly will be connected in my memory with Henry Bright, the author of one of the earliest, most readable and most scholarly of all chatty garden books, *A Year in a Lancashire Garden*, for his daughter was one of the judges who voted in the unanimous verdict of "Maulei" being placed first. That garden, I deeply regret to say, no longer rejoices in the guardianship of a Bright. Two

## NEW OR NOTEWORTHY PLANTS.

## CHIMONANTHUS FRAGANS LUTEUS GRANDIFLORUS.

AT the meeting of the French National Horticultural Society, held on the 26th ult., a Certificate of Merit was awarded to an interesting form of *Chimonanthus*, exhibited by Messrs. Vilmorin and Co., of Paris.

The plant is a yellow-flowered form of *Chimonanthus fragrans*, Lindl., but the flowers are much larger than those of the variety *luteus*, introduced many years ago and always very rare in gardens. In fact, the flowers of the variety *C. fragans luteus grandiflorus* (Fig. 31) are at least as large as those of the *grandiflorus* variety figured in the *Botanical Register*, tab. 451.

The flowers have many segments—twenty, sometimes more—broad and obtuse. The flowers are as remarkable for their rich yellow colour as is the plant for its freedom of flowering. This new variety was raised from seeds collected in 1906 in the district of Zi-ka-wei (Eastern China) by R. P. Ancel.

It is certainly a very interesting shrub from a decorative point of view, and very superior to the type generally met with in our gardens. The Verrières specimen is about three metres high and as much through. *A. M.*

## The Week's Work.

### THE FLOWER GARDEN.

By EDWIN BECKETT, Gardener to the Hon. VICARY GIBBS, Aldeham House, Hertfordshire.

**Border Chrysanthemums.**—Plants lifted in the autumn and placed in cold frames will be making good, healthy growth, and suitable shoots should be selected for cuttings. Insert these in good, sandy compost, and place them in mild heat, and, when well rooted, harden them off, and pot them singly as soon as convenient.

**Shrubbieries, etc.**—Advantage should be taken of the open weather to push forward all outdoor work possible, such as moving shrubs and trees, planting fresh specimens, seeing to the necessary staking, and generally renovating the shrubberies. Pruning and trimming should be proceeded with, so that all may be put in first-class order pending the time when rough, boisterous weather puts a stop to work of this nature.

**Willows and Dogwoods.**—The present is a suitable time to propagate those finely coloured woody subjects, the Willows and Dogwoods. These plants may be used with magnificent effect for winter decoration of the garden, when planted in good stretches by themselves, and especially in close proximity to water, such as a lake or well-tended stream. During the period when flowers are absent from the garden and leaves are few, the bark colours of the Willows and the rich, warm reds and brilliant yellow tones of the Cornuses give a fine effect in the landscape. To raise new plants is quite a simple operation. Cut the old growths into portions about 9 inches long, and insert them in the open to a depth of about 6 inches; make them firm, and thereafter little attention will be necessary, as such shoots form roots readily. The resulting plants should be moved to permanent positions before they are two years old, as they are difficult subjects to transplant successfully. *Cornus alba* and its varieties; *C. sanguinea*, and its varieties; and *C. stolonifera flaviramea* are all finely coloured Dogwoods, whilst *Salix vitellina*, *S. decipiens*, *S. vitellina britzensis*, *S. acutifolia*, *S. daphnoides*, and *S. purpurea* have beautiful coloured stems.

**The Weather.**—Up to the time of penning these notes we have experienced very little severe weather. There has been one brief spell of snow, very little frost, and, generally during the month of January, damp, muggy days of high temperature. We have had one good rain, and things are becoming advanced beyond their season owing to the genial conditions ruling. In consequence of all this, it is necessary to again urge the necessity of protecting tender plants from the possibility of injury by frost.

### PLANTS UNDER GLASS

By T. PARKMAN, Gardener to Sir C. NALL-CAIN, Bart, The Node, Codiote, Welwyn, Hertfordshire.

**Gloxinia.**—The Gloxinia is a useful decorative subject for the warm greenhouse, and to ensure a long succession of flowers a few of the old tubers should be placed in shallow boxes containing leaf-mould and sand. When they have started into growth the plants may be transferred to pots of suitable sizes. Seeds of Gloxinia should also be sown now. The resulting seedlings should make fine plants for flowering in August. It is always advisable to raise a batch of seedlings each year, as such plants are more vigorous in growth than older specimens. Sow the seeds in 6-inch pots filled with equal parts of loam and peat, with a good dash of sand added. Cover the seed as lightly as possible, and place a sheet of glass over the pots, also shade them from bright sunshine.

**Palms.**—Established Palms of any considerable size should receive attention with regard

to potting or surface-dressing, whichever is considered necessary. Palms seem to succeed best, provided proper attention is given to watering and feeding the roots when they are somewhat restricted in root space. Also, such plants are more serviceable for decorative purposes. Top-dressing of the roots and the use of manure water will be found a great assistance to the plants that are cultivated in small pots. Where it is considered only necessary to surface-dress the plants and the roots are too near the surface of the pot to allow for top-dressing, a band of zinc should be fitted around the top of the pot, several inches in depth, to allow of this being done. For established Palms, good loam, with plenty of sand and charcoal added, constitutes a suitable compost.

### HARDY FRUIT GARDEN.

By H. MARSHAM, Gardener to the EARL OF STRATFORD, Wrotham Park, Barnet.

**Bush Apples and Pears.**—Young bush trees of Apples and Pears should be very carefully pruned. All shoots not required for building up the tree should be cut out, keeping those best situated and leaving only sufficient to form a well-shaped fruitful tree. The side growth should be spurred back to within a couple or three buds, whilst the leaders, if they are sturdy and well matured, should be retained for quite two-thirds of their length. In the case of

FIG. 32.—YOUNG BUSH APPLE TREE, THREE YEARS FROM PLANTING; SHOWING PROPERLY-BALANCED HEAD.

bushes (see Fig. 32), a centre leader is not required. The central main growth of pyramid trees should be encouraged to develop. If the trees were summer-pruned, the chief operation needed now is to cut back the side growths to within a couple of buds of their bases and to shorten the leaders to the length required. Cut out entirely a few of the worst-placed branches in trees that are crowded with growth, and reserve suitable young growths for filling open spaces, if desirable. Top-dress and mulch all fruitful trees to encourage them to develop strength. Bush fruit trees should never be over-cropped. The roots should be fed liberally to assist both the finishing of the fruits and the building up of strong, fruitful buds for the following season's crop.

**Espalier trees** that have not filled the available space should be very carefully pruned, retaining suitable growths at equal distances apart, to build up an evenly balanced head. In shortening the leaders leave one bud above the two required to form the side branches; the top bud will form the next year's leader and the side ones young branches; repeat this annually till the top pair of branches has been formed. Side leaders should be shortened, more or less, according to their length and strength. As a rule from 10 to 15 inches of growth will suffice.

### THE ORCHID HOUSES.

By J. T. BARBER, Gardener to His Grace the Duke of Marlborough, K.G., Blenheim Palace, Woodstock, Oxon.

**Cypripedium.**—Members of the insigne section, also the many hybrids which produce their flowers at the same season, having passed out of bloom, may receive attention as regards repotting, should it be necessary. A suitable compost consists of equal parts of peat fibre, Al fibre, and Sphagnum-moss, with clean loam fibre added. The use of the last material may easily be overdone, especially if the loam is of a heavy nature. The pots should be well drained, and the new material kept slightly on the dry side until the roots have entered it freely. These plants may be repotted as soon as their flowers are cut or faded, and after repotting they may be placed in their growing quarters, where, under proper conditions, they should thrive until their flowers appear again in the autumn.

**Zygopetalum.**—Such species as *Z. Mackayi*, *Z. crinitum*, and others of this section, should be repotted, if necessary, as they pass out of flower. The roots of the different species and hybrids vary to a considerable extent, some making large, succulent roots, others roots of a thinner and more wiry nature. The nature of the roots of the different plants offers a good guide as to the nature of the compost to be used. Those with thick, fleshy roots, delight in a rough, open compost, which should be placed quite firmly in the receptacles. The strong growing members may be afforded a substantial rooting material, such as fibrous loam, *Osmunda* fibre, and Sphagnum-moss, in equal proportions, cut up according to the size and nature of the plants, and well mixed together. For the more delicate growers the amount of loam fibre should be slightly reduced. Whilst the weather is favourable, a good stock of Sphagnum-moss, and other material, should be obtained, so that when the busy season for potting arrives there may be no delay.

### THE KITCHEN GARDEN.

By JAMES E. HATFIELD, Gardener to JOHN BRENNAND, Esq., Baldersey Park, Thirsk, Yorkshire.

**Potatos.**—Potatos that were planted in December in pots should now be top-dressed. Another batch should be planted in 10-inch pots half filled with good fibrous loam, manure from a spent Mushroom-bed and leaf-mould. The sprouts on the seed tubers should be reduced to three at the most. Place the pots in a vinery or Peach-house, and, as soon as the haulm begins to grow, expose the plants to plenty of light. An excess of fire heat should not be used otherwise the plant will get drawn. The advantage of growing the early Potato crop in this way is that the pots may be moved into cooler houses as required. Potatos may now be planted in heated pits, and if plenty of space is available it is best to plant for successional cropping. Where heated pits are not available hot-beds should be made and the materials allowed to remain for a week or more until the rank heat of fermentation begins to decline, before putting on the soil. The latter should be at least 8 inches deep, and the sets planted 12 inches apart in rows 18 inches or more apart, according to the varieties used. Sharpe's Victor, Victory, Dargil and Witch-hill are suitable for forcing. Potato sets intended for planting later should be set up in boxes for sprouting, and, if they are backward, a few placed in warmth as required.

**Broad Beans.**—A sowing of Broad Beans should be made in boxes or in turves in a similar manner as was recommended on p. 16 for Peas. Germinate the seeds in a frame or cool greenhouse. A batch may also be sown in the open as soon as the weather permits. Choose ground that has been well manured and trenched; sow in rows made 3 feet apart and 1 foot wide, placing a double line of seeds in each trench. Arrange the seeds on their sides at a distance of 6 inches apart. For early cropping a sheltered position should be selected.

**Asparagus.**—Batches of this vegetable should be introduced to warmth as required. The best method is to force the crowns in frames on hotbeds. Place about 4 inches of soil in the frame and plant the crowns in about 3 inches of soil. The temperature of the frame should not be higher than 65° when the roots are put in, and the frame should be well protected in frosty weather.

#### FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

**Cherries.**—These precocious trees had, down to the end of the past year, an excellent time for plumping up their buds, and one began to fear that the unseasonably mild weather might have a prejudicial effect on the flowers. Sharp frosts have now intervened and lowered the external temperature so that a little fire heat has become necessary to maintain a mean temperature of 40° in the house. Those who wish to have ripe Cherries at the end of May and the beginning of June must exercise patience for the present, and hasten the development of the trees when solar heat favours steady forcing. When the buds begin to swell the mean temperature of the house should range from 40° to 45° at night, and 50° to 55° by day, always with a little fresh air admitted, and atmospheric moisture in proportion to external conditions. As the days lengthen more air may be admitted through the top and front ventilators, especially when the pipes are warm, but the heat should be shut off at night for the present unless the temperature falls below 40°. The very early sorts, such as Guigne d'Annonay, Bigarreau de Schrecken, and Early Rivers will make good progress, but at the same time insect pests, such as green and black fly, will become more troublesome, no matter how carefully the trees were cleansed, but these pests easily succumb to one or two mild fumigations, the last of which should always precede the opening of the first flowers. Few fruits do so well or last so long as Cherries, planted in narrow, inside borders, and the majority of growers restrict their varieties to three or four of the best sorts which ripen in succession; but a dozen or more varieties may be grown in pots. Cherries are impatient of fire heat, and many growers fail with these fruits through maintaining an excessively high temperature and keeping the trees too close in the early stages. A body of mild fermenting material placed amongst the pots, whilst of value for providing warmth in the early stages of forcing, will render direct syringing a secondary consideration. A fairly dry atmosphere and a steady warmth from fire heat, with plenty of air to raise the temperature to 60° or 70° with the aid of the sun, will not only insure a good set of fruit, but a mass of most fragrant blossoms.

### MESEMBRYANTHEMUM AND SOME NEW GENERA SEPARATED FROM IT.

(Continued from p. 55)

CC.—Top of the lobes entirely without tubercles or slight furrows or raised dots when in a plump growing condition, smooth except sometimes in *L. Lesliei*.

(4) *L. pseudotruncatella*, N. E. Br. (Fig. 33).—Growth solitary to many in a clump, up to 1 in. high and 1½ in. in diameter, flat or the lobes slightly convex on the top, varying from pale grey to brownish-grey with a slight pinkish tinge, covered with numerous branching lines or dendritic markings of a darker colour formed of confluent dots, mingled with some separate dots. Calyx 6-7-lobed; lobes 3-5 lines long, 1½-2 lines broad, oblong or ovate-lanceolate, obtuse, pale greyish-green with a brownish tint. Corolla 1½-2½ in. in diameter, opening soon after mid-day and closing between 6 and 7 p.m. for 6 or 7 successive days, odourless; petals 50-60, in 2-3 series, ½-1 in. long, and about 1 line broad, linear, narrowing to the base, obtuse, bright yellow, with a white base on the inner face,

faintly pinkish-white on the back. Stamens 3-4 lines long; anthers and upper part of the filaments pale orange-yellow, lower part of the filaments white. Stigmas 5-7, free almost or quite to the base, equalling or slightly exceeding the stamens, filiform, pale orange-yellow.—*M. pseudotruncatellum*, Berger, *Mesemb.*, p. 239 and 266, Fig. 4 (1903); *M. truncatellum*, W. Watson, in *Gard. Chron.*, 1900, Vol. 27, p. 211, with Fig., not of Haworth; *M. truncatum*, Dyer, in *Ann. of Bot.*, Vol. 20, p. 123, t. 7 (1916), not of Thunberg.

Damaraland, near Jakalswater, Roessing, Farm Hoffnung and Aus Mountains, Dinter!

Described from living plants raised from seeds sent to Kew in 1903, by Mr. N. S. Pillans, who informs me that the locality "Laingsburg District" quoted for it by Dyer in the *Annals of Botany* is entirely wrong, and that when he sent the plant to Kew on January 11, 1903 (by error dating his letter 1902), he wrote that he was "posting a piece of the plant together with some seeds of *Mesemb. truncatellum* from German South-West Africa," which were given

part of the afternoon (at Pretoria about 5 p.m., according to Dr. Pole Evans) in bright sunshine only, scentless; petals 50-60, in about 3 series, rather lax, 5-7 lines long and nearly 1 line broad, linear, acute, obtuse or slightly notched at the apex, bright yellow, whitish or pinkish-white on the back. Column of stamens about ¼ in. long, whitish or pale yellow anthers yellow. Style short; stigmas 4-5, about 4½-5½ lines long, as long as the stamens, pale greenish-yellow.—*M. Lesliei*, N.E. Br. in *Trans. Roy. Soc. S. Afr.*, v. 2, p. 369, with fig. (1912). *M. Hookeri*, Marloth, *Fl. of S. Afr.*, v. 1, p. 205, 206, t. 51, fig. B, not of Berger. N. E. Brown, *Gard. Chron.*, 1921, Transvaal: near Vereeniging, Leslie! Gillfillan! Burt Davy!; near Bloemhof, Burt Davy!; Griqualand West: near Kimberley, Pearson! Pillans! Windsorton, Marloth, Warrenton, Mogg!; near Griquatown, Marloth.

The biological peculiarities of this plant are detailed on p. 250, volume LXX., but I would add that this appears to be one of the hardiest species of this type of plant, for in its native locality during winter it is some-

FIG. 33.—LITHOPS PSEUDOTRUNCATELLA; NATURAL SIZE.

Photo by T. N. Leslie.

him by Prof. MacOwan, who probably received them from Dinter. The latter, in writing of this plant (without a name) in the *Gardeners' Chronicle*, 1900, Vol. 27, p. 115, states that "this plant so closely resembles, when not in bloom, the form and colour of the pebbles among which it grows, that it can only be detected by an experienced eye."

The beautiful flowers of this species afford an excellent example of their daily increase in size which I alluded to on p. 290 of Vol. LXX. One that I measured on the first day of its opening was 1½ in. in diameter, on the third day it was 1¾ in., and on the sixth day 2½ in. in diameter. The time of expansion and closing above mentioned seems rigidly adhered to, but only if the sun is shining and the temperature high enough, otherwise the flower will not open.

(5) *L. Lesliei*, N.E. Br.—Growth solitary or 3-4 in a clump, up to 1½ in. high, 1½ in. broad and 1¼ in. thick, flat on the top, smooth or slightly harsh or irregular to the touch, but without an impressed reticulation, dark green or olive-green, densely or sparsely covered with dull orange or rust-coloured irregular spots or dendritic markings. Calyx 5-6 lobed; lobes 2½-4 lines long, 1½-2 lines broad, oblong or ovate, obtuse, green or brownish-tinted. Corolla 1-1½ in. in diameter, expanding in the latter

times subjected to 20 degrees of frost at night only, not continuously, the days being warm, and the air and ground are both very dry at that period, the rainfall, varying from 20 to 40 inches, taking place during the summer, which corresponds to our winter, when these plants often want to grow.

(6) *L. terricolor*, N.E.Br.—Growth solitary or few to a plant, two only on each of the four plants seen, ¾-1 in. high, 8-11 lines broad, and 6-8 lines thick, with the top of the lobes convex and rounded into the sides, of the colour of dried earth or grey-brown, marked with dark fuscous dots all over or the central area with a dark fuscous patch composed of crowded or confluent dots, and some separate dots on the marginal part. Calyx 5-lobed: lobes about 2½ lines long, ovate, obtuse. Corolla about ¾ in. in diameter, not seen in a fresh state. Stamens, about ¼ in. long, style very short, stigmas 5, overlapping the stamens, filiform, bright yellow.

Laingsburg Division: near Grootfontein, Frith! Living plants of this species were kindly sent to me by Mr. F. Frith, who informs me that the plant "grows on black shale and on gravelly ground, and is very difficult to find." I have only seen withered flowers that were on the plants upon arrival. N. E. Brown.

(To be continued.)

## EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, W.C.2.

Editors and Publisher.—Our correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the EDITORS. The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.

## MR. REGINALD FARRER'S SECOND EXPLORATION IN ASIA.\*

No. 37.—THE MOKU-JI IN AUGUST.

**D**URING the ten days that I have been up the Moku-ji there were moments when it was clear, with rain; there were hours of cloud without. The flowers all about the camp were a picture of gaiety, but how they are ever going to ripen their seed I am really at a loss to say. Fortunately for fertilisation, the insects up there are of Spartan breeding and indifferent to wet; in the intervals of biting the collector it is to be hoped that they fertilise his flowers. The camp was just about at the top limit of the alpine coppice: above it a steep region of Bamboos and glades intervened before the high alpine scrub was reached. Just below, several lateral streams plunged down in cataracts to join the main waterfall in a gorge; and the opposite bank towered up and up in crags and gullies to the high crests above.

On the way up there had not been anything new to note of any great moment; the dulness of the alpine forest in these ranges is phenomenal. The alpine coppice, however, is more profitable; I am struck by an elegant *Castanea* with true Chestnut-looking fruits, which I hope may also prove to be a true Chestnut indeed, as I am told that its nuts are a favourite food. Two shrubby *Hypericums*, too, begin to be pleasant in August, one most graceful, with pendulous Willow-like sprays, and the other coarse-leaved and erect, but with flowers almost as large as in *H. calycinum*. A fat-thyrse *Neillia* also struck me as the most solidly effective of its kind that I have yet seen, and, of course, *Rosa sericea* is the commonplace of all bushy stretches. A little higher and the standing ambition of my heart was gratified by the discovery of a yellow *Daphne*. Desire granted, however, is proverbially disappointing, and I am not, as yet, having sleepless nights about the seed of this species. Of course, one can never tell, either for good or ill, how a plant will develop under cultivation; it is very possible, indeed, that in more favourable conditions in the garden this *Daphne* may reveal much finer characters than it does at the moment. In a narrow region of the alpine zone it occurs quite commonly under the coppice. And there, in the dripping twilight, it cannot do more than make a thin, spindly growth of 18 inches or so, with ill-furnished, inconspicuous heads of Apricot-coloured flowers that appear to be scentless. But I did come on one well-garnished plant, and in this the effect was quite respectable.

A remarkable thing about this region, as compared with that of Hpimaw, is the much greater height to which many species ascend. Conspicuous in the glades of the lower alpine region are the occasional snowy inflorescences of *Lilium giganteum*, which in the southern part of the range has never been seen, at least by me, above 5,000-6,000 feet at the most. Whatever other good things these meadow-slopes contain only the later weeks of August will reveal. Even now the huge snow-mass blocks the glen at ten thousand feet, though higher up the last of

these are now crashing to pieces unexpectedly with a rumbling roar like avalanches—and in a few days more the crowded violet-sapphire eyes of *Primula sonchifolia* will be peering baldly from the dank brown earth banks thus revealed. Imagine finding *Primula sonchifolia* still in bloom or bud in August, at any height, on any of the Hpimaw Alps! With it, rarer, and only on the Moku-ji is to be seen the China-blue loveliness of *P. eusma* still; but there is no doubt that both these species are here (I should say) on the northernmost fringe of their distribution. *P. eusma*, indeed, I have always noted as a severely local species, but on the Hpimaw Alps *P. sonchifolia* is universal, magnificent and abundant. Here, though, I have seen it so poor as hardly to be recognisable, down on the Chinese side (only) of the Chawchi, it is only on the uppermost slopes of the Moku-ji that it is to be met with in anything like proper profusion or character.

Of course, *Primula*, on these granitic ranges, cannot be expected to show great prodigality in species, though with *P. nuda*, *P. eusma*, *P. sonchifolia*, *P. serratifolia*, and the new white and crimson, it certainly makes up in quality for any lack of quantity. But these Alps wholly lack the lowland species so conspicuous further south. Below Hpimaw the glens at 6,000-7,000 feet will give you *P. seclusa*, and the open meadows, *P. Beesiana*, *P. limnoica* (F. 823), and *P. helodoxa*. Even about Hpimaw itself, the open slopes at 6,000 feet are blue in April with *P. limnoica*. But here, though many are the lovely and inviting-looking marshes and green lawns between 6,000-9,000 feet, to which I have rushed panting up, in confident certainty of a *Primula*, not one is to be found in any of them, and I have at last sadly learned that in these parts it is useless to hope for a *Primula* under 11,000 feet at least. They do not even have the fringy *P. obconica* so lovely at 8,000 feet on the Shing-rup Chet. Their only exception is the curious little species of which I spoke as having found it in bud beside a waterfall at 10,000 feet under Shing Hong Pass. On the Moku-ji it fortunately also occurs, and enables me to give its portrait. It always seems to be very occasional and sporadic in the first place; and always to confine itself exclusively to wet vertical faces in the second. Not that too much stress must be laid on these peculiarities, since *P. limnoica*, about Hpimaw, likes the openest, driest banks, and *P. pratensis* (if you please), I myself have never seen, except in the very shadiest depths of the very darkest gorges in the very deepest forest. This new plant, moreover, need not, I think, greatly distress gardeners with its fads. It is a disappointing little species, with handsome sprayed-up foliage, and, at the best, a 6-inch scape, with, at the very best, some 8-12 flowers. But these, though of as bright a golden yellow as *P. Palinuri*, have also *P. Palinuri*'s pinched, narrow outline, and are only about a quarter of the size.

Before, however, we attain the camp, I must also draw your attention to the *Thalictrum* of the lower glades, for this is a truly superb species, of which I hope great things, in rich and cool herbaceous borders at home, if only it has not the nasty kink in its temper which has cheated so many of us out of the pleasure that *T. Delavayi* and *T. diptero-carpum* ought to have afforded. Perhaps it even is *T. Delavayi*, in an unrecognisable condition of health, for certainly no plant could look more comfortable-natured and easy to satisfy, in any circumstances that also suit *T. aquilegifolium*. It is, however, far larger, attaining 6-8 feet, and so impressive, indeed, that while it was still growing I made sure that its flowers would be dull and green. Instead of which, they turn out to be of a lovely lavender-blue, produced in enormous, showery panicles, far above foliage that matches their enormousness, but has all the delicacy of *T. adiantifolium*'s on a quadrupled scale. The Luk Sang *Thalictrum* of last year had much the same stature, I fancy, and purple flowers; but as that was a calcareous plant of dry, rocky slopes, from only 6,000-7,000 feet, I am not disposed to identify it rashly with this granitic lover of cool alpine glades. *Reginald Farrer*.

## GEUM REPTANS.

**GEUM REPTANS** seems always to remain a rather rare plant in gardens. When I look back, the only really prosperous colony I remember in cultivation was at Backhouse's Nurseries, York, about twenty years ago. There the plant grew in a bed of brown river sand (with probably something to its liking underneath) and there it flourished, flowered, and even increased, by means of its Strawberry-like runners. There is never the least difficulty in finding plants labelled *Geum reptans* in gardens, and, moreover, one can generally pay the price of *G. reptans* for *Geum montanum* labelled as *G. reptans*. Often have I speculated on these lines, offering a good herring only to catch a poor sprat!

*Geum reptans* always grows high in the Alps, at about 7,000 to 9,000 feet altitude. It is local rather than truly rare, for it is quite widely distributed, and in its chosen stations it is often profusely abundant. Always it is a moraine or a scree plant, growing on deep beds of big coarse boulders, into which it roots deeply. Mature, established plants are extremely difficult and laborious to collect, and it is a mistake to try, for even if one can secure them intact, they are difficult to deal with and difficult to re-establish.

Until 1920, I had somehow always managed to miss *Geum reptans* in the Alps. But in June of that year I arrived at the Lantaret, and then one of the first things I came upon when I walked out of the hotel was *Geum reptans*. There is a great delta-shaped scree pouring down from the heights that face the hospice, less than a mile away. The intervening meadows were a flowered carpet of every alpine loveliness: *Dandelions*, *Gentiana verna*, *Viola calcarata* of every shape and colour, alpine Forget-me-not, *Anemone alpina* and *Anemone vernalis*, Poet's *Narcissus* and many, many others. It was more wonderful than anything even that I have ever seen at Mt. Cenis itself. I splashed up a shallow stream set with numerous islands, each a perfect tiny garden of turf and rock, *Gentians* and *Pansies*, the largest island no bigger than a tablecloth. And so to the great barren-looking scree, of harsh, tumbled stones, which poured steeply from a high neck in the towering cliffs overhead. Directly I got on to it I realised what a vast unmanageable rough-and-tumble it was. The stones ranged from the size of my fist to the size of my hotel.

Very soon, and quite unexpectedly—though these high screes are always good hunting—I came upon the first *Geum reptans*, and after that, far up the slopes, the plant grew by the hundred. From a thick, woody stem there spouted a tuft, or several tufts, of six-inch feathered leaves of soft, fresh green. Each tuft carried several flowers, often four or five, like very large, rich golden Strawberry blossoms, each set well and boldly up upon its own pink stem. I wandered about over that scree for a long, long time, drawn from one splendid *Geum* to another. There was little else of interest. *Hutchinsia alpina*, *Iberidella*, *Saxifraga oppositifolia*, and a few others, but *Geum reptans* was the most abundant and the most splendid.

Then, despite what I had always read of the difficulties of collecting *Geum reptans*, I settled down lightheartedly to collect it. At ground level I found a thick woody stock, going straight down among the stones. This stock was thumb-thick, or thicker, and its home was like a roadside heap of road-metal, greatly magnified. I took off my coat and sat on it, and settled down to remove stones from around my *Geum*. There was no soil, just big stones. It seemed a simple thing to lay bare the roots of a plant by pulling out stones and tossing them down the slopes, so I tossed stones, big and little, for a very long time, and finally achieved a basin a yard across and some eighteen inches deep. My *Geum* stood up in the centre like a miniature Coco-nut Palm. But still the woody stock descended into the scree, and at 18 inches I had reached no sign of a root,

\* The previous articles by Mr. Farrer were published in our issues for June 21, June 28, July 12, August 9, August 23, September 6, September 27, October 18, November 1, November 22, and December 6, 1919; January 3, January 17, February 7, February 28, March 20, April 24, May 29, July 10, July 31, September 4, October 2, December 4, 1920; January 1, January 29, February 19, April 2, April 30, June 4, July 9, August 6, September 24, October 22, November 12, December 3 and December 7, 1921.

though at this depth the interstices between the stones were filled with coarse, moist grit. Finally I gave up my first *Geum reptans* as a bad job, slid a barrowful of scree down into the basin I had made, and set out for younger plants. But even such younger ones as I found were very hard to lift. Although a few that I got up had a root or two emerging like leather bootlaces from their trunks, I could get none clean out in such condition as to give me any hope of establishing them at home. They have, however, lived in a grudging sort of way.

Undoubtedly *Geum reptans* is difficult to collect. Obviously, the best way would be to get the Strawberry-like runners. These were pushing out in all directions, questing over the rocks and poking down between the stones in search of a rooting place. But in mid-June these long, slender runners were only just beginning to show signs of developing youngsters at their tips; they were far too immature to be taken off.

The following summer, 1921, however, I returned to the Lantaret in mid-July. I had a horrid shock. The flowers were all gone and the visitors had arrived. Those wonderful meadows of the previous year were like my own doormat at home—with less soil. It was only by going very much higher, on the Galhier Pass, that I found any flowers, and then they were a different set. The stream below the *Geum* scree had shrunk, so that the little island gardens were now flowerless and no longer islands. But *Geum reptans* was there, with even a belated blossom or two, and many silky heads of ripe seed, and, best of all, the runners had developed splendid little plants at their tips, each with a leaf or two; some with young roots sprouting and groping for a foothold down in the deep cavities among the rocks; and the rest with a sort of fleshy callus all ready to burst into roots at the least encouragement. These were delightfully easy to collect, and they travelled home in an airtight tin without distress. Dibbled into pans of soil with an inch-thick "icing" of silver sand, they rooted in a week or two, and have looked very pleased with pot life ever since. The seed, too, which I collected, and sowed with more charity than faith, has surprised me by germinating with almost embarrassing freedom.

Now, having overcome the usual difficulty of securing live plants, with roots, of the true *Geum reptans*, there arises the problem of how to flower them. But I do not think that should be so difficult as is generally supposed. *Clarence Elliott, Stereage.*

## PALMS OF THE RIVIERA.

I SHOULD have mentioned the Chinese Hemp Palm, *Trachycarpus excelsus*, H. Wendl (see Fig. 34), before in these notes, because it is one of the commonest Palms in Riviera gardens, and well known also in the warmer parts of England, where this, the hardiest of all Palms, resists the winters, though it is much finer in the warmer climate of the Riviera. It is a very distinct species on account of the blackish fibres, like thick, long hairs, which densely cover the trunk right down to the soil, surrounding the bases of the dead leaf-stalks, which never fall off, however old the Palm is, and never decay. The long, blackish, hair-like filaments, being rather strong, are used by the Chinese for making ropes. The trunk is rather slender, much more so than the trunks of the other Palms I have mentioned hitherto, and which belong to the same tribe, the Corypheae (*Washingtonia*, *Erythea*, *Brahea*). The rather dense crown of palmatifid leaves—the blades being almost of circular form of one metre in diameter and carried on leaf-stalks of the same length of a beautiful dark green—makes this Palm quite ornamental.

It is quick growing in good, sufficiently moist soil, and will succeed anywhere here in the full blazing sun or in perfect shade and, as usual in this last situation, the leaves become softer and of a deeper green, being

thus of a less stiff appearance than when grown in the full sun. It may, on account of its quick growth, be used very profitably for creating Palm woods or clothing such places as have a northern position, where other Palms do not prosper except, as I said in a former article, *Chamaerops humilis*, a much smaller species. The flower spadices are like those of most other Palms, and develop in a circle from the axils of the older leaves. The

I have very rarely met it coming up spontaneously in really wild places, just as is the case with so many species the seeds of which germinate readily enough in gardens where the soil is loosened by cultivation, but hardly ever where such is not the case. Perhaps, also, the fruits of the Palm are not much appreciated by birds or animals, which might disseminate the seed. The Palm grows some ten metres high, and is thus a species of medium height.

FIG. 34.—*TRACHYCARPUS EXCELSUS*; A PALM HARDY IN THE WARMER PARTS OF THE BRITISH ISLES.

flowers, of light-yellow colour, are followed by a great number of ornamental, bluish-black, kidney-shaped fruits that are the size of an ordinary Bean.

Seeds germinate freely under the plant, and seedlings spring up in great numbers.

The species is quite naturalised here in gardens, and is sometimes seen coming up on rubbish heaps constituted of garden refuse, but

Some other species of *Trachycarpus* have been described, but these are exceedingly rare in Riviera gardens. They differ so little, at least those cultivated here as different species, that I should, up to now, hesitate about their identity. Prof. Beccari, who has described these species, admits himself that the characters are little distinct. I may here state that the Palms which I have raised from seeds received

from India under the name *Trachycarpus Martianus*, H. Wendl, cannot be distinguished from *T. excelsus*, at least up to the present. *T. Martianus*, differently from *T. excelsus*, sheds its leaves and thus has a clean trunk, which is not the case with my plants, nor with such as I have met in other gardens. It is, therefore, probable that the true species may not yet have been introduced, and that the Palm going under the name of *T. Martianus* on the Riviera is either chiefly *T. excelsus* or some other species. The true *Trachycarpus Martianus* grows to a height of seventeen metres, has a thin, gracefully bent trunk, and leaves of the same size as those of *T. excelsus*. I should like to obtain fresh seeds of the true species, which is found in the Khasya mountains in Assam and Northern Burma, as well as of other species of this very hardy genus of Palms, and should be pleased to receive them from anyone who reads these notes.

In parts of India, such as Mount Takil, in Kumaon, other species are found at great altitudes, and these Palms should certainly prove hardy, not only on the Riviera, but perhaps in the milder parts of England; also in Yunnan, China, are found one or more wild species. Dr. A. Robertson Proschovsky, *Jardin d'Acclimatation, Les Tropiques, Fabron, Nice, France*.

## RAISING CONSERVATORY PLANTS FROM SEED.

(Concluded from page 56.)

COMING now to seeds for present sowing to carry on the display until November, tuberous-rooted Begonias deserve pride of place. We live in an age of specialists, and where the massive double-flowered varieties are required the best source for the seed is one of the few firms that have built up a reputation for these plants. The new *Narcissus*-flowered type is worth including as a novelty. The pendulous section for hanging baskets is just as easily raised from seed, and few subjects receive more admiration when well grown. *Gloxinias*, under rather warmer conditions, furnish a welcome succession to old tubers in August.

*Streptocarpus* hybrids show as great an improvement as any greenhouse plants which are habitually raised from seed, and are now quite as useful as *Gloxinias*. Stove treatment was at one time recommended, but intermediate conditions are quite as satisfactory. Although *Clerodendron fallax* requires warm house culture, it may, when in flower, be used in the conservatory, and the large heads of scarlet flowers and luxuriant foliage are welcome, since in their season handsome plants are none too plentiful.

*Cannas* are never out of place, and young plants revel in a fair amount of heat and moisture. Messrs. Sutton and Sons have a pink variety which associates well with *M. Crozy's* hybrids. *Browallia speciosa major* is a plant with a neat habit and bright blue flowers. *Exacum affine* produces sweetly scented mauve flowers on bushy little plants 9 inches high.

All the *Impatiens* prove useful during the summer, for they remain in bloom over a long period and give very little trouble in cultivation if fed liberally. Few summer annuals are more attractive than *Statice Saworowi*, with its long spikes of bright rose-coloured flowers, which last well when cut. *Torenia Fournieri* is another profuse-blooming annual with violet-blue flowers. *Gesneras* and *Achimenes*, grown in the same conditions as *Gloxinias*, are useful plants for autumn effect. Although most of the *Asclepias* are of perennial habit, early sown seeds of *A. curassavica* will produce handsome plants in their first season, and the reddish orange-scarlet flowers, borne in erect clusters, are most striking. Blue flowers are not plentiful in the garden in winter, and for its handsome spikes in this shade *Coleus thrysoides* should not be overlooked. Another handsome pot plant is *Campanula*

*pyramidalis*, in blue and white varieties, seeds of which should be sown in August and the plants grown on under cool conditions. *Humea elegans* is another biennial of attractive appearance, and well repays the little extra care needed to grow it.

Amongst indoor plants which are looked upon as more permanent occupants, but which may be raised from seeds, are *Hippeastrum*, yellow-flowered *Richardias*, *Hibiscus Manihot*, *Acacia dealbata*, show *Pelargoniums*, *Fuchsias*, *Solanums*, and several Palms. Y. G.

## CYCLAMEN LATIFOLIUM IN THE UNITED STATES.

THE notes on *Cyclamen* in the *Gard. Chron.* of December 24, 1921, by Mr. John Heal, prompts me to send a few remarks on these plants as grown in the United States of America.

Mr. Heal states that the *Cyclamen* is one of the most popular of winter-flowering plants. This applies to the U.S.A. particularly, for since an Order put an end to the importation of *Azaleas*, the *Cyclamen* has been used most extensively in their place. True, good *Azaleas* are now being raised by a few growers here, but it will be years before enough are produced to replace the Belgian stocks; moreover, their cost will never make them a profitable speculation for the average grower of forced plants.

The *Cyclamen*, however, may be grown by everyone if they have the facilities and the interest; those that haven't can buy the plants half-grown and flower them fairly easily.

It is astonishing how the *Cyclamen* has been taken up by American growers during the past two or three years; until the Germans were able to get their crops of seed over here in 1919 there was not nearly enough seed to meet the demand, and as there were only two or three growers in U.S.A. producing seed, the supply of English seed had to go round as far as possible.

Since 1919, German seed has been coming into this country in quantity, and every plant grower up and down the country has tried his hand. Some, especially those who always specialised in *Cyclamen*, have made a great success of the plants, and, incidentally, much money; others have had bad luck with them, and especially this season. Mite is a serious pest, and, in a general way, it is only those with some European experience who have kept this and other pests in check, due, of course, to the fact that they know the importance of cleanliness, and growing the plants in moist, cool conditions.

I may be wrong, but I do not think anyone at home produces such wonderful plants of *Cyclamen* as are produced by a few growers here, including Messrs. Roland, Boston; Craig, Philadelphia; Petersen, Cincinnati; and Lehning, Hackensack. All these growers have had European training, and probably have European trained labour. Thos. Roland is of English birth, and is one of the greatest pot-plant growers in this country. His largest *Cyclamen* plants, well over 2 feet in diameter in 8-inch pots, were retailing this Christmas in New York at \$20, say, £8 each. I may state that for quality of flowers these commercial growers' plants are not so fine as I have seen in England; generally speaking, English seed produces finer flowers, but not such vigorous plants as the German seed.

At least I am informed that this is so, but for all that I have seen plants raised from English seed in March carrying well over 100 flowers, and nearer 3 feet than 2 feet across. These were shown in New York by a private gardener, a Scotchman named Stuart. He is a great enthusiast on *Cyclamen*, and as he was in England this past summer, he made a pilgrimage to Harlington, Middlesex, just to talk *Cyclamen* with the veteran grower of the St. George's Nurseries, Mr. Tom Avery. I often think that had Mr. Avery been in America during the past ten years he would be rolling along the highways in his twin-six

motor-car, instead of handling a water-can. I may mention that the commercial growers here mostly sow in flats and transplant the seedlings singly at a fairly early stage of their development. The marvel about the seedlings is that they grow so well in large houses, despite the hot summers here; shading is done with scrim on wires, and watering or spraying by means of a hose. I have never seen anyone using a can, but I assume they do adopt this method of watering when the plants are small.

Ashes are used on the benches, which are rarely solid. I have not met a grower who gives his plants cold frame treatment in the summer, although there are some that do so, even in Canada.

American growers make two or more sowings, the first as soon as the seed is available. In this respect the Germans get in first; moreover, as they have been sending such large quantities, doubtless some left-over stock is utilised; the wise grower prefers such seeds, because it germinates more readily than fresh, but others think of fresh seed only, and therefore do not start sowing before some time in August. Plants from the early sowings in the hands of expert growers begin flowering in October, but there are some who can get good plants in 4-inch and 5-inch pots from March sowings.

I am rather surprised that Mr. Heal recommends the saving of old corms, and especially drying them off. Even in England I thought old corms were more or less taboo; at least those who saved them keep them growing. Treated like seedlings, that is, shaken out after flowering and repotted in fresh soil and brought along as seedlings, old corms make fine plants, but if a 2 ft. specimen can be obtained from seed inside eighteen months, old roots are not worth considering. In this country no one appears to save them.

Regarding potting, plants required for blooming early in winter and for the Christmas trade are in their flowering pots by September or October, but later plants are potted on even so late as December. Repotting, of course, checks the blooming somewhat, but it results in finer and more substantial specimens. If allowed to get pot-bound, the plants do not last long after reaching the buyers' home.

It is rather remarkable that the variegated type, such as *St. George* and *crimson St. George*, are not handled by commercial growers here. I have not seen a plant anywhere, yet some of the seedsmen list them. I suppose it is a question of cost; for the average American plant grower is apt to consider price first, and for this reason gives German seed a preference. One German grower here was, I found last year, paying some attention to variegation in the foliage. He had been selecting towards this end. He was quite surprised when I told him that if he kept on another five years he would just about be where the *St. George's* nursery was ten or twelve years before. Yet several seed lists quote the variegated varieties mentioned, and references have been made to them, and even pictures published in the American trade papers.

American growers are no wiser than those of other nations when it comes to waiting for new plants. Indeed, I might hazard that the general run of commercial growers here are even more chary of trying a new thing than growers in England; they wait until someone reads the way, then all follow suit, *Roses* and *Carnations* excepted.

There are probably various reasons for this: many growers are of foreign extraction or foreign born, none too well versed in the English language, and therefore not given to reading much. Others, like some at home, are suspicious, too slow, or too busy to bother about things they know nothing of. And then, of course, there are some who know so much that they do not interest themselves in what others are doing; they assume they are far ahead of the outside world. Luther Burbank once said he was too much concerned with his own work to pay heed to what others were doing. Such people live in a world of their own; there are lots of them everywhere. T. A. W., *New York*

## THE MARKET FRUIT GARDEN

JANUARY was a month of changeable weather, the most cheering feature of which was the substantial rainfall. Here, in East Sussex, rain or snow fell on 21 days, the total for the month being 4.50 in., which is well above the average, and more than was recorded in any single month of 1921. Much of this rain conveniently came at night, so that there was no serious interruption to outdoor work. It soaked away quickly into the dry earth; but drains are running again, and wells that have been dry for weeks are filling at last, which is evidence that we are getting back to normal conditions. There was a good deal of cold east wind during the month, and a blizzard on the 15th, which left the ground covered with snow for three days, on the last of which 14 deg. of frost were registered 4 ft. from the ground. It is to be hoped, therefore, that vegetation has received a wholesome check. It is early to prophesy, but I fancy we shall have a later spring than in the last two years. The first yellow Crocus was in bloom in my garden on the 29th, a fortnight later than last year; and fruit trees do not appear to be so forward. As a late spring is favourable to fruit crops, prospects so far are cheerful.

### PRUNING.

The work of pruning is well forward. As a natural result of last season's drought there is less new wood than usual, and in many instances fruit spurs have formed right up to the tips of the shoots. In such cases the pruners are instructed to search for a wood bud lower down, cut to that, and then clear the shoot of spurs for several inches from the end. This, I hope, will set them growing again. There are fewer fresh canker wounds on Apples than usual, but there is a good deal of scab on the young shoots of such varieties as show the winter stage of this fungus, notably Cox's Orange. When the trees begin to show signs of life they will be sprayed with a simple solution of sulphate of copper, 10 lb. to 100 gallons of water. I believe that this is the best preventive we have at present against scab or brown rot. The later the spraying can be done the better the result, but it must not be delayed too long, as the wash is very destructive to foliage. Slight scorching of the outside leaves of the expanding fruit buds, however, appears to do no serious harm, though one likes to avoid it.

### NEW FUNGICIDE WANTED.

The East Malling experiments with summer fungicides emphasise the fact that we have no really satisfactory wash of this kind. Bordeaux mixture is the most successful against scab, but the fact that it russets the fruit is quite sufficient to condemn its use in commercial orchards, apart from the risk of scorching the foliage of certain varieties. Lime-sulphur, which many of us have adopted as a substitute for Bordeaux mixture, is less effective against scab and causes a proportion of the fruit to drop before it matures. Ammonium polysulphide is almost useless against scab though valuable for mildew. It seems, therefore, that we are badly in need of a new fungicide. Surely the chemists who worked such wonders during the war could accomplish this. There is an urgent need for a fungicide that is really effective as a preventive of scab without being harmful to the crop or the trees, for nothing does more than scab to lower the quality of our Apples and Pears and make it difficult to place a good sample on the market.

Possibly further investigation will discover a safe formula for Bordeaux mixture. It seems absurd that there should still be in use several formulae for such an old fungicide. The 8-8-100 formula (8 lb. copper sulphate, 8 lb. lime, 100 gallons water) may perhaps be considered as the standard; but it is hopelessly liable to cause russetting and scorching. The 8-25-100 and the 6-20-100 formulae are less harmful, but have not proved by any means free from objection at East Malling. The question is, Can the copper sulphate be still further reduced without impairing the value of the mixture as a fungicide? There is reason to believe that this might be done. A visitor to my farm, who has grown fruit in

Tasmania, where scab is apparently much more harmful than it is here, told me that he has used as little as 3 lb. of copper sulphate in 100 gallons of wash with good results. He believed that the wash could hardly be too weak, provided that the spraying was done at the best time. In Tasmania the best time has been established by careful tests. It is just when the fruit buds are in what he called the "final pink" stage, which would be about at the time when we usually spray for aphid and psylla. There is, of course, no reason why this should be the best stage for spraying to control scab in this country. Some time within a fortnight after the fall of the bloom is generally considered to be correct, though we have no definite evidence.

### TASMANIAN STYLE OF PRUNING.

From the same source I gained some interesting information about the system of pruning followed by growers in Tasmania. The trees are grown with about ten branches radiating from a short stem. These branches are never allowed to multiply or sub-divide, but are treated as cordons. So far, the system may not appear to differ much from that followed in a good many English gardens; but the treat-

leaf is prevalent, which have not a trace of the disease. Yet in other places it is practically impossible to grow Victoria at all. What are the conditions that favour the disease? Growers hold conflicting opinions on this question. Some think that starved trees fall easy victims, and claim to keep silver-leaf at bay by generous manuring. Others believe that over-luxuriance brings the trouble.

Whatever the cause may be, there is no doubt that the effect is very serious. Many orchards of Victoria have been grubbed, and few are planting the variety, which is our best mid-season Plum. As a result, we are threatened with a gap between the early and late varieties. In some cases this is filled by Belle de Louvain, which suits me very well, but is a very shy bearer in some districts. Probably a better market variety is the Purple Pershore, which is said to be a very heavy bearer and less liable to silver-leaf than many kinds. The Pershore growers were not unnaturally inclined to keep this variety within their own district, but it has leaked out and is being planted extensively in other parts of the country. *Market Grower.*

FIG. 35.—PEAR THE BLICKLING.

ment of the laterals is quite different. There is none of the foolish short spurring commonly seen in this country. The laterals are left several inches long, or even full length in the case of some varieties, until they form natural fruit spurs, after which they are shortened to one of those spurs. Quite a lot of temporary wood may be left at the base of the tree, so as to bring it early into bearing, this being gradually reduced as the upper part of the tree comes into fruit. The leaders are shortened annually. Both Apples and Plums are pruned on this system. There is no proof, of course, that the plan would prove to be the best in this country, but it would be worth trying on an experimental scale. Trees so trained have several advantages, the chief of which is that the branches can be bent down for pruning and fruit-picking, thus doing away with the nuisance of steps or the damage of ladders. They are also economical for spraying; and the pruning, once the trees are in bearing, is practically fool-proof.

### SILVER-LEAF IN PLUMS.

Without questioning that silver-leaf is caused by the fungus *Stereum purpureum*, there are still mysteries connected with this serious disease of Plums. Why does it attack some orchards and not others? There are old, neglected orchards of Victoria Plum, the most susceptible variety, in districts where silver-

## FRUIT REGISTER.

### PEAR THE BLICKLING.

This variety of Pear (see Fig. 35) gained an R.H.S. Award of Merit, January 8, 1907, when exhibited by Mr. William Allan, of Gunton Park Gardens, Norwich, who discovered it some years previously growing in the gardens at Blickling Hall. Mr. Allan has kindly forwarded us specimens of the variety from Gunton Park Gardens, with the remark that he considers it quite one of the finest flavoured Pears in season in January, if not the best. That such a competent fruit grower as Mr. Allan should express such a high opinion of the variety after some fifteen years' acquaintance with it, is high testimony to its merits. It has been described as a late Doyenné du Comice, and it has a similar white, melting, juicy flesh, but there is just a trace of grittiness in the variety which is absent from Doyenné du Comice. According to Mr. Bunyard, in *A Handbook of Fruits*, the variety is said to have been introduced from Belgium by a monastic order, and he describes it as a delicious fruit, rather like a late Comte de Lamy. The tree makes a moderate amount of growth which is of good fertility; in the majority of gardens it would probably succeed best as a wall tree. The specimen illustrated in Fig. 35 is from a photograph of one of the fruits kindly sent us by Mr. Allan.

## NOTES FROM WISLEY.

A FEW spring flowers are now beginning to appear at Wisley, the most conspicuous so far being Snowdrops. A few Crocuses are showing, and here and there a *Narcissus bulbocodium*. *Hamamelis arborea* is in flower and near by is *H. japonica* var. *Zuccariniana*. The flowers of the latter are of a paler yellow and smaller than those of *H. mollis*, which is seen to great advantage in the wood against the background of evergreens. The flowers give out a pleasant odour, which may often be detected at a considerable distance.

Another shrub with a delightfully scented flower is *Viburnum fragrans*; this was raised from seed sent home by the late Reginald Farrer, and it is now in bloom for the first time at Wisley.

A welcome surprise on the border behind the glasshouses is the unusually free flowering of *Parrotia persica*. The half-opened flowers, which often escape notice, here stand out in the sunlight almost like scarlet berries.

*Pieris (Andromeda) floribunda* is well furnished with its clustered spikes and should soon be a mass of flowers. The common Hazel is beginning to bloom, and many species of *Salix* have already burst their buds.

Under glass, the trial of Carnations is providing some bright colour. An *Antirrhinum* trial is also in progress, but at present the plants are, naturally, quite small.

In the Alpine house the flowers of *Saxifraga Burseriana* major, *S. B. glabra* and, most charming of all, *S. B. crenata*, are to be seen, as well as *S. Irvingii*.

The germination of some of the seeds sent to Wisley by the Mt. Everest expedition is providing a good deal of speculative interest. *J. E. G. White*.

## HOME CORRESPONDENCE.

[The Editors do not hold themselves responsible for the opinions expressed by correspondents.]

**Rhododendrons.**—No one reading Mr. Magor's interesting remarks (p. 42) on the above subject will contradict him as regards the beauty and excellence of the plants he mentions, but I feel that some reference to climate and situation should be made for the benefit of your many readers deeply interested in Rhododendrons, but lacking the knowledge to discriminate between species of service to them as garden plants and those suitable only for very favoured spots where they can not only be grown but flowered. Suppose, for example, a reader should be attracted by the six plants named by Mr. Magor as his choice, and let us assume such a reader lives in Cheshire. The eastern side of this county is one of the best districts for the growing of hardy hybrids, but the probabilities are that he would never see a bloom from any of the six species except *R. Augustinii*, and I conclude that he would be annoyed at the result. The Rhododendrons named by Mr. Magor may be grown by experts in favourable spots, but, even then, many disappointments will follow. I agree entirely with Mr. Magor's contention that the species and finer hybrids he mentions are incomparably more beautiful than the hardy hybrids, but when it is considered that these specialities can only be grown by perhaps 2 per cent. of persons interested in the cultivation of Rhododendrons, it seems necessary to point out their limitations. This is not the moment for me to enlarge upon the possibilities of hardy hybrids, which thrive equally well in the suburbs of Manchester or in gardens side by side with their more delicate relations, but on reading Mr. Magor's article I felt constrained to take up the cudgels on behalf of that somewhat abused section of Rhododendrons. I venture to suggest that, should cultivators in the greater part of England be restricted to the species and few hybrids mentioned by Mr. Magor, the landscape would suffer to a very considerable extent. *F. Gomer Waterer, The Cottage, Bagshot.*

**Libonia floribunda.**—A perusal of several issues of *The Gardeners' Chronicle*, ranging over different years, fails to find any mention of this plant. I may have overlooked such a reference, or perchance the name *Libonia* is otherwise rendered—in which case such information will be much welcomed. Neither is there such a name given in the 1901 issue of *Thompson's Dictionary*, nor is it to be found in a very recently-published gardening dictionary. The omission of this plant from more latter-day writings would seem to indicate that it is none too well known, which is a great pity, as this *Libonia* has real beauty and decorative worth approaching, when well grown, some of the winter-flowering Begonias. The flowers are tubular-shaped, about an inch long and bicoloured, a blending of scarlet and yellow which, when seen in a grouping of several plants, is most distinct and attractive. The foliage is glossy, small and ovate, while the blossoms depend, like those of Solomon's Seal, along the stem, varying in length, according to the strength of each shoot or growth. Cuttings are easily rooted in sandy soil from shoots procurable towards the end of spring and early summer. After their first potting, *Libonias* may be grown in cold frames, while, for a time previous to being housed for the winter, outside treatment is not harmful to healthy plants. During December and January, when at their best, a greenhouse temperature ranging from 45° to 52° is sufficiently high. One plant in a 48-sized pot, or three in a 7-inch pot, give useful results—while specimens grown as "cut-backs" would appear to flower more freely than so-called one-year-old plants. *C. Turner, Amphill Park Gardens.*

[*Libonia floribunda* is a plant common in cultivation, and our correspondent's failure to find the name in some gardening works may be due to its being described under its more correct name of *Jacobinia pauciflora*.—Eds.]

**Winter-flowering Begonias.**—Several correspondents have during the past few weeks referred to these beautiful flowering plants in your pages, and it is true that the autumn and winter-flowering Begonias make a glorious display during the dull months of the year. The *Gloire de Lorraine* type flowers first, in October and November, and at Christmas that magnificent variety *The King* comes into bloom. I have plants of this variety (end of January) two feet high and the same distance through. Plants of Mrs. Peterson, with its beautiful dark foliage and pink flowers, in four inch pots, are as large as those of *The King*. All the plants are clean and have not been fumigated once, and I attribute this freedom from pests to my method of cultivation. The worst evil is rust; as soon as this is detected the plants should be burnt, as there is no practical cure for it. I never allow the water pipes to become too hot; should the pipes be overheated many times a grower will very soon find his plants infested with green fly and thrips. All the Begonias revel in heat and moisture; the house should be closed early, and shaded from sunshine so as to keep the growth soft until the autumn months, when the plants will naturally become harder as the flowering period arrives. For potting compost I use a light mixture of turfy loam one part, leaf-mould two parts, and the same of peat, with plenty of sand. No chemical manure is used. During the past season I used dried sheep manure rubbed through a half-inch sieve, in preference to dry cow manure, but an undue amount of this fertiliser would cause the plants to make excessive growth, which results in fewer flowers. I give the plants plenty of water during the growing season, and use the syringe freely, but during the winter give water only when it is needed. When cutting back the plants it is a good plan to do this gradually, removing the flower stems first and leave six to eight inches of growth for the production of cuttings. It is a barbarous practice to cut the plants down to within an inch or two of the pots. When feeding use liquid cow or sheep manure; soot water may also be given the roots. *Wm. Fulford, Delrow House Gardens, Aldenham.*

## SOCIETIES.

## MANCHESTER AND NORTH OF ENGLAND ORCHID.

JANUARY 19.—Committee present: Messrs. J. Cypher (in the chair), B. J. Beckton, Dr. F. Beiford, J. Birchenall, D. A. Cowan, J. C. Corran, J. Evans, J. Howes, A. Keeling, D. McLeod, J. McNab, E. W. Thompson and H. Arthur (Secretary). Owing to the adverse weather the exhibits were not so numerous as usual.

## AWARDS.

## FIRST-CLASS CERTIFICATES.

*Odatoglossum crispum* X.L. All. A large white flower of perfect shape, with small red spots on the lip. *Cypripedium Viking*. The dorsal sepal is white, with a brownish-green base and a deep broad claret line down the centre; the petals are greenish-yellow with brown lines and a dark brown line along the centre; the pouch is greenish-yellow. From S. GRATIUX, Esq.

*Cattleya Enid Colossus*. An exceptionally large flower of fine shape and dark, round lip. From D. LOSH-THORPE, Esq.

## AWARDS OF MERIT.

*Cypripedium Merlene* var. *Golden Noble* (Selene x Lord Wolmer); *C. Lord Wolmer* *Hestonbirt* var. From Mrs. GRATIUX.

*C. Nyobe Lecanum* var. *Tom Clare*. From Miss BOLTON.

*C. Perseus Regina* (Alcibiades illustris x Lady Dillon). From S. GRATIUX, Esq.

*Laelio-Cattleya Schroderae* var. *Prince Henry*. From D. LOSH-THORPE, Esq.

## CULTURAL CERTIFICATE.

MR. F. COOKSON for *Calanthes* in variety.

## GROUPS.

S. GRATIUX, Esq., West Point (gr. Mr. J. Howes), staged a group of choice *Cypripediums*, for which a large Silver-Gilt Medal was awarded.

A. T. CUSSENS, Esq., Kersal (gr. Mr. F. Cookson), was awarded a Silver-Gilt Medal for a group of *Cypripediums*.

MESSRS. CYPHER AND SONS, Cheltenham, were awarded a Silver Medal for a group of *Cypripediums* in variety.

## ROYAL HORTICULTURAL OF ABERDEEN.

THE first of a series of lectures under the auspices of this society was given in the Botany Classroom, Aberdeen University, on Wednesday, the 1st inst., by Dr. MacGregor Skene, lecturer in vegetable physiology at Aberdeen University. These lectures were previously conducted by the North of Scotland Horticultural Association, a body which for many years did valuable propaganda work for horticulture, but is now merged in the Royal Horticultural Society of Aberdeen. Dr. Skene took for his subject "The Making of a Flower," and delighted his large audience with a most instructive and interesting lecture. To get to the beginning of the long series of evolutionary changes which had produced the flowers which delighted them to-day in their wild state, and which formed the material with which breeders had worked to produce their garden forms, it was necessary, said Dr. Skene, to go back a long way. The seed came before the flower, and it was in the geological epoch, when coal was being laid down, that there first arose a race of Fern-like plants which bore seed. The production of seed might be looked on as giving protection to the reproductive units, guarding them against drought, and so allowing the seed plants to grow in dry places and to conquer great areas of the land surface. Later these early seed-bearing Ferns became the origin of a stock of plants represented to-day by the Cycads. In the vegetation of the secondary geological period the Cycads were dominant, and in that period they produced members in which the reproductive organs were arranged in a primitive flower. From such beginnings the flowering plants of to-day had evolved, the

most primitive type now extant being probably the Tulip Tree.

The factor which had determined the production of colour, scent, and nectar was the insect visit, which transferred pollen from stamen to stigma. All these features were to be explained in relation to the insect, and, if those characters which were determined by this inter-relation were taken away, there was no flower in the ordinary sense left. The dependence of the flower on insect pollination was evident in many ways. The Monkshoods were pollinated by bumble-bees, and in their distribution they always kept within the bumble-bee zone. Red Clover, *Trifolium pratense*, set no seed in New Zealand till bees had been introduced. Foreign garden plants had frequently to be pollinated by hand, in the absence of insects.

With wild flowers as material, man had fashioned the garden varieties, using the tools of selection and hybridisation. He had converted a few wild species of Tulip into thousands of varieties. The Tulip was a capital instance of the fascination of the history of a cultivated flower. Brought by merchant seamen of Holland to Leyden, its cultivation became such an obsession in the seventeenth century in Holland that laws had to be passed to prevent dishonesty in a trade in which incredible sums changed hands for a single bulb. Thus was laid the foundation of the great Dutch bulb trade.

The lecture was illustrated by beautiful limelight views, and hearty thanks were accorded Dr. Skene for the highly instructive evening he had provided.

#### ELSTREE AND DISTRICT HORTICULTURAL.

The annual meeting of this Society, held recently, was followed shortly afterwards by the annual dinner and social evening.

Mr. Edwin Beckett presided at the annual meeting. A very satisfactory state of affairs was reported by the Hon. Secretary, Mr. W. J. Pritchard, on behalf of the Committee. After meeting all claims, and making a donation of ten guineas to the local sports club, the available balance was shown by the accounts to have risen during the year from £9 16s to no less than £36, in addition to which there is a deposit account with the bank of £20. Amounts received during the year as subscriptions, donations, and for special prizes amounted to £65, whilst the Society expended £72 upon prizes at the annual summer show.

Special votes of thanks were accorded to Lord Aldenham, the Hon. Vicary Gibbs, and the Hon. Edith Gibbs, for their great help and support, and it was announced that the show for 1922 would take place at Aldenham Park, on July 15 next. During the evening several new members were elected.

Votes of thanks to the Chairman and Hon. Secretary terminated the business.

The annual dinner which took place at the "Plough Inn," Elstree, was a great success, the chair being taken by H. F. Thomas, Esq., Elstree. The company numbered about 80. The toast, "Continued Prosperity of the Society," was moved by the Chairman in a humorous speech, and was responded to, on behalf of the Society, by Mr. W. Cutbush, who emphasised the usefulness of the Society. The toast of "The Chairman" was moved by Mr. Ed. Beckett in a short but excellent speech, and was suitably responded to by Mr. Thomas. The musical items, which were numerous and varied, assisted greatly in making the evening an exceedingly pleasant and successful one.

#### WATFORD HORTICULTURAL.

The third of a series of lectures promoted by the above Society was given in the Council Chamber on the 25th ult. by Mr. F. W. Miles (County Staff Lecturer). Major E. W. C. Monro presided over a large attendance. Taking "Up-to-Date Vegetable Cultivation" as his subject, the lecturer dealt with it in a style which com-

elled the interest of his audience. Rotation of crops, the art of intercropping, the vexed question of manuring, and the best varieties of vegetables were all dealt with. The Chairman, in proposing a vote of thanks, added interesting remarks concerning the seed-growing industry.

#### BRITISH MYCOLOGICAL.

A MEETING of the British Mycological Society was held at University College, London, on Saturday, January 21, the President, Mr. F. T. Brooks, in the chair.

The first paper was by Mr. W. B. Crow on *Leuconostoc mesenteroides*, which was formerly frequent in sugar works and was principally responsible for the so-called "frog spawn" which appeared in the vats containing sugar solutions.

#### SYMBIOSIS IN *CALLUNA VULGARIS*.

This was followed by a critical review by Dr. M. C. Rayner of a recent German paper by H. Christoph, in which he comes to quite opposite conclusions from her well-known results on obligate symbiosis in *Calluna vulgaris*. The experimental results of her own work were first summarised. Christoph, who is apparently still in ignorance of these experimental facts, concerns himself with the manner in which the roots of *Calluna*, in common with the Ericaceae, become infected by a mycorrhizal fungus, and with the subsequent relations between plant and endophyte. As a consequence of germinating seeds on sterilised and unsterilised soils, he concludes that infection takes place always from the soil, never from the seed-coat. Moreover, he concludes that the relation between plant and fungus is entirely casual in nature and claims to have raised and grown healthy plants, the roots of which remain free from fungal infection. Unfortunately, the records of all experiments carried out by Christoph with sterilised seeds are at present valueless, since he offers no proof whatever that such seeds and the seedlings obtained from them were free from infection from micro-organisms. Nor were his seed cultures grown under aseptic conditions, since he records infection from the soil in some of them by other species of fungi, an infection regarded as of no consequence since the species concerned are incapable of infecting the roots.

Christoph isolated a fungus from the roots of *Calluna*, but was unable to identify it in pure culture as it did not spore. He claims to have established its identity by successful inoculation into seedlings, but the latter were already well rooted. Dr. Rayner pointed out that the obligate relation between plant and fungus which follows from her experimental results and the regular infection of seedlings from the seed-coat in no way involves the absence of the mycorrhizal fungus (a species of *Phoma*) from soil or precludes additional infection of roots from that source. It is obvious, indeed, that the soil about *Calluna* roots will always contain hyphae of this fungus, although the extent to which the latter can grow as an independent saprophyte in soil under natural conditions is at present unknown.

#### DIE BACK OF STONE FRUITS.

Miss D. M. Cayley followed with a description of the "die back" of stone fruit trees due to *Diaporthe perniciosa*. In the investigation of "die back" in stone fruit trees, although different fungi have been found to be very generally present on the diseased tissues, *D. perniciosa* has proved to be by far the most prevalent. The fungus has been isolated from Peach, Peach stock, Apricot, many different varieties of Plum, Apple stock (Type II., Malling), and wild Sloe. This "die back" appears to be of very general occurrence in fruit-growing areas in this country. The disease attacks trees of all ages, but the damage is most noticeable in young ones where the whole tree is killed very rapidly after the first external symptoms have appeared. The development of the parasite in the best plant is slow; infection occurs for a considerable time, in some cases probably years, before any definite external symptoms appear, but once wilting has

set in the affected areas die rapidly and the fungus completes its life history as a saprophyte on the dead wood. The first symptoms may be either rapid wilting and browning of the leaves during the growing season, or premature yellowing and fall of the leaves in autumn. In either case the parts affected are killed outright in a short time. The bark at first looks healthy, and frequently no external symptoms can be seen before wilting sets in. In other cases the bark may take on a reddish tinge, or slightly sunken areas may extend longitudinally down the stem or branch. The smaller branches or stems instead of being cylindrical are inclined to be angular or flattened. This angular appearance is due to the uneven development of secondary thickening, which is arrested in the diseased area, whereas normal growth continues in the parts of the periphery unaffected by the fungus.

Callus may form on either side of the sunken area, with the result that the bark is split longitudinally down the stem. As the disease develops, transverse elongated excrescences form on the bark, very similar to, but much more numerous than, the undeveloped lenticels on normal bark. These excrescences are caused by the development of stomata immediately beneath, or in between the external layers of cork. Pycnidia develop in these stomata, break through the bark, causing the lenticel-like spots, and the spores are liberated as whitish tendrils.

The fungus kills the cortical tissues, the phloem, cambium and medullary rays, and penetrates the wood, causing considerable discoloration of the xylem. The wilting, however is not due to the mechanical blocking of the vessels by the fungus itself. The vessels are, however, considerably blocked by tylosis and gummy deposits.

*Diaporthe* is one of the *Pyrenomycetes*, with a pycnidial stage belonging to the form genus *Phomopsis*. It is difficult to get the fungus to complete its life history on artificial media in pure culture, although sowings of ascospores and pycnosporos grow well on various artificial media. In three instances, however, perithecia have been observed in pure culture, from sowings of pycnosporos, thus proving that both stages belong to the same fungus.

Inoculation experiments on one year old shoots of Prince of Wales Plum, although they showed definite stages of infection, accompanied by gumming, have not produced, so far, the typical wilt. Other inoculations on the current year's young shoots of Peach, with pure cultures isolated from different varieties of Plum, and from Apricot and Peach, gave rise to rapid wilt and die back. These results show that all the strains are definitely parasitic on the Peach.

Experiments with mono-ascospore and mono-pycnosporos cultures have given very interesting results, showing that there probably are two distinct biologic strains occurring on the Plum, and a third on the Peach, which, when grown together in a Petri-dish on an artificial medium, show a peculiar phenomenon of repulsing one another, although they are all capable of parasitising the Peach. So far, all the mono-ascospore cultures derived from the same perithecium have proved to be of the same strain, and the segregation in the different strains appears to take place at some period before the development of the pycnosporos. The investigation of this part of the problem is not yet complete, the initial results being brought forward for discussion.

Dr. W. Brown continued his account of investigations on the physiology of fungi. The germination of fungal spores is markedly affected by the action of volatile substances proceeding from plant tissues. Thus the germination of spores of *Botrytis cinerea* is accelerated by the action of volatile substances arising from the petals of *Rosa centifolia*, and from a large variety of leaves, *Eucalyptus*, *Choisya*, *Pelargonium*, *Apple*, etc., and from *Apple* fruit. The parasitic capacity of the spores is also increased in the presence of such plant tissues, the spores in virtue of their more vigorous germination being enabled to penetrate leaves (e.g., *Bean* leaves) which they are unable to

attack in the absence of such stimulation. In other cases very distinct retardations have been obtained, e.g., in the case of *Botrytis* spores in presence of Orange, Onion, and Potato tissue. These effects are also obtained with other fungi. It was found possible to reproduce the phenomena by use of a chemically pure substance such as ethyl acetate.

Mr. W. J. Dowson's paper on Michaelmas Daisy wilt is published on p. 63.

#### ASSOCIATION OF ECONOMIC BIOLOGISTS.

At the meeting of this Association held on Friday, January 27, the President, Sir David Prain, in the chair, Professor E. P. Stebbing opened a discussion on "The Importance of Research in Forestry and its Position in the Empire." The history of forestry research in India from its initiation to its great post-war developments was described, and the scope and value of the work of the various branches of the research divisions indicated. The speaker then reviewed the state of forestry research in the overseas dominions, pointing out the great value and high quality of timbers obtainable within the Empire. The research organisation in this country was discussed and the general problems needing urgent investigation indicated, the warning being given, however, that the research side should not be developed more quickly than the planting work. A plea was made for the establishment of a fully equipped research institute, which would work in collaboration with the educational centres. Until such an institution was available a fuller use should be made of the study centres. A keen discussion followed, in which the following gentlemen took part: Lord Clinton, Mr. Robinson, Professor Troup, Professor Groom, Professor Crocker, Dr. Munro, Mr. Hiley, Mr. Brooks, Mr. Guilliband, Dr. Brierley, Mr. Chrystal and Sir David Prain.

#### NATIONAL DAHLIA.

JANUARY 31.—The annual meeting of the National Dahlia Society was held in the Lecture Room of the Royal Horticultural Society, Vincent Square, Westminster, on this date, about twenty members being present. The chairman, Mr. Joseph Cheal, was unable to be present, owing to indisposition, and Mr. D. B. Crane was elected to the chair. After the minutes of the previous annual meeting had been read and confirmed, the secretary read the report of the committee for 1921, of which the following are extracts:—

"The committee is glad to record a most satisfactory season, so far as the name flower is concerned. The flowering period was unusually long, and the general quality of the blooms at the annual show was very high. The trade exhibits reached a high standard of excellence and competition was good, especially in the classes devoted to Cactus varieties and decorative sections.

"Encouraged by the success of last year, the Society has arranged to hold an independent show on September 6 next in the R.H.S. Hall.

"The sincere thanks of the committee are tendered to the donors of special prizes and to the Floral Committee, the members of which paid several visits to Wisley in order to inspect the varieties on trial there and to assist in drafting the scheme of Dahlia classification, which seems to have been accepted with general approval. The great assistance given to the Society by the Horticultural Press in assisting propaganda and recording the doings of the Society generally is also recorded.

"Owing to lack of funds, it is not yet possible to resume the publication of the Society's *Year Book*, but lists of the best varieties in the different sections are published as a supplement to the schedule."

The treasurer, Mr. J. Green, read the statement of accounts, which showed a credit balance of over £21, largely made up of unappropriated proportions of life members' subscriptions. The principal items on the receipt side were:—Subscriptions and donations, £53 18s. 9d.; prize fund, £15 18s. 6d.; and

advertisements in schedule, £8 6s. The past year's expenditure included:—Prizes, £40 19s. 9d.; printing and stationery (including the schedule), £24 16s. 6d.

The chairman, in moving the adoption of the report and accounts, referred to the useful work done by the Society during the past year, and appealed for an increased membership, as it was by this means that the Society would be enabled to find funds to carry on its work. The treasurer, in seconding the adoption of the report, stated that the accounts were as good as could be expected; the Society had over £21 in hand, but most of that sum really represented the value of life subscriptions, and should not be utilised for ordinary purposes, unless in very exceptional circumstances. The report and balance-sheet were adopted without further comment. The alteration to by-laws proposed last year, whereby the number forming the General Committee was reduced from forty to twenty-four, exclusive of the officers, was confirmed, and the month of the annual meeting altered to November, in order that the schedule could be published earlier, with a view to enabling those who intended to exhibit obtaining their plants early and making their arrangements in good time.

It was decided to limit the number of vice-presidents to six and to extend the list of patrons. The following were elected vice-presidents:—Messrs. J. Cheal, W. Cuthbertson, J. Green, S. Mortimer, W. Stephens, and J. T. West. Mr. Reginald Cory was re-elected president; Mr. J. Cheal, chairman; Mr. J. Green, treasurer; and Mr. J. Emberson, show superintendent. The following new members of the General Committee were appointed:—Messrs. H. H. Thomas, H. L. Brownson, A. F. Tofield, A. J. Cobb, W. G. Cramp, and Steven Jones. The following gentlemen were appointed members of the joint Floral Committee for adjudicating on novelties submitted for award in conjunction with the R.H.S. floral sub-committee:—Messrs. J. Cheal, J. T. West, J. B. Riding, J. Green, and D. B. Crane. Mr. Gerald Hillier, who resigned the office of hon. secretary, was given a hearty vote of thanks for his services. On the proposition of Mr. J. Green, Mr. A. C. Bartlett, 318, Kew Road, Kew, was elected to the vacancy.

#### BRITISH CARNATION.

THE following new Carnations were registered by the British Carnation Society in 1921:—

*Bartlow Beauty*.—Seedling, salmon colour, sweet-scented. From Mr. FRED M. FOLKILARD, Bartlow House Gardens, Bartlow.

*Cameron*.—Seedling, mauve, parentage *Britannia* × *Mikado*. From Mr. HERBERT G. CULLWICK, Westlake Gardens, West Coker, Yeovil.

*Freedom*.—Seedling from Mary Allwood, salmon-scarlet, fragrant. From Mr. G. CARPENTER, West Hall Gardens, Byfleet, Surrey.

*Leslie*.—Sport from Circe, cerise, clove-scented. From Mr. W. G. DOUCE, The Gardens, Calthorp Towers, Rugby.

*Lorna Doone*.—Seedling, rose pink. From Mr. H. T. MASON, Hampton Hill.

*Nigger*.—Crimson, fragrant. From Mr. C. ENGELMANN, Saffron Walden.

*Nora Wicks*.—Seedling from May-day, pink, fragrant. From G. CARPENTER, West Hall Gardens, Byfleet, Surrey.

*Olive Beckwith*.—Sport from Mrs. C. W. Ward, flesh-pink to light orange. From G. BECKWITH AND SONS, Ware Road, Hoddesdon.

*Sir Edgar Mackay Edgar*.—Seedling, crimson clove, fragrant. From Messrs. STUART LOW AND CO., Bush Hill Park.

*White Queen*.—Seedling, pure white, fragrant. From A. J. WHITWORTH, Datchet, Bucks.

*Wirefield Fancy*.—Seedling, flesh-pink flaked pure rose. From Messrs. ALLWOOD BROTHERS, Haywards Heath.

*Wirefield Pink*.—Seedling, salmon cerise, fragrant. From Messrs. ALLWOOD BROTHERS, Haywards Heath.

#### ANSWERS TO CORRESPONDENTS.

**BULLFINCHES IN THE GARDEN:** *H. M.* Bullfinches are amongst the most destructive of all birds in the garden, and although, as you state, some persons believe that they only attack buds containing insects, Mr. J. G. Blackey, in an article on the subject in *Gard. Chron.*, March 15, 1919, states that although he examined the crops, stomachs, etc., of no fewer than 270 of these birds which he captured or shot in the garden, he never found present in the food a single bud containing an insect. The best method of clearing the garden of these destructive birds is by shooting them with a gun; but many would object to doing this as bullfinches are very handsome birds. Mr. Blackey states that trying to frighten them with a gun is useless, for the birds come back in a few minutes. He recommends placing strips of bright tin, 1 inch by 6 inches, on poles above the trees, so that they may be swayed about by the wind and thus frighten the bullfinches. Considerable correspondence on the subject of birds in the garden was published in *Gard. Chron.*, Vol. LXV., January to June, 1919.

**CHERRY STOCKS:** *C. N.* The stocks were the common Cherry and Mahaleb respectively.

**CHRYSANTHEMUM RUST:** *Y. V.* Seeing that your stock plants were infested with the disease, it is not surprising that you find the cuttings from them are also affected. It would be best, even at this stage, to obtain stock from a fresh source; but if this is impossible, spray the plants at intervals with dilute Bordeaux mixture. Keep a careful watch for any leaves that may show signs of the disease and gather these and burn them at once.

**CHRYSANTHEMUM SPORT:** *S. B. W.* The variety appears to be of fair decorative value, and we would suggest that you propagate the sport and send blooms next season to the Floral Committee of the National Chrysanthemum Society.

**NAMES OF FRUIT:** *Cross Waltham*. 1, Radford Beauty; 2, Dumelow's Seedling (syn. Wellington); 3, Lord Derby.

**NAMES OF PLANTS:** *A. W.* 1, *Haemanthus* species, probably *H. virescens albiflorus*; 2, *Liriope graminifolia* (syn. *Ophiopogon spicatus*); 3, not recognised.

**OUT-OF-SEASON CROPS FOR MARKET:** *H. F. P.* To make a profitable business by growing what you call "out-of-season crops" would require not only experience of how best to grow crops against the natural seasons, but also several greenhouses or frames, and consequently a certain amount of capital. And it does not follow that "out-of-season" crops could be sold to "the moneyed classes" and at "fancy prices," unless you are prepared to attend personally to the marketing as well as the growing. You might begin in a small way by growing Lettuces, Short-horn Carrots, Radishes, Spinach, Endive and Turnips in frames with hot beds of manure beneath them during the winter, say, from October to April. This would be a kind of intensive cultivation, and you could not do better than read how these crops are grown out of season in *French Market Gardening*, by John Weathers, which can be obtained from our publishing department, price 5s. 6d. post free. If you have had no experience in growing these crops the book will tell you how one crop may be cultivated to follow another under the same light, and how to provide for a succession. In a warm greenhouse you could grow early French and climbing French Beans as well as the other crops mentioned. It would be better to start in a small way at first until you began to find out what you could grow best, and what would sell best. Try frame Radishes for a start; good, well-washed roots tied up in neat bundles usually sell well during the winter and spring months.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 39.3.

**ACTUAL TEMPERATURE:—**

Gardeners' Chronicle Office, 5, Tavistock Street, Covent Garden, London, Wednesday, February 15, 10 a.m. Bar. 30.1; temp. 45°. Weather—Dull.

**Soil Conditions and Plant Growth.** The wonderful advances of knowledge of the soil in relation to plant growth which have taken place during the past decade are illustrated by the fact that whereas, in the first edition of Dr. Russell's work\* of this title, published in 1912, 166 pages sufficed to summarise what was known on this subject, some 400 pages are now required; and Dr. Russell does not waste words. It is no exaggeration of language to say that during this period soil science has been remade. In 1912 the old view which regards the soil as an inert assemblage of mineral and decaying humus particles was still widely held; to-day every student of the soil realises that this picture of soil-constitution is as insufficient as it is simple. It is true that before 1912 the foundations of the new science had been laid. The rôle of nitrifying bacteria had been discovered and the importance of humus had, of course, long been recognised. It was known also, long before that date, and thanks in large measure to Sir Humphry Davy, that the physics of the soil is of no less importance in relation to plant growth than is its chemistry. It was also well understood that the water-relations of the soil are of the utmost importance in their effects on fertility. The great progress of soil science of recent years has been due rather to the intensive cultivation of special aspects of that science by numerous and highly skilled workers than to the introduction of any absolutely new ideas. The sole exceptions to this statement are perhaps

the application of the discoveries in the physical chemistry of colloids to the soil, and the extension of the idea that the upper layers of the soil are the abodes of an extensive microscopic flora and fauna composed of bacteria, algae, protozoa and inter-organisms, and that the actions and inter-actions of these minute denizens of the soil count greatly in determining soil fertility and probably in the actual manufacture of plant-food. The puzzling behaviour of clay—its strange properties of puddling under pressure, flocculating and becoming easier to work when subjected to frost or when treated with lime, are becoming more intelligible now that the colloidal nature of clay is recognised. As Dr. Russell points out in his chapter on the colloidal properties of soil, each of the two chief constituents of soil, clay and humus, possesses colloidal properties. To these properties are due the power of soils of absorbing substances from solution, as, for example, potash salts, phosphates and salts of ammonia; with the result that soluble salts of those substances used as artificial manures do not wash out but remain at the service of plants growing in the soil. In the case of clay, the colloidal view bids fair to change fundamentally current opinion as to the cause of certain of its properties. According to the older opinion, the chief physical properties of clay are to be ascribed to the excessive minuteness of its particles, which range downwards until the smallest are invisible under the microscope. The more recent suggestion, however, is that the stickiness and other properties of clay is due to the fact that a watery colloid substance forms a gelatinous film round each of the minute solid clay particles. We may thus picture a clay soil as consisting of an incredibly large number of extremely minute particles, so small as to be invisible even by the aid of the microscope, around each of which is a gelatinous envelope. In the vast tract formed by these envelopes, the micro-organisms flourish much as they may be made to flourish in the laboratory on plates of gelatine or agar-agar. There they live and die, and according to recent views, by their lives and deaths manufacture the food which the roots of plants absorb from the soil. There is no page of Dr. Russell's book which is not of interest both to the scientific student and to the practical grower. The enthusiast for indiscriminate intensive cultivation who urges the conversion of all grass land into arable might also learn wisdom from a perusal of these pages. From them he would discover that cultivation makes a heavy and unavoidable toll on the soil and that the cost of making good the loss—e.g., of nitrogenous food material which ensues from cultivation—must in the case of not a few soils prove prohibitive to their arable cultivation. The amount of loss which ensues when prairie land is brought under cultivation may amount (p. 181) to so much as 63 lb. of nitrogen per acre per annum, and the same loss is observed when heavy dressings of manure are applied to land in this country. The crop is nourished, but the soil is impoverished by a larger amount than the crop is benefited. This leakage of costly plant food appears to be due to the decomposition of nitrogen compounds to gaseous nitrogen, so that instead of all the nitrogen contained in or applied to the soil awaiting obediently the attention of the soil-nitrifying bacteria and appearing as usable nitrates, some is decomposed by other agencies, with the result that the nitrogen escapes into the air. Those, again, who have trouble with sour soils will gain much useful information from a perusal of Dr. Russell's remarks on pp. 239-244. The

sour or acid soils which give an acid reaction with litmus present many interesting features. They may be improved by liming or they may be used for the cultivation of those crops which are not too intolerant of acid conditions, as, for example, Lupins, Alsike, Oats, Potatos and certain grasses. As acidity increases so the number of species growing in the soil decreases. At Rothamsted, on grass plots on soil with a neutral reaction, there are forty-five species; on grass plots which are somewhat acid, fewer, and on the most acid plots only seven species grow. The flora is generally a good index of acidity; for example, where soils are markedly acid, as on the bake land of the Wiltshire Downs, Sheep's Sorrel, Scarlet Pimpernel, Knawel (*Scleranthus annuus*) are present, whereas Toad Flax, the white and Bladder Campion are absent, although abundant on neighbouring chalky soils.

A far more extensive review than is possible in these pages would be required to do justice to the industry and judgment which Dr. Russell has expended in writing this admirable book. Enough has been said, however, to indicate that anyone who cultivates the soil and would like to cultivate it better, should obtain and peruse his book. Admirably written, concise and lucid, Dr. Russell has conferred, by preparing this new edition, a great boon on everyone who makes a study of the right mode of exploitation of the soil in the interest of agriculture and horticulture.

**Alterations at Bishop's Park, Fulham.**—Improvements in Bishop's Park, Fulham, have been sanctioned, entailing an expenditure of £2,445. One item which the Fulham children will appreciate is the importation of one hundred and twenty tons of sea-sand; this is to be placed near the paddling pool in imitation of the seaside.

**Presentation to Mr. A. Shambrook.**—On the occasion of the annual meeting of the Derbyshire Gardeners' Association, held on the 3rd inst., Mr. A. Shambrook was presented with an illuminated address and a suitably inscribed gold-mounted umbrella in recognition of the valuable services he has rendered to the Society during the many years he has been resident near Derby. Mr. Shambrook stands in the front rank of plantmen, and visitors to the Royal Horticultural Society's meetings will remember the magnificent Cyclamen and Begonias he has exhibited at Vincent Square, and for which he has obtained the highest awards; while horticulturists in the Midlands are aware that he has been awarded several large Gold Medals of Birmingham for similar displays. Mr. Shambrook has taken up new duties with Lady Markham, Avonside, Barford, and his loss to the Derbyshire Association will be a gain to the Warwickshire district. The presentation was made by Alderman A. Green, who referred to Mr. Shambrook's capabilities as a gardener and especially to the services he had rendered the Derbyshire Gardeners' Association.

**The New Award of Garden Merit.**—As announced in our issue of February 11 (p. 61), the Council of the Royal Horticultural Society has just established a new award for ornamental plants, especially intended to mark plants of proved and outstanding excellence for garden decoration. It is to be known as the Award of Garden Merit, and will be bestowed by the Council on the recommendation of the Wisley Garden Committee, generally, but not necessarily exclusively, to plants which have been thoroughly tried at Wisley. It may be given to plants long grown in our gardens as well as to more recent introductions, provided they are of outstanding merit in their class and do not require very special treatment to bring out their excellences. We learn from Mr. F. J. Chittenden that the first award was made at the meeting of January 31, 1922, to *Hamamelis mollis*.

\*The Rothamsted Monographs on Agricultural Science, *Soil Conditions and Plant Growth* (Fourth Edition), by Edward J. Russell. Messrs. Longmans, Green and Co. Price 16s. net.

This Chinese species of a genus represented by *H. arborea* and *H. japonica* in Japan and *H. virginiana* and *H. vernalis* in America (all of them now growing in British gardens) was introduced in 1879 by Mr. Charles Maries to Messrs. Veitch's Coombe Wood Nursery, but did not become well known for a long time. It is the finest of the genus both in flower and foliage, and particularly valuable in the shrub border in January, when it produces its delightfully fragrant, golden-yellow flowers in profusion, in clusters along the bare last year's twigs. The long, narrow petals are straight (not crumpled, as in other members of the genus), rich golden-yellow, except for the reddish base, and set in a red-brown calyx, smooth within, hairy without. The bush grows to six or eight feet in height (possibly more), and has stout spreading branches. It is accommodating as regards soil, but grows best in good loam. When young, a little leaf soil aids it, but later it can take care of itself. It requires no pruning, unless to correct a slight tendency to sprawl.

**Legacies to Gardeners.**—The late Mr. Christopher Geiselbrecht, of Beechdale, Eltham Road, Lee, Kent, who, during his life-time was a valuable supporter of both the Gardeners' Royal Benevolent Institution and the Royal Gardeners' Orphan Fund, left the income from £3,000 in trust for each of his gardeners, Mr. George David Judge and Mr. Harry Cox, for life, and £2 a week for their wives if they should survive them.

**Association of Economic Biologists.**—The annual general meeting of this Association will be held at 2.30 p.m. on Friday, February 24, in the Botanical Lecture Theatre of the Imperial College of Science, South Kensington, London, S.W.7. The usual annual business of the Association will be transacted, and Dr. John Rennie, of the University of Aberdeen, will read a paper on "The Present Position of Bee Disease Research"; this will be followed by a demonstration by Dr. Rennie of "Polyhedral Disease in *Tipula* Species." The new councillors will meet on the conclusion of the general meeting to elect the officers of the Association for 1922.

**Honour for M. Le Loup Grimoux.**—In recognition of his services rendered to horticulture in general and to Chrysanthemum specialists in particular, the National Chrysanthemum Society has awarded an Honorary Fellowship to M. Le Loup Grimoux, the organiser, and moving spirit of the Le Mans show, held in November, 1921. M. Grimoux is as skilful a grower as he is an organiser, and is now regarded as the cleverest grower of large Chrysanthemum blooms in France.

**Flowers in Season.**—A sheaf of flowering branches of *Parrotia persica*, sent by Mr. Anthony Waterer, has adorned our editorial office for several days past. Mr. Waterer informs us that *Parrotia persica* is not a plant which flowers in a young state, but is extraordinarily fine when it attains some considerable age and size. The tree from which the sprays were cut is twelve feet high, and has a circumference of thirty feet. Mr. Waterer sent flowering branches to Mr. W. J. Bean, at Kew, who, in acknowledgment, wrote: "Thanks for the *Parrotia persica*. It is extraordinarily fine, and I do not remember having ever seen it so good." The flowers are not conspicuous individually, but the numerous orange red stamens and the rich reddish-brown bracts are very effective when, as in the specimens referred to, they occur in large numbers along every twig.

**Horticultural Lectures at Glasgow.**—A syllabus of interesting lectures on horticultural subjects has just been issued by the Glasgow and West of Scotland Horticultural Society. The subjects and lecturers include "Garden City Problems," by Mr. J. M'Gran, Coodham Gardens, Kilmarnock, on February 22; "Rock and Water Gardening," by Mr. William Besant, Sunlight Cottage, Kelvingrove Park, on March 29; "The Culture and Training of Hardy Fruit," by Mr. D. Grant M'Iver, Miramar Lodge, Skelmorlie, on October 4; and "Our Allotments—As They Are and What They

Might Be," by Mr. Alex Buist, Gryfe Nursery, Bridge-of-Weir, on December 6. The Society's programme includes an outing to Loch Lomond Park on Saturday, June 2, and the great International Show to be held at Kelvin Hall, on August 30, 31, September 1 and 2.

**Dr. E. J. Russell.**—Research stations, like human habitations, come to assume in the course of years a distinctive and individual character of their own. It is as though they absorbed and radiated the spirit of those who abide in them. In this sense Rothamsted, over whose destinies Dr. Russell presides, may with propriety be described as a happy home of research. A succession of remarkably gifted men, Lawes and Gilbert, Warrington, Hall and Russell, have all done notable work there and have established Rothamsted's fame throughout the world. The success which has attended the quest of discovery into soil science by these workers shows no sign of abatement; indeed, thanks in large measure to Dr. Russell, that success bids fair to increase with yet greater rapidity. For Dr. Russell possesses in high degree not only the capacity for research, but also the yet rarer

DR. E. J. RUSSELL, F.R.S.

faculty, that of inspiring research in others. Hence the laboratory at Harpenden has become a great research centre whence issue results which illuminate science and aid practice. The most striking example of Dr. Russell's power to compel belief in research and to get belief expressed in endowment is provided by the Lea Valley Research Station, the origin of which is due no less to the public spirit of the growers than to the foresight and enthusiasm of Dr. Russell. When Dr. Russell became Director of Rothamsted he had already proved himself one of the foremost investigators in agricultural science, and during his tenure of that important office he has enhanced his reputation and that of the Institute. He began his career as lecturer and demonstrator in chemistry in Victoria University, Manchester, in 1888, and after three or four years became head of the Chemical Department of the Agricultural College, Wye, which post he held till 1907. From 1907-1912 he was Goldsmiths' Company's soil chemist at Rothamsted, and at the end of that period he was appointed director of the Research Station. Clear headed, of sound judgment and unbounded enthusiasm, Dr. Russell is the happy possessor of other gifts also, which with his fine training and wide knowledge make him a great power for good. Wonderfully lucid in exposition, he possesses—as people say, naturally—the art of expressing himself with a charming simplicity, which his colleagues admire and envy. As our readers know, he is the author of numerous scientific works, of which the most important

are *Soil Conditions and Plant Growth; Lessons on Soil; Soils and Agriculture of Kent, Surrey and Sussex*, (with A. D. Hall); *A Student's Book on Soils; and Manures and Manuring for Higher Crop Production*. During the war Dr. Russell's untiring energy was sufficient to enable him to keep work going at Rothamsted, and at the same time to perform service of great national importance as technical advisor of the Food Production Department and as member of the Munitions Panel and of the National Salvage Council. His scientific work has been recognised by his election to the Royal Society (1917), and his public services by the award of an O.B.E. Foreign countries have bestowed upon him numerous honours, but what he must hold most dear is the universal regard in which he is held by his scientific colleagues of this country and throughout the world.

**National Institute of Agricultural Botany.**—At a meeting of the Council of the N.I.A.B., held on the 9th inst., the first election of Fellows of the Institute took place. One hundred and ten candidates were elected, among whom were the following:—H.R.H. the Duke of York, the Prime Minister, the Duke of Bedford, the Marquess of Crewe, the Earl of Ancaster, the Earl of Derby, the Earl of Crawford, Viscount Milner, Lord Clinton, Lord Bledisloe, Lord Ernle, Sir Gilbert Greenall, Sir Harry Verney, Sir Matthew Wallace, the Hon. E. G. Strutt, the Rt. Hon. E. C. Pretymann, M.P., Lt.-Col. the Rt. Hon. Sir A. Griffith-Boscawen, Sir Thomas Middleton, Mr. Charles Adeane, Mr. Samuel Farmer, Mr. R. R. Robbins, and Lady Margaret Boscawen.

**Appointments for the Ensuing Week.**—Monday, February 20: Reading and District Gardeners' Association's meeting; lecture on "Flowering Bulbs, Plants and Shrubs; Forcing and Retarding," by Mr. H. Mew.—Wednesday, February 22: Glasgow and West of Scotland Horticultural Society's lecture on "Garden City Problems," by Mr. J. M'Gran; Irish Gardeners' Association's meeting; Wimbledon and District Gardeners' Society's meeting; Elgin Horticultural Society's meeting.—Thursday, February 23: Bristol and District Gardeners' Association's meeting; Royal Botanic Society's meeting.—Friday, February 24: Association of Economic Biologists meeting; Paisley Florists' Society's meeting.

**"The Gardeners' Chronicle" Seventy-five Years Ago.**—A Disclaimer.—In our advertising columns of Saturday last was an announcement by Messrs. Hubbard and Co. that they had for sale, as a cure for the Potato disease, some lime analysed by Prof. Lindley. We beg to state that this use of Dr. L.'s name was without his knowledge; that he never analysed any lime for Messrs. Hubbard and Co., and that he does not recommend magnesian limestone as a cure for the Potato disease. In the year 1844, nearly three years ago, he, in civility to these parties, of whom he has no knowledge whatever, procured an analysis of magnesian limestone, to be made for them, for which he paid one guinea, which was repaid by Messrs. H. and Co., but they were perfectly aware that it was for the analyst whom Dr. L. employed, and that he has no part in the analysis. Under these circumstances, Dr. Lindley cannot but feel that a use has been made of his name by the advertisers which was unauthorised and improper. *Gard. Chron.*, February 13, 1847.

All published by the New York Agricultural Experiment Station, Geneva, New York.

**THE ALPINE GARDEN.**

**SILENE SCHAFTA.**

SCHAFTA'S Catchfly is one of the most valuable of rock plants, but is not so much sought after by those who endeavour to secure novelties and rare species, many of which do not possess a title of the real value of *Silene Schafta*. The plant is very easily cultivated in any rock garden or rockery, and in the usual soil provided for the subjects which are generally cultivated there. I have found that it will thrive and flower in sun and in practically full shade, always provided that it is not under the drip of trees. Other points in its favour are the ease with which it is cultivated and (of special value to those who have to study economy) the cheapness of plants, and still more of seeds from which a good stock may be easily raised for a few pence.

*Silene Schafta* is a pretty little plant, suitable for edgings or for almost any place in rockwork, thriving even in crevices with a fair quantity of soil. It is of trailing habit, but not so vigorous as to be a danger to its neighbours. It has neat leaves and numbers of medium-sized flowers of a colour often called "purple-rose," which is probably as near to a colour description as it is possible to reach.

The plant generally begins to flower in summer, and continues to bloom until the advent of frost. I have, indeed, had it in bloom after a good deal of frost well into October. This long and late flowering habit makes this *Silene* all the more valuable.

It may be increased by division or cuttings, the former being performed at any time—in spring by preference—and the latter struck in summer under a bell-glass, hand-light, or frame in sandy soil. But raising plants from seeds is the best method, as it is cheaper where a stock is required, and gives good plants to bloom the following year. The seeds may be sown in light soil in the open in April or May in shallow drills about ¼ inch deep, and should be covered with sandy soil. If the weather is dry, careful watering through a fine rose is necessary. When the seedlings are large enough to handle, they should be transplanted about 3 inches apart, and removed in autumn to where they are to flower. The seeds may also be sown in pots or pans under glass in spring. *S. Arnott*.

**ORCHID NOTES AND GLEANINGS.**

**ALBINISM AMONG ORCHIDS IN NATURE.**

EXAMINATION of the facts connected with the production of albinos (and varieties resulting from albinism) in the species of Orchids in their native habitats discloses some interesting particulars.

Species with decided yellow colouring, especially in the labellums, such as *Oncidium*s, are very numerous, but none of them has given an albino, and when colour suppression occasionally takes place the result is a paler yellow, with often a tinge of green in place of the purplish colour in the sepals and petals, but never white. On the contrary the species of *Oncidium* marked with shades of rose or purple, invariably give a pure albino, familiar instances being *Oncidium incurvum album* and *O. ornithorhynchum album*. It seems that the yellow and green in the flowers are more in the nature of body colour influenced by the vegetative system, than the various cyanic tints which are floral surface colours and displayed generally on white or whitish ground, which gives the albino after the colour has vanished.

The facts emerge throughout the whole of the Orchid family that true yellows do not give albinos, while purple-tinted species seldom fail to do so. Instances to the contrary have been recorded, viz., the so-called *Anguloa Clowesii* alba, which is known to be the normally white *Anguloa eburnea*, and *Sobralia xantholenca* alba, which was a seedling reversion resulting from hybridisation.

While yellow-flowered species do not tend to produce whites in nature, the purple-tinted ones invariably do so. The matter of albino *Cattleyas* and others has been recently referred to, and other familiar instances are found in the genus *Spathoglottis* where the yellow forms give no whites, but the brightly-coloured rose and purple *S. plicata* furnished Sir Jeremiah Colman's snow-white *S. plicata* alba. In *Odontoglossum* two good examples are *O. Uro-Skinneri* album and *O. bictoniense* album, in which the decided deep rose of the lip disappears and leaves pure white; the sepals and petals losing the purple and brown in their markings, which, however, appear as light

sections give no whites; and so on through the whole tribe.

Except in the *C. niveum* section the *Cypripedium*s give no albinos, the colour in the lip and dorsal sepal being retained, though changed by colour suppression to pale yellow or green. The bright green on pure white in *C. Lawrenceanum Hyeatum* (Fig. 36), and which is transmitted in *C. Maudiae* class in a remarkably beautiful degree, is proof of the almost ineradicable nature of the green, and the evanescent character of the mauve and claret colour which has been eradicated.

The question of colour in flowers is a very interesting one. *J. O'B.*

FIG. 36.—CYPRIPEDIUM LAWRENCEANUM HYEANUM.

green. *Vanda coerulea*, *Saccolabium*s, *Aerides*, and all other species with rose and purple tints give instances of the same kind, even the little African *Stenoglottis fimbriata* and *S. longifolia*, of the same nature as our own British Orchids, also furnish albinos.

It is curious, however, to note that the yellow-flowered Orchids which are firm to their colour in nature rapidly undergo a change when used by the hybridiser in our gardens, and lend themselves readily to the production of white forms, the intensifying of purple and crimson, or the heightening of their own yellow according to the combination which the hybridiser decides on.

Scarlet-flowered species do not give albinos, but, generally, in cases of suppression of their normal colour, the result is yellow, instances being the yellow *Sophrontis grandiflora* Rositteriana and *Saccolabium miniatum* Luteum. *Dendrobium* and *Epidendrum* having sections with rose, purple and other tints of this class readily produce albinos, while the yellow

**NOTICES OF BOOKS.**

**How to Excel with Sweet Peas.**

How easy it is to grow Sweet Peas is shown by Mr. Horace J. Wright in a little brochure on the flower,\* forming one of the excellent series of booklets on gardening subjects published by *Country Life*. Those who have failed to find the secret of success—and it is notorious that many excellent gardeners cannot grow Sweet Peas successfully—will be stimulated to try again by the author's remark that no plant is easier to grow. Wherein lies the secret? Probably it is found in the preparation of the soil, with which Mr. Wright deals fully. Where the soil is suitable, Sweet Peas provide some of the best subjects for decorative purposes, both in the garden and for the provision of cut blooms, and advice from such a noted specialist of the flower on its cultivation will be welcomed, especially by beginners.

\* *Sweet Peas and How to Excel with Them.* By Horace J. Wright. *Country Life* Booklets. Price 9d. net.

## The Week's Work.

### THE ORCHID HOUSES.

By J. T. BARBER, Gardener to His Grace the Duke of Marlborough, K.G., Blenheim Palace, Woodstock, Oxon.

**Miltonia.**—Members of the vexillaria section of Miltonia that were potted last autumn have filled their pots with roots, and are making rapid growth. They require plenty of water, and should not be allowed to suffer for want of moisture, either at the roots or in the atmosphere. Those varieties which produce their flowers in the autumn, such as *M. vexillaria Leopoldii*, *superba*, and several hybrids, may be repotted, should they require it, and be in the necessary condition—that is, about to develop fresh roots. A mixture of equal portions of peat, A.1 fibre, and Sphagnum-moss, with a quantity of broken leaves will furnish a suitable rooting medium. These and other plants should be continually watched at this season, especially after a cold snap, for attacks of thrip, and other insect pests. Owing to the increased amount of fire heat necessary at such times to maintain the requisite temperatures, it is not always possible to provide suitable atmospheric moisture. Dipping the plants in a solution of Quassia extract is a safe and sure remedy, and, as prevention is better than cure, it is advisable to dip them at intervals, as the leaves of Orchids are easily disfigured by this pest, which is particularly partial to Miltonias.

**Calanthe.**—With the exception of the late flowering varieties, of which *C. Regnierii* is an example, Calanthes have passed the flowering stage, and should enjoy a season of rest in a house having an average temperature of 55° to 60°. They should be exposed to all the light possible to ripen the pseudo-bulbs. Many growers, to my mind, rest these plants in a too low temperature, which is often the cause of disease and spot in the leaves and pseudo-bulbs. Water will not be needed, and the atmosphere should be kept on the dry side. The best place in which to rest the plants is on a shelf, where they will receive all the light possible.

### HARDY FRUIT GARDEN.

By H. MAREHAM, Gardener to the EARL OF STRAFFORD, Wrotham Park, Barnet.

**Vines.**—The pruning of hardy vines should be completed at an early date in order that the cut surfaces may become hardened before the sap begins to rise, otherwise bleeding will be sure to follow. Established vines grown on the spur system will need the laterals cut back to two plump buds, and leaders that have not reached their limit may be allowed to extend more or less according to the length and strength of the growth and buds. From 3 feet to 4 feet may be left if the growths are well matured and the buds suitable. After the pruning is completed, remove a little of the loose bark and apply a dressing of Gishurst Compound or some other suitable insecticide, brushing the specific well into the crevices, and dressing the part about the eyes with a little weaker solution. The roots should be top-dressed with a mixture of rich soil, bone meal, and brick mortar, and fed liberally with liquid manure at intervals.

**Orchard Trees.**—Trees that have become grown over with mosses and lichens should have their stems and main branches thoroughly scraped and brushed with a stiff brush, and then well dressed with a mixture of lime and soot, using a whitewash brush for the work. The smaller branches are best dressed with a similar mixture by means of the syringe. Caustic alkali is a safe and excellent material to use if the formula for making it is strictly adhered to. Those entrusted with the application of this strong chemical should be very careful not to let any of the liquid touch the

flesh. Gloves should be worn, and the work should be undertaken when the buds are in a dormant state.

**Woolly Aphis.**—The infestations of woolly aphis last summer were amongst the worst I remember, and entailed much labour in keeping the pest in reasonable check. Nicotine, applied with a soft brush, did much to destroy the aphis, and proved the best remedy, notwithstanding other insecticides were thoroughly tried.

### PLANTS UNDER GLASS.

By T. PATEMAN, Gardener to Sir C. NALL-CAIN, Bart The Node, Coddicote, Welwyn, Hertfordshire.

**Roses.**—Where Roses have been specially grown in pots for flowering indoors, they should be pruned and the drainage put in perfect order. Afterwards place them in a temperature of not more than 45°, and syringe them only on bright days, so that the moisture dries before night. This treatment may be con-

FIG. 37.—AN EDGING OF PINKS.

(See page 77.)

tinned until the buds are formed, when syringing should be discontinued. Admit a little air by the top ventilators when outside conditions will allow, but prevent cold draught, as these encourage mildew to develop, which is very detrimental to successful Rose cultivation under glass.

**Cyclamen.**—The florists' Cyclamen is one of the brightest and most useful flowering plants for the early winter and spring decoration indoors, and well repay a little extra care bestowed on their cultivation. Plants that were raised from seed sown during August and were pricked out into pans or boxes should now be ready for transferring to small 60-sized pots. The soil for this potting may consist of equal parts loam and good leaf-mould, with a little old mortar rubble and sufficient sand added to keep the whole porous. After potting them the plants should be stood on a bed of ashes in a light position, as near the roof glass as possible to prevent them becoming drawn, but it will be necessary to shade them from bright sunshine. Cyclamens at this stage should be grown in a temperature of 50° to 55°, with a rise in the day by sun heat. Mite and greenfly

are the worst enemies of these plants, therefore frequent fumigations or spraying with an insecticide is to be recommended in the early stages of growth.

### THE KITCHEN GARDEN.

By JAMES E. HATHAWAY, Gardener to JOHN BRENNAN, Esq., Baldersby Park, Thirsk, Yorkshire.

**Brussels Sprouts.**—This crop requires a long growing season, and disappointing results are often due to neglect in this matter. A sowing may be made in boxes in a cool, well-ventilated greenhouse. If a cold frame is available, seed may be sown in it, either in rows or broadcast; but where several varieties are grown it is best to sow in rows. A close watch must be kept for slugs, or they will soon destroy all the seedlings. Dusting with soot or lime will help to keep the pests in check, but the best method is to search for them after dusk with a light.

**Spinach.**—To ensure an early crop of Spinach, seed should be sown in frames on a slight hotbed. Let the rows be at least one foot apart. A sowing should also be made on a warm border as soon as the land is in a favourable condition, and, to ensure a regular supply, other small sowings every three weeks from now onwards. The beds of Spinach sown in the autumn should be kept hoed and free from weeds when the ground is favourable for working.

**Cabbage.**—Hoe the rows of autumn-planted Cabbages as soon as the weather permits, as the plants thrive best when the surface is kept stirred regularly. As soon as the plants begin to grow freely a light sprinkling of sulphate of ammonia about the roots will greatly assist them. This fertiliser is best applied when there is rain. Old soot and liberal dressings of wood ash are also valuable fertilisers for Cabbages. All blanks in the rows should be made good at the earliest opportunity, with plants reserved for the purpose.

**Planting.**—At the beginning of each season a plan of the kitchen garden should be drawn up, and the plots allotted to the various crops. This will save a lot of time in the busy planting season, and a glance at the plan will show what each plot has carried for years back, and also the amount of manure which has been applied.

### FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

**Grape Room.**—Examine Grapes in bottles frequently and remove mouldy berries as soon as they appear. Examine the bottles and fill them with water if necessary. If any Grapes are still hanging on the vines, they should be cut and bottled at once, so that the house may be cleaned and the vines pruned and rested. Keep the temperature of the Grape room about 45 deg., and the surroundings as dry as possible.

**Plums.**—Although forced Plums lag behind Cherries at the finish, the two grow well together until some time after the fruits are set and swelling. Their treatment as regards fresh air, a low temperature, and slow development is in every way identical. In the selection of Plums for forcing, none but the very best dessert sorts should be chosen, and the trees should be grown in pots, as the plants may then be turned out of doors as soon as the crop is gathered. There are, however, many cold houses planted with Plums in the north, and many more in Scotland. The plants may be removed to a cool house of any description when the crop is approaching ripeness, but the fruits cannot be rushed into ripening at the finish. Like other stone fruits they respond satisfactorily when started early and attended to carefully through their different stages of growth.

**Routine Work.**—The cleansing of late fruit houses should now be concluded; this is one of the most important operations connected with

successful fruit culture. Remove all loose materials from the borders, taking care not to damage the fibrous roots while doing so, and top dress the borders with good loam, adding a little lime rubble if the loam is very strong; and bone meal, with a sprinkling of vine manure, more or less, according to the age of the vines or Peaches. Wash the vines with Gishurst Compound or other insecticide, but do not remove much loose bark from the rods; rather give the latter an extra dressing of the specific if mealy bug or red spider has been troublesome. These remarks apply also to late Peaches on which scale or other pests were troublesome last season.

**THE FLOWER GARDEN.**

By EDWIN BECKETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Hertfordshire.

**Dahlias.**—A start should be made, where it is desired to increase and raise new stocks of these valuable plants, in propagating them. Last season's tubers that were lifted and stored for the winter should be started into growth in a genial atmosphere, and when the young growths are about 3 to 4 inches long removed

FIG. 38.—PINUS CANARIENSIS; THREE SEEDLINGS IN A CREAM JAR.

from the tuber by means of a sharp knife and inserted in the usual way in small 60-sized pots containing a sandy compost. Strike them in a temperature of from 65° to 70°, and when they have become well rooted, transfer them singly to 48-sized pots. After allowing the plants to become established in the same temperature, gradually harden them off ready for planting out later. The old tubers may also be divided in March or April, to increase the stock. Fresh Dahlia plants should be purchased in April, and potted and grown on for a time in frames prior to planting them in the open at the end of May.

**Rhododendron and Azalea Beds.**—In many gardens, where soil conditions are unsuitable, if not distinctly adverse to the growth of these fine flowering shrubs, special beds should be prepared for them. At this season the beds should be very lightly forked over (without disturbing the roots) and a rich top-dressing, composed of one part good loam, one part peat or leaf soil, and one part well-decayed farmyard manure applied. The materials should be trodden firmly into position, after which the surface should be lightly raked over and the bed made neat and tidy. This treatment will be found of great assistance to these plants. Whilst dealing with Rhododendrons, I may call attention to the necessity of removing all dead flowers during the flowering season, to prevent seed pods from forming.

**SEEDLING PINES FOR ROOM DECORATION.**

I SEND herewith two photographs of Canary Isle Pines growing in moss fibre without drainage. One (Fig. 38) shows three unbranched plants, and the other (Fig. 39) one branched at the base. The seed was sown in these pots (cream-jar size) in the spring of 1917, and they have been growing and keeping healthy in this confinement without drainage ever since, merely given a little water weekly or so. They make pretty table plants, being of a feathery appearance and light glaucous green in colour. So far, they have kept to their seedling foliage of simple needles, though plants grown from seed sown the same time in flower pots formed adult needles in the spring of 1921. Once they do this they lose their youthful charm. The photographs were taken on August 20, 1921, and the plants represented are from seeds given me by Prof. A. Henry. Realising that the seedlings would be of little use for outside planting in this climate, I casually put a few seeds in moss fibre to watch germination and seedling growth, never imagining that they would exist and remain healthy for any length of time. I am not aware that Pines have ever been tried in moss fibre without drainage before. They have the advantage over Oaks and Chestnuts so grown, in being decorative the whole year round. *John Parkin, The Gill, Brayton, Cumberland.*

**PINKS AS AN EDGING FOR BORDERS.**

AMONG old-fashioned garden plants, few are more valuable for providing a dense and continuously beautiful edging for beds and borders than the popular varieties of garden Pinks. In cottage gardens such edgings are very popular and look well throughout the winter, and are particularly attractive in summer when in full bloom. There is no question as to the hardiness of such varieties as Mrs. Sinkins and Her Majesty, and every gardener is aware that Pinks are among the easiest plants to propagate. The accompanying illustration (see Fig. 37) shows a long herbaceous border edged with Pinks, and it will be granted that a live edging of this character is preferable to one of tiles.

**INDOOR PLANTS.**

**BROMELIADS.**

BROMELIACEOUS plants comprise a very extensive family, embracing *Aechmea*, *Tillandsia*, *Vriesia*, *Caraguata*, *Bilbergia*, *Nidularium* and others. Some of them are amongst the most beautiful and ornamental of plants, and should find a place in every collection where plants are grown in warm greenhouses or for conservatory decoration. The exquisite colouring of the bracts and flowers of many of the species and hybrids, and the beautifully marked foliage of the others should place them in the front rank in any collection for the warm greenhouse or conservatory. A great advantage with Bromeliads is that they do not occupy a considerable amount of space. Large specimens are fine ornaments, very distinct and exceedingly useful for grouping. They are of easy culture, and being epiphytes do not require so large an amount of soil as many plants to keep them alive. They thrive well during the winter in a temperature of about 55° to 60° in a house having a comparatively moist atmosphere. When the growing season commences the temperature should be increased to 65° or 70° with plenty of moisture, and the plants should be shaded from the direct rays of the sun. The plants are increased readily by division or from suckers. The soil most suitable for them is a mixture of two-thirds rough fibrous peat, one-third light, tarty loam, and live Sphagnum-moss, with silver-sand added. Over-potting is to be guarded against. Well drain the pots, the best drainage material being clean, broken potsherds with a little charcoal, if procurable.

The following is a list of some of the most beautiful Bromeliads which come within the scope of this note.

*Aechmea Reginae* is a plant of robust habit, with leaves arranged in a vase-like manner. The flower spike is erect, the flowers blue and white, and the bracts carmine, these remaining in perfection for two months. *A. Veitchii* (syn. *Chevalieria Veitchii*) is a showy species with scarlet bracts and flowers. *Nidularium Meyendorffii* has a rosette arrangement of leaves, the central, fleshy leaves being bright rose-crimson, the outer dark green. *Bilbergia Saundersii* is a blue flowered plant with crimson bracts. Another pretty species, *B. vittata*, has strap-shaped leaves and flowers produced in nodding racemes. They are dark indigo blue set off with crimson bracts. *Caraguata Zahnii* (syn. *Tillandsia Zahnii*) is a handsome plant, the base of the leaves being yellow with crimson stripes. The flower is pale yellow with bright scarlet bracts. *C. Osyana* is another pretty species, with red bracts and yellow flowers. *Tillandsia tessellata* is a novel and beautifully ornamental species, with light, glaucous-green foliage, veined with rosy purple on the under surface and mottled with transparent greenish-yellow blotches on the upper surface. *T. hieroglyphica* makes a handsome foliage plant, the leaves being marked with dark purple. *T. Lindenii major* has leaves that are light green on the upper surface, the lower striped with

FIG. 39.—PINUS CANARIENSIS; ONE SEEDLING IN A CREAM JAR.

reddish brown. The spathe rises erect well above the foliage, and is coloured rosy-carmine. The large flowers are a vivid blue with a white eye. *T. Lindenii vera* has narrower and finer foliage than *T. Lindenii major*; both are acceptable when in flower and are a rare adornment to any collection. *T. zebrina* (syn. *splendens*) is one of the best of the *Tillandsias*. It has fleshy leaves, each leaf being banded alternatively with green and chocolate-brown, and bears crimson flower spikes with bracts shaped like a sword. *T. chrysostachys* has bright lemon-yellow spikes of flower.

*Tillandsias* and *Vriesias* are so closely allied to each other that the species and hybrids are often included in each other. *Vriesia* (syn. *Tillandsia*) *brachystachys* is a very distinct species with yellow flower and green and scarlet bracts. *V. Barilleti*, also a yellow flowered species, has yellowish green bracts dotted with brown. *V. fenestralis* has broad, arched, pale green leaves that are beautifully marked with dark green on the upper half. The leaves of *V. psittacina* are yellow-green, recurved and more or less waved. The flowers are tipped with green and surrounded by orange-scarlet bracts. *Ananas* (syn. *Ananassa*) *sativus* (the Pine Apple) requires strong heat and special culture. *A. sativa variegata* is a fine decorative variety, with foliage broadly margined with creamy white suffused with red toward the margin. *John Heil.*

## EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, W.C.2.

## THE GREENHOUSE, HOTHOUSE, AND STOVE.

CHARLES McINTOSH, the author of the above work and of *The Orchard*, in the series referred to on page 30, was born in 1794 at Abercainry, where his father was gardener. He was successively gardener at Tayworth Castle, Stratton, Claremont and Dalkeith Park. He could have been only a brief period at the two first-mentioned places, as he was gardener at Claremont, then occupied by the King of the Belgians, about 1828, and where he carried out alterations that met the published approval of J. C. Loudon. James McDonald, for nearly half a century gardener at Dalkeith, retired in November, 1838, and was succeeded by McIntosh, who laid out new kitchen gardens shortly subsequent to taking up his duties there. Some sixteen years later he commenced as landscape gardener in Edinburgh, and was succeeded by William Thomson, from Wrotham Park, who greatly increased the amount of glass at Dalkeith.

McIntosh first appeared in print in *The Gardeners' Magazine*, 1826, and his first book, *The Practical Gardener and Modern Horticulturist*, was published in 1828 (there was an edition as late as 1840), with a series of very poor coloured plates.

In 1830 the *Flora and Pomona; or, the British Fruit and Flower Garden*, came out in parts at 1s. to 3s. each, with rather poor coloured illustrations, by F. Smith, and in 1838 and 1839 the works under review with beautiful coloured prints by Baxter. In March, 1852, appeared the first number of *The Book of the Garden*, at 5s. each part, the completed work, in two volumes, costing £4 7s. 6d. A ground plan of Dalkeith Gardens is one of the illustrations. This elaborate treatise is of interest to me because it is the first book on gardening that came in my way when a boy at school. The copy belonged to my cousin, the late Mr. James Douglas, of Great Bookham, who obtained it second-hand, and was, I think, the beginning of the fine library of old and new books he collected. At the same time he was taking in Glenny's *Gossip of the Garden* and *The Florist*, while my brother, as well as the former, introduced *The Cottage Gardener* into our circle.

To return to McIntosh. In conjunction with Dr. Kemp, he issued *The British Year-Book* in 1856, and he died in Edinburgh in 1864. Robert Thomson's *Gardener's Assistant* (1859) was, no doubt, the means of setting McIntosh in the background. The portrait of this notable gardener shows him to have been of rather slight build, and, from a remark in one of his communications, it would appear that his was not a robust constitution.

*The Greenhouse* was published at a transitional period. It does not appear that plants were cultivated to the extent or to the dimensions they were a few years later; and, indeed, it may be safely said that pot-plant culture was just emerging from a sort of pristine condition. Plant structures were very heavy in the woodwork, badly glazed with small glass panes, and worse heated, with flues or the new hot-water system still in its infancy. The popular plants were Ericas, Pelargoniums and Camellias, for which in large gardens special structures were erected. Many hothouse plants

were grown in pine-pits, Ericas and Pines being the two subjects that tested the capacity of the gardener of the period. Later, Heaths were reduced to a select list of the best species, but at this period they were grown in collections. Dr. Duncan, of Edinburgh, for instance, cultivated some hundreds. Probably Heaths and Camellias may reassert themselves, and the treatment of these, especially of the former, is given in so full a manner that one could not wish for a better guide than *The Greenhouse*. Epacris, Boronia, Eriostemon, Correa and others are treated along with the Ericas. McNab's system of potting, as practised by him in Edinburgh Botanic Gardens, is illustrated; but I think none now would pursue the same method, the base of the plant being raised several inches above the rim of the pot. Pelargoniums, like the two just mentioned subjects, were being grown so extensively as to cause some to erect more than one structure specially for their cultivation. Some 350 varieties are named, among which are a few species, and the plate of these demonstrates that very little progress had been made in their improvement. Prices ranged from 1s. to 20s. each. The author states that there were in all 800 species and varieties. Specimens, such as were exhibited in London twenty to forty years later, some of which were six feet in diameter, seem not to have been attempted at this date. Bulbous and allied plants were numerous, and the author advises the provision of a structure for these, too.

It is curious to see such things as Antholyza, Babiana, Brodiaea, Ixia, Gladiolus and Alströméria conjoined with greenhouse and stove species. The chapter devoted to succulents is brief and interesting, as containing a letter from Donald Beaton, who states that he had raised 10,000 seedlings from seeds gathered off imported dead specimens, and so preserved the species that otherwise would have been lost. Concerning mixed greenhouse plants, in which Anagallis, Chinese Paeonias and Alonsoas are included, very little is written. Fuchsias, for instance, have less than two lines devoted to them. A plate of Calceolaria shows that this plant, like the Fuchsia, had only recently been taken in hand. The chapter on "Orchidæa," illustrated with a plate of Laelia elegans, Maxillaria Harrisonæ and Dendrobium moschatum, contains the names of very few Orchids that are known new. Cipripedium insigne, Peristeria elata, Dendrobium fimbriatum, Zygopetalum Mackayi and Stanhopea eburnea are the more familiar. The treatment had greatly improved within a few years antecedent to 1838, and no doubt gardeners would be quite successful with such means as they had. Epiphytal species were largely grown on blocks of wood. Of Ferns, the cultivation was as yet in its infancy, and, in fact, it had not been long since it had been discovered that the spores were "seeds." An interesting fact is recorded of a grower germinating spores gathered off dry fronds fifty years old.

In the chapter on Tropical Fruits and Palms it would appear that here and there these were being cultivated in stove houses erected for their cultivation, and in some instances the pine-pit was utilised to keep a few. Thus it had been recorded that Thomas Thomson fruited the Plantain in the Pine stove at Tynningham in 1789, and the Banana, and the latter was so seldom fruited that the fact of its fruiting at Wynstay is noted in this and several other books.

Some of the plates, as already noted, are beautifully executed and finished. One of

Cape Heaths is bound up in *The Flower Garden*, and in this volume those specially fine are one of Epacris and Chorozeza, two of Orchids, one of Euphorbia fulgens, a group of Calceolarias, another of greenhouse flowers, and one of hothouse flowers. Besides their interest as plates, they give a faithful representation of the flowers grown at the period and at the same enable one to comprehend the vast strides made in horticultural subjects in eighty years. An Ixora, for instance, might be taken for a Bouvardia; a Gloxinia is even more enlightening in its minimised proportions, and in Pelargoniums and Calceolarias the evidence is not a whit less. Numerous woodcuts illustrate the text, woodcuts which we find doing duty in other books of the period, and the text itself is not always consistent. A description of a conservatory belonging to Lord Ashburton is said here to be seventy feet in length, while in *The Practical Gardener*, where also it is illustrated and described, it is 100 feet in length. The roof of this structure is on the ridge and furrow principle, and the sides are of glass, down to the ground. It looks like a huge, flat, glass box. All the same, as I know from experience, plants grew perfectly well in such a structure. R. P. Brotherston.

## AN EARLY VILMORIN CATALOGUE.

It is not often much can be added to Mr. Roberts' interesting articles on old catalogues and nursery lore, but I am able to supplement his Vilmorin broadside (p. 54) with a scarce catalogue published by that firm in 1771, only two years after the broadside.

It is an octavo volume of 130 pages, and must be one of the most detailed published at that time, as the descriptions of the fruits in particular are quite elaborated, often running into six lines. It is said this little work was compiled by Duchesne, and it is very possible; it is stated that the Strawberry seed offered was of his sowing.

The enumeration of the Strawberries is of great interest, and 22 varieties are offered, classed as follows:—Fraisiers; F. sylvestris; Breslinges ou Fraisiers Verts; F. pratensis; Caperoniers ou Fraisiers musques (our Haut-bois); and finally the Quimois on Fraisiers d'Amerique. Of this class there are eight varieties—F. Ecarlate (our F. virginiana), F. Ananas, The Pine, F. de Bath, de Caroline, Quimois, Frutiller ou F. de Chili, Frutiller Royal.

A long list of Pears is given, and of other fruits also, but they are mostly well known from pomological works of the period. A few interesting points may briefly be noted.

It is curious to find Medlars recommended as stocks for Pears and "other fruits of this family."

A note refers to the Apple Reinette de Canada, which the firm "hopes shortly to offer." This is apparently the first mention known of this Apple, which is now so largely grown in France, but its connection with Canada, if any, remains a problem.

A part of the catalogue is devoted to a calendar of seed planting, and very full instructions are given for the culture of pasture grasses and clovers.

Among the flowers I notice the Duc Van Thol Tulip, Iris Susiana, I. persica; La "Chrisaine" or Chrysanthemums, double Poppies (Papaver Rheas) of many colours; Zonal Geraniums with various colours and variegated leaves, and Sweet Pea (one variety only). Several hints as to raising seeds are given. Heliotrope, for instance, is advised to be grown on the soil, and not buried, and covered with moss to conserve the moisture. It would be interesting to know if any of your readers have an earlier edition of this catalogue. E. A. Bunyard.

## TREES AND SHRUBS.

### THE SITKA SPRUCE IN SUSSEX.

FOURTEEN years ago several acres of cool, ordinary land at Gravetye Manor, in Sussex, were planted with the Sitka Spruce, more by way of experiment than in anticipation that the trees would attain to anything approaching their present dimensions. The young trees, which averaged a foot in height, were planted at regular distances apart all over the ground, with nurses of the common Spruce between. As the trees grew and encroached on each other, the nurses were gradually removed, until now the plantation is a crop of almost pure Sitka Spruce.

When staying at Gravetye lately, I was agreeably surprised at the splendid growth of these trees, and on taking the measurements of several, found the average cubic contents to be a little over seven feet, some of the biggest, which are 55 feet high, containing a much larger volume of timber. Rarely have I seen a straighter or more uniform crop of boles, and the taper is so gradual, that at 20 feet the stem measurements are little less than near ground level. Owing to close order of growth, the trees are clear of living branches, for fully half their height, and are gradually cleaning themselves as they advance in growth. For its age this is by far the finest plantation of the Sitka Spruce that I have seen, and if cut down at present the value of timber produced would more than pay for the rental of land and cost of trees and planting.

As scaffold poles or for constructional work the trees are of special value, and if placed on the market would find a ready sale at highly remunerative returns. Should growth proceed at an equal rate during the next ten years, after which the first thinning should take place, the value of timber to be removed should be very considerable.

How well the Sitka Spruce is suited for planting in this country may be inferred from the fact that some of the earliest planted trees are over 100 feet in height, with diameters from two to three feet at a yard from the ground, and that the tree succeeds well at over 1,000 feet altitude. The Kincardineshire plantation, at Durris, at elevations from 700-800 feet, where the land is poor, wet and of a peaty nature, is a good example of how well this tree succeeds under the most unfavourable conditions. In some instances deep ditches were required in order to carry off the surplus water, yet in spite of the numerous drawbacks the trees, which were planted forty-one years ago, are in splendid health, growing rapidly and producing fine, clean boles that are straight as the proverbial arrow.

In the plantation that was formed by the writer on one of the spurs of the Snowdon range of hills, on Lord Penrhyn's estate, the Sitka is thriving amazingly at altitudes up to 600 feet. But perhaps the most interesting experiment with this tree was planting it under the most adverse conditions in poor, damp soil and a wind-swept situation, by the side of Lake Ossian, in Scotland, at elevations up to fully 1,200 feet. Even under these trying conditions, several of the leading shoots that were recently measured were 16 inches in length, and the present indications are that the tree will beat all the others that were experimented with on this cold, barren and high-lying land.

It is encouraging to know that several landed proprietors are planting the Sitka Spruce on rather an extensive scale, and when the beauty, hardihood and valuable timber-producing properties are taken into account, it must be admitted that they are acting wisely in so doing. In addition to the Sitka Spruce, many others of the less common Coniferous trees are thriving well at Gravetye, especially a plantation of *Abies grandis*, the trees in which are growing with amazing freedom, some of the best specimens being taller than Douglas Firs that were planted at the same time. The Cephalonian Fir is also doing well as a plantation tree, as is also the Japanese Larch, which has grown with the greatest freedom, and is so far free

from disease. Both the Corsican and Austrian Pines are producing long, annual growths, and the foliage wears a deep shade of green that denotes robust health. Other Pines that have been planted in quantity are the Maritime, Southern Pitch, White or Weymouth, and our native Scotch Fir. Strikingly beautiful is the silvery foliage of the Weymouth Pine and of *Picea pungens glauca*, which are succeeding as well as the Bhotan Pine, which appears to

winter that the chief glories of the trees are apparent, for then the silvery bark shows to the greatest advantage through the network of thin branches, and fully entitles it to be described as The Lady of the Woods. When grouped in a clearing of woodland with undergrowth of Rhododendron and Bracken Fern, as at Warren House, Kingston (Fig. 40), the Silver Birch gives a touch a rare beauty to the landscape and compels the admiration of all lovers of

FIG. 40.—SILVER BIRCHES AT WARREN HOUSE, KINGSTON.

revel in the soil of parts of Gravetye. Amongst many other Coniferous trees, that have been planted in large breadths in order to demonstrate their adaptability for afforesting purposes, are several species of Cypress, *Arbovitae*, Hemlock, Cedar of Lebanon and Douglas Fir. *A. D. Webster.*

### THE SILVER BIRCH IN WOODLAND.

FEW others of our native trees equal the Silver Birch in beauty of outline or in the graceful disposition of the branches, which hang like filigree work of so delicate a nature that the shoots seem almost too fragile to resist the storms of autumn and winter. Indeed, it is in

nature. Apparently the native Silver Birch include two distinct species, *pubescens* and *verrucosa*, the former with stiffer habit of growth and somewhat darker bark, whilst *verrucosa*, the *alba* of Linnaeus and *pendula* of Roth, is slightly more graceful and free from down on the young vegetative parts, by which it is readily known.

The Silver Birch is sometimes used as a town tree, and its ornamental character in winter fully justifies its selection for the purpose, as town streets are usually very dull in winter even when rows of deciduous trees are planted on either side. But the Silver Birch seems most at home in woodland, and when the winter sunshine lights up its silvery bark and frost decks its pendant branches it is exquisitely beautiful.

## MESEMBRYANTHEMUM AND SOME NEW GENERA SEPARATED FROM IT.

(Continued from page 65.)

### BB, FLOWERS WHITE.

(7) *L. marmorata*, N.E. Br.—Growths solitary or few in a clump, increasing very slowly, up to 1½ in. high, 1¼ in. broad, and ¾ in. thick, with the top of the lobes slightly convex, grey-green, mottled with pale grey or creamy-grev. Calyx 6-lobed; lobes 2-3 lines long and about 2 lines broad, ovate or oblong, obtuse. Corolla about 1¼ in. in diameter, expanding after mid-day in full sunshine and closing at dusk, scented; petals about 40, of about 2 closely overlapping series, 6-7 lines long and 1-1½ line broad, obtuse, pure white on both sides, very shining. Column of stamens ½ in. long, white, with yellow anthers. Top of the ovary flat; style very short; stigmas 6, finally about 5 lines long, at first erect, but when the petals fade they spread widely from the base, pushing the stamens away so that the latter form a sort of ring around them, and they are revolute at the tips.—*M. marmoratum*, N.E. Br., in *Journ. Linn. Soc. Bot.*, v. 45, p. 68.

South Africa: locality unknown, Pillans!

(8) *L. optica*, N.E. Br.—Growths forming clumps of 4-15 to a plant, each 6-8 lines high and 6-7 lines in their greater diameter, with the top of the lobes slightly convex, with narrow whitish or whitish-brown margins, and the central part greenish-white or pale greyish-white sometimes tinged with pink, without or occasionally with 1 or 2 whitish spots. Calyx 5-lobed; lobes, 2 lines long, oblong, obtuse, brownish. Corolla, about ¾ in. in diameter, expanding only in bright sunshine; petals numerous, 3-4 lines long, pure white or tinged with pink. Stamens white, with yellow anthers. Stigmas 5, filiform greenish.—*M. opticum*, Marloth in *Trans. Roy. Soc. S. Afr.*, v. 1, p. 405, t. 27, f. 5 (1910). *M. marginatum*, Marloth in a note under *M. rhopalophyllum* Schlechter, on p. 406 of the same work.

Great Namaqualand; near Prince of Wales Bay, in sand-covered fissures of gneiss rocks, Marloth, 4,675; on rocky hills at Luderitz Bay, Poie Evans, 7,210!

I have not seen fresh flowers of this species, as my plants of it have not yet flowered.

(9) *L. bella*, N.E. Br.—Growths at first solitary, forming clumps with age, increasing slowly, each up to about 1 in. high and 1 in. in their greater diameter, with the top of the lobes convex, having a rather broad, light brown or buff-brown border, enclosing an irregularly lobed fuscous or greenish central area with or without 1 or 2 brown spots upon it. Flowers not seen, stated to be white and shining.

Great Namaqualand; near Aus, Phillips!

When sufficiently supplied with water the top of the lobes is even and smooth all over, but under very dry conditions the central part becomes slightly sunk below the level of the marginal part. I am indebted for this pretty species to Q.-M. Sergeant E. C. Phillips, who informs me that it grows on the top of small kopjes in sandy, gravelly soil and is so similar in colour to the soil that it is difficult to detect. It has not yet flowered with me.

(10) *L. damarana*, N.E. Br.—Plant solitary or of few growths in a clump, increasing slowly under cultivation. Each growth ¾-1 in. high and up to 1½ in. in its greater diameter; lobes flat or very slightly convex on the top, very pale brown or fawn-colour, marked with distinctly impressed branching lines and spots forming a sort of pattern of a rich, dark brown or dark grey colour. Calyx 5-6-lobed, much compressed and about 5 lines broad; lobes 2-3 lines long, 2-2½ lines broad, ovate or oblong, obtuse, some with membranous edges, dull reddish-brown. Corolla ¾-1½ in. in diameter, opening about 1 p.m. and closing between 4 and 5 p.m., and lasting for about a week, not scented; petals 30-36, in about 2 closely overlapping series, 5-9 lines long and about 1 line broad, linear, obtuse, pure white on both sides, slightly shining. Column

of stamens 2½-3½ lines long, white with yellow anthers. Top of the ovary flat. Style absent; stigmas 5, filiform, revolute at the tips, light yellow.—*M. damaranum*, N.E. Br., in *Journ. Linn. Soc. Bot.*, vol. 45, p. 67.

Damaraland, locality and collector unknown. I received specimens of this plant some years ago without information, except that they came from Damaraland. Subsequently some plants were sent to me from Omaruru and Aus and arrived in a very shrivelled condition, so that I mistook them for the same species as the above, and, therefore, wrongly mentioned those places as localities for *M. damaranum*, in the journal above quoted. The Omaruru plant died without rooting, but I believe it to have been the same as that from Aus, which, now that I have it in plump condition, proves to be quite distinct from *L. damarana*, and is described above as *L. bella*. I am under the impression that Prof. Pearson sent *L. damarana* to Kew among the plants he collected on the Great Karasberg Range, and that it died, but I have no note to that effect and may be mistaken. *N. E. Brown.*

(To be continued.)

## THE GREAT DROUGHT OF 1921 AND ITS EFFECT ON GARDEN PLANTS.

(Continued from page 56.)

### WARWICKSHIRE

This garden is dry; the soil is very light and shallow, and overlies what is locally called "cat's brain," a poor, slightly clayey sand. It is surrounded by trees, so that there is a tendency for all the borders to be robbed of moisture, which adds to the general dryness. On the contrary, the trees provide cool, shady positions which escape the full effect of such conditions as prevailed in 1921.

We do not appear to have suffered quite so much rain shortage as most places in England, judging by the reports in your columns; and in particular we had a most welcome break on July 30, which lasted well into August, so that the latter month, with the addition of the last two days of July, showed a total rainfall of 5.21 inches. Mr. C. N. Milner, whose measurements are taken a few hundred yards away from this garden, has given me the following figures for the first ten months of the year:—January, 2.43 inches; February, 0.24; March, 1.37; April 1.22; May, 1.58; June, 0.69; July (to the 29th), 0.46; August, (including July 30-31), 5.21; September, 1.05; and October, 1.87 inch.

As I only came here in October, 1920, I cannot compare 1921 with previous years, but one or two things observed may be worth recording. *Violas* planted in a sunny, very dry border perished so completely that no trace of them was left; but a considerable number planted in the Rose garden, which is in a shadier part, with better cultivated soil, did remarkably well. Not only did they do well in their normal season, but, after slacking off in July, they were refreshed by the rains, and, starting a new lease of life, did better than before, and gave a brilliant display which lasted into October. The *Roses*, an ordinary collection of dwarfs, made a very brave show in July, in spite of the fact that they were not once watered; but the second blooming was very disappointing, although in 1920 they flowered very freely all through the late summer and autumn. Evidently, although they had done so well earlier, the effort had exhausted them.

We have actually lost very few plants, almost the only total failures being some *Berberis* and *Heaths*, which were only planted in the spring and moreover did not stand much chance, owing to faulty despatch by the nurseryman from whom they had been obtained. *Rhododendrons* looked very sorry for themselves, but were all saved by means of a few timely soakings, and now they look as healthy as possible and seem well set with flower buds. *Primroses*, too, suffered, as might be expected, and, as I seemed likely to lose

my stock, I watered them several times, but I might have saved myself the trouble, for, although the greater part of the old plant died away, so many seedlings sprang up around them after the rain came that I shall not run short; indeed, it seems to be one of the features of the year that, although the parent plants so often suffered, they ripened seeds so freely and well that, as soon as rain fell, there was an abundance of young plants arising round the old stools to carry on the family traditions.

Some annuals ripened their seed so early and well that young plants from them almost reached the flowering stage before November frosts cut them down. I noticed this particularly with *Brachycome iberidifolia*.

The ordinary spring sowings of vegetable and flower seeds, the latter including the regular supplies of *Wallflowers*, *Canterbury Bells*, etc., came up with unusual freedom. They were for the most part sown in the less exposed positions and received some water, but I never saw such crowded seedbeds, proving that dry, warm conditions, if not too dry, assist germination.

Pests do not seem to have flourished, as a rule, and the garden, on the whole, was much cleaner in 1921 than in 1920, partly, of course, because of our efforts, but not wholly so. American blight was very troublesome in 1920. We sprayed the trees in the early spring and thus reduced it, doubtless; but there was some still in evidence in the early part of the summer. Instead of increasing, however, it died away, and the trees were almost free in the latter part of the summer. Aphides were troublesome on *Brussels Sprouts* and other members of the *Cabbage* tribe, and the *Gooseberry* sawfly was unusually abundant in this neighbourhood; while, curiously enough, mildew was in evidence on the *Roses* and also on some *Apple* trees. However, we felt that we had been unusually free from our usual enemies.

Amongst subjects that suffered severely were many of the *Saxifrages*, especially the *Kabschias* and the mossy ones, the latter dying back in big patches, and the former only surviving as the result of much watering. The common *Arabis albidia* showed distress, but recovered rapidly after the rain, and such countless numbers of seedlings came up as to be a nuisance. *Dablias*, which needed more water than we could give them, started growth with great difficulty, but flowered well later on. *Chrysanthemums* were kept back so much that, when at last they did start to grow in August, they were already behind time in their development, and were, as a consequence, late in flowering. They did very well in the end, however, though most kinds were short in their growth.

Perhaps the most important lesson to be learnt from my garden is the difficulty in drawing general conclusions about the effects of such an experience as we had in 1921. The different behaviour of various plants—notably in the case of the *Violas* referred to above—in different positions shows the necessity for caution and for a full consideration of all the circumstances of each case. *Colbran J. Wainwright, Daylesford, Handsworth Wood, Birmingham.*

### SURREY.

In most parts of Surrey the drought was severely felt. Many *Rhododendrons* and *Azalea mollis* died in these gardens. The soil being light and sandy, vegetable seeds germinated badly from June to November. *Brussels Sprouts* and *Broccoli* were very scarce. *Apple* and *Pear* trees are well set with flower buds for the coming season, after carrying a good crop of fair-sized fruits, which have kept well. Rain fell on 112 days; an average rainfall is 27 inches, and the amount registered in 1920 was 26.50 inches. In 1921 the record was as follows:—January, 2.32 inches; February, 0.47; March, 1.36; April, 0.97; May, 1.66; June, 0.29; July, 0.40; August, 0.72; September, 1.34; October, 0.63; November, 1.84; December, 1.53; total, 13.53 inches. *J. W. Harris, Beverden Gardens, Orshott.*

(To be continued.)

## FRUIT REGISTER.

### APPLE SOPS IN WINE.

No other variety of Apple can vie in colour with this old and very good quality sort.

Noticing a few baskets of it in a West Midland fruit market some weeks since, I was impressed with the intense colour of the fruit this season over and above what I have seen previously. The variety should be perpetuated if only for the beauty of the tree in the landscape.

The fruit is above middle size, very dark red on the sunny side, rich orange red on the shaded side, and has a bloom on the surface.

One of its peculiarities is the red colouring of the flesh. The tree grows vigorously, and is productive.

Apple Sops in Wine is a splendid cooking sort.

### APPLE SACK AND SUGAR.

This pretty old Apple is becoming extinct, it being doubtful if trees could be procured from any nursery in England to-day, and the only specimens I know are large decaying trees in one or two orchards. These trees are so full of flower spurs it is difficult to get suitable wood for grafting purposes; nevertheless, the colouration of the fruits is of great beauty.

Small to medium in size, this Apple has a pale yellow skin with streaks of red; the flesh is white, tender and juicy. Trees of this old variety may be found in Devonshire, Herefordshire and Somersetshire, and probably in other counties.

### APPLE NONE SUCH.

This Apple stands practically in a category of its own, it having most remarkable leaves and wood, the former being covered with a fine whitish tomentum, the latter being somewhat thorny. It has been known since 1668.

One large tree of this peculiar growth I noticed near Ocle Pritchard a few days before the fruits were gathered, and I was impressed with their beautifully finished appearance, after Peasgood's Nonesuch style.

The fruit is of middle size to large, nearly round; eye small, stalk short, slender, inserted in a shallow cavity; skin beautifully marbled with red, yellow and green; flesh very white, melting with a full sub-acid juice, flavour first-class as a culinary sort. It will keep until November.

I think many of these old, useful varieties are somewhat localised and never get far afield.

*Pomona.*

## POTATO CRUSADER.

Amongst the many promising new varieties of Potatoes raised in recent years Crusader (see Fig. 41) holds a high place, and will doubtless become popular with growers, not only for the table, but also as an exhibition sort, as the tubers are of very imposing appearance. The specimen illustrated was from a grand dish of the variety exhibited by Messrs. Dobbie and Co. at the National Potato Society's Exhibition in November, 1921. Crusader is an early main-crop sort and was raised by the late Dr. Wilson, of St. Andrews. It is immune to wart disease and, so far as can be judged, very resistant to late blight. It is a strong grower, and has a most distinct, erect-growing haulm. Given good cultivation it will produce a splendid crop of perfectly shaped kidney tubers of excellent cooking quality. Last year a well-known Ayrshire farmer planted one ton of Crusader in light soil during April, and the crop lifted in September weighed 19 tons.

The early main-crop varieties have a special value in seasons when late blight is prevalent, for the grower is enabled to lift the tubers at a time when the soil is comparatively dry and before the disease has affected the crop to any considerable extent.

## HOME CORRESPONDENCE.

[The Editors do not hold themselves responsible for the opinions expressed by correspondents.]

**Cedrus Libani.**—The estimate of the age of the Cedars at Chorleywood cited by Mr. Stacey (page 56) provides a liberal margin between 450 and 1,000 years. There is no certain evidence of the exact year when the Cedar of Lebanon was first grown in England, but the question was carefully gone into by Messrs. Elwes and Henry in their *Trees of Great Britain and Ireland*, pp. 458, 459, with the result that they could find no authentic record earlier than that of John Evelyn, who states in the third edition of his *Sylva*, published in 1679, that he had received seeds from Mount Lebanon. As he discusses the existing condition of the forest on Mount Lebanon with some detail, he would have been pretty sure to have mentioned any young Cedars growing in England at the time when he was writing. Loudon accepted this as proof that Evelyn was the first to grow Cedars of Lebanon in England, and he considered that the trees mentioned by Sir Hans Sloane as growing in his garden (now the Chelsea Physic Garden) in 1685 were

into this country, it is supposed to have been not earlier than 1663—one of the earliest records is of one planted in 1676 at Bretby Park, Derbyshire. *Joseph Cheal, Crawley.*

—The trees at Chorleywood are well known, and are mentioned in *Trees of Great Britain and Ireland*, Vol. III., p. 463. It is supposed that Evelyn first obtained seed which was planted at Enfield by Dr. Uvedale about 1670, which makes the date of introduction about 250 years. The fine Cedars at Bayfordbury were raised from the Enfield trees and planted in 1765. The largest tree has now, at 5 ft., a clean stem, with a girth of 20 ft., and it is 97 ft. high. Surely a fine tree for 155 years! I do not agree that the Cedar is slow of growth. Many fine trees are mentioned in the above-quoted work by Elwes and Henry. *H. Clinton Baker, Bayfordbury.*

**Wilt in Melons.**—I am very grateful to *C. G.* (page 34) for his kind correction. I should have written Bordeaux mixture powder sulphate of copper (2 lb. tin) guaranteed 58/60 per cent. genuine sulphate of copper. I was advised last year in the *Gard. Chron.* to try Bordeaux paste; this I could not obtain,

FIG. 41.—POTATO CRUSADER.

the oldest in England. The last of these trees died about 25 or 30 years ago, and had to be removed. It is evident that the Cedars at Chorleywood cannot be 300 years old, and are probably much less. *Herbert Maxwell, Monreith.*

—I was interested in Mr. Stacey's note on *Cedrus Libani* at Chorleywood, and I imagine that these are some of the finest trees in the country. I visited the native habitat of the tree a few years since and ascended the Lebanon to see some of the oldest specimens remaining. I took measurements of some of these, and the largest measured 42 ft. in circumference at 4 ft. from the ground. This gives a diameter of 14 ft. through, as against the Chorleywood tree's 25 ft. circumference and 8 ft. 4 in. diameter. Fine as the Chorleywood trees are it will take them some years yet to reach the dimensions of the Lebanon trees. The largest one that I saw was on the Jubal Barak or one of the southern spurs of the Lebanon range, and the altitude was 6,200 ft. according to my aneroid barometer.

The majestic beauty of these monarchs may be imagined as they grip the rocky mountain side and stretch out their enormous pendulous branches towards the valleys below.

As to the date of introduction of this Cedar

and used the above mixture instead. Growers whose Melons suffer from wilt will regard Mr. Allan's treatment of Melons as set out on page 23 as being the very best. Wilt disease is not like the canker caused by excessive moisture, as plants grown in good houses, planted high and dust dry at the collar, wilt just the same as plants in cold frames. My Cucumbers also suffer in the same way. *Anxious.*

—Mr. Bates refers (p. 56) to the causes of "canker or wilt" in Melons, but my own observations have led to the deduction that these are two widely dissimilar diseases. Canker affects various portions of the plants, usually commencing in the stem just above the soil level, and showing first in the form of excrescences on the outside of the stem and midrib of the leaves, and for some days the plants will not show any other sign of ill-health. The mysterious wilt disease, on the contrary, shows no injury to the plant externally, but causes the whole of the foliage to wilt or droop with the first direct rays of bright sunshine. Canker can be guarded against by due regard to watering and ventilation, but I have yet to hear of a reliable specific or preventive for the wilt disease. *J. E. Palmer, Tilstone Lodge Gardens, Tarporley, Cheshire.*

## SOCIETIES.

### MANCHESTER AND NORTH OF ENGLAND ORCHID.

THURSDAY, FEBRUARY 2.—Committee present: The Rev. J. Crombleholme (in the chair), Messrs. Ashworth, B. J. Beckton, J. Birchenall, A. Burns, A. Coningsby, D. A. Cowan, J. Cypher, A. G. Ellwood, W. Giles, Dr. R. N. Hartley, J. Howes, A. Keeling, J. Lupton, D. McLeod, E. W. Thompson, and H. Arthur (secretary).

#### AWARDS.

##### FIRST-CLASS CERTIFICATES.

*Odontoglossum crispum* Hero, a large white flower of perfect shape. *O. Wilckeanum aureum*, one of the best forms of this lovely yellow variety. *Odontioda Viscount Lascelles* (Ohta, Madeline × Odm. L'Aiglon), flowers richly blotched bright reddish brown, on a white ground. *Cypripedium memoria* F. M. Ogilvie var. *Invincible*, a finely shaped flower, the dorsal sepal richly spotted; from S. GRATRIX, Esq. *Cymbidium Schlegelii*, Fowler's var., from Mrs. BRUCE and Miss WRIGLEY. *Lycaste Skinneri* var. *Princess Mary*, a large flower of beautiful rose colour, from Mrs. GRATRIX.

#### AWARDS OF MERIT.

*Cypripedium Conference magnificum*, *C. Porthei* (Alcibiades?), *C. Cotswold* (Blanche Moore × G. F. Moore), *C. Bantire* (Gaston Bullock × leyburnense), from Hy. GREEN, Esq. *Odontoglossum crispum* Lord Derby, *O. Dodderham magnificum*, and *Odontioda Hanmerae* (Ohta, Sauderae × Odm. Jasper), from A. HANMER, Esq. *Odontoglossum Lobbiae*, from Mrs. BRUCE and Miss WRIGLEY. *O. crispum Romeo*, from S. GRATRIX, Esq. *Cypripedium Ferona* var. *Cyme*, from Col. Sir J. RUTHERFORD, Bart.

#### GROUPS.

Mrs. BRUCE and Miss WRIGLEY, Bury (gr. Mr. A. Burns), and S. GRATRIX, Esq., West Point (gr. Mr. J. Howes), were awarded Silver-Gilt Medals for collections of Cypripediums. A. HANMER, Esq., Buxton (gr. Mr. W. Giles), staged a group to which a large Silver Medal was awarded. Hy. GREEN, Esq., Birmingham (gr. Mr. Geo. W. Marsh), was awarded a Silver Medal for a group, and Dr. R. N. HARTLEY, Wigan, was awarded a Bronze Medal for a group. MESSRS. CYPHER AND SONS, Cheltenham, were awarded a Silver Medal for a group of Cypripediums, Masdevallias, Coelogynes, etc.

### NATIONAL CHRYSANTHEMUM.

The annual general meeting of this Society was held in the Floral Committee Room at the Royal Horticultural Hall, Westminster, on the evening of Monday, February 6, when Mr. E. F. Hawes presided. The meeting was of a purely business character, as there were no controversial matters arising, but Mr. C. Harman Payne added considerable interest to the proceedings by referring at some length to the Le Mans show and its attendant functions.

The report of the Committee and accounts for 1921 were presented, and adopted on the motion of the Chairman. Reference was made in the report to the fine exhibition held in November, and to the financial success which attended it. It appears that the Floral Committee granted fourteen First-Class Certificates and four Commendations to new Chrysanthemums; 56 novelties were submitted for its consideration. The educational interest of the Society was well sustained by Mr. M. Mills and Mr. Harold Wells, both of whom gave lectures after the business proceedings at Committee meetings held last autumn. It is a pleasure to be able to record an improved financial position; whereas £3 13s. was brought forward from 1920, £14 19s. 3d. represents the balance in hand at the end of 1921. Receipts included £109 5s. in subscriptions, and £70 2s. 6d. in special prizes, with £78 taken at the gate at the November show. The entire turnover was £335 1s. The Society has a reserve fund of £50, and its surplus of assets over liabilities is given as £87 1s. 6d.

Following the adoption of the report, the election of officers took place, with the result that Sir Albert Rolbit was re-elected President; Mr. J. Green, Treasurer; Mr. E. F. Hawes, Chairman; Mr. D. Ingamells, Vice-Chairman; Mr. C. Harman Payne, Hon. Foreign Corresponding Secretary (for the 34th time); Mr. C. H. Curtis, General Secretary and Editor, and Messrs. R. A. Witty and S. J. Bayley, Hon. Auditors. The eligible retiring members of Committee were re-elected and vacancies were filled by the election of Mr. W. J. Taylor, Pinner, Mr. R. C. Pulling, Lewisham, and Mr. T. Smith, Kingston.

On the proposal of the Treasurer, the members decided to make a small presentation to Mrs. Curtis in recognition of her kindly help to the Society on the occasion of the November show.

### ROYAL GARDENERS' ORPHAN FUND.

THE annual general meeting of the supporters of the Royal Gardeners' Orphan Fund was held on the 9th inst., at Simpson's Restaurant, Strand. Mr. E. Sherwood, Hon. Treasurer of the Fund, occupied the chair, and there were present Messrs. B. Wynne, D. Ingamells, G. F. Tinley, John Douglas, J. F. McLeod, H. J. Jones, R. Leech, W. E. Wallace, C. H. Curtis, J. M. Bridgeford, D. Swain, L. Sutton, and G. Reynolds.

The meeting was of very short duration, and there was scarcely any discussion. The chairman submitted the annual report of the Executive Committee and statement of accounts. The chief items in the report are those following:—

#### EXTRACTS FROM THE REPORT OF THE EXECUTIVE COMMITTEE.

"With a deep sense of thankfulness your Committee is enabled, in presenting their thirty-fourth annual report, to congratulate the supporters of the Fund on the completion of another year's satisfactory work, notwithstanding the adverse influence which the present financial situation everywhere has on all charitable institutions. That the Fund has been enabled to make provision for the disbursement of over one thousand five hundred and twenty-four pounds among no fewer than one hundred and twenty-seven children during the past year in such times as these cannot be other than gratifying, but it must be recognised that this has only been possible owing to the hearty co-operation and support of all who have the welfare of the Fund at heart, and to whom most grateful thanks are due.

"At the commencement of the year one hundred and eleven orphan children were in receipt of the full benefits of the Fund, and sixteen more were added at the annual meeting in February. The fact that there are only four approved candidates appealing for election at the ensuing annual meeting, speaks eloquently of the splendid services rendered to their country by gardeners of military age whose dependents are being provided for by the Ministry of Pensions, instead of having to apply to this Fund for assistance to aid in their maintenance until they can earn their own livelihood. This state of affairs cannot, however, be of long duration, and your Committee very earnestly appeals for con-

tinued financial help to enable the useful work now in progress to be efficiently carried on—and if possible to reinstate the invested funds which had of necessity to be parted with during the war. The Committee feels that this appeal will not be made in vain.

"Gratifying success attended the holding of the annual festival dinner in the Comaught Rooms, on June 22, under the presidency of the Right Hon. Viscount Elveden, M.P., and resulted in a net gain to the fund of over eleven hundred pounds.

"Your Committee again has to acknowledge with great thankfulness an increasing measure of support by the members of Gardeners' Improvement and Horticultural Societies in various parts of the country.

"Among the special contributions received during the year your Committee gratefully acknowledges the receipt of a legacy of £365 18s. 4d. from the executors of Mr. William Phipps, who was well known to the older generation of horticulturists as gardener for many years at Bowood, Wiltshire. We have also to acknowledge generous gifts from Percival David, Esq., the Rt. Hon. Mary Countess of Ilchester, The Lady Battersea, and Mr. Robert B. Ker, part proceeds of a flower and fruit show held in the Liverpool Cotton Market.

"The loss which the Fund has sustained during the past year by the deaths of generous supporters is again a heavy one, and your Committee records with deep regret the passing away of Lady Veitch, The Lord Mount Stephen, Mr. William C. Dawes, Mr. W. E. George, J.P., Mr. George Paul, J.P., Mr. W. G. Rigden, Mr. G. F. Nixon, Mr. J. C. Geiselbrecht, Mr. C. Archer, Mr. F. Harris, and Mrs. Penton."

Mr. D. Ingamells seconded the adoption of the report, which was passed without comment. The chairman proposed the election of Viscount Elveden as a vice-president, and referred to the great success which attended the festival dinner over which his Lordship kindly presided. The election was confirmed by the unanimous vote of those present. The meeting then proceeded to the election of officers. Mr. E. Sherwood was, on the proposition of Mr. J. F. McLeod, re-appointed Treasurer, and thanked for his valuable services in connection with the Fund. Mr. Sherwood, in reply, thanked the meeting for re-electing him and declared that he had the interest of the Fund at heart, and was always ready to render it any benefit that was in his power. The retiring members of the Committee, Messrs. W. H. Cutbush, D. Ingamells, R. B. Leech, J. F. McLeod, A. W. Metcalfe, D. Swain and Geo. F. Tinley, were, on the proposition of Mr. L. Sutton, re-elected, and Messrs. W. L'oupart, J. H. Smith, and T. A. Gardener, who resigned, thanked for their past valuable services. To fill these three vacancies, Mr. V. Auton, Mr. A. Dawkins and Mr. J. Wort were elected members of the General Committee.

The Auditors, Messrs. Peter R. Barr and A. Witty, were also re-appointed and thanked for their services. On the proposition of Mr. D. Ingamells, Mr. Brian Wynne was re-elected Secretary of the Fund. At this stage of the proceedings, there being no ballot, the four following children were, on the proposition of Mr. W. E. Wallace, elected to the benefits of the Fund:—Janet Helen Robertson, Robert David Robertson, Noel G. Tyler and Kenneth Edward Tyler.

## ROYAL HORTICULTURAL.

FEBRUARY 14.—The annual meeting of the Royal Horticultural Society was held on Tuesday last in the Vincent Square Hall, Westminster. The number of exhibits was not so numerous as usual at the annual meeting, but there was a capital attendance. The chief features of the exhibition were Orchids, Carnations, Primulas, Azaleas, early hardy flowers, and, in the fruit and vegetable section, a group of vegetables and collections of Oranges and Apples.

The Narcissus and Tulip Committee held its opening meeting for the season, but only one novelty was submitted. Awards were made to novelties by all the other committees. The Orchid Committee granted one First-Class Certificate and one Award of Merit; the Floral Committee recommended an Award of Merit to a variety of *Primula malacoides* and the Fruit and Vegetable Committee conferred a similar award on Seedling Washington Navel Orange, shown by Messrs. T. S. RIVERS AND SON.

## Floral Committee.

*Present*: Messrs. H. B. May (in the chair), W. J. Bean, W. R. Dykes, Reginald Cory, James Hudson, Chas. E. Pearson, W. P. Thomson, R. W. Wallace, Hugh Dickson, Clarence Elliott, W. B. Cranfield, H. V. Warrender, E. A. Bowles, G. Reuthe, John Heal, Donald Allan, C. R. Fielder, J. F. McLeod, W. Howe, Montagu C. Allwood, W. B. Gingell, H. J. Jones, D. B. Crane and Amos Perry.

## AWARD OF MERIT.

*Primula malacoides Princess Mary*.—A charming and useful plant of much sturdier habit than the typical *P. malacoides*, and with larger blooms. The foliage is stiffer and firmer than in the type and has some white farina on the underside. The flowers are  $\frac{1}{2}$  to  $\frac{3}{4}$  inch in diameter, rich rosy lilac in colour, with a light orange-yellow eye. Shown by Messrs. JAS. CARTER AND CO.

## OTHER INTERESTING PLANTS.

Mr. A. C. T. WOODWARD, Arley Castle, Bewdley, showed *Clematis F. 559*. This has small leaves, each of the three leaflets being divided into three. The flowers are rose coloured, with numerous segments and borne on long stalks. It is from the Da-Tung Alps and, apparently, one of the recent discoveries in China. *Saxifraga Mariae-Theresae*, from Mr. P. ROSENHEIM, Chetwynd, East Molesey, was referred to the Scientific Committee.

## GROUPS.

Composed principally of two sorts of *Primula*, *Hyalinths* and *Tulips*, the exhibit by Messrs. CARTER AND CO. was singularly effective. A whole length of tabling was utilised, and raised along the centre were small collections of *Primula stellata* Fairy Queen Improved—a floriferous variety in which the clear white petals have a distinct rich carmine zone around the yellow eye—alternating with groups of miniature *Hyalinths* in various colours. An informal bordering was composed largely of *Primula malacoides* Princess Mary, and of this excellent variety there were very many plants all as well grown as the stellata variety. Bowls of *Tulips* in such sorts as Prince of Austria and the double-flowered Tea Rose pleasantly interspersed the *Primula* bordering (Silver-Gilt Banksian Medal).

The collection of greenhouse plants shown by Messrs. STUART LOW AND CO. included a very effective standard of *Acacia Baileynana*, little bushes of *Chorizema cordata*, *Erica Veitchii* and many varieties of *Azalea indica*. A goodly collection of cut Carnations adjoined the plants, and of these two large vases of the Hon. C. Knollys and Mrs. C. F. Raphael of the perpetual-Malmaison varieties were admirable, while there were also very many valuable perpetual varieties (Silver Flora Medal).

Carnations were also excellently shown by Messrs. ALLWOOD BROS., who gave special prominence to a large stand containing mixed perpetual-Malmaison sorts. This was an exceedingly effective arrangement, and the many blooms diffused a pleasant fragrance. Near by there was a large stand of Wivelsfield Pink, of glowing colour, which was enhanced by the

good yellow of Maine Sunshine, which is probably the best of all the yellow varieties. Rich deep colour was provided by a massed vase of the velvety crimson Triumph (Silver Flora Medal).

By the use of many artistic bowls and small *jardiniere* amongst his vases of Carnations, Mr. C. ENGELMANN made a novel and effective display. It was a large exhibit, and of the very many good sorts on view it was those of pink shades of colour that were the most pleasing. These included Laddie, Cupid, Lady Northcliffe, Peerless and Bona (Silver Banksian Medal).

*Begonia manicata*, a free-flowering greenhouse species which is equally effective as comparatively small specimens in 6 inch pots as when grown to a much greater size, was given the central place by Messrs. L. R. RUSSELL, LTD., in a collection of plants. There were also well flowered specimens of *Azalea indica*, *A. mollis* and Ghent hybrids, while at one end was a small group of *Prunus triloba* and the double-flowered Peach (Silver Banksian Medal).

A collection of cut blooms of the Sheepwell strain of scented *Cyclamen latifolium* was contributed by E. WORMALL, Esq. (gr. Mr. Lay), Sheepwell House, Potters Bar. The blooms illustrated high cultivation, but, probably owing to the cold weather, the fragrance was not readily apparent (Bronze Flora Medal).

Shrubs with ornamental foliage and in flower were an interesting feature in the hall. Amongst a representative collection by Messrs. J. CHEAL AND SONS there were branches of *Parrotia persica* just disclosing the stamens of its lively red flowers. This medium-sized tree is not only strikingly brilliant when in flower, but is also of great value for its autumn foliage. Flowering shrubs included *Rhododendron praecox* and *Pieris (Andromeda) floribunda*, while of spring flowers there were *Crocus versicolor*, Grape Hyacinths and various *Saxifrages* (Silver Banksian Medal).

*Berberis hyemalis* and sprays of *Hamamelis* were prominent in an exhibit by Messrs. R. WALLACE AND CO., who also showed pans of *Crocuses*, *Primroses* and *Irises* with a goodly mass of *Lithospermum prostratum* (Silver Banksian Medal). A batch of the attractive foliage plant *Veronica glauco-coerulea* attracted attention in the contribution by Messrs. SKELTON AND KIRBY, who also showed some interesting *Saxifrages* (Bronze Flora Medal).

Dwarf Conifers suitable for the rock garden were shown by Messrs. R. TUCKER AND SONS, who also had little colonies of *Adonis amurensis* in full bloom and many *Saxifrages*. Of the latter, *Saxifraga macedonia*, bearing many yellow flowers, and *S. Mr. Leng*, with primrose yellow blossoms, were very attractive (Silver Banksian Medal).

An exceedingly gay and attractive planting of *Irises*, *Crocuses* and other spring flowers was made by Messrs. WATERER, SONS AND CRISP. Amongst the *Irises* were excellent examples of *I. reticulata*, *I. sind-pers*, *I. Sindjarensis* and *I. persica*. The last-named was particularly charming; the contrast between the deep velvety blue lip and the rich orange central marking is most effective (Silver Flora Medal).

Many good varieties of *Polyanthus* were shown by Mr. W. MILLER, who also staged various *Daffodils*, *Grape Hyacinths* and *Snowdrops*, while the Misses HOKKINS had a little rockery suitably planted (Bronze Flora Medal).

Chief amongst the plants shown by Messrs. RARR AND SON were many Christmas Roses and the dainty little hardy *Cyclamen*, such as *C. ibericum roseum* and *C. i. rubrum*. Along the back there were many vases of *Narcissus Grand Soleil d'Or* of very rich colour (Bronze Flora Medal).

*Eucalyptus Gunnii*, as small plants, was again shown by Messrs. WM. CURBUSH AND SON, who also had *Sarcococca ruscifolia*, a lowly shrub which thrives under shade, bearing both flowers and last year's berries (Silver Banksian Medal).

Mr. G. REUTHE again showed various Conifers and alpine plants with little bushes of *Correa cardinalis* bearing its bright little cylindrical flowers (Silver Banksian Medal).

In the Orchid Annex Messrs. SEGERS BROS., LTD., wholesale growers, set up an exhibit of *Tulips*. These had apparently been brought from

Holland and presented a bright and fresh appearance. The double-flowered varieties included Mr. Van der Hoei (yellow) and El Toreador (crimson and fawn), while amongst the singles were Lenôte (a good pink Darwin that forces well), McKinley (carmine and orange) and Victoire d'Olivierre (a darker Bartigon), which may be forced into bloom three weeks earlier than that variety.

## Narcissus and Tulip Committee.

*Present*: Messrs. E. A. Bowles (in the chair), W. R. Dykes, J. W. Jones, G. Churcher, F. Herbert Chapman, George Monro, W. B. Cranfield, G. Reuthe, Arthur R. Goodwin, Peter R. Barr and Charles H. Curtis (hon. sec.).

The Committee met for the first time this season, and the only plant before it was *Narcissus St. Valentine*, an early yellow-flowered *Cyclamineus* hybrid of *Barrii* form.

## Orchid Committee.

*Present*: Frederick J. Hanbury, Esq. (in the chair), Messrs. Jas. O'Brien (hon. secretary), Gurney Wilson, J. Wilson Potter, Stuart H. Low, E. R. Ashton, T. Armstrong, A. McBean, W. J. Kaye, H. T. Pitt, J. T. Barker, J. E. Shill, Fred. K. Sander, H. G. Alexander, Chas. H. Curtis, S. W. Flory, Arthur Dye, W. H. White, C. J. Lucas and R. Brooman White.

## AWARDS.

## FIRST-CLASS CERTIFICATE.

*Miltonia Lord Lambourne*, from Messrs. CHARLESWORTH AND CO., a marvellous hybrid of which the derivation is not recorded, but the fact is clear that nothing equal to it in colour, form or floral beauty has ever been shown. The probability is that it is a further development of Messrs. Charlesworth's *M. Venus* (*Phalaenopsis* × *vexillaria*), the model shape of the flowers giving strong suggestion of that showy hybrid.

The sepals are white, with the inner two-thirds bright violet colour; the petals are broad and coloured reddish-violet. The lip is broad and almost circular in outline, the basal mask being of thick, radiating lines of violet-crimson, fringed by violet, the broad margin being white. It is certainly one of the finest hybrids raised and well worthy of the honourable name bestowed on it. The award of a Silver-Gilt Flora Medal was also made to this superb novelty.

## AWARD OF MERIT.

*Odontida Cora* (*Oda. Coronation* × *Odm. eximium*), from Messrs. CHARLESWORTH AND CO. The large, finely-formed flowers are reddish-purple with some white at the edges and tips of the segments. The lip is white, with ruby blotch in front of the yellow crest.

## GROUPS.

BARON BRUNO SCHRÖDER, The Dell Park, Englefield Green (gr. Mr. J. E. Shill), was awarded a Silver-Gilt Lindley Medal, as a mark of appreciation of his charming group, and the high state of excellence attained by his gardener in the matter of fine cultivation, every plant being a superb specimen, in itself, unsurpassable in its class. The arrangement of the group added to the attraction of the fine plants which were set up with very graceful foliage plants. About twenty grand specimens of *Cymbidium Panvelsii* in many varieties, with their arching spikes of from twenty to forty flowers each, formed the main object, and beneath these were arranged a fine lot of *Calanthe* Baron Schröder, the largest and best *Calanthe*, both the light and the dark forms being included. *Laelio-Cattleya Schröderae* of fine varieties, a large and finely-formed *Cattleya Trianae* and others were included in the collection.

A Silver Flora Medal was awarded to Messrs. SANDER, St. Albans, for an excellent group of *Cymbidium Alexanderi* Gottianum, Yellow Hammer, Martin, and others in fine variety, arranged with *Odontoglossum*, *Dendrobium*, and *Cypripedium*, the last-named including good *C. Eurybiades* and *C. Charlotte Dillon*.

MESSRS. FLORY AND BLACK, Slough, were awarded a Silver Banksian Medal for a group of hybrids, including *Sophrone-Laelio-Cattleya Langleyensis*, *Sophrone-Laelio Nerissa*, two fine forms

of *Laelio-Cattleya* William Pitt, and the white *Cattleya* Brenda.

#### OTHER EXHIBITS.

Lt.-Col. Sir GEO. L. HOLFORD, K.C.V.O., Westonbirt, Tetbury (gr. Mr. H. G. Alexander), showed the pretty little *Sophro-Laelio-Cattleya* Prudence (S.-L. Orpetii × C. Fabia), with four neatly-formed magenta-crimson coloured flowers.

Messrs. J. and A. McBEAN, Cooksbridge, staged a selection of showy hybrids, including *Sophro-Laelio-Cattleya* Marathon, the white *Brasso-Cattleya* Bianca, *Laelio-Cattleya* Eunice alba, *Cattleya* Eunice alba, and yellow *Cypripediums*.

Messrs. R. F. FELTON AND SON, Hanover Square, florists, arranged a very pretty stand of *Cymbidiums* and *Odontoglossums* overhanging their exhibit of fruits from South Africa.

Messrs. CHARLESWORTH AND Co. exhibited a fine yellow and white *Odontoglossum Wilckeanum aureum*.

#### Fruit and Vegetable Committee.

Present: Messrs. C. G. A. Nix (in the chair), E. A. Bunyard, W. Poupart, P. C. M. Veitch, H. S. Rivers, Geo. F. Tinley, P. D. Tuckett, A. L. Smith, Ed. Beckett, S. B. Dicks, G. Reynold, T. Pateman, E. Neal, W. J. Jefferies, E. A. Merryweather, E. Harriss, A. Metcalfe, J. C. Allgrove, W. H. Divers, G. Berry, S. T. Wright and A. Bullock.

#### AWARD OF MERIT.

*Orange Seedling Washington Navel*.—This is a large-fruited variety with a somewhat rough skin of a pale yellow colour and with, in most cases, the characteristic "navel" end. The flesh is exceedingly juicy and of excellent flavour; the foliage is large and of deep lustrous green colour, paler on the under surface. Trees of this variety grown in pots were included in a collection referred to below. Shown by Messrs. T. S. RIVERS AND SON.

#### GROUPS.

A collection of *Citrus* fruits shown by Messrs. T. S. RIVERS AND SON was awarded a Silver-Gilt Hogg Memorial Medal. The collection made a very bright and attractive feature in the hall and the large size and generally fine appearance of these home-grown Oranges was a revelation to many visitors, and especially the profusion in which they were shown. Some were very bulky trees in large tubs and there were also smaller plants in pots more suitable for decorative purposes indoors. All bore heavy crops, the most notable varieties being St. Michael, or Long Orange; Egg Orange, Nonpareil, St. Michaels and the Boscellio Orange. *Citrus corniculata* and the Myrtle-leaved Orange represented distinct forms, and there was also the hardy *Citrus trifoliata* (syn *Aegle sepiaria*), which is used in the south-west of England as a hedge plant and is said to survive as much as 30° or 40° of frost. American raisers have crossed this plant with several of the sweet Oranges in order to obtain a hardy strain, and Messrs. RIVERS showed two of these hybrids; one named Rusk Citrange had home fruits with them, and these are like small Tangerines, but with a very disagreeable flavour.

SIR MONTAGUE TURNER, Bedford, Havering, Romford (gr. Mr. A. Barrett), showed a collection of 48 varieties of Apples, which, considering the late season, were in remarkably fine condition. Amongst the more notable dishes were those of Scarlet Pearmain, Sure Crop, Cox's Orange Pippin, Cornish Gilliflower, Allington Pippin, Melon Apple, Ribston Pippin, Christmas Pearmain, Annie Elizabeth, Margil, Hornmead's Pearmain, Bedford's Seedling, and Scarlet Pearmain (Silver Knightian Medal).

Messrs. SUTTON AND SONS showed some excellent vegetables in a group that was deserving of praise for its arrangement. In the centre was a large batch of variegated Kales and on stands and baskets were Tender and True and Hollow Crown Parsnips; Prize Taker Leeks, Improved Reading and Brown Globe Onions, excellent Chicory, Scorzonera, Seakale and Salsafy, Improved Red Intermediate Carrots, Artichokes, Potatoes and fine heads of Extra Curled Scotch Kale (Silver Banksian Medal).

#### Annual Meeting.

THE Lecture Room was filled with Fellows when Lord Lambourne took the chair at the annual general meeting. In proposing the adoption of the report of the Council, which has been circulated, the President drew special attention to the paragraph on "Bribery and Secret Commissions in Horticulture," saying that he "knew for a fact that commissions are tendered," a state of affairs which, in his opinion, reflects discredit on all concerned. The Council of the R.H.S. was anxious to do all that lay in its power to discountenance such practices, and Lord Lambourne appealed to all Fellows to report any cases that may come to their notice to the proper authority. Home-grown bulbs are again to receive the attention of the Society, and the announcement of a show of dried bulbs next autumn, followed by a display of flowers in 1923, was received with general approval. The work on "Pritzel" was briefly reviewed and it appeared that, up to date, 250,000 cards have been compiled, so that it is hoped to publish the work towards the end of next year. The copyright of the *Botanical Magazine*, which may otherwise have been lost to the country and horticulture generally, has been presented to the Society by a "number of men interested in gardening," so that publication will continue, and it is hoped to issue a complete volume for this year. The alliance with the National Rose Society was commented upon and great expectations raised over the Rose trials which are to be held at Wisley in the near future, which it was confidently hoped would not be adversely affected by soil conditions.

A well-deserved tribute was paid by Lord Lambourne to the public spirit displayed by the members of the various committees who, without recompense, expend much of their time and, in some cases, money in attending the various meetings. Lord Lambourne reminded the meeting that nearly all the members of committees were busy men, and it was always the busy men who found time for such work and whose services were of the greatest value.

Mr. C. A. Nix, who seconded the adoption of the report, explained that his resignation of the post as Treasurer was due to the great increase in the financial work of the Society which, he felt, required the attention of a more experienced man than himself, and this the Society had found in Mr. C. T. Musgrave. Referring to the balance-sheet Mr. Nix explained that the new item connected with insurance related to the large shows which the Council felt, in view of the large attendances, should be safeguarded from loss which might occur through bad weather. He felt that, generally, 1921 had been a good year for the Society, and he was much more optimistic than he was a twelvemonth ago.

The only comments on the report were by Mr. Bickerton, who suggested that the Council consider providing easier means of reaching Wisley: that a gallery at the Hall would ease the congestion, and that attention should be paid to "correlated science." In reply, Lord Lambourne said that the matter of facilities for reaching Wisley were under consideration, and in the meantime he reminded the meeting that a London General Omnibus ran from Weybridge station, and by it Fellows could travel to a point quite near to the Society's gardens. The provision of a gallery was debarred by the L.C.C. regulations. As to correlated science Lord Lambourne frankly stated he was not sure he understood what was meant, but he was sure it would receive due attention from the Council!

In the absence of further nominations the officers and Council as published were declared duly elected.

The most interesting ceremony was the presentation of five Victoria Medals of Honour. The recipients were Lord Lambourne, Messrs. W. A. Binley, William Poupart, John Fraser and the Rev. Arthur Boscawen. Lord Lambourne's medal was presented to him by the Rev. W. Wilks amid great applause. On behalf of Messrs. Dobbie and Co., Mr. W. Cuthbertson received the Lawrence Medal, which was awarded for their display of Tulips at the Hall on May 10 and 11 of last year.

#### Obituary.

**John Smith.**—An interesting personality has been lost to horticulture by the death of Mr. John Smith, who laid out the Comely Bank Cemetery, Edinburgh, and acted as superintendent of it for twenty-seven years. He had long passed the allotted span of life, but remained mentally alert to the end, and died after a very brief illness. A native of Dun-glass, Mr. J. Smith gained experience of gardening in early life at various English and Scottish gardens. He was outside foreman at Shrublands, Ipswich, in the days when it was the correct thing for foremen at that famous establishment to wear top hats. While in these gardens one of his colleagues was the late Mr. Donald Matheson, subsequently of Meikleour Gardens, Perthshire, and the father of the present general manager of the Caledonian Railway Company. For nine years Mr. J. Smith had charge of extensive gardens in Florence, where he acquired a wide knowledge of the Italian language. On his return from Italy he went to Lewis Castle, Stornoway, and subsequently to Edinburgh. A clever gardener and organiser, Mr. J. Smith was also a keen angler.

#### ANSWERS TO CORRESPONDENTS.

**HAWTHORN DISEASED:** C. W. The trouble is apparently caused by one of the Rose cankers, but the material you sent was insufficient for a proper diagnosis.

**NAMES AND ADDRESSES:** T. *Sainte-Mesem*. The following are the names and addresses you require: Messrs. Stredwick, St. Leonards, England; Mr. J. T. West, Tower Hill, Brentwood, England; and Messrs. Burrell and Co., Howe House Nurseries, Cambridge, England.

**NAME OF FRUIT:** J. H. C. Broad Eye Pippin.

**NAMES OF PLANTS:** A. N. 1, *Picea sitchensis*; 2, *Abies nobilis*; 3, *A. concolor*; 4, *Cephalotaxus pedunculata*; 5, *Abies grandis*; 6, *Picea Omorica*; 7, *Picea excelsa* var.; 8, *Abies Veitchii*; 9, *Picea Morinda*; 10, *Thuja plicata*; 11, *Cupressus Lawsoniana*; 12, *C. nootkatensis* var. *pendula*; 13, *C. Lawsoniana* var. *inter-texta*; 14, *Pinus inops*; 15, P. Murrayana; 16, P. Pinaster; 17, P. sylvestris; 18, *Arbutus Unedo*.—G. K. P. *Quercus Lucombeana* (Lucombe Oak).

**POTATO SHARPE'S EXPRESS:** B. P. B. There is no evidence of disease in the tubers you sent; they have the appearance of injury by frost, as you suggest.

**SWEET-SCENTED CLIMBERS FOR A PERGOLA:** W. M. B. It is no easy matter to select nine sweet-scented climbers suitable for a pergola. The following plants would be best for your purpose:—*Akebia quinata*, a species with small, claret-purple flowers; *A. lobata*, small, dull purple flowers; *Boussingaultia baselloides*, small white flowers; *Jasminum officinale*, white flowers; *Holboellia latifolia*, flowers purplish green; *Stauntonia hexaphylla*, whitish-green flowers. It is doubtful whether either of the two last-named would flower away from the shelter of a wall. *Chimonanthus fragrans* (Winter Sweet) might be used to cover the pillars of a pergola. There is a choice of Honeysuckles, *Lonicera Caprifolium*, *L. Periclymenum*, of which there are several varieties, such as *serotina*, which flowers until late in the season, and is commonly known as Late Dutch Honeysuckle, while the var. *belgica* is known as Dutch Honeysuckle, a very strong-growing variety; *Clematis paniculata*, white flowers; and *C. calycina*, which is not over-hardy away from a wall. The *Wistarias* are slightly fragrant, especially *W. multijuga*; in any case, they are beautiful plants for a pergola. *Vitis vinifera* (Grape Vine) is fragrant when in flower, as also is *Vitis riparia*.

**The Director of Kew.**

Sir David Prain, whose retirement from the post of Director of the Royal Botanic Gardens is announced to take effect at the end of the present month, has held that office for some seventeen years. His high botanical and administrative attainments, his tact and address in public affairs and his extraordinary devotion to duty have made the period of his Directorship memorable and have assured him of permanent fame. More than this he has achieved, for he has won not only the admiration but also the affection of all who have had the good fortune to be associated with him in public affairs. The general public are probably unaware of the onerous nature of the work of the Director of Kew or of the inadequate provision made by the State for the execution of that work. Lavish in deputing labours to the Director, the State is, we believe, parsimonious in the provision of assistance to the Director in the discharge of his multifarious duties. If this be true, it is a limitation which should immediately be removed, for it is an extravagance which an impoverished State can no longer afford. In spite of restricted means and notwithstanding the difficult period of the war, Sir David has sustained and enhanced the prestige of Kew. In numberless ways he has helped the various Government Departments, —Colonial Office, Foreign Office, Ministry of Agriculture; and his wise counsel, exquisite tact, unflinching firmness and courtesy have distinguished him as a great public servant. Sir David's training combined with his natural gifts made his success at Kew certain. Educated in a parish school in Scotland and in the Grammar School and University of Aberdeen, he subsequently studied medicine at Aberdeen and Edinburgh and, in 1884, entered the Indian Medical

Service. Within two or three years of his taking up these duties, Sir David became Curator of the Herbarium and Library of the Royal Botanic Gardens, Calcutta. In this post he remained for eleven or twelve years until, in 1888, he succeeded Sir George King as Superintendent and Director of the Botanical Survey of India, which offices he held until his appointment to Kew in 1905. During his career in India honours and offices were showered upon him. Neither could disturb the natural imperturbability of the man nor could the labours involved by multitudinous duties exceed his wonderful powers of work. His publications are numerous and important, and in preparing for them, Sir David Prain worked hard and travelled much, visiting many parts of India, Assam, Tibet, Burma, as well as the Andaman and Nicobar Isles. It is an unfortunate coincidence that three such distinguished and experienced men as Sir David Prain, Sir I. Bayley Balfour and Sir Frederick Moore are retiring from their several posts—at Kew, Edinburgh and Glasnevin—at about the same time. Their ripe experience and mature wisdom were never more needed than at the present time, for economy—which we all recognise as necessary—is likely to affect all these gardens adversely and must make the task of their successors, which in no case could be easy, even harder than it might otherwise have been. As announced in these pages, Sir David (whose portrait we have much pleasure in reproducing on page 86), will be succeeded by Mr. A. W. Hill, who, as Assistant Director, has had a long experience of Kew. In assuming his new and important office, Mr. A. W. Hill will have the good wishes of all horticulturists.

**Royal Horticultural Society's Examinations.**—The following dates have been fixed for the R.H.S. examinations this year:—General Examination in Horticulture: Wednesday, March 29; entries close on February 28.—Teachers' Examination in School and Cottage Gardening; Preliminary and Honours' Written Examination, Saturday, April 22.—Honours' Practical Examination at the R.H.S. Gardens, Wisley, Friday, June 23, and possibly also June 22; entries close on March 18.—National Diploma Examinations (for the members of the gardening profession only): Preliminary and Final Written Examinations, Saturday, May 27; Practical Examinations at the R.H.S. Gardens, Wisley; Preliminary, June 27 and 28; final, June 29 and 30; entries close on Saturday, March 4. Syllabuses and entry forms may be obtained from the Secretary, Royal Horticultural Society, Vincent Square, Westminster.

**Honour for Mr. N. E. Brown.**—We are glad to learn that the Captain Scott Memorial Medal has been awarded to Mr. N. E. Brown, A.L.S., in recognition of his work on the South African flora. This award is made by the Council of the South African Biological Society. Mr. Brown's articles on "Mesembryanthemum and Some New Genera Separated from it," now appearing in our columns, are creating widespread interest among lovers of succulent plants, and especially among scientists resident in South Africa.

**New Keeper of the Kew Herbarium.**—Dr. Otto Stapf is shortly retiring from the office of Keeper of the Herbarium at Kew, and will be succeeded by Mr. Arthur Disbrove Cotton. Dr. Stapf joined the herbarium staff at Kew in 1891, and was appointed principal assistant in 1899. He became Keeper of the Herbarium, in succession to Dr. W. Botting Hembley, in 1908. Mr. Cotton was appointed assistant at the Herbarium in 1904, and subsequently became a 1st Class assistant in the Plant Pathology Laboratory. During recent years he has held an important post under the Board of Agriculture in the Department of Plant Pathology at Rothamsted.

**Summer Time.**—A Bill recently introduced in Parliament provides that summer time shall begin on the last Saturday in March (or if that is Easter Eve on the preceding Saturday), and end on the first Sunday in October. The dates have been fixed in agreement with France and Belgium, in order to obviate the confusion that has occurred in previous years in the railway services, owing to summer time being different in these respective countries. It is probable that these dates will be made permanent for summer time in all three countries.

**Gardeners' Royal Benevolent Institution.**—During the year 1921 the Worcester and District Auxiliary contributed the splendid sum of £125 to the Gardeners' Royal Benevolent Institution. Subscriptions amounted to £66 2s. 6d., while £71 6s. 3d. was the sum derived from the opening of Madresfield, Davenham, and Ynys-y-Maengwyn Gardens to the public by the Right Hon. Earl Beauchamp, Dyson Perrins, Esq., and Roger J. Corbett, Esq., respectively. The opening of the Madresfield gardens realised £35 17s. The officers and committee of the Worcester and District Auxiliary are to be congratulated on the success of their work during the past year.

**Flower Shows and the Entertainment Tax.**—The Hornsey Horticultural Society has been successful in obtaining exemption from the entertainment tax in respect of their last two annual exhibitions, for which a demand of £28 12s. 9d. was made by the authorities. A deputation from the committee interviewed the Excise Department, and the Commissioners stated that, whilst as a society they had rendered themselves liable to taxation by holding a concert in connection with their shows, the fact that during the short history of the society they had distributed £590 among local charities was a big recommendation for sympathetic treatment. The Excise Department withdrew their claim for entertainment duty in respect of members' subscriptions in 1920 and 1921, but required duty, amounting to £9 4s., to be paid in respect of the tickets sold but not used for the shows in those years. As regards the future, the Commissioners stated that the inclusion of any music, sports, racing, side shows, and other extraneous attractions would operate as a bar to exemption from entertainment duties.

**Shrewsbury Flower Show.**—As announced in our advertisement columns last week, the exhibition of the Shropshire Horticultural Society will be held on Wednesday and Thursday, August 16 and 17. The schedule has been issued, and includes classes for all kinds of cultivators. The total value of cash prizes offered amounts to £1,200. In addition there are valuable challenge cups offered for Carnations, fruits, formal and informal flower gardens, Roses and rock gardens. Shrewsbury Flower Show has come to be regarded as one of the greatest horticultural events of the year, and we are glad to know that the society has been enabled to re-establish its exhibitions to their pre-war importance, and it is confidently expected that the one of 1922 will be equal in interest and extent to any that have preceded it.

**Flowers in Season.**—Some finely grown and exquisitely coloured Cyclamen have been received from Messrs. Clibrans, Altrincham. The blooms represent this firm's giant-flowered strain, and, among the several varieties submitted, those which most attracted our attention were Rose, rich reddish-rose; Crimson, a deep red shade; Salmon Scarlet and Salmon, both of brilliant colour; a dainty Giant Pink; and the large Giant White. The flowers all show evidence that Messrs. Clibrans are continuing their work of selection in the direction of improving the form and extending the range of colours in this useful winter flower.

**A New Belgian Horticultural Society.**—A society, or club, for garden lovers, has been formed in Brussels under the name of "Le Jardin d'Egrémont" ("The Pleasure Garden"). The organ of the society, also called *Le Jardin d'Egrémont*, is bound up with another monthly journal, that of the *Naturalistes Belges*. It appears to make appeal more especially to amateur gardeners, and an editorial note gives one of its objects as that of "struggling against

the banality, the poverty, even, of too many gardens in Belgium." Four committees have been formed, to take over special branches of the Society's work—Technical, Design, Botanical, and Editorial—the latter being charged with the production of the journal. The first number of the Society's journal is an attractive issue, and the journal should be able to attain in due course a separate and successful existence.

**"Monro" Concert.**—The twenty-third annual concert, conducted by the "Geo. Monro, Ltd.," Concert Committee on behalf of various charities, was held at Queen's Hall, Langham Place, on the 16th inst. A lengthy and excellent programme of about two dozen items was provided, including some very fine music by the band of the Grenadier Guards. There was a large attendance. The floral decorations on the stage were carried out by Messrs. Wills and Segar, while the Daffodils on the tables were given by Messrs. Lowe and Shawyer. These concerts have been the means of rendering a large amount of assistance to various charities, and during the year 1921 the committee made donations of £10 10s. to the Gardeners' Royal Benevolent Institution, £3 3s. to the Royal Gardeners' Orphan Fund, £5 5s. to the Wholesale Fruit and Potato Trades' Benevolent Society, £6 6s. to the Royal Surgical Aid Society, £6 6s. to the Charing Cross Hospital, £3 3s. to St. Dunstan's, £3 3s. to the London and Home Counties Benevolent Fund, and £2 2s. to the Covent Garden Lifeboat Fund.

**Paper as Mulching Material.**—According to the *Agricultural Gazette of New South Wales*, experiments made by the Hawaiian Pineapple Packers' Association show that when paper is used as mulching material Pineapples give greatly increased yields. The paper mulch consists of a strip of paper, in which are cut holes large enough for the Pineapple plants to grow through. It was found that the plants treated in this way grew uniformly larger, greener, and more healthy, and the fruits were also larger. It was claimed that the paper mulch prevented the growth of weeds and the packing of the soil through heavy rains, thus greatly reducing the cost of cultivation. In the association's experiment station the growth of plants provided with the paper mulch was three times greater in weight and much healthier than those on other plots without the paper.

**Cambridge Horticultural Exhibition.**—In connection with the Royal Agricultural Society's show to be held at Cambridge, a horticultural exhibition has been arranged for July 4 to July 7, which will be under the superintendence of Mr. Peter Blair, Trentham, Stoke-on-Trent. An attractive schedule has been provided, and substantial prizes are offered for a group of miscellaneous plants, for Orchids, Delphiniums, Begonias, hardy perennials, Perpetual Carnations, Border Carnations, Sweet Peas, and Roses. In the group class the first prize is £45 and the second prize £40.

**"Garden Hints."**—A number of useful garden hints and reminders is issued in a booklet under this title by the Hummer Fishing and Fish Manure Co., Ltd., Hull, manufacturers of the "Eclipse" fish manure. The publishers ask us to announce that free copies of the booklet will be sent to readers of this journal on their making application to the firm. In these times, when stable and farm-yard manure are scarce and dear, such useful organic manures as the Eclipse fish manure offer excellent substitutes for animal dung, and many growers, professional as well as amateur, are making extended use of them with good results. The book under notice gives the best methods of employing the fertiliser.

**Le Mans International Show.**—It is interesting to record that this show, held last November, has proved to be a great financial success. The total expenditure amounted to about 100,000 francs, and after taking into account the subsidies granted by the State and the municipality there remains a balance on the credit side of the account of about 10,000 francs. This admirable result reflects great honour upon the organising committee and upon the Mayor of

Le Mans and his energetic helper, M. Leloup-Grimou, neither of whom spared themselves to make a success of the show.

**French Chrysanthemum Society.**—This society, like so many others with a small annual subscription, has found that, owing to the higher cost of postage and printing, it can no longer carry on its work under the old subscription of five francs per year. Consequently the annual subscription for this and succeeding years has been raised to eight francs per member. At the present rate of exchange, and considering the advantages the society offers, members resident in the United Kingdom will probably consider it to be one of the cheapest subscriptions in the horticultural world. The Registrar of Novelties, M. Reiser, appeals to raisers to send him their catalogues, so that the catalogue of his society may be kept up to date.

**A Rhubarb Exhibition.**—The ninth annual Rhubarb show of the Leeds and District Market Gardeners' Association will be held at the Griffin Hotel, Leeds, on Saturday, March 4. Prizes are offered in six classes, and include a gold medal for the best six sticks of Victoria

SIR DAVID PRAIN, F.R.S. (SEE P. 85.)

or any other variety over 5 lb. in weight; a silver cup of the value of thirty guineas for the best six sticks of Dawe's Champion, and a silver cup offered by Messrs. Garcia Jacobs and Co. for the best three marketable bunches of Victoria Rhubarb, not to exceed  $\frac{3}{4}$  lb. each. The cups are to be won three times in all before they are the property of any exhibitor. The annual dinner, followed by a smoking concert, will be held on the same occasion. The secretary is Mr. J. R. Groundwell, Scott Hall Gardens, Buslingthorpe, Leeds.

**A Warning.**—Mr. J. Harrison, jun., President of the Horticultural Trades' Association, requests us to draw attention to an instance of disgraceful trading on the part of an unscrupulous Dutch vendor of bulbs. It appears that an English customer, attracted by the low prices quoted, sent the Dutch vendor an order for bulbs, and enclosed a remittance for £1 1s. Although free delivery was promised, the customer had to pay 1s. 6d. on the consignment. Many of the bulbs were small, broken, and mildewed, and some not true to name. The only passable lot (if true) were Pheasant Eye Narcissus. Mr. Harrison points out that, had a British trader supplied such bulbs, the customer could have repudiated the contract and obtained the return of his money through the courts, but there is practically no redress in such a case as this, owing to the difficulty and cost of taking legal

proceedings outside the jurisdiction of the British Courts. Mr. Harrison considers that it is high time the Government took steps to prevent the British public from being fleeced by an unscrupulous type of Dutch trader, and he believes reputable British and Dutch firms alike will desire to see such cases as this exposed.

**Lecture on Potatoes.**—A lecture on "Practical Lessons from the International Potato Conference" will be delivered by Mr. W. Cuthbertson at the Royal Horticultural Society's meeting on Tuesday, February 28, at 3 p.m.

**Ideal Home Exhibition.**—A series of interesting conferences has been arranged by the Garden Cities and Town Planning Association during the *Daily Mail* Ideal Home Exhibition, to be held at Olympia in March. Several of the lectures will be concerned with horticultural and agricultural questions, notably:—Thursday, March 2, Poultry; Friday, March 3, Utility Small Garden; Monday, March 6, Young Farmers' Clubs (British day); Tuesday, March 7, Young Farmers' Clubs (International day); Tuesday and Wednesday, March 14 and 15, Garden Cities and Town Planning; Thursday, March 16, Utility Small Garden; Monday, March 20, Bees; Tuesday, March 21, Poultry; Friday, March 24, Fruit Growing. Among the chairmen who will preside at these conferences are the Minister of Agriculture and Lord Astor, and the speakers are all authorities on their respective subjects. Tickets for any of the conferences may be obtained from the Secretary, Garden Cities and Town Planning Association, 3, Gray's Inn Place, London, W.C.1., and will include free admission to the Exhibition.

**Appointments for the Ensuing Week.**—Tuesday, February 28.—Royal Horticultural Society's Committee meetings; lecture by Mr. W. Cuthbertson, at 3 p.m.; Cardiff Gardeners' Society's meeting. Wednesday, March 1.—Royal Agricultural Society's Council meeting; National Viola and Pansy Society's meeting. Thursday, March 2.—Manchester and North of England Orchid Society's meeting; Linnean Society's meeting, at 5 p.m.; Wargrave and District Gardeners' Society's meeting.

**"Gardeners' Chronicle" Seventy-five Years Ago.**—*The Marqill Apple.* The origin of this favourite Apple has not been clearly traced; but it is supposed to be English. It has been recognised in no foreign collection, excepting in some in which it has been introduced by its English name. Rogers, in his *Fruit Cultivator*, 1834, states that he has known it for seventy years, it being then in repute as a dessert fruit. The first tree of it he saw was an espalier in the Sheen Garden, planted by Sir William Temple. It deserves notice on account of its very dwarf habit, rendering it most eligible for borders, or other situations where large trees would be objectionable; for its constant and abundant bearing, hence its synonym of *Never-fail*; and, finally, for its close approximation in point of flavour to the Ribston Pippin. The flesh is firm-juicy, sugary and rich, with a Ribston Pippin flavour, but more perfumed. In perfection from November till February. The tree is dwarf, but healthy, and so productive that attention is necessary to prevent it from over-bearing itself. Shoots purplish-brown, sprinkled with minute pale dots. Leaves small, ovately lanceolate, partially folded, regularly serrated; petioles long, slender, downy; stipules lanceolate, an inch or more in length. Flowers middle-sized; petals longish ovate, somewhat cordate at the base. In pruning this variety, instead of only fruit-spurs, a sprinkling of young shoots should be encouraged, by judicious shortening at the winter pruning, and the spurs should be individually thinned. Sometimes the entire cluster may be dispensed with, but in this case the cut should not be quite close to the branch, for at the base of the spur latent buds generally exist to form a fresh succession. *R. T., Gard. Chron., Feb. 20, 1847.*

## NOTES FROM KEW.

## THE WILD CHINESE PRIMROSE.

ONE of the most interesting subjects in flower in the Conservatory (No. 4 Greenhouse) at the present time is a group of some fifty plants of *Primula sinensis*, the wild Chinese Primrose. They are the progeny of plants raised from seeds collected by Mr. E. H. Wilson. The plant was first introduced in 1820, and a figure of it appears in the *Botanical Magazine*, tab. 2564. The plant figured has purplish-crimson blossoms, but those flowering at Kew are a dainty shade of pale lilac. One item in the *Bot. Mag.* description is very interesting, because it still holds good of the species to-day, i.e., "it is generally considered very shy of producing seeds." Persistent pollination is necessary to obtain any seeds at all, but, fortunately, the plants are perennial.

## RHODODENDRON HIPPOPHAEOIDES.

Growing in its habitat at from about 10,000 feet to 14,000 feet elevation, this is one of the hardiest and most distinct of the newer Chinese Rhododendrons. It is a much branched, small shrub up to 4 or 5 feet high, with small somewhat hoary leaves, hence the name *hippophaeoides*. The flowers are borne in a terminal inflorescence of six or seven blooms in a crowded, head-like umbel. Plants raised from seeds vary very considerably in the shade of colour, which includes lavender blue, blue purple, pale purplish rose, and rosy lilac.

*R. hippophaeoides* has been described as a tall-growing *R. intricatum*. In addition to its value in the rock garden, the subject of this note should find a place in groups along the front of the shrubbery border, whilst for lawn beds it will be a delightful companion plant to the popular *R. racemosum*. It is readily increased by seeds and cuttings.

*R. hippophaeoides* was collected by Mr. George Forrest in several localities of Yunnan during 1913-14. His numbers include 10,333 F. (open situations, alpine shrub), 11487 F., 12461 F. (open marshy meadows), 12562 F. and 12633 F. Mr. Kingdon Ward also collected this species in Yunnan (269 B., K.W.) in May 1913.

## PYRACANTHA CRENULATA VAR. YUNNANENSIS.

In some respects, this Chinese *Pyracantha* is proving one of the most valuable and distinct of the family. Now, during the second half of February, it is the only one adorned with quantities of shining, light red fruits. Rather smaller than the popular variety *Lalandei*, the fruits ripen later than those of that form and also those of *P. Gibbsii*, a closely-allied species, from which it also differs in the coarsely crenate, spatulate leaves. It was first introduced from Yunnan by Mr. R. P. Ducloux, in 1906.

## THE ALPINE GARDEN.

## NIEREMBERGIA RIVULARIS.

A good plant of *Nierenbergia rivularis* is a beautiful object in the garden; its cup-like blooms of pearly white are set above the heart-shaped, dark green leaves. It is one of the most lovely of dwarf plants, and where it is happy makes a spreading carpet of growth. Its habitat is the River Plate, whence we have but a few flowers which are truly hardy; there it grows on the muddy river banks. The ideal conditions with us would almost appear to be a rich, sloping bank facing south, with water flowing underneath, so as to be within reach of the roots. These conditions are not easy to secure, especially as a drier medium in winter is advisable. The finest plants I have ever seen were grown in pots and pans set in zinc pails of water, and standing on inverted pots, the water being only at such a level that the base of the pots was immersed about a couple of inches in the water. In late autumn the pots were removed from the pails and placed in a frame for the winter, being brought out again in the spring and subjected to the same treatment as before. Some are fortunate enough to find *N. rivularis* do well on the level in the ordinary soil of their gardens. *S. Arnott.*

## TREES AND SHRUBS.

## PYRUS LATIFOLIA.

THE above tree is generally known as the Service Tree of Fontainebleau from the fact that it was first found in the Forest of Fontainebleau, in France. It is the most common form in private gardens, but might be more often planted than it is, for it is very handsome in fruit, and seems to bear more regularly than *P. Aria*. The fruits are large, abundant, and orange-coloured when mature. A tree I had under observation for the past two years bore down the branches with the weight of fruit. The tree is regarded as a hybrid between *P. Aria* and *P. torminalis*, yet the seeds are fertile and come true to the parent, for I have seen a self-sown tree in fruit and also much younger seedlings. The tree is somewhat variable, and a form with shorter, broader leaves grows wild in the west of England. Indeed, there are several forms, but I refer to that with the largest and broadest leaves, which suggests the supposed

flourish anywhere in our islands, given reasonable shelter and a soil devoid of lime. What would the Rhododendron Dell at Kew, which affords delight annually to tens of thousands, be if none but natural species were grown there?

It is quite true, as Mr. Mager has stated, that there are very many places in our country where the choicer species might be grown successfully, and are not; but he is the last person who should disparage hybrids, forasmuch as, if the crossing of natural species be a crime, he himself is deeply dyed in guilt, being the fabricator of a whole crowd of Asiatic cross-breeds!

There is a purpose, too, to which those who prize and can grow the tenderer species can put the showy hybrids. Suppose it be intended to plant a woodland glade with some of the nobler species — *calophytum*, *Falconeri*, *Griffithianum*, *sino-grande*, or the like—they must be set wide apart, having regard to the dimensions they will one day attain. But it must be many years before they bloom, whereas

FIG. 42.—A SPECIMEN *HYDRANGEA HORTENSIS* IN A TUB PLUNGED IN A LAWN.

parents. From some source or other this has got into Park Place, Henley-on-Thames. The best situation for trees of this class is on the outside of belts or clumps in parks, because they are of moderate height, and fruit best when fully exposed to light and air. On the contrary, they soon get overtopped when surrounded by tall-growing trees. *J. F.*

## RHODODENDRONS.

MR. F. GOMER WATERER's note of warning (p. 70) is a timely one. If, living as I do on the west coast, where most of the Asiatic species introduced in recent years will thrive—*if*, I say, I have ever spoken disrespectfully of hybrids, let me make amends by acknowledging gratefully the splendid results of the work of Mr. Waterer's firm and other skilful and patient cultivators. If it were possible to revisit Great Britain as it was in the eighteenth century, how one would miss the glow and glitter which they have ensured for early summer in thousands of parks and gardens. I confess to sharing Perdita's strong preference for natural species over hybrids, but that should not blind one to the magnificence of the illicit offspring of *Rhododendron arboreum*, *caucasicum*, *Griffithianum*, etc., which will

the hardy hybrids flower freely in their youth, and will not only illumine the glade with colour, but provide shelter for the species that are set there for permanence, and be cut out when these approach maturity. *Herbert Maxwell, Monreith.*

## HYDRANGEAS IN TUBS.

FOR providing floral displays in courtyards, on terraces, and in large bare spaces contiguous to dwellings, tubs and vases filled with various subjects are much used, but of the wide range of plants available for such purposes none is more satisfactory than a large, well-flowered *Hydrangea*, especially where the barrenness of the situation is unduly great. Another position for which such a specimen is supremely suitable is a circumscribed piece of lawn devoid of flower beds. Set in such a spot is the specimen herewith shown (Fig. 42), and it represents one of several so used. The illustration suggests a more natural setting, as distinct from the impression given when *Hydrangeas* are used in association with flagged paving or gravel; moreover, the natural effect is enhanced by the sinking of the tub in the grass. *C. Turner, Amphill Park Gardens*

## The Week's Work.

### THE ORCHID HOUSES.

By J. T. BARBER, Gardener to His Grace the Duke of Marlborough, K.G., Blenheim Palace, Woodstock, Oxon.

**Vanda, Aërides, and Saccolabium.**—Although these old-world Orchids are not seen in many collections at the present time, they are worthy of cultivation, for when in bloom they are delightful objects. Those showing signs of renewed root action may be given attention in such matters as repotting or resurfacing the compost. I do not advocate resurfacing Orchids as a rule, but in repotting these plants there is a danger of breaking many of the thick, fleshy roots when turning the plants out of their receptacles. In the case of well-rooted, healthy specimens it is desirable to renew the compost on the surface after the long resting season. Care should be taken that the drainage is perfect. Plants that have become leggy through the loss of their lower leaves should be reduced by cutting away a portion of the stem. This shortening must be governed by the condition of the roots; for it is not desirable to remove them all. The growths should be fastened securely to neat stakes, sufficiently strong to hold them in position. A suitable compost consists of clean, broken crocks, and live Sphagnum-moss, pressed moderately firmly, for unless the compost is made firm the moss will not grow satisfactorily, and the plants will not thrive. The majority of these plants do best grown in the warmest house, preferably standing on a damp base. *Vanda tricolor*, *V. suavis*, *Aërides crispum*, *A. crassifolium*, and *A. Warneri* do better in a warm, intermediate temperature.

**Masdevallia.**—Plants that are in need of fresh rooting material may at this season receive attention in this respect. Any of the stronger growing species such as *M. Harryana* and *M. ignea*, that did not receive attention in the autumn may now be dealt with. The strong growing members are best grown in pots; the smaller varieties in shallow pans, suspended well up to the roof-glass. Equal parts peat, Polypodium and *Osmunda* fibres, and Sphagnum-moss, with some broken leaves add form a suitable rooting medium. *M. tovarensis*, with others of the same nature, are amongst those requiring attention at this season, just as they commence to grow. As the roots are incapable of pushing through hard masses of material, the plants should not be potted too firmly. They are best grown at the warmer end of a cool house at all seasons.

### THE KITCHEN GARDEN.

By JAMES E. HATHAWAY, Gardener to JOHN BRENNAN, Esq., Balderby Park, Thirsk, Yorkshire.

**Horse Radish.**—This useful vegetable does not receive nearly the attention it should, for it is usually planted in some out-of-the-way corner and practically left to take care of itself. The same ground may be continually used for this crop, but it is best to take up half the bed every year, store the thick roots, and select long, straight pieces for replanting. The longer the cuttings are the better will the results be. The ground should be trenched and enriched with well-rotted manure. If of a heavy texture, add such materials as mortar rubble and wood ash to lighten it. Holes should be made 1 ft. apart, and the sets placed in them, with the top end at least 4 in. above the surface.

**Chinese Artichokes.**—These tubers should now be lifted and stored if this has not been done already, otherwise they will begin to grow again. New beds should be made on ground that has been dug deeply or trenched; the plants do best in open, sandy land. Plant in rows made 18 in. apart and set the tubers 10 in. distant in the

rows. The quickest way of planting is to rake the ground over and insert the sets with a dibbler, about 3 in. deep.

**Herbs.**—Perennial herbs, such as Mint, Sage and Thyme should be lifted, divided and replanted. A border facing west is best suited for these plants. The ground should be trenched and well manured; heavy land should be lightened by adding wood ash, lime rubble, sand and other material of a gritty nature. Mint, and especially on heavy land, benefits greatly by such materials.

**Cucumbers.**—Plants raised from seed, as previously advised, are ready for planting out. A hotbed should be made of litter and leaves, and the materials allowed to ferment for a week. The ventilators should be opened sufficiently to allow the rank gases of fermentation to escape. A mixture of good loam, leaf-mould, horse-droppings, wood ash, and mortar rubble forms a suitable rooting medium, and should be placed in mounds 3 to 4 ft. apart, according to the height of the house. The soil should be thoroughly warm before the Cucumbers are planted. Each plant should be carefully staked and tied to the supports. It is not advisable to tie the shoots to the wires for a few days until the bed has finished sinking. A temperature of 70° should be maintained at night; but if the weather is severe 65° will be sufficient, with a day temperature of 75° to 85°, according to the weather. Plenty of atmospheric moisture must be maintained, or red spider will soon make its appearance.

### PLANTS UNDER GLASS.

By T. PATRMAN, Gardener to Sir C. NALL-CAIN, Bart The Node, Codicote, Welwyn, Hertfordshire.

**Seed Sowing.**—Seeds of the following subjects may be sown forthwith: *Gloxinia*, *Streptocarpus*, *Browallia speciosa* major, *Begonia*, *Gesnera*, *Saintpaulia ionantha*, and amongst foliage plants *Asparagus medeoloides* (*Smilax*), *Asparagus plumosus*, and its variety *nanus*; *A. Sprengeri*, *Grevillea*, *Acacia*, and *Eucalyptus*. The soil for raising seed should be made as light as possible, and the receptacles should be clean and dry before filling them with the soil. For raising small seeds I prefer to use 6-inch pots, with ample drainage, to pans or boxes; in my opinion small seed germinate much better in these pots. For *Gloxinias*, *Begonias*, and all small seeds the pots should be filled with soil and watered through a fine rose several hours before sowing the seed, which should be distributed evenly over the surface without any covering of soil. Place a sheet of glass over the receptacles, and shade from bright sunshine; under these conditions no further watering is required until the seeds have germinated. When moisture is needed, the pots should be held in a vessel containing water. Hard-coated seeds, such as those of *Asparagus* and *Acacia*, will germinate more readily if soaked in warm water for twelve hours or more before sowing.

**Propagating.**—If a suitable house or pit is available where a bottom heat of 70° to 75° may be maintained, cuttings of various subjects will readily take root provided the temperature mentioned is afforded them. The following are all useful for decorative purposes: *Codiaeums* (*Crotons*), *Cordylines*, *Dracaenas*, *Pandanus Veitchii* and *Abutilons*. Low-growing plants, suitable for carpeting and the covering of pots, such as *Pilea muscosa*, *Panicum*, *Selaginella*, and *Tradescantia* may also be propagated. Grow these plants in small pots of varying sizes adaptable for arranging with other flowers.

**Canterbury Bells.**—Seedlings of *Campanula Medium* that were potted on in October may now be brought on steadily in a cool greenhouse. These imposing hardy biennials may be had in flower six weeks or more before those growing in the open without forcing them in the least. *Canterbury Bells* are most beautiful plants for the conservatory, as well as being useful for decorating purposes generally.

### THE FLOWER GARDEN.

By EDWIN BECKETT, Gardener to the Hon. VICEAR GIBBS, Aldenham House, Hertfordshire.

**Frame Plants.**—Keep a close watch on all plants that are being raised in frames for planting in the beds later, and ventilate the frames freely on all suitable days. *Calceolarias* that are being raised in boxes should have the points nipped out, and afterwards potted to encourage the development of side growths to make bushy specimens.

**The Shrubbery.**—The *Witch Hazel* (*Hamamelis*) and *Winter-sweet* (*Chimonanthus fragrans*) have flowered freely during January and early February, the blossoms being of quaint, yet simple, beauty. They are not large, spreading subjects, and may well be planted in tiny groups of shrubs, where they will flower from November to March, according to the weather conditions and situation. Another beautiful, early-flowering shrub, well deserving of extended cultivation, is *Daphne Mezereum*, and its variety *album*. This year the plants are furnished with a considerable number of flower buds, which, at the time of writing, are just beginning to open, and the plants should prove a wonderful sight until such time as the leaf buds begin to unfold. Work in the shrubberies should now be almost completed, though possibly many climbing subjects and climbing *Roses* still require attention. *Clematis Jackmanii*, and similar kinds, should be attended to now, with a view to removing surplus and worn-out shoots. Care should be taken with this work, as the present view is that disease of the hybrid *Clematis* enters the plants through damaged wood. Climbing and rambling *Roses* should have sufficient of the older growths removed from their bases to permit of room for younger and healthier growths, which will furnish the plants with vigorous flowering shoots. When pruned, tie the growths neatly and securely to their supports.

**Antirrhinum.**—This plant probably gains in favour year by year as a bedding and border subject, and there are many charming varieties. Autumn-sown plants may be planted out at the end of the present month if the weather conditions are at all favourable, and, with this object in view, the plants should be carefully hardened off, so that they are in a suitable condition when required.

**Montbretia.**—Every two or three years *Montbretias* should be lifted, and the strongest corms selected to form fresh beds on a new site. The other corms should be discarded as worthless. Three years should be considered the limit for the corms to remain undisturbed by lifting, and thereafter a new position should be selected for them.

### FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

**Strawberries.**—Where the earliest *Strawberry* plants in pots are throwing up their flower stems and young leaves are pushing freely, liquid of a slightly stimulating nature may be given more liberally, especially where the pots are five inches in diameter, and filled with busy roots. Many growers are of the opinion that pot *Strawberries* cannot be over-watered, but this is a mistake, as many plants are completely ruined by becoming water-logged early in the year. Mischief generally proceeds from the opposite cause, and this fact strengthens the belief that even when water is really not wanted, it can do no harm. Experienced growers can tell by the appearance of the plants when the roots need water, which should be given without wetting the crowns. As the plants come into flower they should be placed rather thinly in the lightest part of the house, where fresh air will circulate freely amongst them. In the event of small blooms being numerous, a number of the flowers may be pinched off with great advantage to the others. When the berries are well

set complete the thinning to eight fruits per pot at this early season, and remove the plants to shelves in a vinery or the hottest house at command. Feed the roots freely until the fruits show signs of turning colour, when clear water only should be given, and the supply gradually reduced when the berries are coloured. Succession plants should be placed in light pits, where they can be kept in a temperature of 45° to 50° on mild nights, and a few degrees higher by day, but on no account should they be hurried, therefore admit plenty of air whenever possible without creating cold draughts.

**HARDY FRUIT GARDEN.**

By H. MARSHAM, Gardener to the EARL OF SPRAFFORD, Wrotham Park, Barnet.

**Peaches and Nectarines.**—These trees may be pruned and the branches regulated to form an evenly balanced head. If the branches and young shoots were given attention last summer in the matters of thinning and disbudding, very little pruning will be needed now. The aim of the pruner should be to furnish the tree with young fruiting wood in all parts, and especially near the main stems, so that there will be ample shoots of a suitable type to take the place of any of the older growths that may be removed. The crowding of young shoots should be guarded against, and although thin training is repeatedly advocated by experts, it does not seem at times to be strictly adhered to. Take care to allow ample room in the shreds and ties for the swelling of the wood, and be mindful not to damage any of the bark with a rap from the hammer when driving in the nails. All sturdy, well matured shoots that are needed should be trained in their full length, but those which are long and unripe may be pruned back to triple buds. Do not use more shreds or ties than are absolutely necessary to hold shoots or branches in position, as this is a waste of time and shreds.

**Planting Young Trees.**—In preparing the stations for the reception of the roots of fresh trees, remove the old soil to the depth of 2 feet or a little more. See that the drainage is perfect. Use a rich mixture of fibrous loam, old brick mortar, wood ash, and some well-decayed manure for placing about the roots. It is advisable to first cover the drainage with turves placed grass side downwards to prevent the drainage from getting choked with the finer particles of the fresh compost. In planting, keep the stems a few inches from the wall, and do not bury the roots too deeply, but spread them out evenly. A few good varieties are: Peaches, Hale's Early, Rivers' Early York (a fine Peach), Peregrine, Dymond, Stirling Castle, Noblesse, Barrington, Bellegarde, Violette Hative, and Sea Eagle. Nectarines: Early Rivers, Lord Napier, Elruge, Pineapple, Humboldt and Milton.

**Loganberry.**—The main details to observe in the cultivation of the Loganberry are to train the best of the younger shoots in position, to remove the old growths, feed the roots freely and apply a rich dressing of manure more or less, according to the nature of the soil and the strength of growth made annually. The shoots of the Loganberry are very brittle, and great care must be taken in training them in position.

**HERBACEOUS BORDERS.**

**SOME SUGGESTIONS FOR PLANTING.**

HARDY herbaceous plants are extremely popular, for there is nothing more beautiful and useful than a well arranged border of hardy herbaceous plants pleasingly grouped. Either a long border similar to the one at Hampton Court or a double border separated by a path, as seen at Petworth Park, is a glorious garden feature practically the whole summer and autumn. Colour schemes are often attempted, but these usually end in disappointment, because the plants used do not flower at the same period.

A fine effect may be obtained with Delphiniums, Phloxes and perennial Asters in quanti-

ties, if bold clumps of each are intermixed throughout the whole length of the border. The result will be a beautiful display of Delphiniums in June and early July, and Phloxes at the end of July and August, while the Asters will carry on the display throughout September and October.

Where space permits and arrangements can be made for separate beds, orange-crimson and yellow flowered plants together make a brilliant effect. Plants of *Geum Mrs. Bradshaw*, *Rudbeckia speciosa* (Newmanii), *Montbretias*, red and scarlet *Phloxes*, *Heleniums Riverton Gem* and *Riverton Beauty*; *Solidago Golden Wings*, *Alstroemerias*, *Hemerocallis*, *Kniphofias*, *Lychnis chalcidonica*, *Monarda didyma*, *Rudbeckia Golden Glow*, *Trollius*, *Heuchera sanguinea*, *Centaurea glastifolia*, *C. macrocephala*, *Rudbeckia californica*, and *R. nitida* are all suitable for the purpose.

For a cool, partially shaded border a blending

Spark's Variety; *Boltonia asteroides* and *B. decurrens*. The above-named plants properly arranged in a suitable position will give a charming effect, and will be found a decided change from the ordinary mixed borders. *R. H. Holton, Crawley.*

**MICHAELMAS DAISIES.**

PERENNIAL Asters, or, as they are sometimes termed, Starworts, form splendid border subjects by themselves, the plants ranging in height from 2 feet 6 in. to 6 feet 6 in. I strongly advocate the lifting of the plants and dividing them each year for replanting, and the work should be done now. The plants should be placed on one side whilst the border is being prepared for their further reception—by deep trenching and the incorporation of well-decayed manure—and protected from frost and drying winds by lightly covering them with spent manure, leaf-mould, or fine cinder ash.

FIG. 43.—CAMPANULA CARPATICA IN THE FRONT OF A HERBACEOUS BORDER.

of blue, mauve, pink and purple colours is very delightful. A display of beautiful flowers may be had from May until October with the following selection of plants:—*Lupinus polyphyllus*, *L. roseus*, *Anchusas Opal* and *Dropmore*, *Campanula grandis*, *C. persicifolia*, *C. humosa*, *C. bononiensis*, *C. carpatica* (see Fig. 43), *C. glomerata*; *Delphiniums* in variety; *Dracocephalum speciosum*, *D. virginicum*, *Erigeron saluginosus*, *E. speciosus*, *E. grandiflorus*, *E. g. superbus*, and the varieties *philadelphicus* and *quakeress*; *Eryngium amethystinum*, *E. planum*, *E. Violetta*, *E. Zabellii*; *Galega Hartlandii*, *Irises* in blue and mauve shades; *Linum perenne* and *L. narbonense*, *Phloxes Le Mahdi*, *Iris* and *Widar*; *Nepeta Mussinii*, *Phloxes Elizabeth Campbell*, *Pantheon* and similar shades of pink and mauve; *Polemonium Richardsonii*; *Sidalea Sussex Beauty*, *S. Listeri*, *S. malvaeflora* and *S. Rosy Gem*; *Statice latifolia*; *Veronica longifolia*, *V. subsessilis*, *V. scabiuscula*, *V. spicata*, *V. s. rosea*, and *V. s. Royal Blue*, together with a good selection of Michaelmas Daisies *St. Egwin*, *Pluto*, *Climax*, *Rosy Morn*, *Feltham Blue*, *Lil Fardel*, *Rose Queen*, and others of the sections *Amellus* and *Aeris*; *Aconitum Fischeri*, *A. Napellus*, *A. japonica*, *A. pyramidalis*, and

This method of soil preparation is of great benefit to the plants, and the ground should be allowed to settle before replanting. When the time arrives for doing this, say towards the middle of March, the old stools should be carefully divided, not chopped apart by a spade, as is often so faultily done, and suitable-sized pieces selected for planting, making the roots firm in the soil. Allow a space of 4 feet between the rows, and 3 feet 6 in. between the plants in the rows. Label them carefully at the time of planting. Later, as growth progresses, the plants should have a number of stakes, usually five, inserted close in around them, but spreading out at the top, and to these the growths should be tied as they make progress and need support.

Where it is desired to increase the stock of a certain variety, this may easily be done at the time of lifting, by potting portions of the new growths and allowing them to root in a cold frame, that should be kept close until the plants are well established. Plants of named varieties may also be raised from cuttings made from the young growths, and by this method very strong growing, single-stemmed plants are obtained in the one season. *B. Beckett.*

## MR. REGINALD FARRER'S SECOND EXPLORATION IN ASIA \*

No. 38.—IN CAMP ON THE MOKU-JI.

HOW true it is that one should never judge a plant prematurely, or when one is in a peevish mood oneself. In a late article I turned down with faint praise a pale Sikkimensis Primula of which I managed to find the first opening flowers down on the Chinese side of the Chawchi, at one point only, and there both poor and single-hearted. It was feeble, starved, anaemic—all sorts of bad things. Yet on the Moku-ji this same plant is happy, fat, abundant, waxing proud in enormous tussocks in all damp places, beside rills, and even in the moist cliff-chinks and screes above the torrents. And, in these conditions, it reveals itself as a royalty in the race, no less. Its elegance is inimitable, its profusion of flower-stems beyond praise, and the flowers themselves not only of a fragrance that scents the whole air, but of a moonlit, elfin loveliness that makes me always see them as phantom blossoms in the fields of the dead. They are of a yellow so vanished as to be virtually white under one's eye, and quite white at ten yards distance. The countless delicate bells of them swing and hang with all the demure daintiness of a Sikkimensis. And when the main shoot is over, up from the centre (in the fatter, stouter specimens) rises a hitherto unsuspected second one, from the centre of the umbel.

Associated with it is F.1187, which I sent with comminations last year as the false *Omphalogramma Delavayi*, and have already spoken of this year as such. But I am getting more and more puzzled and unhappy about this, and the relations with F.1053, of which I spoke as the real *Delavayi*. Now, to forewarn all raisers against disappointment, this is the state of the case. On the top of Hpwashi Bum, among the brakes, there was this one unvarying magnificent *Omphalogramma*, with great, fringed flowers of imperial violet and broadly Violet-shaped leaves. But this was never seen elsewhere in bloom, so that the only seed of which we can be absolutely certain is a podful or two at Edinburgh, off these same Hpwashi plants—though, of course, I still hope and believe that my differentiations between this and the impostor will prove to have been sound elsewhere. The impostor is essentially a wet-ground plant, and, like so many others, is much finer and more abundant here than in the southerly ranges, forming very large masses, and often filling a damp, grassy dell with hundreds, if not thousands, of its flowers out at once. And these flowers have, in a very high degree the *Omphalogramma* quality of enlarging after they open. Last year I had no chance of noting this; but now I find that the little pinched star of pale or glowing amethyst develops, ultimately, on a tall scape, to a big fringed blossom, sometimes approaching to the Hpwashi Bum species in size, but never, in millions of examples, showing the smallest tendency to improve on its own dim red-magenta by approaching the Hpwashi Bum plant's sumptuous violet. Of a specific difference I

still remain humbly confident; but what I want to know, and am impatient to hear from Edinburgh, is, which is the real *O. Delavayi*. Considering its wide distribution over these ranges, and its abundance, I should not be surprised to learn that the rightful owner of the name is, after all, F.1187, and that it is Hpwashi Bum's noble F.1053 that is to prove the new species.

But the sordid shades of F.1187 are wiped out by livelier colours on the glades of the Moku-ji. At last I have been blessed with a *Roscoea*. What collector in these countries would be complete without one? Mine, too, is a nice modest one, making no sort of impudent claim to set me on a level with the giants responsible for *R. Humeana* and *R. cauleoides*. Not to put too fine a point upon it, mine is but a secondary plant, more like a big, fat, few-flowered *Orchis mascula* than anything else. If you want to think of it at its best, imagine a stumpy *R. cauleoides* with flowers of rosy purple. In the same key, but paler and prettier, is a *Pleione* with which I am most heartily pleased. A prettier member of its race there never was; and as it abounds all over the damp granitic boulders and mossy rocks at 11,000 feet elevation I have no doubt whatever of its enjoying our own climate if only I can induce it to make the experiment. But the climax in rose-purple comes from a most entirely (by me) unexpected quarter. It is a *Caltha*, a perfectly plain, ordinary King-cup or Marsh-Marigold, that sets the whole fashion of its family at defiance with quite typical ordinary Marsh-Marigold flowers indeed, but of so lively a magenta-rose colour that at first one is always taking them, in the distance, for some large *Primula* of the Lichiangensis persuasion. It is a very fine thing indeed, and bears out my impression as to the extreme localness of this flora's species by seeming only (as yet) to occur on the Moku-ji Pass, and only on the southerly face, even, of that. But here this beautiful paradox is abundant, in all damp, typical King-cup places, which it even shares, to the possible confusion of the seed-collector, with our humble but old and highly valued friend, *Caltha palustris*, itself.

Nor is even this all that greeted my eyes from the camp. By now I really had believed that the great book of *Rhododendron* must certainly be closed for the year. Yet no; the Moku-ji has yet a speciality of its own in the form of yet another species in that curious and very definite group distinguished by particularly brilliant flowers, and by their remarkable corolloid attachment at the base. We have already had F.1024 (1883), F.1669; here is yet another, a low bush with the leaf-reverse either pure white or ashen, and with way bells, more lively in outline than those of F.1669 or F.1683, and in a freely-varying series of flame-velvet tones. *R. haematodes* and *R. flaccigerum* I do not know, but their ally, the true *R. enchroum*, has no cupular base such as distinguishes this closely allied Sino-Burmese association, which seems, therefore, to form a group apart. Their special feature is this corolloid "calyx." This is not really a proper *Rhododendron* calyx at all; when the trumpet falls, the irregularly lobed cup, of similar colour, hangs on for a while, and then comes off in separate tabs, like sepals, on its own account. Traces of this strange additional beauty already begin, as I have pointed out, in *R. semulorum* (F.815), but in the three species of this season it is an unvarying diagnostic feature.

So that, with the glowing crimson-scarlet bushes of the *Rhododendron* to crown the varied scene, there was no reason to accuse my limited prospect from the Moku-ji camp of dullness; nor to quarry material for further raptures out of such smaller fry as a high-alpine *Clematis* trailing big white Maltese crosses over the bushes up above, and arousing false hopes of a long-hoped-for white high-alpine *Maddenii* *Rhododendron* to match *R. sunranubium*, or of a big silver *Edelweiss* abounding all about in masses, which stands out in my mind from all its kin for English gardens on account of its unique preference for damp and even wet places. *Reginald Farrer*.

## AUSTEN ON FRUIT TREES.

*A Treatise of Fruit Trees, etc.*, by R. A. Austen (Oxford, Robinson, 1657, sm. qto., 2nd ed.), contains many interesting matters. In the matter of grafting, like many other old authors, he advises different lengths of graft, according to circumstances, thus: "If the stock be low as near the ground for a standard tree, grafts need be short, three or four buds or but a couple; if for wall trees or a fruit hedge, then long grafts about a quarter of a yard are best."

In budding (p. 51), he states, "cut the bark on both sides of the bud and about a quarter of an inch above and as much below, let that end which is to be downwards be a little sharp that it may more easily go down and throw away the bark on the opposite side of the bud, then with a quill, the one half cut away, a pen of steel (made thin for the purpose, like one half of a goose quill), take off buds and bark, by putting it between the bark and wood; and be sure that the root of the bud be in it, if there be a little hole in the middle of the bud within, then the root is not there, throw away that bud, such will not grow." The interest here centres somewhat on the "steel pen," the introduction of which is often ascribed to a much later date.

In regard to Quinces, we find (p. 60), "Also to inoculate such Quince buds upon old Pear trees, which take better than grafting. But first this must be done, cut off the top or head of a Pear tree (or some of the boughs), and the next summer inoculate the young shoots; I find the buds take well on Pear trees." I have asked many whether they have met with a Pear stock for the Quince, but without any affirmative reply. Austen also grafted the Medlar on the Pear and states that "the fruit will be much better and the trees larger than upon White-thorne."

For manuring fruit trees he endeavoured to get some direct action (p. 71): "So also take a bar of iron (in winter time) and make many holes among their roots and power in Bests blood, washings of beer vessels, fat water or the like; these very much refresh the trees." Canker: "To cure it, cut it out, if it be on the body or great boughs of trees and wash the place with cow dung and urine mixt; and then cover up the place with clay mixed with horse dung, and cut off the small branches that are dead, but withall endeavour to stop the fountain and cause of it (being a sharp and virulent sap) by laying cole ashes, or ashes of burnt wood, nettles, ferns and such like vegetables to the roots, but if the trees grow on gravel ground they will hardly be cured without altering the soil in great measure." The application of dung was in much favour in later times, as in Forsyth's celebrated composition, and besides tending to keep the bark edges moist and protected from the air the bacterial action may have helped to kill off or inhibit the *Nectria*, just as so many saprophytic bacteria are able to kill off pathogenic sorts of man. Such applications are perhaps worthy of renewed trials. Dealing again with budding and grafting, he asks and answers the question, "What flags are best to bind withall. Those flags are best to use for binding grafts and buds inoculated, which are three square of a brown colour, of a middle size; the biggest are too hollow and spongy, the least are too small and weak: they are to be had from the mat makers at all times of the year, or else they may be cut out of the ditches and dried in summer, and laid up to use as occasion is." The question of identification of the "flags" is of interest, and on consideration it seemed likely that they were obtained from the Burr Reed (*Sparganium*). I put the problem of diagnosis before one of our Botany Professors, and he kindly examined a number of possible "flagges," with the result that he also came to the conclusion that they must be *Sparganium*. It may be noted that *Baltet* in *L'Art de Greffer* gives high encomium to this material, second to which comes the leaf of *Typha*. It may well be that he was attracted to it from tradition. Anyhow, it is a good material and common enough in some parts of the country, though I have not yet found it close to Hereford. *H. E. Ditcham*.

\* The previous articles by Mr. Farrer were published in our issues for June 21, June 28, July 12, August 9, August 23, September 6, September 27, October 18, November 1, November 22, and December 6, 1919; January 3, January 17, February 7, February 28, March 20, April 24, May 29, July 10, July 31, September 4, October 2, December 4, 1920; January 1, January 29, February 19, April 2, April 30, June 4, July 9, August 6, September 24, October 22, November 12, December 3, December 17, 1921, and February 11, 1922.

**DEFINITION OF "ISABELLE."**

It is encouraging to find that Dr. Durham thinks the correct use of the word Isabelle is desirable, and that he goes straight to his Littré for the meaning of a French word rather than to a French-English dictionary as recommended by Sir Herbert Maxwell. At the best of times a dictionary is a good servant but a bad master; hence the higher the authority the greater the value of the information. It is fair to presume that Sir Herbert really meant that some French-English dictionaries give dove-coloured as one of the meanings of Isabelle, and if dove-coloured means a brown in any shade or variation, there is an end of this question so far as I am concerned, but according to common usage it does not. Following his advice given, I turned up Boyer's, the first French-English dictionary that I always use for old words, and there read: "Isabelle, a light bay. It is also subs.: *Voilà un bel isabelle*, this is a fine isabella colour." Nothing is said in that definition about doves or the colour of them.

Isabelle is not only a French colour name, but a German one, too, and with the slightest deviation in spelling it is also an English and an Italian word used to denote a colour. What the exact shade of that colour is, or, in fact, any other colour, I venture to say is impossible to define by any art of mere verbal description. Some other more effectual means must be employed, as will be shown later.

But we can arrive at something like a general idea by consulting standard authorities. The invaluable "Larousse," like others, gives us the romantic story of Isabella and her vow, which we may dismiss as a mere fairy tale. Fortunately the authenticity of this story is a thing apart from the definition of the colour, and, true or false, does not affect the question. Larousse tells us that Isabelle is *café au lait* colour—very explicit, no doubt, if one knows precisely what quantity of "lait" is put into the "café."

As we are considering the word as a French one we must go to Littré. He gives a most copious account of it. Dr. Durham has condensed the definition rather severely, or perhaps it would be better to say he has omitted to quote all the most forceful examples of the use of the word, that appear to bear upon the case. A very material omission on Dr. Durham's part is that of Sect. 3. "Isabelle," says Littré, quoting a passage from the memoirs of the great Cardinal de Retz, "is to-day what we call *ventre de biche*." There is not much dove-colour about that. The great French lexicographer evidently paid scant attention to the Ostend siege story, for he dismisses it thus—*rien ne garantit cette historiette*.

Now as an English word. Isabelle can be found in many of our dictionaries, and is entitled to be considered such, particularly when it can be proved historically to have been in use for more than three centuries, as we shall see when we come to deal with another authority. But, firstly, let us turn to Dr. Brewer, who in his *Reader's Handbook* speaks of Isabella or Isabelle in these terms: "A pale brown colour or buff, similar to that of a hare." He, too, relates the story of its origin. The same writer in his *Dictionary of Phrase and Fable* states: "Isabelle—the colour so-called is the yellow of soiled calico. A yellow dun horse is called in France *un cheval isabelle*, or, as we English term it, especially in connection with those horses used to draw the royal carriages in processions, cream-coloured."

Without unduly multiplying examples, Ogilvie and Annandale's *Student's English Dictionary* has this entry: "Isabel, Isabella. French Isabelle said to be fr. for a queen or princess of this name. A pale brownish yellow colour." The popular Nuttall includes it, and states: "Isabel, a brownish yellow colour, so-called from the colour of the linen of Isabella of Spain."

Now comes a very severe blow to the authenticity of the romantic story which is currently supposed to have given rise to the use of the name as a colour. In the *Oxford Dictionary*,

Vol. V., p. 499, there is, in a way similar to that adopted by Littré, not only a definition following each word given, but also examples of its use, with dates and references to the works from which those examples are taken. Quoting from Webster under Isabel, it gives: "Isabel yellow is a brownish-yellow with a shade of brownish red," while Isabella is described as "greyish yellow, light buff." Then follows the oft-repeated story about Isabella's vow. The first example given of the use of this word in English absolutely demolishes the authenticity of its derivation. The siege of Ostend lasted from 1601 to 1604, prior to which latter date the colour name Isabelle is not supposed to have been in existence. Yet it was, notwithstanding. A quotation, dated 1600, shows

In pomology Isabelle or Isabella is probably no longer in use. And yet the great French gardener, La Quintinie, used it to describe the colour of a Pear. In his *Instructions pour les Jardins*, Vol. I., 1700, p. 354, we read: "*La Poire Rousseline . . . son coloris est d'un Isabel fort clair*," and again on p. 356, "*Poire Chat . . . le coloris est d'un Isabel fort clair, et beaucoup plus que l'Isabel ordinaire de Chat brûlé*."

That this term was not unknown in English at that period finds confirmation in London and Wise's translation of La Quintinie's work, *The Complete Gardener*, 1704, where it is used in the form Isabella in both cases. May I be permitted to inquire were these dove-coloured Pears? After all, readers can even now have only a

FIG. 44.—MILTONIA LORD LAMBOURNE. R.H.S. FIRST-CLASS CERTIFICATE AND SILVER-GILT FLORA MEDAL, FEBRUARY 14. SHOWN AND RAISED BY MESSRS. CHARLESWORTH AND CO. (SEE P. 83).

that the term was already in use in English; for in an Inventory of Queen Elizabeth's wardrobe item 505 was "one rounde gowne of Isabella-colour satten . . . set with silver spangles." So much for the romantic story.

Isabelle, in German, means light bay or cream-coloured for a horse. *Isabellen farbe*, a yellow dun, or cream colour.

In Italian, Isabella is also used as a colour name for dun or bay, and in none of these notices can any reference be found to dove-colour, no matter what the compilers of some French-English dictionaries may have added to the old signification. Although Isabella is a Spanish proper name, it is curious that it does not appear to serve the purpose of a colour name in that language, the nearest equivalent being *bayo*,

vague, and each one probably a different, notion of the exact shade of bay, *café au lait*, pale brown, buff, brownish yellow, dun, or cream-colour, that the above-named writers intended to convey by the use or definition of Isabelle. The proper force of words lies not so much in the words or names themselves as in their application and in the ideas that they convey. And this want of correspondence of the colours themselves with their verbal descriptions is the very reason why a standard colour chart for florists and others was devised some years ago by the French Chrysanthemum Society. Let the reader turn to the *Répertoire de Couleurs*, find plate 309, entitled Isabelle, and there he will at once have ocular demonstration of what that colour is in four different tones. C. Harman Payne.

ORCHID NOTES AND GLEANINGS.

CEPHALANTHERA RUBRA (RICH.) IN BRITAIN.

Your valued and able correspondent, Mr. A. D. Webster, recently drew my attention in your pages (p. 10) to that excellent account of West Ross Natural History by Mr. Osgood Mackenzie. He stated that there is a record of the above plant in it, but I think there is no doubt some other species of Orchid was mistaken for this very local plant.

FIG. 45.—CEPHALANTHERA RUBRA.

apparently considered that any narrow-leaved plant with a fibrous root was his longifolia. This led to Haller publishing an elaborate paper on the Orchids professedly to correct his errors. In the later editions of the *Systema* Linnaeus adopted many of Haller's suggestions.

*C. rubra* was first made known as British in 1797, when it was published as *Serapis rubra* in *Sm. Eng. Bot.*, t. 437, having been gathered in "last June on Hampton Common, Gloucestershire, by Mrs. Smith, of Barnham House." In a letter to Sowerby the Rev. W. Lloyd Baker, however, says he found it some

nomenclature, which they have rather confounded than improved."

In more recent times *Cephalanthera rubra*, to use the authentic name as defined by the French botanist Richard, who established the genus *Cephalanthera* as distinct from *Helleborine*, had been recorded from South Somersetshire by Collins in 1835 (a solitary specimen), but no one else has verified it, and I am not aware if anyone has seen the specimen, and certainly no one has recorded it again. Watson (*Top. Bot.*, 386) gives with a query "Hunts., Mr. Woodward." No one else has found it in that county, and the plant was doubtless a form of *Helleborine*. Watson also brackets York Mid-West, of which no trustworthy record exists. We must say the same of the West Ross-shire record. In more recent times my friend Mr. T. W. Attenborough tells me he has an impression of seeing it near Wye, in Kent—a much more likely locality, and Mr. A. D. Webster seems confident he has seen it near High Elms in that county; but I still await a Kentish specimen. Gloucestershire is still the only British county known to produce it.

The *Helleborines* have occasionally red or reddish flowers, and I feel pretty sure that some of the above records refer to these and not to *Cephalanthera*. I may add that the figure in *Eng. Bot.*, t. 437, and the new plate in *Syme's Eng. Bot.*, t. 1483, are, neither of them, good since they show the flower closed, so I send a photograph (Fig. 45) of a specimen I gathered near Stroud some years ago, which may assist in its correct identification, and by drawing attention to the matter may result in its discovery in another county. I should add that the curvature of the stem in the photograph is not natural, but was caused by its being put in a tin to bring home. *G. Claridge Druce, LL.D.*

JEWEL ORCHIDS.

*ANOECTOCHILUS* and the allied genera *Macodes*, *Haemaria*, and *Goodyera* are known as Jewel Orchids, and are grown for their beautifully marked foliage. They are small growing plants, and take up but little space in the plant houses. They may be grown in small pots or planted in a fairly deep Orchid pan, filled half its depth with drainage material. If the latter is chosen, several plants should be plunged in a pan eight or ten inches in diameter and then covered with a bell-glass. The compost for these Orchids should consist of Sphagnum-moss and a little peat fibre, with a few pieces of charcoal intermixed. They should be grown in a shaded, moist part of a warm house. *B.*

There has been great confusion in Britain respecting the above species, and that is in some measure due to the perplexing changes which the name of the plant has undergone. The plant has long been known on the Continent, although Linnaeus is at his very worst in describing the section to which it belongs; indeed, he has jumbled the Marsh, the Red, and the White *Helleborines* together under one species! He

years ago. Smith (*English Flora*, iv., 46, 1824) gives it another name and calls it *Epipactis rubra*, and he uses some words which are quite applicable to-day and may be worth quoting: "Old authors, indeed, are so full of mistakes respecting [the synonyms] that the greatest attention is requisite to understand what they mean, and they often misunderstand each other. Recent writers have not been more happy as to

MESEMBRYANTHEMUM AND SOME NEW GENERA SEPARATED FROM IT.

(Continued from page 80.)

Argyroderma, N.E. Br.

STEMLESS succulent plants. Each plant or growth with two or (when a new pair is forming) four (rarely six) short, thick, ascending-spreading leaves, united for about half their length at the base, flat above, very convex on the back, and sometimes with the dorsal part prolonged beyond the flat face and very obtusely rounded; with or without a faint keel; very firm or hard in substance, with a very smooth white or greenish-white (or rarely rosy-tinted) skin, without dots or markings. Calyx produced above the ovary into a short tube, 6-lobed. Petals numerous, free. Stamens very numerous, erect, arranged in a dense ring at the base of the petals. Stigma sessile on the top of the ovary, circular, entire or faintly crenate. Ovary inferior, 10-24 celled. Capsule 10-24 valved. Seeds numerous in each cell.

This genus is distinguished from all its allies by its sessile entire stigma, and the very smooth white skin of the short broad leaves, the latter characters serving to distinguish these plants at a glance when out of flower. The generic name is derived from the words *argyros*, silver, and *derma*, skin.

Berger associates the type of this genus (*A. testiculare*) with *Mesembryanthemum Bolusii*, but in the nature of the leaves and structure

of the flowers the two plants are entirely different.

The species of this genus are easy to discriminate at sight when seen growing together, yet I find it very difficult to define them in words so that they can be determined from description, especially as I have seen flowers of only two species. They are not difficult to cultivate if properly attended to and not overwatered. Like most of their allies they attempt to grow and flower between October and March, which is their summer season in their native country; during this period the rainfall of that region takes place, so that under cultivation it is necessary to give them just sufficient water to enable them to develop their flowers and new growth during that period. At the same time their roots should be kept fairly warm, for in their native country the ground gets much heated during the day and keeps them from being harmed by the rain. A cold, moist soil does not suit these plants. The following are all the species known to me. For brevity in the synonymy the letter *M* is used to indicate the genus *Mesembryanthemum*.

\* Leaf from nearly as broad as, to broader than long, white, with the edge of the flat face sharp and outlined by a very slender, slightly raised line or ridge that is not cartilaginous.

1. *A. testiculare*, N.E. Br. Plant usually of only a single growth. Leaves with the flat face  $\frac{3}{4}$ -in. long,  $\frac{2}{3}$ - $1\frac{1}{2}$ -in. broad, and  $\frac{1}{4}$ -in. thick, broadly ovate or somewhat oblong, pointed like a Gothic arch or broadly rounded at the apex, with the dorsal part often prolonged beyond that apex. Flower sessile between the leaves, with two bracts under it. Calyx-lobes 2- $3\frac{1}{2}$  lines long, deltoid-ovate, obtuse. Corolla 1-2 in. in diameter; petals numerous in about 4 series, white or whitish. Stamens in a dense ring, with yellow anthers. Top of the ovary flat. Stigma  $1\frac{1}{2}$ -2 lines in diameter, circular or elliptic, concave, entire or faintly crenate. Capsule 6-7 lines in diameter, flattish or very slightly convex on the top, 12-24-valved and 12-24-celled.

*M. testiculare*, Ait. *Hort. Kew*, ed. 1, v. 2, p. 181 (1789); *Haw. Rev.* p. 85.

Var. *luteum*, N.E. Br. Petals bright yellow. *M. testiculare*  $\beta$ , Sims in *Bot. Mag.* t. 1573. *M. octophyllum*, Verlot in *Rev. Hort.* 1869, p. 35, f. 10, copied from *Bot. Mag.* (This is not *M. octophyllum*, Haw., although quoted as such by him, but wrongly.)

Var. *roseum*, N.E. Br. Petals bright magenta-purple. *M. testiculatum*, Jacq. *Fragm.* p. 20, no. 73, t. 12, f. 2. *M. octophyllum* var. *roseum*, *Haw. Rev.* p. 85.

Var. *Pearsonii*, N.E. Br. Flower with a distinct pedicel up to about  $\frac{3}{4}$  in. long. Corolla with the outer petals magenta-purple and the inner ochraceous yellow more or less striped with purple. *M. Pearsonii*, N.E. Br. in *Kew Bull.* 1912, p. 277, and *Bot. Mag.* t. 8463.

A native of Van Rhynsdorp Division; originally introduced by Masson, who discovered it in company with Thunberg, whose type specimen I have seen. This species offers an excellent example of the manner in which some of these plants vary in the colour of their flowers, as stated on p. 290 of vol. LXX. Dr. Rodier Heath has raised from seeds taken out of one capsule some plants with yellowish-white, others with yellow, and others with purple flowers. I now think it probable that the variety *Pearsonii* may be a hybrid between a purple-flowered and a yellow-flowered form. Its flower is exceedingly beautiful.

2. *A. subalbum*, N.E. Br. Plant tufted with age. Leaves with the flat face  $2\frac{1}{2}$ -7 lines long, 4-8 lines broad, and 3-5 lines thick, broadly ovate in outline, obtusely pointed or circularly rounded, the dorsal part not produced beyond the flat face, obtusely rounded, faintly keeled. Flowers not seen. Capsule 4 lines in diameter, convex at the top, 10-valved and 10-celled. *M. subalbum*, N.E. Br. in *Journ. Linn. Soc. Bot.* v. 45, p. 91.

Van Rhynsdorp Division. Near Bakhuis, Pillans, 5476; Hardeveld, Marloth.

A much smaller species than *A. testiculare*, but very similar to seedling specimens of that species. It becomes tufted with age, and has a smaller and more convex capsule than *A. testiculare*. It has not yet flowered with me. *N. E. Brown*.

(To be continued.)

## NURSERY NOTES.

### PROGRESS IN PRIMULAS.

It is practically impossible for anyone who has not visited Messrs. Sutton and Sons' Reading establishment regularly for at least a dozen years in succession to fully appreciate the wonderful progress this firm has made in the development of greenhouse Primulas. If an annual inspection has been made for a period of twenty-five years, then the appreciation becomes all the greater, because memory will call to mind the habit, form and colour of the Primulas of those earlier days, and enable comparisons to be made between them and the delightful varieties now offered by the Reading firm.

These latter provided a feast of floral beauty during January and early February that it is difficult to imagine could be surpassed in any

law. Consequently, scientists are intrigued, and progress in Primulas is as fascinating to them as to the gardener, who is more concerned with the result rather than with the manner and method of its achievement.

So careful are the records kept at Reading that if certain Primulas were lost they could easily be produced again provided the parents survive. A most interesting part of the display at Reading this year consisted of sets of parents and seedlings, the latter in the  $F_1$  and  $F_2$  generations. In certain cases the Mendelian ratio was obviously correct; in others it could not be worked out. Again, the special seedlings and selections which will form the basis of future progress in colour were of immense interest, and, perchance, the results of crossing with mixed pollen not the least so. In some of these seedlings the colours were exquisite, especially those of rich pink, crimson and scarlet shades, whilst the arrangement of the colours—picotee edging, blotching, starring

FIG. 46.—PRIMULA SILVER STAR; A PURE WHITE, EYELESS VARIETY.

other establishment in the United Kingdom. Thirty-five thousand plants, each a model of skilful cultivation, mostly in 48 sized pots, and all massed in distinct varieties, arrest attention by means of their beauty and usefulness for home and conservatory decoration. But the appeal is equally to the mind as to the eye, for this wonderful display is not provided for the pleasure it gives the proprietors and visitors, nor for the opportunity it affords Mr. James of showing what a clever successor he is to Mr. James Martin and Mr. J. McDonald, both of whom took a prominent share in the painstaking work, and made the Reading Primulas progressively beautiful over a long series of years. These thousands of plants are grown to provide seeds for customers.

The scientific work carried out by Messrs. Sutton and Sons among greenhouse Primulas is well known to students of Mendelism, because the children of these highly bred descendants of *Primula sinensis* do not always obey Mendel's

and flaming—in certain seedlings, suggests at once that finality has not been reached, and that if quaint colour combinations are desired by the flower-loving public, Messrs. Sutton and Sons have the material already to hand to meet it.

Regarding the Primulas catalogued by Messrs. Sutton and Sons, it is commonly known that they group themselves naturally into Florists', Giant, and Star varieties. Where all are so fine personal taste must always be the final selecting factor, but for ourselves we find no difficulty in choosing Giant Pink, Giant Royal White and Giant Scarlet in the superb Giant section; Coral Pink, The Duchess, the new Etna, The Czar (violet blue), Crimson King, Reading Scarlet and Royal White among the Florists' group; and Coral Pink, Silver Star (Fig. 46), Ruby Star, and White Star in the Stellata group; but we fail to decide whether Light Blue or Dark Blue is the better of the two blue sorts, so they must have equal praise.

## VEGETABLES.

### MAIN CROP PEAS.

THE period over which seeds of Peas may be sown to obtain pods for successional use is very lengthy as compared with that of most other kitchen garden crops, and may be said to extend from the end of February to June, and even July in some cases.

Whether dwarf, medium, or tall varieties are grown, they require identical treatment as regards the preparation of the ground. Shallow or, as they are sometimes termed, hot soils should be dug as deeply as the nature of the sub-soil will permit, and manure should be freely mixed with both spits. Deeper, naturally retentive soils will grow Peas well without being trenched; in fact, more rows of Peas are spoilt owing to the rooting medium being too retentive of moisture than from any other cause. The roots of culinary Peas are by no means robust, and when they enter a cold, wet sub-soil many of them perish, or become knotted and incapable of performing their functions. Early trenching of the soil may be necessary to ensure the pulverisation of the surface, but if the work is done in fine weather just prior to sowing the seed, and the surface trampled firmly at the time of sowing the seed, the result will be much more satisfactory. In any case trenching alone will not guarantee a healthy growth in very hot weather, and nothing but anticipating dryness at the roots and well moistening the soil to a good depth will prevent a great check being given. Nor do I believe in the plan of digging narrow trenches and filling them with manure. If manure and labour are scarce, then concentrate the former, but not in trenches. Instead of this, double dig the proposed site of the row to a width of 3 ft., and well trample the ground prior to sowing the seed; allow ample space between the rows, which should run north and south. Growing another crop, such as Potatoes, between the rows of Peas, is better than arranging the latter closely together with an idea of economising space.

In any case, the rows should be arranged as far apart as the varieties are known to attain in height. It is not easy to state the exact distances apart at which to sow the seed in the drills, so much depending on the habit of the variety, some branching more strongly than others. Many of the main crop varieties are of spreading habit, and if sown thickly in the rows, the plants produce a light crop, which is soon over. Such sorts should be sown 6 in. apart. The drill should be made fairly wide, and 3 in. or 4 in. deep, and the seed covered with not less than 2 in. of fine mould. Coating the seed with red lead is the surest preventive against mice eating them.

As soon as the plants are through the soil, give them a dusting of newly slaked lime, and afterwards sprinkle each side of the row with soot. These materials will ward off snails and birds, and at the same time act as fertilisers.

Staking requires a little practice to be done well, yet so small an amount of judgment and care is usually bestowed on this work, that before the haulm is half as high as the sticks, it is through on one side and falling over, so that the sticks are of but little use. Small boughs should be placed on each side of the row to support the young plants until the tendrils are strong enough to take hold of the larger stakes. Nor should the final staking be delayed until the plants have fallen about. Better use stakes that are too tall than not tall enough; they need not be very thick, and should not meet at the top, so that there may be plenty of room for the foliage as it grows larger. When staking is finished, fork up the ground on each side of the row, and give another dusting of lime. When the pods commence to swell they will be greatly improved, both in size and fulness, by the application of liquid manure to the roots when the soil is moist and also by thinning the pods and stopping the plant at its growing point as soon as the setting of the pods commences. The rows should also be mulched, where necessary, with manure or other material to check evaporation.

A mixture of one part kainit, two parts nitrate of soda, and four parts superphosphate of lime,

applied at the rate of 6 lb. or 7 lb. to the square rod when the plants are about nine inches high, favours the development of vigorous, healthy growth, which is not very susceptible to attacks by either insect or fungous pests. The mixture should be applied during periods of heavy rain. Those who do not use this special mixture may stimulate the plants with native guano or one of the recognised fertilisers—Thompson's or Clay's, for example. Such stimulants as liquid manure from stables and cowsheds, or that made by immersing soot and manure in tubs or tanks, are also highly beneficial if applied near the roots after the flowers have set; and they greatly assist in improving the plant's growth of both haulm and pods. Soft water, or water which has been exposed to the air for some time, should only be used, as hard, cold, water arrests free growth, and in the case of Peas renders them susceptible to attacks of mildew, which seems impossible to cure when once it has attacked the plants.

There are few vegetables that differ so much constitutionally as the different varieties of Peas, and those only should be grown to any extent which by experience have proved to be best suited for the grower's particular district. In giving a list of the best varieties, I do not for one moment pretend to name those only which are worthy of cultivation, or that will succeed best in every county, but simply those which I have proved to be of exceptional merit, and which seldom fail when properly grown. High quality is, in my opinion, the most essential point in this vegetable, and those enumerated below are some of the finest maincrop varieties:

Selected Duke of Albany, Quite Content (one of the best sorts, and I have never known it to fail), Peerless, Centenary, Perfection, and Alderman. Successional sowings should be made—planting one or two rows at a time about every fortnight up to the middle of June; or the old rule followed of waiting until one sowing is just through the soil before making another may be adopted. *James A. Paier.*

## FRUIT REGISTER.

### THE ORIGIN OF THE PINE STRAWBERRY.

MR. RICHARDSON in his article on the Strawberry (p. 57) speaks of the origin of the Pine Strawberry as being unrecorded. It is, however, very definitely stated by Duchesne in his *Historie Naturelle des Fraisiers* as coming from seeds of the Chili variety as first brought to France and planted at Cherbourg. The following are his exact words:—

*Les graines des Framilles envoyées de Cherbourg en 1760 et Semées, tant dans notre Jardin, qu'à Trianon et au jardin du Roi, y ont produit de véritables Ananas. Nous venons de l'observer dans leurs premières fleurs, qui sont hermaphrodites parfaites. Cela nous apprend l'origine du Fraisier Ananas; et quelle est la dégénération du Framiller en Europe.*

*Fruitilles*, it should be said, was the name given to *Fragaria chiloensis* when first imported into France, from *frutilla*, a Spanish word meaning a little fruit.

This information is to be found at the end of Duchesne's book, in an appendix, which may account for it having been overlooked by Strawberry historians. *E. A. Bunyard, Maidstone.*

### APPLE ST. EDMUND'S RUSSET.

HAVING known and grown this variety of Apple for a number of years I can fully endorse the remarks of your correspondent, Mr. G. M. Taylor, on p. 46.

This Apple was first brought to my notice by my old friend, Mr. H. French, who was at the time in charge of the gardens at Forthampton Court, Tewkesbury, Gloucestershire.

In the autumn of 1914 I procured some espalier trained trees of this variety from Messrs. Wheeler and Sons, Gloucester. These were planted at Moreton House, near Dorchester. The soil in that district is light and sandy, but the trees have never failed to carry a crop of good, clean fruits, which are just the right size for dessert purposes. My employer (who is very keen on a really good Apple) asked me

on one day early in October what kind I was bringing in for dessert at that time. When I told him it was St. Edmund's Russet he remarked: "What a splendid flavour. I wish for nothing better." I always recommend this variety to those contemplating planting Apple trees and should not hesitate to include St. Edmund's Russet in the most select collection. *F. C. Tribble, Stowell Park Gardens, Foss Bridge, Gloucestershire.*

### APPLE ORLEANS REINETTE.

YOUR correspondent, Mr. G. J. Warren, is quite right in his statement (p. 23) that Orleans Reinette has also been known as Court Pendu de Tournai. There seems, however, no evidence to connect it with Tournai. The matter is fully discussed in Leroy's *Dictionnaire de Pomologie*. *E. A. Bunyard.*

### APPLE CALVILLE BLANC.

(See pp. 11, 47.)

CALVILLE, according to Littré, is a masculine substantive (e.g., *voilà du beau Calville*), and means a kind of Apple; he, however, states that some lexicographers make it feminine. The authoritative spellings may be considered to be those of the Soc. Nat. d'Hort. de France and of the Soc. Pomologique de France; the former (*Meilleurs fruits*, etc., 1907) gives the feminine form as a synonym; the latter (*Cat. descript.*, 1906) does not even mention it.

Among synonyms there also appears to be confusion in German, for both Weisser Winter Calvill and Weiss Winter Calville are given. Leroy only gives the feminine form as a synonym; he maintained that the correct spelling should be Calleville, a place name in Normandy, whence he derives the origin of the term; but his spelling does not seem to have met with favour. Some authors, e.g., Mas, give the feminine form.

A similar state of things exists among Pears; for instance, with Doyenné, which is masculine; hence "un doynné d'hiver, du Comice," etc., are correct; but if the full academic or pedantic expression is used, the terms become "une poire de doynné d'hiver, du Comice," etc. *H. E. Durham.*

### APPLE COURT-PENDU-PLAT.

THE name of this Apple appears to have suffered confusion, and what is known in this country under the name is, apparently, the Capendu, or "Court-Pendu rouge," chiefly a cider Apple, which is all that it is fit for, except, perhaps, for drying, when cored and peeled, to make "Normandy pippins." The French authoritative societies make the term the proper synonym of the Court-Pendu gris, which is described as having little, if any, red about it. *H. E. Durham.*

### RUSSET APPLES.

THERE is no doubt, as *Pomona* mentions in the issue of this journal for Dec. 31 (p. 337), that the russet varieties include some of the best-flavoured of our Apples, whilst in several cases the habit of the tree and the cropping qualities are all that could be desired. This being so, it is a pity that the public are not prepared to pay a fair price for russet Apples, so that they might be worth growing for market. It is the old story of bright colour being worth more in a market Apple than flavour. We are said to be badly in need of a good variety to follow Cox's Orange Pippin, and we have it in several of the russets, if only the public would forgive the dull appearance. Curiously enough, the Canadian Golden Russet sells freely enough; but the fact remains that attempts to market English russets are not encouraging.

I am thinking particularly of Duke of Devonshire, which is not included in *Pomona's* list, and is possibly not a true russet. A fine tree of this variety in my garden gives me the nicest Apples I can find to eat at Christmas and after. It crops well and regularly, makes a big tree, and is perfectly healthy. Nothing better for market culture could be desired, if only one could be sure that the fruit would realise the price which its high quality deserves. *Market Grower.*

## HOME CORRESPONDENCE.

[The Editors do not hold themselves responsible for the opinions expressed by correspondents.]

**Gloxinias.**—All plant-lovers will have read with interest the very instructive articles by Mr. John Heal on the Gloxinia in your issue of January 7. The Gloxinia deserves all the praise he gives it as a decorative plant, and it is a pity that the plant cannot (owing to its requiring a relatively high temperature and moist atmosphere) become a plant "for the million." As an ornament for the conservatory its weak point is its foliage, which is in most cases not very attractive and easily broken or injured. With a view to remedying this defect, Mr. Ernst Benary, of Erfurt, some years before the war, did a good deal of hybridising between the finest types of Gloxinia and a species of *Sinningia* (or *Gloxinia*) introduced from Brazil, the specific name of which has escaped me. The flowers of this species were small and drooping, but the foliage was handsome, being of a deep purple with silvery veins. The object was to combine the best Gloxinia flowers with ornamental and stronger (tougher) foliage. The seedlings from these crosses gave all sorts of results, mostly inferior, but amongst them were some good plants, notably one with erect, bright purple flowers and handsome, dark, silver-veined leaves, which would withstand a considerable amount of handling. I do not know what further measure of success Mr. Benary achieved, but I see he offers seed of these hybrids in this year's catalogue as "Gloxinia (or *Sinningia*) Regina hybrids or Imperial Gloxinia," and lovers of this beautiful genus would do well to give them a trial. *L. S. A., Richmond.*

**Begonia martiana gracilis as a Bedding Plant.**

—Mr. G. Horne, on p. 56, having referred to the bulbils of this plant, recommends it with great justification for the decoration of the conservatory. The bulbils of this species I had quite forgotten when I replied to the inquiry of *Coombe*. There is no other *Begonia* that produces so many bulbils, but they are small, while those of *B. Evansiana* are large and comparatively few. To this I need not refer, but as an ornamental plant I should point out that it is a lovely and uncommon-looking subject for a bed. It has the disadvantage, however, of not being propagated easily, like the majority of ordinary bedding plants. There was a very charming bed of it one year in the Cambridge Botanic Garden, and there may not be great difficulty with it if proper attention can be devoted to it. *Begonia martiana*, according to the *Kew Handlist* of Tender Dicotyledons, is a synonym of *B. gracilis*. *B. martiana gracilis* is, I expect, merely a garden name. I have known a *B. martiana* (without the *gracilis*) much weaker in habit, said to be hardy, at Tregoney, in Cornwall. *R. Irwin Lynch.*

**Are Plants Aware of Time?** (see pp. 31, 47).—In answer to Mr. Diver's query as to what is a klinostat, it may be described as a clock-work arrangement in connection with a mechanism for revolving the subject under experiment, or for altering its position with relation to the earth or to light, at intervals of time determined on. An account of its use and some of the experiments performed by its aid will be found in any good modern work on plant physiology. It is a somewhat expensive apparatus, and I suggest to Mr. Diver that he can get a result without its use in the Dandelion stem experiment to which I referred, if only he can find time to devote to it. I would suggest that he select a vigorous Dandelion stalk nearly, but not quite, fully grown; let the lower end be wrapped in wet moss, and lay it flat on the table. When the stalk has turned up in its attempt to assume the vertical, he should note the time. This done, place it on the edge of the table or on the edge of a box, with the tip pointing downwards. Note the time, and, when it again

turns upwards, observe how long it has taken to turn from one position to the other. At this interval now indicated, keep the stem turned, as by the klinostat, until the stem bends by itself automatically without any turning over. I am sorry I can give no reference to a book in which this experiment is described. I believe the account I give must be perfectly reliable. It was told to me by the late Sir Francis Darwin, I, no doubt, having provided the Dandelion stalks, and there would have been nothing for me to remember, had it not been the automatic and periodic turning of the stalk, all the rest being commonplace enough. It is well known that certain plants do flower, as in the case of the Aloe, about the time they are in flower in the country of origin; but I am very anxious for precise information as to what happens, in the case of such plants, when seedlings are raised from seed saved in this country. How far does the dormant seed convey a knowledge of the calendar to the seedlings? There must, I think, be some conveyance of this knowledge—if I may use this word for want of a better term. *Begonia Gloire de Lorraine*, a hybrid raised in Europe, blooms, I believe, as required by parentage, at a time not the happiest for its comfort in our plant houses; the parents were *B. socotrana* and, I believe, *B. Dregei*. *R. Irwin Lynch.*

FIG. 47.—PHACELIA CAMPANULARIA.

**A Good Blue Flowered Annual.**—To those who are fond of blue flowers, I would recommend sowing seeds of *Phacelia campanularia* (see Fig. 47), as it is one of the earliest of annuals to bloom, and a succession of flowers is maintained over a long period. This strikingly beautiful annual did exceptionally well in the hot, dry summer of 1921, and it is especially effective as an edging plant, for it only grows some 8 or 9 in. tall. The flowers are bell-shaped and of a brilliant ultramarine blue. In some respects the foliage is very ornamental, for the colour is sage green with a purple sheen about the margin, which is very deeply lobed. *Phacelia* was formerly included in the genus *Whitlavia*, of which the most useful species is *gloxinioides*, so named from the resemblance of the flowers to a *Gloxinia*. The blooms have a blue lip and white throat. *Annual.*

**Apple Trees Damaged by Voles.**—A case has been reported to me of Apple trees being gnawed by voles to a very serious extent. I advised painting the stems with a strong mixture of lime and cow manure. This is stopping the pests, but the operation is too slow as there are fifty acres of fruit trees concerned. I think I remember reading something in the *Gardeners' Chronicle* a short time ago about voles, and I wonder if your readers can give any information about stopping the depredations of these pests that would be helpful. *G. H. Hollingworth.*

## SOCIETIES.

ROYAL HORTICULTURAL.  
Scientific Committee.

JANUARY 31:—*Present*: Mr. E. A. Bowles (in the chair), Rev. W. Wilks, Messrs. Balfour, Loder, Hales, Arkwright, Hosking, Fraser, and Chittenden (hon. sec.).

**Hybrid Plums.**—Mr. J. FRASER showed a series of dried specimens of hybrid Plums which he had collected, growing wild, in various places, and commented upon their probable derivation.

**Quercus coccifera.**—Mr. WORSLEY showed acorns of an Oak growing in the mountains of Arragon, from which he had cut walking sticks. The Oak was apparently *Quercus coccifera*, which usually makes a bush not more than six feet in height.

## Awards to Broccoli.

The following awards have been made by the Council of the Royal Horticultural Society to the undermentioned varieties after trial at Wisley.

## AWARDS OF MERIT.

No. 29, *Early Angers*, from Messrs. NUTTING AND SONS; Nos. 30, 31, *Early Feltham*, from Messrs. WATKINS AND SIMPSON and Messrs. BARR AND SONS; No. 38, *Spring White*, from Messrs. SYDENHAM; No. 55, *Snow White*, from Messrs. SUTTON AND SONS; Nos. 54, 57, 58, *Leamington*, from Messrs. J. CARTER AND CO.; Messrs. BARR AND SONS and Messrs. COOPER TABER AND CO.; Nos. 69, 70, *Champion*, from Messrs. BARR AND SONS and Messrs. NUTTING AND SONS; No. 75, *April*, from Messrs. FINNEY; No. 79, *Evesham Giant*, from Messrs. WATKINS AND SIMPSON; No. 81, *Easteride*, from Messrs. SUTTON AND SONS; No. 82, *Reading Giant*, from Messrs. SUTTON AND SONS; No. 98, *White Emperor*, from Messrs. BARR AND SONS; No. 96, *Alexandra*, from Mr. SCARLETT; No. 99, *Edinburgh Market Late*, from Mr. SCARLETT; No. 101, *Eclipse* (Cattell's), from Messrs. COOPER, TABER AND CO. (these last-mentioned three varieties were considered to be much alike); No. 103, *Swan*, from Mr. CLUCAS; No. 106, *Late Queen re-selected*, from Messrs. J. CARTER AND CO.; No. 112, *White Mammoth*, from Messrs. BARR AND SONS; No. 122, *Edmonton*, from Messrs. WATKINS AND SIMPSON; Nos. 125, 126, 127, *June*, from Mr. CLUCAS; Messrs. FINNEY and Messrs. NUTTING AND SONS.

## HIGHLY COMMENDED.

Nos. 51, 52, *Late Feltham*, from Messrs. WATKINS AND SIMPSON and Messrs. BARR AND SONS; No. 65, *Victory*, from Mr. H. HILL; No. 88, *Model*, from Mr. DAWKINS; No. 91, *Tender and True*, from Mr. WOODWARD; No. 93, *Satisfaction*, from Messrs. SUTTON AND SONS; No. 94, *Lathom Late*, from Messrs. ARINGSTALL; No. 97, *Longstander*, from Messrs. BARR AND SONS; No. 104, *May*, from Messrs. NUTTING AND SONS; No. 116, *Latest of All*, from Messrs. SUTTON AND SONS.

## COMMENDED.

No. 39, *Mid Feltham*, from Messrs. WATKINS AND SIMPSON.

## CARDIFF GARDENERS'.

At the January meeting held at the Queen's Hotel, Cardiff, Mr. M. Toy presided. Mr. C. Chipman, a representative from the Bristol Gardeners' Association, read a paper on "Dry Wall Gardening." This subject is finding favour in the Cardiff district, and is one of which Mr. Chipman is a master.

The CARDIFF PARKS DEPARTMENT exhibited very fine *Lachnalia*, and Mr. FREEMAN some good Roman *Hyacinths*. Some fine sprays of *Pyracantha angustifolia* and *Hamelis mollis* were also shown.

### UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

The monthly meeting of this Society was held in the R.H.S. Hall, on Monday, February 13. Mr. Chas. H. Curtis presiding. Seven new members were elected. Two members over the age of 70 years were allowed to withdraw £36 3s. 9d. and £55 5s. 5d. respectively, from their deposit accounts, and two members withdrew interest amounting to £12 9s. The death certificate of one deceased member was received, and the sum of £20 13s. 1d. was passed for payment to his nominee.

The sick pay for the month on the private side amounted to £102 13s. 6d., and on the State side to £90 13s. Maternity benefit claims came to £6. Seven members were assisted in respect of cost of dental treatment.

The draft of the Committees' annual report and balance-sheets of both sections of the Society was read and passed for presentation to the annual general meeting, which will be held at the R.H.S. Hall on Monday, March 13, at 7 p.m.

### EAST ANGLIAN HORTICULTURAL CLUB.

At the February monthly meeting of this Club, J. A. Christie, Esq., Framingham Manor, gave a most interesting discourse on "The Lolette system of fruit tree pruning." Mr. Christie has made a close study of it and carried it out with great success with his fruit trees. A striking evidence of this was that from trees so pruned he won the first prize in the large class for Pears at the R.H.S. 1921 Fruit Show.

Mr. Christie, by means of a blackboard and chalk, showed how this system of pruning is done, down to the finest details.

### DIDSBURY AND DISTRICT HORTICULTURAL.

A MEETING of the above Society was held on the 19th ult., and in the absence of the President, the chair was taken by Mr. Doidge.

A lecture on "The Cultivation of the Sweet Pea" was given by Mr. Hamblett, of Stockport. The lecturer dealt with such details of cultivation as the chipping or soaking of the seeds; seed-sowing, which, he said, is best done in October; planting the seedlings in the open, for which operation the month of April is to be preferred if the weather is favourable; tying, disbudding and feeding. He recommended removing all the soil from the roots before transplanting the seedlings in the open. The following varieties were recommended by Mr. Hamblett:—Constance Hinton, Elegance, Mrs. T. Jones, Charity, Splendour, Hawmark Pink, Melba, Royal Scot, Tangarine, R. F. Felton, Gladys, Annie Ireland, Picture and Mrs. A. Hitchcock.

At the meeting held on the 2nd inst., the President, P. Schill, Esq., occupied the chair, and Mr. Leach, of Altrincham, gave a paper on the "Culture of Peas and Beans."

### ROYAL CALEDONIAN HORTICULTURAL.

The ordinary monthly meeting of this society was held at 5, St. Andrew Square, Edinburgh, on the 7th inst. Mr. David King, president, in the chair.

Mr. King delivered the opening address for the session, taking as his subject "The Training of the Youth Who Takes up Horticulture as the Serious Business of Life." Any youth of ordinary capacity, said Mr. King, might become a gardener, but to be a successful gardener he must have a real love of plants and for all that is beautiful in Nature, and he must make up his mind to take his share in all the work connected with his profession when he enters on his apprenticeship and to perform it to the best of his ability. He was not one of those who thought that the day of the fine private garden had gone, but their number was becoming fewer, and when it became a matter of choice with a well-trained young gardener whether he should aim at becoming a head gardener in a private establishment or

enter commercial gardening he unhesitatingly said that, if ability was to be rewarded to the full, the latter held out the greater inducement. But only those who had plenty of grit, and well-directed energy and perseverance, could hope to succeed in a business of this nature.

Dr. Burns, Economic Botanist to the Bombay Government, gave a short address on "Horticulture as it is Practised in India."

### Obituary.

**William Bain.**—The news of the death of Mr. William Bain, for 47 years gardener to the late Sir Trevor and Lady Lawrence, will be learned with regret by our readers. He died at Gairloch, Ross-shire, on the 2nd inst., in his 30th year. Mr. Bain retired from the position of gardener at Burford Lodge when Lady Lawrence died in 1916, and went to spend the evening of his life at his native village of Gairloch. He resided with his nephew and enjoyed good health up to some three months ago; he was able to be about a week before his death, although during the last few days he suffered intense pain. The older generation of gardeners will remember the many rare and interesting plants which Mr. Bain brought to the meetings of the Royal Horti-

THE LATE WILLIAM BAIN.

cultural Society from Sir Trevor Lawrence's garden at Burford Lodge, which was not only full of interesting plants, but charmingly designed, and under Mr. Bain's care maintained in great perfection. In a letter to us Mr. Aubrey T. Lawrence refers to Mr. Bain as a devoted friend of his family and states that he was happy in his retirement and greatly interested in his little garden, and that he was laid to rest in his mother's grave in one of the most beautiful spots in Gairloch.

**Samuel Tisdale.**—We learn with much regret that Mr. Samuel Tisdale died on the 14th inst., aged 88, at the residence of his son-in-law, Mr. Wm. Wiles, florist, 33-34, Upper George Street, Bryanston Square, W. Mr. Tisdale started his career as Rose propagator with the firm of Messrs. Richard Smith and Co., of Worcester. He afterwards entered the service of Messrs. Barr and Sugden (now Messrs. Barr and Sons) as manager of their nursery, Garrett Lane, Tooting, where the firm's famous collection of Daffodils was grown, and where they conducted their seed trials, and he remained with this firm some 25 years, retiring in 1901, when Messrs. Barr and Sons were establishing their nursery at Surbiton. He then went to live with his son-in-law at Bryanston Square, assisting him in his florist business. Mr. Tisdale was always a very active and intelligent gardener, and was closely associated with the cultivation of the famous collections of new seedling Daffodils raised by Edward Leeds and William Backhouse which were acquired by the late Mr. Peter Barr.

He was buried on Saturday, the 18th inst., at Streatham Cemetery, which occupies the site of Barr's old nursery, where for so many years he was cultivator of the many plants which were grown there.

### ANSWERS TO CORRESPONDENTS.

**NAMES OF FRUIT: Gardener, Herts.** Pear Vicar of Winkfield; Apples: 1, Calville St. Sauveur; 2, Mannington's Pearmain.—*E. A. H.* 1, Lady Henniker; 2, Golden Noble; 3, Christmas Pearmain; 4, Newton Wonder; 5, Lord Derby; 6, Annie Elizabeth.—*A. E. H.* 1, Scarlet Nonparil; 2, Reimette Van Mons; 3, Newton Wonder; 4, Small's Admirable; 5, Round Winter Nonsuch.

**NAMES OF PLANTS: Mrs. P.** 1, Begonia fuchsoides; 2, Eupatorium riparium; 3, Echeveria secunda.—*Pychurst.* Impossible to identify with certainty the specimens sent; send when in flower or fruit.

**PRIMULA OBCONICA CROSS: J. E. M.** The variety appears to be pure *P. obconica*. Reputed hybrids of *P. obconica* and *P. sinensis* have been exhibited at the R.H.S. meetings. On May 8, 1917, Adeline Duchess of Bedford showed a variety stated to be a hybrid between *P. obconica* and *P. sinensis*, and it received an award of merit under the name of *P. obconica* Eureka.

**PROPAGATION OF PLANTS: C. W., Durban.** We do not know of any special work dealing with this subject, but it is fully dealt with in the larger dictionaries of gardening, such as *Thompson's Gardener's Assistant*.

**SEEDS OF PRIMULA GERMINATING SLOWLY: G. J. H.** The reason of your Primula seed taking so long in germinating is probably due to its being old; old Primula seed that has become very hard always comes up very erratically. Seeds of most Primulas germinate best if sown as soon as they are ripe, and in some cases even before being perfectly ripened. Another cause may be careless watering of the seed pan. If the soil is not kept continuously moist, the seed coats, after having become soft, will harden again, and this is especially likely to happen in the case of the *sinensis* type, resulting in irregular germination.

**STOCKS FAILING: R. S. B.** As no fungus was present in the plants we can only assume that the trouble is due to some cultural error, probably an excess of moisture at the roots.

**SWEET PEAS DYING AT THE ROOTS: J. C.** The roots are not attacked by a fungous disease, but a few eelworm were present and these may be the cause of the trouble. Take the precaution to sterilise your potting soil by steaming or baking, as eelworm is evidently present in your garden.

**THE LATE MR. G. MASSEE: W. H. S. ME.** George Massee, author of *Diseases of Cultivated Plants and Trees*, died in February, 1917 (see *Gard. Chron.*, February 24, 1917).

**TOMATO FLOWERS: D. S. F.** The flowers of the Tomato are hermaphrodite, that is, the stamens and pistils are both present in the same blossom.

**WHITE FLY ON OUT-DOOR PLANTS: F. K.** So far as we are aware there is no effectual remedy for White Fly on out-door plants.

**WORMS IN SOIL: Mrs. C. M. E.** The droppings collected from your fowhouse would make useful manure if allowed to become dry and then mixed with a good quantity of dried soil before applying it to the land. The white worms have nothing to do with eelworm, which are microscopic creatures, and you need not fear that they will follow through the use of poultry manure. Fowl manure is a very rich nitrogenous fertiliser, and, if you use it in the way advised—that is, allow it to become dry and then mix it with several times its bulk of dry soil—it may be used with advantage for any kind of crop.

COLOURED SUPPLEMENT: *Exacum macranthum*.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 40.4.

ACTUAL TEMPERATURE:—*Gardeners' Chronicle* Office, 5, Tavistock Street, Covent Garden, London, Wednesday, March 1, 10 a.m. Bar. 30.1; temp. 52°.—Weather—Fine.

**Allotments.** The Report of the Departmental Committee appointed by the Ministry of Agriculture to investigate the present position with respect to the provision by local authorities of allotments in Great Britain\* was briefly referred to on p. 50. The brief historical review which prefaces the Report traces the origin of the small allotment to the nineteenth century, but—no doubt because of the devotion of the committee to more pressing subjects—it contains no reference to the interesting and early experiments in small cultivation which were made during that and probably earlier periods. The number of allotments increased considerably during the years 1909-1914. Those provided by local authorities numbered 58,648 in the former year and 130,526 in the latter. The great expansion of allotments which, as is well-known, occurred during the war, was in large measure due to the powers taken by the Board of Agriculture under the Defence of the Realm Regulations to enter on land for the purpose of cultivating it; which powers were delegated to urban local authorities. Of the large numbers of new allotments which came into existence during the war many, and particularly those provided by urban local authorities, were situated within town boundaries, and hence the allotment problem has become in increasing measure an urban problem. The extraordinary powers taken under D.O.R.A. expired in 1920, and the powers of possession in September, 1921, but by a subsequent Act the possession may be continued for two years from the termination of the war, and for a further three years with the consent of the Railway and Canal Commission. Holders of allotments were naturally con-

cerned at the prospect of the land they cultivated ceasing to be available, and it was largely as the result of this widespread feeling of apprehension that the Departmental Committee was appointed. The committee speak highly of the value of allotments from the national and social points of view, and that the beneficial effects operate on large numbers may be judged from the fact that the number of allotments in 1920 is estimated at over one million, occupying 157,620 acres. The committee recognise the importance of security of tenure to allotment holders, and recommend that local authorities should adopt a long-sighted policy and purchase land for allotment purposes whenever practicable, also that where the land so acquired is on the outskirts of towns the authority should be empowered to give special transport facilities to allotment holders. The committee further recommend that loans for the purchase of allotment lands should be excluded from the debt of the local authority under the Public Health Act, and in order not to diminish the borrowing power of the authority for other purposes. They hold also that provision of land for the purpose of allotments should be borne in mind in preparing schemes under the Housing and Town Planning Acts. The committee recognise that in large towns the cost of conveniently situated land may be beyond the purse of the local authority, and urges therefore that in those circumstances, and when State finance shall admit of it, the central authority shall have power to make grants towards the acquisition of land. Other recommendations concern the length of notice to terminate tenancy, and include the sensible suggestion that notice given between Lady Day and Michaelmas in any year shall be invalid, but on the contrary they advise, if their own recommendations are adopted, that compensation shall not be paid for disturbance or for crops, provided that a proper six months' notice be given. The committee offers the following definition of an allotment garden: "A piece of land not exceeding forty poles in extent which is cultivated by a person not as a market garden, but for the production of vegetables and crops mainly for consumption by himself and his family." The Committee suggests that twenty poles is the largest area which, if used for vegetable production, can be cultivated properly by an individual in his spare time, and therefore proposes that the maximum size of an allotment should be of this dimension.

**Coloured Plate.**—The subject of the coloured illustration presented with the present issue, *Exacum macranthum*, is remarkable for the deep and rich blue colouring of its flowers. As blue is a popular colour, and blue-flowered plants for flowering under glass are comparatively few in number, it is regrettable that *Exacum macranthum* is so seldom grown. That it severely tests the skill of the cultivator would appear to be a reason for, rather than against, its inclusion in a selection of choice flowering plants for the stove and greenhouse. On p. 104, Mr. J. Coutts, Kow, gives directions for the cultivation of this handsome plant.

**Cup Competition for Hove Allotment Holders.**—Mr. E. Bull, a member of the Hove Town Council, has signified his appointment as chairman of the Hove Allotment Holders' Association by offering a Silver Cup, to be competed for by allotment holders at the next annual exhibition. The former chairman of the Hove Allotment Holders' Association was Sir George Casson-Forbes.

**Two Forthcoming Exhibitions in Paris.**—M. Lucien Chauré advises us that the National Horticultural Society of France will hold, in 1922,

at the Jardin d'Acclimatation, Paris, two International Horticultural Exhibitions. The first will open on May 26 and continue to June 2; it will consist of Roses, flowering shrubs, flowering plants, forced fruits, vegetables, horticultural sundries, horticultural fine arts, etc. The second exhibition will be held from October 27th to November 5th, and will consist of Chrysanthemums, seasonable flowering plants, fruits, fruit trees, vegetables, etc. Horticulturists, arboriculturists, market gardeners, working, professional or amateur, of all allied and neutral countries are invited to exhibit. There will also be conferences, excursions, and meetings in connection with these exhibitions. The full programme may be obtained from the secretary of the society, 84, Rue de Grenelle, Paris, 7, on and after March 15th.

**Demand for Bulb Land at Spalding.**—At a public auction at Spalding, on the 22nd ult., there was keen bidding for properties at Pote Hole, near Spalding, that came under the hammer, and which were in a high state of cultivation and suitable for bulb growing and market gardening. A farmhouse and 68 acres of land, known as Trent Farm, in the occupation of Mr. Charles Scott, under a lease expiring April next, realised £4,200, Mr. A. E. Simons, of Ramsey, being the purchaser; 21 acres of land in the same occupation, with cottages, were bought by the same gentleman for £1,350, and he also gave £900 for 17 acres of grass and arable land.

**The Queensland Fruit Crops.**—Following upon very favourable weather conditions, a record crop of all varieties of fruit is indicated this season in Queensland. Late varieties of Orange were marketed fairly early, when a good demand existed. In the Cook district there is a frequent variation in the season of ripening for this fruit, and by the aid of irrigation ripe Oranges may be obtained in any month of the year. The quality is exceptionally good. The area under Pineapples has greatly increased during the past few years, and up to the present canning has been the only means of dealing with the increased product. In addition to Bananas, Papaws now find much favour with planters, chiefly because they give early returns, a tree being usually productive within twelve months of planting. Cherrimoyer trees, though usually about five years before coming into bearing, were much in demand last season, and inquiries suggest an increased demand for the next planting. This luscious fruit is rather exacting in its choice of location, but under favourable conditions is very profitable. Mangos are doing well in the more tropical parts of the State, and even in cooler regions good results are obtained by inarching the trees.

**Flower Paintings at the Brook Street Art Gallery.**—A visit to the exhibition of paintings by H. d'Arcy Hart, at the Brook Street gallery, is like stepping straight out of the cold rain of February into the warm sunshine of full summer, for nearly all the subjects are taken from the summer garden. Zinnias, Delphiniums, Scabious, Antirrhinums, and Pansies adorn the walls and provide the rich colouring which makes a herbaceous border so cheerful and satisfying. From the point of view of arrangement, most of the flowers which form the subjects of the various paintings are too tightly packed in the vases, reminding one of the compressed posies from a hospitable cottager's garden. The colours, however, with very few exceptions, are excellently blended, and tone well with the blue vases in which most of them are displayed. "Zinnias and Larkspur" is a pleasant arrangement of Zinnias and Delphiniums, with a few Pansies intermixed, set in a pot of blue china. "Tulips and other Spring Flowers" is a very bold picture, and well illustrates the value of long-stemmed flowers for decoration. In two paintings of Tulips the colours tone excellently with the china of the vase. "Autumn Flowers" is one of the larger paintings, in which Delphiniums and Zinnias also figure. The flowers are well done, but again it must be remarked that they are too tightly packed in the vase to look really artistic.

\* Published by His Majesty's Stationery Office, 1922. Price 7d. post free.

"Marigolds" is a really delightful picture of Marigolds set in a position where they get, and hold, the sunshine. "A Summer Bouquet," is, from our point of view, the best picture in the exhibition. The Zinnias have plenty of room to display themselves to the best advantage, and are thoroughly well painted. Three spikes of Delphinium behind give just the variety that is needed. There are several pictures of Anemones, of the St. Bridgid type; one of the prettiest arrangements consists of blue and red flowers, possibly a trifle too closely packed. "Asters in a Glass" is a very simple but very pleasing conception, and the one next to it, "Autumn Tints," is another illustration of the advantages of high top light on Marigolds and single Asters.

**Orchid Mycorrhiza.**—The value to the gardener of a complete knowledge of the habits of the plants he cultivates is shown in a striking degree in the case of Orchids, a race of plants that includes some of the most beautiful subjects in the floral world. These plants are amongst those which Dr. Rayner refers to on page 102 in her interesting article on plant partnerships, wherein she shows that certain plants are dependent on fungi in association with them, for their successful growth. It has been found that the roots of Orchids have a sort of mantle about their roots, which, when examined under the microscope, is found to consist of the mycelium of a fungus. Should the medium in which the Orchid is grown be sterile of the particular fungus which it favours, the flowering plant is unable to succeed, but it is not likely to be absent when the plants are propagated vegetatively, for the roots will carry sufficient of the particular fungus—to which the general term mycorrhiza is applied—with them when they are repotted. In the case of Orchids raised from seed the medium in which they are germinated is not likely to contain any of the necessary mycorrhiza, and this explains the difficulty the earlier raisers had in obtaining seedlings. Our present knowledge of Orchid mycorrhiza is most lucidly summed up by Mr. J. Ramsbottom in an article included in Messrs. Charlesworth and Co.'s catalogue of Orchids, 1922, accompanied by several excellent illustrations showing sections of Orchid roots and seedlings with the fungus associated with them. Mr. Ramsbottom refers to other plants which show the same consistency of fungus infection besides Orchids, and we hope to deal with his paper in greater detail in a subsequent issue, for the subject is one of absorbing interest to raisers.

**St. Lucia.**—The success of our Empire depends upon the good will and industry of all its parts, but few other than those who have travelled extensively, fully understand how great is the good will and industry of the officials who deal with horticultural and agricultural matters in the smaller and distant colonies. To this office come copies of many and varied annual reports indicating progress in these directions, and the one just to hand, from St. Lucia gives a very good idea of the work performed under the Imperial Department of Agriculture for the West Indies. We learn that in 1920 no fewer than 36,208 plants and cuttings, chiefly of economic subjects, were distributed to planters from the nurseries attached to the Botanic Station, in addition to a large number of seeds. The control of insect and fungus pests which attack Bananas, Sugar Cane, and Coco-nut Palm, occupies a great deal of attention from the Department, and the need and use of preventive measures is emphasised in the programme of agricultural education carried out in the primary schools at St. Lucia, and in connection with the instruction given to teachers in practical agriculture. The report of the Government Ground Provisions Depot show that the public institutions in St. Lucia were kept regularly and fully supplied through the year with Potatoes, Farine, Peas, Yams, Bananas, Breadfruit, Plantains and Pumpkins, and that on the occasion of the visit of His Royal Highness, the Prince of Wales, in September, 1920, this Depot supplied the ships accompanying him with 2,000 Oranges, 57 bunches of Bananas, six barrels of Mangos, two barrels of green Limes, and a few dozen Pineapples. It is interesting to

observe that there are numerous Agricultural Credit societies in St. Lucia, and that the total loans against these societies at the end of the year was £2,811.

**Dr. A. W. Hill.**—The new Director of the Royal Gardens, Kew, Dr. A. W. Hill, has already proved himself to be a man of great ability, with a thorough knowledge of botanical science and wide horticultural sympathies. Moreover, he has travelled extensively and held many positions of importance. Dr. Hill is a native of Harrow. After early schooling at Margate, he entered Marlborough College in 1890, and while there displayed a great taste for biology, a taste subsequently developed into keen study. From Marlborough he went as an Exhibitioner to King's College, Cambridge, becoming a scholar of his college in 1896, and obtaining a First Class in Part I. of the Natural Science Tripos in 1897, with a First Class in Part II. of the same Tripos in the following year. He worked for some time under Dr. W. Gardiner, and in 1899 became Senior Demonstrator in Botany at the Cambridge University, and in 1905 University Lecturer in Botany. Since his appointment at Kew, Dr. Hill has applied botanical knowledge to the

DR. A. W. HILL, F.R.S.

furtherance of economic ends, and in this connection he has added to his knowledge of economic botany, and its value to the Empire, during an official visit to the West Indies in 1912, and more recently during an official visit to the Cameroons. In 1910 he paid a naturalist's visit to Algeria. Dr. Hill's work in connection with the War Graves Commission is well known. Apart from his official duties, Dr. Hill shows a warm interest in those employed at Kew, and his sympathy with the large body of Old Kewites, by whom he was appointed President of the Kew Guild for the year 1920, has been shown on numerous occasions. To follow in the train of a succession of such a series of directors as Kew has enjoyed might intimidate a weak man, but on the contrary it must, and we are convinced will, serve as a stimulus and inspiration to the new Director, for whom we wish as long and brilliant a career as that of his predecessors in this great office.

**Potinarina: a New Multi-generic Hybrid Orchid.**—Among many remarkable hybrid Orchids exhibited at the Royal Horticultural Hall, Westminster, on the 28th ult., none was more interesting than Messrs. Charlesworth and Co.'s new Potinarina Juliettae, derived from a cross between *Sopbro-Laelio-Cattleya* Marathon and *Brasso-Cattleya* Ena. As the parentage indi-

cates, the new hybrid is a combination of four genera—*Cattleya*, *Laelia*, *Brassavola* and *Sophrontitis*. The new generic title follows the general rules for such names and has been given in honour of M. Potin, Vice-President of the National Horticultural Society of France, and President of the Orchid Committee of that Society. M. Potin gave a prize of 1,000 francs last year for the finest hybrid obtained by crossing the genera *Cattleya*, *Laelia*, *Brassavola* and *Sophrontitis*, and this was awarded to M. Marcoz, of Brunoy, by *Brasso-Cattleya* Chandon (*Cattleya* Jeanne Payet × *Brasso-Cattleya* Mrs. Leemann). M. Potin has announced that he will give a prize of the same value during 1922 for a hybrid raised under similar conditions.

**Appointments for the Ensuing Week.**—Tuesday, March 7: Royal Caledonian Horticultural Society's meeting; Bournemouth Gardeners' Association's meeting. Wednesday, March 8: East Anglian Horticultural Society's meeting; Sheffield Chrysanthemum Society's meeting; Wimbledon and District Gardeners' Society's meeting. Thursday, March 9: Bristol and District Gardeners' Association's meeting. Friday, March 10: Paisley Florists' Society's meeting. Saturday, March 11: Ringwood Society's meeting.

**"The Gardeners' Chronicle" Seventy-five Years Ago.**—Covering *Vine Borders with Glass.*—I have covered Vine borders with glass in a temporary way, and with such beneficial results that I have made provision for covering with glass the outside borders of an extensive range of vineries erected here last summer. It is a move in the right direction, and will do away with the unsightliness of fermenting materials, but will never supersede them in beneficial results, when the latter are supplied with proper care. In the case of early forcing through a long and severe winter, borders covered with glass alone will not produce that equality of temperature betwixt root and branch, which is so essential to the Vine, that fermenting manure and leaves would do. My outside borders are 20 feet in width, with a fall from the houses of 2 feet 8 inches; and I have run a flue along the front of the border and up the ends, working into wing walls; next the soil is a 4½-inch brick wall, then a 4½-inch vacuum next a flue 15 inches deep and 11 inches wide, and upon the cover of the flue is placed at 3 feet distances bricks on edge, which carry a stone coping hvelled off on the surface in order to throw the water off to the walk in front. The coping is so contrived that the heat from the flue is thrown on the surface of the border. Other minor details, as temporary rafters, etc., will be supplied when the border is about to be covered with glass. The glass will be something like 10 inches above the soil, a space sufficient for the heat given out by the flue to circulate in. The furnace is placed in the centre, so that I can either heat the border of two houses or of four at the same time. I shall not be able to fix glass on the border, however, before the winter of 1848, or until my young Vines have become permanently established; till then, dung and leaves must suffice, a covering to which I am very partial. *James Roberts, Raby Castle, Gard. Chron., February 27, 1847.*

**ORCHID NOTES AND GLEANINGS.**

**COLOUR AND FORM IN CYPRIPEDIUMS.**

AMONG hybrid Cypripediums we see more plainly than in most other genera the wonderful results obtained by raisers in the development of rich colours and the improvement of size and form of the flowers. In Cypripedium, as in Laelia, Cattleya, Sophronitis, and Cochlioda Noezliana crosses, the smaller and least florally perfect species have played the most important part in the production of the magnificent hybrids which have commanded the attention of modern Orchid lovers.

Cypripedium Boxallii, a species which was slighted on its introduction on account of its smaller size and narrow dorsal sepal, with the edges rolled back, as compared with C. villosum (of which some wrongly considered it a variety), has in its ungainly dorsal sepal intense, almost black, blotching on a shining surface. This species alone could have conveyed to the charming set begun in C. Hera (Euryades), resulting from the cross between C. Boxallii and C. Leeanum (insigne x Spicerianum), the colour combination, which appears with intensified beauty in C. Eurybiades, C. Pyramus, and a host of others. The size of the blotching, and its ultimate blending into a broad central band of colour on the dorsal sepal, are marked features that appear in intensified form in C. Mrs. Wm. Mostyn and allied forms, of which C. Boxallii is an ancestor.

C. insigne in its many varieties has laid the foundation of one of the largest, best and most popular sections of Cypripedium. C. exul, however, of smaller size, stood in the same position to C. insigne as C. Boxallii did to C. villosum, and it was at first thought to be a small form of insigne. But the hybridist proved the error, as its pretty little flowers, of model shape, with well-defined dark blotching on the shining surface of its dorsal sepal, produced a characteristic section commencing with C. Earl Tankerville, and quite distinct from the C. insigne crosses.

C. Spicerianum, beyond reproach as a species—it has a large, pure white dorsal sepal, with, in some varieties, a broad median band of dark claret colour—heads another section of excellent form, but the important point is that the broad coloured band on the dorsal sepal gives a feature which no other species could supply, and this appears in many hybrids having this species as an ancestor. One of the best examples is C. Viking (Bnehamianum x illustre), one of the finest of Cypripediums, and which can only have obtained the deep violet band on its white dorsal sepal through the C. Spicerianum in its ancestor C. Lathamianum.

C. Fairrieanum, small of stature, beautiful to the artist, but far from perfect from the florist's view, gave us one of the most beautiful of sections in the Cypripedium family. The delicate tracery on its flowers, and the characteristic form appear in some degree in the larger and more ornate varieties raised from it.

C. nivenum, C. Godefroyae and C. bellatulum give a beautiful and distinct section, ranging from pure white, purple spotted, to heavily blotched forms, the characters of which appear in repeated crossings with dissimilar hybrids.

C. Chamberlainianum, C. Rothschildianum, C. Stonei, and others of this class, give us sections with longer spikes of several beautiful flowers; all are favourites in gardens, but the most deservedly popular classes are those usually giving but one flower to the scape, such as C. C. insigne, C. villosum, C. barbatum and C. Spicerianum groups.

We see these remarkable flowers obtained by crossing very dissimilar parents, but few stop to consider the wonder of it all. Imagine, for example, the strap-shaped, leathery, green leaves and totally different flowers of C. insigne, and then examine the smaller and more delicately formed C. bellatulum, with its thick, mottled leaves, with a glassy layer on its upper surface covering the cellular tissues beneath, and then call to mind the fairly intermediate C. Helen II., resulting from the crossing of the species

named and one can but marvel at the powers of adaptation in nature whereby two such dissimilar structures—and others equally wide—could be merged. J. O'B.

**TREES AND SHRUBS.**

**OLEARIA STELLULATA.**

Of the fine species of Olearia described by Mr. W. J. Bean in his indispensable work on *Trees and Shrubs Hardy in the British Isles*, he specifies O. stellulata as the least hardy; but here, on the west coast of Scotland, it has stood uninjured for many years. It has a longer flowering season than any other member of the genus known to me, usually beginning with a few scattered flowers in January, and gradually increasing the display, until in May the bushes are closely sheeted with snowy, or rather with chalky, bloom. The flowers produced in winter seem as insensible of cold as those of the Witch Hazels. We had a snowstorm last week (early February) with 8°, 9°, and 8° of frost on three

makes, every February, a picture visible a good many yards away. Seen against the occasional blue sky that even dull February gives, the jewelled branches of the Parrotia are particularly beautiful. It is strange that a plant so hardy, so glorious in crimson and gold in autumn, and so pleasant a sight in earliest spring, is not more often planted. F. J. Chittenden.

**LITHOSPERMUM ROSMARINIFOLIUM.**

BLUE flowers are always welcome. We never grow tired of them, and we never have enough of them. Unlike the better-known Lithospermum prostratum of trailing habit, the species under notice is of compact and upright habit, growing from one foot to two feet in height. It is an evergreen shrub with bright green, narrow, Rosemary-like foliage and pure Gentian-blue flowers.

That distinguished writer and traveller, the late Mr. Reginald Farrer, formed a very high opinion of this plant, as witness the following excerpt from his historical musings in *Among the Hills*. "It is seldom, indeed, that the

FIG. 48.—LITHOSPERMUM ROSMARINIFOLIUM.

successive nights, yet the sprays of blossom on this Olearia never drooped, and I gathered some on February 6th quite fresh.

In the figure of this plant in Mr. Bean's book, Vol. II., page 107, the leaves are represented as having smooth margins, but in our plants they are distinctly and symmetrically toothed.

Of the amazing profusion of seed ripened by this and most other species of Olearia not one in a million gets a chance of germinating here owing to the rankness of our native herbage. We grow eight species, but I have found only a single self-sown specimen of O. nummularifolia. On the other hand, another shrub from the same region, Veronica parviflora, is a positive nuisance owing to its multitudinous progeny. Herbert Maxwell, Monreith.

**PARROTIA PERSICA.**

You do well, on page 74, to call attention to the flowering of Parrotia persica. Mr. Gerald Loder tells me that at Wakehurst it has been quite conspicuous this year, and others have remarked upon its beauty. There is a specimen at Wisley, planted in 1905, and now forming a large spreading bush about 14 feet in height, with every branch set densely with the curious scarlet-anthered flowers. Probably it is flowering in most places with greater freedom than usual, but for the past five years this plant has annually produced a good many flowers. The hazy, red effect they give composes well with the dangling tassels of the Hazel and the yellow and red Hamamelis arborea near by, and

plant-collector in Europe can escape the ubiquitous royalty of Queen Mary; as Duchess of Milan it is she who allows him to pluck her Saxifrages from the cliffs of Tenda: as Countess of Tyrol she watches him hammering out Daphne rupestris: as Queen of Naples and Jerusalem she has a vested right of guardianship over Iris Lortetii and Lithospermum rosmarinifolium: as Queen of Spain she is the sovereign lady of Erinacea pungens: and to the Queen of Sicily I am quite happy to leave her monopoly of ngly little Antirrhinum sieulum."

Lithospermum rosmarinifolium has been found wild in Italy and Greece. It is said to be hardy in many English gardens—in others not. It is certainly a plant for a warm and favoured spot. The plant should be protected in winter with branches of Bex or Pine, though it has withstood several winters unprotected in an Essex garden. Speaking generally the Lithospermums prefer soils of peaty character, though L. rosmarinifolium has been known to thrive amazingly over chalk. The flowering season of this species varies. It will persist in producing stray blooms in winter, and should there be a mild spell of weather between snowstorms this Lithospermum is almost certain to open its lovely blue flowers. The main season of flowering is May and June, though it will throw a strong bloom here and there in the autumn, as it does in its native habitat on the rocks of Naples and Capri. Herbert Cowley.

## The Week's Work.

### THE FLOWER GARDEN.

By EDWIN BECKETT, Gardener to the Hon. VICAR  
GRASS, Aldenham House, Hertfordshire.

**The Shrubberies.**—The moving and replanting of shrubs and trees should be completed as soon as possible, and the work of pruning, staking and tying completed. Staking is an essential operation where standard trees are concerned, not only in the young stage, to train a suitable leading shoot, but also with older subjects that have been moved, to support them against heavy winds, otherwise they may grow out of the upright and lose many of their finer roots through the tree being swayed to and fro by the force of the wind. Creepers should be examined, trained in position, and relieved of wood, so far as this is considered necessary, to prevent severe crowding of the shoots. Especially look to climbing subjects trained

FIG. 49.—AGAPETES MACRANTHA (see p. 101).

up poles, with a view to tying the growths, to prevent an untidy appearance. At the same time carefully examine the poles, to see if they need reinforcing or replacing. Where it is desired to plant creepers, the present is a suitable time to do this work, and those of a tender nature should receive wall protection. There are many beautiful subjects that may be trained up poles in shrubberies, adding considerably to the interest and beauty of the latter. When all necessary operations are completed, the soil should be forked over carefully, leaving the surface rough for the time being. Care should be exercised so as not to fork too deeply, or too closely, around the plants, otherwise detrimental root disturbance may be caused.

**Cuttings in Frames.**—Plants of Pentstemons and Violas, raised from cuttings inserted in frames in the autumn, should be ventilated freely and the soil around them stirred occasionally with a pointed stick. It will sometimes be found that plants of Pentstemons raised in this way appear to have died off, but this is generally found only to be a fading-off to the base from whence healthy young growth will appear at a later period.

### PLANTS UNDER GLASS.

By T. PATEMAN, Gardener to Sir C. NALL-CAIN, Bart  
The Node, Codiocote, Welwyn, Hertfordshire.

**Hydrangea hortensis.**—Where these plants have been kept under very cool conditions during the winter, a batch may be started into growth. Examine each specimen carefully, cut away the weak and useless growths, and, where it is considered necessary, repot them into larger receptacles. Specimens that do not require repotting should have some of the surface soil removed and be top-dressed with a rich compost. Plants raised from cuttings last autumn and now in small pots may be transferred singly to 4½-inch pots, or three may be grown in a 6-inch pot. Presuming the cuttings were well ripened when inserted the plants should, in most cases, produce excellent flowers this season.

**Salvia splendens.**—Old stock plants of *Salvia splendens* may be cut back and stood in gentle warmth to obtain young growths suitable for use as cuttings. Syringe the plants occasionally to induce them to break into growth. When the young shoots are a suitable size insert several of them around the edge of a small pot and root them in a propagating frame. Roots

### HARDY FRUIT GARDEN.

By H. MARRHAM, Gardener to the EARL OF STRAFFORD,  
Wrotham Park, Barnet.

**Strawberries.**—In favourable weather, trench and heavily manure land that is required for planting with Strawberries that have been forced in pots under glass, so that by the time the fruits have been gathered, and the plants duly hardened, the soil will have settled down again. The plants may then be planted firmly in good time, and will thus have a longer season to develop sturdy crowns, which are so very necessary for the production of good crops of fruit the following season.

**Young Strawberry Plants** in nursery beds or in pots propagated from layers last August should be planted in rich land which has been prepared for them in advance. Plant rather firmly at 20 inches by 24 inches apart, and put two or three in a clump if they are somewhat small and weak. Last season, owing to the continued spell of drought, strong, healthy layers were not plentiful, and those that were raised and planted early did not make satisfactory crowns; and especially was this the case on light, porous soils.

**Old Strawberry Beds.**—When the soil is in a workable condition, remove any weeds that may be present, stir the soil amongst the plants with the Dutch hoe, dress the land freely with soot and apply a good mulching of rich farmyard manure. All Strawberries, and especially those growing on light land, are somewhat weak, and I greatly fear the coming crops will not be good. Plants that received good attention and were freely mulched as soon as the crops were gathered are looking much stronger than plants that did not receive this attention.

**Fruit Room.**—Keep the fruit room clean and well ventilated in favourable weather. Remove any decayed fruits, and see that the atmosphere is sweet, as the flavour of Apples is quickly impaired when the fruits are stored in a musty fruit room.

### THE ORCHID HOUSES.

By J. T. BARBER, Gardener to His Grace the  
Duke of Marlborough, K.G., Blenheim Palace,  
Woodstock, Oxon.

**Cymbidium.**—The Cymbidiums comprise some of the most popular and beautiful Orchids in existence. They are easy of culture, and do not require much fire heat. They are evergreen, and send up long spikes of flowers, which may be used for a variety of purposes in decorations. Plants that have passed out of bloom (either species or hybrids), and sending up young growths, should, if they are in need of fresh material, be attended to when the new roots appear from their bases. These Orchids resent disturbance at the roots, and if the compost is still suitable, and there is room in the pots for the new pseudo-bulbs to develop, it will be wise to defer the operation of repotting until next season, as the plants produce flowers more freely when in a pot-bound condition. The species and hybrids of this useful genus grow well in a cool position in a house having an intermediate temperature, and should not be subjected to the direct rays of the sun at any time. Red spider will sometime attack the leaves, especially if the plants are grown in a dry atmosphere, and should be kept in check by sponging the plants from time to time with a weak insecticide. These Orchids will succeed in a similar compost to that used for Cypripediums, but slightly more loam may be added, provided it is of good quality. They should be potted firmly, and watered with extreme care for some considerable time. Those that are now developing their flower spikes may have attention at a later date. These should have water afforded them whenever they become dry, and well rooted plants will benefit from weak liquid manure given the roots occasionally.

**Temperatures.**—As the days lengthen, and the sun has more power, the temperatures of the different houses should be gradually increased; at the same time the atmospheric moisture should also be increased.

will develop readily in such conditions, and when suitably established may be potted singly. This plant is subject to attacks of red spider, and white fly is also very partial to it; in view of this fumigating or spraying with an insecticide will be necessary on frequent occasions.

**Salvia leucantha.**—Cuttings of this strikingly pretty *Salvia* may be inserted in small pots. This species roots readily in very cool conditions. Although very rarely met with, this Sage produces flowers over a very long period and makes a useful plant for grouping with foliage and other plants indoors. When rooted the plants may be grown on in 7-inch pots, using a compost of loam, leaf-mould and manure from a spent Mushroom-bed.

**Primula obconica.**—A sowing of one of the best strains of this *Primula* should be made now. From this sowing fine plants may be had in flower during the early autumn and winter; in fact, *P. obconica* may be termed a perpetual greenhouse flowering plant, for, fed judiciously, it will continue to flower throughout the year. The sprays of flowers are invaluable for use as cut blooms in vase decoration.

## FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Lieut.-Col. SPENNER CLAY, M.P., Ford Manor, Lingfield, Surrey.

**Pot Vines.**—Yearling vines that were cut down to two buds last month and kept dry in a cool house may now be placed in heat, where they must be gradually moistened to cause them to break into growth before they are shaken out for repotting. If the cut surface received a dressing of styptic, little or no bleeding will take place. When the shoots have grown from one to two inches long the strongest and most promising plants should be selected for repotting. Meanwhile prepare a suitable number of 11-inch pots, and get the crocks and compost ready for use. All composts in which hone-meal or other highly concentrated stimulants form a part are greatly improved by lying for two or three weeks in a dry, warm potting shed or vinery before they are used.

**Fruit Trees in Pots.**—The chief points to observe in pot fruit culture are to grow the trees in a light, well ventilated house, with at least one row of 4-inch pipe running around the interior, and to have healthy thoroughly established trees that have filled their pots with roots at the time the plants are taken in for the mildest forcing. Experienced gardeners buy maiden trees, pot and grow them on, and in this way prepare them for forcing. Amateurs lacking the convenience to do this may purchase mature trees specially prepared by the nurseryman. None but the very best sorts of each kind should be grown under glass, and the grower will do well to duplicate some of the best varieties. The secret of success in growing hardy fruits in pots lies in preventing a high temperature or close atmosphere when the weather is fine, and seeing that the temperature does not fall below 40° in severe weather. Those who observe these conditions with the usual cultural attention should succeed in forcing pot fruit trees successfully. Pears and Apples may be quickly increased in size, once the pips are formed, by closing the house for three or four hours on fine afternoons.

## THE KITCHEN GARDEN.

By JAMES E. HAZHAWAY, Gardener to JOHN BRENNAN, Esq., Baldersby Park, Thirsk, Yorkshire.

**Parsley.**—To maintain a good supply of Parsley leaves a succession of sowings should be made throughout the season. The first sowing should be made in boxes filled with soil sifted through a half-inch sieve and placed in a gentle heat. Covent Garden Garnishing is one of the best varieties.

**Red Cabbage.**—Where the autumn-sown Red Cabbages have not been a success, a sowing of Dwarf Blood Red should now be made in boxes and the seedlings brought on in gentle warmth. These seedlings will form good heads by the autumn.

**Jerusalem Artichokes.**—As soon as the soil is in a favourable condition this crop should be planted on ground manured the previous season. The tubers should be planted 4 in deep and in rich land, in rows made 3 ft. apart, allowing 2 ft. between the tubers in the lines. Sutton's White is the best variety. Artichokes are very accommodating subjects, and will thrive in corners where not much else will grow. They should be planted much more extensively, especially by cottagers.

**Asparagus.**—Where new beds are required it is a good plan to sow seeds in thumb pots and raise the seedlings in gentle warmth. Place about two seeds in each pot; by this method strong plants will be available for planting in the beds in May.

**General Remarks.**—The weather during the week has been favourable for ground operations and all trenching and digging should be completed at the first available opportunity.

## NEW OR NOTEWORTHY PLANTS.

## AGAPETES MACRANTHA.

THIS is certainly one of the most beautiful of the tender *Vacciniads*, a class of plant that is now rarely seen in gardens. The flowers have a very attractive appearance, and a good description of them is given by the late Sir William Hooker in his remark that "in texture and marking they resemble some handsome piece of china or porcelain." I have rarely seen a more lovely plant. The individual flowers are larger and handsomer than those of *Thibaudia pulcherrima*, which was at one time looked upon as the prince of East Indian *Thibaudias*, both these plants at that time being included in the latter genus, but under more recent revision the Asiatic species are referred to the genus *Agapetes*, while the *Thibaudias* are all American.

The flowers of *Agapetes macrantha* (Fig. 49) last a long time; they are 2½ inches long and

but, unfortunately, like so many others, it is seldom met with outside botanical collections.

When in flower, this plant immediately attracts attention with its broadly ovate, acuminate spathes, 4 inches long, which recurve after opening, and are of a beautiful yellow colour inside and out, with a large, suffused purple blotch at the base. The spadix is 1½ inch long, the upper third being free and densely clothed with hexagonal anthers that are shortly columnar, the lower two-thirds densely clothed with ovaries which are hemispherical and two-celled, with a five-angled discoid stigma surrounded by five to eight short clavate staminodes.

The leaves are oblong-ovate, acuminate, peltate, concave, with distinct notches at the base and a strong midrib which proceeds back as from the insertion of the petiole; the upper surface is dark green, while the under surface is glaucous green, with two large purple blotches between each pair of nerves, which

FIG. 50.—STEUDNERA DISCOLOR, HORT. BULL.

1 inch in diameter, and produced on the woody parts of the stem, two or three peduncles sometimes springing from the same point. The peduncles are red, and thicken from the base up to the flower. The corolla is white and five-angled; between the angles are numerous distinct, oblique, wavy, red lines, more or less V-shaped; the mouth is contracted, while the five acute lobes are reflexed. The stamens and styles are exerted, the styles being longer than the stamens. The somewhat leathery leaves are lanceolate acuminate, quite entire and glabrous.

*Agapetes macrantha* was first raised in this country by Messrs. Veitch, of Exeter, from seeds received from the Kola Mountain, Moulmein, and sent by the well-known collector, Mr. Thomas Lobb. It is sometimes spoken of as being sub-epiphytic, but here at the Botanic Gardens, Cambridge, it is easily cultivated in peat in a pot, just as in the case of *Pentapterygium serpens*.

## STEUDNERA DISCOLOR, HORT. BULL.

THERE are numbers of Aroids that are worth a place in the warm greenhouse, and the subject of this note is certainly one of them.

makes the plant very decorative as a foliage subject.

*S. discolor* (Fig. 50) is often confounded with *Stendnera colocasieafolia*, and sometimes known by that name, but *S. colocasieafolia*, C. Koch, described and figured in Regel's *Gartenflora*, Vol. XVIII., page 325, t. 633, and in *L'Illustration Horticole*, Vol. XIX., t. 90, is quite a distinct plant in many respects, the spathe being yellow on the outside and a rich purple brown within, with only two staminodes and the ovary is five-celled, while the leaves are scarcely notched at the base and are green on both sides. *Stendnera discolor* is said to have been introduced from India, but probably is not indigenous to that country, for, according to Koch and Regel, it is a native of South America and was first imported by Linden, while the other species, and the genera most nearly allied to *Stendnera*, belong to Schott's section, or tribe, *Asterostigmeae*, which are for the most part American, although *S. discolor* is said to closely resemble in the form of foliage *Colocasia alinis* var. *Jenningsii*, which is found in the Khasia Mountains. F. G. Preston, Cambridge Botanic Gardens.

**EDITORIAL NOTICE.**

**ADVERTISEMENTS** should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, W.C.2.

**Special Notice to Correspondents.**—The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.

**NOTES ON MYCORRHIZA PLANTS.**

**A**LTHOUGH partnerships of one kind or another are so familiar, the frequency of such associations in the plant world and their resemblance to those known to us in the social and political worlds, is probably little realised. In the case of many associations between plants, especially those between green and non-green plants, the original relation was not improbably one of attack and defence; from this has been evolved the more or less stable condition frequently described as symbiosis and regarded as involving a state of mutual benefit between the partners.

It is proposed in this and a succeeding article to give some account of what has been revealed by recent research about those curious and unexpected partnerships between vascular plants and fungi known to botanists as mycorrhiza.

It is well known, not only to botanists, but also to practical gardeners, that the roots of many plants are beset with fungus threads or hyphae. The mycelium may invest the tip and the younger part of the root, forming a conspicuous sheath from which project numerous thread-like hyphae, as in the Beech and many of our forest trees, or it may ramify sparingly upon the surface of the root and penetrate deeply into the living tissues. When thin slices of such roots are examined microscopically, it is often difficult to realise that the tissues are indeed those of a healthy plant, so vigorous is the development of the fungal invader. This remarkable combination of root tissue and fungus in healthy plants was named mycorrhiza by Frank nearly half a century ago, and to this botanist and his immediate successors we owe much detailed knowledge of the occurrence of the condition among flowering plants and the distribution of the fungus upon and within the root tissues.

Frank and his colleagues distinguished rather sharply between the condition common to so many forest trees, in which fungal hyphae form a conspicuous sheath about the tip of the root, penetrating the tissues slightly or not at all, and that found in plants such as Orchids, in which mycelium is scantily developed upon the outside of the root but deeply distributed in the tissues. Extreme forms of the two conditions certainly occur, although it is somewhat doubtful if they are so sharply distinguished from one another as was believed when Frank named them respectively ectotrophic mycorrhiza and endotrophic mycorrhiza. What impressed the earlier workers was the invariable presence of mycorrhiza in the roots of plants belonging to certain families, and the fact that the relation between vascular plant and fungus was evidently very different from that which exists when a parasitic fungus invades the tissues of a flowering plant and gives rise to the symptoms of disease.

Speculation naturally followed as to the physiology of the relationship. For long, nothing was known of the systematic position of the fungi concerned, since they do not form spores when growing in and upon roots, and the isolation of any such fungus from the root with which it is associated has only recently been accomplished. On the other hand, sections of the roots of Orchids and certain other plants when examined microscopically yielded evidence pointing to an exchange of food material, and the view became current that mycorrhiza was a manifestation of so-called symbiosis between flowering plants and various fungal species, i.e., that in each case the two organisms were growing together in an intimate partnership involving exchange of food materials and some degree of mutual benefit.

Since mycorrhiza is specially characteristic of the roots of woodland and other plants frequent-

ing soils rich in organic remains, and since there is great competition in such soils for water and mineral salts, the somewhat obvious suggestion was made that the fungus partner aids in absorption of water and mineral salts from the soil.

Until quite recently it was assumed by botanists that the fungi present entered the roots from the soil, and experiments were put on record which were believed to show that plants which normally formed mycorrhiza did not do so and did not thrive when planted in soil which had been "sterilised" in such a way as to destroy the mycelium, or spores present.

Beyond the fact that an exchange of nutritive materials obviously takes place in certain cases in which there is ocular proof of digestion of mycelium by the cells of the invaded root, little or nothing has been known with certainty of what may be called the bionomics of these plant associations. Working partnerships of this kind between plants so different in their food requirements and mode of life as vascular plants and fungi must always be of great interest to the biologist. Recent discoveries bearing on the nature of the "symbiosis" which exists in certain mycorrhiza plants are not only of great scientific interest, but have a practical bearing on horticulture, inasmuch as they relate especially to two groups of commonly cultivated plants—the Orchids and the Heaths.

The discovery of the real state of affairs in Orchids at once threw light upon the difficulty experienced by growers in raising plants from seed and the favourable effect produced by mixing small pieces of root from the parent plant in the seed pans, a procedure long familiar to practical men.

In the mycorrhiza of Orchids, hyphae occur sparingly upon the outside of the roots; within, the tissues are extensively invaded by mycelium, which penetrates to the very limits of the vascular tissue in the centre of the root. Certain cells show the fungus in an active condition, others contain only a dense mass of structureless material. It is not difficult to relate these two types of cell one to another by others showing an intermediate condition and to satisfy oneself that in the first case the fungus is growing freely at the expense of a supply of starch and other food materials obtained from the Orchid plant, while in the second case the tables have been turned, and the root cells have digested the mass of mycelium contained in them. Now recent researches have shown that invasion of the roots of Orchids is not due, as was formerly supposed, to a casual infection from the soil in which the seedling Orchid plant is growing. More interesting still is the fact with which we are now familiar, that infection by the root fungus ordinarily is essential for development of the embryo within the seed into an Orchid plant.

When the minute seeds are taken from an unopened Orchid fruit, they are free from contamination by any other organism. When sown under controlled conditions on a sterilised substratum they do not develop a seedling plant unless the fungus present in the roots of the parent is also introduced. The stage of development which can be reached by the seedlings without this preliminary infection varies with the species of Orchid. It may be a very early one or extend to the formation of a couple of leaves. In the vast majority of Orchids root-formation awaits the signal of infection and does not occur without it. Failing infection at the stage critical for each species, development ceases and the embryo perishes prematurely.

The root-fungi have been isolated from the roots of many Orchid species, their behaviour on different kinds of artificial media is known, and their manner of forming spores when grown independently outside the plant. As a rule, only the fungus strain present in the root can induce development of the seedling in any given species, and in this and many other ways is indicated how advanced is the degree of adaptation between the two partners. Let us now review what is known of the nutritive relations of the two partners in Orchids.

It is clear that the fungus can profit by a supply of sugar and can thus indirectly tap

sources of supply otherwise inaccessible except to green plants. Since it is not possible to raise an Orchid plant without its appropriate fungus, it cannot be proved definitely that absorption of water and salts by the plant is really facilitated by the distribution of the fungus within and without the roots. On the contrary, it seems clear that the green plant can profit by the wholesale digestion of hyphae which takes place in the root-cells, because the fungus can utilise sources of nitrogenous food in the soil and in this way place them indirectly at the disposal of the plant. There is at present no evidence whatever that any of the Orchid fungi can use atmospheric nitrogen as a source of food. It may possibly be assumed that advantages associated with the increased food supply counterbalance the drawbacks attendant upon the indispensable character of the association. The latter will certainly operate as a check upon the spread of any Orchid species in nature, since a seed carried away by the wind can grow into a new plant only under conditions favourable to infection, e.g., in the neighbourhood of roots of the same species.

The bionomics of the partnership is even more puzzling in the case of those curious non-green Orchids, e.g., the Bird's Nest Orchid—which grow in Beech woods and elsewhere. These species are not infrequently rootless, and in no case can they serve as sources of sugar formed from the carbon dioxide in the air. It would seem that here the fungus is the working partner, since it can draw upon the soil humus for both its carbonaceous and nitrogenous food materials. Indeed, in the case of a remarkable Japanese species, *Gastrodia elata*, it has been proved that the Orchid plant is parasitic upon the fungus during part of the life cycle; a turning of the tables indeed! and one, moreover, of the most unexpected kind, since the fungus host is that well-known and troublesome parasite, the Honey Agaric (*Armillaria mellea*).

The *Gastrodia* plant consists of a rootless tuber which periodically throws up an immense inflorescence. Owing to the absence of roots and the corky covering of the tuber, fresh supplies of food material can enter the plant only through the root-like strands or rhizomorphs of the fungus. These invade the tuber in the manner usual to any fungus parasite, but for once have found a victim well able to cope with their activities. Food materials pass into the tuber from the soil mycelium, with which the penetrating strand is continuous, and eventually the whole of the invading hyphae are digested and the soluble products absorbed by the cells of the tuber. Only when this happens can the plant reproduce itself by means of seed. Those tubers which escape infection develop small branch tubers which dwindle in size as the food material contained in the mother tuber becomes exhausted. The behaviour of the seed at germination is not known.

To label these non-green Orchids "saprophytes" is but to advertise our ignorance of the facts. The story of *Gastrodia* gives an indication of the possibilities provided by the relationship, although it is quite probable that each species may have solved the problems of nutrition in a different manner; and when studied experimentally, each may unfold a life history of equal or even of greater interest.

In the light of our present knowledge, it is clear that the satisfactory raising of Orchids calls for control of infection at germination, and that this can best be ensured by bringing seeds into contact with a "pure culture" of the appropriate fungus soon after they are sown. It is satisfactory to learn that this method of culture has already been adopted with excellent results. The most recent researches on the conditions controlling the germination of Orchids tend to show that it may be possible to replace the effect produced by entry of the appropriate fungus by other means, for example, by the addition of certain substances to the substratum on which the seeds are germinating. It remains to be seen whether such methods can be utilised commercially by Orchid growers. *M. C. Rayner.*

**PLANTING GLADIOLUS.**

THESE beautiful bulbous flowers may be planted during March and the beginning of April, the time varying according to the locality and kind of soil. On light, warm soils they may safely be planted now, but in the case of cold, heavy ground, it is wise to defer planting until the end of the present month or beginning of April. On light soils the corms should be placed at least four inches deep; on heavy soils the planting should be done more shallowly and a little coarse sand sprinkled around each corm. There is a wide range of colours to choose from, and the plants are useful for various situations, such as in large beds or borders by themselves, or in groups in the herbaceous border. In the last situation they may be planted for a succession between Paeonias, Oriental Poppies, or other early-flowering perennials. They may also be grown in beds of dwarf shrubs, or in vacant spaces in the front of shrubbery borders. The ground should have been well prepared some-time in advance of planting; and, just before putting in the corms, it is well to lightly fork the surface, after first dusting the surface freely with lime. J. C.

**GARDENING BOOKS AND THEIR DISPOSAL.**

DURING the past two years I have sold hundreds of gardening books, to buy rarer items for my library and to make room for others. The best medium for the sale of these books has proved to be *The Gardeners' Chronicle*, the sales being obtained by advertising in a small way and following up inquiries for other books. As regards the general Press, no paper beats *The Publishers' Circular*.

Readers who wish to dispose of their books must be careful not to ask five or six times as much as they are worth. Thus, to offer twelve volumes of a gardening paper for £7, when the volumes are obtainable for 15s. the lot, is waste of both time and money. I have refused thousands of offers of books which, if prices had been "possible," I would have taken, and much time is wasted in needless correspondence with those who do not wish to dispose of their books except for a small fortune.

Some idea of suitable prices for works readers often wish to dispose of is given below:—*R.H.S. Journal*, 1s. each part, or 3s. a volume unbound. For bound volumes, in the usual poor condition (needing rebinding), 5s. a volume is the maximum. *The Gardeners' Chronicle*, unbound, sale practically nil. Bound and complete before 1900, 4s. to 5s. a volume maximum; after 1900, 6s. to 7s. 6d. For completing sets there is a market for single volumes up to 15s., but they must be "very much wanted." *The Garden*, early bound volumes, 2s. 6d. each, later 4s. to 5s. each, for quantities much less. *Horticultural Society's Transactions*, 1820-26, about 25s.; badly soiled incomplete sets much less. Bunyard's *Fruit Garden*, if for re-sale, 25s. to 30s., otherwise up to £2 for clean copies (not £4 as sometimes offered). *Thompson's Gardeners' Assistant* varies in price. Old sets are sometimes valued as low as 30s.; good clean recent sets fetch £4 to £5. Old *Floral Magazines* about 2s. 6d. each, sometimes less. These very often have missing plates, and are then quite unsaleable. *Cottage Gardener*, complete, 1s. a volume, sometimes up to 2s. 6d. *Lowe's Ferns*, 8 volumes 30s. *Nicholson's Dictionary of Gardening* up to £7 for really good sets; no sale at all for parts. *Schlich's Forestry*, if complete, about £4; and *London's Arboretum et Fruticetum Britannicum*, eight volumes, up to 50s.

Many books offered by gardeners are useless, but in some cases such items can be disposed of if the would-be vendor makes up collections containing a proportion of works the public wants. It pays to price big books

low if one wants to turn this class of thing into money. It is possible to come across stray cases where garden libraries are being made up, and where those who are planning them will be glad to take one or more parcels; if not, certain purchasers may buy the useless with the useful and burn the former. The writer has on occasion bought several such collections. Parcels of 25 books for a round sum, say £4, are saleable.

Messrs. Dulau and Co. Messrs. Foyles also buy a fair number. I am on the look-out for about 500 books at the present time, and may be able to relieve readers of some of their rarer works. If these books are offered to dealers, however, take one-third off the prices (and do not quibble about post or carriage extra), so that they may make something on the transaction. Send them full details of title, author, and publishers' name, date

FIG. 51.—PRIMULA MALACOIDES VAR. PRINCESS MARY. R.H.S. AWARD OF MERIT, FEB. 14, 1922. SHOWN BY MESSRS. J. CARTER AND CO. (see p. 83).

Odd parts of periodicals are the worst bug-bears in unsaleables. Collate these and complete them in as long a run as possible, however, and it will be surprising what good prices they fetch.

Failing to dispose of the books by advertising, they should be offered to booksellers, such as Messrs. Wheldon and Wesley, Ltd., and

edition, size, binding, illustration, coloured or plain, number of volumes, and, above all, whether clean or soiled, as these details are essential. Above all, do not work on the principle that those who reply to your advertisements are out to "do" you, otherwise you cannot expect to transact business. A *Book Collector*.

## INDOOR PLANTS.

### EXACUM MACRANTHUM.

(SEE COLOURED SUPPLEMENTARY ILLUSTRATION.)

The subject of the coloured plate presented with this issue is a native of Ceylon, where it is found at elevations of 6,000 ft. It is really a variety of the older *E. zeylanicum*, which was figured in the *Bot. Mag.*, t. 4423, in 1848, while the subject of the coloured plate was first flowered in 1853, and figured in *Bot. Mag.*, t. 4771, the seed being sent from Ceylon by Mr. Thwaites.

There are some twenty species of *Exacum*, natives of India, Eastern Asia, the Malayan Archipelago and Socotra. Of this number, only four or five have ever been in cultivation. The subject of this note differs from the type, *E. zeylanicum*, in its larger and more richly-coloured flowers. The latter are bright blue-purple, with large yellow stamens, consequently a freely flowered plant is a very striking and beautiful object.

It is a matter for regret that *E. macranthum* is a scarce plant in gardens, for since Messrs. James Veitch and Sons gave up business seed has not been offered in any home or Continental list. That this *Exacum* was never a common plant in gardens, is, no doubt, due to the fact that, like many other beautiful plants belonging to the natural order Gentianeae, its successful cultivation is by no means easy. It is best treated as a stove biennial, and grown in a temperature of about 60°, although when in flower it will do well in a warm greenhouse.

The seed is very fine, and should be sown on the surface of the soil, and covered with the merest sprinkling of sand; cover the pots with a piece of glass until germination takes place. It is best to defer sowing until the later part of July, as the smaller plants have a better chance of coming through the winter in good condition and flowering is deferred until the following summer, when weather conditions are all in their favour. The potting compost should consist of one half good fibrous loam, and one half peat, adding some charcoal and enough clean, coarse sand to render the mixture porous. Plants of *Exacum macranthum* require careful watering during all stages of cultivation, especially during the winter months; and I suspect it is in the lack of care in this respect that most cultivators have gone wrong. If kept in a fairly dry atmosphere and artificially pollinated, the flower will set and ripen seeds under cultivation. But although best raised from seeds, this *Exacum* may be propagated by means of cuttings. Among batches of seedlings a pure white flowered form has appeared at rare intervals. Well grown plants should attain a height of eighteen inches.

*E. affine* is a native of the island of Socotra. It is figured in the *Bot. Mag.*, t. 6324, and has small bluish-lilac coloured flowers, which are sweetly scented. It is a small, compact growing species, some six to nine inches high, and is generally classed as a warm greenhouse biennial, but is best treated as an annual, for if seed is sown early in the year, the seedlings will flower towards the end of summer.

*E. tetragonum* var. *bicolor*, figured in the *Bot. Mag.*, t. 1847, is a native of the East Indies.

*E. bicolor*, which has been in cultivation, is, I believe, a rare species, endemic to Ceylon, where it is found at elevations of 5,000-6,000 ft.; the flowers are described as nearly white, shaded with blue. *J. Coultts.*

### ANTIRRHINUMS FOR SUMMER BEDDING.

As the days grow longer and brighter, the thoughts of all garden lovers turn naturally to the arrangement of their flower beds and borders for the coming season; to those who may be in doubt as to what plants would make the best and most effective display all through the summer and autumn at a minimum cost, the following remarks may be useful. Apart from *Pelargoniums* (*Geraniums*), I consider that the

*Antirrhinum* is the most adaptable plant for furnishing a succession of bloom, and a bed of the newer named varieties rivals in brilliancy some of the finest beds of *Pelargoniums*, and the plants certainly withstand the weather conditions of our fickle climate much better. There are three types of *Antirrhinums*; tall, intermediate and dwarf or Tom Thumb, and these may all be grown to advantage in masses of one colour or in ribbon borders. To obtain a display of bloom about the first week in July the seed should be sown at the end of January or early in February. I usually sow the seed in boxes filled with compost consisting of three-parts good sifted loam, one part leaf-mould, and sufficient sharp sand to render the soil porous.

The compost should be pressed moderately firmly in the boxes, leaving the surface level, and well watered the day before sowing the seed. Sow thinly, and cover the seed lightly with a mixture of half fine soil and half sand. Place a sheet of glass over the box and stand the latter in a house or frame having a temperature not over 50°, until the seed germinates.

As soon as the seedlings are large enough to handle, prick them off into boxes about two inches apart. Grow them as near the roof glass as is convenient, admitting plenty of air after the first week. I advise sowing the tall and intermediate varieties a fortnight earlier than the Tom Thumb type.

About the middle of March, place the boxes of seedlings in cold frames and grow the plants on slowly, removing the lights altogether during the day time in dry weather, as the *Antirrhinum* is very hardy, but thrives best when the soil is not excessively wet. With cool treatment it is quite safe to plant *Antirrhinums* in the beds in which they are to flower, the first week in May.

*Antirrhinums* will grow well in any soil, but to get the best results it is necessary that they should be planted in well-prepared soil containing a liberal quantity of well-rotted manure; it is not advisable to use rank or fresh manure. Tread the soil almost as firmly as for an Onion bed and rake the surface level before planting. As subjects for a dry situation there are few plants superior to *Antirrhinums*; the addition of well-rotted dung to the soil will serve to retain moisture about the roots in hot weather besides furnishing food to the plants.

There are so many good varieties to choose from that come true from seed that it is difficult to know which to select, but I have found the following 12 varieties of the intermediate type make a most effective show of colour when grouped in beds: Amber Queen; Bonfire, orange-scarlet; Coccinea, intense orange-scarlet; Cottage Maid, rose-pink with a white tube; Crimson Queen; Prima Donna, apricot, with white tube (an immense flower); White Beauty; Fascination, pink self (a very charming variety); Fiery Belt, brilliant orange with a white tube; Maize Queen; Mauve Queen; and Yellow Queen.

For borders, the finest of the tall section are: Crimson King; Moonlight, apricot with red flush; Cottage Maid, rose pink with a white throat; White King; Torchlight, orange-scarlet with a yellow centre; and Dobbie's Yellow King, the finest *Antirrhinum* of its colour.

To prolong the flowering period, cut away all exhausted flower spikes before they seed. A good plan to prevent robbing the flower beds for house decoration is to plant a bed of mixed varieties in some odd corner of the garden. The flowers from these surplus plants may be used for cut blooms, and will last in water from ten to fourteen days. *Donald Allan, Marks Tey.*

### THE ALPINE GARDEN.

#### PRIMULA GRANDIS.

The specific name of *grandis* has an attraction to many, conveying, as it does, the impression of flowers of massive proportions, or, at least standing out above those of other species by a considerable degree. We are apt to imagine that it is only the flowers which are referred to by

this specific name, forgetting that a plant has other features which might justify the appellation. In the case of *Primula grandis*, the specific name refers to the large size of the heart-shaped leaves. At flowering time, there rises from amid these large leaves a tall scape bearing a cluster of flowers. The plant seems to have exhausted itself in its effort to produce such big leaves and so tall a stem, and has little material left to form flowers at all commensurate with its other features. The tubular yellow flowers hang from long pedicels, but their size is so insignificant that they seem out of place on such a commanding plant. This *Primula* is a native of the Caucasus, and appears to be hardy in this country, but it resents drought in spring and summer. It is most suited for the bog garden, but will grow in a moist border, or, better still, in a low spot at the base of the rock garden, where, planted in peat and loam, it will receive the moisture draining from above. The plant is easily, though slowly, raised from seeds, and is also increased by division. *S. Arnott.*

#### CALCEOLARIA POLYRHIZA.

*CALCEOLARIA POLYRHIZA* has small, curiously-formed yellow flowers and neat leaves. It is of creeping habit, and a stretch of it rambling among the stones of a retaining wall makes a pretty sight in summer when it blooms. Although it has not the large flowers of such *Calceolarias* as *C. plantaginea*, *C. Kellyana*, or the still more tender *C. violacea*, it is a distinct and pretty alpine of easy growth, and hardy well into Scotland. It is increased by division, and seems to prefer a rather peaty soil, moist in summer but rather dry in winter. I have, however, grown it quite well in a dry, sandy loam. It likes the sun, but will do in partial shade. Those who desire a pleasing addition to the usual subjects planted in the crevices of paved paths will find this *Calceolaria* valuable for the purpose. *S. A.*

### THE PROBLEM OF IMMUNITY TO WART DISEASE IN POTATOS.

IN the summer of 1917 a number of Potato seed balls were collected from large crops growing in Scotland. In each case the fruits were taken from near the centre of large areas, the presumption being that the flowers would be selfed and would not be cross-fertilised, at least by any other varieties. In the spring of 1918 the seed was sown, and in the autumn the tubers produced by each seedling were saved. In the spring of 1919 the best half-dozen or so tubers of each variety were planted in the workhouse grounds at Ormskirk. They were lifted at the end of September, and accurate records made as to their immunity from Wart Disease. The records were mislaid after Mr. John Snell's death, but they were recently found and forwarded to me by Mrs. Snell. They consist of 163 pages of notes on nearly 500 seedlings. The following are the most interesting, and, I think, indicate that a Potato will be found that will breed true to immunity from seed:—

Number of plots.	Parent of Seed.	Number clean	Number affected with Wart Disease.	Doubtful or failed.
29	President ...	14	15	—
8	Priory Queen ...	8	—	—
17	Favourite ...	14	2	1
29	Climax ...	26	2	1
38	Templar ...	28	5	5
62	Admiral ...	43	5	9
63	Majestic ...	38	22	3

Priory Queen, Favourite, and Admiral are all varieties of the Abundance type, and carry a strong resistance to Wart Disease. Had Mr. Snell been spared, the work would, no doubt, have been continued on these lines. *W. Cuthbertson, Duddingston, N.B.*

## THE GREAT DROUGHT OF 1921 AND ITS EFFECT ON GARDEN PLANTS.

(Concluded from page 80.)

LONDON.

It is, no doubt, difficult for some of us whose interest lies in the land to realise that the great heat and drought of 1921 may be for the general good.

Large trees suffered for want of moisture, to say nothing of field and garden crops, herbaceous plants and shrubs, and the presence of hordes of insect pests. But underneath all the temporary loss and inconvenience there lies a very deep vein of good, which, I think, ought not to be lost sight of. Perhaps one of the most potent reasons for satisfaction lies in the effect of the sun's hot rays on the physical condition of the soil. On fallow land, that which was sparsely cropped, and to a limited extent on land which was fully cropped, the effect was similar to that brought about by winter frost, and the more nearly the soil approximated to clay the more was this effect noticed. If the surface of heavy land is kept loose, cracking of the soil will never be a formidable danger.

The sweetening of the soil during such a period must be a real gain to much cultivated land, while many enemies failed to survive such a course of drought as we were subjected to. I am convinced that many ground insect pests are dependent on at least a certain degree of moisture to enable them to move about easily and multiply, if not quite dependent on it to live. Moreover, these pests are searched for, in a droughty period, much more intensively by the birds which prey on them, for at such times birds have a difficulty in finding sufficient food. In this connection one often observes a disturbance by birds in places they do not trouble to search at times when their quarry is found by much less intimate searching.

Hot and dry conditions are very trying to all forms of vegetation, but there is little doubt in my mind that in the long run they may be very beneficial to the cultivator, enabling him to get better returns afterwards for his labour. *E. J. Platt, Parkfield Gardens, Highgate.*

### DEVONSHIRE.

THE remarkable amount of sun-heat during 1921 enabled many tropical plants to blossom in the open air which are not often seen in perfection in our gardens. This is especially true of the scarlet Pomegranate (*Punica Granatum*), which opened many brilliant, waxen blooms of the brightest scarlet here in the open garden. The plants grow in a sheltered corner facing the south-west, in South Devon; but if grown in an embrasure between two sunny bow-windows, or on a south wall, this beautiful plant will grow in colder parts of the kingdom if the site be well-drained and fully exposed to sunshine. As it drops its leaves rather early (i.e., as soon as the weather becomes frosty) and remains in a bare state until the following May, it is not often injured by a late frost; it blossoms every year in the writer's garden from August to the beginning of October, although not always in such profusion as in 1921. *I. L. Richmond, Lustleigh.*

### LEICESTERSHIRE.

THE interesting articles on the effects of the dry season of 1921 raise the question as to what effect the hot, dry weather will have on all kinds of vegetation during the season now opening? Hardly a week passes but that some unusual change in plant life is observed. I am sure it will prove highly interesting and instructive to take careful note of the progress of vegetation in gardens. Fruit trees that were planted on good soil and carefully tended do not appear to be much the worse for the hot weather, in fact, there is less wood and more fruit buds. Pears and Plums were scarce last season, no doubt owing to frosts when the trees were in bloom. The weather during the first two months of 1921 was unseasonably warm,

hence the flowers were too far advanced to withstand the cold spell. Apples escaped, and there was a great crop. This year, all fruit trees are full of fruit buds, and promise another good crop, and as we have not had what is called a "summerish January," we may hope for a mild spring and the opportunity for fruit blossom to set properly.

Many Apples produce good crops in alternate years, and as last year was an "Apple year," it will be interesting to note if these particular trees produce a good crop two years in succession. They certainly look as though they will do so. I have never seen so many fruit buds on our Pear trees before, and conclude the past season is responsible for this. This year's report on the fruit crops will, no doubt, give us many surprises.

I should have thought berry-bearing shrubs would have been likewise affected, but, evidently, this is not always so. Some bushes of *Berberis Wilsonae* growing on a partly-shaded border were loaded with berries, while others in full sunshine had none at all, neither did they make so much growth. *Chimonanthus* fragrans on a south wall has flowered abundantly for several weeks, and I gathered a quantity of seed, which is encased in large green pods. Our plant has flowered before, but never produced seed. *Rhododendrons* look exceedingly promising, especially those that were well watered, and all are well set with buds. *Azaleas* planted in partial shade are covered with buds, while those in exposed places are almost without any. It was exceedingly difficult to soak the roots of these latter specimens with water, as the peaty

FIG. 52.—ARGYRODERMA ROSEATUM, N.E. BR. NATURAL SIZE.

soil became so hard; however, of about a hundred plants, we were fortunate enough not to lose one.

The hot weather of 1921 assisted the ripening of seeds. Such seeds as have been sown here have germinated quickly, and I should say, this will be true of all kinds of seeds, and especially those of outdoor subjects. *R. W. Thotcher, Carlton Park Gardens, Market Harboro'.*

## MESEMBRYANTHEMUM AND SOME NEW GENERA SEPARATED FROM IT.

(Continued from page 93.)

3. *A. roseatum*, N.E. Br. (Fig. 52). Plant solitary, or perhaps tufted with age? Leaves 2-6 to a plant or growth, but probably in nature only 2-4, with the inner pair sub-erect, united below for nearly half their length and but slightly separated above, with the inner face flat; 4-6 lines long and 5-6 lines broad, broadly ovate, sub-acute, with sharp edges, and the back very rounded and distinctly keeled at the apical part, which is not prolonged beyond the flat face, about 4-5 lines thick; surface very smooth, white, prettily tinted with rose, especially at the margins and keel. Flower and capsule unknown.

Little Namaqualand: Locality and collector unknown, possibly from the vicinity of Warmbad.

I obtained this distinct and very pretty species from the late Mr. W. J. Doree, but have no other information concerning it. In size and form it somewhat resembles *A. subalbum*, but

the rosy tint of its leaves at once distinguishes it from that and all known species.

4. *A. necopinum*, N.E. Br. Plant tufted with age. Leaves 6-12 lines long, 5-9 lines broad on the flat face, and 3-6 lines thick, deltoide-ovate, obtuse, the dorsal part not or but shortly produced beyond the flat face, obtuse, faintly keeled. Flower sessile between the leaves, with two compressed bracts under it. Calyx 6-lobed; tube obconically campanulate, about 2 lines long and 2½ lines in diameter; lobes 1-2 lines long, ovate or oblong, obtuse, green with membranous margins. Corolla 7-9 lines in diameter; petals numerous, in 2-3 series, widely spreading, 3-4 lines long, linear, bright yellow. Stamens very numerous, in a dense ring at the top of the calyx-tube. Stigma less than 1 line in diameter. *M. necopinum*, N.E. Br. in *Journ. Linn. Soc. Bot.* v. 45, p. 90. *M. testiculare* var. *v.*, *Haw. Misc.* p. 24, and *Synop.* p. 205. *M. octophyllum* var. *β*, *Haw. Rev.* p. 85.

Locality unknown. Introduced by Masson, and by Pillans.

\*\* Leaf distinctly much longer than broad, with the edge of the flat face blunt or somewhat rounded and somewhat cartilaginous, and when decaying often becoming reddish-tinted.

5. *A. duale*, N.E. Br. Plant tufted with age. Leaves with the flat or slightly convex face 4-10 lines long and 3-6 lines broad at the base, thence tapering to a more or less acute point or narrowly oblong and obtuse, with the dorsal apex sometimes produced shortly beyond it, slightly keeled, up to 4 lines thick. Flowers unknown. *M. duale*, N.E. Br. in *Journ. Linn. Soc. Bot.* v. 45, p. 89. Van Rhynsdorp Division: on ridges near Bakhuis, Pearson and Pillans, 54E3.

This species is very similar to *A. necopinum* in general appearance, but readily distinguished by the blunt, somewhat cartilaginous edges and keel of the leaves. It has not yet flowered with me.

### DOUBTFUL SPECIES.

Possibly the plant I described as *M. socium* (*Journ. Linn. Soc. Bot.* vol. 45, p. 91) may belong to the genus *Argyroderma*, but I have not yet seen its flowers, and the skin of the leaves does not seem to be of quite the same texture. It is a small species, quickly forming a tuft, with half-cylindric, suberect leaves 3-10 lines long, 3-4½ lines broad, and 2½-4 lines thick, obtusely rounded and faintly keeled at the apex, whitish-green tinted with rose when exposed to the sun.

Another plant that may also prove to belong to this genus is *M. octophyllum*, *Haw. Rev.*, p. 85, excluding the reference to the figure of *M. testiculare* in the *Botanical Magazine*, t. 1573, and all varieties. From Haworth's descriptions of this plant (which is as follows, "Leaves on the living plant 6-8, oblong-ovate, half-terete, more erect than those of *M. testiculare*") it is impossible to form an opinion of it, especially as he quotes the *Bot. Mag.* figure as belonging to it, which is most certainly due to some error, I think probably by Haworth entering the reference by mistake in the wrong place in his manuscript. Fortunately there is a drawing of it preserved at Kew, which is labelled "*M. octophyllum*, *Haw.*, May 7, 1827. Received in 1826 from A. H. Haworth Esq." This drawing, therefore, represents the typical plant of Haworth, and is all that is really known of it. For the only plant I have ever seen of it was in the rich collection of Mr. W. Wilson Saunders at Reigate, about the year 1866, when Mr. T. Cooper called my attention to it and said it was believed to be a descendant of Haworth's original plant. That plant, to the best of my recollection, was the same as in 1873 I found to be represented in the Kew figure. It is a tufted species, each growth with three or four pairs of smooth, whitish-green or whitish leaves about 7-12 lines long, 3-4 lines broad, and 2½-3½ lines thick at the much thickened or dilated apical part, which is twice as thick as at the base, flat on the face, very convex on the back, and keeled at the apical part. Flowers sessile and yellow, according to Haworth. Locality unknown. *N. E. Brown.*

(To be continued.)

## HOME CORRESPONDENCE.

[The Editors do not hold themselves responsible for the opinions expressed by correspondents.]

**A New Kind of Fuel for Heating Green-houses.**—Having seen an advertisement in *The Gardeners' Chronicle* of a new fuel, and as the cost of fuel is a serious consideration in these times, especially where the consumption is a heavy one, I thought I would give the new material a trial. Previously we used anthracite coal and coke, but the new fuel surpassed them in the maintenance of a steady temperature I believe the new fuel contains a mixture of anthracite, coal, and other materials; it is machine-pressed into egg-shaped lumps, and easy to handle. One great recommendation in its favour is the lasting heat it produces, and I believe it will be possible to bank the fire to last several days during the summer months, where a gentle artificial heat is required for the growing of Cucumbers, etc. There are no clinkers; the material burns down to a fine ash, which is of a gritty nature, and valuable as a dressing for heavy land. In addition to the recommendations mentioned, the use of this fuel has effected a very considerable saving on our fuel bill. *J. W. Forsyth, Putteridge, Luton.*

FIG. 53.—STAPELIA GIGANTEA; MUCH REDUCED.

**Stapelia gigantea.**—This very interesting, large-flowered, succulent plant is not often seen in bloom. After cultivating a specimen for six or seven years it has at last condescended to produce a flower, of which I send a photograph (see Fig. 53), in the hope that it may interest those of your readers who are interested in Cacti and other succulents. The flower measured 14½ in. in diameter. *T. Sharpe, Horticultural Instructor, Wiltshire County Council.*

**Musa Cavendishii.**—Your readers may be interested to learn that we have fruited *Musa Cavendishii*, and that our specimen carried a bunch of thirty fruits, one of which I enclose. I think you will agree that the flavour is far superior to that of imported fruits. *Musa Cavendishii* does not occupy so much room as some Bananas, and the specimen referred to was grown in a pot and is about four feet high. I have grown much larger specimens, but never had one fruit before. The plant just fruited was grown in a pot in a compost of equal parts of rotten manure and turfy loam, with a little sand. It is about four years old, and was grown in a house the temperature of which never fell below 50°. *W. Hill (gr. to G. W. Ryder, Esq.), Broadhill, Hassocks, Sussex.* [The photograph

accompanying the above note was unfortunately unsuitable for reproduction. The fruit received was of particularly fine flavour.—Eds.]

**Trapping Mice and Voles.**—At this time of the year, when bulbs are coming up and gardeners are beginning to set their house in order, it is very necessary to deal with mice. I believe that the damage market gardeners suffer from mice throughout the country must run into many hundreds of thousands of pounds, and the greater part of this waste could be saved by careful trapping. My own experience, which extends over very many years, has taught me that by the use of a balance trap it is possible to deal with the spring invasion and to keep vermin in check. For forty years past I have used the old Colin-Pullinger Trap, as made by the late inventor. Four traps kept set in a garden, with woods and meadows adjoining, have caught annually from 200 to 400 field mice and bank or field voles. Perhaps it might be of interest to your readers to learn something of the simple precautions that experience has taught me to adopt. In the first place, the trap stands on a piece of slate or a thick piece of wood about an inch wider than the trap itself, and covered with an inverted lidless box large enough to leave a space of four inches or more above and around it. This affords the concealment which mice like, and also protects the trap from the weather, and allows it to work effectively, as mine has done for twenty years or more. The bottom of the box needs to be covered on the outside with oil-cloth or sheet metal to keep out the wet. Pieces of wood projecting about an inch and a half, and nailed at each corner for supports, serve to keep the box raised from the ground. I use no other bait than a drop of oil of aniseed on a piece of flannel on the bait rack. This is renewed by the garden boy every fortnight. The trap, being a balance trap, is always set, and I find that most voles and field mice are caught on a wet night. If market gardeners and the many amateurs who delight in raising choice flowers, and often find their best efforts spoilt by mice, would care to follow my plan, they would be able to carry out their work in complete security. Certainly as a result of my own efforts I am able to raise garden produce without molestation, even in years when the number of field mice assumes the proportion of a plague. The increased number of allotments has favoured the spread of these troublesome pests in many parts. *Mark Hovell, Lemsford House, near Hatfield, Herts.*

**Topiary as an Aid to Advertising.**—Garden-lovers who have a leaning towards topiary work, have now an opportunity of turning their surplus, trimmed trees to account. A London firm of advertising agents has formulated a scheme by which Yew trees, grown and clipped to resemble animals, birds or other objects, may be utilised as an adjunct to advertisements of food-stuffs, beverages, polishes, pocket pens, and other commodities in general demand. The idea is that suitably-shaped Yew trees, bearing the name of the manufacturer, his branded goods or trade-mark, are to be planted alongside railway lines, near popular highways, or on suitable sites in cities, to call attention to the wares so advertised. Thus, for a brand of tinned milk, butter or cheese, they offer the figure of a cow; for eggs—presumably of the preserved variety—they have Yews shaped like a hen, or a duck; while for a certain make of margarine, they propose trees cut to resemble a pheasant. Yew trees can easily be grown in an open, circular form, which, resembling a life-buoy, would obviously fit a certain brand of soap which rejoices in that somewhat incomprehensible sign as its cognomen. Figures of swans, again, are easily trained in Yew, and trees so shaped would

serve to advertise a certain fountain pen. So great is the variety of forms of these clipped trees that the promoters of the scheme profess their readiness to supply suitable shapes for practically any article now prominently placed before the public. The charges vary according to complexity of the design. This novel method of advertising obviously opens up a new market for specimens of the topiary art. *E. W. R.*

**Mistletoe on an Almond.**—Since writing you *re* Mistletoe, two years ago, I have noticed a strong clump of the parasite on an Almond; it is the first case of a stone fruit having Mistletoe on it that I have met with. *Geo. W. Stacey, The Gardens, Chorleywood Cedars.*

## SOCIETIES.

## MANCHESTER AND NORTH OF ENGLAND ORCHID.

FEBRUARY 16.—*Committee present:* The Rev. J. Crombleholme (in the chair), Messrs. B. J. Beckton, J. Birchenall, A. Coningsby, D. A. Cowan, J. C. Cowan, J. Cypher, J. Evans, J. Howes, A. Keeling, J. McNab, D. McLeod, E. W. Thompson and H. Arthur.

## AWARDS.

## FIRST-CLASS CERTIFICATES.

*Odontoglossum Orestes var. Mary.*—A fine variety, of good shape; the clear, white ground is covered with brown spots and blotches. *Lycaste Skinneri Our Princess:* A large flower, the broad sepals light rose, the petals darker rose, lip claret colour, from Mrs. GRATRix.

*Cypripedium Odin, West Point var. (Antinous × Becktonii).*—The dorsal sepal is white with a green base and dark purple spots up the centre; the petals are yellow, barred with brown; ground yellow, from S. GRATRix, Esq.

*Odontioda Bradshawiae var. Brilliant.*—A large flower of fine shape and well coloured, from A. HANMER, Esq.

*Cattleya Tityus var. The Emperor.*—A large flower with broad sepals and petals coloured dark mauve; the lip is deep purple and the side lobes yellow, from P. SMITH, Esq.

*Cattleya Douai var. Prince Henry.*—A large pure white flower of fine shape, from D. LOSH-THORPE, Esq.

## AWARDS OF MERIT

*Cypripedium Hestia Edgenoor var., Odontoglossum amabile Princess* (crispo-Harryanum × crispum); *O. Iphis* (harvingtense × Queen Alexandra), all from A. HANMER, Esq.

*Cypripedium Pyramus West Point var.* and *Lycaste Skinneri Perfect Gem*; both from S. GRATRix, Esq.

*Cypripedium aure-Euryades var. Whitecap.*—From the Rev. J. CROMBLEHOLME.

## CULTURAL CERTIFICATE.

To G. GILES for a fine specimen of *Odontioda Bradshawiae var. Brilliant.*

## GROUPS.

S. GRATRix, Esq., West Point (gr. Mr. J. Howes), was awarded a Silver-Gilt Medal for a group. The Rev. J. CROMBLEHOLME, Clayton-le-Moors (gr. Mr. E. Marshall), staged a group for which a Silver Medal was awarded.—Messrs. CYPHER AND SONS, Cheltenham, were awarded a Silver Medal for a collection.

## CARDIFF GARDENERS'.

A MEETING of the above association was held on February 14th at the Queen's Hotel, Cardiff, Mr. M. Toy presiding. A paper on "Spring Bedding" was read by Mr. A. E. Gibson, of Llanishen. Prizes for the best six pots of encrusted varieties of *Saxifraga* were given by Mr. W. Rockey, and there was an interesting competition. The first prize was won by Mr. G. Wilkins; second, Mr. P. Myers; third, Mr. Fry.

## ROYAL HORTICULTURAL.

FEBRUARY 28.—Those who turned aside from the surging crowds after Princess Mary's wedding on Tuesday, and paid a visit to the Royal Horticultural Hall, were amply repaid. Although the exhibition was not an exceptionally large one, it was bright and spring-like, as Tulips, Daffodils, Crocuses and Hyacinths were well displayed, in addition to other early flowers. The Orchids were, however, the great feature of the exhibition, and the outstanding feature among these flowers was the superb exhibit of new, home-raised *Cymbidium* hybrids from Sir GEORGE HOLFORD. The Orchid Committee recommended a Gold Medal for the group; a Silver-Gilt Lindley Medal to Mr. H. Alexander, the grower, for excellence of culture; and no fewer than eight awards to new and distinct plants in the group. The latter is probably unique; we do not remember any exhibitor having so many awards for plants of one genus on any previous occasion.

Novelties, apart from Orchids, were few in number, and no award was made by either the Fruit Committee, the Floral Committee or the Narcissus Committee.

## Orchid Committee.

Present: Frederick J. Hanbury, Esq. (in the chair), Messrs. Jas. O'Brien (hon. secretary), R. Broonan White, S. W. Flory, Chas. H. Curtis, Fred. K. Sander, J. Cypher, W. H. Hatcher, H. T. Pitt, A. McBean, T. Armstrong, H. G. Alexander, Gurney Wilson, J. Wilson Potter, and E. R. Ashton.

## Awards.

## FIRST-CLASS CERTIFICATES.

*Cymbidium Miranda* var. *Bronze Beauty* (*Lowio-grandiflorum* × *Alexanderi*), from Sir GEO. L. HOLFORD. A superb, yellow-ground variety with bronze hue, and yellow lip with heavy claret marking.

*Cymbidium Redstart* var. *Bright Eyes* (*Dryad* × *Pauwelsii*), from Sir GEO. L. HOLFORD. Flowers of perfect form, milk white with dark ruby-red blotches on the lip.

*Cymbidium Thrush* (*Schlegelii* × *Holfordianum*), from Sir GEO. HOLFORD. Flowers large and finely formed, yellow, beautifully marked with red.

*Cattleya Tityus* var. *Wedding Bells* (*Enid* × *Octave Doin*), from Messrs. SANDERS. A noble variety, and the best of a very favourite class. The very large flowers have rosy-mauve sepals and petals and rich purple lip, with yellow markings on the disc.

*Angulo-caste Sanderæ* (*Anguloa Clowesii* × *Lycaste Skinneri alba*), from Messrs. SANDERS, St. Albans. A charming and distinct bigeneric hybrid with large lemon-yellow flowers, having a darker yellow centre to the lip which has a claret-red blotch at the base.

*Potinara Juliettæ* (*Sophro-Laelio-Cattleya Marathon* × *Brasso-Cattleya-Ena*), a splendid production by Messrs. CHARLESWORTH AND Co., and named after Mons. Potin, President of the Paris Orchid Society. It is a new multi-generic cross. The large *Cattleya*-like flowers have orange-red sepals, with the petals intense reddish-violet, and the white mid-rib displayed at the base. The pretty lip is rich ruby-red with a rose flush and some fine gold lines at the base.

## AWARDS OF MERIT.

*Cymbidium Miranda* (*Lowio-grandiflorum* × *Alexanderi*), from Sir GEO. HOLFORD. Flowers large, greenish-yellow, with dark markings on the lip.

*Cymbidium Redstart* (*Dryad* × *Pauwelsii*), from Sir GEO. HOLFORD. A perfect, light rose flower with darker lines, and claret markings on the lip.

*Cymbidium Curlew* var. *Rosy Gem Butterfly* × *Alexanderi*), from Sir GEO. HOLFORD. Flowers of a good, clear rose-colour, with darker markings and bronze-red blotches on the lip.

*Cymbidium Kittiwake* (*Gottianum* × *Dryad*), from Sir GEO. HOLFORD. A fine, clear white flower with ruby-red markings on the lip.

*Cymbidium Butterfly* (*Lowio-grandiflorum* × *insigne*), from Sir GEO. HOLFORD. A beautiful yellow hybrid, with red markings on the lip.

*Sophro-Laelio-Cattleya Mars.* (*S.-L.-C. Marathon* × *C. Clotho*), from Messrs. ARMSTRONG AND BROWN, Orehidhurst, Tumbidge Wells. A fine, purplish-red flower, with a heavy purple band on the petals, and a rich ruby-purple lip.

*Odontioda Venus* (*Odm. Aglaon* × *Oda. Coronation*), from Messrs. ARMSTRONG AND BROWN. A grand hybrid with the general characters of *Oda. Coronation*, but with larger flowers, which are blush-white, finely blotched with rose.

*Odontioda Cissie* (*Oda. Lambeauiana* × *Olm. King Arthur*), from Messrs. J. and A. McBEAN. A grand, rich red flower, with a reddish-purple blotch on the lip in front of the yellow crest.

*Brasso-Laelio-Cattleya Canada* (*L.-C. Artemis* × *B.-C. Mrs. J. Lecmanis*), from Messrs. CHARLESWORTH AND Co. A remarkable hybrid with large, clear yellow flowers which have a lightly fringed margin to the lip.

*Odontioda Latona* var. *Lilacina* (*Oda. Broadshawiae* × *Odm. crispum-Harryjannum*), from Messrs. STUART LOW AND Co., Jarvisbrook. The plant bore a noble spike of fine flowers, with blush-white ground, heavily marked with claret-red.

## GROUPS.

Lt.-Col. Sir GEO. L. HOLFORD, K.C.V.O., Westonbirt, Tetbury, was awarded a Gold Medal for the grandest group of *Cymbidiums* ever staged, and his gardener, Mr. H. G. Alexander, received the Silver-Gilt Lindley Medal, for the marvellously fine cultural perfection attained, and indicated by the profuse flowering of all the plants, many of which carried five or six grand, arching spikes. The group occupied nearly the whole of the broad staging across the end of the hall, and fine specimens, all raised at Westonbirt, exhibited every shade of colour and variety of form known to the genus. A number of the best are enumerated in the list of awards above, but many well worthy of distinction remained, the richly-coloured *C. President Wilson* being specially selected by the Committee to see again when the flowers were fully expanded. *C. Redstart Purple Gem* and *C. Merlin* var. *Jasper* were also much favoured, but where all were so far beyond the average, selection was difficult.

Messrs. CHARLESWORTH AND Co. were awarded a Silver Flora Medal for a select group, the central plant of which was a grand specimen of *Odontoglossum ardentissimum album*, with a branched spike of seventy flowers. *Neomooera irrorata*, a very rare species, *Dendrobium Bancroftianum*, and a showy selection of *Cattleyas* and *Laelio-Cattleyas*, were also noted in this display.

Messrs. SANDERS were awarded a Silver Flora Medal for a good group of varied hybrids and species, among the latter being an entirely pale yellow form of *Oneidium splendidum* and the fine *Angulo-caste Sanderæ*.

Messrs. STUART LOW AND Co. secured a Silver Flora Medal for a showy group, in which *Dendrobium* and *Sophrontis* crosses were conspicuous arranged with handsome *Cattleyas*, *Laelio-Cattleyas* and *Odontoglossums*. Messrs. J. and A. McBEAN were awarded a Silver Flora Medal for a showy group of *Cymbidiums*, *Odontiodas* and *Odontoglossums*. With the *Laelio-Cattleyas* was a very large golden-salmon tinted *L.-C. Linda*, with a rose flush and richly-tinted lip quite distinct from the several fine forms for which certificates have been obtained by this firm.

Messrs. FLORY AND BLACK, Slough, were awarded a Silver Banksian Medal for a very interesting selection of hybrids, with several good white *Cattleyas*.

## OTHER EXHIBITS.

R. G. THWAITES, Esq., showed the prettily marked *Odontoglossum Meridithiae*. T. A. STEPHENSON, Esq., Aberystwyth, showed a fine collection of beautifully executed paintings of British *Oreohids*. Messrs. ARMSTRONG AND BROWN showed their handsome *Odontoglossum The Prince* (*Colossus* × *Doris*). PANTIA RALLI, Esq., Ashted Park, sent the white *Cattleya Gravesiana alba*.

## Floral Committee.

Present: Messrs. H. B. May (in the chair), W. R. Dykes, W. B. Cranfield, G. Reuthe,

M. Williams, R. C. Noteutt, George Harrow, Amos Perry, Donald Allan, J. F. McLeod, W. Howe, J. Jennings, C. R. Fielder, Hugh Dickson, G. W. Leak, Thomas Stevenson, H. J. Jones, M. C. Allwood, W. B. Giugell, Arthur Turner, Chas. E. Pearson, D. B. Crane, W. P. Thomson, W. G. Baker, W. J. Bean and J. W. Barr.

## GROUPS.

Forced trees and shrubs made several dainty and attractive displays in the hall. Messrs. L. R. RUSSELL, LTD., made a central feature of a group of particularly well-flowered *Wistarias*, and also gave special prominence to the graceful *Prunus triloba*. Various *Lilacs*, *Azaleas*, *mollis* and *indica*, with *Camellias* and a bordering of *Azalea Hexe* were all tastefully arranged (Silver-Gilt Banksian Medal).

Such flowering shrubs as *Pyrus Malus* varieties, *P. spectabilis*, *P. purpurea*, *P. floribunda* and *P. Sargentii* were shown by Messrs. WM. CUTBUSH AND SON in association with an informal rock garden in which the Japanese forms of *Azalea Kaempferi* were represented by well-flowered little specimens. The miniature bush named *Azalea Hidomango*, which was covered with small salmon coloured flowers, was particularly good (Silver Flora Medal).

The earliest Himalayan *Rhododendrons* were shown by Mr. G. REUTHE, who, at the other end of his exhibit, staged a goodly quantity of the decorative *Andromeda japonica*. Amongst a number of alpine groups of *Iris reticulata* and *Narcissus minimus* made bright patches of colour (Bronze Flora Medal).

*Iris reticulata* was also shown in quantity by Messrs. J. CHEAL AND SONS. *Rhododendron praecox* was represented by several floriferous bushes, and these, together with the long catkins on a plant of *Garrya elliptica*, attracted considerable attention. Besides these shrubs, there were many shapely little *Conifers* and some early alpine (Bronze Flora Medal).

Carnations were the subject of several large groups. Messrs. ALLWOOD BROS., LTD., had a very bright display, in which the scarlet *Edward Allwood* was very prominent. Amongst several perpetual "Malmaison" varieties the yellow flowered *Jessie Allwood* was particularly meritorious, and a large stand of mixed sorts was also very effective (Silver Flora Medal).

By the use of artistic earthenware jars in place of the conventional stands and green vases Mr. C. ENGELMANN displayed his excellent Carnations to great advantage. The American varieties *Maine Sunshine* and *Laddie* near the dark crimson *Nigger* were again prominent in Mr. Engelmann's collection (Silver Banksian Medal).

A few very good *Hippeastrums* (*Amaryllis*) were included in an exhibit by Messrs. STUART LOW AND Co., who again showed *Dahne indica* and *Acacia Baileyana* with *A. ovata*, various *Camellia* and *Azalea* varieties (Silver Banksian Medal). A nice little group of well-grown plants of *Primula malacoides* *Pink Beauty*, arranged by Mr. WILLIAM YANDALL made an effective display (Bronze Flora Medal).

Alpines were shown in rather greater numbers than at the previous meeting. Messrs. TUCKER, Oxford, submitted a series of blue and violet purple *Primulas* obtained by crossing *P. Juliae* with *P. Wilson's Blue*; there was considerable variation in length of flower stem and form of flower. *Purple King* and *Brilliant* were two of the best. In a group in the hall Messrs. TUCKER had some attractive plants of *Primula Juliae*, various *Saxifrages*, *Soldanella montana* and the yellow flowered *Anemone ranunculoides* (Silver Flora Medal).

In a well-concealed rock garden Messrs. WATERER, SONS AND CRISP displayed *Adonis amurensis*, many *Crocuses*, *Iris reticulata*, *Iris sibirica* and a dainty bush of *Cytisus White Gem* (Silver Banksian Medal).

The bronzy green foliage of *Berberis dulcis* nana served as an excellent foil to the flowers of *Erica darleyensis* in the collection of Messrs. SKELTON AND KIRBY, who also had various alpine and *Nandina domestica* (Bronze Banksian Medal). Besides various *Saxifrages* and other alpine, with *Ericas* and *Iris reticulata*, Messrs. MAXWELL AND BEALE showed some excellent *Violets*. The blooms of *La France*

were grown under glass, while the bunches of Princess of Wales were from the open ground (Bronze Banksian Medal).

Several vases of attractive Narcissi, including the dainty *N. cyclamineus*, with Hyacinths, were displayed by Messrs. BARR AND SONS. Besides the ordinary Snowdrop, there were bunches of the larger *Galanthus nivalis grandis*. Some attractive Crocuses and Hellebores were also on view (Bronze Flora Medal).

Under the clock Messrs. SUTTON AND SONS had a colour scheme in Crocuses. The shades used were purple and lilac with white, and these made an attractive display. All the flowers were exceptionally large and fresh (Silver Banksian Medal).

From the MAYTHAM GARDENS, Rolvenden, was shown a batch of *Anchusa myosotidiflora*, which attracted a great deal of admiration. The blue Forget-me-not-like flowers were freely produced, and made quite an effective display.

#### Narcissus and Tulip Committee.

*Present*: Messrs. E. A. Bowles (in the chair), J. Jones, G. Churcher, G. W. Leak, F. H. Chapman, W. B. Cranfield, W. R. Dykes, A. R. Goodwin, G. Renthe, Herbert Smith, W. A. Watts, and Chas. H. Curtis (Hon. Sec.).

This Committee made no awards to novelties.

A particularly effective group, composed entirely of Tulips, was arranged by Messrs. SUTTON AND SONS in the centre of the hall. The flowers were set almost on the ground level, arranged in bowls of various size, and in large baskets, over a ground work of black velvet. About fifty-six varieties of Tulips were displayed, and their quality and arrangement well maintained the high reputation the Reading firm has achieved with bulbous plants (Silver-Gilt Flora Medal).

Another capital group was the one from Messrs. R. H. BARR, LTD., and in this display practically every Tulip and Narcissus, in every bowl or pot, was of outstanding merit from the point of view of high cultivation. Tulips Brunhilde and King of the Yellows attracted general attention and merited all the admiration they received (Silver-Gilt Flora Medal). Mr. W. A. WATTS, St. Asaph, showed an early incomparabilis Daffodil named Princess Victoria; it has yellow flowers carried on stems 2 feet long.

#### Fruit and Vegetable Committee.

*Present*: Messrs. O. Thomas (in the chair), E. A. Bunyard, Geo. F. Tinley, S. B. Dicks, W. F. Giles, G. Reynolds, W. Pope, Geo. Kelf, J. C. Allgrove, W. H. Divers, Rev. W. Wilks, and J. Harrison.

Mr. W. POPE, Welford Gardens, Newbury, showed a seedling Apple named Pope's Nonesuch. It is of the Radford Beauty type, has a large, wide eye without any depression, and a stalk about three-quarters to an inch long set in a fairly deep cavity. The fruit is round in outline and heavily flushed with red on the sunny side, the shaded portion being a rich mellow yellow. It is a late-keeping Apple of good quality, and the fruits shown had the appearance of keeping in good condition for another two months or more.

Captain H. B. TATE (gr Mr. A. E. Moss), Billesby Manor, Alcester, Warwickshire, showed a dozen dishes of Hanwell Souring Apple.

An interesting example of Burr-Knot on Apple shoots was brought to the notice of the Committee. This abnormal condition of growth is caused by the development of adventitious roots and might be mistaken for galls caused by woolly aphid. The abnormality gives the name to the old Burr-Knot variety of Apple (syn. Bide's Walking Stick), a good culinary sort in use during October and November. Hogg states in *The Fruit Manual* that "the tree is a close and compact grower, and a profusion of burrs are produced on the branches, which emit incipient roots. If a branch furnished with these burrs is inserted in the ground it will take root and become a tree. The name of 'Bide's Walking Stick' originated from a person of that name having cut a branch from a walking-stick in Cheshire and brought it to his place near Hertford, when, having inserted it in the ground, it took root and became a tree."

## Obituary.

**George Tough.**—We regret to record the death, at his residence, The Neuk, Banchory-Ternan, Kincardineshire, of Mr. George Tough, forester, Crathes Castle. He had reached the goodly age of 74, and was 37 years in the service of Sir Robert Burnett, Bt., and Sir Thomas Burnett, Bt., of Leys, Crathes Castle, Kincardineshire. A highly respected member of the community, Mr. Tough was well versed in his profession, and had under his charge one of the finest and most valuable wooded areas in Scotland. Few, indeed, were the strangers who visited Scotland in quest of information on woods and woodcraft who failed to pay a visit to Crathes Castle Woods, and never did they go away disappointed. Mr. Tough was steeped in the lore of the profession he loved so well, and a day spent with him was an education, and a pleasure not soon forgotten. The large and representative body of tenants and estate staff which followed his remains to the grave showed the respect and esteem entertained for him. He is survived by a widow, six sons and four daughters.

## NEW HORTICULTURAL INVENTION.

### LATEST PATENT APPLICATIONS.

3,639.—Bradbury, B. M. F.—Combined flower holder and watering can.—February 8.

### SPECIFICATIONS PUBLISHED LAST MONTH.

174,521.—McBride, T. J.—Machines for distributing seeds and, or, fertilisers.

167,452.—Witzel, K.—Hand tools for cultivating the soil.

148,560.—Eberhead, R. P.—Process for the manufacture of a natural plant manure.

### ABSTRACT PUBLISHED LAST MONTH.

Insecticides.—Patent No. 172,462.

A new insecticide particularly for use on fruit trees has been invented by Mr. W. Coker of Canberra, Linton Road, Hastings. The insecticide is applied either by spraying or by saturation of rag, etc., wrapped around the trunk. It is made by soaking Tomato plants, after the fruit has been picked, in water, or by expressing the juice therefrom.

Messrs. Rayner and Co. will obtain printed copies of the published specifications and forward on post free for the official price of 1s. each.

This list is specially compiled for *The Gardeners' Chronicle*, by Messrs. Rayner and Co., Registered Patent Agents, of 5, Chancery Lane, London, from whom all information relating to patents, trade marks, and designs, can be obtained gratuitously.

## ANSWERS TO CORRESPONDENTS.

**ARAUCARIA IMBRICATA TIMBER:** *S. R. A.* The wood of *Araucaria imbricata* may be cut up into boards and used much in the same way as the timber of Scots Pine is employed. It should not be allowed to come into contact with the ground unless it is first creosoted. *Araucaria* wood may be used for interior work in buildings or for the making of common

furniture, boxes and many other purposes. It is one of the most widely used soft woods of South America.

**LAWN GRASS SEED:** *Wulfruna.* The approximate weight of seed needed to sow an area of 100 feet by 40 feet, in order to make a good lawn quickly, would be 27 lb. The value of lawn grass seed has increased considerably of late, so that its present price cannot be stated definitely, but we should not expect it to be less than 3s. per lb. The seed may be sown as early in March as the conditions of the soil and weather permit. A dry, calm day should be selected for the sowing, and the suitability of the soil is generally tested by treading on it; if it adheres to the boots, the work should be postponed until it is drier. To ensure even distribution of the seed, it is good practice to set out the ground into strips, three feet wide, with the garden line.

**LILY-OF-THE-VALLEY AS A MARKET FLOWER:** *H. F.* The average prices for Lily-of-the-Valley in Covent Garden market last year were 3s. per bunch for spikes of extra special quality; 2s. per bunch for special quality, and 1s. per bunch for spikes of second grade quality. These grades are known in the market as extra specials, specials and seconds respectively; each bunch contains twelve spikes with a little foliage. These flowers travel best packed in shallow boxes. We know of no special work on the Lily-of-the-Valley.

"BULBS" FROM A PHEASANT'S CROP: *G. A. C.* The "bulbs" are the swollen root stocks of *Arrhenatherum avenaceum* var. *bulbosum*, the Onion Couch. This is a tall growing kind and one of the Oat grasses. The swollen root stocks develop just below the surface of the soil. Each "bulb" is solid, round, and smooth, about the size of a large Pea, and capable of withstanding drought for a long time.

**MUSHROOM GROWING IN A CELLAR:** *L. G. A.* Turn the manure about four times on alternate days in a cold shed, until it is well mixed and the rank gases of fermentation given off into the air. Make the bed about 15 in. deep, ramming the materials as firmly as possible. When the heat has declined to 75 deg. or 80 deg. the spawn should be inserted just under the surface, about 9 in. apart, using pieces about 2 in. square. The surface should then be made firm and cased over with about 1½ in. of fine loam and again made firm with the back of a spade. The bed should not be watered during the first month or six weeks; a covering of two or three inches of long, light litter will help to conserve the moisture arising from the manure. Should water be necessary afterwards, it should be applied through a fine rose over the litter. If you maintain a temperature of 50 deg., a little more or less warmth according to the weather, loss of moisture will be much less marked, and when no fire heat is employed syringing or damping is not necessary or advisable. If you harvest 25 or 30 per cent. of the Mushrooms that show you will have a good crop.

**MUSHROOM HARDENED BY DISEASE:** *W. F.* The specimen received is a somewhat large form of the ordinary cultivated Mushroom, but the gills have become somewhat malformed and drawn away from the stem, as a consequence of an attack of *Mycogone perniciosa*. The disease appears to be in an early stage, as only the verticillium is at present apparent.

**NAMES OF FRUIT:** *T. A. C.* 1, Broad Eye Pippin; 2, Sturmer Pippin.—*D. I.* Winter Strawberry.—*J. H.* Branley's Seedling.

**NAMES OF PLANTS:** *J. M.* The large leaf represents an *Aristolochia*, probably a form of *A. gigas*. The spotted-leaved plant is *Maranta maculata*, and the other is an Orchid.

**Communications Received.**—*G. C.—H. F.—W. H. F.—L. and B.—J. B.—Y. S.—H. M.—R. J.—J. P.—C. F. S.—R. W. R.—T. R. M.—A. F.—A. B. W.—A. G. L.*

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 40.9.

### ACTUAL TEMPERATURE:—

Gardeners' Chronicle Office, 5, Tavistock Street, Covent Garden, London, Wednesday, March 8, 10 a.m. Bar. 30.1; temp. 44°.—Weather—Raining.

### The National Institute of Agricultural Botany.

The second annual report of the Council of the National Institute of Agricultural Botany is a record of achievement of which the Council, and particularly the chairman, Sir Lawrence Weaver, have every reason to be proud. Notwithstanding building difficulties, the Institute has been provided with a permanent and worthy home. The buildings at Cambridge are admirably planned, adequate, at all events for many years, for the manifold work which is carried on there, and, thanks to the good taste of the architect, Mr. P. Morely Horder, they demonstrate that it is possible in the laboratory-type of building to combine utility and grace. As we have explained on a previous occasion, the work of the Institute is two-fold—the improvement of crops and the testing of seeds. Both branches of work call for a high degree of experience and skill, and out of both important advantages to British agriculture and horticulture are bound to accrue. It is, however, to the former branch that general interest will be chiefly directed. The work of this branch falls into several sections, the chief of which are those concerned with Cereals and Potatoes. The methods employed cannot by the nature of the case be quite identical in the case of these two crops. The latter of them stands by itself, and the task of improving the Potato is in the charge of a committee presided over by Dr. Salaman, who has had wide experience in Potato breeding and whose enthusiasm for and devotion to this work are a guarantee that the interests of Potato raisers and growers will be most actively promoted by the Institute. Beside the immunity trials carried out at Ormskirk on behalf of the Ministry

of Agriculture, there have been established by the Institute an important series of maturity trials, the object of which is to gain and impart certain information as to the time of maturing of the chief varieties, particularly those belonging to the early section. Knowledge of this subject, which is of great practical importance, is still very scanty. In the absence of certain information it cannot even be asserted—although it is probable enough—that the times of maturity of given varieties of Potatoes are constant relatively to one another. Visitors to the Royal Agricultural Show, which is to be held at Cambridge this year, will have an opportunity of seeing the methods adopted by the Institute with the object of investigating time of maturing. About one and a half acre of the ground on which the show is to be held has been set aside for demonstrating trial plots of Potatoes, Wheat, and other Cereals. What is to be regarded as the main function of the Institute is to bridge the gap between the producer of a new variety and the commercial exploitation of that variety. Before a new and promising variety can be put on the market, it must be tested thoroughly and a sufficient stock of it worked up. These tasks are heavy and tedious, and it says much for the enterprise of British seed houses that they have in the past been discharged so well. It is by no means the object of the Institute to enter into competition with firms engaged in this work, but rather to provide a means whereby everyone who has a good thing may secure its being put to a searching and authoritative test. Already numbers of promising new varieties of Potatoes are under trial, and so also are several new hybrid, winter, white Oats, which have been raised at the Plant Breeding Institute at Cambridge. The plan to be generally adopted in these trials is to provide, first, a preliminary trial for the purpose of ascertaining that each new variety comes up to a certain standard, and for providing seed grown under known conditions, sufficient for the full trial which will take place in the following year and in several localities simultaneously. We hope that everyone interested in improvement of crops will lend support to the Institute. It is open to all to do so by becoming Fellows of the Institute, and when it is realised that 2,000 Fellows would suffice to provide the Institute with a means sufficient to enable it to carry out its programme in its entirety, we are sure that that number will speedily be enrolled.

**Arnott Lectures at Aberdeen.**—There was concluded on Friday evening, 3rd inst., in Robert Gordon's Technical College, Aberdeen, the annual Arnott course of lectures. Founded a considerable time ago for the benefit of the humbler classes these lectures have ever proved a great success. This year the lecturers and the subjects they dealt with were as follow:—"American Forests," by Mr. Peter Leslie, M.A., B.Sc.; "Insect Gardeners and Flower Lovers," by Dr. Macgregor Skene; and the "Measurement of High Temperatures," by Dr. William Maitland. All these gentlemen held lectureships in Aberdeen University, and with the aid of lantern slides, specimens, etc., worthily upheld the traditions of the Arnott lectures. Naturally, horticulturists predominated in the audiences.

**Scottish Forestry Commission's Work.**—Keen satisfaction is being expressed in the Highlands of Scotland on the good news that, despite the recommendations of the Geddes Committee, the work of the Forestry Commission is to be continued. Lord Lovat, chairman of the Commission, has received intimation that the Government has decided to continue its grant. The sum arranged is understood to amount to about

£220,000. True, this is considerably less than the amount sought, but it will be adequate to enable the Commission's work in the Highlands to be continued. Complaint was made in certain quarters regarding the large allocation to Scotland, but those now carrying out afforestation operations in the north very quickly impressed upon the Government authorities that the Scottish Highlands offered the best opportunities for the successful development of the scheme. Needless to say, the good news will remove apprehensions which existed regarding unemployment and other consequences which might have arisen had the work of the Commission been upset.

**Holland County Potato Show.**—The Holland County Potato Show is to be held in Boston on Thursday, October 26, 1922. All the local Agricultural and Farmers' Societies are co-operating with the Show Committee, and representatives have been appointed by the following Societies:—Boston Farmers' Union, Boston Agricultural Society, Holland Farmers' Union, South Lincolnshire Potato Merchants' Association, and the Boston Allotments' Association. A preliminary schedule is to be issued immediately for the information of competitors; it will include open classes for traders, classes open only to the County of Lincoln, and also a class for new or improved implements used in the cultivation of the Potato.

**Proposed National Daffodil Society.**—A meeting to consider the proposal to form a National Daffodil Society will be held in the Lecture Room at the R.H.S. Hall at 4 p.m. on Tuesday, March 14, and not on Wednesday, March 15, as previously announced. All who are interested in Daffodils are invited to attend the meeting.

**Standardised Plant Names.**—We learn that the American Joint Committee on Horticultural Nomenclature proposes to issue an "Official Catalogue of Standardised Plant Names." This work will represent the labours, extending over five years, of Messrs. Frederick Law Olmsted, Frederick V. Coville, and Harlan P. Kelsey. These gentlemen have had all possible help from the Bureau of Plant Industry in the Department of Agriculture at Washington, together with the aid of many capable collaborators. The "Catalogue of Standardised Plant Names" will include the approved scientific names of plants in American commerce, and the synonyms which have been most generally used for such approved names; the approved common names of such plants where the names have been formulated, and important synonymous or unapproved common names; authoritative lists of varietal names, in important classes, such as Rose, Iris, Peony, Dahlia, Lilac, Rhododendron, Chrysanthemum, Sweet Pea, etc.; and the approved varietal names of fruits, according to the newly revised code of the American Pomological Society. These important lists will be included in the main alphabetical order, or where more than five pages long, in an appendix, such lists being either supplied by the various organisations devoted to the subjects treated, as the American Rose Society, the American Iris Society, or by a known authority. A distinct arrangement of type faces will indicate the various values of the names listed. Orders for this catalogue sent to Mr. Harlan P. Kelsey, Salem, Mass., U.S.A., prior to March 31, will be executed for \$3.75 if remittance accompanies the order; after March 31, the price will be \$5.

**Journal of the R.H.S. Gardens' Club.**—The issue of this journal for 1921 has as a frontispiece the handsome tablet that was erected as a memorial to the Wisley students who fell in the war, of which an illustration was given in *Gard. Chron.*, June 25, 1921, with a notice of its unveiling by Lord Lambourne. The fauna and flora of Wisley are dealt with in articles by Mr. G. Fox Wilson and Mr. Edwin E. Turner, in "Wild Plants as Hosts of Insect Pests at Wisley" and "The Wisley Flora," respectively. There is also an interesting paper on "Insects and their Environment," delivered by Mr. W. J. Lucas, before the Wisley Scientific Society. A short notice of Wisley Church, by "W.D.C." shows the present building to be

of late 12th century date, although there are traces of the foundations of a Saxon church. The most imposing feature of the church is considered to be the rounded chancel arch. There is a good deal of old timber in the roof, and on a rectangular panel in one of the oaken pews is the date 1630 in raised figures. The church received extensive restoration in 1872, and all the internal fittings are modern, except an old, 16th century, wrought-iron hour-glass bracket fixed on the wall near the pulpit. The cup and paten of the church date back to 1713 and 1714 respectively. Mr. J. Fraser gives an account of a botanising expedition on Ben More in June. This mountain has an elevation of 3,840 feet. Amongst the plants which he discovered were *Caltha palustris* minor, *Saxifraga myrsinites*, *S. herbacea* and *S. Lappunum*. Mr. Fraser repeated his visit in September, when he found *Saxifraga stellaris*, *S. aizoides*, *S. nivalis*, *Polygonum viviparum*, *Carex atrofusca* and *Juniperus sibirica*. On this occasion he experienced one of those storms of rain and driving cloud which are common in the Highlands, and he states "I got wetted for half my length, and my boots would hold no more water. When I got on the public road they made such a noise that I removed and emptied them, wrung my stockings and soon forgot all about it, as the wind dried me long before I got to Killin, as on many a previous occasion." The activities of the various clubs associated with the gardens, and the doings of old students, are recorded, and there is a list of the Club members, with their addresses.

**Trial of Potatoes in Wales.**—Trials of Potatoes conducted in various centres by the Department of Agriculture, University College of North Wales, Bangor, in association with the County Councils of Anglesey, Carnarvonshire, Denbighshire and Flintshire show great differences of yields of the same variety in the different centres; in some cases as much as one hundred per cent. The highest average yields amongst early varieties were Dargill Early, 7 tons 14 cwt., and Witch Hill, 7 tons 1 cwt., compared with Arran Rose, 6 tons 16 cwt., and Resistant Snowdrop, 6 tons 12 cwt. The highest yield in the second earlies was King George, 12 tons 18 cwt., while amongst late sorts Lochar, 13 tons 19 cwt., and Kerr's Pink, 13 tons 13 cwt., gave the heaviest yields. As showing the influence of district on the yield, the crop per acre at the centres in Flintshire was in every respect higher than in the four other stations. At Tre Eden Owain, Flintshire, Great Scot gave a yield of 15 tons 4 cwt., the average of four centres in Flintshire for this variety being 14 tons 5 cwt. This was also the average yield in the Flintshire centres for Kerr's Pink. The second earlies, Ally and Arran Comrade, gave yields of 12 tons 8 cwt. and 12 tons 11 cwt. respectively. Most of these varieties have been tested for three years by the University College, Bangor, and the results of the different years agree very closely.

**Lime-Sulphur.**—Messrs. E. S. Salmon and E. Horton\* have discovered that calcium caseinate is a valuable material for adding to lime-sulphur for increasing the wetting properties of the fungicide. Their experiments were conducted with Hop plants, grown in a greenhouse, affected with the Hop mildew. Although calcium caseinate has been used in conjunction with lime-sulphur as an insecticide, there are no records of its having been previously used in improving lime-sulphur as a fungicide. In the first experiments one per cent. of calcium caseinate was used with lime-sulphur (1.30 sp. gr.) at the dilutions 1:99, 1:149 and 1:199, containing respectively 0.16, 0.11 and 0.08 per cent. of polysulphide sulphur. At the first two strengths the patches of mildew on the sprayed leaves were killed, but at the strength 1:99 the specific was clearly not quite fungicidal. In another series of experiments the lime-sulphur was used at the dilution 1:99 with 0.5 per cent. of calcium caseinate, and this again proved completely fungicidal. The value of calcium caseinate appears to be simply to secure the

\* *Lime-Sulphur and Calcium Caseinate as a Fungicide.* By E. S. Salmon and E. Horton. Research Department, S.E. Agricultural College, Wye.

complete wetting of the fungus, and is made by stirring two parts of commercial casein and one part of slaked lime in twenty parts of water for about two hours and allowing any undissolved solid to settle. The supernatant liquid, used without filtration, is, roughly, ten per cent. solution of calcium caseinate and half a gallon or one gallon of it is used in the preparation of ten gallons of lime-sulphur wash according as it is desired to have 0.5 or 1.0 per cent. of calcium caseinate present. It is considered probable by the experimenters that lime-sulphur mixed with calcium caseinate would be valuable for use against American Gooseberry mildew, and with this dilution there would be little risk of disfiguring the ripening Gooseberries.

**Mr. J. Fraser, V.M.H.**—The Royal Horticultural Society has recently awarded its highest honour, the Victoria Medal of Honour in Horticulture, to Mr. John Fraser, and on no one has that honour been more worthily bestowed. We doubt whether anyone possesses such a wide general knowledge of horticulture and botany as does Mr. Fraser, and he is ever ready to place that knowledge at the disposal of others. A man of untiring energy, studious, a voluminous note-taker, a careful and kindly critic, always genial, and of a retiring, modest

MR. JOHN FRASER, V.M.H.

disposition, Mr. Fraser is greatly beloved by all who know him, and as he has resided for very many years at Kew, and has visited the majority of horticultural meetings held in London during that period, he has a very wide circle of friends. To this circle he has added many other friends, seeing that he is an ardent British botanist, and has tramped over a very considerable part of England and Scotland in search of, or to verify, native plants. He commenced his gardening career in 1874, and continued his studies for 5½ years in Scotland. In February, 1880, he came south, joined the staff of the Royal Horticultural Society, at its famous old Chiswick gardens. There he remained two years, and left to take charge of the new rock garden at Kew. Later, he had care of some of the glasshouses, and altogether he remained in the gardens at Kew for three years. In 1885, he commenced work in the Jodrell Laboratory on behalf of Sir John Lubbock, who later became Lord Avebury. Mr. Fraser's chief work was the study and description of seedlings, seeds, buds, stipules, pollen, and other botanical matters for Lord Avebury's classical works on *A Contribution to Our Knowledge of Seedlings*, and *Buds and Stipules*, and he remained as botanical assistant to Lord Avebury from 1885 to 1912. In 1887 he became Assistant Editor of the *Gardening World*, and was its Editor

from 1895 until 1909. Several books on horticultural subjects have been written by him, whilst he has contributed to such well-known works as *Thompson's Gardeners' Assistant*, *Cassell's Popular Gardening*, and *Cassell's Popular Science*, and edited the 1917 edition of *Johnson's Gardener's Dictionary*. Mr. Fraser has also been a regular contributor to *The Gardeners' Chronicle* since 1883. He is a member of the Floral and Scientific Committees of the R.H.S., and probably no one contributes more specimens for the consideration of the latter body than does Mr. J. Fraser.

**Appointments for the Ensuing Week.**—Monday, March 13.—United Horticultural Benefit and Provident Society's Annual meeting; Bath Gardeners' Society's meeting; Purley Horticultural Society's meeting. Tuesday, March 14.—Royal Horticultural Society's Committee meeting (two days); lecture by Dr. A. B. Rendle on "Plants of Interest in the Day's Exhibition"; Cardiff Gardeners' Society's meeting. Wednesday, March 15.—Hertford Horticultural Society's meeting. Thursday, March 16.—Manchester and North of England Orchid Society's meeting; Linnean Society's meeting at 5 p.m.; Wargrave and District Gardeners' Society's meeting. Friday, March 17.—Perthshire Royal Horticultural Society's spring flower show; Eastbourne Horticultural Society's meeting. Saturday, March 18.—British Mycological Society's meeting at Cambridge.

**"The Gardeners' Chronicle" Seventy-five Years Ago.**—*Quinoa.*—In 1841 my employer, Sir J. S. Richardson, Bart., gave me a package of Quinoa seed, with instructions to sow it on a warm border about the end of March, in rows 18 in. apart. The plants came up in about three weeks very closely; they were thinned out to 4 in. apart in the row when 2 in. high, and the thinnings were transplanted the same distance from each other as those left. They all grew most luxuriantly till the beginning of August, the plants being then about 5 ft. high, with an extraordinary quantity of seed, which was ripened by the middle of September. The seed was cooked in various ways, and tried by my employer; but I do not think it was relished by any of the family. I also had it boiled both with milk and with water, and made in the form of a pudding, but none of my family liked it. Sir John sent plants of it for inspection to the late Dr. Graham, of Edinburgh, who replied: "Your plant is called in S. America Quinoa, and is, in botanical phrase, *Chenopodium Quinoa*. It is much cultivated in mountainous situations and very extensively used as food on the western side of the continent. I believe it is used in various forms, but the principal are two—first, boiled with water into a kind of gruel, and variously seasoned according to taste; second, roasted, boiled in water like coffee, seasoned to taste. The South Americans are said to be very fond of it, and live in great part upon it. Europeans rarely relish it. It is extensively used from Lima all along the west coast. I ought to have said the seeds alone are used in the above way. It hears cultivation well in the open air here, and ripens its seed very freely." I may remark that to sow it in a Cucumber frame answers no good end, as it grows freely in the open air and transplants well. *William Sharpe, Pitfour Castle Gardens, March 1. Gard. Chron., March 13, 1847*

**Publications Received.**—*Experiments and Suggestions for the Control of the Codling Moth in the Grand Valley of Colorado.* By E. H. Siegler and H. K. Plank. Bulletin No. 959. *Results of Work on Blister Beetles in Kansas.* By F. B. Milliken. Bulletin No. 967. *Studies in the Clarification of Unfermented Fruit Juices.* By Joseph S. Caldwell. Bulletin No. 1025. *Relation of Initial Temperature to Pressure, Vacuum, and Temperature Changes in the Container During Canning Operations.* By C. A. Magoon and C. W. Culpepper. All published by the United States Department of Agriculture and obtainable from the Government Printing Office, Washington, D.C.

NEW OR NOTEWORTHY PLANTS.

CLEMATIS MACROPETALA, LEDEBOUR.

THOUGH known to botanists for some years through specimens collected in Siberia, the late Mr. Reginald Farrer appears to have been the first to introduce living plants of this distinct Clematis to our gardens. His numbers F. 315 and F. 559, the latter exhibited by A. C. T. Woodward, Esq., Arley Castle, Bewdley, at the meeting of the Royal Horticultural Society on February 14, have been identified as *C. macropetala*.

It is a slender, climbing, deciduous species, belonging to the Atragene section. The leaves are biternate, the flowers solitary, two to three inches across, sepals lilac and white, petal-like segments filling the centre. Mr. Farrer described it as a charming climber scrambling over rough shrubs in Kansu. A. O.

TREES AND SHRUBS.

CEDRUS LIBANI.

THE correspondence arising from Mr. Stacey's note on page 56 on the Cedar of Lebanon is very interesting and instructive. I am in accord with Mr. H. Clinton Baker (page 81) that *Cedrus libani* is not slow of growth, although the nature of the soil would have an influence in this respect. Here at Coombe House, Croydon, are four specimens planted in a row in front of the residence, and it is my opinion that the whole four trees are about the same age, although each tree is entirely different, leading me to believe that they were from seedlings raised about the same time as the Bayfordbury specimens. One of our trees is very much smaller than the other three, which I attribute to it being planted on the site of some ancient underground building. The Chorleywood specimens (see Fig. 54) are, no doubt, about the same age as those at Coombe House. The largest of our four trees is 20 ft. in circumference. The fact of the Chorleywood tree being 5 ft. more in circumference would depend on the rapidity of growth in its earlier stages, and not so much on a given number of years. The falling of the needles every third or fourth year in such large quantities may be due to fogs. The Cedars here and in the neighbourhood drop their leaves annually, and I have noticed that if we have a succession of heavy fogs the trees shed their needles when the latter are in a green state. There are other specimens close to Croydon namely, at Beddington, Addington, and Hayes, and these appear to be about the same age as those at Coombe House. I give the circumference of each tree at 3 ft. from the ground (they are greater above and below that height) and the spread of branches:—No. 1, circumference 15 ft. 8 in., width of branches 94 ft., height about 75 ft. to 80 ft.; No. 2, circumference 20 ft. 8 in., width of branches 107 ft., height about 90 ft. to 95 ft.; No. 3, circumference 16 ft. 3 in., width of branches 92 ft., height about 75 ft. to 80 ft.; No. 4, circumference 8 ft. 8 in., width of branches 61 ft., height about 60 ft. Nos. 1, 2, and 3 bear cones and produce catkins; No. 4 is barren of both.—Mark Mills, Coombe House Gardens, Croydon.

WITH reference to the correspondence on the Cedars at Chorleywood, I used to know these as a boy, and I thought the estimate of their age—from 450 to 1,000 years—was excessive as well as vague. I wrote to a gentleman who is well informed and who knows the Cedars, and he writes as follows:—"It is not definitely known when the first Cedar was introduced into England, but the fact that it is not mentioned in John Evelyn's *Sylva*, written in 1664, is fair evidence that there were no big specimens in the country then. The first brought to Europe is said to have been introduced to France in 1549. A tree still (1901) growing at Bretby Park, Derbyshire, has been thought to be the oldest in England; this was planted in 1676." P. L. Govett, Lavershot Homestead, Windlesham.

THE ALPINE GARDEN.

THE CORSICAN HEDGE-NETTLE.

IT will be news to many who have seen the little *Stachys corsica* offered as a novelty at distant intervals to know that it has been in cultivation for almost one hundred years. I am informed on good authority that it was introduced to this country in 1823. The fact that the plant is occasionally lost in winter is one which has a good deal to do with its being offered afresh. Small plants do not suffer so much from adverse weather as large ones, and I have had spreading masses so crippled by rain, followed by hard frosts, that they were not worth retaining and had to be replaced by small ones. It is a remarkably pretty little plant, which makes a close carpet of small, rather hairy-looking leaves, and is almost covered with little flowers in July and August. The plant grows scarcely six inches high.

The plants I have seen have white flowers, but Wooster writes of the flowers as pink, adding the remark that there is a variety with

NOTES FROM WISLEY.

THE spring flowers have at last overcome their shyness, and are appearing at Wisley, the most conspicuous being Crocuses, Leucocjums and Snowdrops. There are some charming little Narcissi in various parts of the wild garden, including *N. Bulbocodium*, *N. minimus* and *N. cyclamineus*, the last having spread by natural seed distribution. There is also a very pretty hybrid resembling *N. cyclamineus* except that the perianth is not reflexed, but stands out straightly, the arrangement of the parts being very regular and pleasing.

Other gems are *Iris Histrio* and *I. reticulata*, both of which are in flower in the open. There are some ten-inch pans of the latter in the Alpine House, from each of which arise about twenty blooms dispersing a delightful odour like that of Violets. Another fragrant-flowered inmate of the Alpine House is the creeping, evergreen shrub *Epigaea repens*, which grows so well in the peaty soil of woods.

There are now three species of *Daphne* in

FIG. 54—SOME OF THE LARGE SPECIMENS OF CEDRUS LIBANI AT CHORLEYWOOD CEDARS.

white blooms. I rather think that this is a mistake, probably arising from the fact that the flowers rapidly pass off to pink. On the other hand, such a keen alpinist as the late Mr. Reginald Farrer speaks of *Stachys corsica* as giving "such a profusion of blushing flowers that the whole mass becomes and remains a sheeted field of soft and creamy flesh pink." Wooster in his *Alpine Plants* gives on the frontispiece a coloured drawing of *S. corsica* with the white flowers, and this is the plant which I have always had, even from several different sources, and which I have observed in numbers of gardens. Maund also gives a coloured illustration of *S. corsica*, and this shows the flush of pink, which certainly appears after the flowers have been open for a day or two. Nicholson's *Dictionary of Gardening* does not mention *S. corsica*; this omission being followed by quite a number of works wherein one would expect to see some notice of this charming little plant.

So far as regards culture it may be said that it prefers a light, sandy soil with full drainage, and I have grown the plant successfully in a moraine of whinstone chips with a little lime intermixed, although the latter is not necessary. S. Arnott.

flower in the gardens, which lovers of sweet-scented flowers enjoy. On the Rock garden is *Daphne Blagayana* with creamy white flowers, the yellow anthers showing conspicuously at the mouth of the corolla tube, while near the round ponds is *Daphne Mezereum*, whose scent is at times a little overpowering, and close by our native *Daphne Laureola*. The flowers of the last are most fragrant towards evening. The odour of the bark, however, when bruised, is most unpleasant, and the same remark applies to *Daphne Mezereum*, which possesses poisonous properties.

It requires a sharp pair of eyes to see the spathe of the Skunk Flower or Skunk Cabbage (*Symplocarpus foetidus*), which is growing by the Rock garden pond. The inflorescence somewhat resembles that of *Arum maculatum* (Cuckoo Pint), but is of a dirty brown colour.

Another curious plant in flower is *Lathraea clandestina*, a leafless parasite growing on the roots of Willow, and having comparatively large purplish flowers. It was first planted on the island in the round pond, but was thought to have been lost; but it reappeared sometime afterwards on the mainland, where it has remained. J. G. White.

## The Week's Work.

### THE ORCHID HOUSES.

By J. T. BURKER, Gardener to His Grace the DUKE OF MARLBOROUGH, K.G., Blenheim Palace, Woodstock, Oxon.

**Sophrontis grandiflora.**—This Orchid is now in bloom, and will continue in flower for some considerable time. The flowers are produced on the partly developed pseudo-bulbs; immediately the flowers have faded is the best time to do any necessary repotting. In some respects they resemble Cattleyas, which succeed in the cool house; they require a similar compost to these plants, and the materials should be cut up finely. The plants are best grown in pans suspended from the roof rafters. Care must be taken that water does not remain in the centres of the young growths, as it would cause them to turn black and decay. These plants resent frequent disturbance at the roots, and if the compost is sweet and in good condition it should not be interfered with. The material should be placed around them quite firmly, as its lasting qualities are greatly prolonged by so doing. This small Orchid dislikes a saturated compost, hence the necessity for ample drainage. While in active growth the roots need to be well supplied with water, but much less moisture will suffice when their small pseudo-bulbs are fully matured. *Sophrontis* is the parent of some gorgeous hybrids, and enjoys all the light available during the winter.

**Thunia.**—The *Thunias* are commencing to grow, and should be repotted before the new shoots commence to push forth roots. The compost should consist of half peat and half loam, from which all the fine particles have been removed, mixed with Sphagnum-moss and dried cow-manure. The pots should be well drained, as when in full growth and well rooted these plants need an abundant supply of water. They should not be potted too firmly, as the roots are not capable of penetrating a close, heavy medium. *Thunias* enjoy a sunny position in the warmest house, and should be placed close to the roof-glass. Afford water sparingly at the roots until the flower spikes appear at the axils of the newly made pseudo-bulbs. If the plants are watered too freely in the earlier stages of their growth, flowers will be very sparingly produced. The plants may be potted singly, or made into large specimens, according to the requirements of the cultivator. When in full growth, and the flower sheaths have formed, an occasional watering with weak manure water will assist the development of the flowers.

### THE KITCHEN GARDEN.

By JAMES E. HATHAWAY, Gardener to JOHN BRENNAND, Esq., Baldersby Park, Thirsk, Yorkshire.

**Outdoor Tomatos.**—To ensure good crops of Tomatos in the open the seed should be sown early and the plants grown on without a check. Late sowing of the seed is often the cause of failure with outdoor Tomatos, especially in the north. Seed of Sunrise and similar varieties should be sown now in 6-inch pots containing plenty of drainage material and finely sifted soil. As soon as the seedlings are large enough to handle they should be transferred singly to 3½-inch pots. Another batch of Princess or Wales, Aviator and other types should also be sown for indoor cropping. If a very large Tomato is required Brotherston's A1 may be grown, but this sort requires much more warmth all through the growing season than most varieties to ensure success.

**Peas.**—Another batch of Peas should be sown in the open as soon as the weather permits. Pioneer, Chelsea Gem, and similar varieties may be selected. Place the seeds in rows made 4 feet apart, with a row of Spinach along the centre as an intercrop.

**Box Edgings.**—Where Box is used as an edging plant in the kitchen garden the present

is a suitable time to make good any gaps in the rows. A reserve supply of plants should always be available for this purpose, and these may be procured by taking up large plants and laying them out thinly in a trench on a west border, leaving about 3 inches of the young shoots above the soil. By the following season they will have rooted freely along the stems and be ready for dividing and planting. If edgings of this nature have become very gappy and untidy it is best to replant the whole. The ground should be dug and afterwards made firm and flat. Place a line along the full length of the edge, make uneven parts level with the spade, then take out a trench on the border side, and place the plants in by hand. In treading the soil firmly about the plants take care to see that they are kept level in the row and upright.

**Paths.**—When the carting of manure and composts is finished, garden paths should receive attention, and, if necessary, fresh gravel applied and rolled in. If the work is deferred until later, the weather may be so dry that the material will not be moist enough to consolidate, and will remain in a loose condition all the year. Grass paths with bare patches should be made smart by putting down fresh turves where needed.

**Slugs.**—The best means I know for combating slugs is to allow about four runner ducks to ramble about the garden in the winter. I have used ducks in this way for about six years, and have had no trouble with slugs since, and I generally let the birds run round the garden for a short time on a wet morning in summer. The only time I find them do harm is in dry weather; they should be old ducks, as young ones are more destructive. Boards laid flat on the ground and left for a time form an excellent trap for slugs, whilst a free use of new lime also tends to keep slugs in check, but only for a time.

### PLANTS UNDER GLASS.

By T. PATEMAN, Gardener to Sir C. NALL-CAIN, Bart., The Nole, Cudicote, Welwyn, Hertfordshire.

**Winter-flowering Begonias.**—These Begonias are valuable for producing brightly coloured flowers during the autumn and winter. They are very easy to cultivate, and may be had in bloom over a very long season provided careful attention is given to their requirements. As one of the chief causes of failure in growing these delightful subjects is attacks of rust and mite, it is very necessary to watch the plants carefully for these pests, and take steps to check them directly they are detected. I find that dusting the plants with sulphur, and especially on the underside of the foliage is a good preventive for rust disease, whilst frequent fumigating will destroy mite.

**Tuberous-rooted Begonias.**—The newer hybrids which have been obtained by crossing *B. socotrana* with the old summer-flowering tuberous Begonia, such as Optima, Elator, Exquisite, Emita, Mrs. Heal, and others, are not so extensively grown as their merits warrant. The varieties enumerated have been in commerce for several years, but for some reason or other they are not so generally grown as Begonias of the Gloire de Lorraine type. Plants of these Begonias that have been kept on the dry side, as previously advised, should have the old soil shaken from the roots and be repotted in smaller receptacles than those in which they have been previously grown. The soil for this potting should be open in texture, and may consist of three parts turfy loam, one part leaf-mould, and a dusting of bone-meal, with small pieces of charcoal and sufficient sand added to render the compost porous. At this stage the soil should not be pressed too firmly, otherwise the roots will not ramify freely. After potting, the plants should be grown in a house having a night temperature of 60° with a rise by sun heat. Very little water will be required, beyond frequent sprays in bright weather until growth commences, but the plants should be shaded from bright sunshine. By this treatment good, strong shoots suitable for use as cuttings will soon be available for propagating purposes.

### THE FLOWER GARDEN.

By EDWIN BECKETT, Gardener to the Hon. VIVIAN GIBBS, Aldenham House, Hertfordshire.

**Delphinium.**—Healthy young shoots obtained from the sides of the old plants may be inserted in 48-sized pots, as cuttings. Use sandy compost for the purpose, and root the cuttings in a cold frame, keeping the light closed until such time as roots have commenced to form, after which air should be admitted with increasing freedom.

**Phlox.**—These plants form admirable subjects for massing in borders by themselves, as well as being most useful components of the herbaceous border proper. Where large numbers of plants are available, they should be planted out without further delay. They repay for good cultivation, revelling in deeply trenched and enriched soil. If placed on the herbaceous borders they are best planted in groups of five or six plants of the same variety, allowing up to 30 inches from plant to plant, and setting them in irregular clumps. The stock may be increased from cuttings similarly to Delphiniums; small pieces of the old stools will soon make useful, healthy plants.

**Sweet Peas.**—The ground selected for growing Sweet Peas should now be prepared. Choose land that has been well trenched, and open trenches of sufficient width to accommodate a double row of plants, about 30 inches deep. Into these place a good layer of well-decayed farm manure, and cover the dug with soil up to general level of the land, then, when the whole has settled, a shallow trench will be formed that will greatly facilitate watering the roots later.

**The Rock Garden.**—If the rock garden has not yet received attention, it should be overhauled now, restricting the very robust-growing species to reasonable limits, replenishing those subjects that have suffered during the winter, and putting out fresh plants that until now have been growing in the frames. Plants with a tender constitution will be best planted at a later period. Let the soil requirements of the various plants be seen to. Pockets should be excavated for the purpose of accommodating new plants, and compost suitable to the subject used for refilling. Lime lovers require plenty of old mortar rubble incorporated with the compost; others grow best in peat, others in loam.

**East Lothian Stocks.**—Seedlings of these Stocks that were pricked off into boxes in good time may be potted singly in 48-sized pots filled with a rich, loamy compost. Grow them on sturdily in gentle warmth, and be careful to guard against them damping off. The plants should make good progress, and later, when of a sufficient size, gradually and thoroughly hardened off with a view to planting them out-of-doors.

### FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

**Melons.**—If all has gone well, every lateral on the earliest plants will now be showing fruit; of these latter not more than two, or at the most three, should be allowed to swell to maturity, but it is important that all should be fertilised in order to secure a crop of fruits of an even size. If plants in 12-inch pots are plunged closely together, space for laterals will be extremely limited, consequently very close pinching will be necessary. The laterals should be pinched at the first joint when they are very small, and all succeeding spray growth removed; in this way the true cordon form will be retained. Where space is abundant and each plant has plenty of room the laterals may be allowed to continue to grow until the fruit is set, and then shortened to one joint in advance of the latter. These remarks apply to plants intended to furnish ripe fruits early, and not to Melons grown on the extension system. When Melons commence opening their flowers the warmth should be increased slightly to 70° by night and 80° by day. No water should be allowed to touch the plants, but atmospheric moisture should be regularly supplied when

bright sun permits of ventilating the house. When the fruit is swelling freely, each specimen should be supported by a net fastened to the trellis. A brisk bottom-heat is most important, and heat and moisture may be freely employed after the fruits are set and swelling. A top-dressing of stiff loam and bone-meal may be applied in solid layers, and warm diluted liquid manure, soot and guano water, may be given the roots freely, but care must be taken not to wet the stems.

**Successional Plants.**—Melons raised from later sowings may be put out in pots or ridges for maintaining a succession of fruits as often as suitable houses become vacant. Tropical warmth, both in the house and bed, plenty of moisture, and an abundance of light, are required, but these will not suffice unless the house is kept free from insects, and proper attention paid to ventilation. Manipulation under the different methods of culture is always the same, but the soil, as the season advances, may be heavier in texture than that recommended for the January plants. A stiff, calcareous loam, enriched with bone-meal, old mortar rubble, and burnt garden refuse will be suitable for the plants whether grown in pots or on mounds.

**Frame Melons.**—Where Melons are grown in frames the present is a suitable time to make a start by building up a substantial bed for the frames. As frame Melons do not require one-fourth of the soil frequently used for them, it is a good plan to restrict the root run by fixing two rough boards a foot or more in width on their edges, and about 18 inches apart, before the roots require top-dressing. Some turf or a little soil should be placed all over the bed to prevent an excess of moisture arising from the dung. When the soil is thoroughly warmed through, and the bottom heat falls to 80°, the plants may be set in position. Covering the frames every night with mats is necessary, with a little air admitted at the back of the frame to allow any excess of atmospheric moisture to escape. If the temperature does not reach 70° in the morning, a good external lining of fermenting material will be necessary.

**HARDY FRUIT GARDEN.**

By H. MARKHAM, Gardener to the EARL OF STRAFFORD, Wrotham Park, Barnet.

**Autumn Fruiting Raspberries.**—If not done already, the canes of autumn-fruiting Raspberries should be cut down almost to the ground level and the roots heavily mulched with well decayed manure. There are several good varieties that produce large, useful berries late in the autumn, and the plants are deserving of extra care in their culture. If new beds are to be made, prepare the ground at once, and plant young rooted portions taken from the sides of the old stools. Plant them either in clumps or rows at a reasonable distance apart, and mulch the roots with suitable manure. Queen Alexandra and Lloyd George are two dependable varieties.

**Quinces.**—Thin out the branches of Quince trees that are crowded with growths to allow the air and light to reach the interior parts. The Quince will grow and fruit well in somewhat damp soils and situations if there is a free drainage for surplus moisture.

**Nuts.**—The various kinds of Nuts may be pruned. Cut out all strong, last year's growths that are not required for the extension of the heads or for filling bare spaces. Aim at keeping the main stems well clothed with twiggy, fruitful shoots, which are now in flower. Do not remove the shoots that are clothed with catkins until the tiny pink flowers have been fertilised. Grub out all suckers and apply a good top-dressing of suitable material to older bushes that are growing on poor, thin land, and in need of assistance at the roots.

**Young Nut Trees.**—To obtain well-shaped, fruitful heads, select suitable shoots to form a vase-shaped bush, keeping the centres of the trees open. Prune to an outside bud, and shorten the selected growths more or less according to their length and strength.

**FRUIT REGISTER.**

**APPLES COURT-PENDU-PLAT AND ST. EDMUND'S PIPPIN.**

SURELY Dr. Durham (p. 94) is mistaken about Court-pendu-plat, as grown in this country, being a cider fruit. The Capendu, or Kilpandy, as it is known here, is a greyish fruit of no great value, but the other, of which a finely-coloured specimen is given in McIntosh's Orchard, is certainly a valuable late dessert variety.

St. Edmund's Pippin has been compared with Cox's Orange Pippin, to the disadvantage of the latter. It certainly is a more certain doer in the north and of fine quality, but even were it superior in flavour, it must be remembered that Cox's Orange Pippin fills a period when there is no St. Edmund's Pippin to fall back upon. It is, therefore, essential to grow both sorts. R. P. B.

**PLANT BREEDING IN CALIFORNIA.**

BELOW high-water mark and separated only by an earth wall from the salt marshes of San Pablo Bay, California, lies the plant-breeding farm of Mr. Richard Diener, well known in the United States as a breeder of Petunias and Gladioli. The task which he undertook of reclaiming the land from the sea, securing it from inundation by the highest tides, constructing a drainage system and water supply essential for summer irrigation, must have been a formidable one.

In less than a decade Diener has attained remarkable success. His work among Gladioli involves the raising of many hundreds of seedlings annually. The seedlings vary not only in rate of development—some flowering in the first year, others not until the third—but also in floral colour, resistance to disease and production of cornets. The many beautiful novelties raised

FIG. 55.—POTINARA JULIETTAE, R.H.S. FIRST-CLASS CERTIFICATE, FEBRUARY 28. SHOWN AND RAISED BY MESSRS. CHARLESWORTH AND CO., HAYWARDS HEATH (SEE P. 107).

**DUAL-PURPOSE APPLES.**

Market Grower touches on this topic in his notes on p. 23. For many years I have advocated the use of such varieties. I have been a very heavy consumer of Apples for quite ten years of my life; from the age of 25 to 35 I lived almost entirely on Apple pies made of sweet Apples and wholemeal flour. I have never been able to enjoy the sour varieties, and besides, owing to the enormous amount of sugar which they require, they are not economical. Nearly every variety of dessert Apple cooks perfectly and is delicious without added sugar. The variety Blenheim Pippin is splendid as a cooker.

Orlean's Reinette has been recently discovered. I find it a most admirable Apple in every respect as regards quality, and it certainly is best when allowed to hang on the tree for as long as possible. Rosemary Russet is another Apple of very fine quality and a late keeper; it is also a very good cropper. Speaking generally, the Apple is probably our best fruit, and the most useful, but it is my decided opinion that, from a health point of view, the sweet varieties are incomparably the best, and, in my own case, the only ones that I can regularly tolerate. W. J. Farmer, Redruth

at Kentfield are testimony to this breeder's perseverance and discrimination.

Petunia breeding is also an important part of the work. The plants are grown in pots in large wooden lath or lattice-work houses.

On the occasion of a recent visit the writer saw a large glasshouse full of new Amaryllis seedlings, some of which were just coming into flower, with handsome heads of as many as five flooms. Cuttings of a blight and drought resistant Tomato filled a long series of frames. A supply of pure seed of the Diener variety is maintained by propagating the plants vegetatively.

During the past five years Mr. Diener has given much attention to Wheat breeding, and has produced a strain of Polish Wheat with remarkably large grains, and another with large, flinty grains and stiff straw, which has given very high yields. I understand that Diener has bred a blue Rose and an improved sweet Loganberry. As a result of his experience with Petunia Mr. Diener has been much impressed by the predominant influence of the male parent in hybridisation. He claims that both in size and colour the pollen parent has an effect far outweighing that of the seed parent. J. W. Lesley, Mills College, California, U.S.A.

**EDITORIAL NOTICE.**

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, W.C.2.

### CHINESE SHRUBS AT ALDENHAM,

THE third expedition to China undertaken by Mr. E. H. Wilson, V.M.H., for the Arnold Arboretum during the years 1907-1909 was remarkable for the discovery of a large number of plants suitable for cultivation in American and English gardens. Through the kindness of Professor Charles S. Sargent and others, a representative collection of the seeds was received by the Hon. Vicary Gibbs, and sufficient time has now elapsed to test those species which it had been expected would prove hardy and distinct.

The soil at Aldenham is a particularly cold clay, and late spring frosts are very prevalent, but one cannot help being impressed by the

Henryi) has made a large bush, 12 feet high and 10 feet through; it has showy black fruits. *A. lasiogyne* is meritorious, either grown as a standard or as a bushy shrub. In both cases judicious pruning is required to maintain a good form in the plants. *A. leucorrhizus* is a free-growing bush, 10 feet high, and very attractive when in fruit.

**BERBERIS.**—This genus has contributed many desirable new species, and the following is a selection of the most distinct:—*B. candidula*: This is a low-growing evergreen of much value for the rock garden and similar planting. The silvery under sides of the leaves are very charming, but, owing to the plant's close, compact habit, this feature is not seen so conspicuously as could be wished. When first sent out by the nurserymen, the plant was wrongly supposed to be a variety of *B. Wallichiana*, and received the varietal name of *hypoleuca*. Wilson sent home seeds of it but the species was first collected by Farges, and the plant was first raised by M. Maurice de

members of the family. *B. verruculosa* is a plant of dwarf, compact habit, and one of the most pleasing of these new Barberries. The foliage is dark green on the upper surface and very glaucous beneath. *B. Wilsonae* is now fairly well known in this country. It forms a shapely, spreading bush about 4 or 5 feet in height. It is beautiful in flower, fruit, and autumnal colouring. Mr. Gibbs informs me that he has found it to vary so much, even when raised from Chinese seeds, that he suspects it is a natural hybrid. It is now generally recognised that it is almost hopeless to attempt to raise *Berberis* true to name from seed gathered in English gardens.

Of the numerous deciduous species of *Berberis* introduced by Wilson, *B. aggregata* has the berries set so closely together as almost to crush one another. A fine bush of *B. aggregata* *Prattii* at Aldenham is 6 ft. high; this and *B. Caroli* var. *hoanghensis* are amongst the best. They are most beautiful in the late summer, when carrying great quantities of bright red, or salmon-red, fruits, which last in good condition well into the winter. *B. aggregata* *Prattii* is, by many, considered to be the finest of all Barberries for the charm of its rose-pink berries, but against this is the fact that, so far as habit is concerned, it ranks very near the bottom, as its growth is unduly tall for the width, being stiff in outline and yet weak in the stem.

**CLERODENDRON TRICHOTOMUM.**—What is known as the mountain form of *C. trichotomum* has proved a valuable late summer flowering shrub for the colder parts of the country. Unlike the older form, the young wood suffers no injury from being imperfectly ripened.

**CORNUS PAUCINERVIS,** which flowered first in this country at Aldenham in 1911, is a useful addition to the shrubbery, as it produces many corymbs of white flowers during August. It is a plant of neat habit, and has interesting black fruits.

**COTONEASTER.**—The numerous species and varieties of Cotoneasters are among the most important of Mr. Wilson's introductions, and include some of our best ornamental shrubs. Though generally grown as bushes, some may be successfully trained as half-standards by taking up a central growth and pruning off the lower branches, thus displaying the graceful pendulous growths to advantage. As will be seen by the dimensions given, some species grow to a large size, and I know of few shrubs more beautiful either in flower or fruit. Though not strictly relevant to the subject of this paper, as the plant was originally found in the Khaisa Mountains on a date long before Mr. Wilson's birth, I may mention that far the largest member of this genus which I have seen is an example of the well-known *C. Simonsii* at Aldenham, and aged about 25 years. *C. acutifolia villosula* is a strong-growing variety, the Aldenham specimen being 6 feet tall and 15 feet in diameter. It has large leaves, 4 inches long by two inches in width; white flowers and conspicuous black fruits. *C. Dielsiana* is one of the handsomest of all Cotoneasters, and particularly good when grown on a single stem, as the slender, pendulous branches are then seen to the best advantage. A specimen at Aldenham, grown in this way, is 15 feet tall, and, when laden with its scarlet fruits, is a very beautiful object. *C. divaricata* I consider one of the most desirable members of the family, and a first-class shrub for any garden. It is deciduous, with small, dark green leaves and somewhat slender pendulous branches, a mature specimen being about 6 feet in height. The red fruits are abundantly produced all along the stems, and are very attractive in the autumn. *C. Henryana* forms a singularly handsome evergreen of graceful habit, with large, dark green foliage and white flowers that are succeeded by dull crimson fruits. A finely grown specimen at Aldenham is 12 feet high. *C. humifusa* (syn. *C. Dammeri*) is also evergreen, but of flat growth. This plant is admirably suited for clothing

FIG. 56.—COTONEASTER SALICIFOLIA VAR. FLOCCOSA. (SEE P. 115.)

well-trained and healthy appearance of all the specimens.

Though the collection of hardy Chinese woody plants at Aldenham is very extensive, yet, owing to unsuitability both of soil and climate, no attempt has been made to acquire any of the new Chinese *Abies* or *Piceas*, and but a few very hardy *Pines* have been planted; neither are the numerous, newly discovered *Rhododendrons* such a feature there as they are in some some Cornish gardens. The following plants are some which give great promise as useful garden subjects, and there may be other deciduous species which I have overlooked, but which may be very beautiful in summer:—

**ACANTHOPANAX.**—The new species of this genus are valuable additions on account of their very distinct foliage. The fruits of the plants resemble those of the Common Ivy; indeed, the two genera are closely related. *Acanthopanax Henryi* (syn. *Eleutherococcus*

*Vilmorin* (who named it *B. Wallichiana pallida*), and from him directly or *via* Chenault's Orleans Nursery this Barberry reached Mr. Gibbs. It is a dense and very slow-growing plant; there are few, if any, large specimens in the British Islands, the one at Aldenham,  $3\frac{1}{2}$  feet, with a diameter of 7 feet, is believed to be the biggest in this country. *B. Gagnepainii* is another very pleasing evergreen Barberry, and develops large quantities of bright yellow flowers in early summer. The undulating, dull green foliage is attractive at all seasons; a specimen at Aldenham is 7 feet high. *B. Sargentiana*, named in honour of the Director of the Arnold Arboretum, is one of the handsomest of all evergreen shrubs. The strong, upright-growing stems are clothed with large, dark green foliage and conspicuous spines which in winter assume the colour of old ivory, and meritously distinguish this Barberry from all other

banks or positions where a good ground cover is desired. *C. moupinensis* is most conspicuous when in fruit, the berries being black and produced in great numbers. A tree of *C. salicifolia floccosa* (see Fig. 56) is 8 feet high and 15 feet in diameter. It is a pretty, graceful evergreen, with somewhat narrow leaves of medium length, glossy on the surface, and, when furnished with numerous clusters of bright red berries, is one of the showiest members of the genus. *C. salicifolia rugosa* is also a strong-growing evergreen, with larger foliage and fruits than the preceding. *A. E. Thatcher.*

(To be continued.)

**MR. KINGDON WARD'S SIXTH EXPEDITION IN ASIA.\***

**No. 10.—AN ALPINE LAKE.**

THE ascent to the pass took us along a narrow path under a bare limestone cliff over 11,000 feet above the sea. Here there ought to have been plenty of flowers, but there empha-

surface. Another somewhat similar species was more bashful and showed no signs of waking up just yet. A *Cucurbita*, with large, bright gamboge-coloured flowers, looked out of place on the barren cliffs. Two species of *Primula* I noted in fruit, but both were out of reach on these horrid precipices; and there were several shrubs, including a *Lonicera*. Conspicuous here and there were the large leaves and opulent inflorescences of a *Rheum*. However, all these were but oases in a desert of naked rock; on the southern slopes the limestone mountains always seem to break off in horrible scarps of this nature.

From the pass we had a fine view to the north, but no snow was visible. Instead, a bleak, rocky range with peaks like the Monument or Cleopatra's Needle, some 15,000 feet high, filled the horizon. The nearest snow peaks were away to the north-west, towards Ching-tien, and were hidden by lower ranges.

The north side of the range was very different. Here the scarps were mercifully hidden by forest, beneath which grew a wilderness of tall herbs—*Ferns*, *Thalictrum*, *Aquilegia*, *Rodgersia*, and others. This very soon gave way to dry

other flowers, but what took me altogether by surprise was to find here, of all unlikely places, a *Nomacharis*! Now, if anything is a plant of the moist meadows, *Nomacharis* is. I recall *N. tricolor* of the Mekong-Salween divide, and *N. pardanthina* of the Htawgaw Hills; and anything more completely contrasted than the meadows of the North-East frontier and the scrub flooring the dry Pine woods above the Yung-ning Lake it would be hard to imagine. However, there the plant was in all its quaint glory. It had white flowers, the inner perianth segments generously spotted with purple, the outer more scantily. Each whorl formed an equilateral triangle, the edges of the outer whorl being smooth, those of the inner crimped and fringed. The haughty, nodding flowers, so symmetrically arranged, so equally spotted, were a revelation; and I thought to myself that if *Nomacharis* was found here, anything might be possible in this country. And so down to the lake side, the water so transparent that from the path along the cliff we could look down into the clear depths, and count the fish. We crossed meadows filled with lemon-yellow *Iris* and purple with *Primula*. The orange Can-

FIG. 57.—CYMBIDIUM CURLEW VAR. ROSY GEM. R.H.S. AWARD OF MERIT, FEBRUARY 28. SHOWN AND RAISED BY SIR GEORGE HOLFORD, WESTONBIRT. (SEE P. 107.)

tically was not. In the first place the steep slope under the scarp was clothed chiefly with Bamboo, the whipping boy of all mountain floras. It thrives where nothing else deigns to show itself. In the second place, a great deal of the available room was occupied by bare rock. In the third place, such plants as did occur made themselves very much at home, occurring in great masses; the lemon yellow *Roscoea*, for example, which coloured the slope between the patches of Bamboo. So that, on the whole, this high ridge proved very disappointing. However, we found a few flowers hiding themselves meekly in the cracks and crevices. An early *Meconopsis* had opened one purple blossom, and a *Didissandra*-like *Gesnerad*, with sulphur-yellow flowers, lurked in the cran- nies, its flat rosettes of leaves glued to the rock

Pine woods, and immediately there burst into view, far below, shimmering in the sunlight, the sapphire lake of Yung-ning. A more glorious sight can hardly be imagined, the turquoise sky curdled with cloud, the dark, forested mountains towering up into the white, crested waves, and the jewel of sapphire water, with its little island crowned by a lovely monastery. So enchanting was it that for a long time I had no eyes for the vegetation. When at last I did turn to it, a great surprise awaited me. The dry, rocky slopes between the slender, dark trunks of the Pines were covered with masses of milk-white and rose-pink *Rhododendron*, a perfect little gem smothered in flowers. But this was not all. Amongst this Heath-like carpet grew many flowers we had not yet come across—an *Androsace*, with deep crimson flower; a *Cypripedium*, rather like *C. luteum*, but with the pouch a paler yellow, and the remaining perianth segments purplish-brown, more as in *C. tibeticum*. There were several

delabra *Primula* also grew here. We had lunch by the lake in the warm sunshine, and in the afternoon went on to Yung-ning. Mile on mile we travelled by the lake side till, as the sun began to disappear behind the lofty ranges, we crossed a low col and the lake was lost to view. Now we entered a narrow valley which presently began to widen out; cultivation appeared, and as dusk came on, riding through lanes of scented *Hazel*, past bogs purple and gold with flowers, under spreading Walnut trees, we reached the outskirts of Yung-ning. It was dark before we reached the monastery, whither the courier, who had come over from the island monastery at the bidding of the Lama to escort us, now led us.

In the rambling old monastery we were well received and given comfortable quarters. A couple of days later the big Lama came over from the island to see me, and after some discussion I decided to go north to Mu-li and work round there, since the immediate neighbour-

\* The previous articles by Mr. Kingdon Ward were published in our issues of May 14, June 18, July 23, August 20, September 3, October 8, October 29, 1921, January 7 and January 31, 1922.

hood of Yung-ning was very dry, despite its 9,500 feet elevation, and the mountains round about scarcely exceeded 12,000 feet. Between Yung-ning and Mu-li, however, was a high, rocky, limestone range; and beyond Mu-li itself were other lofty ranges, so that though Mu-li itself was as dry—or drier, since it is right down in the gorge of the Litang River—yet there was more scope there. Results quite justified this argument. As regards snow peaks, they are scattered over this huge region at some distance from each other; but of these I hope to have more to say later.

We remained four days in Yung-ning, and I ascended one peak about 11,000 feet, but got nothing for my pains. However, that did not worry me, as every morning, when I looked northwards, I saw those immense limestone pinnacles towering up to the clouds which frothed about them; and though I entertained no illusions as to the possibility of climbing those formidable peaks, yet it was clear we should find some interesting plants there. I found a pretty little pink Briar in Yuog-ning, but nothing else of note except those referred to found by the lake.

On June 2 we set out once more. Our long journey to the scene of action was now rapidly drawing to a close—already we had been fifty-two days on the road, including necessary halts, but from Yung-ning onwards I considered that our quest had seriously begun. I had not intended to collect many plants during the journey, meaning to confine my attention almost exclusively to alpine and sub-alpines; yet somehow the herbarium already numbered over two hundred species, and by the time we reached Mu-li it was approaching four hundred, and we were only five days on the road, spending two days in camp on the divide. But I anticipate. The journey from Yung-ning to Mu-li certainly deserves a chapter to itself; and there are so many flowers to talk about that it will doubtless require two chapters. Let us, therefore, hurry over the first stage out of Yung-ning, which takes us to the foot of the range, and there begin. *L. Kingdon Ward.*

## THE MARKET FRUIT GARDEN.

WEATHER prophets have been saying that we are to have another drought this year. Up to the present there is no sign of it. The first two months of the year gave us more than double the rainfall of the same period of 1921, namely, 6.76 in. against 3.14 in. February is a very variable month. In the last ten years its rainfall has ranged from 0.75 in 1921 to 4.64 in 1926. In the month just closed we had 2.46 in., which is above the average, rain being recorded at my place on 14 days. There was a cold period from the 4th to the 12th, starting with a fall of snow; and frosts of 7° or 8° occurred on several nights. Afterwards conditions became milder, with much wind and drizzle, which hindered outdoor work a good deal, including winter spraying.

### FRUIT BUDS.

Fruit buds of Plums, Pears, and Apples kept nicely backward during the greater part of the month, but made a decided move in the last few days. Present appearances point to the probability that the blooming of fruit trees in general will be later than it was in the last two years. Pears are now full of buds, and so are Plums; and as both of these gave light crops last season, we can hardly be deprived of satisfactory crops this year unless it be by unfavourable weather at blooming time. Apples are more doubtful. They are generally reported to be showing plenty of buds, but we seldom have two good crops in succession, and, the trees having been half-starved during last season's drought, makes it unlikely that we shall see an exception to the rule. You can never be quite certain about Apple buds. In some seasons many that have every appearance of being fruit buds produce mere whorls of leaves, the bloom which should appear in the centre being

absent. This frequently happens with Allington Pippin, which always seems to be full of fruit buds, but is decidedly given to biennial bearing. However, young trees, which were not quite old enough to crop last year, stand a good chance of giving a good account of themselves. The drought was evidently just the thing to check their growth and throw them into bearing, for they have formed fruit buds freely. Some gardeners predict a good crop on the score of the wood having been so thoroughly ripened last autumn. I can never see the justification for this ripe wood theory when applied to such crops as Apples, which do not bear on the previous year's wood to any extent. The ripening of last year's shoots can hardly influence this year's crop, though it may favour the formation of buds for the next.

Cob-nuts were in bloom throughout February. Both catkins and female blossoms were very plentiful, the latter much more so than they have been for several years. If they were able to put up with frost and a good deal of rough weather, there should be a full crop of nuts.

### IMPROVED MARKETING METHODS.

The scheme for improved and standardised grading and packing, introduced by the Federation of British Growers, was brought into operation to some extent last year with regard to Apples. In the coming season it will embrace all the other fruits commonly grown commercially. The trademark label has now been registered, and schedules have been drawn up to govern the packing of the various fruits. The main feature of the regulations is that the grower is required to declare on the Federation label attached to each package the net weight of the contents when packed. That is naturally a matter of vital importance to the retail purchaser, who has long complained of the lack of system, or even honesty, of many growers in this respect. Buyers certainly will not fail to appreciate the value of the guarantee afforded by the Federation label, and growers who are wise enough to use it will benefit accordingly. For Plums and the various soft fruits, non-returnable chip-handled baskets and chip "bonnets" are recommended whenever suitable, in addition to the usual wicker pecks and half-sieves.

### ENGLISH *versus* IMPORTED APPLES.

Can we grow Apples equal to the boxed fruit which comes to us from America and Australia? Mr. C. R. Wimshurst, who gives in the *Journal of the Ministry of Agriculture* an interesting comparison of the conditions obtaining in those countries and in England, is rather sceptical on this point. He says that all boxed Apples exported to England come from localities that can mature a "cob" of Maize in the open during the summer; whereas the climate of S.E. and E. England, which is the driest we can manage, is not warm enough to do this, and is far moister than is good for box Apple country. S.E. England approximates in climate to what is called "berry country" in America, more suitable for bush fruits than for Apples. He considers that our moist climate encourages scab, brown rot, canker, and other fungous diseases, to an extent not met with in countries with a dry climate.

Is a dry climate really so desirable? Most of us had a dose of it last year, which we hope never to experience again. Yet personally I had a good deal of scab, and so did growers in some other districts, whilst brown rot was exceptionally prevalent amongst Apples. Keeping qualities have seldom been worse, probably because most of our varieties are not suited for such dry conditions. But supposing that we do have to put up a bigger fight against diseases—Mr. Wimshurst admits that they can doubtless be kept under in England, but at an outlay considerably greater than in dry regions—I submit that we ought to be able to afford that outlay, considering that we have the compensation of a market at our doors.

### WHY NOT SCAB-RESISTING VARIETIES.

Of the fungous diseases mentioned above, scab is really the only one which presents a serious obstacle to the marketing of a clean sample. It must be admitted that, so far, we have no completely successful means of preventing it; but we have a fair number of varieties which are not affected by scab, and there is no reason why we should not have more. If plant-breeders set themselves the task of producing scab-resisting varieties, there is no doubt that it could be done. Even if it had to be at some sacrifice of flavour, the Apples might still easily be fully equal to most of the imported varieties in this respect. At present raisers of new varieties almost invariably aim at high quality, especially flavour. Cox's Orange Pippin is generally one of the parents. If they aimed at producing good market varieties, and bred for colour and constitution, using as parents some of our scab-free varieties, we should certainly get some valuable additions to our list of commercial Apples. Plant-breeders have given us Wheats resistant to rust, and Potatoes resistant to wart disease. They can surely give us also Apples that will prove immune to scab.

### PIGS IN ORCHARDS.

Some growers have found a cheap solution of the orchard cultivation difficulty by running pigs amongst the trees. Messrs. W. Seabrook and Sons, of Chelmsford, are amongst those who have tried the plan, and they are so well satisfied with the result that they intend to extend the practice largely. The experiment was made in a plantation of bush Apples, interplanted with Black Currants and Gooseberries, which had become foul with weeds as a result of neglect during the war. The pigs cleaned the ground entirely, and kept it cultivated, so that all that was needed was to harrow it level after they had done their work. Little pigs were turned in straight off the sow, and were not rung. They did no damage to the trees or bushes beyond eating windfall Apples. It was found best to confine them to long, narrow strips of half an acre, twenty pigs cleaning this space in a fortnight. Wire fencing with light Ash stakes was used, this being moved from plot to plot as required; and portable shelters of thatched hurdles were provided for sleeping. As the pigs were fed with dry food, the land was well manured. A constant supply of water is considered to be essential, as it is thought that, without this, the pigs would be more likely to bite the trees.

For the same reason, and because they become less active as soil tillers, the pigs are not kept in the orchards after they reach the age of six months. They have to be removed, of course, whilst there is a crop on the Currant and Gooseberry bushes, and for a short period during the time of spraying operations. *Market Grower.*

## ORCHID NOTES AND GLEANINGS.

### CYPRIPEDIUM CHARLES PUDDLE.

From the gardens of Lady Aberconway, Bodnant, Tal-y-Cafn, North Wales, Mr. F. C. Puddle, the gardener, sends a fine flower of a clear white and yellow *Cypridium* named after his youngest son, and which has been raised by G. F. Moore, Esq., Chardwar, Bourton-on-the-Water.

It was raised between *C. aureum virgale* (nitens × *Spicerianum*) and *C. chrysotoxum* (*Lathamianum* × *villosum*), and seeing that *C. Lathamianum* is from *Spicerianum* × *villosum*, those two species take the lead in the hybrid in form and colour, resulting in one of the whitest of *Cypridium*s without *C. niveum* in the parentage. The dorsal sepal and margins and outer halves of the petals are pure white, the rest of the flower being pale yellow, with a slight rose flush and thin median line on the petals.

**NURSERY NOTES.**

**CONCERNING BEARDED IRISES.**

IRISES are a great feature in Messrs. R. Wallace and Co.'s new nursery at "The Old Gardens," Tunbridge Wells, and last summer they appeared vigorous and strong in their new surroundings. In June, when from the south-east corner (the highest point) the sloping hillside was covered with spikes presenting endless colour combinations, the beauty of many varieties being enhanced by the evening light. Beyond and below the Irises were masses of large specimen

FIG. 58.—IRIS ASIA.

Rhododendrons, whilst in the far distance the famous Tunbridge Wells Common, with the picturesque surroundings of Rusthall and its church tower amidst tall trees, combined to produce one of the fairest views of the district.

I can only mention briefly a few Irises that appeared to be of outstanding merit. Foster's Crusader is a notable plant, with grand spikes of the deepest blue, in fine form. It is certainly one of his best. Near by was Kashmir White, very stately and pure in colour; Shalimar, with many branching stems, was typical of the Shelford seedlings. A small selection from Miss Sturtevant's seedlings, a noted American raiser, next claimed attention. Sarahand, with biscuit coloured standards and purple falls, with a wide margin, and B. Y. Morrison, of purple colouring with similar falls, struck me as distinct and novel, especially the former, though possibly this Iris would not appeal to all. This wide margin to the fall, corresponding to the colour of the standard, with a deep central streak of darker hue, is quite a novel break. Afterglow, 4 feet high, was a study in subdued tones, with its falls

shading from pale yellow to deepest gold. Dream is a tall, pale pink, very refined Iris. Amongst many others was the famous Lent A. Williamson, named after the raiser's father. I understand this Iris is highly thought of in the United States, and has been much sought after. It is on Alcazar lines, but richer in colour and not so sombre.

Varieties of another noted raiser, Mr. George Yeld, include the incomparable quartette, Lord of June, Neptune, Prospero, and Asia (Fig. 58). Limits of space will not permit a discussion of the qualities of each, but they are all good.

Have those who grow Lord of June noticed the strong fragrance of this variety? I do not know any Iris more heavily scented. Mr. R. W. Wallace did not know, nor could I obtain from Mr. Yeld, the parentage of these fine plants. Perhaps he does not know himself! It is a curious fact that these hybrids all do well in America. Maybe there is no Cypriana or Riccardii blood in them, which accounts for their being able to stand the rigours of the American winter. Mr. Yeld was impressed with the French Souvenir de Mme. de Gaudichau, which is a superb hybrid, early, and of deep violet colour and magnificent form.

Among the many fine introductions from Mr. Bliss, the two pallida forms, Rodney (dark blue) and Drake (light blue) were very striking. Dusky Maid, with its broad, spreading, margined falls, and Marsh Marigold, an improved Maori King, were in good form. The latter also appealed to Mr. Yeld. Knysna is good though somewhat small. Still, the pure yellow colour and good shape of the standards, coupled with its tall branching habit, give it almost pride of place amongst all clear yellows in cultivation to-day. A few superb blooms of Iris King made me pause and consider whether the raisers had advanced so far as they are apt to think on the road of progress. It is a grand plant, and there was evidence that others thought so too, as every flower had been cross fertilised.

Tomtit is good for the front row of a border, and the freshly opened flowers of Blue Bird are of the brightest blue.

Dominion was not in flower, it having only been moved from Colchester the previous autumn, and was not yet established, but I hear that it was the centre of attraction at the show of the American Iris Society last season. A new seedling named Susan Bliss, a daughter of Phyllis Bliss (see Fig. 59) showed great promise, being tall and shapely and a deep shade of pink, the best of this class I have so far seen. A seedling of Dominion, called, if I remember rightly, Bruno, a harmony in bronze and red purple, held our attention, and Mr. Yeld saw in it a great development and a vision of a wonderful race of fine garden plants. Vilmorin's Ambassadeur was growing near by and, though very fine, Bruno surpassed it. It possesses what perhaps is best described as an improved Dominion fall, which is so outstanding in that remarkable variety.

Time and space do not permit me to dwell on all I saw, but some of Mons. Denis' new seedlings testify to his skill in no small measure, and a group from Newlands, raised by Sir Arthur Hort, contained the finest so-called purple bi-colors I have seen, such as Aun Page (Fig. 60), Hermione, Angelo, and Leonato. The collection at Tunbridge Wells includes the finest types of every raiser, and also a very fine set of Mr. Wallace's own raising, and is clear proof that here will be found for many years to come a unique assemblage of magnificent Irises well worth a visit in Iris time by all interested in these flowers.

To wander up and down amongst nursery beds of Irises is very delightful to the enthusiast, but for sheer enjoyment, an Iris garden well arranged and planted with the newer forms finds no rival in June. Such gardens have been made in recent years by many garden lovers, and I would mention a few, such as that owned by the late Mrs. Agnew at Halingbury Place; Herodine, belonging to Mr. Harold Terry; "The Mountains" garden of Miss Du Cane's, and one more recently laid out by Lady Elphinstone at Marylands.

Gardens like these afford endless opportunity and scope to the owner, and there remains the fact that the Iris increases rapidly and can always be moved and replanted.

As I want these notes to be of some practical use, I give the following short lists of varieties. List A contains what I consider the most essential ten varieties for any beginner to plant who is desirous of forming a collection. (A) florentina, Kochii, Kharput, Gracchus, Queen of May, Amas, flavescens, Madame Chereau, Mrs. Darwin, and Jacquinianna. (B) This second list is for those who possess most of the former and want to advance—Alcazar, Eldorado, Ossian, Nibelungen, Prosper Langier, Rhein-Nixe, Stamboul, Caprice, pallida dalmatica, Iris King, Lord of June and Monsignor.

The prices are reasonable for these varieties, and any garden that possesses a good clump of each will have laid the foundation of a good collection. They will also have

FIG. 59.—IRIS PHYLIS BLISS.

avoided buying many old varieties of little worth to-day.

The Iris has been aptly named the Poor Man's Orchid, and I doubt if any Orchid has more beautiful colours or a stately appearance. In the wonderful improvements that have been made in recent years, and especially with the tall, bearded type of Iris, the gardener has at his disposal a race of plants that is amongst the easiest to cultivate and one of the most beautiful in the floral world. The plants are adaptable for a variety of purposes and, being perfectly hardy, are suited for gardens in any part of the country. Traveller.

## VEGETABLES.

## ONIONS.

MANY gardeners make the mistake of sowing their Onion seed too late in the spring, and those who have not already prepared their Onion beds should do so at the earliest opportunity. Some of the most successful growers of Onions prepare their beds as soon in the New Year as the condition of the soil permits, and I have seen excellent bulbs raised from seeds sown in January. On no account, however, should the seed be sown before the ground is in a suitable condition for working. A liberal dressing of lime, soot, and plenty of wood ash will not only serve to supply food to the plants, but help to render the land friable and bring it into a good condition for a seed bed. After these materials have been applied, the surface should be forked lightly, or disturbed with a Planet Junior scuffle, and then made level with a wooden rake, placing all the stenes, clods, and rubbish on one side. Scan the bed carefully, and, if any part appears to be lower than the other, make it level by means of the spade. When these details have been completed, tread the soil to ensure a firm rooting medium for the seedlings, rake it level again, and, when the surface is perfectly even, draw a light roller over it. It will then be in a condition for making the drills, which should be one foot apart and very shallow. Sow the seed evenly, using sufficient to ensure a good crop of seedlings. The seeds may be covered by pressing the soil in the drills on either side by means of the foot, and after this is done a final raking will be necessary to ensure a neat and tidy bed.

Autumn-sown Onions constitute a very useful crop, as they are available at a time when the summer crop is over. Now is a suitable time to transfer the seedlings to their final quarters. Select ground that has been well trenched and prepared as for the summer crop. The seedlings should be planted in rows made one foot apart, allowing a distance of nine inches between the plants in the rows. In setting the plants by means of a dibber, take care to damage the roots as little as possible, and any that are broken in lifting, or that are decayed, should be cut off. Make the plants very firm in the soil. The work of either sowing or transplanting Onions should, if possible, be done on a day when rain threatens to fall later, as this will save much labour in watering. *J. H.*

## SPRING CABBAGE.

It is early yet to estimate how the autumn-sown Cabbages will turn in in most districts. The growth made last autumn does not, however, impress one as being altogether of the right kind for the season. Spring Cabbages seldom suffer while they are protected with snow, but alternate freezing and thawing, with perhaps strong winds to follow, are very trying to the plants, even though such weather may be of only short duration. Where there is any doubt at all concerning them, the wisest plan is to sow a quick-hearting variety on a gentle hotbed as soon as possible. If care is exercised, sturdy plants will be available, which, after being pricked out into nursery beds, will be ready for putting out in their final quarters in April, and ready for cutting very little later than the earliest plants which have survived the winter. This is due to the fact that growth is very rapid at this season, provided the soil is favourable, and the stimulating effect of nitrate of soda is not overlooked. First of All and Earliest are excellent varieties for spring sowing. As for winter-maturing Cabbage, there is a risk attending their culture in late districts, but it is well worth taking, for, although present prospects are only moderate, excellent heads were available until the turn of the year. Last spring we had June-sown plants in excellent condition in April, and a little later they compared most favourably with those sown in August. Winter Cabbages, of which Christmas Drumhead is a fair example, are remarkable for their short stems, self-protecting habit, and hardness. *Y. G.*

## HOME CORRESPONDENCE.

[The Editors do not hold themselves responsible for the opinions expressed by correspondents.]

**Lilium testaceum.**—The above name was given by Lindley, and published in the *Botanical Register* (1842), Misc. 51, and Japan was given as the country of its origin. The name *L. Isabellinum* was given by Kunze in *Bot. Zeit.*, I. (1843), 609, and is therefore a year younger than Lindley's name (see p. 3). I have also been interested in the discussion concerning the meaning of the word Isabelle in connection with this Lily. One of my French dictionaries states that it means dove-coloured, or cream-coloured; another gives light bay or dun. As many translations have been given for testa-

FIG. 60.—IRIS ANN PAGE (SEE P. 117).

ceum, Nicholson, in his *Dictionary of Gardening*, gives light brown; Johnson, in his *Gardeners' Dictionary*, has this same translation; but in the edition for 1917 it is given as yellow-red. Lloyd's *Encyclopaedic Dictionary* translates the word as brownish-yellow for botanical or entomological purposes. Testaceus was an adjective used by Pliny, and it comes from the noun test, a piece of burned clay, brick or tile, a piece of baked earthenware, the shell of a shell-fish, etc. As clay exists in a variety of colours, so would the baked article vary, and no doubt some samples might readily be described as brownish-yellow or yellow-red. The colour of the flower in England has been described as orange-red, dull yellow, and yellow tinged with dull red, by different authors. Bixa Orellana (see p. 56) produces the Arnotta of commerce. It is obtained from a red pulp that covers the seeds, but can be used to produce orange and yellow dyes for silks; also to stain cheese, and to give a yellow colour to butter and milk. The plant forms a small tree about twenty or thirty feet high and produces rose coloured flowers. *J. F.*

**Canker in Melons.**—A frequent cause of this disease is the practice of mixing manure in the soil previous to planting. The late Mr. R. Gilbert, of Burghley, was the best Melon grower of his time and the raiser of many new varieties; he used nothing but good turfy loam for his plants and had no trouble with canker. If growth was not sufficiently vigorous weak liquid manure was given as required. I had frequent opportunities of seeing his Melons during the last seventeen years of his life, and they were always in the best condition. A bottom heat of 70° to 75° was secured for starting the plants, and a minimum temperature of 65° provided whenever possible. He had the advantage of special houses and plenty of good soil from the new red sandstone formation. "Anxious" and many others are not so fortunate in this respect. "Wilt" disease was unknown in those days, and is no doubt far more difficult to control than canker, especially where other plants are grown in the same structure. Probably sterilising the soil and houses is the only way to prevent wilt. *W. H. Divers.*

**Do Plants Know Time?**—Regarding Mr. R. Irwin Lynch's notes on page 31, it may be interesting and knowledge to some that at Coombe House, among exotic plants cultivated in a stove, in a temperature of not less than 65°, were half a dozen specimens of *Dracaena Goldieana* in 9-inch pots. One of these plants produced a terminal inflorescence, a conical growth, formed of clasping bracts; from beneath these large bracts about one dozen flowers would protrude about an inch, in bud form only, about twenty-four hours before they opened. Then for about one week, punctually at 3.55 p.m., this number of flowers would open and fully expand, and exactly at 4 p.m. the flowers closed, never to open again. Some years later, another specimen flowered, and this plant I observed, watch in my hand. I then concluded that the pollen was released but fertilisation took place while the flower was closed; it is evident that *Dracaena Goldieana* knew the time. *Mark Mills, Coombe House Gardens, Croydon.*

**Voles.**—Mr. Hollingworth's inquiry on page 95 as to the best methods of stopping the depredations of these insignificant quadrupeds is not easy to answer. There seems to be a general invasion of them all over our island, and, as in that of some 40 years ago, the only means of extermination must be by natural enemies, owls and hawks. Neither dogs nor cats have a dislike to them, and they thrive where rats and mice would be destroyed by our domestic friends. Nor do they seem to care for the usual baits fatal to the last mentioned, but traps baited with Grapes, Figs, Pears and probably Apples are irresistible. Many dozens were destroyed here last autumn with Grapes and pieces of Figs as bait. I have caught them with a piece of Carnation leaf, and of no plant do they seem so fond as Carnations. Of course, in a large orchard, these means would be of little service, and probably the best way of getting rid of them would be to burn the grass, if that could be done by spraying with petrol. The voles have not touched Apple trees here, but Pears have not escaped injury by them. *R. P. Brotherton.*

**Garden Irises.**—So great is the interest in Irises in France that a special Iris conference is being held in Paris this year. In this respect our Continental friends have seemingly stolen a march on us. However, the *Journal of the R.H.S.*, Vol. XLVII., Part 1, January, 1922, just issued, leads one to hope for a whole-hearted recognition of the Iris in this country. The *Journal* in question contains a classification of Irises. This is a sign of the times, and a step in the right direction, and it leads one to hope that the Iris will come into its own in England as it has done in France and America. This classification of Irises is an attempt (and a very commendable one) to arrange varieties in colour groups. The adoption of colour as a basis of arrangement leads, of course, to the vexed question of names of colours, which is dealt with in a very able way. The groups are conveniently arranged and carefully thought out. *Traveller.*

## SOCIETIES.

### ROYAL HORTICULTURAL.

The following awards have been made to vegetables after trial at Wisley:—

#### Cauliflowers

##### AWARDS OF MERIT.

No. 1, *Feltham Forcing*, from Messrs. WATKINS AND SIMPSON; No. 16, *Improved Large Erfurt*, from Messrs. SUTTON AND SONS; No. 18, *Early Dwarf Erfurt*, from Messrs. NUTTING AND SONS; No. 20, *Early Emperor re-selected*, from Messrs. J. CARTER AND CO.; No. 23, *Early Favourite*, from Messrs. BARR AND SONS; No. 33, *Early Dwarf Midsummer*, from Messrs. BARR AND SONS; No. 40, *St. Omer*, from Mr. DAVIDSON; No. 43, *Magnum Bonum*, from Messrs. SUTTON AND SONS; No. 44, *Purity*, from Messrs. SUTTON AND SONS; Nos. 61, 63, *All the Year Round*, from Messrs. SIMPSON AND Messrs. SUTTON AND SONS; No. 69, *Empress*, from Mr. DICKS; No. 135, *Incomparable*, from Messrs. BARR AND SONS; No. 150, *Autumn Giant*, from Messrs. DOBBIE AND CO.

##### HIGHLY COMMENDED.

No. 8, *Forerunner*, from Messrs. CARTER AND CO.; No. 12, *Early Dwarf Best of All*, from Messrs. BARR AND SONS; No. 38, *Snowwhite*, from Mr. CLUCAS; No. 38, *Enkhuizen Market*, from Messrs. BARR AND SONS; Nos. 57, 58, *Snowdon*, from Mr. DAWKINS and Mr. CLUCAS; No. 90, *Autumn Queen*, from Messrs. BARR AND SONS; No. 91, *Summer Favourite*, from Mr. SPEED; No. 99, *Snowman*, from Messrs. TOOGOOD AND SONS; Nos. 107, 147, *Walcheren*, from Messrs. COOPER, TABER AND CO. and Messrs. DOBBIE AND CO.; No. 136, *Late Giant*, from Mr. DAWKINS; No. 137, *Metropole*, from Messrs. J. KELWAY AND SON.

##### COMMENDED.

Nos. 115, 116, 117, *Eclipse*, from Messrs. BARR AND SONS, Messrs. NUTTING AND SONS and Messrs. J. KELWAY AND SON; No. 118, *Johnson's Market*, from Messrs. BARR AND SONS.

#### Celery.

##### AWARD OF MERIT.

No. 1, *Golden Self Blanching*, from Mr. J. B. RICE; No. 5, *White Plume*, from Messrs. BARR AND SONS; No. 15, *Early Rose*, from Messrs. R. VEITCH AND SON.

##### HIGHLY COMMENDED.

No. 3, *Paris Golden Yellow*, from Messrs. BARR AND SONS; No. 6, *Dwarf White*, from Mr. CLUCAS; No. 7, *Dawn*, from Messrs. J. CARTER AND CO.; No. 8, *Paris Rose*, from Messrs. BARR AND SONS; No. 17, *Easy Blanching*, from Mr. J. B. RICE; Nos. 20, 21, *Defiance* (Bibby's), from Messrs. R. VEITCH AND SON and Messrs. WATKINS AND SIMPSON; No. 31, *Hawmark White*, from Messrs. A. DICKSON AND SONS; No. 38, *Favourite Pink*, from Messrs. DOBBIE AND CO.; No. 40, *Perfection*, from Mr. H. MILLER; No. 41, *Matchless Pink*, from Messrs. A. DICKSON AND SONS; No. 42, *Giant Pink*, from Messrs. J. CARTER AND CO.; No. 44, *Champion Pink*, from Mr. F. DICKS; Nos. 49, 50, *Standard Bearer*, from Messrs. J. CARTER AND CO. and Messrs. WATKINS AND SIMPSON; Nos. 51, 52, *Covent Garden Red*, from Messrs. R. VEITCH AND SON and Messrs. WATKINS AND SIMPSON; No. 60, *Exhibition Pink*, from Messrs. RYDERS.

##### COMMENDED.

No. 23, *Champion Solid White*, from Messrs. BARR AND SONS.

#### Celeriac.

##### HIGHLY COMMENDED.

No. 2, *Ne Plus Ultra*, from Messrs. R. WIBOLTT; No. 3, *Giant Prague*, from Messrs. WATKINS AND SIMPSON; No. 5, *Giant Smooth Prague*, from Messrs. BARR AND SONS; No. 11, *Large Erfurt*, from Messrs. R. VEITCH AND SON; No. 12, *Celeriac*, from Messrs. SIMPSON.

#### Tomatos.

##### AWARD OF MERIT.

No. 1, *Ariator*, from Messrs. DICKSON AND

ROBINSON; Nos. 16, 17, 18, *Kondine Red*, from Messrs. WATKINS AND SIMPSON, Messrs. SYDENHAM and Messrs. R. VEITCH AND SON; No. 23, *New Sceptre*, from Mr. DAWKINS, and No. 24, *Beatall*, from Messrs. LAXTON BROS., were considered to be too much alike; No. 61, *Hillside Comet*, from Messrs. R. VEITCH AND SON; No. 121, *Golden Nugget*, from Messrs. BARR AND SONS.

##### HIGHLY COMMENDED.

No. 7, *Victoria, Whole Salad*, from Messrs. ATLEE, BURPEE AND CO.; Nos. 32, 33, *Ailsa Craig*, from Messrs. LOWE AND SHAWYER and Messrs. ROCHFORD; No. 115, *Orange Sunrise*, from Messrs. WATKINS AND SIMPSON, and No. 120, *Golden Sunrise*, from Messrs. BARR AND SONS, were considered identical.

##### COMMENDED.

No. 58, *Water Baby*, from Mr. A. BALCH.

## Obituary.

**The Viscount Harcourt.**—The death of the Rt. Hon. the Viscount Harcourt has removed from the world a man who can ill be spared. Although ill-health had led to his partial retirement from public affairs, his sound and ripe judgment, his gracious urbanity and kindly spirit made and kept him a real force among men. At no time in his career did the rare qualities with which he was endowed enable him to do finer work than during the war. In unobtrusive manner, yet with untiring energy, he devoted himself to the service of his country. Among his many activities of this time, his chairmanship of the Army Agricultural Committee deserves to be specially remembered. By his tactfulness and his accessibility to ideas, he was able to achieve through that Committee remarkable results in food production by our armies in all parts of the world. Always a keen gardener, Lord Harcourt, in his later years, enjoyed more and more acutely working in and improving and planning his garden at Nuneham. At home there in his garden he was that rarest of men, the perfect host. Every plant that grew there he knew, and although the formal gardener found in the *déshabillé* of the Nuneham Gardens a subject of lament, no one who made its tour with Lord Harcourt could fail to fall presently under the enchantment of the place. Beautifully situated in pastoral country with the river winding about beyond the meadows which lie below the garden and encircled by woods stretching away for miles, Nuneham is a gardener's paradise. The house looks over a broad expanse of country, away to the heights of Peers Hill and Cumnor. The terraced gardens offer ample opportunity for the growing of wall plants of some tenderness. Among the many plants which Lord Harcourt was wont to point to with pride as doing admirably, clothing terrace walks and some reaching almost to the housetop, were Banksian Roses, *Vitis purpurea*, which last autumn presented a marvellous mass of colour; *Bridgesia spicata*, *Ceanothus papillosus*—more tender than *C. dentatus*—*Stauntonia latifolia*, *Sollya heterophylla*, *Buddleia Colvillei*, *Mandevilla suaveolens*, *Cestrum aurantiacum* and *C. Newelli*, *Fabiana imbricata*, *Actinidia scandens* and *A. Kolomikta*, *Smilax sp.*, *Ampelopsis sempervirens*, *Tropaeolum speciosum*, *Crinodendron Hookeri*—doing well on a north wall—*Berberidopsis sp.*, *Celastrus scandens* rooting in a north aspect, *Akebia lobata* and *A. quinata*, the last with smaller fruit, but better flowers than the other species. One of the most pleasing features of the garden is the pillars of Rosemary growing against the terrace piers. Something of a wilderness it is true, but, nevertheless, Nuneham is a garden in which anyone who loves plants and beauty of scene would fondly linger, and from which reluctantly depart. And now the owner who made it and who loved it yet more than might any visitor is gone, leaving behind a memory of distinction and courtesy and a blending of wit and kindness as delightful as it is rare.

**John Page.**—We learn with very deep regret that Mr. J. Page, of Hampton, and of 35, Wellington Street, Covent Garden, passed away early on Tuesday, the 7th inst., after a very severe illness. Mr. Page was one of the most remarkable men in the Flower Trade, with which he had been connected for upwards of forty years, and for twenty-one years he had been associated with his brother Edward (Messrs. J. and E. Page) as salesmen in Covent Garden. Endowed with a strong personality and wonderful business ability, he was nevertheless one of the largest-hearted and most generous of men, and in any special case of need brought to his notice he was as generous with his time as with his money. He was a type of man who can ill be spared from any branch of industry and he will be very greatly missed by all who are connected with the Covent Garden flower industry. Mr. J. Page was 63 years of age, and the second son of Mr. Matthew Henry Page, who practically founded the flower-growing industry in the Hampton district. The funeral takes place to-day (Friday); the service will be held at 2.45 at All Saints Church, Hampton, and the interment takes place at Tootington Cemetery at 3.30 p.m.

**E. H. Battram.**—By the death of Mr. E. H. Battram, of Parknevydd Farm, Abercynon, on March 3, a remarkable personality has been lost to the world of horticulture. About 54 years ago, Mr. Battram went to Merthyr as head gardener to Mr. R. T. Crawshaw, who had a very fine establishment at Cyfartha Castle. Mr. Crawshaw, known as the Iron King, encouraged his gardener to exhibit, consequently fruits and plants from Cyfartha won prizes at numerous exhibitions throughout the country during the 'seventies. Eventually, Mr. Battram became manager of the Merthyr and Aberdare Joint Sewerage Farms' Committee, and removed to Abercynon, where he resided for the last 37 years, making a vast number of friends and endearing himself to the people of the district. He was probably the best known and most popular person in the locality, as he was brought into contact with many people through his work in connection with the Congregational Church, the Merthyr Ragged School, the Abercynon Horticultural Society—which he founded—and local allotment associations. He was unsparring in his efforts to raise the fallen and to improve the homes and gardens of those around him. He was a capital speaker, and, as a chairman of meetings, had scarcely a rival in South Wales.

**Dr. W. Van Fleet.**—The American horticultural papers record the death of this distinguished plant breeder of the United States Department of Agriculture, on February 26, following an operation. Dr. Van Fleet in early life studied medicine, graduating in that profession in 1880, but he soon abandoned his profession as a doctor to take up farming, and later became editor of the *Rural New Yorker*. In 1910, he entered the service of the U.S.A. Department of Agriculture, and achieved notable success as a plant hybridiser; he was especially successful in the raising of Roses, of which he made several hundred crosses. He was the raiser of American Pillar, which may be described as the finest of all the rambler varieties, and other famous Roses which he gave us are Dr. Van Fleet, Silver Moon, Miss Mary Wallace and Beauty of Rosemawr. He also developed a blight resistant Pear, and raised several new varieties of Strawberries. Dr. Van Fleet also turned his attention to the improvement of the Gladiolus, two of his best known varieties being Princeps and Mastodon; he was the author of a useful book on the Gladiolus.

**Francis Peckham Russell.**—We learn with regret of the death of Mr. Francis Peckham Russell, who was formerly gardener at Farringford to the late Lord Tennyson, the Poet-Laureate. Mr. Russell, who was eighty years of age, had been for 48 years in the service of the Tennyson family. The funeral took place at Freshwater, Isle of Wight, on Tuesday last, amid many manifestations of the high esteem in which Mr. Russell was held.

**TRADE NOTES.**

For the past 18 months, the Transport Sub-Committee of the Chamber of Horticulture, comprising one delegate each, and the Secretaries, of the Horticultural Trades' Association, the Federation of British Growers and the Chamber, have been engaged in fighting the railway companies' proposed reclassification of goods by merchandise trains. This Committee is now in the happy position to announce success of its case for the nursery side of horticulture.

In Court A, Judges' Quadrangle, Royal Courts of Justice, on Thursday, February 23, the Rates Advisory Committee, who have plenary powers in fixing future classification, gave judgment on the outstanding differences between the Chamber and the companies, and in every instance a reduction was the result, in addition to which reductions had already been made by direct conference with the railways.

This is very tangible evidence of what organisation can do for industry. Thirty years ago, when the existing classification was compiled, horticulture was not strongly organised, and consequently many injustices crept in unchallenged. The position is entirely different to-day, and a brief review of the Sub-Committee's activities may not be out of place.

Early in 1920, the Rates Advisory Committee was appointed by the Ministry of Transport for the purpose (*inter alia*) of revising classification of merchandise traffic, and later in the year the railway companies issued a huge volume listing their traffic, and proposed new classification. Objections to those proposals could be lodged, otherwise they would stand. The Sub-Committee made a minute examination of those proposals, and unfairly-classified goods were objected to. In this preliminary work complete harmony existed between the Sub-Committee and the National Federation of Fruit and Potato Trades Association, who were energetically taking up the matter from the fruit and vegetables standpoint, and latterly it was agreed that this Federation should conduct the case for fruit and vegetables and leave the nursery side to the Sub-Committee. Then followed the conference with the companies who allowed some objections, the remainder being dealt with by the Rates Advisory Committee, whose decisions are given below, together with the original proposals for purposes of showing the gains:—

	New Classification	Company's original proposals
	Classes.	Classes.
Trees. Min. 50 cwt. p. truck	15	16
Trees. e.o.h.p.	17	18
Plants and shrubs. Pots, baskets, tubs.	20	20
Plants and Shrubs. Bundles.	18	20
Plants and Shrubs. e.o.h.p.	17	18
Bulbs	16	18
Quicks.	15 & 17	18 & 20
Evergreens.	18	19 & 20

The accepted concessions by direct negotiations with the railway managers are:—

Asparagus, Rhubarb and Seakale Roots.		
2 ton lots.	Class 10	} 18
Min. 20 cwt. p. truck	" 12	
Less than 20 cwt. p. truck.	" 14	
Seeds—Vegetable	" 16	19

It will be observed that the new classes are differently numbered to those now in use—comparative tables are as under:—

Present Class.	Revised Class.
C. equals	7, 8, 9, 10.
1. "	11, 12, 13
2. "	14, 15, 16.
3. "	17, 18.
4. "	19.
5. "	20.

As an illustration of the real value of the above reductions, Mr. G. Hewlings Barr has kindly supplied the following figures, comparing Classes 3 and 2 (equivalent to new classes 18 and 16, which will apply to Bulbs).

London to Holbeach—58s. per ton, against 49s., saving 17 per cent.

London to Glasgow—132s and 94s., saving 28 per cent.

These figures are based on existing rates, but whatever the actual rates may be when the revised classification operates, probably within the next two years, pro rata saving will be effected.

The inaugural meeting of the British Glasshouse Produce Marketing Association, Ltd., was held on Thursday, the 2nd inst., in the Central Hall, Westminster, for the purpose of considering an advertising and publicity campaign in connection with the sale of Tomatos. The meeting was held under the auspices of the Lea Valley and District Nurserymen's and Growers' Association, Ltd., and there were present about 150 representatives of various bodies concerned with the growing and marketing of Tomatos. The chair was occupied by Mr. H. O. Larsen, chairman of the Lea Valley Association. A representative of the London Press Exchange, Ltd., outlined a scheme of advertising, and gave examples of industries that had adopted publicity campaigns, pointing especially to the great advance made in the Californian Orange industry by this means. In 1906, before the Californian growers adopted their publicity campaign, they produced 8,973,342 boxes of Oranges, and had great difficulty in disposing of this large number in the United States, but by advertising the fact of the value to the public of such delicious and healthy fruit the sales rose in 1919 to nearly 19,000,000 boxes, and the home market absorbed the whole of the output, so that there was very little available for export. Although in 1921 the Californian growers spent £200,000 in advertising, it was done at a cost of 1d. per box. It was suggested that what was done in California with regard to Oranges could be done here in the case of Tomatos. When prices are low at the period of the highest production, the public should be stimulated to purchase by means of advertisements, posters, and showcards displayed in the greengrocers' and fruiterers' shops. Another means of increasing the sales would be to pack the fruits in non-returnable containers of a cheap, yet attractive type. It was also suggested that small recipe-books, showing the various methods in which Tomatos may be employed, should also be distributed free to housewives. The estimated cost of the scheme was £12,000. It was calculated that would involve a contribution by the growers of 1/12th of a penny per pound of their crop, but, if the scheme was widened to embrace the whole of the growers in the country, 1/27th of a penny per pound would suffice. It was suggested by some of the speakers that the various growers' associations should be brought together under one central body, which should be responsible for the advertising. It was pointed out, however, that the funds of such an association would hardly be likely to be available for the special purpose of advertising one particular crop, such as Tomatos. The chairman said that it would be a good thing to have a national advertising committee to advertise all produce, and that the Lea Valley growers would be willing to work with any other associations to make such a national scheme a success. It was stated that the average yields of Tomatos in this country were:—In the Lea Valley district 20,000 tons, Guernsey 20,000 tons, Jersey 10,000 tons, and the rest of the country 20,000 tons, making a grand total of 70,000 tons or 12,000,000 strikes. It was recognised that it would be impossible to utilise new, non-returnable containers for the marketing of the whole of this very large annual yield, but it would be desirable to bring them into use gradually, as this would be one of the best means of tapping new sources of sales, such as the large multiple shops, which would not be bothered with returnable baskets. The following resolution was proposed by Mr. C. H. Shauls and carried unanimously:—"That the advertising and publicity scheme, as outlined, be carried

through, and that a National Association be formed and registered under the name of the 'British Glasshouse Produce Marketing Association, Ltd.'" It was also resolved that the growers should have the option of contributing on the basis of output of crop or area of glass under cultivation. The members present pledged themselves to support the scheme financially, and an Executive Committee, consisting of eight members of the Lea district, three from the Worthing district, three from Guernsey, two from East Sussex, two from North-West Hants, and two from any other district, with power to add to their number, was formed to carry out the scheme.

**ANSWERS TO CORRESPONDENTS.**

**EARLY-FLOWERING THORN:** R. V. There is little doubt that the specimen sent is the Glastonbury Thorn, *Crataegus monogyna* var. *praecox*. The most likely solution is that this particular bush was grafted in a nursery as a Glastonbury Thorn, but is only now revealing its true character. An alternative suggestion is that the bush has sported, repeating the precocious flowering of the Glastonbury Thorn. Whatever legend there may be attached to it, there is little doubt that the famous tree at Glastonbury Abbey originated as a sport from *Crataegus monogyna*.

**FLOWERS FOR MARKET:** A. G. H. (1) The best kind of perennial *Statice* is *S. latifolia*. This may be raised from seeds sown now in heat and planted out in May or June, but would not flower profusely till next year. It may also be raised from root cuttings about an inch long, and covered with about an inch of sandy soil, in October. Young plants will appear about March and April, and may be transplanted 2 ft. apart each way the following September to their permanent positions. There are several annual *Statices*, among the best being *Bonduelli*, yellow; *S. sinuata*, with blue, white and rose-coloured varieties—perhaps the most suitable for market work. *Suworowi* is also handsome, with bright rose flowers. These annuals may be raised from seeds grown in a temperature of 60° to 65° in February and March, afterwards pricking the seedlings out and hardening them off before transferring them to the open ground in May or June, to flower the same year. (2) *Physalis Francheti* is easily raised from seeds sown in spring, or better still, by dividing and replanting every portion of the rootstock to obtain quicker results. The finest coloured "lanterns" are produced in open, sunny situations. (3) *Gypsophila paniculata* (or rather its double variety) is an excellent market flower and will flourish in your limestone soil, being a lime lover, as the generic name indicates. The single variety is easily raised from seeds sown to produce flowering plants the next and following years. It may also be increased by division of the thick roots in autumn or spring. Your calcareous loam and southern aspect should suit all these plants well, and if a little organic manure is hoed in about once a month, the soil should keep in good condition and retain its moisture during the growing season.

**NAMES OF FRUIT:**—T. T. T. 1, Fearn's Pippin; 2, Grey Leadington.—S. H. 1, Downton Pippin; 2, Minchul Crab.

**NAMES OF PLANTS:** J. R. Probably *Asparagus asiaticus*, so far as can be determined in the absence of flowers.—T. M. W. *Lonicera fragrantissima*. A hardy shrub, native of China. It does not require any particular care as regards cultivation, beyond cutting out dead or old wood to prevent crowding of the growths. This species is often confused with *L. Standishii*, a very similar looking plant, but with longer, narrow, pointed leaves. Both species were introduced from China in 1845 by Robert Fortune.

**AVERAGE MEAN TEMPERATURE** for the ensuing week deduced from observations during the last fifty years at Greenwich, 41.6.

**ACTUAL TEMPERATURE:—**

*Gardeners' Chronicle* Office, 5, Tavistock Street, Covent Garden, London, Wednesday, March 15, 10 a.m. Bar, 30.3; temp. 45°—Weather—Dull.

The boisterous winds of March serve as a warning—much needed by all save experienced gardeners—that the staking of plants is the most necessary of all the lesser operations of the garden. Firm planting at the proper time and in the proper place will ensure trees and shrubs of a good chance of success which, even so, may be marred by such a season as that of last year. But if there be neglect of staking at planting time, even a propitious growing season may be powerless to establish or even save the plants. Such great importance—and rightly—do good gardeners attach to staking that they stake as they plant, knowing full well that in the multitudinous operations which unceasingly require attention day by day, that which is omitted to-day may be forgotten to-morrow. Needless to say, if staking be done at planting time it must be done again presently, otherwise the plant tends to be held up in the soil, instead of settling as the soil settles. When planting is done during the still days of late autumn, with soil in kindly state, the firmness with which the newly-planted shrubs and trees stand up is apt to make the inexperienced think that staking is unnecessary and that before the winds of March come the plant's own root hold will suffice. Anyone, however, who either knows the method of holdfast action practised by roots, or who has traced failures of planting to their source, will appreciate the fact that it is dangerous to leave any woody plant unstaked. It is, indeed, a counsel of perfection to urge that all should be staked. In this life some risks must be taken and when

large-scale planting is undertaken the less precious subjects may have to be left to fend for themselves. Yet it is a good thing to impress on the young gardener the maximum—spare the rod and spoil the plant. It is also a good thing to urge on him the importance of adequate staking. The rod—that is the stake—must be strong and long enough to admit of its being thrust so deep in the earth that the detailed movements of the soil which take place during winter may be prevented from reacting detrimentally to the plant's stability. The duty of a stake is to support and not to sway in unison with a wind-tossed plant. Of the perfect stake it may be said—it looks on tempests and is never shaken. The sharp eye of the observant gardener will detect the least tendency "to ride," that is, for a plant to sway backward and forward—as in a socket in the loosened soil about its collar, and he will know that spring is the season when great and often irreparable harm is done. Again, everyone who knows the explosive power of frost—to lift plants out of the ground—knows also that staking, if not firm, is useless. Even in the absence of frost many plants have the tendency to lift themselves out of the soil—a tendency which in others is more than counterbalanced by their system of contractile roots that serve to draw the plant down in the soil and to hold it firmly there. Roots of well established plants are generally efficient holdfasts, but even with such plants a stake is often necessary for many years. Cupressus macrocarpa, for example, in light soils, growing vigorously, and of ten or twelve feet in height, may begin to lean and almost topple over if its roots are not helped to regain their firm hold in the soil. The roots of a newly-planted shrub or tree are at first held passively. When root growth begins—and it apparently goes on whenever soil temperature and other conditions allow of it—the plant hangs on to the soil by the tips of its roots only. The growing region of each root is but an inch or so in length and is situated just behind the tip. By the elongation of that region the tip is driven wedge-wise into the soil. Behind that growing region is the absorbing region, where the root-hairs grow. If these latter delicate tubular outgrowths are torn away from the soil particles to which they attach themselves they can do no work or absorption, and the plant—if it be an evergreen—will assuredly wither. The young fibrous roots also, which grow out from the larger, thong-like roots, if they lose their attachment to the soil, cease to grow—each tap they receive as they knock against the hollow tunnel in which they lie, as is the case with a "riding," i.e., a swaying plant, serves to start them curving away from the direction in which the blow fell and there is no stability from them. Wherefore it is that when the Daffodils "take the winds of March in beauty" is the latest time for the gardener to look over all newly-planted things and re-stake those which need it. It ought to be done earlier, but although it is not true to say in this case "it is never too late to mend," there is always a good prospect of a plant which has begun to "ride" being restored to health by being brought back to a stable state.

**Mr. Kingdon Ward's Seventh Expedition in Asia.**—Readers of *The Gardeners' Chronicle* will be glad to learn that Mr. Kingdon Ward has completed his Sixth Expedition in Asia and has already started his seventh. On this occasion he will follow an entirely different

route to that of last year, consequently the accounts of his journey, which he has promised to send us, should prove unusually interesting. We have also received from him a package containing further accounts of his recent journeys. Apparently Mr. Kingdon Ward is in good health and, judging from his letter, he starts his Seventh Expedition with great hopefulness and in excellent spirits.

**Gardeners' Royal Benevolent Institution Festival Dinner.**—Lord Lambourne, President of the Royal Horticultural Society, will preside at the 77th Anniversary Festival Dinner in aid of the funds of the Gardeners' Royal Benevolent Institution at the Grocers' Hall, London, on June 27 next. The names of ladies and gentlemen willing to act as stewards in connection with the festival, are earnestly solicited, and will be gratefully received by the Secretary, Mr. George J. Ingram, at 92, Victoria Street, Westminster, S.W.

**Hedge Trimming Competition.**—A series of competitions in hedge trimming was held recently under the auspices of the Quorn Hunt, in the parish of Old Dalby. Prizes to the value of £40 were offered in five classes, and they attracted 120 entries. In each case the competitors were required to cut, lay and bind eleven yards of hedge as a bullock fence, not less than 4 ft. 6 inches high, and four and a half hours was allowed for the work. The first was the Championship class, and the other classes were restricted to men of different ages, from 45 and upwards in class II., down to those under 25 years, in class V. The first prize in the Championship class was won by Mr. Job Dilks, Queenborough. In presenting the prizes, Mr. G. W. Brewitt remarked that such competitions encouraged skilled labour, and the man who was a skilled hedge cutter need not be unemployed, for there was always work for a good hedge cutter. The object of the competition was to educate men how to stop a gap in a hedge without resorting to the use of barbed wire.

**Fruit and Potato Traders.**—*The Handbook and List of Members* of the National Federation of Fruit and Potato Traders' Associations (Incorporated) Ltd., is an interesting, useful, attractively got up, and well bound book of large octavo size, extending to 430 pages. The Annual Report of the Federation occupies a prominent position, and we gather from the financial statement that in connection with the Propaganda Fund over £2,200 has been spent; £582 in connection with the Inspector of Empties Fund, and £2,368 by the Railway Defence Fund. The General Fund shows a substantial balance of £1,863. Rules of the Federation and various reports are included, but the bulk of the book is devoted to the names and addresses of the members. These are given under the various towns, commencing with Aberdeen and concluding with York, and where there are several members resident in one town, their names are given in alphabetical order. It is the most complete list we know of those engaged in the fruit and Potato trades.

**Potato Trials by the National Institute of Agricultural Botany.**—The National Institute of Agricultural Botany will this season begin a series of yield and quality trials of Potato seedlings. The series will last for five years: for the first two or three years the trials will be carried out in Scotland, and for the last two in Scotland and different Potato districts in England. Tests will be applied to determine the time of maturity, resistance to disease, cropping and keeping capacity, and culinary properties of the seedlings entered. The following conditions, fuller details of which are given in a form of agreement now being drawn up, will apply to the acceptance of such seedlings as the Institute may decide to admit to the trials: (1) The owner must deliver the whole stock of the seedling, which he must guarantee to be the only existing stock thereof, to the Institute free of charge. (2) The Institute retains the right to reject any stock at any stage

\* Handbook, 1922, of the National Federation of Fruit and Potato Associations (Incorporated), Ltd., 31 and 35, Southampton Street, Strand, W.C.2.

of the trials; if rejection takes place after the first year, the owner may recover the stock on payment of costs of removal; if in subsequent years by payment of a fee prearranged to cover the Institute's expenditure on testing the stock up to the date of rejection. (3) The Institute will make all arrangements for trial and marketing of the stock; the owner may, however, veto the marketing of the stock at any stage on payment of the Institute's expenditure on the stock up to the date of veto. In the event of the veto being exercised the stock will be destroyed. (4) If and when the stock has been sold to the trade, half the net profit on the whole transaction will be paid to the owner. Individuals, institutions, or other bodies wishing to enter stocks for these trials must apply before March 31, 1922, to the Superintendent, Potato Testing Station, Ormskirk, Lancs., from whom forms of application are obtainable.

**Proposed National Daffodil Society.**—The meeting of Daffodil enthusiasts, arranged to be held at the Royal Horticultural Hall, at 2.30 p.m., on Tuesday last, to consider a proposal to form a National Daffodil Society, was postponed to four o'clock the same day, consequently several interested persons were unable to be present. Mr. G. W. Leak presided over a moderate attendance, which included Messrs. George Monro, F. H. Chapman, P. R. Barr, W. R. Dykes, H. G. Hawker, G. Churcher, W. B. Cranfield, Herbert Smith, W. F. M. Copeland, J. Duncan Pearson, R. W. Wallace, J. W. Jones, Guy L. Wilson, W. A. Milner, and the Rev. G. H. Engleheart. The proposal was discussed at some length, and views were freely expressed both for and against it. The absence of the Rev. Joseph Jacob was deeply regretted, and those present felt that no further action should be taken until Mr. Jacob could attend, consequently the meeting was adjourned until a date in April convenient to him.

**Kew Guild Journal.**—Amongst all the numerous publications dealing with special horticultural societies and associations of gardeners, none is of more general interest to horticulturists than the *Journal of the Kew Guild*. This annual journal is not only a record of domestic matters connected with the Guild, but shows better than any other publication the importance that horticulture plays in the development of the resources of our vast Empire. The members are spread over every part of the globe, and each issue of the journal contains long letters from those abroad describing their experiences in gardens and botanical stations. The frontispiece is a portrait of Mr. Charles Cundy, the president for the year, and accompanying it is a short biographical notice showing that he entered Kew in 1878, and afterwards became a nurseryman at Sudbury, in Suffolk. The changes in the staff at Kew, owing to retirements, include the Directorship, Keeper of the Herbarium and Library, Medical officer and the official artist, Miss M. Smith, who has been responsible for most of the plates in the *Botanical Magazine* since 1878. The principal events under the term of office of all these officials are referred to in special articles. Reference has already been made in these pages to the appointment of Dr. A. W. Hill, as Director, in succession to Sir David Prain, and Mr. A. D. Cotton, as Keeper of the Herbarium in succession to Dr. Stapf. That Kew is as popular with the public as ever is shown in the number of visitors to the gardens, 3,236,308 during 1921, an increase of more than 100,000 as compared with 1920. On Whit Monday last year, nearly 60,000 people were present in the gardens. We learn that M. L. Gentil has resigned the position of Curator of the Brussels Botanic Gardens, and is settling at Neugele, near Lusambo, on the Sankura River of the Belgian Congo, to help his brother in the exploitation of forest products. We regret to learn that damage done to plants in the gardens and greenhouses by the use of salt water pumped from the lake, is still continuing, owing to the deposits of salt in the soil. The lake itself is being cleared, and the work has

occupied a gang of sixteen men for twelve weeks.

**W. A. Bilney, V.M.H.**—Mr. W. A. Bilney, of St. George's Avenue, Weybridge, and of the firm of Messrs. Morgan Veitch and Bilney, solicitors, is one of several Devonshire men who have rendered invaluable services to the Royal Horticultural Society. For many years he has been a member of the Council of the R.H.S., and it is somewhat difficult to particularise the services he has rendered that body. He is regarded as a general utility man by his colleagues, and whether it is a matter of legal advice, business methods, arrangements for a great exhibition, drainage for the Chelsea show, or the merits of a new plant, Mr. Bilney's advice and opinion are always sought. A great lover of Orchids, Mr. Bilney had a large collection of these plants at Weybridge a few years ago, and was especially successful in the cultivation of Dendrobiums, but for the present his tastes run more in the direction of alpine and herbaceous plants. Some evidence of Mr. Bilney's services to horticulture may be gathered from the statement that he is Chairman of the R.H.S. Exhibition Committee, a member of the Wisley Gardens Committee, and also of the Finance and

MR. W. A. BILNEY, V.M.H.

General Purposes Committee of the Society, consequently it is not difficult to understand the reasons that led the Council of the R.H.S. to award Mr. Bilney the Victoria Medal of Honour in Horticulture at its recent annual meeting. It is Mr. Bilney's good humour and infectious enthusiasm that, coupled with great business ability, have made him such an important member of the R.H.S. Council and earned for him the respect and regard of all horticulturists. We may also add that Mr. Bilney represents the R.H.S. on the Council of the Chamber of Horticulture.

**Horticultural Invalids.**—The treacherous weather experienced of late has not been without its effect upon horticulturists, and we regret that several well-known personalities in the horticultural world are indisposed. Sir Harry J. Veitch has not attended any meetings recently, but our readers will be glad to learn that, although confined to his home, he is not seriously indisposed. Mr. S. T. Wright, the popular Superintendent of the R.H.S. Gardens, Wisley, is recovering from an illness that threatened serious consequences. Mr. John Heal, the eminent raiser of new plants, has been dangerously ill, but is recovering, and in a cheerful letter we have received he expresses the hope that he will be among his friends, as usual, on the occasion of the next R.H.S. meeting, at Westminster. Mr. Brian Wynne, Secretary of the Royal Gardeners' Orphan Fund, is

laid aside with influenza at a time when he is desirous of perfecting arrangements for the Festival Dinner; various members of the committee are, however, assisting him in the more pressing duties of his office, thus relieving him of anxiety and aiding his recovery. The Rev. Joseph Jacob was too ill to attend the meeting of the R.H.S. Daffodil Committee on Tuesday last, and his many friends regret that news concerning his progress towards recovery is not so favourable as they could wish. Mr. T. W. Taylor, of Kew, who underwent a serious operation at Charing Cross Hospital some time ago, has recovered from a long and severe illness, and we are glad to hear he has resumed charge of the Tropical Department at the Royal Gardens. Another invalid is Mr. David Ingamells, Chairman of Committee of the Royal Gardeners' Orphan Fund and of the British Florists' Federation; he is suffering from a slight attack of influenza, but hopes to return to business at Covent Garden during the latter half of the present week.

**British Mycological Society.**—A meeting of the British Mycological Society will be held in the Botany School, Cambridge, on the 18th inst. The programme includes the following papers: "Diseases of Apples in storage," by Mrs. M. N. Kidd; "The parasitism of *Nectria cinnabarina*," by Mr. J. Line; "Observations on the occurrence of Wheat rusts near Cambridge," by Mr. K. C. Mehta; and "Mould growths on cold-store meat," by Messrs. F. T. Brooks and C. G. Hansford. Opportunity will be given during the afternoon to visit some of the laboratories and other buildings in Cambridge. The party will travel from Liverpool Street at 8.30 a.m., and depart from Cambridge at 7.7 p.m., arriving at Liverpool Street at 8.35 p.m.

**Appointments for the Ensuing Week.**—Monday, March 20.—Reading and District Gardeners' Association's meeting; lecture by Mr. H. Wynn on "Sweet Peas for Exhibition and Decoration." Tuesday, March 21.—British Carnation Society's show at Royal Horticultural Hall. Wednesday, March 22.—Wimbledon and District Gardeners' Society's meeting. Thursday, March 23.—Royal Botanic Society's meeting. Friday, March 24.—Paisley Florists' Society's meeting.

**"The Gardeners' Chronicle" Seventy-five Years Ago.**—*Cottage Garden Cropping.*—You will be glad to know that the good advice given in the *Chronicle* (February 27) has been acted upon by a young gentleman in this neighbourhood. He has "exerted himself to the utmost in his small sphere"; first, by distributing about 200 hand-bills, with extracts from the *Chronicle*; and, secondly, by enabling the cottagers to purchase seeds at wholesale prices. A respectable and benevolent seedsman in the county town (to his praise be it spoken) not only supplied the seeds at wholesale prices, but took the trouble of making them up into small packets of different prices, from 1d. to 6d. each, to suit the wishes and pockets of the people, which, of course, greatly facilitated the work of the gentleman, who has already disposed of a variety of seeds to upwards of ninety cottagers, and is still going on. He has had no difficulties to contend with from "obstinacy or prejudice," they have all come willingly to his shop, and have eagerly purchased what he offered; though, of course, they were allowed their own choice. Almost every one took Beans, Peas, Carrots, Turnips and Onions. Many have also added Cabbage, Beet, Parsnip, and Kidney Beans; and some indulged themselves in Spinach, Radishes, Mustard and Cress. Many of them do not know the Parsnip or Beet, but some roots of each were produced in the raw state, and some were boiled for them to taste, and which induced many to become purchasers of the seed. There cannot be a greater charity than that of helping the poor to help themselves; and when they find their superiors taking a real interest in their welfare they are seldom found ungrateful. The Oswestry Society for Bettering the Condition of the Poor has offered prizes to cottagers who have in their gardens the best crops of any useful vegetables, excepting Potatoes. *Oswestry, March 15. Gard. Chron., March 20, 1847.*

**CHINESE SHRUBS AT ALDENHAM.**

(Continued from page 115.)

**DEUTZIA.**—Of the numerous Deutzias introduced from China, some of the handsomest are *D. glomeruliflora*, which for brilliancy of bloom stands probably highest among the white-flowered species; *D. longifolia*, with rose-coloured blooms; *D. longifolia Veitchii*, the finest of the pink-flowered forms; and *D. Wilsonii*, another large white-flowering species. All make fine bushes, which bloom with great freedom, and are benefited by the entire removal of the old stems from time to time.

**DIPelta.**—It is very gratifying to record the success of *Dipelta floribunda* and *D. ventricosa*, two delightful members of the *Caprifoliaceae*, and one may venture to predict that they will become two of our most popular flowering shrubs. *D. floribunda*, with pink and yellow blossoms, is the freer flowerer of the two, and the blossoms are very fragrant.

**EUONYMUS.**—*Euonymus lancifolius* and *E. Wilsonii* are two very distinct species, and, though not notable for their flowers, the latter is said to have remarkable fruits. *E. Wilsonii*, an evergreen, has pretty pale green foliage, and a fine specimen at Aldenham in tree form is now 10 feet high. So distinct is it that I do not think anyone who was not a great expert, and who saw the plant for the first time, would recognise the family to which it belongs.

**HYDRANGEA.**—There are apparently two forms of *Hydrangea anomala*—one of dwarf, spreading habit, and the other of upright or tree growth. The latter, with its flaky, light brown bark and red buds, is much the finer garden plant. *Hydrangea Sargentiana* is a singularly handsome member of this beautiful genus, and is worthy of inclusion in all gardens for the beauty of its velvety leaves. On the flowerless shoots these are of great size, nearly 1 foot long and 7 inches wide, dark green on the upper surface, and densely clothed with hairs. The under side is paler. The sterile flowers, produced in mid-summer, around the edges of the flat corymbs, are very pale pink, or white, whilst the fertile ones are deep red to lavender, and oftentimes shades of purple or violet. In winter the thick, light-coloured stems and dark brown buds show conspicuously. A fine specimen at Aldenham, 6 feet high, is perfectly happy in a partially shaded place, and it seems to be necessary to select such a position so that the hottest rays of the sun do not reach the leaves. Mr. Gibbs informs me that, although he was assured by Wilson that the plant flourishes in full sun in its native habitat, yet, when grown in England, it cannot endure the direct rays of the sun without burning badly.

**HYPERICUM PATULUM HENRYI.**—This St. John's Wort, originally introduced by Dr. Henry and afterwards sent home by Mr. Wilson, is one of the most satisfactory members of the genus, and from June until October the large, bright yellow flowers are very conspicuous objects. It is also a much stronger grower than the type, and is extremely hardy.

**ILEX.**—It would be sufficient recommendation to say that *Ilex Pernyi* is one of the most attractive of evergreen Hollies, and one of the best of Mr. Wilson's introductions with persistent leaves. It was originally found by him during his expedition in 1900. The Aldenham specimen is 6 feet tall, densely clothed with small, dark green leaves, and has a very pleasing, pyramidal habit. Though the bush has thriven well, it is far from being a rapid grower—at any rate, in Europe—for 6 feet is not much growth to make in nearly twenty years. The species was originally discovered by the Abbé Perny so far back as 1858. The variety named *Veitchii* has larger foliage; a specimen at Aldenham is 6 feet in height.

**KOLKOWITZIA AMABILIS.**—I know of few more charming shrubs than *Kolkowitzia amabilis*, and if its pink and yellow, *Abelia*-like flowers

are produced as freely in this country as in America it will, indeed, be a delightful addition to our gardens. In general appearance it suggests a *Deutzia*, and is perfectly hardy. Specimens at Aldenham are 4½ feet high, and as much through. *A. E. Thatcher.*  
(To be continued.)

**TREES AND SHRUBS.**

**ACACIA DEALBATA.**

I ENCLOSE a photograph (see Fig. 61) of a tree of *Acacia dealbata* flowering in the open in these gardens. This tree was planted in 1915 from a 6-in. pot, and is now 34 ft.

FIG. 61.—ACACIA DEALBATA FLOWERING IN THE OPEN AT WALHAMPTON GARDENS, LYMINGTON.

high, with a diameter of 21 ft. It was placed as the central plant of a group of five, but its rate of growth was so far in excess of the others that it was considered expedient to isolate it by removing the other four to allow it to develop into an evenly balanced tree. Although during the past three or four years it has promised very favourably for a good show of bloom, it has never, until this season, fulfilled that promise, which, I take it, is another instance of the benefits certain plants are reaping as a result of the hot, bright summer of 1921. Some hardy *Camellias* growing in close proximity to the *Acacia* are also giving a good crop of flowers, the combined display being very fine, especially in this, the dull time of the year in the garden generally. These plants, in association with *Trachelocarpus excelsa*, *Cordylines* and *Eucalyptus*, give a fine sub-tropical effect. *Physianthus albens*, growing unprotected on

a south wall of the mansion, flowers very freely each year, and sets as many as 60 fruits in a season, some of which I enclose. *W. H. Hoess, Walhampton Gardens, Lyminster, Hants.*

[Magnificently flowered shoots of the *Acacia* and fruits of *Physianthus albens* were sent by our correspondent.—Eds.]

**LEPTOSPERMUM SCOPARIUM.**

WHEN our distinguished countryman and navigator, Captain Cook, arrived in the distant southern regions now known as Australasia, after long and harassing voyages, his first act was to search for some wholesome herbs on shore as a corrective to the effects of scurvy. This

*Leptospermum*, which is known throughout Australasia as Captain Cook's Tea Tree, was found by him to contain a curative principle against scurvy, and in addition a decoction of its leaves tasted like tea. The leaves of the *Leptospermum* are much smaller than those of the true Tea Plant, but the seed vessels are very similar. The plant bears rosy-white blossoms eight months in the year and grows most luxuriantly on marshy ground attaining a height of from six to twenty feet. What are termed Tea Tree scrubs among the settlers are dense thickets of this plant along the swampy margins of streams, where the stems grow as straight and supple as Willow wands and are useful in wattling the sides of huts, *i.e.*, forming a kind of basket-work on upright posts, to be covered with mortar. In Van Dieman's Land and New Zealand, the plant grows abundantly. *Geo. Bartlett, Worslop.*

## The Week's Work.

### THE ORCHID HOUSES.

By J. T. BARBER, Gardener to His Grace the DUKE OF MABLBOROUGH, K.G., Blenheim Palace, Woodstock, Oxon.

**Calanthe.**—Plants of the deciduous section need repotting when the new growths are a few inches high and are about to push forth new roots. Previous to repotting it is advisable to examine the pseudo-bulbs closely for scale, and any other insect pests which may infest them. Care must be taken in cleansing the pseudo-bulbs not to injure the eyes or young growths at the base. The old, dead roots may be cut off to within an inch of the base, to leave a support that will keep the plants steady in the pan until the young roots have a firm hold of the new compost. The pseudo-bulbs may be repotted singly, or three or four large ones, or even more, may be placed together in a large pot, but it must be remembered that over-potting is detrimental to the success of the plants. Perfect drainage is essential. The compost should consist of half turfy loam from which the earthy particles have been shaken out; one-fourth chopped A1 fibre, and one-fourth dry cow-dung, with a moderate quantity of live Sphagnum-moss, small crocks, and coarse silver sand. The materials should be well mixed together, and allowed to become warm before being used. In repotting make the compost moderately firm, allowing sufficient space for a top-dressing at a later period, when the plants have become thoroughly established and are growing rapidly. Care should be taken that the compost is neither too wet nor too dry. For several weeks after repotting these Orchids require little or no water until the new roots have entered the fresh material freely. Their surroundings should be kept moderately moist by damping between the pots occasionally. When the roots have grown freely in the new material, and the growths made considerable progress, an abundance of water is required, and an occasional watering with liquid manure is beneficial. Care must be taken that this stimulant is suitably diluted, as many cases of spot in the leaves are attributable to strong doses of liquid manure.

**Phaius.**—Most members of this genus of terrestrial Orchid succeed in similar compost, and under similar conditions as regards watering and temperatures as *Thunias*. Many of them are a success in an ordinary plant stove, and make fine specimens, bearing handsome foliage and strong flower-spikes. After the plants have ceased to flower, and the new growths are sufficiently advanced and about to produce new roots, any necessary repotting may be done. The plants should be grown in fairly large, well-drained pots, and space for watering should be left below the rim of the pots, as in the case of ordinary plants. During the time these Orchids are in full growth they delight in an abundant supply of water at the roots, and must be shaded from strong sunshine.

**Arundina.**—The pretty *Arundina bambusifolia* and *A. Philippii* are terrestrial Orchids, and require similar treatment to that afforded *Thunias*.

### HARDY FRUIT GARDEN.

By H. MAREHAM, Gardener to the EARL OF STRAFFORD, Wrotham Park, Barnet.

**Regrafting Old Apple Trees.**—Regrafting is only to be recommended on healthy stocks, and not on old, worn-out trees. Cut the shoots back almost to the main stem, and see that the scions are heeled in on a north border until the sap is rising freely in the stocks, when the grafts may be inserted. In heading back very large trees, cut the branches back according to their thickness; in some cases quite 2 feet or more of the branch may be retained.

**Figs.**—The present is a suitable time for preparing the borders and planting young Fig trees. The amount of rooting material for

these trees should be somewhat restricted and the soil should be rammed firmly. Fig trees with an unlimited root run usually grow too strong and coarse, and rarely fruit satisfactorily, excepting when the roots are frequently lifted and pruned. When preparing the border, see that the drainage is perfect, and use fertile soil containing a goodly amount of lime rubble, chalk, burnt earth, and a little decayed manure. Figs require a good deal of wall space for extension, otherwise the knife must be brought into excessive use to keep the growth within bounds, and much pruning usually militates against sturdy, fruitful growth.

**Pruning Established Figs.**—Old Fig trees may have their branches regulated, and all pruning should be finished at the earliest opportunity. Guard against crowding of the shoots, and endeavour, so far as is possible, to keep the wall space covered with rather short, firm growths. All shoots of a soft texture should, if not required, be removed, and others may be pruned back more or less, but leave all the fruit-bearing growths their full length. Remove some of the old soil over and about the roots, and top-dress the latter with good soil; also apply a mulching of manure if necessary.

**Fruit Trees.**—As soon as the soil is sufficiently dry, make the roots of late-planted trees quite firm in the ground, previous to finally securing the stems to their supports. After treading the soil firmly over the roots, prick up the surface to the depth of one inch to prevent the upper layer from caking, and, should the weather set in dry, apply a light mulch of rather strawy manure.

### PLANTS UNDER GLASS.

By T. PATEMAN, Gardener to Sir C. NALCAIN, Bart., The Node, Codicote, Welwyn, Hertfordshire.

**Begonia Gloire de Lorraine.**—Plants that were cut back as previously advised have developed good strong shoots from their bases. These should be severed and inserted, several together, in a small pot containing a mixture of loam, leaf-mould, and a little peat, with sufficient sand added to insure a free drainage. The cuttings should be rooted in a propagating frame, for preference on a mild hotbed, where an atmospheric temperature of 65° to 70° may be maintained. The light should be removed each morning, and the condensed vapour removed. Such varieties as *The King*, *Turnford Hall* and *Mrs. Peterson* require similar treatment.

**Chrysanthemums.**—Some of the earliest of the Chrysanthemum plants are ready for transferring to 6-in. pots. The soil for this potting may be of a heavier nature to that previously advised for those growing in smaller receptacles. Use two-thirds good loam and the remainder leaf-mould and manure from a spent Mushroom-bed, after it has been passed through a half-inch sieve. To each barrowload of soil add a 6-in. potful of bone-meal, a little wood ash and soot, also some old mortar rubble and sand in sufficient quantity to keep the compost porous. After they are potted the plants may be kept in fairly close conditions for a few days, but when the roots are well established in the new soil remove the lights entirely on all possible occasions. Watch carefully for the presence of green-fly, and take measures for the destruction of the pest directly it is detected, either by fumigating or by spraying with an insecticide. If the plants are sprayed see that the tips of the plants are well wetted by the specific, for the fly generally protects itself in the unfolding leaves.

**Statice Suworowi.**—This annual *Statice* is greatly appreciated when grown as a pot plant for the decoration of greenhouses, and the blooms remain in perfection for a considerable length of time. If a few seeds are sown now in small 60-sized pots and the resultant seedlings potted on in 4½-inch receptacles without in any way disturbing the roots, fine, decorative plants will be available for the summer. A rich, open compost is necessary for this plant, and careful attention in watering at all times.

### THE FLOWER GARDEN.

By EDWIN BECKETT, Gardener to the Hon. VICAR GIBBS, Aldenham House, Hertfordshire.

**Vines.**—The hardy members of *Vitis*, and especially the newer Chinese species, form charming garden subjects. Under *Vitis* are included such familiar plants as the well-known Virginia Creeper, the useful and decidedly ornamental *Ampelopsis*, as well as other groups, including the true Grape Vines. Many are the uses to which these plants may be put; for instance, the self-clinging varieties, that have haustoria at the ends of the slender tendrils, are admirably adapted for growing on walls, others form splendid subjects for furnishing pergolas, whilst many readily adapt themselves for training up poles in the shrubberies, where they form prominent features. One other method that we adopt at Aldenham is to train the plants up a series of poles arranged in a straight row, each pair of poles being connected by two stout chains swung loosely, and the growths of the Vines are trained along the chains; the whole presents a very picturesque feature during the leafing season, and even in the drear period of the fall of the leaf makes an ornamental detail of the garden. These vines should be attended to carefully at the present season, and such as require it pruned back sufficiently to ensure a tidy appearance, especially the non-clinging varieties, and they may also be planted now. Vines are not very particular as to soil, though they probably do best in a warm situation in loamy ground of a sufficient depth to provide a deep rooting medium. The true vines are easily increased from small "eye" cuttings inserted in pots filled with good sandy soil, during the spring and struck over gentle bottom heat. The "eye" or bud should be one from the previous summer's growth, and the wood should be trimmed so that on the bud side about half an inch protrudes on either side of the bud, but on the under side the cut surfaces of the wood should almost meet. The cutting should be inserted in the soil horizontally, so that only the bud protrudes through the soil. Cuttings may also be inserted in the ordinary way during autumn, just after the fall of the leaves, and should comprise a length of the growth with a couple of buds thereon; these may be struck in a cold frame. Those of the self-clinging groups are easily increased by inserting cuttings at the end of the summer, selecting firm, leafy shoots for the purpose, inserting them in the usual way, and placing them in a cold frame to take root. There are many fine subjects in this group that are especially valuable for the autumn colouring of their foliage, including *Vitis flexuosa* Wilsonii, *V. Henryana*, *V. himalayana*, *V. himalayana rubrifolia*, *V. Pagnucci*, *V. P. var. Piaszekii*, *V. inconstans* (the *Ampelopsis* Veitchii of gardens), *V. Thunbergii* and *V. Thompsonii*. *Vitis aconitifolia*, *V. brevipedunculata* *V. Coignetiae*, *V. pulchra*, *V. Labrusca*, *V. leucoides* and *V. sinensis* have all handsome leaves. One of the prettiest of the fruiting Vines is *V. heterophylla*, which has turquoise-blue coloured berries, and does better when the roots are restricted to a limited area. Somewhat similar to this species, and probably only a variety of it, is *V. humulifolia cyanoclada*.

### FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY M.P., Ford Manor, Lingfield, Surrey.

**Figs.**—If a steady bottom-heat of 75° has been maintained about the roots of Fig trees growing in pots or tubs of compost, and the temperatures recommended on p. 16 maintained, the foliage will be fully developed, and the young fruits swelling freely. As the days increase in length, and the sun gains power the syringe may be used twice daily when the weather is bright and fine, the first time when the temperature begins to rise, and the second about 2 p.m. or immediately after closing the house. On dark, cold days unfavourable to ventilation, it may not be wise to wet the foliage, but a moist atmosphere should be

maintained by syringing the stems, walls and especially dry corners, and turning the fermenting materials. The pots being plunged, and the heaps of compost surrounded by moist fermenting materials, the roots will not readily become dry. Still, these conditions will not justify trusting to appearances, as deficiency in the supply of warm, diluted liquid manure will soon result in serious consequences. Another important matter is the removal of superfluous fruits. It is common practice to allow the most fertile trees to carry all the fruits they develop, whereas the best method of preventing dropping of the fruits is to thin them judiciously before they come into flower. Brown Turkey, one of the most prolific and best varieties for forcing, may, by feeding, be made to ripen two distinct crops of unthinned fruits, but when timely thinned this sort may almost be made a perpetual bearer. The pinching and tying of the more forward shoots will require attention, especially in the case of trees which have attained their full size, and cannot be extended without becoming crowded. Pot trees, other than those trained on trellises, which are branch thinned in winter to make room for continuous growth in summer, may be pinched at the fifth or sixth leaf. The night temperature may still range about 65°; through the day it may reach 75°, and 80° to 85° after closing the house with sun heat and moisture.

**Strawberries.**—The present is a suitable time to introduce a batch of Strawberries to a warm house, as the rapidly lengthening days and increasing sun heat will cause the plants to grow freely, and produce more and better fruits than if they had been started into growth several weeks ago under the same conditions.

**THE KITCHEN GARDEN.**

By JAMES E. HATHAWAY, Gardener to JOHN BRENNAND, Esq., Baldersby Park, Thirsk, Yorkshire.

**Potatos.**—An early batch of Potatos should be planted in a well-sheltered, sunny situation. Set the seed tubers in rows made from 18 in. to 2 ft. apart, allowing a space of 15 in. between the sets, which may be dibbled in on ground that has been previously prepared, as this is a much quicker method than making trenches. Potatos growing in pots should have plenty of liquid manure supplied to the roots as soon as the tubers become ready for use, as it improves the latter to withhold water from the roots for a few days before they are required for table. Potatos growing in frames should be earthed up and fed with stimulants; admit plenty of air to the frame on bright days.

**Climbing French Beans.**—Where room can be spared in the houses, nothing repays the grower better than a batch of climbing French Beans. Sow the seed in rows made 2 ft. 6 in. apart in well-cultivated soil. These Beans do best if they are not forced too hard, and the house should be closed early in the afternoon and the interior well syringed. Princess of Wales and Veitch's Climbing are two of the best varieties.

**Carrots.**—Select a warm position for sowing Champion Scarlet Horn and Scarlet Model Carrots as soon as the ground is in a suitable condition.

**Seed-sowing.**—Brussel Sprouts, Cabbage, Lettuce, and Turnips should all be sown now. Where birds are troublesome, first put the seeds in a tin containing red lead, with sufficient oil to make the red lead adhere to the seeds. By doing this and placing a few branches over the beds, birds will not do much damage.

**General Remarks.**—The weather has been unsuited for work in the kitchen garden. At Baldersby Park (March 1) we have not been able to get on the land since Christmas. Every endeavour should be made to catch up arrears. Broccoli and green crops have suffered severely through the wet and frost, so that crops in frames should be given every attention. Cauliflowers sown last month should be pricked off into boxes.

**FRUIT REGISTER.**

**APPLE ST. EDMUND'S PIPPIN.**

The remarks by your correspondents (see pp. 46, 94) on Apple St. Edmund's Pippin are of great interest to me. Owing to this particular variety having so great a resemblance to Golden Russet, I have often wondered why it was named "Pippin."

The russet family of Apples one generally associates with winter or later keeping sorts.

The fruits of St. Edmund's Pippin (syn. St. Edmund's Russet) are somewhat on the small size, and mature early, but as many other second-season sorts are grown in counties favourable to fruit culture the variety under notice has been somewhat neglected. It seldom keeps in good condition beyond October, and fruits grown in the western counties have a tendency to shrivel, even before that month.

It appears to have longer-keeping qualities in the north, especially in certain districts of Scotland.

Anyone in doubt as to the variety may recog-

broken streaks of pale crimson on one side, and here and there a few russet patches. The flesh is yellowish-white, tender, crisp, and juicy. Fruits from trees grown as half-standards on grass gave better-flavoured specimens than those under cultivation in the garden. This variety has long-keeping qualities, and I have handled sound fruits in April.

I have found that a winter dressing of basic slag gives intense colouration to the fruits.

**REINETTE DU CANADA.**

This is, to my mind, one of the best late Apples in cultivation, the quality being first-class, and furnishes a succession to Ribston Pippin after the month of March.

A few trees in an orchard, within walking distance of where I am writing, have always produced satisfactory crops, and the shape of the trees is a picture to behold. The fruit is of medium to large size; the skin greenish-yellow, with a tinge of brown on the side next to the sun, and in orchards many fruits have a crimson patch, coloured with brown,

FIG. 62.—PLUM RIVERS' LATE ORANGE.

nise it readily by its skin, which is entirely covered with pale, greenish-brown russet, with irregular and small patches of greenish yellow, and a pale, thin, brownish-red tinge, a few streaks of crimson being present on the side next to the sun.

The flesh is yellowish, tender and juicy, with a scented flavour.

It was raised by a Mr. R. Harvey, of Bury St. Edmunds, and received the R.H.S. First-Class Certificate on October 6, 1875.

The tree flourishes in a loamy soil, and may be trained as a bush, espalier, or half-standard.

**ROUNDWAY'S MAGNUM BONUM.**

This Apple is of first-rate quality and useful for dessert or culinary purposes, although the fruits are on the large size for a dessert Apple.

This sort succeeds most satisfactory grown as a bush, espalier, cordon, or half-standard, and does well in Herefordshire and Somersetshire. The fruit is large, ovate, angular on the sides, with ridges around the crown.

The skin is pale yellow, with a few broad,

russety dots. This colouration always denotes quality, the flesh being yellowish-white, firm, very juicy, brisk, and highly flavoured *Pomona*.

**PLUM RIVERS' LATE ORANGE.**

This excellent late dessert Plum (see Fig. 62) was raised by Messrs. T. S. Rivers and Son, and it received the R.H.S. First-Class Certificate on November 1, 1892. The fruits are roundish in shape, something like that of the Greengage, but larger, and the skin is of a beautiful bright orange colour, covered with a heavy bloom. It will be seen by the date on which the variety received the R.H.S. award that its season is exceptionally late, and, where the plants can be grown in orchard houses in pots, the trees will, if introduced into the house late in the season, mature the superb fruits to perfection, as they will, indeed, on a warm wall out-of-doors. We saw in Messrs. Rivers and Son's nursery, last October, some pot trees of this variety furnished with bountiful crops of fruit, and we can testify to their excellent flavour in comparison with such fine sorts as Coe's Golden Drop, McLaughlin Gage, and Jefferson.

### EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, W.C.2.

Illustrations.—The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.

Editors and Publisher.—Our correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the EDITORS. The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.

Special Notice to Correspondents.—The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.

### CROCUS SPECIES.

THE Crocus species have done so well this year and so few people seem to know them, that it may be worth while to call attention to a few of the many that may be grown. It should be realised that Crocuses are easily cultivated. Once the corms are planted in well-drained, fertile soil, they may be left alone for three years until, in fact, they become so crowded together that they must be lifted, separated and replanted. To obtain the best effect they should either be planted in clumps along the sunny edge of groups of shrubs, or given a border to themselves in a position where they will receive the benefit of all the midday sun in the early months of the year.

I do not propose to deal here with the autumn-flowering species, which, with the exception of the earliest of all, the golden *C. Scharojani*, produce flowers that are either white or of some shade of purple. By December the last of these autumn species is over, but it is soon succeeded by the deep golden-yellow *C. vitellinus*, a common species in Northern Syria, but one which is comparatively rare in cultivation.

After Christmas, a few warm days soon bring up the earliest buds of *C. Imperati*, whose home is near the shores of the Bay of Naples. It is a large Crocus which has the advantage of producing its rather prostrate, straggling foliage at the same time as, or even before, the flowers. It is also peculiar in that, though each strong corm sends up four or five flowers, these do not develop simultaneously, but in succession, so that the display lasts more than two months. Typical flowers of *C. Imperati* are buff coloured on the backs of the outer petals, which are conspicuously veined with dark purple, while their inner surfaces, as well as both surfaces of the three inner petals, are of a bright mauve purple. There are creamy white forms with similar purple veining on the outer petals, as well as a very sturdy, pure creamy-white variety, on which there are no veins and which comes perfectly true when raised from seeds.

As soon as February is reached, and unless the weather is too wintry, numbers of Crocus species burst into flower, and on a fine sunny morning the Crocus border is likely to be the great attraction of the garden. Quite early in the month we get the bright blue purple of the Greek *C. Sieberi*, which shows its golden throat when the flowers open widely in the sun. At the same time we have the rather dull yellow of *C. Korolkowi*, from the neighbourhood of Samarkand in Turkestan. This is the most castrally of all Crocuses and the individual flowers vary considerably in the amount of brown-purple colour that tinges the backs of the outer petals. Similar variation in an even more striking degree is seen in *C. Balansae* from the neighbourhood of Smyrna, of which the outer petals of the golden yellow flowers may be either only slightly veined with brown purple or wholly covered with an outer coat of deep mahogany. In this

form the buds look almost black at a little distance and it is interesting to watch them open in the sun and display the deep gold of the inner segments.

Another very beautiful early Crocus is the Cilician *C. Tauri*, with flowers of a delightful shade of clear blue purple. Unfortunately, it is still comparatively rare in cultivation, as is also the equally desirable *C. aërius* with beautiful globular flowers of some shade of pale or deep blue purple and a yellow throat. This species comes from the mountains of northern Asia Minor in the neighbourhood of Trebizond.

But these rare species are not yet sufficiently plentiful in cultivation to give us the masses of colour that can be obtained by planting the various forms of *C. chrysanthus* and *C. biflorus*. Of these, the former comes from Greece, Turkey and Western Asia Minor, and is extraordinarily variable in its colour forms. Its flowers may be either wholly of a deep golden yellow or have their outer petals more or less heavily veined with purple. Other forms are white with a golden throat, and of these, the outer petals may also be more or less tinged with purple. Others again may be of a bluish purple, but in every case the throat is golden and the style of a bright orange scarlet. A peculiarity of the species is that the anthers are often marked with black at the base. One of the best garden forms of this species has been named after Mr. E. A. Bowles, and produces in great numbers large globular flowers of a deep butter-yellow, which contrasts admirably with the orange-scarlet style. This form grows so strongly and increases so rapidly that it ought soon to challenge the position of the common yellow Crocus. It is certainly far more beautiful and seems to be an equally good doer.

Equally numerous are the various forms of the Italian and Dalmatian *C. biflorus*, of which one has long been known in cultivation as the "Cloth of Silver" or Scotch Crocus. This is white with the backs of the outer segments heavily veined with dark purple. Other forms have the outer segments more or less heavily mottled with finely dotted blue-purple, or the colour may run together and cover the whole surface with a deep plum-purple, as in the variety *Alexandri*. To this species also belongs the variety *Weldeni*, of which the flowers are either pure white or are faintly freckled on the outside with pale blue or lavender.

The mountains behind the French Riviera yield the conspicuously veined *C. versicolor*, which has the peculiarity that its inner segments are almost as distinctly veined as the outer. The petals are also curiously broad and rounded in the upper part. The ground colour may be either white or of almost any shade of light or dark purple. Further east from the neighbourhood of Trieste, through Macedonia and Southern Russia to Odessa, the Crimea and the Caucasus, grow *C. reticulatus* with heavily-veined outer petals and inner petals of a clear lavender blue. It derives its name from the coarse network of fibres, which forms the outer covering of the corm, and those who are interested in the classification of these species, will find that *C. reticulatus* is a good example of that section of the genus which has no basal spathe or membranous wrapping round the short stem that raises the ovary above the corm, while in *C. versicolor* this basal spathe becomes at once apparent as soon as the stem of the flower is exposed by splitting the outer wrappings and sheathing leaves.

A very richly-coloured little species is *C. minimus*, from Corsica, somewhat inappropriately named, for it is not the smallest of all. The flowers are of a deep lilac colour, heavily veined on the outer petals with dark purple. With it, late in February or early in March, flowers the Dalmatian *C. Malyi*, with large white flowers, which I once found growing on the hills by the coast above Carlopago. The colour of the base of the petals varies a little, and may be either yellow or brown purple.

The common Dutch yellow Crocus is a puzzle, for it is sterile and never apparently produces seed, though it is obviously either a form or a hybrid of *C. aureus*, a species whose home is in the Dobrudscha, Turkey and Western Asia Minor. The various purple Crocuses, which are commonly grown with this yellow Crocus, are

all derived from *C. vernus*, which extends in the wild state from the Pyrenees, over the Alps to the Carpathians and down to the mountains of Dalmatia, where I have collected the small pure white variety *albiflorus*, with rounded petals notched at the apex. This breeds quite true from seeds and is one of the smallest of all the forms of *C. vernus*. Further south in Dalmatia grows the nearly allied *C. Tommasianus*, which seeds itself freely in this country and which has now spread widely over the rock garden and other parts of Kew Gardens. Some forms of this Crocus are very pale and slender, though others occur of a rich, red-purple, with the peculiarity that the colour becomes most intense at the upper extremities of the petals. *W. R. Dykes.*

### MR. REGINALD FARRER'S SECOND EXPLORATION IN ASIA.\*

#### No. 39.—THE TOPS OF THE MOKU-JI.

I AM afraid that the bushy (or flat) little *Cistus*-like *Rhododendron* must be the same as last year's; so precisely does it imitate *F.1045* in all its habits. So copiously does it abound, too, down in the marshy flats of the valley-heads that from far aloft one sees its rosy smears down on the green. Those little oases of lawn, however, among the Bamboos, are disappointing. I always think their open expanses ought to yield marvels, and toil down towards them assiduously, tearing my way with hopeful heart through the Bamboos. But when I get there, never does any novelty meet my eye; only fine turf, and acres of golden *Potentilla*, and the little crimson *Primula* in sheets, and abundance of a horrid *Pedicularis*, which does its best to be taken for a *Primula*. They are curious places, though, these "plans," either in process of becoming lakes or in process of not becoming them. I cannot quite tell which. I think the latter is more likely—that they are old lakes gradually breaking up into ponds, on their way to becoming land as dry as this climate will permit. At present they present a most oddly artificial appearance, like an irregular expanse of Rice-pools, each banked up from the other by a thin rampart, along which one tight-rope among the Bamboos to the next comparatively open space, where one always hopes one may not meet Mrs. Bear in an unpropitious moment of bringing up her family.

Let us, therefore, re-ascend to the heights. This means fighting up through the cane-brake for a few hours, until we come into the first open slope that slides away from the cliffs overhead. Here *Rodgersia* at once abounds, and the *Cathartica*, *Meconopsis* and blue *Anchusa*, also sprouting *Aconite* and *Cimicifuga*, a green *Thalictrum*, and a huge and hideous *Smilacina* which is a very popular article of diet. Higher up one comes into the zone of *Anemone narcissiflora*, in stretches like snowdrifts, but the great white *Primula* is very rarely and very poorly to be seen until over on the Chinese side. I now learn that I knew nothing of it when last I wrote. It has revealed itself by this time as something so superlative that, superlative as I had already thought the *Shinghong* plant, I really doubted for a time whether the *Moku-ji* one must not be a new species, especially as it had a white powdered reverse to its leaves, and a most odd disposition of powder on its scape, just reaching an inch or so below the inflorescence, and there ceasing sharply, making the stem look as if it were clad in one short and tight white "short." This snowy pantalette, however, elongates with the scape, so that, in full flower-

\* The previous articles by Mr. Farrer were published in our issues for June 21, June 28, July 12, August 9, August 23, September 6, September 27, October 18, November 1, November 22, and December 6, 1919; January 3, January 17, February 7, February 28, March 20, April 24, May 29, July 10, July 31, September 4, October 2, December 4, 1920; January 1, January 29, February 19, April 2, April 30, June 4, July 9, August 6, September 24, October 22, November 12, December 3, December 17, 1921; February 11 and February 25, 1922.

time the powdered portion is longer and vaguer, even if the flowers then allowed one to think about it at all, for I now find that so far is the plant from being 2-3-blossomed, as I had at first seen it, not only does it usually bear from four to eight, but even sends up a secondary shower above the first. So superb, then, is the plant's effect when happy, that it must be seen to be believed. At the same time these newly discovered habits gave me several sleepless nights, for—powdered leaf-reverse, double tier of blossom, what about the Nivalis Group? And, if so, what about *P. chionantha*? I could hardly bear life till I got down here again and could look up *P. chionantha*. Dentate leaves, long, pendent, graceful pedicels, great cup-shaped Sikkimensid flowers, these never belonged to any *P. chionantha*, no matter how snowy. My plant, indeed, still puzzles me about its placing, for it seems as yet, just nicely, to combine the qualities of three sufficiently distinct groups—*sonchifolia-petiolaris*, *nivalis*, and *sikkimensis*. It comes up as a pure *sonchifolia*, with hugely fat bulb, sitting on the ground, not in it, and sheathed in stout, crimson scales. Its leaves, scape and inflorescence promise *nivalis* unambiguously. Until at length its long, fine pedicels and its noble hanging bells of virgin white transfer it obviously into *sikkimensis*. For many reasons, therefore, I await its fruit with eagerness. If we can fill our Rose-beds with this *Primula*, we shall not have much to complain of.

The very moment the col is reached, there the plant is; and down on the Chinese side it abounds in drifts and masses among the snow-white Anemones, which often even get taken for it from afar. But even yet the snowfields hold possession and the full riches of these valley heads remain still to be unfolded. I do not believe they will have much more to unfold. And, after all, with the great white *Primula* alone, they would already have yielded fairly well. Certainly the rocks and cliffs above show but little. They are moist, they are mossy, they seem to offer every facility. But, apart from a graceful if not particularly interesting yellow *Corydalis*, they rewarded me with nothing except fine masses of *Scrophularia Delavayi*. This certainly is a lovely thing. One is not accustomed to think of *Scrophularias* as even tolerable, but I shall be thoroughly pleased if I can get *S. Delavayi* home to England and see it made happy there. It is low and lax, not a foot high, and its large flowers are of a most unusual pure and blazing pale yellow; it loves cold, dank places among stones in the high-alpine region, and there shines like an electric flame. The only other rival for our attention at present is a Thistle which starts life in quite a proper, ordinary way, but ere long develops a fancy for becoming a Cobweb or a Saussurea, and sends up its buds in a dense great ball of glistening silver gossamer.

Where the high tops are all rock or Rhododendron, there is no point in yet ascending them, but we may now as well worry our way up to a towering headland that appears bald of scrub. The toil is rather like that of climbing a long slope of Heather, three times as deep as normal Heather, and full of snags and rocks and pitfalls. The pleasure, however, of attaining the smooth skull-cap of the hill is ample reward, so gay a galaxy of flowers is immediately unrolled at one's feet. One treads a velvety lawn entirely hidden in a carpet of Rhododendron, *Potentilla* and *Aster*. The *Potentillas* alone, after a long course of sameness and cloud, which dazzle one; and the delight, after weeks of Bamboo-brake and scrub, of feeling light and free on velvety, springy, open ground, is something memorable in itself. Unfortunately, however, snow is the

limit of the scene; it does not fulfil its glittering promise with any novelty. No cushion-*Primula* (which is very odd); not even any version of *P. coryphaea* or *P. bella* (which seems even odder); only the fruiting-heads of *P. nuda* standing up all about. Nor is the *Aster* as yet a sensational species, though quite a pretty little bright purple Daisy in the fine turf. So now, as the clouds are still deep around us, and it would not be advisable to lose what way there is among these precipices, we had best return down to the col, and thence, again down and down, to the camp. One more period of exploration up on the highest tops of the Chawchi, and discovery will, I suppose, be ended for the year, and nothing will be left to do but rest and gather strength again.

ORCHID NOTES AND GLEANINGS.

ODONTOGLOSSUM BELENUS.

THIS remarkable new *Odontoglossum* flowering with Messrs. McBean, Cooksbridge, and raised between *O. amabile* and *O. Olympia* well demonstrates the advantage of careful selection in hybridising, the *O. amabile* parent being a plant specially reserved for the purpose.

The hybrid is of fine habit, and the flowers are large and of firm substance. The sepals and petals are of rich dark olive-red colour with a slight yellowish margin, and the abnormally broad lip, is rose-purple around the yellow crest, the middle area being white with rose-purple spotting.

FIG. 63.—CYPRIPEDIUM IDINA, BECKTON'S VAR. FIRST-CLASS CERTIFICATE, MANCHESTER AND NORTH OF ENGLAND ORCHID SOCIETY, MARCH 2, 1922.

against the final whirlwind of the harvest. *Reginald Farrer.*

[This chapter closes the absorbingly interesting narrative, which the late Mr. Reginald Farrer specially contributed to *The Gardeners' Chronicle*, of his second plant collecting expedition in Asia. His account of the flora of the remote regions he visited reveals the deep love he possessed for plants of all kinds, and it is pathetic to realise that most of the novelties which he describes, with his usual lavish praise, in his later chapters, still await introduction by some future explorer in the same district. His closing words, written, as we now know, only a short time before his death, seem to us to be sadly prophetic.—Eps.]

CYPRIPEDIUM IDINA, BECKTON'S VARIETY.

THE handsome *Cypripedium Idina*, Beckton's var., illustrated life-size in Fig. 65, obtained a First-Class Certificate from the Manchester and North of England Orchid Society on March 2, when it was exhibited by Mr. Bertram J. Beckton, of Daisy Bank, Irlams-o'-th'-Height, Manchester. This fine Orchid is the result of crossing *C. insigne* Harefield Hall variety with *C. Countess of Carnarvon*. In colour this new hybrid is very similar to its well-known parent, *C. insigne* Harefield Hall, but the ground colour and the marginal area in the dorsal sepal is of a soft cream shade.

## THE FLORISTS' TULIP.\*

In order to make clear the points in the story of the Tulip that I want to explain, I must begin by a little consideration of what a Tulip bulb is and how it grows. If a Tulip bulb is taken before planting and cut in half vertically, in the centre of the bulb the future stem, carrying an incipient flower, will be seen. Surrounding this are four, or more often five, fleshy coats, like those of an Onion, making up the mass of the bulb, and outside these a loose brown skin. These coats spring from the base of the bulb round the rim of which, on the outside, the future roots are probably beginning to push. At the base again, one or two buds may be observed in the form of incomplete bulbs.

When the bulb is planted the stem and the roots push upwards and downwards respectively, their growth being at first entirely maintained by transfer of the materials stored in the fleshy coats of the bulb, until the leaves are above ground and can begin to feed upon the air and the roots are sufficiently developed to draw nutriment from the soil. The material in the bulb is thus steadily depleted until at flowering time the original thick fleshy coats have been reduced to dead skins. Meantime also one or more of the buds at the base have been accumulating material made by the leaves for the formation of a new bulb at the side of the old stalk. When the bulbs are dug up one cleans away the old dead skins which represent all that is left of last year's bulb, and there remains a new bulb with one or two bulbils or offsets, which have grown from other weaker buds on its base. Thus in a material sense the Tulip gives rise to a new bulb every year; in a botanical sense there is no new bulb, only one or more pieces of the old one.

The original starting point was a single bulb arising from a seed, and however many may be the actual bulbs arising thus by division from the original (and the numbers may run into millions every year in the case of a popular variety like Clara Butt, while the first bulb may have originated more than a century ago), to the botanist as to the florist they are still parts of one individual or variety. With certain exceptions, to be dealt with later, all the bulbs thus arising by division or asexual propagation yield plants exactly similar in all respects both in flower and foliage to the original and to one another.

How then does the new individual arise in the seed? In the formation of seed the germ cells of two individuals unite when the pollen grains of one reach the ovules of another. There is a reshuffling of the characters, latent or apparent, carried by the two germ cells, and a new germ cell is started containing characters taken at random from either parent. This new germ cell develops into the seed.

As the selection from the manifold parental characters is at random, every seedling is apt to differ from every other seedling and from the parents, and in the case of the Tulip the greatest diversity is exhibited by the batch of seedlings issuing from a single cross-fertilised pod. From the point of view of the florist the majority of seedlings are worthless, being inferior in some respect to the parents or other individuals; out of the batch he may find one or two which represent an improvement on existing varieties and are worth multiplication. But it is in this way that the new individuals we know as "varieties" have arisen.

The material out of which the plant breeder has built up these varieties by crossing and selection is nothing more or less than the wild species, the origin of which I cannot now discuss. England possesses, and that perhaps doubtfully, but one wild Tulip, the little yellow sweet-scented species with a nodding head, known as *Tulipa sylvestris*. But other members of the genus are to be found along the line of the Mediterranean region of the old world so far east as Turkestan, Persia, and even China. Despite the very considerable knowledge we now possess of these Tulip species, we are still

unable to say which of them went to the making of garden Tulips. They came to us ready-made, and the first record we have of them is that in 1554 Busbequius, then Ambassador to the Emperor, noticed them growing in a garden near Constantinople, and that within a few years they were brought from that region to Western Europe. We have Turkish manuscripts which go to show that at least a century earlier named varieties existed in the gardens of Baghdad which possess all the special characters distinguishing the garden Tulips of to-day.

(To be continued.)

## ANNUALS FOR GARDEN DECORATION.

THE persistent call for economy in the garden at the present time will have the effect of increasing the popularity of annual flowers for garden decoration. Annuals are not only much cheaper to grow, but many of them are quite as effective as the more permanent subjects which have been used for bedding purposes for many years past. There is now a very wide range from which to choose—so much so, indeed, that it is very difficult for many people to make a selection of the right subjects for their particular requirements.

It is often argued that the flowering season of annuals is too limited to permit of their use to any great extent for bedding purposes. In some measure this is true, but, if a selection of the right kinds is carefully made, and the plants are given the same liberal treatment as is usually afforded Pelargoniums, Begonias, Heliotropes, Lantanas, and the like, there would be little to complain of in this respect. With few exceptions, annuals require a deep, well-manured soil in which to grow; they must also have plenty of room in which to develop their natural habit. Overcrowding often curtails their flowering season.

Antirrhinums, which may be treated as annuals, are more useful as ordinary bedding plants when raised early in the year under glass. I know of nothing to equal them in the glorious range of colours they produce. Given liberal treatment, they will flower from July until late autumn. The early-flowering varieties of *Cosmea* are invaluable for planting in the mixed border. Gaillardias, when treated as half-hardy annuals, are most useful either in the border or for cutting. *Eschscholtzias* make a fine display in the mixed border, but they must be sown where they are to flower. Larkspurs, or annual Delphiniums, are invaluable for garden decoration or for cutting. Lavateras, or Mallows, are extremely beautiful, and must be sown out-of-doors and given plenty of room to develop.

Other annuals which may be sown out-of-doors during the next two or three weeks are *Nigella*, especially the variety *Miss Jekyll*; *Phacelia campanularia*, and *Sweet Sultan*, the last-named a splendid plant for the mixed border, bearing flowers that are valuable for cutting. The *Swan River Daisy* must not be omitted, as it is most useful in the front of beds or borders, and blooms continuously throughout the summer. Annual Poppies make a glorious display in the mixed border, but their season of flowering is not so long as could be desired. For brilliant colouring, the dwarf *Nasturtiums* have few equals, but they should be grown in poor soil, in a position which is fully exposed to the sun, to secure the best effect. *Godetias* are distinctly useful for bedding purposes or for cutting. *Cornflowers* may now be obtained in several beautiful colours, and are indispensable for the mixed border. *Coreopsis* in various shades are equally useful for the garden or room decoration.

*Clarkias* are desirable in every way, as also are annual *Chrysanthemums*. *Linum grandiflorum rubrum* makes a gorgeous display when massed in the front of mixed borders or beds. *Salvia Blue Beard*, with its bright purple bracts, is conspicuous the whole season through, and makes a striking setting for

standard plants of *Calceolaria amplexicaulis*. *Leptosyne Stillmannii* is a charming plant with golden yellow flowers. Annual Lupins are splendid when grown in bold masses in the mixed border, and they are also invaluable for the supply of cut flowers. There are now many beautiful varieties of this useful plant. *Cacalia coccinea*, with its orange-scarlet flowers, is a particularly pretty subject, and very useful for table decoration. *Gypsophila elegans* is a very attractive plant, and very useful for all kinds of decoration indoors. *Linaria* sown in large clumps makes a striking display in the mixed border, and there are now several beautiful varieties of *Toadflax*. The Night-scented Stock should be grown, if only for its exquisite perfume; so, also, should *Mignonette*, which requires a firm, rich, rooting medium to grow it to perfection.

There are many half-hardy annuals, more or less well known, and which need only the protection of a cold frame in the early stages of growth. One which needs special mention is *Phlox Drummondii*, which almost equals the *Antirrhinum* as a bedding plant. *E. Harriss, Lockinge*.

## CURL IN POTATOS.

THE reference to Curl in Potatoes in 1798 cited by "D. H., Penrith," in *The Gardeners' Chronicle* for December 31, 1921, is one of the best of the old references to this disease. The suggestion that the disease is contagious had to wait more than a century for verification.

Curl attracted a great deal of attention in England at about the end of the eighteenth century, and there are some references earlier than the above. The earliest record I have seen is by Arthur Young, under date of July 26, 1782, published in 1784 in Young's *Annals of Agriculture*, Vol. I., p. 133. He merely reports that certain varieties were curled, and others not curled, and evidently considered that his readers knew the disease, and did not consider it new. Young reported other observations in 1784 (*Young's Ann. Agr.*, Vol. II., pp. 98-115). In *Young's Annals* (Vol. XLIII., p. 595), "Howdeniensis" wrote under date of October 16, 1804, that "the curl has only been known about forty years," and reported that sets from the north of Scotland produced few curled plants. Cathcart (*Journ. Roy. Agr. Soc. Eng.*, Ser. II., Vol. XX., p. 266, 1884) agrees in assigning the date 1764 as the year the curl was first noted, under the authority of Rahn. In view of the fact, as noted by Miller in his *Gardeners' and Botanists' Dictionary* of 1771, that it was not "till some time after the middle of the eighteenth century that the Potato came to be generally used as an esculent root through the greater part of England," it is probable that curl occurred in some of the earliest Potato fields in the British Isles. Miller did not, however, mention curl in this edition of his dictionary.

William Marshall in 1788 (*The Rural Economy of Yorkshire*, Vol. II., pp. 51-67) wrote that "there is some reason to believe that the disease, which has of late years been fatal to the Potato crop in this and other districts, under the name of 'Curled Tops,' has arisen from too long a continuance of declining varieties." He reported that "fresh varieties raised from seed are not liable to that disease." He noted that "the district under survey furnishes a remarkable instance respecting this disease. The Morelands are at present in a manner free from it, while the Vale is still in some degree infected with it. Plants procured from the Morelands remain free from it in the Vale the first year; but being continued, become liable to that disease." Marshall described the symptoms, and, as a control measure, gave the suggestion, "Where the attack has been partial, weeding out the diseased plants, as they failed, is said to have had a good effect."

Mordaunt (*Young's Ann. Agr.*, Vol. XIV., pp. 444-450, 1790) discussed the disease, and

\* A lecture delivered by Sir Daniel Hall at a recent meeting of the London School Gardening Association.

attributed it to millipedes. Hollins (*Trans. Soc. Encour. Arts, Manuf. and Comm.*, Vol. IX., 1791) believed that earthing up the plants caused the disease.

At the beginning of the nineteenth century Thomas Andrew Knight (*Trans. Hort. Soc. London*, Vol. 1., pp. 57, 187, 1815; Vol. 11., p. 64, 1819) gave good descriptions and interesting suggestions concerning the disease. After the blight reached the British Isles between 1830 and 1840, curl was overshadowed by the destructiveness of the new disease, and only during the past decade has our attention again been focussed upon "curl." *G. R. Bisby, Imperial Bureau of Mycology, Kew, Surrey.*

**MESEMBRYANTHEMUM AND SOME NEW GENERA SEPARATED FROM IT.**

(Continued from page 105.)

**Gibbaeum, Haw.**

VERY dwarf-tufted succulent plants, sometimes with short prostrate stems. Each growth consisting of two very unequal leaves united into an obliquely ovoid, oblong-ovoid, or sub-cylindric body, with an oblique fissure on one side of it, at or below the middle, resembling a closed or slightly open mouth, formed by the free part of the smaller leaf being closely pressed against or slightly separated from the larger one, with the body often more or less swollen or gibbous below the top of the fissure. Flower solitary, pedicellate, without bracts. Calyx 6-lobed; two of the lobes longer than the others, acutely keeled, and the keel continued down the pedicel. Corolla rather small, petals numerous. Stamens numerous, erect or spreading. Stigmas 6, more or less plumose. Capsule small, 6-valved and 6-celled; valves winged; cells roofed with thin membranous cell-wings and with the outer end of the cell open.

This is another genus proposed by Haworth in 1821 that has remained unnoticed by all subsequent authors. Under his definition of the characters of the section, *Gibbosa* of *Mesembryanthemum* (*Rev. Plant, Succ.* p. 104) he remarks: "A good genus, I propose the name *Gibbaeum* for it." Although in that work he enumerates the species under the genus *Mesembryanthemum*, Haworth was undoubtedly right in considering that the plants forming his section *Gibbosa* should be generically separated from that genus, for they are distinguishable from all others included in it at a glance. I have, therefore, compiled the above characters for it, partly from the account given by Haworth, partly from living plants. Unfortunately, I have not yet seen flowers of any species of this genus, as the conditions under which I am obliged to cultivate these plants are not conducive to their flowering, for I am surrounded by houses, and during three winter months, at the very period when, under natural conditions, they get the brightest sunshine, no direct sunlight falls upon them, and the glass gets begrimed with falling soot, tending further to decrease the light.

**I.**

Growths somewhat velvety to the touch from being covered with some kind of pubescence, visible under a lens, quite smooth, silvery-white, greyish-white or greyish, but under cultivation becoming greenish or whitish green.

1. *G. PUBESCENS*, N.E. Br. (Fig. 64, A, B and C.) Plant under natural conditions, nearly stemless, with the growths crowded into a tuft upon a woody, shortly-branched rootstock, but under cultivation developing short branches up to 2-3 inches long with age. Growth 1-1½ (or under cultivation up to 1½) inch long, and 5-7 lines thick, or stouter under cultivation, obliquely ovoid or cylindric-ovoid, or, under cultivation, oblong-ovoid, obtusely rounded and often slightly compressed and more or less keeled at the apex, with the fissure usually at or just below the middle of perfectly developed growths, which much resemble a shark's head in appearance, silvery-white or greyish-white, from a dense pubescence of minute simple hairs pointing

downwards and closely pressed to the surface, as represented by Fig. 64, C., greatly magnified. Flower not seen, but, according to description and figure, the calyx-lobes are about 2 lines long, deltoid-ovate, acute, and the petals about 5 lines long, narrowly linear, pale purple. Fruiting pedicels 6-9 lines long, pubescent, with deflexed hairs like the growths; capsule about 3 lines in diameter, 6-valved, whitish.—*G. argenteum*, N.E. Br. in *Gard. Chron.*, 1921, v. 70, p. 273, f. 121. *M. pubescens*, Haw. *Obs.* p. 138 (1794) and *Rev.* p. 104; Hegi in *Gartenflora*, 1910, p. 13-14, t. 1579bis; Berger, *Mesemb.* p. 230 and 229, f. 48; Marloth in *Trans. S. Afr. Phil. Soc.* v. 18, p. 44.

Ladysmith Div., near Ladysmith, Pillans, Marloth 3500, Pole Evans 6932.

The plant figured and described as *G. argenteum* is so different in appearance from the figure of *G. pubescens* in the *Gartenflora*, as may be seen by comparing the growths repre-

the *Gartenflora*. My own plant has now changed from silvery-white to greenish-white, and is making short branches, so that there can be no doubt of their identity.

2. *G. SHANDII* N.E. Br. (Fig. 64, D and E).—Habit and general appearance of the plant almost the same as that of *G. pubescens*, but in the only specimens seen the growths were rather shorter and stouter, being 10-13 lines long and 6-8 lines thick at the basal part, at the apical part they are slightly compressed and faintly keeled down the front. The smooth surface is velvety to the touch from being covered with a very minute pubescence of very short irregularly stellately branched hairs that are totally different from those of *G. pubescens*, as represented, highly magnified, in Fig. 64, E, and are only distinguishable under a strong lens, greyish-green or hoary-green, not so silvery as in *G. pubescens*. Flower not seen. Fruiting pedicels 5-4 lines long, compressed, puberulous like the growths at the upper part only.—*M. Shandii*, N.E. Br. in *Gard. Chron.* 921, v. 70, p. 151, fig. 62, capsule only.

Swellendam Div. Near Sevenfontein, Pole Evans 6921.

I have much pleasure in naming this species after Mr. John Shand, Magistrate of Ladysmith, who is interested in the flora of South Africa, and assisted in the collecting of some of the species of this genus.

Although so similar to *G. pubescens* in general appearance, the character of the minute pubescence is so very different that it is at once distinguished from that species by it, when examined under a lens. I have raised seedlings of both species, and the pubescence on the seedlings of each kind remains distinct and constant, exactly like that of their parents. The peculiar stellately branched hairs of *G. Shandii* are not deflexed and not half so long as those of *G. pubescens*.

3. *G. GEMINUM*, N.E. Br. (Fig. 64, F.)—Plant developing prostrate branches 2-3 inches long in the specimen seen, and 1.1½ line thick, with internodes 2½-7½ lines long, bearing a pair or sometimes only one growth at each node. Growth 9-12 lines long and about 3 lines thick, or larger under cultivation, erect, cylindric or slightly compressed at the upper part and more or less keeled on the front and back, obtusely rounded at the apex, which is often slightly incurved, with the mouth-like fissure much below the middle, and the body slightly bulging on that side below it, smooth, velvety to the touch, glabrous to the eye, but under a strong lens seen to be covered with a pubescence of very minute branched hairs like those shown in Fig. 64, E. Whitish-green. Flowers unknown. Fruiting pedicels up to 6 lines long. Capsule 2-3 lines in diameter, 6-valved, white; valves winged; cells roofed over by membranous wings, and the outer end of each cell open.

Ladysmith Div. Karoo south-west of Touwsberg, Pole Evans 6925.

This singular species is readily distinguished from its allies by the more slender and less conical form of its growths. The pubescence on this species is just the same in character as that upon *G. Shandii*, represented by Fig. 64, E. *N. E. Brown.*

(To be continued.)

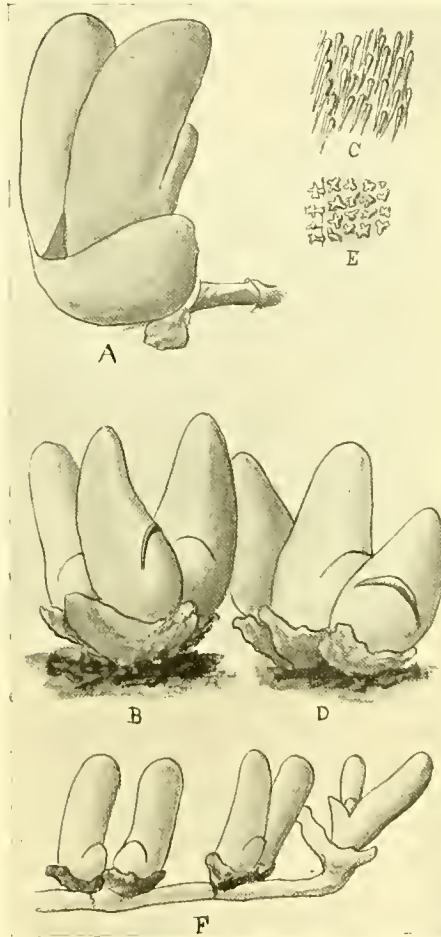

FIG. 64.—SPECIES OF GIBBAEUM.

A.—C., *Gibbaeum pubescens*; A., a growth from a cultivated plant, copied from the *Gartenflora*; B., growths from a wild plant, natural size; C., hairs, greatly magnified. D., *Gibbaeum Shandii*, from an imported plant, natural size; E., hairs of *G. Shandii*, greatly magnified. F., *Gibbaeum geminum*, natural size.

sented by A and B in Fig. 64, that I had no suspicion that they could be the same species until I found upon looking up the literature of this species that both came from the same general locality, and then suspected that I had made a mistake. Upon inquiry of Mr. N. S. Pillans, he has given me particulars which confirm my suspicion that both belong to the same species, different as they appear. For plants of *G. pubescens* that he cultivated near Cape Town (owing to the greater moisture of that region) lost their silvery-white colour and became greenish-white, and produced growths somewhat like those represented by Fig. 64, A, copied from

**THE ALPINE GARDEN.**

**CAMPANULA BARBATA.**

THE Bearded Harebell is practically a biennial and requires to be sown annually to maintain successive generations of plants. Sometimes a specimen survives its first year's flowering, but almost invariably the plants are lost after they have bloomed. Fortunately, they are easily raised from seeds. There are some differences of opinion regarding the best position for the Bearded Harebell, but, in my estimation, the ideal spot is a partially-shaded ledge of the rock garden. With this shade the flowers last longer than in full sun. Frequently, if rain should fall when the flowers are open, and this is followed by strong sun, the blooms are soon over. The albino form finds many admirers. *N. Arnott.*

## GARDENS AT THE IDEAL HOME EXHIBITION.

For all horticulturists the Ideal Home Exhibition at Olympia, London, W., provides a special attraction. This is found in the extensive annexe, which is wholly given over to gardens. The walls have been brought into the general picture in the wonderful and interesting fashion adopted at continental shows, and on these the scenic artist has wrought with such taste and skill that at a little distance it is difficult to know just where the gardens end and the scenery begins—the gardener and the artist have each done their work well. The genius who thought of having a series of gardens designed by royal ladies deserves to be congratulated upon the success he obtained, and especially upon the success with which the various firms have carried the designs into effect. The majority of the gardens are formal in outline, and, though no two are alike, there is some sameness about their general construction. Nevertheless, the effect is good, and, remembering the season of the year and the difficulties that have had to be surmounted, a capital exhibition has been arranged. Further, the atmosphere of the place is spring-like, while the blue screen high overhead and the careful lighting add to the vernal effect.

Messrs. J. Carter and Co. have a semi-circular garden (see Fig. 65), designed by Queen Alexandra, and reproduced from Her Majesty's "Pansy Garden" at Sandringham, which was illustrated in *The Gardeners' Chronicle* of June 21, 1902. There is a central and beautiful well head and a surrounding border of Daffodils and Tulips, backed by some trees and shrubs, and a light colonnade of elegant character. The beds, of various size and shape, are all edged with Box and set in gravel walks. These are filled with Tulips, Daffodils and Hyacinths, and the whole effect is bright and cheery without being gaudy. An artistic touch is seen in the two big vases filled with the lovely *Prunus triloba*. In striking contrast to this garden is a bold rock and water garden arranged by Messrs. Pulham and Son after the design of Princess Mary. The idea is an alpine lawn at the foot of bold rocks, between which a cascade of water rushes down in a manner which must excite the envy of exhibitors at Chelsea show. A little mountain track passes along one side amid spring flowers, and extends "over the hills and far away." In the foreground beds of *Rhododendron praecox*, Azaleas and Heaths form an attractive feature, while hardy Ferns luxuriate in the spray from the very realistic waterfall. Messrs. Van Ness and Co. have provided one of the most brilliant displays, filling in a formal design by the Queen of Holland. This is a gorgeous arrangement of Daffodils, Wisterias, choice *Rhododendrons*, and a wonderful selection of *Mollis* Azaleas, including new varieties.

Princess Alice's garden, planted by Messrs. Gaze, is a sheltered plot surrounded by a Yew hedge. There are two levels, the higher portion containing a grass plot, a pleasant seat, and a surrounding of Lilac, with an entrance gateway of live Yew. The lower portion is gay with Tulips, Hyacinths, blue Hydrangeas, Wisteria and *Prunus triloba*. Mr. E. Dixon has filled in the bold, simple and formal design sent by the Queen of Romania. In the sunken centre a "swastika" shaped bed of Tulips is very effective. Daffodils, Crocuses and Wallflowers are used effectively, and combine admirably with the scenic background. Lady May Cambridge designed four children's gardens, which have been effectively planted by Messrs. R. Wallace and Co. One of these is a formal arrangement with a Lily pool, sundial and tiny beds of Daffodils and Tulips. Another is a pleasant little rock garden containing a wonderful variety of interesting plants; another is a woodland garden charmingly planted with Birches, *Fyrus* and *Magnolia stellata*, and with Crocuses, Daffodils, Squills and blue Primroses rising from the grassy and mossy floor. The bulb garden is of formal outline, with a charming blending of

colours provided by Tulips. The Queen of the Belgians' garden, planted entirely with blue flowers by Messrs. A. Luff and Son, is excellent in effect, but not convincing, seeing that a considerable portion of the effect is obtained by Cinerarias, which are greenhouse plants. The Cinerarias are very fine and combine well with the masses of Hyacinths in every shade of blue. Messrs. Luff have also a pleasing "approach" garden with handsome gates beyond, leading to a distant and scenic horticultural paradise. Good use has been made of Magnolias, *Prunus*, Azaleas and Saxifragas on either side of the gateway, and these are set in raised banks.

Messrs. Whitelegg and Page have had a difficult task in filling the design from the Queen of Spain. The design is somewhat florid, but planted with Roses, with climbers around the graceful pillars, and some Palms to mark the special points, it would have been a great success—and also a great expense. However, the Chislehurst firm has contrived to provide an attractive garden with beds of Azaleas and Heaths, a central fountain and basin, and Carnations growing in bowls set along the walls. Near by, this firm has a small rock garden, raised so that the plants may be inspected without stooping. Messrs. Neal, of Wands-

young wood that ripens well. Last spring all the six canes broke into growth splendidly from the base to the top of the rods, and showed two and three bunches on each lateral. The bunches burst into flower beautifully in fine sunshine, and were most carefully pollinated, but to no avail; simply bare stems of bunches resulted and there was a woeful disappointment. Now comes the interesting part of the story. The same vines broke out again after being stopped, two or three leaves above the bunch. Flower bunches showed in profusion, and some of these we retained to see what would happen. Without any artificial aid whatever, these set well, and the berries swelled up like Greengage Plums. Two of these bunches were 2 lb. in weight, and bore amber coloured fruits. Muscat of Alexandria, in the same house, set splendidly, and finished in fine condition, fit for exhibition, as did Madresfield Court, Mrs. Pince and Black Hamburg. Why did not Canon Hall do so also? We are experimenting with a different mode of pruning to see what results, and should be pleased to know if any good specimens of this Grape were seen on the show benches last season. I am told Canon Hall Grape does well in the Worthing district. We shall report again in autumn if our different

FIG. 65.—GARDEN DESIGNED BY QUEEN ALEXANDRA AND ARRANGED BY MESSRS. J. CARTER AND CO. AT THE IDEAL HOME EXHIBITION AT OLYMPIA.

worth have planted the Queen of Norway's design, which is after the Dutch style, with a low wall surrounding the whole. There are wide paths, a sunken central fountain, and an attractive planting of pink Hyacinths, Emperor Daffodils, and beds of pink Azaleas. Messrs. Waterer, Sons and Crisp have carried out Lady Ramsay's design, which has a central formal Lily pool and an attractive surrounding of *Cupressus obtusa* var. *filifera aurea* and masses of Daffodils. At each corner of the design is a standard of the golden *Cupressus*, each with a clear stem about a yard high, set in grass. Other attractions include a well-filled conservatory constructed by Messrs. Duncan Tucker and Co.; a bed of Carnations by Messrs. Allwood Bros.; and a little bungalow front garden by Messrs. Bryseon.

## HOME CORRESPONDENCE.

[The Editors do not hold themselves responsible for the opinions expressed by correspondents.]

**Failure of Canon Hall Grape.**—Not many gardeners like to confess to a failure, but here is one. At Bradley, where my son is gardener, there is a new model span-rooted viney, 100 ft. long, built by Foster and Pearson. The borders are made of the best yellow loam, and the drainage is perfect with a concrete bottom. Forty vines are planted 5 ft. apart; seven varieties have done remarkably well, and Canon Hall is the most robust of them all, making fine

method of pruning has good effects. *J. Irvine, Bradley New Gardens, Grimsby.*

**Tomato Victory.**—This variety, which is being distributed by Messrs. Clibrans, is a cross between Bide's Recruit and Sensation. It carries an enormous crop, the fruits being of good form and excellent flavour. Seed was sown here on March 16, 1921, and the resulting seedlings potted on into 6-inch pots. The plants were then placed in pits and grown under cool conditions, abundance of air being admitted on all favourable occasions. As a consequence, the first truss of fruit was set before the plants were put into their permanent quarters out of doors. A site was chosen close to a galvanised iron fence. Weather conditions were favourable, and rapid growth was made. Each plant developed five to six trusses of fruits, which eventually ripened where they hung. The height of the plants was approximately 4 feet 9 inches, and the photograph was taken on August 24. I do not wish to convey the impression that "Victory" is specially recommended for outdoor cultivation, as such is not the case. Under glass I had excellent results from the same variety. Grown side by side with Bide's Recruit it ripened a fortnight earlier than the latter.—*J. Ritchie, Newtown Hall Gardens, Newtown, N. Wales.*

[The photograph which accompanied Mr. Ritchie's note was not suitable for reproduction, but it showed about 20 plants carrying either five or six large clusters of fruit, and confirming Mr. Ritchie's statements.—*Ens.*]

## SOCIETIES.

### ROYAL HORTICULTURAL.

MARCH 14 AND 15.—The first of the two-day shows for 1922 was held on the above dates, and the exhibitors combined to make it a great horticultural success. Spring bulbs, notably Hyacinths, Tulips and Daffodils, were prominent features, and there were several very artistic displays of these flowers. Orchids, Primulas, Cinerarias, Camellias, Alpines and forced flowering shrubs were other subjects largely shown. Novelties were few in number, but they included the fine new *Pieris taiwanensis*. The medal awards for groups were unusually numerous, the Floral Committee recommending no fewer than twenty-eight medals.

#### Orchid Committee.

*Present:* Frederick J. Hanbury, Esq. (in the chair), Prince Shimadzu, Messrs. Jas. O'Brien (hon. secretary), Arthur Dye, C. J. Lucas, S. W. Flory, H. G. Alexander, Chas. H. Curtis, J. E. Shill, H. T. Pitt, T. Armstrong, W. J. Kaye, A. McBean, J. Wilson Potter, Stuart Low, Gurney Wilson and R. Brooman White.

#### AWARDS.

##### FIRST-CLASS CERTIFICATE.

*Sopbro-Laelio-Cattleya Falcon*, *Westonbirt* variety (*L.-C. Aureole* × *S. grandiflora*), from Lt.-Col. Sir GEO. L. HOLFORD, K.C.V.O., Westonbirt, Tetbury (gr. Mr. H. G. Alexander). The finest and most brilliant *Sophrontis* cross yet raised, and well sustaining the advantages of using favourable hybrids for crossing with the colour parent desired. The original form received a First-Class Certificate and was illustrated in *The Gardeners' Chronicle*, February 19, 1921, p. 91, but the present variety is larger and deeper in colour, the flowers being uniformly deep scarlet red, with slightly darker lip. The plant bore a spike of five expanded flowers and another of two in bud.

*Cymbidium Alexanderi Westonbirt* variety (*burneo-Lowianum* × *insigne*), from Lt.-Col. Sir GEO. L. HOLFORD. *Cymbidium Alexanderi* is probably the finest and most beautiful of the class and is a variety of handsome form and colouring. The superb specimen shown bore two spikes of seven and five flowers respectively, large, wax-like in texture, clear white, with dotted lines of rosy mauve on the front of the lip.

*Odontioda Opal* (*Odm. crinillus Rex* × *Oda. Cooksoniae Fowler's* variety), from Messrs. ARMSTRONG AND BROWN, Orchidhurst, Tunbridge Wells. Much is now expected of an *Odontioda* worthy of a First-Class Certificate, and *Odontioda Opal* realises expectations perfectly. The spike of finely formed flowers had the individual blooms broad in all the segments, the sepals and petals nearly covered with confluent blotches of ruby red colour, the margins and tips being bluish white. The broad lip, forming a great contrast, is bluish white with a few ruby blotches in front of the yellow crest.

#### AWARD OF MERIT.

*Cymbidium Alexanderi Rosalind* (*burneo-Lowianum* × *insigne*), from Lt.-Col. Sir GEO. L. HOLFORD. A bluish white form of perfect shape, coloured rose pink on the margin of the lip, which has spottings of rose in front.

*Sopbro-Cattleya Prince Shimadzu* (*S.-C. Doris Cobb's* variety × *C. King George*), from Messrs. FLOREY AND BLACK, Slough. Flower of good shape, golden yellow, with ruby-red front to the lip.

#### GROUPS.

Sir JEREMIAH COLMAN, Bart., Gatton Park (gr. Mr. J. Collier), was awarded a Silver Flora Medal for a very fine group of splendidly flowered varieties of *Lycaste Skinneri*, the flowers varying from the white alba and Purity to the dark forms of the splendens type. Two very delicately tinted varieties were Pink Pearl and Robin. The rare *L. Skinneri armenica* with ivory white flowers was also shown, with some hybrids.

H. T. PITT, Esq., Rosslyn, Stamford Hill (gr. Mr. Thurgood), was granted a Silver Flora Medal

for a good group of *Odontoglossums*, *Odontiodas* and other showy hybrids. Among the *Cypripediums*, *C. Memoria F. M. Ogilvie* well maintained its high reputation, and the species included an elegant little *Spiranthes*, *Odontoglossum pulchellum* and other species of *Odontoglossum*.

Messrs. CHARLESWORTH, Haywards Heath, received a Silver Flora Medal for an excellent group of bright scarlet *Odontiodas*, showy *Odontoglossums*, and white *Cattleyas*; *Brasso-Laelio-Cattleya Joan*, with clear yellow flowers; the best form of *Brasso-Cattleya Cliftonii magnifica*, some good hybrid *Phaius*, *Charlesworthara Alpha* and the clear yellow *Habenaria rhodocheila* were also conspicuous.

Messrs. STUART LOW AND CO., Jarvisbrook, Sussex, were awarded a Silver Flora Medal for an extensive group in which *Dendrobiums*, *Brassavola* hybrids, *Cattleyas* and *Laelio-Cattleyas* were specially well represented. The novelties included *Laelio-Cattleya Triton* (*L.-C. Tunis* × *C. Trianae*), chrome yellow with ruby lip; *Sopbro-Laelio-Cattleya Gilda* (*S.-L.-C. Helen* × *L.-C. Colmaniana*), nearest to the *L.-C.* parent; *Cattleya Omar* (*Enid* × *Leda*); *Brasso-Laelio-Cattleya Melba* (*B.-C. Digbyano-Mossiae* × *L.-C. Rubens*), rose with yellow disc to the lip; and other pretty, new forms.

Messrs. SANDERS, St. Albans, were awarded a Silver Flora Medal for a pretty and interesting group of *Cymbidium*s, *Dendrobium*s, *Cattleyas*, *Laelio-Cattleyas*, and *Odontoglossum*s, all of which were well represented. Among the species it was interesting to see several *Restrepias*, *Masdevallias*, *Dendrobium*s, and the rare natural hybrid, *Cattleya guatemalensis*. Messrs. J. and A. McBEAN, Cooksbridge, were awarded a Silver Banksian Medal for a group in which four forms of *Laelio-Cattleya Eunice*, white, with variously coloured lips; the fine white *Cattleya Cowanii*; *Laelio-Cattleya Monique* (*Mendelii* × *Schrödera*), a perfect flower nearest to the *Mendelii* parent; the richly coloured *Odontoglossum Rosina*, and the dark *Odontioda Joan* were specially good. Messrs. FLOREY AND BLACK, Slough, were awarded a Silver Banksian Medal for a group of rare hybrids, in which the yellow *Sopbro-Laelio-Cattleya Prince of Orange* (*S.-L.-C. Eros* × *L.-C. Thyone*); and *Potnara Gratrixiae* (*S.-C. Gratrixiae* × *B.-C. Mrs. J. Leemann*), were good novelties.

#### OTHER EXHIBITS.

D. BARNARD, Esq., Leighton Dene, Watford, showed *Brasso-Cattleya mirabilis*, *Leighton Dene* variety (*C. Mendelii* × *B.-C. Mrs. J. Leemann*), a very fine white with large yellow disc to the fringed lip. Messrs. STUART LOW AND CO. showed the clear white *Brasso-Cattleya Albion*. RICHARD G. THWAITES, Esq., Christchurch Road, Streatham Hill, showed *Odontioda Atalanta* var. *Pamela* (*Odm. Atalanta* × *Oda. Latona*).

#### Floral Committee.

*Present:* Messrs. H. B. May (in the chair), W. B. Cranfield, G. Reuthe, G. Harrow, W. Cuthbertson, H. J. Jones, D. B. Crane, J. F. McLeod, W. Howe, A. G. Jackman, W. B. Gingell, Hugh Dickson, C. R. Fielder, E. A. Bowles, W. J. Bean, R. C. Notcutt, M. C. Allwood, John Dickson, John Jennings, Jas. Hudson, Reginald Cory, W. P. Thomson, Chas. E. Pearson, and C. Wilson.

*Pieris taiwanensis*.—A beautiful and quite new species collected by Mr. E. H. Wilson in Formosa. It has larger leaves, a more erect inflorescence and rounder, whiter flowers than *P. japonica*. A very fine evergreen shrub and apparently quite hardy. Shown by the MANQUIS or HEADFORT, Kells, Co. Meath.

*Freesia Wistaria*.—A very pretty addition to the now numerous coloured *Freesias*. It is well-named, as the lavender-mauve colouring is very suggestive of *Wistaria* blooms. The flowers are well expanded, and the three inner segments are much deeper—bluish-mauve—than the outer one, and lines of this deeper shade extend down the tube towards the yellow base. We failed to detect any fragrance in this otherwise charming variety. Shown by Mr. G. H. DALRYMPLE, Bartley, Southampton.

#### GROUPS.

Hyacinths were a noteworthy feature of an attractive meeting. A large, low table space was splendidly filled by Messrs. SUTTON AND SONS with a great number of excellent plants. Not only were these of exceptional quality, but the arrangement was in excellent taste and the group was very much admired. Large baskets along the centre of the group were amply filled with such sorts as *Queen of the Pinks*, *Purity*, *Schotel* and *City of Haarlem*, while in porcelain blue vases there were handsome, bold inflorescences of *Perle Brillante*, *King of the Reds*, *King of the Blues*, and *Grand Maitre*. For the most part the groundwork of this memorable exhibit was composed of similar sorts, but all the many plants indicated the excellence of the bulbs no less than the skill and care exercised in their cultivation (*Silver-Gilt Flora Medal*).

A great variety of Hyacinths was shown by Messrs. R. AND G. CUTHBERT. For the most part these were in five-inch flower pots, and of the useful decorative type that is valued for market. Amongst the thirty or more sorts the very best were *City of Haarlem*, *Hein Roogen*, *Enchantress*, *Hoffgartner*, *Dr. Lieber*, *Lady Derby*, and that darkest of all dark blues, *King Menelik* (*Silver-Gilt Banksian Medal*).

Exceedingly effective use was made of several varieties of *Primula malacoides*, associated with splendid *Narcissus King Alfred* and various Hyacinths, by Messrs. J. CARTER AND CO., The Primulas included *Princess Mary*, *Princess Patricia*, *King Albert* and *Single White*, and these were shown in generous quantities of most elegant plants grouped in shallow, round baskets raised fairly high along the centre of the tabling (*Silver-Gilt Banksian Medal*).

Flowering shrubs were again prominent and of considerable attraction. On the floor under the clock Mr. WM. PAUL set up an admirable group of Camellias, which was probably the best collection of pot plants at present available in this country. Of the many sorts the singles were perhaps the most numerous, and these included *Lady McKinnon*, *Vesta*, *Adelina Patti*, *The Swan*, *Mrs. J. Buchanan* and *Jupiter* (*Silver Flora Medal*).

Near by in a corner space Messrs. WM. CUTBUSH AND SON had an attractive collection of such hardy shrubs as *Wistarias*, *Pyrus*s in variety, with some very good plants of *Hippastrum* and very floriferous little bushes of *Genista fragrans*. On a table space near by Messrs. Cutbush and Son had a well-designed little rock garden, appropriately planted (*Silver Flora Medal*).

*Pyrus*s, in several varieties, with double-flowered *Peaches*, *Camellias*, *Clematis*s and *Azaleas*, were shown by Messrs. L. R. RUSSELL, LTD., and these made a very effective group (*Silver Banksian Medal*). Amongst a somewhat similar exhibit by Messrs. R. W. WALLACE AND CO. were a couple of vases of *Corylopsis pauciflora*, well-flowered bushes of the double *Cherry Hisakura*. Some good *Freesias*, particularly the rich golden *Buttercup*, were also shown (*Silver Flora Medal*). Early *Rhododendrons* with catkin-bearing sprays of *Populus alba* and *Pieris japonica* were shown by Mr. G. REUTHE, who also exhibited a quantity of *Anemone fulgens* and various alpine (*Silver Banksian Medal*).

*Prunus Pissardii*, in unusually well-flowered sprays, was shown by Messrs. J. CHEAL AND SONS, who also had a few alpine and Primulas (*Bronze Flora Medal*). The soft salmon pink coloured *Cydonia Aurora* and *C. Apple Blossom* were prominent in the stand of Messrs. BARE AND SON, who also had several interesting *Hellebores* and many *Crocuses* (*Silver Banksian Medal*).

The collections of alpine were particularly rich in *Saxifrages*, and of these varieties of *S. Burseriana* were frequently to be seen. Mr. C. ELLIOTT had many good white sorts, such as *S. B. speciosa*, *S. apiculata alba*, and also the interesting *S. Greisbachii* (*Bronze Flora Medal*).

A rock garden by Messrs. WATERER, SONS AND CRISP contained goodly breadths of *Chionodoxa Lucillae* and *Anchusa myosotidiflora* (*Silver Banksian Medal*). Mr. G. W. MILLER showed a good range of his excellent *Polyanthuses*, *Pul-*

monaria angustifolia and the very bright crimson Daisy Rob Roy (Silver Banksian Medal). Oxalis splendens, O. cernua, Delphinium nudicaule and Saxifraga Irvingii were prominent items in an exhibit by Mr. M. PRICHARD (Silver Banksian Medal). The silvery grey Veronica Hulkeana associated with Daphne Cneorum and Rhododendron racemosus, was effective in a group by Messrs. PIPER AND SON, who also had several well-flowered pans of Lithospermum prostratum Heavenly Blue (Silver Banksian Medal).

Many pots and pans of alpines shown by Messrs. MAXWELL AND BEALE included Myosotis Ruth Fischer and a variety of Saxifrages (Bronze Flora Medal). The soft rosy salmon pink flowers on many plants of Azalea Hidomango were exceedingly attractive in an exhibit by Messrs. G. G. WHITELEGG AND CO., who also had a quantity of the dwarf Iris Formosa which is so delightfully fragrant (Silver Banksian Medal).

The yellow Saxifraga Faldouise, contrasting with the elegant S. lilacina and S. Burseriana speciosa, were well shown by Messrs. R. TUCKER AND SON (Silver Banksian Medal). Alpines were also shown by the Misses HOPKINS, Messrs. SKELTON AND KIRBY, and Mr. F. G. WOOD (Bronze Banksian Medals).

Excellent Carnations were again shown by Messrs. ALLWOOD BROS., who had a large vase of the perpetual-Malmaison Mrs. C. F. Raphael containing blooms nearly as large as the best true Malmaisons. Jessie Allwood, a yellow flowered variety, was also of uncommon merit (Silver Flora Medal). In the collection by Mr. C. ENGELMANN such pink sorts as Laddie, Cupid, Peerless and Boadicea were particularly good (Silver Banksian Medal). Carnations were also shown by Messrs. STUART LOW AND CO., who included excellent Hippeastrums, Acacias and Epaeris cunosmaeflora fl. pl. (Silver Flora Medal).

Large sprays of Roses Yellow Banksian bearing abundant flowers, and Fortune's Yellow were arranged by Mr. GEORGE PRINCE (Silver Banksian Medal). Many excellent plants of large flowered Cinerarias were shown by Mr. S. MORTIMER. The flowers were exceptionally large and of good substance, illustrating a very desirable strain (Silver Banksian Medal).

Fragrant Violets were staged by the REEDENS SCHOOL OF GARDENING (Bronze Flora Medal), and Mr. B. PINNEY (Bronze Banksian Medal). In the former collection Princess of Wales was particularly good and much attention was directed to the bunches of the uncommon variety Sulphurea. Messrs. REAMSBOTTOM AND CO. displayed their St. Brigid Anemones.

#### Narcissus and Tulip Committee.

Present: Messrs. E. A. Bowles (in the chair), George Monro, P. R. Barr, Herbert Smith, J. S. Arkwright, G. W. Leak, W. A. Milner, H. G. Hawker, W. F. M. Copeland, H. F. Chapman, W. B. Cranfield, Reginald Cory, J. W. Jones, Guy L. Wilson, J. D. Pearson, G. Churcher, and W. R. Dykes; Miss Wilmott and Charles H. Curtis, Hon. Secretary.

*Narcissus White Dame.*—A chaste and beautiful trumpet Daffodil of large size and excellent form. The colour is paper white. The perianth segments are somewhat thin in texture, almost transparent. The finely formed trumpet has a beautifully frilled rim, which is slightly rolled back. Shown by Mr. GUY L. WILSON, Broughshore, Co. Antrim.

#### GROUPS.

An excellent collection of bulbs grown in bowls of fibre was shown by Messrs. R. H. BATH AND CO. Almost every seasonable kind was included, and all illustrated first-rate bulbs and skilful cultivation. There were Darwin Tulips, Narcissus and Hyacinths of many sorts attractively arranged along the centre of a large table space, while all around were many shallow bowls of Crocuses in great variety and many of the dainty and fascinating Fritillaria Meleagris (Silver-Gilt Banksian Medal).

What was decidedly the best collection solely of Narcissi was arranged by Messrs. J. R. PEARSON AND SONS. Not only was there a great variety, but the quality was high and the arrangement was very attractive. Generally, several

vases of each sort were shown, and this method served to illustrate their great decorative value. The large-flowered trumpet varieties were especially prominent, and these included immense but refined blooms of Mrs. J. H. Veitch, Weardale Perfection, King Alfred, Norah Pearson, Florence Pearson and Victoria. The vivid colour of the coronas of such varieties as Gipsy Queen, Firetail and Lucifer attracted a deal of admiration, as also did the incomparabilis variety Brilliancy (Silver-Gilt Flora Medal).

Large trumpet varieties were also prominent in the exhibit by Messrs. BARR AND SONS, but many of these were shown under their seedling numbers, though many of them were of great merit. Of the named sorts, Golden Herald, Yorick and Gwendolin were excellent. Many particularly good Leedsii sorts were also on view, and bright colour was present on the corona of Blackwell, a good incomparabilis variety (Silver Flora Medal).

Near the Orchid annex Mr. G. L. WILSON had a select little exhibit. The centre was occupied with a goodly quantity of his new trumpet variety, White Dame (see awards), while adjoining it was a vase of Goldbeater, a rich yellow trumpet variety of great size and excellent shape. Darius, another trumpet sort, which has a primrose coloured perianth and a canary yellow trumpet, and Vestal Virgin, sulphur yellow tube, rising from a paper white perianth, were particularly good (Silver Banksian Medal).

#### Fruit and Vegetable Committee.

Present: Messrs. C. G. A. Nix (chairman), Jos. Cheal, S. Rivers, Geo. F. Tinley, S. B. Dicks, W. Giles, T. Pateman, P. D. Tuckett, A. Bullock, E. Neal, W. Bates, E. A. Merryweather, A. Metcalfe, G. Berry, W. H. Divers, W. Wilks, P. C. M. Veitch, G. Reynolds, J. C. Allgrove and Ed. Beckett.

There was very little for this Committee to consider, and only one award was made, to a variety of Apple from Devon

#### AWARD OF MERIT.

*Apple Peter Lock.*—This variety had been before the Committee on two previous occasions, and a member, having visited the tree, reported favourably on the cropping and growth, which is of somewhat upright habit. The fruit is of the Bramley's Seedling shape, some of the specimens weighing 5 oz. to 6 oz. each. At this season the skin is a mellow yellow, freely marked with crimson lines. The eye is set in a shallow cavity, with closed segments. The stalk is set in a relatively deep, cone-shaped cavity. Trees of this Apple are said to be common in the neighbourhood of Dean Prior, near Buckfastleigh, Devon, and are the earliest to bloom in the orchards there. The quality is good and the variety is suitable for either culinary or dessert purposes. Shown by Mr. J. A. DEVENISH, Goulds, Staverton, South Devon.

## Obituary.

**W. H. Clarke.**—We learn with regret that Mr. W. H. Clarke, of the Royal Hampton and Gloucester Nurseries, Hampton, Middlesex, died on the 28th ult., after a severe illness, most patiently borne over a period of five months. Mr. Clarke had been in business at Hampton for thirteen years, and previous to that had a varied horticultural experience, being at one time head gardener to Sir W. Plowden at Aston Rowant. Early in life he gained experience in nursery work at his father's nursery at Wellington, Somerset, and this served him in good stead when he gave up private for commercial gardening. The funeral took place on the 4th inst., at Hampton Cemetery, and was attended by a large number of horticultural friends, who admired his personal qualities and business ability. Mr. Clarke was fifty-seven years of age. He leaves a widow, a daughter and son three years of age. The business will be carried on by Mrs. Clarke, who managed it during her late husband's long illness.

## ANSWERS TO CORRESPONDENTS.

**Books:** A. D. F. We recommend you to obtain *The Classification of Flowering Plants*, by A. B. Rendle, published by the Cambridge University Press, Fetter Lane, E.C.4, at 20s. net.—B. P. G.—The best books for your purpose would be *Forests, Woods and Trees*, by Augustine Henry. Published by Constable and Co., London; *English Estate Forestry*, by A. C. Forbes, published by E. Arnold, Maddox Street, Bond Street, W.; and Webster's *Practical Forestry*, published by W. Rider and Son, Cathedral House, Paternoster Row, E.C.4.

**NAMES OF PLANTS:** R. W. N. 1, Cedrus Deodara; 2, Juniperus chinensis var. albo-variegata; 3, Sequoia gigantea; 4, Juniperus virginiana; 5, Pseudotsuga Douglasii; 6, 8, 9, 10, 15, and 18, forms of Cupressus Lawsoniana; 7, Picea excelsa; 11, Cupressus pisifera var. plumosa; 12, Abies nobilis var. glauca; 13, Pinus excelsa; 14, Juniperus chinensis; 16, Abies Pinsapo; 17, Cupressus Lawsoniana var. lutea; 19, Pinus Cembra; 20, Cupressus Lawsoniana var. lutea; 21, Thuja occidentalis; 22, Taxus baccata var. fastigiata; 23, Ligustrum japonicum; 24, Osmanthus ilicifolius; 25, Arbutus Unedo; 26, Quercus Ilex; 27, Santolina Chamaecyparissus; 28, Cedrus atlantica.—E. W. S. Skimmia japonica.

**R.H.S. LIBRARY:** H. P. K. Under certain conditions Fellows of the Royal Horticultural Society are allowed to borrow books from the Lindley Library. The principal stipulations are: (a) That the borrower be personally known to one or more of the officers of the Society, or, at least, shall produce satisfactory references; (b) that the borrower sign a receipt for the volumes, before removing them from the premises, in a book provided for that purpose (or by postcard if unable to do so in person); and undertake to restore the books in good condition, and generally to comply with the regulations; (c) that not more than three volumes be lent to one person at one time; and (d) that borrowers through the post pay the cost of the postage both ways.

**VEGETABLES FOR THREE HUNDRED PEOPLE:** W. S. To grow a liberal supply of vegetables for 300 people per annum would require about 5 or 6 acres of land, or perhaps a little more, as your soil is of a "poor, sandy nature." As all the cultivation is to be done by the spade, there would be plenty of work on 6 acres of land for three or four good men, assuming that in addition to ordinary digging, hoeing, seed growing, transplanting, etc., there would be a certain amount of trenching or double digging done each year. Potatoes, of course, would require a good deal of space, as 300 people would consume at least half a ton of tubers per week. It would be necessary to grow from 26 to 30 tons a year of early, mid-season, and late varieties, and from 3 to 4 acres would be absorbed by this crop alone from the spring to the end of autumn. Other crops such as Peas, Beans (broad, dwarf and runners), Carrots, Parsnips, Beetroot, Onions, Shallots, Turnips, Cabbages, Cauliflowers, Kale, Brussels Sprouts, Savoys, Lettuces, etc., would have to be accommodated at the same time; but it would be possible to get Cabbages and Winter Greens on ground occupied by the early Potatoes, Peas and Beans. It would require too much space here to give an approximate estimate of the quantities of each kind of vegetable likely to be consumed by 300 people in the course of twelve months, but it works out at a figure that would astonish most people. The value in money of such vegetables is also considerable, and should more than repay the entire cost of labour, manures, etc. Plenty of well-rotted stable manure should be incorporated with your sandy soil, or meagre quantities might be supplemented with a good organic fertiliser.

**Communications Received:**—A. M.—A. R.—Neushon—G. H.—J. H.—W. H. D.—E. H. W.—J. A. P.—J. P.—H. H.—T. S.—H. B.—M. L. C.—J. F.—E. T. E.—W. R.—H. C. B.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 42.1.

ACTUAL TEMPERATURE:—

Gardeners' Chronicle Office, 5, Tavistock Street, Covent Garden, London, Wednesday, March 22, 10 a.m. Bar. 30.1; temp. 40°.—Weather—Cold winds with occasional snow.

The Chamber of Horticulture has been engaged for some time past in considering the subject of how growers of horticultural produce may best meet the competition of foreign-grown produce. The subject is one of great difficulty. With the larger aspect of the question—whether it is to the ultimate interest of this country to admit foreign produce—the Chamber does not deal in its recent memorandum. In this we think it shows wisdom; for, as is well known, opinion is sharply divided on the principle involved. On the other hand, agreement is fairly general that whether it is or is not good policy to admit of free competition between home-grown and foreign-produced fruit and vegetables, there is little prospect of any political party taking action to inhibit the free importation of such produce. Wherefore the Chamber has confined its attention to the secondary, but nevertheless extremely important question—whether it is not fair and equitable that action should be taken by way of amendment to the Merchandise Marks Act to secure the systematic and conspicuous marking of foreign horticultural produce. The President of the Board of Trade has invited the Parliamentary Committee of the Chamber to submit a case, and will, we believe, shortly receive a deputation from the Chamber in order to hear the views of horticulturists in greater fullness. The recommendations which the Chamber of Horticulture make are that horticultural produce should be included in any new Bill brought in to amend the

Merchandise Marks Act, that "all containers in which horticultural produce is imported should be labelled or marked 'Foreign Produce,' and that all foreign fruit and vegetables exposed for sale in shops or on stalls should bear clearly a label indicating its foreign origin." In support of these recommendations the Chamber relies first on the undoubted fact that it is the national interest to increase home production. Horticulturists need no reminder of the fact that the raising of fruit and vegetables employs more labour than any other kind of cultivation and that an extension of the area under these crops leads to a corresponding and not inconsiderable increase of rural population. The Chamber also points out that at present actual misdescription is common and that foreign produce is not infrequently sold as of British origin. To these facts the Chamber attributes, in part at least, the diminishing proportion of home-grown fruit and vegetables consumed by the British community. Thus, in the case of Tomatos, Holland has become of recent years a large producer. Dutch Tomatos come in the market at much the same time as those grown here and the competition which ensues is becoming increasingly severe. The Chamber does not suggest the exclusion of this produce but points out that foreign raised Tomatos, which it claims are inferior in flavour and quality to British grown, often gain an unfair advantage by being sold as "real English." Every fair-minded person—whatever his views on the vexed question of Protection and Free Trade—will recognise that this is a practice which should be opposed by every practicable means. To achieve this end the Chamber proposes that local authorities should be empowered to act for the detection of cases of misdescription and that misdescriptions of this kind should be punishable offences. It is further proposed that any recognised Horticultural Association should be empowered to institute proceedings in cases of misdescription. In addition to Tomato-growing, Grape-growing under glass suffers from foreign competition—particularly from Belgium and Holland—which are now large exporting countries. So serious is this competition that in the last five years the area of the home crop has been reduced by over one hundred acres of glass, and the Chamber predicts that if the competition goes on unchecked, the Grape-growing industry will shortly cease to exist in this country. Similarly in the case of jam-fruit, large quantities are imported—particularly Strawberries from Holland—but the jam made from such imported fruit is often sold under some such misleading description as "made in the Orchard factory." The facts that the Chamber and its affiliated associations comprises a body of 25,000 horticulturists, and that it and the National Farmers' Union are united in these efforts to check the abuses to which attention has been drawn entitles them to a sympathetic hearing on the part of the President of the Board of Trade.

Summer Time.—The Earl of Onslow stated in the House of Lords on the 14th inst. that summer time would operate this year from the last Saturday in March to the first Saturday in October, as this country was bound to carry out its agreement with France and Belgium to enforce summer-time during the period stated. He gave an understanding that when the matter is raised next year, the question of alteration of date should again be considered, and before coming to any decision, the Government would review all the interests of the community. The French Senate, which last November voted against the resumption of summer-time, this

year has agreed to the project adopted by the Chamber, whereby, in accordance with arrangements made with Great Britain and Belgium, summer-time will be adopted for 1922. It is stated that next year, unless the French Parliament has changed its opinion, summer-time in France will automatically lapse.

Flower Show Abandoned.—The Botanical and Horticultural Society of Durham, Northumberland and Newcastle has been compelled to veto the proposal to hold an exhibition during the present year, owing to a serious deficit of £225 on the exhibition held last season. The Newcastle Flower Show, as the Society's exhibition is termed, is a very important one in the North, and we regret that the Society is compelled to forego the show for 1922. Although an appeal was made for subscriptions, only about £130 was forthcoming, and of this sum £110 was given by the members of the Council themselves.

British Superintendent for a Canadian City's Parks.—Mr. James M. Craig, who has been appointed Superintendent of Parks for the City of Regina, Saskatchewan, Canada, was employed for ten years as Superintendent under the City Council at Port Arthur, Ontario, where he did excellent work for that city. He was previously head gardener to the Countess de Morella, at Wentworth, in Surrey, and prior to that was engaged on the Royal estate at Sandringham during the reign of King Edward VII. The newly-appointed superintendent hopes to make Regina a beauty spot in the centre of the great wheat-growing plains of Saskatchewan.

"Popular Gardening."—We congratulate our contemporary, *Popular Gardening*, on the excellent issue forming the special spring number of the paper, dated March 28. The advertisements and text occupy 52 pages, and there are numerous illustrations. The reading matter is of varied and general interest to gardeners and especially to amateurs. An excellent supplementary plate of *Lilium Brownii* shows a fine spike of this beautiful Lily with some fifteen open flowers and buds, and there are full-page illustrations in colour of varieties of *Dianthus Allwoodii* and Pansies. There are other illustrations in colour, but much the finer pictures are those in black-and-white, depicting, amongst other subjects, a dry wall garden, Flag Irises by a garden path, and rambler Roses in the Chalkwell Park, Westcliff—not at Leigh-on-Sea, as stated in the inscription.

The Genus *Eucalyptus*.—Dr. Botting Hemsley writes: "Many readers of *The Gardeners' Chronicle*, both at home and abroad, will welcome the appearance of Mr. Maiden's *Critical Revision of the Genus Eucalyptus*, the fiftieth part of which has been received. The first part of this large work was published in 1903. Part 50 contains illustrations of *Eucalyptus Honseana*, *E. Jutsonii*, *E. adjuncta*, *E. panulua*, *E. rariflora* and *E. mundijongensis*. The last species mentioned bears a name in the Australian vernacular which is also the name of a railway station in Western Australia. In addition, Part 50 contains the continuations of Part 49. A review of the fiftieth part must remain for a future time."

The Carnation Year Book.—We are glad to learn from the *Carnation Year Book* for 1922 that the British Carnation Society has increased its membership and that the finances are in a satisfactory condition, there being a balance of over £30 in hand on the year's work. The frontispiece of the *Year Book* is a portrait of the President, Lady Mond. One of the most valuable features of the *Year Book* is the classification list, in which Perpetual Carnations are classified in their various sections; (1) by colour, (2) by habit. In the colour classification the varieties are given in order, according to some special quality; thus those in the light rose and deep pink varieties begin with sorts of the lightest bluish and end with those of deep cerise colour. In the classification by habit, nine types are selected, of which we quote a typical example: Lady Northcliffe type, growth light and short, producing plenty of side shoots; free and continually flowering; flowers inclined to come in quickly succeeding crops; plants do

not grow very tall; stems short to medium in length, mostly thin and wiry. This classification, carried out by a special committee, has been rendered possible by the co-operation of Mr. C. Engelmann, who cultivates an enormous number of varieties at his nursery at Saffron Walden. Mr. S. A. Pascoe, of the Royal Gardens, Windsor, gives some good advice, in an article entitled "Why grow Carnations," on the cultivation of the plants, whilst some hints on the raising of new varieties are contributed by Mr. W. Bishop, Elmhurst, Windsor. Many pages are devoted to reports of the Society's shows, meetings and annual dinner, and there is a useful list of varieties certificated each year since 1907.

**Presentation to Mr G. Swift.**—At the annual dinner of the National Federation of Fruit and Potato Trades' Association, held on Tuesday last at the Hotel Great Central, an illuminated address and a silver tea and coffee service were presented to Mr. George Swift in recognition of his services during the past two years at President of the Federation. Mr. F. R. Ridley, the newly-elected President, presided at the dinner, which was a great success.

**A New Rose.**—The American Rose Society has passed for registration the new variety Greatheart, a sport from the H.T. Mrs. Walter Easlea, and offered for registration by Mr. E. M. Rosenbluth, Wallingford, Pennsylvania. The colour is pale flesh, shaded salmon. The variety is said to be similar to and an improvement on Mme. Edmond Rostand, but more reliable in flowering. It has also a better stem and every bud opens perfectly. The plants bloom well in spring, summer and autumn.

**Association of Economic Biologists.**—The general meeting of this Association will be held at 2.30 p.m. on Friday, March 31, in the Botanical Lecture Theatre of the Imperial College of Science, South Kensington, London, S.W.7, when Dr. W. Lawrence Balls will discuss "Advantages and Defects of Team Work in Economic Biology," and Dr. Franklin Kidd will lecture on "Problems of Fruit Storage."

**The Late Mr. Bisset.**—The widow and other members of the family of the late Mr. Bisset, who was show superintendent to the Royal Horticultural Society, desire to express their grateful thanks for the deep sympathy shown them in their bereavement, and for the generous help they received from exhibitors at the R.H.S. meetings. We understand that donations amounting to over £85 were received by Mr. Frank Reader, who acted as treasurer to the fund.

**Flora of Greenland.**—At the early March meeting of the Linnean Society an interesting part of the proceedings was the display of lantern slides representing the Flora of Greenland. These were used to illustrate the remarks made by Mr. R. E. Holtum, who accompanied Prof. A. C. Seward to Disko Island and the neighbouring parts of the west coast of Greenland during the summer of 1921. Mr. Holtum observed that the most widely spread vegetation consists of a low Heath, the most important species being *Empetrum nigrum*, *Cassiope tetragona*, and other Ericaceous plants. In specially protected localities a scrub of *Salix glauca* may be found, which may reach eight feet in height, and accompanying this is a luxuriant vegetation of herbaceous plants of southern type. In unfavourable situations the ground is not covered by the vegetation, which consists of isolated plants of resistant herbaceous and woody species. The total flora of the whole of Greenland consists of 416 species of vascular plants, of which eighteen per cent. are high arctic in type, 22 per cent. widely distributed, and 60 per cent. of southern type. The problem of the means of arrival of the last-named group after the glacial period is an interesting one. Prof. Seward, who was present, stated that the main object of his visit to Disko Island was the collection of fossil plants. He recommended Greenland as a summer resort, the only difficulty being that of getting there. Mr. E. G. Baker and Mr. A. J. Wilmott commented on the absence of Leguminosae from the flora of Greenland, and in reply to questions, Mr. Holtum stated that

next to Leguminosae in order of sparseness came Cyperaceae and then the Grasses. Only four species of *Salix* had been recorded in Greenland.

**Mr. W. H. Divers, V.M.H.**—It is appropriate in the first week of spring to publish the portrait of Mr. W. H. Divers, who, in addition to being one of the most successful all-round gardeners, made a special feature of spring gardening and published the best work on the subject in *Spring Flowers at Belvoir Castle*, in which celebrated gardens this phase of gardening was brought to the highest state of perfection by Mr. Divers. He was born at Wierton Place, near Maidstone, where his father was head gardener for forty years. He commenced his professional career at Wierton Place and served for four years under his father, after which period he went to Linton Park as a journeyman and gained further experience in the gardens at Brantingham Thorpe, near Brough; Sandbeck Park, near Rotherham; Hatfield House, Hertfordshire; Tandridge Court, Godstone; and Burghley Park, Stamford. In 1884 he was appointed gardener and agent to J. T. Hopwood, Esq., at Ketton Hall, near Stamford. This celebrated garden contained the

MR. W. H. DIVERS, V.M.H.

largest private collection of Peaches and Nectarines in the country, and many prizes were won by Mr. Divers with these fruits. Another speciality of the place was the Marechal Niel Rose, and as many as 16,000 blooms of this variety were cut in one year. In 1889 Mr. Divers went to Florida to advise Mr. Hopwood on his estate near Winter Park, Orange County, and his experiences of that country were published in *Gard. Chron.*, May 31, 1890. In 1894 he was appointed gardener to the Duke of Rutland, Belvoir Castle, where he remained until his retirement, in 1917. During his 23 years at Belvoir Castle, Mr. Divers enjoyed a high reputation as a capable gardener in all aspects of horticulture, and his name was constantly before the public, both as an exhibitor and writer. A list of trees and plants at Belvoir compiled in 1904 showed that upwards of 2,000 species were in cultivation there. The natural scenery of the place is very picturesque, and many beautiful views of Belvoir have been published from time to time in these pages. Mr. Divers was awarded the Victoria Medal of Honour in Horticulture in 1913. He is one of the most regular attendants of the Fruit Committee of the Royal Horticultural Society, to which body he was appointed in 1892. Soon after his retirement from Belvoir he was appointed Special Representative and Lecturer for the Royal Horticultural Society for Middlesex, Essex and North-East Kent. He is a lec-

turer on horticulture to the Surrey County Council, and has served on the Committees of the Royal Gardeners' Orphan Fund, United Horticultural Benefit and Provident Society and the Enham Village Centres for disabled soldiers.

**Appointments for the Ensuing Week.**—Tuesday, March 28: Royal Horticultural Society's Committee meetings (2 days); first day, Masters' Memorial lecture by Dr. Harold Wager, at 3 p.m.; Bath and West and Southern Counties Society's Council meeting; Cardiff Gardeners' Association's annual general meeting.—Wednesday, March 29: Irish Gardeners' Association's meeting; Elgin Horticultural Society's meeting; Glasgow and West of Scotland Horticultural Society's lecture on "Rock and Water Gardening," by Mr. W. Besant.—Thursday, March 30: Bristol and District Gardeners' Association's meeting; Stockport Horticultural Society's annual meeting.—Friday, March 31: Association of Economic Biologists' meeting.—Saturday, April 1: Paisley Florists' Society's exhibition.

**"The Gardeners' Chronicle" Seventy-five Years Ago.**—*Horticultural Society's Garden, Turnham Green, March 15.*—The Orchid house here is now beginning to assume a gay appearance, the more favourable influence of longer days and brighter sunshine causing many of that beautiful tribe to come fast into beauty. The greenhouse next the Orchid house is also gay, most of Mr. Fortune's plants in flower having been placed here. Among them were *Azalea obtusa*, whose glowing red flowers have already sufficiently distinguished it to ensure it a place in every greenhouse. Whether or no it may turn out to be hardy has not yet been satisfactorily ascertained, plants of it having been hitherto too scarce to afford of the experiment being made. Associated with it was the beautiful yellow-flowered *Forsythia viridissima*. This has been proved beyond a doubt to be hardy, plants having stood the winter in various aspects without any protection beyond that afforded by the wall on which they have been trained. The Lilac-blossomed *Daphne Fortunei* has also been blooming here since the last meeting of the Society. This has likewise proved itself to be hardy in the open border, the buds being plump and good, and the shoots perfectly uninjured to the very points. *Jasminum nudiflorum* and the handsome *Weigela rosea*, the latter in the border near the Council room, with various *Paeonies* from Mr. Fortune, have also stood the winter. *Azalea ovata* has sustained no injury as yet, planted out in the American border; and we learn that it has also proved quite hardy in other quarters. In the greenhouse already mentioned was *Akebia quinata*, a brown-flowered climbing plant from hedges in Chusan, just coming into bloom, which, being sweet-scented, promises to become a desideratum; as does also another of Mr. Fortune's plants, in the shape of a double-flowered white variety of *Prunus sinensis*, which is now in blossom. *Gard. Chron.*, March 27, 1847.

NOTICES OF BOOKS.

Manual of the Trees of North America.\*

PROFESSOR SARGENT published the first edition of this book in 1905; the second has recently appeared. It is really a condensation into one convenient volume of his *Silva of North America*, a magnificent work issued between 1891 and 1902, and consisting of fourteen quarto volumes, with 704 plates. It is no doubt, the finest work on trees ever published. In the present *Manual* much interesting information given in the larger work has naturally had to be omitted, and the author has limited himself chiefly to giving a full and detailed description of every North American tree, an enumeration of its various habitats, and a description of its timber and the uses to which it is put. A system of keys is provided which enables one to identify any tree native of North America.

For the lover of trees in North America this work must be indispensable; and in the British Isles, where gardens owe so much to the arboreal vegetation of North America, its value is almost as great. This new edition has been prepared on the same lines as the original one, since the publication of which eighty-nine species of trees and many varieties have been discovered. A few species regarded in the first edition as trees are now considered more properly to be shrubs and are omitted. Thus we find that, according to this work and in Professor Sargent's estimation, there are now seven hundred and seventeen species of trees native of the North American continent, exclusive of Mexico.

An admirable feature of the book is the illustrations of the leaves, flowers and fruits of every species and most of the varieties described. There are 783 of them, reproductions of line drawings made by the late C. E. Faxon and, since his death, by Mary W. Gill. Mr. Faxon was one of the most talented of botanical artists.

There is every evidence that the work of revision has been most carefully done. In the course of many years' study of, and reference to, the first edition, I noted various mistakes, mostly due to printers' errors overlooked in proof reading and other trivial causes inevitable in a work of this character and dimensions. Nearly all these have been detected and made right. The authority for the genus *Malus*, however, is still given as "*Hall.*," when no doubt "*Mill.*" (in abbreviation of Miller) was intended. I am glad to see the old name of *Carya* for the Hickories is restored, displacing *Hicoria*, and that the duplication of one word for the generic and specific names of a tree—resulting in such dreadful combinations as "*Catalpa Catalpa*," and "*Sassafras Sassafras*"—has disappeared. It is gratifying, too, to find that the author has been able to drop the name *Magnolia foetida* for *M. grandiflora*.

In one respect I think the book might have been improved. It would have been a convenience if more well-known synonyms had been given. Professor Sargent follows the Vienna Code of Rules, and this involves the use of many names still unfamiliar. Probably he feels that the sooner all others except those he considers the proper ones are consigned to oblivion the better. At any rate, many names well known and long in use do not appear in the text or in the index. One looks in vain, for instance, for *Pseudotsuga Douglasii* or *Picea alba*; we get instead *Pseudotsuga taxifolia* and *Picea glauca*. To the professional botanist this does not matter, but to the amateur it is a hindrance. However, "popular" or English names are given wherever possible, and in these two cases "*Douglas Spruce*" and "*White Spruce*" point the way.

In his preface to this new edition of the *Manual*, Professor Sargent remarks that it contains the results of forty-four years' continuous study of the trees of North America, carried on in every part of the United States and in many foreign countries, and that if these studies serve to increase the knowledge and love of

\* *Manual of the Trees of North America (exclusive of Mexico)*. By Charles Sprague Sargent. Second edition. Boston and New York, 1922. Price \$12.50.

trees he will feel that those years have not been misspent. To one like myself, who has had the first edition in constant requisition, that seems a very modest way of putting it. The real fact is, there is no person living who has done so much for tree lovers as the author of this book. When we remember the admirable works he has written, the others he has inspired and edited, the innumerable living plants he has been the means of introducing to our gardens, and his forty years of labour in the Arnold Arboretum, we cannot but be thankful that a man of such genius and powers of work should have devoted his life to our interests. W. J. Bean.

FOREIGN CORRESPONDENCE.

A NEW KIND OF FUEL. (See p. 10b.)

In the war years coke was very scarce here, and we heated our greenhouses with briquettes, as used by our steam-trams. The convenience of these tarry briquettes appeared so considerable that we planned to use permanently this kind of fuel, which, however, proved later disappointing! Our heating apparatus was a sectional,

by Hooker. The reason that the famous botanist gave it this name is that when the flower fades there forms in the middle and in the direction of the length of the petal a reddish stripe, so that the corolla presents five such stripes. Those who do not know this truly magnificent plant will never, of course, judging by its name, realise that it has flowers of the purest sky-blue colour. The sky of the Riviera is famous for its deep, intense, pure blue, and often have I looked at the flowers of *Ipomaea rubro-caerulea* against the sky and never saw colours blend so absolutely. The flowers are some ten centimetres in diameter and produced in such numbers as to almost hide the heart-shaped leaves. The flowers open towards early morning and remain open till near evening time, when the above-mentioned red stripes are formed, just before the flower fades. The plant does not survive the winter here, and may be an annual, but it is of very rapid growth and flowers here all through the summer and autumn. Dr. A. Robertson Proschowsky, *Jardin d'Acclimatation Les Tropiques, Nice, France*.

[*Ipomaea rubro-caerulea* formed the subject of the coloured supplementary illustration in *Gard. Chron.*, Feb. 15, 1913.—Eds.]

FIG. 66.—CYMBIDIUM ALEXANDERI, WESTONBIRT VARIETY. R.H.S. FIRST-CLASS CERTIFICATE, MARCH 14. SHOWN BY SIR GEORGE HOLFORD, WESTONBIRT (SEE P. 131).

oval, cast-iron boiler, a "counter-current" system, with central fire and many smoke-canals on two sides of the fire, downwards to the smoke-chamber. After some months the burning of the fuel was less and less satisfactory, and the cleansing of the smoke-canals became gradually more difficult. Needle-sharp, glassy, black cones hung on both sides, like black icicles, into the smoke-chamber. A kind of crystallised asphalt had stopped up nearly half the smoke-canals. The only means we adopt to counteract this result of burning tar-containing fuel with slow draught consists in running off the water and heating the empty boiler, till the glass-hard asphalt is melted and can be scraped out. P. v. B., *Wageningen, Holland*.

IPOMAEA RUBRO-CAERULEA.

It is well known how very few flowers are a pure blue colour, and that nearly all so-called blue flowers really are not blue, but of different combinations of other colours with blue. When it is considered that several plants with flowers not pure sky-blue have received the name *caelestis*, it seems unfortunate that this *Ipomaea*, probably the most pure sky-blue coloured of all flowers, should have been named *rubro-caerulea*

THE BULB GARDEN.

TECOPHILAEA LEICHTLINII.

THIS exquisite, Crocus-like, bulbous flower is not generally known to garden lovers, but when once seen its fascinating blue flowers cannot fail in their appeal. The plant is well worth growing and its requirements are simple. When grown in light, sandy loam it is quite hardy, and the best position for it is one facing south, and if a place at the foot of a wall is available so much the better, as the wall affords shelter from cold winds, which prevail when the flowers appear. This *Tecophilaea*, a form of *T. cyanocrocus*, is from 3 to 4 inches high, and has slender foliage. If a sheet of glass is placed on supports over the plants just before the buds open the flowers will last a long while in beauty and will not be splashed during rain storms. Propagation may be effected by sowing seeds, and by means of offsets planted in the dormant season. Bulbs planted about three to four inches deep, in very sandy soil, will flower at the beginning of March in a normal season. R. H. Crockford, *Weston Park Gardens, Stevenage*.

## The Week's Work.

### THE ORCHID HOUSES.

By J. T. BARKER, Gardener to His Grace the DURE OF MARLBOROUGH, K.G., Blenheim Palace, Woodstock, Oxon.

**Phalaenopsis.**—These Orchids are not grown so numerous as formerly, and by many they are considered refractory subjects; still, there are few plants which can compare with them for beauty. They are best grown in baskets or shallow pans suspended from the roof rafters, but not too near the glass, as they are liable to suffer from extremes of heat and cold. Plants that are commencing to make new roots may be supplied with fresh rooting material if necessary. These Orchids are often allowed to suffer for the want of new material, as many growers are afraid to disturb them. Healthy established plants that have roots clinging to the baskets in which they are growing should not be disturbed, beyond removing the old decayed rooting material, and this must be done with care. Specimens in need of fresh receptacles should have any clinging roots carefully detached with the aid of a thin-bladed knife or similar article. Select for each plant a suitable basket or pan, then work the compost carefully amongst the roots, finishing with the crown of the plant slightly higher than the edge of the receptacle. A clean, fibrous compost, with live Sphagnum-moss, provides a suitable rooting-medium. These Orchids are best grown in a house by themselves, where a hot, humid atmosphere may be maintained while they are making their growth; they need a lower temperature and drier atmosphere whilst resting. Having no pseudo-bulbs, every care is necessary at all seasons to prevent any harm overtaking the plants.

**Temperatures.**—A slight increase in the temperatures of the different houses is now permissible, with a corresponding increase in the atmospheric moisture, according to the requirements of the plants grown therein. The increase in the amount of both warmth and moisture should be gradual until the summer or growing conditions are reached.

**Ventilation.**—As all Orchids delight in a pure atmosphere, and depend entirely upon the conditions provided for them in their artificial homes, every attention should be given to the admission of fresh air without exposing the plants to draughts.

**Shading.**—With the sun's increased power shading will now come into general use, but it should not be applied to excess. In the abnormally hot summer of last year the majority of Orchids made robust and perfect growth, which should produce an abundant crop of flowers this season. Heat and light are essential to certain classes of Orchids, and these should be kept apart from the shade-loving kinds, which are incapable of withstanding an excessive amount of light.

### THE FLOWER GARDEN.

By EDWIN BECKETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Hertfordshire.

**Pampas Grass.**—This beautiful plant is worthy of inclusion in all gardens, and now is a suitable time for planting the various kinds. There is no more striking or lovely feature than a fine old-established plant of Pampas Grass on a lawn. Old specimens should be cleaned carefully, and, if it is desired to increase the stock, this may be done now by division of the old stools.

**Lobelia cardinalis** and **L. siphilitica.**—A word must be said as to the beauty and utility of these two species for border work, with their fine red and purple colours. The first-named is, however, not very hardy, and is best lifted in the autumn, boxed and wintered in cold frames, and where this has been done, the old

stools may now be replanted. There are some very fine varieties of this plant, and one especially worthy of note is Queen Victoria; this and allied varieties are very useful plants for inclusion in the summer bedding scheme.

**Paths and Lawns.**—Where it is desired to form new gravel paths, the present is a suitable season of the year to do the work. When the excavation is made for the site of the path, place a thick layer of coarse material, such as small flints, broken brick, etc., in the bottom to act as drainage, for nothing is more annoying than to find water remaining on the surface of paths after heavy rains. Place finer material on this bottom layer, and finish with material of a binding nature to the required level, and roll it well down. Old gravel walks should be renovated; in this case the surface should be well loosened, and the material drawn up to form a slight rise to the centre, before applying fresh gravel, which should be rolled in thoroughly. Bare patches on lawns should be renewed with fresh turf. Lawns from now on require careful and continual attention if they are to be kept in the finest order. Rolling should be frequent; edges should be trimmed with an edging tool, and, where mossy patches exist, the surface dressed freely with fine soil. Before rolling is commenced, the whole of the lawn should be efficiently swept, otherwise stones and portions of branches from trees may get rolled in, only to project again when mowing commences, a happening likely to cause damage to the mowing-machine.

### PLANTS UNDER GLASS.

By T. PATEMAN, Gardener to Sir C. NALL-CAIN, Bart., The Node, Codiote, Welwyn, Hertfordshire.

**Trachelium coeruleum.**—The blue Trachelium is a most useful plant for the greenhouse and house decoration. Seedlings raised from seeds sown last July that have been growing steadily require their final potting. Where large specimens are required they may be repotted in as large receptacles as needed, up to 12-in. pots, but plants in 6-in. or 7-in. pots are generally the most useful. Large plants may be obtained by liberal feeding of the roots as soon as the latter are in a condition to assimilate plenty of food. Tracheliums will thrive in almost any soil; a mixture consisting of three parts loam and the remainder leaf-mould and manure from a spent Mushroom-bed will suit them admirably.

**Ruellia macrantha.**—This plant is a useful flowering subject during the winter for the warm greenhouse, and will also be found excellent for grouping in warm corners of the house, but will not succeed in draughty corridors. Cuttings inserted now will make fine plants by the autumn. They should be grown on in 6-inch pots, and will make fine, bushy specimens, provided the shoots are pinched once or twice during the growing season. Rich, open loam mixed with a little peat and leaf-mould and a good dash of sand provides a suitable compost for these plants. During their growing season they should be placed in a house having a fairly high temperature, such as where Melons are grown.

**Euphorbia jacquiniæflora.**—Stock plants of this Euphorbia that have been cut back and rested as previously advised, may be stood in a warm house to encourage them to break into growth, with a view to obtaining cuttings for next season's plants. Syringe the plants frequently on bright days to encourage them to break freely. Plants of Euphorbia pulcherrima, which is better known in gardens as Poinsettia pulcherrima, may also be stood in a warm house and given the same treatment, with a view of obtaining suitable shoots for use as cuttings. The pink Poinsettia Trebstii and the white form may be left in their resting quarters for several weeks, as these plants break into growth more readily and root more freely than those of the red variety.

**Shading.**—The blinds should now be fixed to the conservatory and other plant houses, for plants in flower and others growing in small pots require protection from the direct rays of the sun.

### THE KITCHEN GARDEN.

By JAMES E. HATHAWAY, Gardener to JOHN BRENNAN, Esq., Baldersby Park, Thirsk, Yorkshire.

**Herbs.**—If it is desired to increase the stocks of Sage and Thyme, the plants may be propagated from cuttings inserted now under a bell glass in a shaded position. The cuttings will root quickly. Mint, also, may be struck this way. Sage is much better increased from cuttings than from seed, as many of the seedlings run to flower.

**Parsley.**—This herb is always in demand, and a sowing should be made in a long drill near the edge of a path, where the leaves may be gathered easily. The ground should be dug deeply; light land should have plenty of manure added to it. Soot should be scattered on the land and raked in before sowing the seed, and light dressings of this material should be applied once a fortnight afterwards.

**Rhubarb.**—Fresh plantations of Rhubarb should be made now. Few other crops pay better than Rhubarb for generous cultivation, which does best in light soil that has been trenched deeply and manured. In the case of heavy land old garden refuse and leaf soil should be dug in to lighten it. Crowns that do not show a tendency to flower should be selected and planted singly. Plenty of space should be allowed between the rows, for, if planted too closely, the sticks will be poor and weak. Make the rows 5 feet apart, and allow a space of 4 feet between the plants in the rows. Work the soil well around the crown and make it firm, leaving the tip of the crown just showing through the surface. Stalks should not be pulled from the plants in their first year after setting, but flower stems should be cut off as soon as they show. A mulching of half-decayed manure should be put around the crowns before dry weather sets in. Daw's Champion is one of the best varieties. The leaf stalks are a beautiful colour when forced.

**Carrots.**—Where Carrots are required for exhibition in early autumn seed should be sown now. To ensure well-shaped roots make holes about 2 feet to 3 feet deep according to the type grown, and fill them with fine, light soil. Sow a few seeds at each station, and subsequently thin the seedlings to one. Exhibition Carrots should be grown in rows made 20 inches apart, allowing a space of 1 foot between the plants in the rows.

**Globe Artichoke.**—The protecting material should be removed from Globe Artichokes, and the ground between the rows well manured and dug. Plants that have failed should be made good by planting suckers which have been potted up for the purpose in the previous autumn. Fresh plantations should be made during the next week or two on ground that has been well trenched. Very heavy land should have plenty of sand or roadside grit well worked into it. Plant suckers that were potted in the autumn in rows made 3 feet 6 inches apart and allow a space of 3 feet between each plant in the row; if pot plants are not available use suckers from the old plants in the bed. Slugs are often troublesome to Globe Artichokes; soot or lime should be dusted around the plants, a dressing of ashes also tends to keep them away. Large Green Globe is the best variety.

### HARDY FRUIT GARDEN.

By H. MARHAM, Gardener to the EARL OF STRAFFORD, Wrotham Park, Barnet.

**Orchards.**—Large trees that have borne good crops of fruit annually should be top-dressed with rich farmyard manure and fed with liquid manure. Our best Apples at Wrotham are produced on trees planted in a grass orchard; the grass at all times is kept very short, and poultry have a free run beneath the trees, the manure from the birds being washed well down to the roots by the rains with gratifying results.

**Wall Trees.**—As the soil about the roots of wall trees is very apt to become hard through the grower treading on it whilst training and

**CHINESE SHRUBS AT ALDENHAM.**

(Continued from page 123.)

*LONICERA MAACKII* was introduced by Wilson in 1900, but had been known before that year, for plants were sent to St. Petersburg from Manchuria in 1880. It is a strong, almost rampant-growing, bush Honeysuckle; specimens at Aldenham raised from Wilson's seed have attained a height of 10 feet. When allowed sufficient room to display its spreading branches, it is a beautiful object, either in flower or fruit, the latter being red and produced in great numbers. It is, however, necessary to add the caution that no shrubby Honeysuckles can be depended on to fruit with the same constant profusion in our English climate as they do in the United States, where, whatever else they may have to put up with, gardeners do not suffer from frosts after winter is over. *L. nitida* (see Fig. 67) is

The handsome, dark green foliage and bright yellow flowers are most pleasing, and this Chinese form will prove a valuable garden addition to the genus. Although native of a high altitude and much hardier than *P. nepalensis*, *P. concolor* is not quite hardy in Hertfordshire. A few winters since a big established plant was killed to the ground, though it sent up root suckers freely the next season, nevertheless, it is quite hardy enough to make it worth growing in the open even in a cold district such as Aldenham, whereas *P. nepalensis* would not survive two winters there without wall protection.

*STAPHYLEA HOLOCARPA* and its variety *rosea* are both perfectly hardy, and grow freely, either in bush or standard form. Mr. Wilson informed me that they are both very attractive in flower. When of sufficient age to blossom freely the tree form would undoubtedly prove very ornamental. *A. E. Thatcher.*

(To be continued.)

**FRUITS UNDER GLASS.**

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY M.P., Ford Manor, Liogfield, Surrey.

**Cucumbers.**—Where the winter plants have failed, an early start with stout young plants is of great importance. The Cucumber delights in a compost of rich, turfy loam, a little leaf-mould and rough lime rubble. Good drainage is essential as the plants need an abundance of water. Do not use manure in the compost, or for mulching, as it encourages worms, and does not promote steady growth that is secured by the use of constant supplies of warm diluted liquid manure, soot water and guano water. If other operations are well timed the hillocks of soil placed about four foot apart will be warmed through by the time the first rough leaves appear, therefore as root-bound seedlings are of little use, planting should not be further delayed. Place a straight stick from the compost to the trellis, turn the plants out of their pots, cover the roots with warm soil, and water the latter. The heat from the pipes and bed combined should warm the soil to 80°, with an atmospheric temperature of 66° to 70° by night, and 75° to 80° in the day, this being the greatest amount of warmth that should be permitted when the sun is shining.

**Thinning Fruits.**—Judicious thinning of the various kinds of fruits reacts beneficially on the size and quality of those that are retained, for the crop, and colour is rarely perfect when the quality is only second rate. Grapes, Peaches, Figs and Melons should never be overcropped. Large crops of Peaches and Nectarines appear to be fairly satisfactory until the stoning stage is reached, but later they remain small and lack colour. The inexperienced grower who fails to thin these fruits, and, after stoning, that they drop, until the tree is furnished with less than half a crop, and these seldom finish well, for the mischief has been done, giving the tree a check at a critical stage. The same is true of forced Figs; each well-ripened shoot of a Fig tree will produce three times as many fruits as are required, and if they are all left to swell a large percentage is sure to drop at the period of the final swelling, and often all are lost in this way. Bad culture may sometimes have something to do with this defect, but in many instances it may be traced to over-cropping. It is impossible to say how many bunches a healthy vine should be allowed to carry, for one must not overlook the fact that under-cropping is as big a fault as over-cropping. It is safe to reduce the bunches to one on each spur, and this would give a very heavy crop indeed; generally one-third of the bunches should be removed, as soon as the best bunch can be determined. Thinning the berries of Grapes is a tedious operation, and requires practice with the different varieties. The proper time to thin is immediately after all free-setting varieties have finished flowering. Muscats and others which require artificial pollination need a little more time. Lady Downe's, Gros Colmar, and other winter Grapes should be thinned until there is no danger of the berries "binding." Early and summer Grapes that are under-thinned do not suffer so much as the preceding.

FIG. 67.—*LONICERA NITIDA*.

one of the most useful of evergreens, which has, I believe, been employed very successfully as a hedge plant. As a single specimen it grows about 5 feet high and as much in diameter. *L. pileata* is a low-growing evergreen of neat appearance, and well suited for the rock-garden, or as a choice ground cover. It is apparently happy in partial shade. The foliage is larger, and the growth flatter, than that of the preceding, but both alike bear purple fruit, though the latter produces them the more freely. They are closely related botanically. *L. Standishii lancifolia* is a narrow-leaved form of this winter-flowering shrub, and a welcome addition at this time of the year. It is very sweetly scented, and flowers freely in January and February. Although having no special claim to beauty, *Lonicera prostrata* has a most pleasing habit, and is admirably adapted for rock-work planting. It is particularly good when seen, as at Aldenham, scrambling over large rocks on the edge of a stream.

**PIPIANTHUS CONCOLOR.**—To the ordinary observer this species differs in no respect from the well-known *P. nepalensis*, which is only hardy in the more favoured parts of this country, but *P. concolor* has proved quite a success at Aldenham, where it has grown and flowered freely as a bush in a very exposed situation

**TREES AND SHRUBS.**

**AZALEA PROCUMBENS.**

It is regrettable that this plant should be so intractable in gardens, yet so abundant in the wild state. The species was the original *Azalea* of Linnaeus; it is now known as *Loisleria procumbens*. The rose pink coloured, bell-shaped flowers are regular, and the seed vessel is rarely more than two to three-celled. In Britain it is confined to the high Scotch alps, and wherever I have seen it, the situation was fully exposed to sun and wind. On a level plateau, at an elevation of 2,500 feet, where it covered many square yards, the peaty soil was very shallow and hard, while the plant covered most of the space with a close evergreen carpet. Evidently the compact soil and the exposures were to its liking, for it flowered and fruited freely. These conditions could not be imitated in lowland gardens, because the soil would get too dry in summer. I have seen *Azalea procumbens* planted to face the east, and also where it could get no sunshine till late in the afternoon; yet it made no visible progress, although various other mountain plants grew freely in the sod brought from the native habitat of the *Azalea*. The small leaves, revolute at the margins, can carry on transpiration in spite of heavy dews and mists. *J. P.*

**EDITORIAL NOTICE.**

**ADVERTISEMENTS** should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, W.C.2.

**Illustrations.**—The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.

**Editors and Publisher.**—Our correspondents would oblige by delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the EDITORS. The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.

**THE ORCHARD AND FRUIT GARDEN.**

THIS is by far the best of the series (see p. 78), and exhibits Mr. McIntosh as a remarkably well read man in the literature of gardening, but also as possessed of a degree of education extending to a knowledge of Latin and of ancient writers in 'that tongue which would be regarded as uncommon among gardeners at the present day. He is probably only one among the many early Victorian gardeners who filled a position that few, if any, are called upon to occupy in the present Georgian period.

In the course of his review of the history of the various fruits treated of in *The Orchard and Fruit Garden*, McIntosh mentions familiarly nearly all of the early writers on Pomology, and quotes extensively from their works to illustrate and enforce his own propositions. Lists of fruits, unlike those of plants in previous volumes which were merely names of varieties, are in this volume select and reduced to moderate proportions. It would extend these notes beyond the necessities of the case to mention all the fruits treated more or less fully, and therefore only the more important will be chosen.

The fruits are arranged in alphabetical sequence which is followed here. Of Apples, 136 varieties are named and described, and the descriptions, as one might expect, are not copied from *The Practical Gardener*, but are re-written. Naturally there are many varieties which have passed out of cultivation, but there are also large numbers that still are grown. The Golden Pippin held its own as first among dessert varieties, only in estimating its qualities at the present day it should be noted that it required a fine season to bring out the unique flavour that an earlier generation did not find in newer varieties. Ribston Pippin, Claygate Pearmain, Irish Peach, Reinette du Canada, Court-pendû-plat, Blenheim Orange and Gravenstein are a few well-known sorts that were recognised as indispensable at the beginning of the Victorian era. The King of the Pippins of McIntosh is the one grown still by that name.

Were one given to conceit, such instructions as McIntosh gives would demonstrate how vain it is to imagine that anything new is to be discovered in practical gardening. In planting, the author notes that it is no benefit to a tree to preserve the small fibres, and that it is beneficial to root prune at intervals of five or six years. The reduction of fruit at a young stage to a moderate crop is recommended, both because it is a means of producing a finer sample, and because it ensures a constant crop, year after year. He also notices that some varieties were immune from the attack of American blight, which was found only on certain varieties of Apples. Types of stocks, methods of propagation, grafting, budding, etc., are very fully described and illustrated.

Only eight varieties of Apricots are recommended, and of the stocks used he strongly favours the "Muscle" Plum. The sudden decay of branches is attributed to electrical shock, and the routine management is similar to that followed by experienced cultivators at the present day. Gathering the fruit previous to

maturity is also noted. It is asserted that the name Apricot was first applied in 1782 by a gardener named Kyle, of Moredun, near Edinburgh. An anecdote from the French relying for its wit on the French name of the tree is recorded, and may be worth reproducing:—

"Après la mort de Louis XI., au commencement de la régence de Mme. de Beaujeu, plusieurs personnes furent disgraciées; entre autres Cotier, premier médecin du feu roi, qui s'applaudissant d'être échappé de cette cour orageuse, fit sculpter sur la porte de sa maison un abricotier avec cette inscription 'A l'abri Cotier.'"

Of Cherries, all are old varieties, 15 being named and described, and nothing worthy of particularising occurs, while other kinds may be passed over till we arrive at the Fig, of which twelve varieties are named, the descriptions being not always correct, as we know them. Moreover, the culture is scarcely so good as we should expect, the method of propagating by eyes being unknown, as likewise the stopping of shoots in early autumn to ensure a crop the next year. In a brief chapter on Filberts the author informs his readers that anciently they were eaten after fish, and quotes a Latin saying:—"Post pisces nuxes, post carnes caseus adsit." In the lists of Gooseberries are such well-known sorts, as Crown Bob, Roaring Lion, Red Champagne, Warrington, Sulphur, Glenton Green, Hedgehog, Green Gascoigne and Whitesmith.

Of Melons, 19 kinds are described. These were cultivated entirely in pits or frames heated by manure and leaves, entailing a vast amount of labour extending from the marshalling of the material, till its removal in an exhausted condition to the kitchen garden quarters. We are informed that some growers carried Melon seeds in their pockets for weeks or months previous to sowing, in order to induce fruitfulness, and other methods equally satisfactory to the grower were practised. The small Early Cantaloupe was grown extensively round London in beds sunk in the ground filled with hot manure, and covered with hand glasses, and even in the open. They were also grown for a time in pots and in baskets. Nothing is said of canker in the stem, but it was known in the branches and in the fruit. Thrips and red spider were the insect pests of the period.

McIntosh esteemed the Pear next to the Apple in value as a British fruit. Seventy varieties are named and described, a goodly number of which are still in cultivation. Such are Beurré Diel, Beurré Rance and Beurré d'Aremberg, Brown Beurré, Beurré Capiaumont, Catillac, Duchesse d'Angoulême, Easter Beurré, Hacon's Incomparable, Jargonelle, Marie Louise, Williams' Bon Chrétien and Winter Nelis. Brief historical notes are included in the descriptions, and the proper stocks recommended to give the best results. Double grafting is noted as productive of an earlier bearing condition, and heading down old trees as a certain method of renewing fruitfulness. He accords to Forsyth the discovery of this cultural procedure which, no doubt, is effective for a time. Regrafting is also mentioned for the same purpose. Another system was to cut back all old spurs to the branch from which they sprung—valuable alike for Apples and Pears. The root pruning of old trees is also recommended, but it is a dangerous operation for old Pears.

The chapter on the Peach is a lengthy one, 26 varieties being noted. Bellegarde, Noblesse, Grosse Mignonne, Late Admirable and Royal George being the best known, and of the 16 Nectarines, Elruge, Pitmaston Orange and Violette Hâtive. There is also a list of introductions from America, but none of these has survived. Several pages are filled with the opinions of various cultivators. One of the most important matters treated of is the early thinning of the fruit, which it would appear was neglected to a large extent. "Hot walls," that is walls heated by means of flues, were not yet out of fashion, but McIntosh recommended their assistance only to ripen late varieties and the young wood. For forcing under glass the structure recommended was to

be no more than five feet wide, the trees to be trained to the back wall.

The Pineapple follows, of which 30 varieties are described. Of this chapter it needs only be noted that the author records "two curious paintings, representing Rose presenting a Pineapple to King Charles." He mentions also a painting preserved at Cambridge in which a Pineapple produced in the garden of Sir M. Decker, of Richmond, is depicted. The author, after referring to various authorities, regards this as being the first Pineapple produced in England. The Plum occupies only a few pages, 36 varieties being described. Green Gage, Coe's Golden Drop, Kirk's, Washington, the Magnum Bonums, Goliath and Orleans alone surviving.

Of all fruits the advance shown by the Strawberry has been the greatest. Of the 21 varieties named I possess only one, the Grove End Scarlet, but probably few besides myself grow it. The author says it is "large," yet it is because of the smallness and the colour of the fruit that, where it exists, it is retained for preserving.

The list of fruits closes with the Grape Vine. Black Hamburg, Black Prince and Muscat of Alexandria only of the 21 sorts named being now in general cultivation. It is noted that the Hampton Court Vine produced annually 2,000 bunches, totalling 2,000 lb.; the Cumberland Lodge Vine, a nearly equal quantity, and that of Valentine's, near Ilford, similarly. When I saw the last-named, now a number of years ago, it was reduced to a few feet of stem. It is interesting as being the parent of the Hampton Court Vine. These and other old Vines are remarkable for virility and fecundity. The Tynningham Muscat growing here was introduced about the year 1760, and on many of its shoots three clusters are shown: last year bunches up to 3 lb. weight were produced. Owing to the light soil the berries are smaller than they would be on a strong loam, and consequently the clusters would weigh even more on such a soil.

The volume under consideration contains many engravings descriptive of fruit culture of the period. The training of fruit trees was quite a science, and a science which young gardeners seem to have no wish to master. Indeed, there are gardeners who ridicule perfect training as a waste of time. There are also many coloured plates of various fruits, some of which can scarcely be equalled, Currants, Nectarine, Apricot, Peach (Noblesse), Washington Plum and Green Gooseberries being the best. There is also a pretty vignette of various fruits and a frontispiece that adds no credit to the volume. R. P. Brotherton.

**MR. KINGDON WARD'S SIXTH EXPEDITION IN ASIA.\*****No. II.—SOME CHINESE PRIMULAS—A DIGRESSION.**

It does not fall to the lot of every man—and not even to a plant collector in China every day—to find seven Primulas in the course of a day's march. That was my luck on June 3. True, only five of them were in flower; but it required no esoteric imagination to picture the other two, whose corpses strewed the slopes, one of them being a *Capitata* and the other *P. Littoniana*, or more probably a geographical variety, since it was found on the opposite side of the Yangtze to its prototype; and what we know of the distribution of Primulas in far western China leads us to expect some degree of variation in plants found on opposite sides of that gulf.

And yet these two species were not quite corpses after all, for I extracted a few seeds from their skeletons. They would not flower for another six weeks at least—this year's bud was barely visible underground.

\* The previous articles by Mr. Kingdon Ward were published in our issues of May 14, June 18, July 23, August 20, September 3, October 8, October 29, 1921; January 7, January 31, and March 11, 1922.

NEW OR NOTEWORTHY PLANTS.

PIERIS TAIWANENSIS, HAYATA.

THE Marquis of Headfort showed a plant of this new and beautiful species of *Pieris* (Fig. 68) at the R.H.S. meeting on Tuesday, March 14th. It was raised from seed collected by Mr. E. H. Wilson in Formosa during his visit to that island in 1918. It is an evergreen shrub with perfectly glabrous young shoots and leaves. The latter are leathery in texture, oblanceolate to oval, tapered towards both ends, bluntish at the apex, shallowly toothed, 1 to 3 inches long,  $\frac{1}{2}$  to 1 inch wide, deep glossy green. The flowers appear in a terminal cluster of racemes or panicles, each of them 3 to 6 inches long, minutely downy, the flowers nodding. The corolla is pure white, pitcher-shaped,  $\frac{3}{8}$  inch long,  $\frac{1}{4}$  inch wide, with five small, slightly reflexed lobes at the contracted mouth. The sepals are normally five, but sometimes reduced to four or three by the union of one or two

violet flowers and abundance of silver green meal. We had reached 10,000 feet by this time, and the crimson *Primulas* were beginning to be replaced by species with blue and violet flowers.

This last is probably a new species. It grows on limestone outcrops in open spaces in the forest, being rather abundant in certain spots. It is not above 9 inches high, with as many as fifteen flowers in the umbel. The leaves are brilliantly silvered beneath, and there is a powdering of meal on calyx and pedicels; add to which the plants are fragrant. The colour varies, being often lilac.

A climb up to the jagged precipices above the forest next day brought to light yet another two species of *Primula*, one of them being also a *Nivalis*, a section which apparently flourishes in this region.

This *Nivalis* had larger flowers in smaller umbels, not above four or five flowers, of a violet or purple shade, with white eye. The leaves are bright silvery white beneath, and,

It is becoming more difficult each year to find distinctively new *Primulas*, even in prolific Yunnan. And yet there must be scores more hidden away, waiting to be discovered. Assuredly they will be disclosed in time, only the pace is slower, that is all. Meanwhile, geographical varieties, types, etc., and new species, which superficially are old species, continue to arrive. So far as appearance goes, it makes little difference whether we grow *Primula Beesiana* or *P. burmanica* in the garden; *P. helodoxa* or *P. chrysochlora* (only the latter is not in cultivation), *P. malacoides* or *P. Forbesii*, *P. secundiflora* or *P. vittata*. However, convincing reasons are given for their distinction.

Botanists have multiplied the *Primulas* and not increased the joy. But I say deliberately, "so far as appearance goes." The minute distinctions between two very closely allied species are merely what we see. We know nothing of what they stand for, and yet they probably connote some invisible difference. They may

be correlated, with differences of constitution, immunity, fertility, or other abstraction; the outward and visible sign of some internal change which we can only discover empirically. Thus, even in the interests of horticulture, quite apart from the scientific (or, I should say rather, academic) interest of geographical races, and so on, it behoves us to secure the best of each species, which is only to be achieved by repeated trial.

But about these seven *Primulas*. The first was in the way of *P. lichiangensis*, but on a smaller scale—a jolly little plant just coming into flower in the deep and dark bed of the stream. The second was *P. Littoniana*, or near to it. The third and fourth were the two *Candelabras* of the marshes, both crimson, and already referred to in these notes. One of them appears to be *P. Poissonii*; the other I have not seen before. The fifth was—well, I do not know what the fifth was, as I have never seen anything like it. We found a single plant smothered in small, crimson flowers, the habit being that of a *geraniifolia*. The sixth was the corpse of a *Capitata*; and the seventh was a lovely *Nivalis* form, with

as usual in the section, there is a coating of meal inside the calyx, which shines through between the teeth. The plant was not exactly common on the precipices, always occurring singly; but we found perhaps a score just in this district.

The weather was so bad this day, with dense mists and slashing rain, that we were rather afraid to venture far amongst these frightful precipices, or we might have found more. As for the other species just hereabouts, it was quite rare—I found but three plants. It was not apparently a *Nivalis*, being entirely without meal, save for a spot in the centre of the corolla, which gave it a white eye. The flowers, though small, are a fine rich purple, darker than the darkest purple met with in the preceding species; the tube, on the other hand, is crimson. Both species grew in sheltered nooks and crevices on the crags, and there were signs that they crossed with each other, though that is hardly likely, unless they were both *Nivalids*.

I thus found nine *Primulas* in two days, and am hopeful of finding more in the immediate future. *F. Kingdon Ward.*

pairs; ovate, green, glabrous,  $\frac{1}{2}$  inch long. The stamens are white, 1-10 inch long, thickened towards the base, downy at the base; anthers, brown; style, 1-5 inch long. I cannot find that either Hayata or Wilson have recorded the height of this shrub in a wild state, but it is probably from 5 to 8 feet high.

It is too soon yet to say anything definite as to its hardiness. Lord Headfort's stock of plants has, I believe, been grown and brought into flower in a cold frame, but small plants at Kew have passed through the last two winters in the open without injury. That, however, has not constituted a real test of hardiness. There is little doubt that the species will be hardy in the maritime counties of the south and west at least, and that it will make a lovely addition to the *Pierises* that are already cultivated there. Compared with *P. japonica*, which is now in flower, it has the merit of holding its racemes more erect, and thus shows the blossoms to better advantage. Of the older species it is probably allied most closely to *P. formosa* from the Himalaya, but that has much larger leaves of lanceolate shape, with smaller, sharper teeth. *W. J. Bean, Kew.*

FIG. 68.—PIERIS TAIWANENSIS. R.H.S. AWARD OF MERIT MARCH 14. SHOWN BY THE MARQUIS OF HEADFORT.

THE ROSE GARDEN.

SEASONABLE WORK.

WHERE protection has been afforded Tea and Hybrid Tea Roses during the winter, the material may be removed at the end of the present month. Pruning of the Hybrid Perpetual group may be commenced, but the trimming of the plants of other sections, such as Teas and H. T.s, should be deferred until a little later. In pruning, do not hesitate to cut the shoots well back, especially those of newly-planted Roses, which need severe pruning their first season; it is not too much to shorten them to within two or three eyes from the base. This treatment will go a long way towards ensuring the future success of the plants. Remember to prune to an outward eye, so that the growth is from the centre of the bush. With older plants, first thin out all weak and worn out growths, and thereafter prune back the shoots of the previous season to three or four eyes from the base. The great object in thus dealing with Roses is to promote healthy growth, encourage them to grow in a good shape, and secure new growths from the base to replace, in due course, the older ones. The foregoing remarks apply to Roses grown for general garden decoration, but where the object of the grower is to have exhibition blooms, even more severe cutting back is desirable, and shortening to two buds is not excessive. H. T.s do not require such hard pruning as the others.

Standards should be treated somewhat similarly, but care should be taken not to damage the shapeliness of the head. Dwarf Polyantha Roses may be cut hard back in the same way if small plants are desired, but should large specimens be desired, then only the old wood should be cut hard back, merely shortening the shoots of last season a little.

Whilst dealing with Roses, it is well to consider the many lovely species of Rosa that are available for garden decoration. There are several that are well worthy of inclusion in the shrubbery. Rosa nitida, for instance, always looks well with its bright red wood, the year round, and being of fairly short growth forms an ideal front row plant. Rosa Moyesii, with its beautiful dark red flowers,

that are followed by fine red fruits, is another species that should be planted. Being of sturdy habit, the plant requires looping to a stout stake to show it at its best. R. sericea pteracantha, a variety that bears remarkable translucent bright red spines, always stands out clearly in its beauty amongst other shrubs, nor must we overlook the claims of such as R. Willmottiae, with its beautiful purplish rose flowers. R. Helenae, with its wonderful trusses of extremely fragrant pale pink or white flowers that are followed by scarlet fruits; and R. Prattii, a species with deep rose-pink flowers and conspicuous red wood, that makes it so useful for giving colour in the garden in winter. Many more could be named, and there are also many that form fine subjects for the wilder parts of the garden, where they can be allowed perfect freedom of growth, rambling over masses of piled tree roots, or growing happily over other supports.

Where Violas are used for carpeting Rose beds, the plants may now be set out in the open in well favoured districts, though where weather conditions are likely to be adverse to tender vegetation, it will be as well to defer their planting until the season is more advanced. E. B.

ORCHID NOTES AND GLEANINGS.

ODONTOGLOSSUMS WITH BRANCHED SPIKES.

THE white form of Odm. ardentissimum, shown by Messrs. Charlesworth and Co., with a tall branched spike of about seventy flowers, at a recent R.H.S. meeting, is an example of the habit of most Odontoglossums and Odontiodas which, having produced a simple inflorescence in their earlier flowerings, on reaching maturity generally develop branched spikes of many rather smaller flowers, the lack in size being amply compensated for by the graceful, branched display. The branched spike is not a fixed character, as the plant may again return to the single spike with two rows of flowers, and indeed when such plants are divided and the portions potted as single specimens, they invariably do so unless there are branched species in their ancestry.

THE FLORISTS' TULIP.\*

(Continued from page 128.)

THE garden Tulip was therefore "a made flower" as early as the 14th century, and we have little chance of doing more than guessing at its origin. Once made known, its spread in Western gardens became rapid; by 1629 Parkinson enumerated about 140 varieties grown in English gardens, and a few years later began the famous Tulip mania in Holland. At the outset of the mania the high prices represented the genuine enthusiasm of the planters, but at its height they were the outcome of pure speculation—the bulbs had little more significance than railway scrip or rubber shares, or any other counters with which men gamble. It is reported that 3,000 florins were offered for two bulbs of Semper Augustus; finally, the bulbs were sold by weight, and there is an auction record of 510 florins per azen (rather less than a grain being paid in 1637. But long after the mania ceased florists were accustomed to pay good prices; about the 'thirties and 'forties of last century in London it was no uncommon thing to find a Tulip priced at £100, and a Mr. Davey, of Chelsea, refused £172 10s. for La Joie de Davey—a short-lived joy, for the variety never made an enduring reputation.

We now turn to garden Tulips as we know them. In the first place they may be divided pretty sharply into the early sorts, used for bedding and decoration, and flowering in the open about the middle of April; and the late sorts, which flower from the middle to the end of May. They have much in common, but the florists have always concerned themselves only with the late sorts. In order to understand the classification it is necessary to examine a flower or two. If we take a common pink Tulip we notice first that at the base of the flower round the stigma there is a more or less circular patch of a different colour, white or tinged with blue. Detach a petal, and with a little management we find that from both inside and outside we can strip off a thin skin, and that the pink colour resides in the skin, leaving a white tissue between. If we deal similarly with a scarlet or a bronze Tulip we can equally strip off the pink or purple skins and find between them a yellow foundation. Here, then, we have the first great division, yellow grounds and white grounds, overlaid with a skin which may be of any shade of pink, crimson or purple. Pink to purple Tulips have white grounds, the same skin colours on a yellow ground give rise to shades of scarlet, bronze and brown. Most Tulips are self-coloured, but those the florist chiefly esteems are marked or striped in ways to be considered later, either with shades of pink, crimson or purple on a white ground, or with brown on a yellow ground. How do these markings arise? This is a special peculiarity of the Tulip, which makes it unique among flowers.

When a seedling first blooms, some five to seven years after sowing the seed, it is self-coloured, and the offsets it throws are just like it, to whatever extent it may be multiplied. But sooner or later, it may be after two or three years, it may be after twenty, without any warning or apparent cause some of the flowers will be found to have become striped, as though the colouring matter in the skin had segregated into particular streaks or patches, leaving the white or yellow ground to show through in the other places. We call the self-coloured form a "breeder," and the marked form "broken" or "rectified." The offsets from a broken bulb are also broken and never revert to the breeder. All the bulbs of a particular variety do not break at the same time, so that we may have both breeder and broken forms growing together; some break more readily than others, and some soils seem to induce breaking, but the breaking habit is inherent in all garden Tulips, little as it is desired in some varieties. What is the cause we cannot even surmise, it only occurs with Tulips, and it is quite out of control.

(To be continued.)

\* A lecture delivered by Sir Daniel Hall at a recent meeting of the London School Gardening Association.

## WINTER-FLOWERING CARNATIONS.

EVERY Carnation grower has, at some time or another, been keenly disappointed in the behaviour of some of the varieties he has attempted to grow for the first time. Differences of soil, the house in which the plants are grown, or the methods of cultivation may have something to do with the failure. While certain varieties will flourish in a high and dry situation, some may resent being grown in one that is low and damp. Most gardeners are anxious to give all new varieties they fancy a trial, and with this I am in agreement; but should the new-comers not come up to expectations after giving them a fair trial, I would strongly recommend discarding them and trying another variety of that particular shade of colour. I do not propose to go fully into all details of cultivation, but I would specially point out to beginners and growers of a few plants only that, to be successful with the smallest collection, it is necessary to give up the whole of the house to their cultivation. No attempt should be made to grow other greenhouse plants under the same roof. Carnations need fresh air on all possible occasions, and, unless there is a strong wind, frost, or a dense fog prevailing, air should be admitted, both day and night, by the top ventilators.

In the early months of the year, do not maintain a high temperature by the use of fire heat, for this would result in weakened growth. A night temperature of 48° to 52° will suffice, and on very cold nights it will be wise to aim at the lower temperature rather than cause the atmosphere to become dry by excessive heating of the hot water pipes. It is not desirable to use much concentrated manure during mid-winter, but now that the days are lengthening a top dressing of rich material will be very beneficial to the plants.

My object in giving the following list of varieties is to help the small grower in selecting a list of reliable sorts to grow. As there are well over 200 varieties in cultivation, one becomes bewildered when making a selection for a small private garden, and, whilst giving my experience with the varieties mentioned below, I am fully aware that they may not be so consistently good in other localities as with me.

**WHITE.**—Crystal White is undoubtedly one of the best white Carnations of recent introduction. The flowers open most kindly, even in the dullest months of the year, and the calyx is good. The plant is of vigorous habit, and produces flowers with great freedom. This variety should not be stopped after the third week in June. White Pearl (see Fig. 69) is most probably the largest white perpetual Carnation in cultivation, and the flowers open most freely, but it is not so free as Crystal White. It is a vigorous grower, which should make it very popular with amateur growers. Cuttings of this variety should be struck early, and the last stopping should be done about the first week in June. White Wonder is one of the older varieties, and, in my opinion, it ranks with the best. The flowers attain a good size and open freely in winter.

**CRIMSON.**—In this colour there is not a great selection to choose from. Perhaps one of the most popular crimson varieties for private growers is Triumph. The habit of this plant is robust and healthy, and the flowers are developed on good stems. Cuttings of this variety should be obtained early, for I have found it difficult to strike them when the days are lengthening. The blooms last well when cut. Carola is a massive crimson of a beautiful shade, but it is not so free as Triumph. It should be included in all collections, for its beautiful flowers are produced early in the spring.

**RED AND SCARLET.**—Edward Allwood is undoubtedly a most promising variety in this section, and most probably will become very popular with growers. I prefer to give it a further trial before commenting on its habit of growth and flower production. General Joffre is a scarlet sport from Lady North-

cliffe, and has good qualities. It produces its flowers very freely, and the blooms remain in good condition for a considerable time when cut. To obtain good plants, the cuttings should be struck early in December. Lord Lambourne is another fine scarlet variety, and the plant is very vigorous in growth. The flowers open well, and the variety will most probably be grown in all private collections for its fine habit of growth and large flowers. The cuttings should be struck early, and the last stopping should be done about the first week in June. Tarzan is a new variety which is being distributed this year. It has been shown in fine condition at the R.H.S. meetings, and should be given a trial where a scarlet variety is sought after. Where Carola can be grown, Scarlet Carola should be included in large collections.

**PINK AND SALMON.**—Lady Northcliffe, of a light salmon shade, is one of the best varieties I grow. It produces its flowers freely in mid-

and have perfect stems and calyces. The colour is far more pleasing in the spring than in winter. This variety is one of the easiest to cultivate. Cupid is a salmon pink variety of merit. It is a strong grower, and the flowers last well when cut.

**YELLOW.**—Saffron is undoubtedly one of the best of the yellow shades, being a vigorous grower and one that opens its flowers well. Cuttings should be rooted early, and the plants pinched not too late in the season. Sunstar is a parent of Saffron. The colour is yellow, with a few pink markings, but in a small collection it is not necessary to grow both sorts. Saffron being the best flower. Those who prefer a yellow Carnation would do well to keep an eye on Maine Sunshine, a sulphur yellow coloured variety.

**FANCY VARIETIES.**—Wivelsfield Apricot is a very free bloomer in winter. The flowers are not so large as some of the fancies, but they are produced with freedom in mid-winter.

FIG. 69.—CARNATION WHITE PEARL.

winter, and the bloom has a perfect calyx. The flowers keep well when cut. The cuttings should be inserted in December, and the plants pinched twice during the growing season. Laddie is undoubtedly a very fine flower that opens well, and this sort should be included in all collections. The only fault of this variety is that, after the flowers are cut, it appears to be slow in making new growth. Mrs. Walter Hemus is a pale shade of salmon fringed with pink. It is not so free in winter, but for early spring flowering it is worthy of a place in private collections. The fine old pink Enchantress and its descendants are worthy of a place in most collections, being good, strong growers, and they produce a fair number of flowers in winter. Baroness de Brienen is not one of the freest bloomers in mid-winter, but it is deserving of a place in all collections for the fine flowers produced in early spring. The cuttings should be rooted early, and the plants stopped only once. Destiny is a beautiful flower of soft cerise colour. The blooms are produced very freely

which does much to recommend it. Freckles is another variety of the Lady Northcliffe type, and produces its flowers much in the same way. Jazz is a variety of very free habit that produces good yellow blooms flaked with reddish-bronze. Benora is white pencilled with carmine. The flowers are produced very freely. The cuttings should be rooted early, but the plants should not be stopped after the third week in June. When well grown, I consider that this variety is one of the best of the fancies.

**MAUVE AND HELIOTROPE.**—Mikado is with me still one of the best of its colour. It produces its flowers freely in winter, which is a great asset. Circe is a deeper heliotrope than Mikado, and, being speckled with pink, is an attractive flower, but I do not find it so free as Mikado in the winter months, although plenty of blooms are developed in early spring. Conquest is a deep heliotrope variety and a very free bloomer. The habit is good and the plant produces a fair number of flowers in mid-winter. T. Pateman.

## HOME CORRESPONDENCE.

[The Editors do not hold themselves responsible for the opinions expressed by correspondents.]

**Musa Cavendishii.**—Having been interested for many years in the cultivation of Bananas, it was with great pleasure I read the remarks of Mr. W. Hill on p. 106 in the issue of March 4th. During the 12 years I spent under the late Mr. H. J. Clayton at Grimston Park, Tadcaster, Yorks, we fruited many plants of *Musa Cavendishii*. Some years ago, when gardener at Farnley Hall, Otley, we fruited one there, which carried a bunch of 120 fruits weighing about 36 lb. Since that time I introduced the cultivation of Bananas at another place, and so successful was the venture that my employer instructed me to fill a house with them, which I did with 6 plants. I do not remember ever having a plant under my charge which failed to fruit. My experience is that in a high temperature Bananas may be fruited and ripened easily in 18 months to 2 years from the sucker. The 6 plants alluded to were, I believe, planted out. The aroma from the ripe fruits is an indication of their superior flavour. *J. Snell, Sunderland.*

—During my service at Colwood Gardens, Warminglid, near Haywards Heath, we fruited two plants of *Musa Cavendishii* in 1911. I enclose a photograph [not reproduced.—Eds.] of one of the bunches containing over 80 fruits. The bunch of the other plant contained a far greater number than 80, but the Bananas were not of such good form. I went to Colwood at the beginning of March, 1911, and the two suckers were in 8-inch pots. At the end of the following winter they were carrying these two bunches, the plants being then growing in tubs made from a paraffin barrel cut in halves. The soil used consisted chiefly of loam, decayed farmyard manure, leaf soil, and mortar rubble. The roots were stimulated with fresh cow manure and "Clays" fertiliser. Plenty of one-inch holes were bored in the tubs, and the soil from the bed thrown half-way up the tub. Very little air was admitted to the house. The temperature at night was about 60° to 65°, and the day temperature was allowed to rise as high as possible. The thermometer was hanging on the door frame facing north, so that only the shade temperature was recorded. These Bananas have been grown exceptionally well at Lydhurst, Warminglid, Haywards Heath. *H. Hills, Pawke Wood Gardens, Sevenoaks.*

**A New Kind of Fuel for Heating Greenhouses.**  
—I beg your permission to endorse the remarks of Mr. J. W. Forsyth (p. 106) *re* the new fuel supplied by the National Coal Exporters. A truck of nine tons is now in store here for garden and other heating apparatus. I find it all that the manufacturers claim for it, giving a very even heat. It was most difficult here to make up greenhouse fires so as to last over night, with the result that the temperature was low in the mornings. Now it is quite a different matter, as a bright fire exists in the morning, and with less than half the quantity of coal previously used. I am certain the saving will be quite 50 per cent. *David Jones, Hartsheath, Mold, N. W.*

**January and February Rainfall in South Wales.**—In your issue of March 11, page 116, *Market Grower* compares the rainfall of the first two months of this year with the corresponding period in 1921, namely, 6.76 inches, as against 3.14 inches. It may interest your readers to compare the rainfall in *Market Grower's* district to that in South Wales. In January we had 6.44 inches of rain and twenty-six rainy days, the largest fall being 0.86 inch on the 18th of that month. The total rainfall in February was 6.20 inches. There were nineteen rainy days and the heaviest fall was 0.88 inch on February 27; the total for the two months was 12.64 inches. Unfortunately, I have no record of the corresponding months of 1921. *J. Wiggins, Ty Clyd, Govilon, nr. Abergavenny, Monmouthshire.*

**Bryophyllum calycinum.**—My sister and I were in Jamaica in March 1920, and in the course of our wanderings picked a flower and leaf of *Bryophyllum calycinum*—"The Leaf of Life." This plant grows wild very freely in the island. My sister pressed the leaf between sheets of blotting paper, under a heavy weight, and brought it to England. The leaf was left untouched for five weeks, and on being examined, the entire outline of the leaf was found to be encrusted with the minutest white roots—as if edged with lace. The leaf was kept in the blotting paper for another two weeks, after which it was laid upon earth in a greenhouse, and lightly sprinkled with soil. In due course, the original leaf produced a little forest of small plants, which, up to last autumn, gave no promise of flowering. As will be seen, however, by

FIG. 70.—BRYOPHYLLUM CALYCIUM.

the enclosed photograph (Fig. 70), one plant has now produced flowering stems more than five feet in height, bearing flowers which are of a delicate green shade—though, in its native country, the flower is of a very pale buff colour. Such is the fecundity of this plant that any leaf which falls to the ground attempts to reproduce its kind. *H. Arden, Ardenne Hall, Tarporley, Cheshire.*

**Voies.**—It may interest you to know that many of the readers of your paper have written to me to inquire where the Colin Pullinger Balance Mouse Trap may be obtained, and it occurs to me that as probably many more are making inquiries about it, you might like to mention in your next issue that the trap is manufactured wholesale by Messrs. Duke, Waring, Crisp and Co., 139, Wardour Street, London, W.1., and may be procured retail through any ironmonger. *T. Mark Howell.*

## SOCIETIES.

## MANCHESTER AND NORTH OF ENGLAND ORCHID.

MARCH 2.—*Committee present:* The Rev. J. Crombleholme (in the chair), Messrs. H. Astworth, B. J. Beckton, J. Birchenall, A. Burns, A. Coningsby, D. A. Cowan, J. C. Cowan, J. Cypher, J. Evans, J. Howes, A. Keeling, D. McLeod, E. W. Thompson, J. Thrower, H. Arthur, sen.

## AWARDS.

## FIRST-CLASS CERTIFICATES.

*Cattleya Douai var. Our Princess.* A pure white flower of grand shape. *Brasso-Cattleya Queen of England* (C. Germania × B. C. Mdm. Ch. Maron). A large flower with light rose sepals and petals; lip deep magenta, coloured with a yellow throat; from Mrs. GRATRIX.

*Sophro-Laelio-Cattleya Samuel Gratrix.* The sepals and petals are deep purple-crimson, the lip an intense purple. *Cattleya Linda var. Radiance.* A variety with broad sepals and petals; the lip is deep purple, throat yellow; from S. GRATRIX, Esq.

*Cypripedium Idina Beckton's var.* (see Fig. 63). A large flower of the Harefield Hall type, of grand shape and colour; from B. J. BECKTON, Esq.

*Cattleya Tityus var. Evansiae.* Sepals and petals mauve; lip large and coloured dark purple; side lobes yellow. *Odontioda Madeline var. Evansiae.* A large flower of grand shape and brilliant colouring; from Mr. J. EVANS.

*Brasso-Cattleya Penelope var. rubra.* Sepals and petals dark mauve; lip rich magenta with yellow side lobes; from MESSRS. MANSELL AND HATCHER, LTD.

## AWARDS OF MERIT.

*Lycaste Skinneri vars. Symmetry, Apple Blossom and Purple Emperor,* all from Mrs. BRUCE and Miss WRIGLEY.

*Sophro-Cattleya Saxa West Point var. Lycaste Skinneri Lady Patricia Ramsay and Dendrobium nobile rotundum;* from S. GRATRIX, Esq.

*Cymbidium Dryad var. Silvarum, C. Castor var. Primo;* both from the Rev. J. CROMBLEHOLME.

*Cattleya Trianae var. Dreadnought and Odontoglossum aspersum Hartley's var.;* both from Dr. HARTLEY.

*Cypripedium Victor Hugo var. Little Gem;* from B. J. BECKTON, Esq.

*Cymbidium Nirvana;* from Capt. W. HERRIDGE.

*Odontioda Wilsonii var. Sunbeam;* from P. SMITH, Esq.

## GROUPS.

S. GRATRIX, Manchester (gr. Mr. J. Howes), staged a group for which a Gold Medal was awarded. Mrs. BRUCE and Miss WRIGLEY, Bury (gr. Mr. A. Burns), were awarded a large Silver Medal for a group of *Lycastes* of the *Skinnerii* section. The Rev. J. CROMBLEHOLME, Clayton-le-Moors (gr. Mr. E. Marshall), was awarded a Silver Medal for a group of *Cymbidiums*.

Messrs. HASSALL AND Co., Southgate, were awarded a Gold Medal for a group of *Cattleyas* in variety. Messrs. CYPHER AND SONS, Cheltenham, staged a group for which a Silver Medal was awarded.

## ROYAL CALEDONIAN HORTICULTURAL.

MARCH 7.—The ordinary monthly meeting of this Society was held at 5, St. Andrew Square, Edinburgh; Mr. David King, presiding.

A paper on "Table Decorations" was read by Mr. W. M. Macdonald, St. Leonard's School Gardens, St. Andrews, who said that to carry out decorations pleasingly, ability to conceive an effective plan, an artistic temperament, and deftness in arranging the flowers were essential. He also dealt with the effect of artificial light on the colours of the flowers.

A decorated table was exhibited by Messrs. TODD AND Co., Edinburgh, which was awarded a gold medal. The other exhibits were: Tulips, from the President (Mr. King), who was awarded a Cultural Certificate; and Narcissi, from Mr. D. Arnott, Corstorphine.

## BRITISH CARNATION.

MARCH 21.—The twenty-seventh annual show of this society, which was formerly known as the Perpetual-Flowering Carnation Society, held at the R.H.S. Hall, Westminster, on Tuesday last, was a particularly good one from nearly every point of view. The quality of the blooms at this early season was high and the extensive trade exhibits were especially meritorious. While good quality was sustained in all the competitive classes, the competition was not so large as could be wished, though the new "florists'" class for an exhibit illustrating the various decorative uses for which the Carnation is adapted resulted in an excellent competition and demonstrated the many interesting styles of arrangement possible with this flower. These and the large non-competitive exhibits were a great feature of the show, which was opened by Lady Mond, D.B.E., the President of the Society.

## AWARDS OF MERIT.

*Torcedor*.—A very showy Fancy Carnation of good size and form, and, apparently, great freedom in flowering. The blush ground colour is freely striped with scarlet. Shown by Messrs. ALLWOOD BROS.

*Atlantic*.—This is a perpetual-Malmaison of great promise. The exhibitors informed us that in their nursery this American variety flowers freely and "finishes well"—a statement which was borne out by the plants which accompanied the vase of blooms. The large, fragrant flowers are borne erect on stout stalks and the white petals have just a suggestion of the old Malmaison colour. Shown by Messrs. ALLWOOD BROS.

*Wivelsfield White*.—Visitors to the London shows have often had the opportunity of admiring this valuable white perpetual variety. It makes a shapely bloom which travels well. During warm weather it has quite a pleasant fragrance, though none was apparent on Tuesday. Shown by Messrs. ALLWOOD BROS.

*Nigger*.—The reason for the name is not readily apparent, for there are several Carnations of distinctly darker hue which would not warrant the suggestion. It is, however, a splendid, deep velvety crimson perpetual-flowering variety. The blooms are held well up on long stalks. Shown by Mr. C. ENGELMANN.

## OTHER NOVELTIES.

MESSRS. ALLWOOD BROS.'s Vivid was the most dazzling bloom in the whole show. The general colour may be described as rose cerise. Its peculiar, crimped appearance, suggesting that the blooms have been artificially opened, may not appeal to everyone, but its glowing colour is very striking. Oceanic is a medium-sized perpetual Malmaison and, like the former, was shown by Messrs. ALLWOOD BROS. In form it more nearly approximates the perpetual type, but has the broad leaves and sturdy habit of the Malmaison. The colour is a clear shrimp pink and the centres of the blooms are fuller than is usual with this type.

## OPEN CLASSES.

As at the previous show of this Society Mr. C. ENGELMANN, Saffron Walden, was the principal prize-winner. He won the first prizes in 14 of the first fifteen classes. The exception was the class for a vase of not fewer than 100 Carnations, and here Messrs. A. F. DUTTON, LTD., Iver, Bucks, were decidedly first with beautifully coloured blooms of Lady Northcliffe. Mr. ENGELMANN was second with a well-arranged vase of paler pink blooms.

In the other classes Mr. ENGELMANN's blooms were of outstanding quality. In class 1, which required 7 varieties, 25 blooms of each, he showed Topsy, Jona, Tarzan, Cupid, Circe, White Wonder and Laddie. White Edward Allwood, Messrs. ALLWOOD's second prize exhibit, was also a good one.

The best of the British novelties in class 2 was Thor, shown by Mr. C. ENGELMANN, while Wivelsfield Claret by Messrs. ALLWOOD BROS. was the best of the second prize set. Amongst the American novelties Topsy in the first prize exhibit was pre-eminent.

In the colour classes Mr. ENGELMANN's first prize varieties were Peerless, light rose; Laddie, salmon pink, a magnificent vase which also received the Silver-Gilt Medal as being the best

in classes 9 to 22 inclusive; Aviator, red; Carola, crimson; Saffron, yellow; Jazz, fancy; and White Wonder. He also had an admirable vase of 25 blooms of Topsy in class 7.

There were two excellently packed boxes of 36 blooms as sent to market, and Mr. ENGELMANN was placed first and Messrs. ALLWOOD BROS. second.

## AMATEURS' CLASSES.

The only group of Carnation plants was by Sir CHAS. NALL-CAIN, the Node, Welwyn (gr. Mr. T. Pateman), and it deservedly received the first prize, Lord Howard de Walden's Challenge Vase. It was composed of particularly well-grown, well-flowered plants in a pleasant variety. The principal varieties were Lady Northcliffe, Laddie, Mikado and Rose Sensation.

There were only two decorative arrangements of cut Carnations, and the first prize was won by Lt.-Col. Sir R. BAKER, Ranston, Blandford (gr. Mr. A. E. Usher), with a plentiful display of excellent blooms, while Mr. W. HOLDER, Upper Gatton Park Gardens, Reigate, was second with a light and elegant display of rather smaller blooms.

The Cory Cup, which is offered for 6 plants in bloom, was won by Sir CHAS. NALL-CAIN, who showed well-grown examples of Lady Ingestre, Mrs. W. Hemus and Lady Alington. Sir C. NALL-CAIN, was also first with three good plants of Wivelsfield Apricot, Lady Alington and Chastity. In each instance Mr. W. HOLDER was second with well-grown plants.

In the remaining classes chief honours were won by Sir CHAS. BAKER, who, in various classes, had especially good blooms of White Wonder, Rose Enchantress, Laddie and Aviator.

LADY MOND won first prize with beautiful vases of Carola and Circe, and Mr. E. W. BISHOP, Windsor, was first with a vase of British-raised novelties.

There were three exhibits in the decorated dinner-table class, and the first prize was won by Mrs. A. ROBINSON, Bourne End, with a table of Wivelsfield Apricot Carnations and Croton leaves and other foliage. The first prize in the class for a drawing-room vase was not awarded, but the second prize was awarded to Mrs. ROBINSON.

## FLORISTS' CLASSES.

In the florists' classes the Covent Garden Challenge Trophy with a cash prize of £30 induced keen competition. Mr. R. F. FELTON, Hanover Square, London, was first with magnificent vases of Carnations and elegant Palms. The arrangement of the Carnation blooms was admirable, the small basket of Croton turnfordiensis and Saffron Carnations being particularly praiseworthy, but the Lady's Hat and Model Ship made up of innumerable Carnation petals were decidedly *outré*. The second prize was won by Mr. N. B. SHEARN, who included an admirable decorative screen and a wall bracket of Carnation blooms. In the third prize exhibit by Mr. R. SILVESTER, Sloane Square, London, there was a very charming basket of mixed Carnations and Croton foliage.

In the remaining florists' classes all the first prizes were awarded to Mrs. HAMMOND, Chelsea, for admirable exhibits.

## NON-COMPETITIVE EXHIBITS.

Mr. C. ENGELMANN set up a great number of excellent blooms in large groups on either side of the entrance. The principal varieties were Cupid, Lady Northcliffe, Delice, Aviator, Mrs. Walter Hemus and Tarzan. These and many more arranged in artistic vases and *jardinières* made a memorable display (Large Gold Medal).

Nearly the whole of the wall space at the end of the hall was occupied by Messrs. ALLWOOD BROS. with an admirable and tastefully arranged collection. The central feature was of the yellow perpetual-Malmaison Jessie Allwood, nearly surrounded by Edward Allwood. Mrs. C. F. Raphael, Wivelsfield Claret and Marion Willson were also shown in quantity (Large Gold Medal).

Amongst the many varieties shown by Messrs. STUART LOW AND CO., Brilliant, Red Ensign, Eileen Low and the new cerise scarlet Reginald Cory were prominent (Silver-Gilt Medal).

On a table space Messrs. KEITH LUXFORD AND CO. had a number of vases of excellent varieties,

including Aviator, Mrs. C. W. Ward, Enchantress Supreme and Carola (Silver Medal).

Miscellaneous exhibits included St. Brigid Anemones by Messrs. REAMSBOTTOM AND CO.; Roses by Mr. E. J. HICKS; Alpines by Mr. F. C. WOOD; and boxes of admirable fruit by Mr. N. B. SHEARN.

## UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

THE annual general meeting of this useful Society, held at the Royal Horticultural Hall, Westminster, on Monday, March 13, was more largely attended than any similar meeting since 1912. Mr. Charles H. Curtis presided.

The annual report for 1921, as presented, showed that many young gardeners who served in His Majesty's forces during the war had failed to take advantage of the special conditions provided, whereby they could retain their membership on easy terms. This was unfortunate, as the conditional time limit was reached in 1921, and as a consequence about eighty of these members had lapsed. A fair number of new members had been elected; some deaths were recorded. Financially, the Society is in a very happy position, as its members have an excellent health record. The trustees invested £2,000 during the year, bringing the total investments to well over £61,000. An interesting paragraph in the report had reference to the long periods of service rendered by various officers and members of Committee, and special mention was made of the fact that Mr. C. H. Curtis had been Chairman of Committee continuously for twenty-one years.

The report and accounts, after a few remarks by the Chairman, were adopted. Mr. T. Winter unfortunately absent through illness, was re-elected Treasurer. Messrs. J. Hudson, Riley Scott and C. H. Curtis, the trustees, were thanked for their services, and thanks were also accorded to Mr. George Monro, for presiding at the annual dinner, to the Horticultural Press, and to the honorary members. The retiring members of Committee were all re-elected, and Mr. Brown, Burford Lodge Gardens, Dorking, was elected to fill a vacancy. Following a brief report and statement concerning the working of the State Section, the meeting agreed to the recommendation of the Committee, that for the year 1922 the Secretary's salary be paid in equal proportions from the State and Private sections of the Society's activities.

Some discussion as to ways and means of advertising the advantages of membership took place after the formal business, and it transpired that the advertisement in the *Gard. Chron.* had hitherto proved the most effective means of bringing the Society into touch with gardeners likely to become members.

Mr. C. H. Curtis and Mr. A. Bedford were re-elected Chairman and Vice-Chairman of Committee respectively.

## Obituary.

W. A. Crowder.—A well-known horticulturist has been lost to the Horncastle district by the death of Mr. W. Ashley Crowder, of Messrs. W. Crowder and Son, seedsman and nurserymen, Thimbleby Nurseries, Horncastle. His death, which was totally unexpected, took place suddenly at his residence. Mr. Crowder was a quiet and unassuming man with a wide circle of friends, who loved and respected him. He held several offices in connection with the public life of Horncastle and Thimbleby, and also with St. Margaret's Church, Thimbleby. Mr. Crowder is survived by his wife, one son, and one daughter, another son having given his life in the war.

Harry A. Barnard.—On March 14, Harry A. Barnard, a man as beloved in horticulture as in his private life, passed to a well-earned rest. His death removes one more link with the past, for he commenced his career with the Lows, of Clapton, over 60 years ago, and remained with his firm, at Bash Hill Park, until the last. Few men were better known in horticultural circles either in Great Britain, the United States, or

Canada, and readers of *The Gardeners' Chronicle*, spread all the world over, who spent some of their early days at the Clapton Nurseries, will recall the ready wit, or kindly help of Harry Barnard, and a host of other old comrades, among whom were the brothers Casey (William, Frank and James) and John Newberry, will mourn the loss of their old colleague Horticulture is all the poorer for his passing, for his knowledge of plants was most catholic. He was a man who always did the right thing in his own vigorous way, and for this reason alone his memory will remain green for many years to come. The interment took place at Abney Park Cemetery on the 18th, the grave being next to that of the late Hugh and Stuart Low. Among these present were Mr. Stuart H. Low (grandson of his first chief), Mr. Hugh Low, and three old comrades, Messrs. Fred Jenkins, E. Groves and W. Isobell, whose service with their firm aggregate some 130 years. It is only a few weeks ago that another old employee, Mr. Ted Heath, passed away after having been with the firm for nearly half a century.

**Hugh Williamson.**—The American horticultural papers record the death of Mr. Hugh Williamson, for 35 years gardener on the W. W. Aster estate. Mr. Williamson was a native of Ayrshire, and settled in U.S.A. in 1886. According to the *Florists' Exchange*, "he enjoyed the friendship of every florist and his knowledge was at the disposal of everyone."

**Charles Willingham.**—We much regret to learn of the death of Mr. Charles Willingham, on March 17, at the Pineapple Nurseries, Maida Vale. The announcement of his death in the *Times* for March 18, states that he was "For 40 years devoted gardener and valued friend of Sir Lawrence Alma Tadema, O.M., R.A., and family."

## TRADE NOTES.

MANY gardeners and other horticulturists will be pleased to hear that Mr. F. J. Duck, who represents Messrs. Dicksons, Ltd., Chester, has just completed 50 years service with the firm. On the 27th ult. Mr. Duck had represented the firm for 42 years.

FOLLOWING its recent announcement, the Chamber of Horticulture states that Cabbage plants have now been placed in the new Class 15, as against Class 18, proposed by the railway companies. This minor point was not decided on at the hearing before the Rates Advisory Committee on February 23 last, as Mr. Pike (representing the railway companies) asked for an opportunity to look the matter up. This completes the Chamber's case for reclassification of goods by merchandise trains. The Council's decision to postpone the publication of a Bulletin was received with great regret by the Technical Committee of the Chamber, and the following resolution was passed: "That this Committee regrets to learn of the decision to postpone the publication of the Chamber's Bulletin, and is of the opinion that having regard to the important material available, and in pursuance of the resolution of the joint Conference of Insecticides and Technical Committees, the publication of a Bulletin is not only essential, but urgently necessary."

We learn that Queen's Club, Kensington, have decided that all their hard tennis courts are to be En-Tout-Cas; five new courts have been ordered, and older ones are to be converted into the En-Tout-Cas type.

MESSRS. RANSOMES, SIMS AND JEFFERIES have constructed a type of light motor lawn mowers, of 18 in. and 20 in. size respectively, suitable for use in moderate-sized gardens. These machines have been introduced to take the place of a two-men outfit as used on small sports grounds and in private gardens. The cutting knives are driven by a petrol motor and the machines are suitable for dealing with the work on grounds not exceeding from one to

three acres in extent. The general construction is simple, and the controls for machine and motor are easily operated from the handles.

AN interesting exhibit at the Ideal Home Exhibition is a two-roomed bungalow erected by Messrs. T. Bath and Co., Savoy Street, Strand. It is substantially built, delightfully furnished, and with its climbing plants, window boxes and borders of flowers, presents a very cosy appearance.

IN our account of the gardens at the Ideal Home Exhibition, we stated that Messrs. Whitelegg and Page had planted the garden designed by the Queen of Spain. We should, of course, have stated that it was Messrs. G. G. Whitelegg and Co. who carried out the work so pleasingly.

A SECOND Conference on the Marking of Foreign Produce was held by the Chamber of Horticulture on Friday, 17th instant, Mr. Geo. Monro presiding.

The Secretary reported that the National Farmers' Union had given their entire support to the case, and that the same had been submitted to the President of the Board of Trade. Tuesday, March 21, was fixed for the deputation to be received by Sir Sydney Chapman, K.C.B., C.B.E., Permanent Secretary, and the following gentlemen were appointed:

Mr. Geo. Monro, to introduce the deputation; Mr. G. W. Leak, to be the chief speaker, supported by Messrs. A. C. Daniels, A. C. Leoney, W. P. Seabrook (Federation of British Growers), W. Talbot Edmunds (National Farmers' Union), H. C. Larsen, J. Rochford (Lea Valley Growers), C. J. Miller, F. W. Ladds (N.W. Kent Growers), and C. M. Matthews, Secretary.

A meeting of the Council of the Chamber was held on Wednesday, March 15, Mr. Geo. Monro presiding.

The Secretary's report dealing with the decisions of the Rates Advisory Committee and meetings of the Technical and Parliamentary Committees was submitted and adopted.

The following gentlemen were duly elected as representatives to the International Conference, to be held at the Hague, on April 20 next: Messrs. J. S. Brunton, W. E. Wallace, E. A. Merryweather and Geo. Monro (for the Chamber), Messrs. E. A. Bunyard, C. E. Pearson, G. W. Leak, and C. G. L. Du Cann (for the Horticultural Trades' Association), and Messrs. A. W. White and C. H. Curtis (for the British Florists' Federation).

The Annual General Meeting has been fixed for Wednesday, May 3 next. A resolution from the Spalding and District Bulb Growers' and Market Gardeners' Association deciding to become affiliated to the Chamber was submitted and agreed to. Mr. J. B. Slade gave a most interesting and helpful address on the subject of Assessments, and he has promised to further assist the Council on these matters when desired.

A letter from the Horticultural Trades' Association referring to the threatened extension of the American Quarantine Regulation 37, and asking the co-operation of the Chamber with a view to taking immediate measures to prevent such action, was submitted and agreed.

WITH a view to getting cheaper postal rates, a large and representative deputation from all the chief commercial associations of Gt. Britain was received by Sir Robert Herne, Chancellor of the Exchequer, at the Treasury, on Friday last. Mr. G. B. Barr attended for the Chamber and its affiliated associations, and the reply of the Chancellor is considered to be fairly satisfactory.

## INQUIRY.

A CORRESPONDENT, resident at Helsingfors, Finland, asks: "Is there anyone who grows *Nomocharis pardanithina* successfully? If so, will he kindly state the cultural conditions adopted. I have some small bulbs planted in leaf soil, in pots, but they do not grow strongly."

## ANSWERS TO CORRESPONDENTS.

**BLIND FLOWERS FROM DAFFODIL BULBS:** *C. E. S.* It is a difficult matter to decide why the bulbs have thrown the blind flowers. Excessive temperature with lack of water during the plants' growth will cause the flower buds to behave similarly to the specimens received. Daffodils enjoy an abundance of water during growth, and should be grown in a temperature of 60°, increasing the warmth to 65-70° when the buds are about to burst. Again, inefficient root action may be the reason, and bad root action may be due to bringing the bulbs into the house before they are sufficiently well rooted. The presence of diseases such as eelworm or corky base may also react on root action, and thereby cause failure in the development of the flowers.

**FAILURE WITH ORCHIDS:** *W. H. B.* The cause of failure with your Orchids cannot be attributed to a low temperature, for 50° during the winter months is sufficient warmth for *Cypripedium insigne*, *Coelogyne cristata*, and *Dendrobium nobile*, which would be in a dormant condition. The *Cypripediums* should be repotted at once in a mixture of good fibrous loam, peat, and Sphagnum-moss. After being disturbed, afford the roots water in moderation, and keep the plants shaded from strong sunlight. Light spraying overhead will be beneficial in bright weather. *C. cristata* should also be repotted when the new growths begin to root. At the same time reduce the number of back pseudo-bulbs to three behind each lead or growing point. A suitable rooting-medium consists of three parts *Osmunda* fibre or peat and one part Sphagnum-moss. Once *C. cristata* gets into a bad state of health, it will take quite two years for the plant to recuperate. This Orchid could be grown with the *Cypripediums*, and a minimum temperature of 50° should be maintained in the house. With sun heat this degree of temperature may be exceeded with beneficial results. Due attention must be paid to ventilating and shading, while the surroundings should be kept moist throughout the growing period. When the new pseudo-bulbs are fully matured, only enough water should be given to keep them in a plump and rigid condition. *Dendrobium nobile* will need repotting in a similar manner to *C. cristata*, and, if you possess a stove-house, the plants should be suspended from the roof-rafters of that house during the growing season. If such a warm house is not available, place the plant in a light position at the warmer end of your greenhouse. A Cucumber or Melon pit is also suitable while the plants are in active growth, but when they have completed the season's growth a cooler and drier structure is necessary. If the *Cattleyas* are not too unhealthy, repot them when root action is evident, and place them in a warm, moist house. Most of your Orchids will probably need smaller pots, which should be filled half their depth with drainage material. The Orchids you enumerate should not be grown in a dry atmosphere, nor exposed to strong sunlight, although they should not be densely shaded.

**FOREST TREES AND TREE SEEDS:** *B. P. G.* Write to Messrs. Little and Ballantyne, Nurserymen, Carlisle.

**NAMES OF FRUIT:** *G. W. S.* Fearn's Pippin.—*J. C. C.* Franklin's Golden Pippin.—*R. W. T.* Galloway Pippin.

**NAMES OF PLANTS:** *Old Subscriber.* *Ornithogalum lacteum*.—*A. F.* *Crinum* sp.; it is impossible to determine the species from a bulb only.—*G. H. F.* 1, *Azara microphylla*; 2, *Acacia dealbata*; 3, *Pieris japonica*; 4, missing; 5, *Colletia cruciata*.—*A. G. L.* 1, *Cypripedium Hera-Beeckmanni*; 2, *C. Leoniae*; 3, *C. calophyllum*.—*J. E.* *Iris japonica* (syn. *I. chinensis*).

**Communications Received.**—*D. A. C.*—*R. & Co.*—*C. E. H.*—*R. H. C.*—*F. P.*—*A. W. E.*—*J. C.*—*G. M.*—*H. C.*—*J. C.*—*A. M.*

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 44.1.

### ACTUAL TEMPERATURE.—

Gardeners' Chronicle Office, 5, Tavistock Street, Covent Garden, London, Wednesday, March 29, 10 a.m. Bar. 30.1; temp. 44°.—Weather—Cold and bright.

A sight which recently caused astonishment to several interested amateurs of gardening is not without general interest and significance. A group of Rhododendrons which had been hurriedly planted in a nursery last spring had made excellent growth and were rich with flower buds. When lifted last autumn, however, the balls of black earth around their roots in which they had originally reached the garden were seen to be intact and not a root had penetrated into the soil beyond. The phenomenon served for a simple homily on the advantages of root restriction in the cultivation of various kinds of flowers and fruit, and it was surprising to find that those amateurs of keenness and experience who listened to it were not aware how much floriferousness and fruitfulness may depend on limiting the run of roots. Everyone who gardens is, of course, aware of the fact that such plants as Figs require to be severely restricted as to the range of their roots. Pot-culture of Figs as practised with such success at Wisley and elsewhere, illustrates clearly the fact that large masses of soil are not only unnecessary, but often harmful to fruit development. Similarly anyone who has planted rock plants on "dry" walls

must have noticed that the plants which are wedged tightly in with a limited amount of soil—connected it need not be said with a fair depth of soil—will become established quicker and flourish better than those which are inserted in large pockets and provided with ample masses of rich earth. A little physiological knowledge is not a dangerous thing, and a realisation that both the roots of a plant and the soil itself need air will often help the young gardener to improve his practice. So, also, will a knowledge that the amount of mineral substances which a plant requires for its development is extraordinarily small. One of the oldest experiments in plant physiology illustrates this fact in a striking manner. Nearly 300 years ago, Van Helmont planted a Willow in a pot of dried and weighed soil; watered it regularly with rain water, and found that although the Willow had increased by nearly 200 lb. in weight in five years, the weight of soil in the pot at the end of the experiment was only about two ounces less than at the beginning. It is true that this old experimenter drew a wrong conclusion from his results. He inferred that water was the "active principle" out of which plants make all their materials. The right conclusion to be drawn is, of course, that the two ounces of lost soil represented the essential—albeit actually small amounts of mineral food, which plants must have if they are to live at all. Many garden practices are based on the recognition of these facts. A Vine border which may be increased at intervals is better than a larger one made up once for all. Top dressing of relatively small heaps of compost is better than planting in large heaps. The common saying that a gardener is either good at flowers or vegetables but not both is, of course, untrue, and thousands of gardens testify to its erroneousness, yet there is this basis for the charge, that root and stem vegetation at all events yield their maximum when root run is unrestricted, that is when the soil is rich and worked deeply, whereas flowers in general do best in soils which, though well worked and well drained, are not too liberally supplied with organic matter. Sparing applications of farmyard manure—to which a light dusting of basic slag is added, will make a brighter border than will heavy applications of dung. Often it is advisable both to feed and starve as it were. Thus to renovate a lawn nothing is better than heavy winter dressings of farmyard manure raked occasionally and renewed as they disappear. Yet when the lawn is established, provided there be some bottom soil, dressings of lawn sand—sharp and not too fine—will improve and fine down the turf. Of course there are flowering plants which have special predilections for heavy soils; Roses and Pyrethrums for example, but for one of this class there are dozens of the other which flourish and flower best in light, well drained and therefore readily warmed soils.

**Retirement of Sir Isaac Bayley-Balfour.**—Sir Isaac Bayley-Balfour relinquished his duties as Regius Keeper of the Royal Botanic Gardens, Edinburgh, at the end of March. Sir Isaac had held the post, which his father, the late John Hutton Balfour, filled for many years, since 1838. He also relinquishes the position of the King's Botanist for Scotland, and the Chair of Botany in the University of Edinburgh, which appointments he has held for the past thirty-four years. His successor has not yet been announced. We take this opportunity of congratulating Sir Isaac Bayley-Balfour on the recent honour of Doctor of Laws conferred on him by the Senatus Academicus of the University of Edinburgh.

**Summer Time.**—In view of the misconception which exists among certain classes of agriculturists as to the effect of Summer Time, the Ministry of Agriculture desires to point out that neither the Order in Council, which provides for Summer Time this year from March 26 to October 7, nor the Summer-Time Bill which has been introduced by the Government, imposes any obligation on farmers or their labourers to revise their customary hours of work according to the sun. There is nothing in the Order in Council or in the Bill which would prevent farmers or their labourers from making any arrangements they like as to the hours of work, which can, therefore, be fixed by agreement so as to provide for whatever working day may be most convenient for the special conditions of agriculture.

**Proposed New Park for Edinburgh.**—The Parks Sub-Committee of Edinburgh Town Council have had under consideration the suggested purchase of Pirig House and grounds as a public park for the Leith district, and have resolved to recommend that the Council should purchase the same. The total extent of the ground is about twenty acres, and it is proposed that the present proprietor should remain in the house (with a portion of the ground) as a life-renter. The proposed new park is in a very suitable position and would serve a considerable population.

**Grey Squirrels in Kensington Gardens.**—The grey squirrels introduced to Kensington Gardens have increased so rapidly that the Office of Works has decided to reduce their numbers. The principal reason for this decision is that the squirrels are very destructive to bird life; grey squirrels have been systematically shot, by order, in Richmond Park ever since the first official bird sanctuary was established there in 1915. There is ample evidence that the grey squirrel sucks the eggs of any bird, and it has even been known to destroy duck's eggs in Regent's Park. This type of squirrel was introduced from America, and in many parts of the country has practically exterminated our pretty, indigenous, brown or red squirrel, which is far less destructive. Sir Lionel Earle, Permanent Secretary of the Office of Works, states that so well are the bird sanctuaries in Kensington Gardens and Hyde Park developing that there is reason to hope that the nightingale might be heard at Kensington during the coming summer, and the great crested grebe be seen on the Serpentine.

**Bee Diseases.**—At a meeting of the Association of Economic Biologists on February 24, Mr. J. Rennie gave a paper on "The Present Position of Bee-disease Research." Recent research has shown that there are at least three bee diseases of importance prevalent in this country which have hitherto been confounded with Isle of Wight disease. Besides Nosema apis, there are acarine and bee paralysis. It appears that Nosema is less common than acarine disease, but it is maintained to some extent by the importation of foreign bees. The mite causing acarine breeds in the thoracic tracheae and feeds on the blood of the bee. Bee paralysis is an intoxication due to phenolic acid developed in the combs and pollen by the growth of various moulds.

**Hybrids of Primula Juliae and P. acaulis.**—At a recent meeting of the Société Botanique de France, M. Jacques de Vilmorin showed some hybrids of Primula Juliae of which the particular interest lay in the fact that the seed parent was a form of P. acaulis with a "calycanthemum" or "hose-in-hose" flower. All the plants of the first generation, nineteen in all, had the "calycanthemum" feature more or less accentuated, which fact confirms, as regards the dominance of this characteristic, the results of the experiments formerly made by Correns with Campanula and Mimulus. It was interesting to study the heredity of this feature in a cross with so distinct a form as P. Juliae. All the plants raised showed the colouring of P. Juliae, with some slight differences in intensity. The flowers were about the same size as those of the P. acaulis, used as a seed parent, and the

foliage was intermediate in form between that of the two parents. That result had already been observed in various crosses made in England, and described from time to time in *The Gardeners' Chronicle*.

**Leeds Chrysanthemum Show.**—The Leeds Paxton Society has decided to hold an exhibition of Chrysanthemums in the Leeds Town Hall on November 17 and 18, and to devote the proceeds to the funds of the Leeds General Infirmary. Irrespective of a challenge cup and shield, the prizes offered will amount to £130. Numerous interesting classes have been provided, one of which is open to nurserymen, seedsmen, and florists, who will be allowed to fill a ground space of sixty square feet with plants and flowers arranged at their own discretion. The awards offered are a gold, silver and bronze medal for first, second and third prizes respectively. Mr. A. Colborn, 4, Laurel Grove, Armley, Leeds, will be glad to forward schedules on application.

**The Genetics of Vegetables.**—The Royal Academy of Belgium offers a triennial prize of 2,500 francs, to be known as the Prix Joseph Schepkens, for the best experimental work on the genetics of vegetables.

**Honour for Professor J. B. Farmer and Mr. John Garton.**—We learn with very great pleasure that the Senatus Academicus of the University of Edinburgh has conferred the honorary degree of Doctor of Laws upon Prof. J. B. Farmer, D.Sc., F.R.S., Professor of Botany and Director of the Biological Laboratories, Imperial College of Science and Technology, London; and a similar honour to Mr. J. Garton, founder of the Garton Lecture ship in Indian and Colonial Agriculture.

**Influences Affecting the Functioning of Stomata.**—Mr. J. V. G. Loftfield makes some interesting observations\* on the behaviour of stomata in relation to the environmental and physiological conditions of the plant. He found that while illumination affects the action of stomata, weather conditions also control the size of the openings, and with varying water supplies, the stomata may change their behaviour from day to day. Low morning temperatures cause the stomata to open very gradually, and even moonlight affects the size of the aperture. In cereals the stomata are very sensitive and never open at night. In the Potato and some other plants the stomata normally open at night and close only under conditions of high evaporation or low water-content. Light induces the opening of stomata by causing the conversion of starch in the guard-cells into sugar, and so increasing their osmotic pressure. The investigations proved that the regulations of water-loss by the stomata is very effective when they are nearly closed.

**Boy Gardeners' Club.**—In connection with the *Daily Mail* Young Farmers' Club, Messrs. Sutton and Sons have promoted a Horticultural Club at Reading, given half an acre of land, and promised to supply seeds, tools, etc., for the purpose. Membership of the club will be limited to twenty. The Reading Education Authority is interested in the scheme, and there is every prospect that the movement will develop in the locality.

**Royal Gardens, Kew.**—Eighty-one years have elapsed since the Royal Gardens, Kew, were first opened to the public as a national institution; the opening day was April 1, 1841. When *The Gardeners' Chronicle* was eleven weeks old, in our issue of March 20, 1841, the following notice appeared:—It is with great satisfaction that we are at length enabled to announce upon authority that Sir W. J. Hooker has been appointed to the charge of the Royal Botanical Gardens at Kew. We trust this wise step will be accompanied by such other changes and improvements in this important establishment as will ensure its efficiency, and prove that the ill-advised plan of destroying it, last year entertained by certain gentlemen connected with the Government, was never approved of by Her Majesty's responsible advisers.

**Mr. E. White, V.M.H.**—On leaving school Mr. E. White, the eminent landscape gardener, had no intention of taking up landscape gardening as a profession, but turned his attention to farming and estate management, and it was not until he met the late Mr. H. E. Milner that he started upon the horticultural career which has proved so successful. For some years he studied garden design and landscape gardening under Mr. Milner, and eventually became associated with him, as managing director of the Estate Development Company, in laying out the grounds of Dartmouth Naval College, Christ's Hospital, and other places. Later he married Mr. Milner's eldest surviving daughter, eventually joined Mr. Milner, and since 1903 he has been the responsible partner of the firm of Messrs. Milner, Son and White. In his boyhood Mr. White had a horticultural environment, as his father, the late Alderman James White, seven times mayor of Worthing, was a keen amateur horticulturist with a great love for his garden and an excellent knowledge of plants, consequently Mr. E. White inherited a love of gardens, which has stood him in good stead in his work as a designer. Although recognised as one of the leading British landscape gardeners, Mr. White's reputation and work are not confined to the British Isles. At home he has ad-

MR. EDWARD WHITE, V.M.H.

vised on the construction and alteration of such famous gardens as those at Bagshot Park, Kedleston, Cowdray Park, Sundridge Park, Bovey Manor, Salford Park, Sandon Hall, Gatton Park, Langley Park, Marden Park, Stobo Castle, Ardross Castle and Moreton Paddox, among many others. In France his work is to be seen in the gardens of the members of the Rothschild family; in Sweden he advised the King in connection with the Royal Gardens, and the late Crown Princess in connection with her garden at Sojiero. Many important estates in Germany owe some of their best features to Mr. White's skill. Farther afield still, in India, Mr. White is well known for his work in connection with the Victoria Memorial at Calcutta, carried out in conjunction with the late Lord Redesdale. In Canada he provided the plan for the laying out of the grounds surrounding the new Government building at Ottawa. Mr. White came prominently before the horticultural world when he became Hon. Secretary of the Royal International Horticultural Exhibition of 1912; his appointment commenced in 1910 and continued until an organising secretary was appointed. It was Mr. White who planned the arrangements of that great exhibition in the Chelsea Hospital grounds. He possesses administrative ability of the highest order, with urbanity and courtesy which have won him hosts of friends, and skill as a landscape artist and

garden designer which has earned for him a foremost place in his profession and the Victoria Medal of Honour in Horticulture.

**The U.S.A. Nursery Trade.**—According to the latest census reports there are in the United States approximately 4,500 nurseries, covering 172,000 acres. It is estimated that these nurseries represent a capital of \$52,500,000, and they employ 45,600 men and 2,300 women. The amount of stock in these nurseries includes 3,400,000 woody plants and trees, in addition to millions of flowering plants. The American Association of nurserymen is the largest society of its kind in U.S.A. and embraces some 300 of the largest and most important nurseries in the United States.

**R.H.S. Medal Awards.**—The Council of the Royal Horticultural Society has arranged that the various medals of the Society shall be granted in future to specific subjects. Thus the Chairman of the Fruit and Vegetable Committee announced on Tuesday last that the Hogg Medals only would be awarded to fruit and the Knightian medals to vegetables. The Flora and Banksian Medals will be awarded for flowers and ornamental plants; the Lindley Medal will be given for a plant or plants of special interest or beauty, or showing exceptional skill in cultivation; the Grenfell Medal will be awarded to pictures, photographs or exhibits of a similar nature of botanical or horticultural interest. The Lawrence Medal, which is struck only in gold, is awarded directly by the Council; only one such medal is awarded annually and never to the recipient in either of the two previous years. The Society's Gold Medal will be awarded to exhibitions of special excellence. The Flora, Banksian, Hogg, Knightian, Lindley and Grenfell medals are struck in silver-gilt, silver and bronze.

**Turnip Gall Weevil.**—Quite frequently the galls produced by the grubs of the Turnip Gall Weevil on Turnip and other members of the Brassica family are mistaken for the swellings which indicate the presence of the dreaded Finger and Toe disease. A cursory examination and the use of a knife to cut open one of the rounded out-growths will enable anyone to determine whether the attack is due to insect or fungus, whilst the admirable description and illustrations given in the current issue of the *Journal of the Ministry of Agriculture* will render further assistance. Mr. Isaac\* points out there are two races of the weevils, each producing one brood during the year. The race which appears in spring and breeds mostly in Charlock, and of which the adult beetles hibernate during the winter, is not of much economic importance. The other race, however, which appears in early summer and lays eggs in Cabbage, Turnip, and other cultivated Crucifers, remains in the galls, in grub form throughout the winter, and pupates in cocoons in spring. This is the race which does the greatest harm to farm and garden crops, hence it is of the utmost importance that infested roots and stems which have been in the ground all the winter should be removed early in March, and in the case of Spring Cabbages, the stems and roots should be removed at the earliest possible date. All infested stems and roots should be burnt so that the grubs may have no opportunity of reaching the adult or beetle stage and producing another brood. Mr. Isaac suggests that the land should be ploughed deeply immediately an infested crop has been removed, as this operation will crush and destroy numbers of the cocoons with the pupae within.

**Stand Rents in Covent Garden Flower Market.**—The standholders of Covent Garden Flower Market owe a debt of gratitude to the British Florists' Federation for successfully negotiating between them and the Covent Garden Estate Company. The latter proposed to raise the rents to £65 per year per stand; this has been reduced to £40 a year for the 208 market days, and if a tenant wishes to occupy his stand on the 104 bye-days, he may do so at 1s. 6d. per day; therefore he may occupy his stand every day the market is open at a cost

\* "The Turnip Gall Weevil." By P. V. Isaac. *The Journal of the Ministry of Agriculture*, March, 1922. His Majesty's Stationery Office, Kingsway, W.C.2. Price 6d., post free.

\* Carnegie Institution of Washington. Publication No. 314.

of £47 16s. This arrangement, which comes into force at midsummer, is a great boon to growers who sell their own produce, because pot-plant growers rarely use their stands other than on market days; for such tenants a saving of £20 5s. per year per stand has been effected, while for flower growers and flower salesmen always in the market the saving, as compared with the proposals, amounts to £17 4s. We understand the negotiations have been proceeding for three months, that the B.F.F. has acted for all the stallholders, whether members of the Federation or not, and that the British Florists' Federation has further established its position as the body to be consulted by the Covent Garden Estate Co., in all matters affecting the Flower Market.

**Appointments for the Ensuing Week.**—Reading and District Gardeners' Association's meeting and lecture by Mr. H. H. Cook: Tuesday, April 4.—Royal Caledonian Horticultural Society's meeting; Bournemouth Gardeners' Association's meeting: Wednesday, April 5.—Royal Hort. and Arbor. Soc. of Ireland Spring Show (2 days); National Viola and Pansy Society's meeting; Wimbledon and District Gardeners' Society's meeting. Thursday, April 6.—Manchester and North of England Orchid Society's meeting; Linnean Society's meeting at 5 p.m. Friday, April 7.—Paisley Florists' Society's meeting. Saturday, April 8.—Ringwood Society's meeting.

"The Gardeners' Chronicle" Seventy-five Years Ago.—*The Fa-tee Gardens, near Canton.*—In his book entitled *Three Years' Wanderings in the Northern Provinces of China*, Mr. Robert Fortune refers to the Fa-tee Gardens, long celebrated for their beauty by English residents, as follows: "It is, of course, in spring that the Fa-tee Gardens possess the greatest attractions. They are then gay with the Tree Paeony, Azaleas, Camellias, Roses and various other plants. The Azaleas are splendid, and reminded me of the exhibitions in the gardens of the Horticultural Society at Chiswick, but the Fa-tee exhibitions were on a much larger scale. Every garden was one mass of bloom, and the different colours of red, white and purple blended together, had a most beautiful and imposing effect. The principal kinds grown were *Azalea indica*, *indica alba*, *phoenicea*, *lateritia*, *variegata*, and the yellow *Azalea sinensis*. I may mention, in passing, that I found the latter plant wild on the Ning-po hills, so that there is no doubt of its being a genuine Chinese species. The air at this season around Fa-tee is perfumed with the sweet flowers of *Olea fragrans* and the *Magnolia fuscata*, both of which are grown extensively in these gardens. Dwarf trees, as may be supposed, occupy a principal station; they are trained into most grotesque and curious forms. The plants which stand next to dwarf trees in importance with the Chinese are certainly *Chrysanthemums*, which they manage extremely well, perhaps better than they do any other plant. So high do these plants stand in the favour of the Chinese gardener, that he will cultivate them extensively, even against the wishes of his employer: and, in many instances, rather leave his situation than give up the growth of his favourite flower. I was told that the late Mr. Beale used to say that he grew *Chrysanthemums* in his gardens for no other purpose than to please his gardener, not having any taste for this particular flower himself. Tree Paeonies are not natives of the south of China, but are brought down in large quantities every year, about the month of January, from the northern provinces. They flower soon after they arrive, and are rapidly bought up by the Chinese to ornament their houses, after which they are thrown away, as they do not thrive well so far south as Canton or Macao, and will not flower a second season. They are sold according to the number of flower-buds they may have upon them, many of them fetching rather high prices." *Gard. Chron.*, April 3, 1847.

**Publication Received.**—*Agricultural Co-operation in England and Wales*. By W. H. Warman. Williams and Norgate, 14, Henrietta Street, W.C.2. Price 5s. net.

## COLOURED FREESIAS.

A NUMBER of raisers, including Van Tubergen, Jacob, Dalrymple, Manger and Chapman have in recent years been as busy as bees among *Freessias*, and as a result new varieties in many colours are to be seen at every meeting of the Royal Horticultural Society at this time of the year. The colours range from the yellow of Buttercup to nearest-to-blue Bluebeard. There is the bright carmine Le Phare, the rosy pink Robinetta, the bright pink of Apple Blossom, and the violet lilac of Mr. Jacob's Merry Widow. Strange to say, the old *F. refracta alba*, which gained a First-Class Certificate in July, 1878, is still the favourite pure white, one of the best-known of all forcing plants and largely grown for market. Some varieties are more or less tubular, as in Buttercup, and in Treasure, in which the tube is restricted; others open Streptocarpus-like, and one of this type, named Eldorado, was shown by Messrs. Wallace and Co. at the Vincent Square meeting on March 14. This variety is as remarkable for its colour as for its form, and it has a resemblance to *Iris Eldorado*, in its rich combinations of yellow, heliotrope and clear gold. *H. C.*

FIG. 71.—FREESIA ELDERADO; A VARIETY WITH WIDE-MOUTHED FLOWERS; COLOUR, HELIOTROPE AND GOLD.

## THE BULB GARDEN.

### GALANTHUS IKARIAE.

LADY MOORE, writes in *The Garden* in commendation of *Galanthus Ikariae*, which I consider one of the best members of the genus, on account of its good constitution, which none of the other Greek Snowdrops seem to have, its free increase both by seed and offsets, in which, so far as my experience goes, it is unique, and in its lateness of flowering. In my garden it is now (March 22nd) in perfection when all others have passed, except a form (or hybrid, as supposed by Mr. Bowles) of *G. Elwesi* of unknown origin.

Now comes the question: What is *G. Ikariae*? It was described by Baker in *Gard. Chron.*, April 29, 1893, p. 506, from half-dried specimens in flower sent by Mr. Whittall from Smyrna, without the experience in cultivation, which is so important in deciding the systematic position of most bulbous plants. All the characters relied upon by Baker are very variable; but they remain constant in my garden, which is not the case with many oriental plants of this nature. It seems to me nearer to *G. plicatus* than to *G. Elwesi*, and if it is confined to the little island

of Nikaria it has as good a claim to specific distinction as any. But we know little or nothing of the geographical limits of *G. plicatus*, and it may be that *G. Ikariae* is not indigenous or restricted to the island; and we have only the word of unknown Greeks for that locality, as I have not heard of any botanist who has found the plant. Boissier, *Flora Orientalis*, V., p. 145 (1831), describes *G. graecus*, *Orph. in litt.*, as intermediate between *G. Elwesi* and *G. nivalis*, flowering in April at 3,800 feet on Mt. Pellinos, in the island of Chios. Halacsy, *Flora Graecae*, III., p. 206 (1904), gives *G. nivalis* var. *coreyrensis* from the Cyclades, and *G. "graecus"*, *Orph.*, from Chios, but does not mention any other species except *G. Olgae*, an autumn-flowering form of *nivalis* from Mt. Taygetus. On referring to a good map, I find that Nikaria is only about thirty miles south of Chios, with no intermediate land, and the elevation of the mountains are much about the same. It therefore seems likely that the plant referred to by Boissier and Halacsy is the same as Baker's *G. Ikariae*. *H. J. Elwes, Colesborne.*

### AMERICAN LILIES FOR THE GARDEN.

OF American Lilies, some of the finest are *Lilium pardalinum* and the exquisitely

coloured *Humboldtii*—both natives of far distant California. Another very beautiful Lily, introduced into this country from the Western States of America, is *Lilium Washingtonianum*—whose exquisite, somewhat miniature flowers have the rich fragrance of the Honeysuckle. When strongly established, it adapts itself to its environment in a marvellous manner. I saw it once in a "forsaken garden" flowering with the utmost composure among very rank grass.

Among the most grandly effective Lilies in our gardens are *L. auratum* and *L. speciosum*. Of the former, two of the most reliable forms for growth and floral impressiveness are the varieties named *platyphyllum* and *rubro-vittatum*; *platyphyllum* is a veritable giant in growth, occasionally approximating to the dimensions of *L. giganteum*, with broad and massive flowers; while *rubro-vittatum*, with its blood-red bands down the centre of each petal, is one of the most distinctive Lilies in cultivation. The *speciosum*, of which perhaps the finest representations are *Melpomene* and *Kraetzerei*, are invaluable in autumn for garden decoration. They have, in comparison with other Lilies, this supreme fascination: that their fragrance, like their aspect, is very refined. The long-florums are, I think, especially adapted for conservatory cultivation. *David R. Williamson.*

## SPRING FLOWERS AT DRYNHAM.

The winter, up to the present very cold spell, was unusually mild, and vegetation in the neighbourhood of London was particularly forward. Almonds, which do remarkably well on light soil, have been splendid this spring, the flowers being large and bright and the trees laden with them. *Prunus Pissardi* has also developed a wealth of bloom and with the pretty purple tips of the young growths, which are just developing, makes a pleasing contrast with the Almonds. In this district, both these trees have been beautiful features during the past few weeks. Forsythias have also flowered unusually well this season. One of our trees is ten feet in height and fifteen feet in diameter and has been covered with the beautiful yellow blossoms. Standard specimens have also been laden with flowers; some of the pendent shoots, which sweep almost to the ground level, have carried their full share of beauty.

The showy *Rhododendron praecox* has been exceptionally good and so has *Clematis Armandii*, which is fully a fortnight earlier than

blooms. *Osmanthus Delavayi* is a mass of white flowers which greatly resemble those of the *Bouvardia* individually. *Cornus Nuttallii* is showing profusely for bloom; apparently the hot summer of last season suited the plant. Our border of *Rhododendron Pink Pearl* promises better than ever; so numerous are the flower buds, it will be necessary to resort to severe thinning. This also is true with some of the Himalayan *Rhododendrons*.

Of the lowlier plants, Crocuses have been extra good, both the species and varieties. We have thousands of these plants dotted in various parts, and large numbers in the Rose garden, where each bed is massed with Crocuses in one colour and one large bed is filled with *Scilla sibirica*. These Crocuses and *Scillas* make the Rose garden gay at the dull season of the year and we find that they do not affect the Roses in the least. The smaller flowered *Narcissi*, such as *N. minimus* and *N. cyclamineus* are planted freely on a grass terrace surrounding the tennis lawn here and they look fine in this prominent position. We have also planted *Narcissi*, together with Snowdrops, on a mound around an old Thorn, with other bulbs such as

## HARDY FLOWER BORDER.

### ASTER PORTERI.

*ASTER PORTERI* is one of the plants I have had and lost, but this was not the fault of the plant, but of an unusually wet and trying winter that is naturally unsuited to this Starwort, which comes from Colorado, where the climate is quite different to that of the rather humid West of Scotland. But it is quite hardy on dry, well-drained soils in a climate fairly dry overhead. The plant needs a specially light and well-drained soil. It is quite worth some consideration, even among the plethora of members of the genus *Aster*. It is a suitable subject for the border, and grows to a height of two to three feet, and on neat stems carries a pleasing head of flowers that are a good white and prettily formed. It is not, I think, plentiful in cultivation in nurseries, but specialists in hardy flowers may be glad to know of this good *Aster*.

### CAMPANULA RADDEANA.

*BELLEVAMPUS* of beauty abound, and the choice is a most embarrassing one when only a few can be accommodated. But one which may well be included in all good rock gardens, is that called *Campanula Raddeana*, a beautiful species from the Transcaucasian mountains, which has not been very long in cultivation, but has gained a high reputation for its beauty and obliging character in our gardens. Almost any soil which is not of a heavy nature will meet its wants, and as for position, it will grow in sun, partial shade, or full shade, although not under the drip of trees. It has elegant little foliage, rather heart-shaped and prettily notched, and made more pleasing by its glossy green. Its full beauty is revealed when it flowers in summer, and we can enjoy its exquisite violet bells of a shade difficult to describe, but of a most glorious colour. The plant will attain a height of nine inches in some places, and is then exceedingly pretty with its bells hanging from the graceful stems, but in poor soil it is much dwarfed and hardly reveals its full grace through the brevity of the stems. No one can grow it without pleasure.

### ASTER SUBCAERULEUS.

SOME confusion has always appeared to exist between *Aster subcaeruleus* and *A. diplostephioides*, and this seems difficult to dispel. The main distinguishing feature which should be sufficient for identification is the eye of the flower, which in *A. subcaeruleus* is yellow, and in *A. diplostephioides* purple. Of the two, also, *A. subcaeruleus*, besides being longer lived, is a little taller in most places, being about sixteen inches high, while the other is about a foot or so.

*A. subcaeruleus* is very frequently met with under the name of *A. diplostephioides*; but the foregoing remarks should enable the reader to discover whether he has the plant under its proper name. The one under notice has almost leafless stems, each surmounted by a grand flower, like that of *Aster alpinus*, and rising from a carpet of soft green leaves. The plant is not difficult to cultivate in the ordinary border in good loam, and is one of the most acceptable of our June-flowering perennial *Asters*. It is increased by division or seeds. *S. Arnott*.

## TREES AND SHRUBS.

### PINUS CANARIENSIS.

*PINUS canariensis* (see p. 77) is found wild only in the Canary Islands, where it becomes 80 feet or more high, with a trunk 10 feet in girth. The leaves are in bundles of threes, and average 8 or 9 inches in length; the cones are about 5 inches long. The Canary Pine is not hardy at Kew, but there are several plants in the Temperate House. Even in Cornwall it does not seem to thrive well, but it is very good on the French Riviera. See *Gard. Chron.*, p. 723, fig. 94 (1888); and Vol. XV., p. 333 (1881). *W. J. Bean*.

FIG. 72.—*SAXIFRAGA IRVINGII*; FLOWERS FAINTLY TINGED WITH PINK.

last year. *Lonicera Halleana* has been a mass of blossoms, which give off a most beautiful perfume. *Pieris (Andromeda) japonica* has a profusion of flowers and is a most glorious object. *Ericas* that escaped injury by the drought of last summer are very good, including *E. lusitanica*, *E. Veitchii*, *E. mediterranea* and *E. australis*. All kinds of *Pyruses* give great promise for rich displays of their pretty blossoms, a few being already out. Some of the later flowering shrubs are also very promising and especially the *Magnolias*. Our plants of *Viburnum Tinus (Lanrustinus)* have given an unusual quantity of bloom this winter and never before have I seen *Jasminum nudiflorum* so fine as this season. Early-flowering *Barberries* have been glorious, especially *B. japonica (Bealei)*, whose blossoms have a delicate perfume. *Daphne indica* has wintered well and is now in bloom. This is one of the most sweetly scented of all shrubby plants. *D. Blagayana* is also finely in bloom and this, like the other species, is an evergreen. Our plants of *D. Mezereum*, both red and white kinds, are excellent; several specimens of the white form are over six feet high. *Sarcococcus ruscifolia* is an early-flowering evergreen which produces small, white, flinny

Grape Hyacinths and other forms of *Narcissi* to furnish a succession.

Early *Saxifragas* are flowering well in the rock garden, and amongst the most beautiful are *S. Faldonside*, the finest of all the yellow *Saxifragas*, *S. Irvingii* (see Fig. 72), a pretty pink hybrid, and *S. Burseriana*. Of blue flowers, *Anemone blanda* is flowering very freely, as also is *Scilla biflora*. *Iris reticulata* makes a fine show amongst the many patches of yellow *Saxifragas*. Where these *Irises* are planted in sunny nooks, the blooms appear early and the plants ripen off before they have time to become shabby. *W. A. Cook, Drynham Gardens, Walton-on-Thames*.

**Berries of *Aucuba japonica*.**—We have an extra fine display of berries on our *Aucubas*, the branches bending down with them; they make a cheerful show at this season, in contrast to the Snowdrops and Crocuses. The reason of our plants being so well berried is that a goodly number of male specimens were included at the time of planting. The buds of the male plants are opening their scales and showing the flower buds; but there are no signs of the female buds bursting. *J. P., Aberaman*.

## NEW OR NOTEWORTHY PLANTS.

RHODODENDRON PRAETERITUM,  
HUTCHINSON, NEW SPECIES.\*

For two or three years, in early spring, there has flowered at Kew a *Rhododendron* with much the appearance of *R. maculiferum* and *R. oreodoxa*, but with a very different corolla, which has not up to the present been referred to any described species. In the two species mentioned, the corolla is funnel-shaped, whilst in the new species here described it is very widely campanulate (see Fig. 75).

It differs further from *R. maculiferum* in having no blotch at the base of the corolla, and in having a perfectly glabrous ovary, but like that species it has a hairy mid-rib on which, however, the hairs do not persist for any length of time. From *R. oreodoxa*, it is at once distinguished by the shape of the 5-lobed corolla and by the eglandular pedicels.

The specific name, from *praeteritus*, passed over or left behind, is intended to commemorate the fact that though this species has flowered consistently since 1918, it has only just been deemed worthy of a name.

*RHODODENDRON PRAETERITUM*, HUTCHINSON, new species allied to *R. MACULIFERUM*, and *R. CREODOXA*.

A shrub; older parts of the branchlets reddish-brown, terete, about 6 mm. thick, laxly and minutely pustulate; one-year-old branchlets short, sparsely and finely pubescent, bright green and shining. Leaves crowded and supporting the flowers, evergreen, oblong or oblong-elliptic, rounded and obtusely mucronate at the apex, slightly unequal and rounded at the base, dull dark green above, pale green and closely reticulate below, glabrous, except for the sparsely hairy mid-rib, from which the hairs soon fall off; mid-rib prominent below, pale yellowish green, soon becoming glabrous; lateral nerves 12-14 on each side of the mid-rib, diverging at an angle of 45 deg., slender, fading away and forking towards the margin; petiole 1.5-2 cm. long, rounded below, narrowly grooved above, at first finely pubescent, soon becoming glabrous. Inflorescence shortly racemose; axis 2 cm. long, pale sap green, glabrous except around the base of the bracteoles, larger bracteoles yellowish-white, spatulate-oblancoolate, obtuse, up to 3 cm. long and 1.5 cm. broad, appressed-villose outside; pedicels rather unequal, the lower about 1 cm. long, the upper 2 cm. long, reddish, with a few scattered white non-glandular hairs which soon fall off. Calyx oblique, small, shallowly 5-lobed, lobes broadly triangular-ovate, very slightly hairy on the

margin, up to 2 mm. long. Corolla, pink or white, flushed outside with pink, sinuag, widely campanulate, 5-pouched at the base, about 5.5 cm. across the top; tube 3.5-5 cm. long, with a few carmine spots inside the back, but no blotch; lobes 5, transversely oblong, deeply emarginate. 2.5 cm. broad, about 1.5 cm. long. Stamens 10, declinate, the longest slightly shorter than the corolla; filaments up to 3.5 cm. long, very slightly and sparsely pubescent towards the base; anthers chocolate-purple, 4 mm. long. Ovary glabrous, abruptly merged into the style, 7 mm. long, 6-celled; style glabrous, longer than the corolla, curved below the stamens, with a pale yellow lobed stigma. Cultivated in the Royal Botanic Gardens, Kew, from Wilson's Veitchian Seed, numbers 1800, 1864. *J. Hutchinson, Kew.*

## PAEONIA MLOKOSEWITSCHI.

A FLOURISHING plant of this yellow-flowered Paony in the gardens of Rev. B. Douglas-Dick, St. Mary's, Newabbey, in the S.E. of Kirkcudbrightshire, flowers with comparative freedom each season. The owner of the garden, who is a keen plant-lover, informed me, however, that

## ORCHID NOTES AND GLEANINGS.

## BRASSO-CATTLEYA THORNTONII ALBA.

A VERY fine clear white form of the cross between *C. Gaskelliana* alba and *Brassavola Digbyana* is sent by Messrs. H. E. and W. Lack (gr. A. J. Mayes), Wellingborough, who state that the flower has been open a month, and that the seed parent was *B. Digbyana*. The cross on to the *Brassavola* is rare, the *Cattleya* as seed bearer in all the sections being usual. The large flower is of very firm substance (a character always shown when *Brassavola* is the seed bearer); it is pure white, with a sulphur-yellow disc to the fringed lip.

## ONCIDIODA STUART LOW.

A FLOWER of this remarkable cross between *Oncidium macranthum* and *Onciodia Cooksoniae* (*O. macranthum* × *C. Noezliana*) sent by Messrs. Stuart Low and Co., shows a decided advance towards imparting rich red colour to the yellow *Oncidium macranthum* and retaining its large size. The flower in the new combination again with the *Oncidium* has attained to two-thirds of the full dimensions of the *Oncidium*, with its broad segments. The

[Photo by R. Kellv.]

FIG. 75.—RHODODENDRON PRAETERITUM; NEW SPECIES; FLOWERS WHITE, FLUSHED WITH PINK IN THE OUTER SURFACE.

he considered *P. Wittmanniana* the better coloured species of the two.

Although I have seen both plants, I have not had an opportunity of comparing them at one time, but Father Dick's opinion confirms the one I had formed regarding the respective merits of the two. In the *Journal of the Royal Horticultural Society*, Vol. XLVI. (May, 1921), in the report of the meeting of the Scientific Committee, held on April 20, 1920, it is stated, regarding various plants shown by Mr. H. J. Elwes, *inter alia*, that "Paonia Mlokosewitschi is the best and earliest yellow Paony." It is, generally, I think, the earliest yellow one, but I wonder if Mr. Elwes has compared this species with *P. Wittmanniana*. The latter is reputedly difficult to cultivate, but in the garden at St. Mary's and in a few other South of Scotland gardens known to me, it thrives and flowers well. I may add that this Paony grows well in an ordinary border of good soil. *P. Mlokosewitschi* was the subject of the Supplementary Illustration in *Gard. Chron.*, July 25, 1903. *S. Arnott.*

broadly ovate sepals are dark purplish-red, the upper one being rather lighter. The broader petals are red with yellow margin and tips. The lip, which adheres closely to *O. macranthum*, is fleshy in substance, the two side lobes purple at the base and yellow outwards; the narrow intermediate lobe is yellow at the tip and red around the prominent crest.

## Laelio-Cattleya Sol.

A FLOWER of this finely-coloured new cross is sent by C. J. Lucas, Esq., Warnham Court, Horsham. It was obtained by crossing *L.-C. Apollo* (*C. Schröderae* × *L.-C. Warnhamensis*) and *L.-C. Luminosa*, most of the parents having been raised at Warnham Court. The flower, which is of good size and shape, has light yellow sepals, slightly tinged with pink. The broad petals, show the white mid-rib at the base, from which a faint mauve flush extends to the outer parts, which are pale apricot yellow. The broad lip is entirely bright violet-purple, except for a small white space beneath the pure white column.

\* *Rhododendron praeteritum*, Hutchinson, sp. nov.; affinis *R. maculifero*, Franch., et *R. oreodoxa*, Franch., ab illo pedicellis fere glabris corollae tubo emaculato ovario glabro, ab hoc pedicellis eglandulosis, et ab ambobus corollae tubo late campanulato differt.

Frutex; ramuli vetustiores rubro-brunnei, teretes, circiter 6 mm. crassi, laxè et minute pustulati; ramuli annotini breves, parce et tenuiter pubescentes, virides et nitidi. Folia conferta, rosulata, sempervirentia, oblonga vel oblongo-elliptica, apice rotundata et obtuse mucronata, basi leviter inaequalia et rotundata, supra opaca et atro-viridia, infra pallide viridia et crebre reticulata infra costa pilis deciduis excepta glabra; costa infra prominens, pallide flavo-viridis, mox glabra; nervi laterales utrinque 12-14, a costa subangulo 45° abeunt, graciles, marginem versus evanidi et furcati; petioli 1.5-2 cm. longi, infra rotundati, supra anguste canaliculati, primum tenuiter pubescentes, mox glabri. Inflorescentia breviter racemosa; axis 2 cm. longa, pallide viridia, circumbracteolarum hasos parce pubescens, strum gibba bracteolae majores flavo-albae, spatulato-oblancoolatae, obtusae, usque ad 3 cm. longae et 1.5 cm. latae, extra appresse villosae; pedicelli parum inaequales, inferiores circiter 1 cm. longi, superiores 2 cm. longi, rubescentes pilis albidis eglandulosis deciduis parce induti. Calyx obliquus, parvus, 5-lobus, lobis late triangulari-ovatis, marginibus leviter pubescentibus usque ad 2 mm. longis. Corolla alba, extra roseo suffusa, nitida, late campanulata, basi 5-saccata, apice circiter 5.5 cm. diametro; tubus 3.5-5 cm. longus, intra dorso maculis carmineis ornatus; lobi 5, transverse oblongi, profunde emarginati, 2.5 cm. lati, circiter 1.5 cm. longi. Stamina 10, declinata, corolla leviter breviora; filamenta usque ad 3.5 cm. longa, basin versus leviter et parce pubescentia; antherae purpureae, 4 mm. longae. Ovarium glabrum, in stylo abrupte contractum, 7 mm. longum, 6-loculare; stylus glaber, staminibus longior, curvatus, stigmatibus pallide flavo lobato

## The Week's Work.

### THE ORCHID HOUSES.

By J. T. BARKER, Gardener to His Grace the Duke of Marlborough, K.G., Blenheim Palace, Woodstock, Oxon.

**Dendrobium Phalaenopsis.**—Plants of this delightful Orchid are developing new growths, and as soon as fresh root action commences any necessary repotting should be carried out. The plants will grow best suspended from the roof rafters of the warmest house, where they will receive plenty of light. They should be grown in shallow pans, as they do best in a small amount of compost. In potting, half fill the pans with drainage material, and arrange the plants so that the bases of the young growths are on a level with the rim of the receptacle. Tie the pseudo-bulbs to neat sticks, and not to the wire, as in the swaying of the pan the plants may be disturbed at the base, which will prevent them rooting into the new material. A suitable rooting medium is composed of equal parts of *Osmunda* and *A1* fibres, and one part *Sphagnum*-moss cut up rather short, according to the size of the pans to be used. Pot firmly, and keep the plants on the dry side until the new roots have entered the fresh material, after which they will require liberal supplies of moisture, both in the atmosphere and at the roots. If water is applied too soon, there is a danger of moisture getting in between the new growths and causing them to decay. The plants should only be shaded from bright sunshine during the hottest part of the day, and then only when there is a danger of them scorching. The chief needs of these Orchids, which comprise such species as *D. superbiens* and *D. Goldi*, are plenty of heat, light, and moisture whilst they are in full growth, with a dry rest after blooming.

**Various Dendrobiums.**—At one time spring-flowering *Dendrobiums* were in great demand, and formed a prominent feature in most collections. The majority of the plants are passing out of bloom, although it is possible to have them in flower until well into May, by keeping them in a moderate cool house until the inflorescences are nearly developed. As soon as the flowers are faded, the plants will develop new growth rapidly, and when fresh roots are observed those that require repotting should have attention. Like other Orchids, all the plants will not be ready for potting at one time, therefore it is advisable to attend to them as they become ready. At this stage let the plants receive the least possible check in repotting. Large, healthy, well-established specimens should not be disturbed too much, only the decayed, sour compost removed. Plants with a quantity of leafless pseudo-bulbs should have them removed and be placed in receptacles which just accommodate them. *Dendrobiums* of all kinds resent a large quantity of material about their roots, and the compost should be of a clean, open nature, such as coarse *A1* fibre mixed with live *Sphagnum*-moss.

### THE FLOWER GARDEN.

By EDWIN BECKETT, Gardener to the Hon. Vicar GIBBS, Aldenham House, Hertfordshire.

**Border Carnations.**—The present is a suitable time to plant young Carnations raised from layers last autumn, and if placed in groups, all of one sort, they will form a very beautiful and important feature of the herbaceous border. The modern race of *Dianthus Allwoodii* is a valuable addition to the Carnation family, and includes many lovely named varieties.

**Kniphofia.**—The old-fashioned Red-hot Poker Plant, sometimes known as *Tritoma*, is a favourite flower still, and when well grown is a fine ornament to the herbaceous border. About the middle of March such species as *K. Uvaria* (*aloides*) may be lifted and divided, where this is deemed advisable. Some of the smaller species, such as

*K. Nelsonii*—a dainty plant for the front of the border—are rather impatient at being disturbed, and where they can be left it is far better merely to clean them over, removing dead foliage and any rubbish that may have accumulated around them. *Kniphofias* are somewhat tender, and for winter protection they should have a good layer of fine cinder ash placed well round them; the foliage of the taller varieties should also be gathered together, twisted lightly, and then formed into one loose knot. *Kniphofias* prefer well-drained sandy or loamy soil that has been freely enriched with manure, and should be planted in a sunny spot.

**Seedlings.**—Young plants of annuals and perennials raised from seed sown in boxes, etc., last month, should be pricked out into other boxes, and grown on in the same temperatures as those in which they were raised, until they are well established, when they should be hardened gradually, with a view to planting them in the open when suitable weather arrives.

**The Fernery.**—Where hardy Ferns are grown in beds or other places by themselves, they should receive attention at this season. A previous caution was given not to remove the dead fronds too early, but this may now be done, and where desirable the plants lifted and replanted. New borders should also be prepared, and a description of the border at Aldenham may be useful, as this phase of outdoor gardening may well prove one of the most interesting. The border in question, containing upwards of 130 hardy species and varieties of Ferns, is about 6 to 8 feet wide, and runs along the northern side of a fruit wall. Our soil is heavy and tenacious, but a good bed is formed of decayed leaf-mould, and in this the Ferns thrive happily and well, and are a constant source of interest to our many visitors.

### PLANTS UNDER GLASS.

By T. PATEMAN, Gardener to Sir C. NALL-CAIN, Bart., The Node, Codiote, Welwyn, Hertfordshire.

**"Malmaison" Carnations.**—One-year-old plants of *Souvenir de la Malmaison* Carnations that were transferred to 7-inch pots are growing freely, and when it is found that they are well rooted an occasional light dose of some approved Carnation fertiliser may be given the roots. The stimulant will be best applied in a liquid form; soot water is also beneficial to the plants and also makes a change of food. In my opinion these Carnations resent overfeeding, and where excessive stimulants of an organic nature are given, the flowers will, in all probability, show coarse centres, but when the plants are fed judiciously the flowers show a marked improvement in quality. Greenfly is very partial to these plants, and must never be allowed to infest them; occasional fumigations will keep the pest in check. Air should be admitted freely on all favourable occasions. Warmth from the hot-water pipes will not be necessary except on very cold nights.

**Primula sinensis flore pleno.**—The old double white *Primula* is now very rarely grown in gardens, although it is still worthy of its place among greenhouse subjects. The plants are now passing out of flower, and should be prepared for propagating, as this variety cannot be raised from seed. The bottom leaves should be carefully cut away, and a slit made with a sharp knife in each division of the stem in an upward direction, placing a small piece of crock or charcoal in the cut to keep it from closing up. The plant should then be packed around with *Sphagnum*-moss, leaf-mould, and silver sand to encourage roots to develop. When it is found that the top-dressing is filled with roots, the plant should be pulled to pieces carefully and potted in a very light compost. The plants should then be stood in a propagating frame for a few days to favour root action, but they should not remain in a closed frame for any length of time or they will probably damp off very badly. Double-flowered *Primulas* require very similar treatment to the single type after they are established, but they will bear a little higher temperature after flowering is over.

### THE KITCHEN GARDEN.

By JAMES E. HATHAWAY, Gardener to JOHN BRENNAND, Esq., Baldersby Park, Thirsk, Yorkshire.

**Pricking Off Seedlings.**—Plants of Onions, Leeks, Cauliflowers, etc., sown in boxes, should be carefully watched and transplanted as they become ready. After the roots have been disturbed in this way use the syringe freely, but not to the extent as would cause the soil to become excessively wet.

**Peas.**—Plants raised from seed sown in curves or boxes should be gradually hardened off ready for planting out of doors. If they are placed in a cold frame the lights should be removed during the day and air admitted on mild nights. Sowings of Peas should be made every fortnight from now onwards to ensure continuous supplies.

**Asparagus.**—Asparagus beds should be raked over and the rough material put in the alleys and dug in. The beds should then be dressed with Asparagus manure, and the surface forked over lightly. This plant is greatly benefited by frequent dressings of salt, and the best time to apply the salt is just before or during a shower. New beds should be made on ground which has been previously trenched 3 feet deep; on heavy land the beds should be raised; this may be done by marking out the beds 4 feet wide with 2-foot alleys between them, and throwing the soil from the alleys on the top of the bed to raise it about 1 foot above the general level. The planting should then be done quickly so as not to expose the roots to the air longer than is necessary. Plant three rows in each bed, allowing a space of about 18 inches between each plant in the row. Where old plants are not available, seed may be sown in drills and the seedlings thinned to a requisite number; but this method is a very slow one, and means waiting a long time before the crop is ready to cut. It is much better to sow a few seeds annually on a special seed bed, and have a reserve of three-year-old plants.

**Carrots.**—The main sowing of Carrots should be made in ground that has been well trenched in the autumn. Apply a liberal dressing of lime and wood ash, and well work the materials in the soil either by forking or the use of a Planet Junr. scuffler. The surface should afterwards be levelled and the seed sown in drills made 12 inches to 15 inches apart, according to the variety. As soon as the seedlings begin to show apply light dressings of soot along the rows.

### FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY M.P., Ford Manor, Lingfield, Surrey.

**Successional Figs.**—Trees growing in restricted borders with warm fermenting material packed about the turf walls need a temperature of 55° to 60° at night, and 10° higher by day. The season being well advanced, the house may be closed very early to make full use of the sun's heat. Syringe the trees well with tepid water twice on fine days, and occasionally with clear soot water. Let the roots have ample supplies of liquid manure made 5° warmer than the bed. Remove all superfluous side shoots to prevent crowding; at the same time look well to the proper furnishing of the tree with spur wood, that is short pieces with good points, and train in all leaders at their full length, as these will produce a continuous succession of fruits throughout the season.

**Thinning Grapes.**—Grapes should never be touched by the hand or rubbed by the hair, as when the bloom is removed in this way the berries "rust." The operator should use a short, forked stick for keeping the bunch steady and lifting the shoulders; then, with the scissors, cut away all stoneless berries, and plenty in the centre of the bunch to keep it open. The outside berries may then be regulated to a nicety, and the first thinning finished. Thinning in the morning is to be preferred, as the house as well as the body is cool and free from moisture. The bunches should be gone over again for thinning after

they have stoned, and, finally, when they commence their last swelling.

**Vines from Eyes.**—Single eyes, rooted as recommended on page 16, should be ready for planting in 6-inch or 7-inch pots. An atmospheric temperature ranging from 70° to 85° is suitable, with a steady bottom-heat of 75°. These vines should make good plants for putting into new borders in May and June. The soil for the border should be similar to that recommended for fruiting vines, and should be kept somewhat dry and warm with the pots plunged to the rims. When the vines have become well established at the roots, the pots may be drawn out of the bed and placed thinly apart on the surface.

FIG. 74.—GIBBAEUM PERVIRIDE; NATURAL SIZE.

#### HARDY FRUIT GARDEN.

By H. MADKHAM, Gardener to the EARL OF STRAFFORD, Wrotham Park, Barnet.

**Grafting.**—The sap is on the move, and the bark of most trees intended for grafting will part freely. Push forward with this work as fast as time will allow. Select scions of the best varieties, and those most useful for furnishing a long supply of good fruits. For large stocks that have been suitably headed back in advance, crown or rind grafting is the best method, whilst whip grafting is the kind usually adopted for smaller stocks. There should be no difficulty in getting the majority of the scions to unite quickly at this season, provided the inner bark of the graft and stock are made to meet. Do not bind the scion too tightly, and use a broad material in a moist condition for the purpose. When the binding is completed encase the whole with a mixture of clay and cow manure made into a paste. The clay should be examined at intervals, and where it has cracked or parted from the wood make good again.

**Peaches and Nectarines.**—The flowers of both Peaches and Nectarines are opening fast; the flower buds appear to be strong and plentiful, so that, should the weather prove favourable, we may expect good crops of these fruits. Protection from cutting winds and keen frosts will be necessary: canvas blinds, raised and lowered by means of ropes and pulleys, are easily manipulated, but they should only be lowered when frosts threaten and very cold winds prevail. Two or three thicknesses of fish netting will keep out a lot of frost and prevent sleet and cold winds from doing much damage to the blooms, especially when the flowering wood is neatly nailed to the bricks. In very favourable districts protection may not be needed, but the grower should be on the safe side by having protective material in readiness in case the weather proves very severe.

**Espalier Trees.**—In building up evenly balanced trees of this type, great care should be taken to have the horizontal branches suitably placed. If there is any doubt about the bud needed to form a "tier" remaining dormant, it should be made to break by practising what is termed notching, that is, making an incision just above the bud deep enough to penetrate the wood and check the sap passing beyond it. If this is done carefully good results are certain.

## MESEMBRYANTHEMUM AND SOME NEW GENERA SEPARATED FROM IT.

(Continued from page 129.)

### II. GROWTHS, GLABROUS AND SMOOTH.

4. *G. PERVIRIDE*, N.E. Br. (Fig. 74). Plant with age, forming short, branching, woody stems 1-2 inches long and  $\frac{1}{4}$ - $\frac{1}{2}$  inch thick, spreading upon or partly buried in the ground; each branch bearing one growth or a small cluster of growths. Each growth  $1\frac{1}{4}$ - $1\frac{1}{2}$  inch long, 8-9 lines broad across the two component leaves when resting and closed together, and 6-7 lines thick, with the apical part of the larger leaf more or less compressed, with a slight keel down the front and over the obtusely rounded apex, and the smaller leaf ovate or ovate-oblong, flattish on the inner or upper side, and rounded on the back, deep grass-green, not at all glaucous, shining when in a plump growing condition, and then with the two leaves widely separated. Flowers not seen, described by Haworth as having a "small unequally 6-lobed calyx, as in *M. gibbosum*,"

Although I have cultivated *G. perviride* for many years, it has never attempted to flower. The variety *luteoviride* I have never seen.

5. *G. GIBBOSUM*, N.E. Br. Stem of old plants 1 inch long, densely furnished with very short, alternate, prostrate branches. Leaves variable, expanding, scarcely two of equal size on the whole plant, one of each pair always larger, longer and more gibbous than the other on the back, few of them more than 1 inch long, very thick, united at the base, all more or less blunt, compressed and gibbous on the back, dullish glaucous-green. In another place they are described as "one short and gibbous, the other much enlarged and oblique at the apex, spreading, ovate, semicylindric, rarely keeled at the apex, yellowish-green." Pedicel very short, compressed, 2-edged or almost winged. Calyx unequally 6-lobed; 4 lobes flattish, with more or less membranous sides; 2 larger, with an acute keel decurrent upon the pedicel. Corolla small, about half an inch in diameter. Petals linear, reddish, with paler margins; stamens numerous, short, convergent; anthers yellowish-white. Styles 6, erect, very short, greenish-yellow. *M. gibbosum*, Haw. *Obs. Mesemb.*, pp. 137 and 451 (1794).

FIG. 75.—GIBBAEUM GIBBOSUM (?) IMPORTED PLANT; NATURAL SIZE.

and a corolla "a little larger and paler than in *M. gibbosum*. Petals uniformly red, very obtuse. Stamens short, spreading, with white filaments and yellowish anthers. Styles 6, very spreading, as long as the filaments, with subulate subvillose recurved tips." *M. perviride*, Haw. *Obs. Mesemb.*, p. 136 and 451 (1794), and *Misc. Nat.*, p. 37.

South Africa. Locality unknown, introduced in 1792; collector not stated.

Var. *LUTEOVIDE*, N.E. Br. Leaves larger and longer than those of the type, yellowish-green. "Calyx 2-edged at the base, 6-lobed, the two outer lobes larger than the others, obtuse, keeled, the remainder flattish, subovate, retuse, with purplish, membranous margins. Corolla almost as in *M. perviride*; petals numerous, somewhat imbricate at the base, rather broad or cuneate-linear, often notched, pale reddish, with a darker mid-line, whitish at the sides at the base. Stamens nearly three times as short as the petals, spreading, white, with sulphur-coloured anthers. Styles 6, strongly plumose, at length spreading, but very short and much shorter than the stamens." *M. perviride*, var. Haw. *Misc. Nat.*, p. 37 (1803). *M. luteoviride*, Haw. *Synop.*, p. 226 (1812).

South Africa. Locality and collector unknown; introduced about 1795.

South Africa. Locality unknown.

The above description is compiled from that of Haworth, and represents all that is known of this species, for no plant at present in cultivation that is known to me corresponds to the above characters. But I have a plant, collected near Matjesfontein, and sent to me by Dr. Pole Evans under No. 968 that I strongly suspect to be *G. gibbosum*. It is reproduced in Fig. 75, and consists of a number of growths crowded upon a very shortly branched woody rootstock, forming a hemispherical tuft about 4 inches in diameter. Each growth is  $1\frac{1}{4}$ - $1\frac{1}{2}$  inches long and 7-8 lines thick at the lower part, stoutly conical-ovoid, tapering from about the middle into a conical obtuse point, slightly keeled down the front, with the smaller leaf (measuring from the base of the fissure) about half as long as the larger one; at first they are closely pressed together, afterwards more or less separating, smooth, quite glabrous, of a light and somewhat yellowish-green at the basal part, suffused with purple on the upper part, and with a faint glaucous tint. I have not seen a flower of it. If this proves to be Haworth's *M. gibbosum*, then Fig. 75 will represent its appearance as it grows under natural conditions. *N. E. Brown.*

(To be continued.)

**EDITORIAL NOTICE.**

**ADVERTISEMENTS** should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, W.C.2.

**Editors and Publisher.**—Our correspondents would oblige by delaying in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the EDITORS. The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.

### NOTES ON MYCORRHIZA PLANTS.

THE story of the Orchids and their root fungi (*Gard. Chron.*, March 4) teaches us how remarkable and varied may be the relation of the two partners in mycorrhiza plants. In general, Orchid plants are not formed with the roots free from fungus mycelium, nor can seeds produce normal seedlings unless sown under conditions favourable to infection.

The only other group of vascular plants in which a similar dependence has been discovered is the Heath family (Ericaceae). Here, as in Orchidaceae, we are dealing with plant species showing marked soil preferences and a well-defined distribution in Nature. How this distribution is affected by the double nature of the plant is not easy to say, but it seems probable that the two sets of facts may be causally related, since it is obvious that unfavourable conditions in the environment are likely to be intensified in the case of plants with which are regularly associated fungal species of a potentially parasitic nature.

Before giving a brief account of the remarkable state of affairs in Ericaceae, it may be of interest to review our modern knowledge of the mycorrhiza habit in general.

In the first place, the occurrence of mycorrhiza of the type described by Frank as endotrophic is known to be far more widespread than was formerly imagined. Not only is it a constant feature of the anatomy of certain families, e.g., Orchidaceae, Ericaceae, Epacridaceae, etc., but it is known to be present in a vast number of species belonging to widely separated groups of both Monocotyledons and Dicotyledons. Nor is the condition confined to flowering plants; it is found also among Gymnosperms, and is not infrequent in Ferns and their allies. Even among the lower plants an association between plant cells and fungus hyphae other than that of parasite and host has been recognised in Liverworts, although in the case of rootless plants the term mycorrhiza can hardly be used to describe it.

Turning once more to the flowering plants, we find in some species mycorrhiza invariably present, in others frequently recorded; affecting sometimes all the roots of the plant, or confined to the younger roots. It is rare for roots to show external features whereby the condition may be identified without microscopic examination. Within the root the distribution of mycelium varies from species to species, and not infrequently features are present pointing to an advanced stage of specialisation in the fungus and a high degree of adaptation between the two partners. Thus, the mycelium often develops special organs, the microscopic appearance of which indicates exchange of food materials, the evidence usually pointing to a balanced relation, in which now one partner and then the other profits. This interpretation is consistent with the fact that the fungus is doubtless always of the nature of a facultative parasite; that is, an organism which, given appropriate conditions, lives and grows at the expense of living tissues, but can also exist if supplied with dead organic material.

Among the many species known to form mycorrhiza may be mentioned the following:—*Asparagus officinalis*, *Colchicum autumnale*, and various species of *Allium*, *Scilla*, *Yucca*, *Agave*, and *Aloe* among Monocotyledons; *Anemone nemorosa*, *Teucrium*, *Scorodonia*, *Stachys*

*Betonica*, *Ranunculus* spp. and many other Dicotyledons.

In none of the plants, however, is the systematic position of the root fungus known, nor has any attempt been made to cultivate any one of them under experimental conditions such that mycorrhiza is not formed. Were all the facts available it is probable that a series could be traced leading from a relatively un-specialised condition in which a flowering plant suffers infection of the root-cells and tolerates mycelium in the tissues—a condition comparable with that of an individual who "carries" the bacilli responsible for causing typhoid fever or diphtheria without himself showing symptoms of these diseases—to that found in the Orchids and Heaths, where the very existence of the species is bound up with early infection of the seedling.

In Ericaceae, the facts are fully known in the common Ling (*Calluna vulgaris*), and there is abundant evidence that a similar state of affairs

microscopic examination of germinating seeds shows that an infection of the seedling tissues takes place regularly from the seed coat.

Observations such as these led to a successful attempt to sterilise the seed-coat without damaging the viability of the seed, and to the discovery that seeds so treated germinate normally, although the resulting seedlings fail to develop roots or to form more than a couple of pairs of leaves. The evidence pointed to superficial infection of the seeds by the root fungus, while still within the fruit, followed by inoculation of the seedling from the seed-coat at germination. All the necessary experimental proofs have now been supplied that this is actually what happens in Ling. This peculiar mode of infection involves the spread of the root fungus throughout the green, actively-assimilating tissues of the shoot and within the organs of the flower, a condition contrasting sharply with that found in Orchids, in which growth of the fungus is usually restricted to the colourless parts.

The remarkable fact emerges that the Ling plant, like a Lichen, is always of a dual character, involving the intimate association of the cells of a green plant with the mycelium of a fungus. Only for a brief space of time within the resting seed does the embryo retain its individuality as an independent plant. Subsequent to germination, mycelium soon becomes active and vigorous in the roots and spreads throughout the shoot, although in the green tissues it is greatly restricted in growth, and there is evidence of digestion by the cells of the leaf. A plant partnership indeed of a unique and remarkable kind! Cases of equally wide distribution of mycelium without obvious injury to the host are not unknown in certain of the parasitic "Smut" fungi, which attack cereals, but here the "balanced" relation between parasite and host is maintained only for a relatively short time.

Now what do we know of the bionomics of this curious partnership? On the one hand we have a green plant which can absorb water and salts and manufacture abundant sugar in its leaves; on the other, a fungus species which, when grown independently outside the plants, produces the characteristic spore bodies of the parasitic genus *Phoma*. The Ling plant grows naturally in poor, peaty soils, deficient in nitrates; the fungus can doubtless use the organic remains abundant in such soils as a source of the carbon and nitrogen compounds required for growth.

Speculation on the history of the relationship leads to some such view as the following:—The ancestors of the Ling plant suffered invasion by a parasitic fungus, which became widely distributed throughout the tissues. In the roots a relation was established which permitted the two organisms to carry on their nutritive processes without injury to one another, leading eventually to a symbiotic partnership with some degree of mutual exchange and benefit. The exact chemical nature of this exchange is difficult to establish with certainty, since it is not possible at present to produce a *Calluna* plant free from the fungal partner. In the shoot of the plant the balance of profit would tend to be on the side of the fungus, and it is not surprising to find that in this region growth of the invader is extremely restricted, and that there is evidence of digestion of mycelium by the cells of the leaf.

Within the fruits infection of the seed-coats takes place apparently during the late stages of ripening and may possibly be associated with the alteration and breaking down of the outer cells of the hard seed-coat. Certain it is that the seeds are shed carrying the hyphae of the fungus partner with them, and that their germination is regularly accompanied by a corresponding activity on the part of the mycelium which they bear.

Now in the case of plants like Ling and Heather, which often monopolise large areas of soil very poor in available salts of nitrogen, the suggestion is almost inevitable that possibly the fungus partner possesses in some degree the power of utilising the free nitrogen of the air as a source of food.

This matter has been studied experimentally

FIG. 76. — ARECASTRUM ROMANOFFIANUM, DIFFERENT VARIETIES, IN A PALM WOOD AT GOLFE JUAN, NEAR NICE (see page 153).

is widespread in the group. Throughout the family, mycorrhiza of a characteristic kind is invariably found, and the condition observed in Ling may be regarded as typical. The root system is richly branched, with a relatively large proportion of young, very slender roots, all of which develop mycorrhiza. Mycelium grows sparingly on the outside of the root, but fills the majority of the outer cells with masses of closely branched hyphae.

It had always been assumed that infection of the roots in Ericaceous species took place directly from the soil. This theory is at once discredited by the observation that the seeds of Ling, sown on moist blotting paper and protected from contamination, produce seedlings showing early and characteristic infection. Moreover,

and the evidence is very strong that such is indeed the case. This in itself provides an intelligible explanation of the successful competition of such slow-growing plants as Ling and Heather on poor soils, a fact otherwise difficult to understand in view of the small size and slow growth of their seedlings. Assuming that this is the correct interpretation the general relation is probably not unlike that between Leguminous plants and their nodule bacteria, although the details of the association may differ widely.

We do not yet know how infection by the fungus and root formation on the part of the seedling are related to one another in either the Orchids or Ericaceae. It is likely that the effect is one closely related to nutrition, and an attractive problem is presented by the possibility of replacing the stimulus produced by entry of the fungus in some other way, for example, by a supply of some special nutrient.

Many other observations bearing on these curious cases of symbiosis might be described, but enough has been told to enable the reader to judge how fascinating is the task of unravelling the complicated story involved in each one of them.

Partnerships they undoubtedly are, although the actual condition in both the Orchids and Ling at any given moment would perhaps be better described as one of mutual and balanced parasitism rather than symbiosis in the ordinary sense.

From the evolutionary point of view, all such relations between plants are of the nature of compromises brought about by the severity of the struggle for existence. Many of them are as yet only in the experimental stages; the Orchids and Ling represent extreme cases in which a relatively high degree of stability has been reached. In both cases the balance of profit is probably on the side of the vascular plant. The condition in Ericaceae is the most specialised yet recorded. The seedling is insured against risk of non-infection. Some problems of nutrition have doubtless been solved, but the premium paid by the plant has been a heavy one: the loss of independence and the presence of a parasite fungus throughout the vegetative tissues. *M. C. Rayner.*

## PALMS OF THE RIVIERA.\*

I now come to a Palm which is considered the most beautiful of the many grown on the Riviera, a Palm which usually goes here and elsewhere under the names of *Cocos plumosa*, *Cocos flexuosa* and *Cocos Romanzoffiana*, but which has been separated from the genus *Cocos* by Prof. O. Beccari and given the name *Arecastrum Romanzoffianum*. Prof. Beccari considers, though it seems to me hardly justified, that all these Palms—which he himself admits have rather different characters, especially as concerns the shape of the fruit and its endocarp, form only one species, with six varieties. All have most beautiful leaves resembling enormous ostrich feathers and of an extraordinarily graceful shape because the leaf stalk is erect and only the upper third of the leaf curves outwards with its point slightly bent down, so that a bouquet of utmost grace is formed by the crown of some fifteen or twenty-five leaves, which are of some three to four metres in length, and even longer in certain varieties. The colour of the leaves is a pure, glossy, dark green, which contrasts well with the whitish, grey, smooth, and mostly slender trunk so different from the trunks of the Palms which I have mentioned hitherto. As the leaves die, they fall off, leaving a distinct, annular mark on the whole circumference of the trunk, and as the leaves are not closely packed, as in many Palms, the annular marks of the fallen leaves are rather distant and show distinctly against the whitish trunk, constituting quite an ornamental feature. Everybody has heard of the famous royal Palm of Cuba, *Ore-*

*doxa* (*Roystonia*) *regia*, which is too tender to survive the winter on the Riviera (at least up to now it has not succeeded); certain forms of *Arecastrum Romanzoffianum* may be compared favourably with this famous royal Palm, to which they bear some resemblance, mainly on account of the shape and position of the leaves. The different varieties of *Arecastrum Romanzoffianum*, being indigenous in far distant parts of South America with different climates, are, as is to be expected, of different hardness here. Some varieties, such as *Arecastrum Romanzoffianum* var. *ensifolium*, from the country around Bahia, which has a tropical climate, are, of course, less hardy than others like *Arecastrum Romanzoffianum* var. *australe* from Argentina, Uruguay and Rio Grande do Sul. Some varieties have trunks thicker than others, and some have a crown of leaves more dense than others, but all are ornamental in the highest degree, and the extra-tropical varieties have proved so hardy, that they can be planted safely anywhere on the Riviera. Still, these remarkable Palms are not nearly met with so commonly as most of those I have mentioned before, because they do not as a rule succeed well in calcareous soil, and among a great number of seedlings one finds differences as to re-

and therefore *Arecastrum Romanzoffianum* is eminently adapted as a cover and shelter tree, where it is desired to produce in the highest degree the aspect of tropical scenery, for instance, that of a Palm wood. The flowers of *Arecastrum Romanzoffianum* are whitish and followed by large bunches of orange-yellow fruits of different size, from that of a Cherry to that of a small Plum, according to variety, and these fruits give an additional ornamental value to the plant. Of a few varieties, the flesh of the fruit is fairly edible, but of most, it is insipid and full of fibres. M. Paul Nabonnand, horticulturist of Golfe Juan, some thirty-four years ago pollinated *Butia capitata* var. *pulposa* with pollen of *Arecastrum Romanzoffianum* var. *australe*, and obtained a most strikingly characteristic hybrid, having intermediate characters, which I have described and named in *Riviera Floricole* as *Butiareastrum Nabonnandii*. As is often the case with hybrids, it has proved to be of rapid development, like that of *Arecastrum Romanzoffianum*, and much quicker than that of *Butia capitata* var. *pulposa*, but is as hardy as this parent, which is much harder than *Arecastrum Romanzoffianum*. *Dr. A. Robertson Proschowsky, Jardin d'Acclimatation, Les Tropiques, Nice, France.*

FIG. 77.—THE PARENTS OF *BUTIARECASTRUM NABONNANDII*; IN FRONT *BUTIA CAPITATA* VAR. *PULPOSA* ♀; BEHIND (THE TALL PALM) *ARECASTRUM ROMANZOFFIANUM* VAR. *AUSTRALE* ♂.

sistance to lime, which is the kind of soil found in most parts of the Riviera; but where the soil is only moderately calcareous, as is the case with most of the red clays, these Palms succeed fairly well. I know a plant lover who decided to possess this remarkable Palm, and tried hundreds of seedlings for years, with the result that he has obtained at last a dozen prosperous plants. However, the Palm never succeeds so well in other soils as in the micaschiste of Golfe Juan, a form of granitic soil, in which also Camellias, Rhododendrons and *Acacia dealbata* are quite happy, and in the gardens of Golfe Juan are seen specimens of splendid development and perfect beauty, having that pure dark green colour of foliage which these Palms never have in calcareous soils. The different varieties of *Arecastrum Romanzoffianum* attain different heights, varying from 12 to 25 metres or more, and groups of these tall, slender Palms, as they may be seen in different gardens of Golfe Juan, present a view of beauty not to be forgotten. On account of its very fine narrow folioles and crowns of leaves of no great density, this Palm does not shade the ground underneath too much for the growth of many other plants, including Palms and others that enjoy a position in half shade,

## BEGONIA F. OEBELII.

For some years after its introduction in 1872 this *Begonia* was extensively grown; but it is now met with much less frequently than at one time was the case. It is both an interesting and showy species, that differs from the garden varieties of the tuberous-rooted section in some well marked particulars. In the first place the tuber proves to be little more than a mass of fibres, the actual fleshy portion being but small. For this reason, it kept too dry during the winter, it will suffer more than the fibrous kinds. Another feature is that it is quite stemless, both the leaves and flower spikes being pushed up direct from the centre of the tuber. The flowering season, too, is later than those of the more generally grown members of the tuberous rooted section, excluding, of course, the newer scrotrana hybrids. It will frequently maintain a succession of blooms till autumn is well advanced, or sometimes till the early days of winter. Though the flowers are, as a rule, of a bright crimson or scarlet colour, seedlings show a certain amount of variation in this respect. This *Begonia* was introduced by Messrs. Froebel, of Zurich. *T.*

\* The previous articles by Dr. Proschowsky were published in our issues for May 1, June 12, July 10, September 7, November 20, December 18, 1920; May 12, April 30, June 11, October 8, November 19, 1921; January 21, February 11, 1922.

## INDOOR PLANTS.

## DRACAENA.

No ornamental foliage plant, taking into consideration the habit, freedom of growth, and distinct colouring of the foliage, is superior to the *Dracaena*, the members of which are indispensable for all kinds of decorative purposes. The late Mr. John Gould Veitch, on his return from his trip to Australia and South Sea Islands in the 'sixties of the last century, brought home some most beautiful *Dracaenas*, hitherto unknown in this country, and these became the forerunner of the handsome race which now stands out so prominently among fine foliage plants. They are peculiarly adapted to purposes of ornamentation, whether in the conservatory, the mansion, for table decoration, or for grouping at floral exhibitions. All are comparatively easy of culture

include *D. Jamesii*, *D. norwoodiense*, *D. elegantissima*, *D. Duchess of York*, *D. Mayii*, *D. The Queen* and *D. angustata*. Of medium leaved varieties we have *D. Exquisite*, *D. His Majesty*, *D. Lord Wolseley*, *D. De Smetiana*, *D. amabilis*, and *D. Youngii*. Among the broad-leaved section are *D. Baptistii*, *D. John Luther*, *D. Thomsonii*, *D. Lindenii*, *D. Mrs. Robert Turner*, and *D. Victoria*. This last is a very distinct and handsome plant, exquisite in colour. The broad leaves are striped with a little green on a golden ground. It is a beautiful foliage plant, and colours well in small pots. The members of this section require a stove temperature during their season of active growth, and a warmth of about 60° to 65° on winter nights. As the weather gets warmer during the summer a temperature of 70° should be maintained. A moist atmosphere is necessary, as the plants are subject to attacks of thrip and red spider, which are especially troublesome in houses that are kept

any other are *D. Godseffiana*, a plant of bushy growth with ovate, bright green leaves thickly spotted with creamy yellow; *D. Sanderiana*, a very distinct variety with narrow, bright green leaves striped and margined white—three or four cuttings rooted together in small pots are very useful for furnishing small vases—*D. Goldieana*, with leathery leaves of pea-green ground colour, barred and striped with dark green, and *D. Broomfieldii*, of which the variety *superba* is illustrated in Fig. 78.

The members of this section are best propagated, if the plants are small, from side shoots that will soon develop if the leading shoots are stopped. If the plants have strong stems and are furnished with leaves, cut the foliage off and lay the stem in a warm case in fibre or other light material, when it will soon throw out shoots suitable for use as cuttings. All these *Dracaenas* require a warm temperature. There are others suited to ordinary cool greenhouse or conservatory decoration, that require during the winter months a temperature from 40° to 45°. The plants of this section are most useful during the summer for outdoor purposes, such as furnishing vases, planting on terraces, or in sub-tropical bedding. The majority have green foliage, but a few have coloured leaves, although none have the beautiful bright tints of the warm-house section. The best are *D. indivisa* and its varieties, *atropurpurea*, with deep reddish brown foliage, *D. Doucettii*, a species with variegated leaves, and *D. Veitchii*, with bright red midrib. Others are *D. Brantii*, *D. australis*, *D. congesta*, and *D. Eckhautei*, a graceful variety of *D. rubra*. The majority of these plants are increased from seed imported from their native country. The seed should be sown as soon as it is received from the seedsman, and germinated in a warm house of 60° to 65°. When seed is not procurable, cuttings may be obtained by placing the stem in a warm case similar to the stove varieties to obtain cuttings. When the seeds begin to germinate, care must be taken in watering, for if kept too wet the seedlings will damp off. As soon as the seedlings are strong enough they should be potted singly. *John Heal, V.M.H.*

FIG. 78.—DRACAENA BROOMFIELDII VAR. SUPERBA.

with few exceptions, and afford as great a variety in habit, style of growth and colour of foliage as in any plant known. Their utility in a small state is well recognised, particularly, the light and more elegant kinds. They vary much in character of growth, thus affording abundant choice of material for all purposes.

The coloured leaved section may be divided into broad, medium and narrow leaved types. Those of the broad-leaved section make the finest specimens, and are best adapted for exhibition purposes. The medium leaved varieties adapt themselves to all purposes, while the narrow-leaved varieties are best suited for table decoration. Not only by importations has much progress with these plants been accomplished, but the hybridist has contributed some valuable and varied forms.

The following are a few of the best in their sections. Those of the narrow leaf section, suitable for table decoration or small vases,

dry. Syringe the plants well under the leaves once or twice daily in hot, dry weather. If grown in a very high temperature with a moist, close atmosphere, the foliage is apt to become tender and the coloured leaves do not last so long. Admit a little air on warm, fine days, but be careful not to expose the plants to cold draughts. For potting soil use a compost consisting of two-thirds good fibrous loam, one-third good leaf-mould or peat, with silver sand added. Well drain the pots. Shade the plants from the strong rays of the sun.

*Dracaenas* are easily propagated from cuttings. A good plan is to lay the old stem on moist cocoanut fibre or sandy soil, just covering it lightly, in a warm case or frame. Young growths will soon appear, and when sufficiently strong, may be taken off as cuttings and inserted in small pots. They will root in a frame with a temperature of about 70° to 75°. Other types of *Dracaena* forming very handsome, variegated plants quite distinct from

### HARDY HERBACEOUS PLANTS SUITABLE FOR NATURALISING BY SHADY WOODLAND WALKS AND DELLS.

CERTAIN well-known hardy herbaceous plants do remarkably well in cool, shady situations. They produce a charming effect planted in large, natural drifts either in open spaces, in woodlands, or partly shaded spots by woodland walks. *Campanula lactiflora* planted in masses is very fine as seen in the R.H.S. gardens at Wisley. The plants provide natural groups of beautiful pale blue, tall spikes, and flower luxuriantly from June until August.

*Aconitum pyramidale*, A. Sparks' variety, A. Fischeri and A. Wilsonii are all very effective in partial shade, and may be planted in bold masses, giving a fine display of blue and purple colours from July until September.

*Artemisia lactiflora* is a tall, stately white flowering, hardy perennial that produces white plumes of sweetly scented blooms, and does splendidly in moisture and shade. *Lythrum Salicaria* Rose Queen and *L. roseum superbum* are both excellent in cool, partial shade, producing a fine display of tall spikes of rich rosy-purple flowers from June until August.

*Solidago Golden Wings*, planted in large groups, is one of the best yellow, tall flowering plants. The branching spikes, forming pendulous sprays, show to advantage in bold groups in open glens. The plant grows six feet in height and flowers from August until October.

*Spirea Aruncus* has creamy white flowers on pendant spikes about four feet tall. *S. palmata*, rose crimson, and *S. venusta* are both fine for damp positions in partial shade. The effect produced by these Meadowsweets through July and August is excellent. *R. H. Holton.*

**NOTICES OF BOOKS.**

**The Perpetual-Flowering Carnation.\***

IN the preface of this "pocket edition" of the larger work, which, unfortunately, is out of print, Mr. Montagu Allwood apologises for his "presumption" in writing it. One is certainly inclined to the opinion that an apology is due from the writers of certain books on gardening subjects, but no apology is needed from an author who is recognised as one of the greatest authorities on his subject.

Mr. Allwood tells the whole life-story of the ideal Carnation plant which ultimately bears a profitable crop of high-class blooms, and he is convinced that anyone with a garden who reads the book and has a greenhouse must be fired with his own confident enthusiasm. One feels that it is so easy—almost fatally easy. All that is needed is to have a good stock, to give the cuttings a good start in life, and keep them going in the right way. Then, on second thoughts, one realises the need, insisted upon by Mr. Allwood, of meticulous care in all the various operations connected with the Carnation. As he writes on page 22, "the best care and the best position in the house is none too good for the young Carnation stock. It is folly to select only the best cuttings and take every care in their propagation, if this good work is to be destroyed later. Too often the young plants are looked upon as a sort of necessary evil, and, being non-productive of bloom, are crowded into any out-of-the-way place, regardless of surrounding conditions."

Besides treating of the perpetual-flowering Carnation in all its aspects, Mr. Allwood devotes useful chapters to the true border Carnation, perpetual-border Carnation, and the now well-known Allwoodii hybrids, and for the two last-named types he predicts a great future. *Dianthus Allwoodii*, in particular, is the garden plant in excelsis. With his well-known and infectious enthusiasm, Mr. Allwood contends that it is the best plant for forcing, for retarding, for the cool greenhouse, for the window box, the dry wall, and the herbaceous border—in short, for anywhere and everywhere. Anyway, Mr. Allwood has given the world a charming and useful race of Carnations of which one feels certain he has even better sorts for the future.

With a wise discretion, no lists of best varieties are given. It is fully realised that such lists all too soon become out of date, and they can always be obtained from the various current catalogues. But there is a sufficiency of illustrations which tell their story excellently, and altogether the book can be confidently recommended to all interested in Carnations.

**THE FLORISTS' TULIP.†**

(Continued from page 140.)

THE breaking is accompanied by certain other changes in habit; the Tulip does not grow so tall and is less vigorous and prolific, the leaves take on a peculiar mottling of lighter and darker green, the stem becomes streaked with colour.

From the first the florist has treasured these broken varieties, and from the earliest days of the Dutch Tulip cult he began to lay down degrees of excellence in the marking, and bred for points. We can trace clearly enough the progress of the fancy; during the seventeenth and eighteenth centuries the Dutch florists led the world, and they sought for clear and finely pencilled markings. Towards the close of the eighteenth century they drew a distinction between feathered flowers, which had only pencilled markings along the edge of the petal, and flamed flowers, which, in addition to the feathering, carried a beam of marking up the centre

of the petal. But about the beginning of the nineteenth century the fancy which had been common to all countries passed over to England, and British florists gradually evolved a much severer standard.

In the first place they turned their attention to the base of the flower. One of the wild parents of the garden Tulip must have had a blue blotch at the base, and though some of the old Dutch Tulips had a clear circle of white at the base, in the majority it was still more or less stained with blue. The English florists made the clean base and clean filaments to the anthers a *sine qua non*; any speck or stain disqualified the flower, and many were the heart-

Show began to be held alternately in the north and in the south, but, alas, not many years later, began the decay of the fancy. The Tulip had always been mainly a working man's flower, and from the middle of the nineteenth century the working man began to lose his garden. The spread of the town hit the London growers first, but the same process gradually overtook the men of the midland and northern manufacturing towns. In the early 'sixties there would be at least 100 Tulip shows a year held in public-houses round the smaller manufacturing towns of Lancashire, Yorkshire, Cheshire, Nottinghamshire and Derbyshire. Only one lasted on into this century. Nowadays there is a local show

FIG. 79.—*DRACAENA FRAGRANS* VAR. *LINDENII*, IN FLOWER (see p. 154).

burnings through old favourites being cast out because of their lack of "purity." It was the London florists, men who had their gardens in Clerkenwell or the City Road between 1810 and 1840, who carried the day for purity; the northern growers were more concerned about marking, a point on which the southern growers were inclined to be weak. Both sides concurred in a standard of form. The old Tulips were inclined to be long and lop-eared, with pointed petals; the English florists insisted on a short cup and broad-rounded petals, half a hollow sphere when open. The standard was fully established about 1850, when the National

at Wakefield, and a National Show which owes a somewhat precarious existence to the hospitality of the Royal Horticultural Society. There are perhaps a hundred growers of the English florists' Tulip, all told; and though I am still raising seedlings in the pursuit of the perfect flower, there have only been two or three others doing so in my time. The Dutch raisers dropped out long ago. There seem to be no florists in Holland now; only raisers of bulbs for sale. Years ago I saw in Provence the ruins of what I believed to be the last French collection, and America has never taken up the fancy.

(To be concluded.)

† A lecture delivered by Sir Daniel Hall at a recent meeting of the London School Gardening Association.

## RAISING ALPINE PLANTS FROM SEED.

THE simple, extremely interesting, and generally profitable method of raising the majority of rock and alpine plants from seed may not be generally known to lovers of alpine plants. Quite extraordinary results may be obtained by only ordinary care, when this method is understood and followed along rational lines. Plants raised from seed vary to some extent in colour, in form and sometimes in habit; this variation, however, is greatest among what are known as florists' flowers, and, although always more or less present in the progeny of species, for our present purpose, in dealing with rock plants, this variation may be entirely disregarded. I have an English seed catalogue in front of me, from which I take the following three dozen genera, some of which contain quite a dozen species, so that at a rough calculation there are probably something like 150 different sorts of rock plants offered as seed by this firm alone. The genera are as follow:—*Acaena*, *Actinella*, *Adonis*, *Aethionema*, *Alyssum*, *Androsace*, *Anemone*, *Antirrhinum*, *Arenaria*, *Asperula*, *Aubrieta*, *Campanula*, *Dianthus*, *Draba*, *Erinus*, *Gypsophila*, *Geranium*, *Hutchinsia*, *Hypericum*, *Iberis*, *Leontopodium*, *Lithospermum*, *Onosma*, *Papaver*, *Phyteuma*, *Primula*, *Ranunculus*, *Saxifraga*, *Sedum*, *Silene*, *Thymus*, *Tunica*, *Veronica*, *Viola*, *Wahlenbergia*, and *Zauschneria*.

Having selected the species or varieties most likely to suit the purpose of the grower, sowing may be done as soon as the seed comes to hand in spring, March being one of the best months for this work, although it must be remembered that certain alpine are best sown within a few days after harvesting the seed, notably *Gentiana* and *Primula*, while bought seed of these may lie dormant, after sowing, for quite twelve months. Should germination fail within a normal period, stand these pans of seed in a north aspect, keeping them moist and the pans covered with glass, in the hope that germination may take place at a later period.

The method I have successfully practised for years is to sow in pots, pans or shallow boxes, the finest and smallest seed in pots and pans, larger seed in boxes. These receptacles are provided with liberal drainage, in the form of potsherds, covered with a few pieces of rough compost. The remaining space is filled with a fine compost, consisting of yellow loam, leaf-mould and sand in equal parts. The soil is made moderately firm and level on the surface. Seeds of such plants as *Erinus*, *Papaver* and *Tunica* are extremely small and require a very light covering of soil, whereas those of *Dianthus*, *Gentiana* and *Primula* will bear covering to a depth of  $\frac{1}{4}$  of an inch.

Great care must be exercised in watering the seed pans, and to those inexperienced in watering fine seeds with water pot and rose I would suggest a safe method is to stand the pots or pans almost to their rims in a tub of water. By this means the seed is not displaced, as may readily occur from careless use of a waterpot. After the surplus water has drained away stand the seed pans in an ordinary glasshouse or in a frame on a slow hot-bed and cover each pan or box with a square of glass. This helps to retain moisture over the maximum period and thereby hastens germination. Then, as the seedlings appear, gradually tilt the glass cover and admit air until eventually the glass is removed entirely.

Once germination takes place, the seedlings should be kept well up to the light, and from this stage onward an unheated garden frame will give the best results, using sunheat alone to maintain a growing temperature. When the seedlings are sufficiently large to handle, prick them out singly into pans or boxes, using a compost similar to that advised for seed sowing, to which the addition of some rough grit and crushed brick or mortar rubble is added. In pricking out and at all subsequent pottings keep the soil moderately firm, otherwise growth will be coarse and sappy and the plants will give trouble in hardening them off before planting

them permanently out-of-doors. When the plants have attained a fair size, they should be potted singly in small pots, and either plunged in nursery rows or in beds of coal ashes. This system simplifies watering and results in stocky, hard-grown plants, which rarely fail to give satisfaction when used in the permanent scheme of the garden.

Reference has been made to alpines that frequently fail to germinate when first sown, and the course to follow in these cases has also been indicated.

There is another class, of which *Ranunculus* and *Haberlea* are typical, in which the seed is exceedingly fine, and the seedlings make very slow growth. Such seeds should be sown very thinly and considerably more grit should be used in the compost to facilitate the free passage of superfluous moisture.

The great majority of rock and alpine plants that can be raised from seed will flower in the year following that in which they were sown. Plants raised and grown in the manner indicated will give a good account of themselves in whatever garden scheme they are employed: the finer kinds will, perforce, have precedence in kindly crevices and fissures on the rock gardens. More robust sorts will form ideal material for clothing the bolder slopes of the same, or to beautify the rugged courses of dry walls, while paved paths, garden steps and edging to flower borders are suggestive positions where seedling rock plants will display themselves to good effect. *Thomas Smith, Coombe Court Gardens, Kingston Hill.*

## EARLY FLOWERING CHRYSANTHEMUMS.

THOSE beautiful Chrysanthemums, which, in the early autumn, brighten our gardens and lend colour and charm to our homes, may be divided into two sections.

The first of these sections is represented by varieties of the Masee type, dwarf and bushy in habit, and by sorts like the old *Madame Desgrange*, with its more upright growth, yet possessing the inherent quality of commencing to flower in August and September. These may strictly be termed "early-flowering." The second section, which, if left to itself, would not commence to open its terminal buds until October is well advanced, forms a distinct class.

With proper management, members of the second section will produce flowers on long stems from mid-August onwards, and it is with this group that these notes are principally concerned.

Naturally, the story should begin when the last flowers are cut and the stools ready to lift, but the time is rapidly approaching when the young plants should be ready for transference to their permanent positions. At all events, the end of April should see the business started and it should be completed before May is out.

I am assuming that the cuttings were rooted in cold frames, the lights of which may be removed on all favourable occasions, as it is most essential to maintain a stocky growth; and, at the same time, to harden them so that the young plants will not suffer from the frosts that are often experienced during the month of May, after they are planted out.

In many gardens, the usual place assigned to early Chrysanthemums is the herbaceous or mixed border, on the share-it-amongst-you principle. In consequence of this, the plants often present a straggling appearance and the resulting bloom is anything but pleasing and attractive. A border or piece of ground quite free from other plants should, for preference, be set apart, with some provision for protecting the blooms from early frosts and fogs; and, for this latter purpose the best material is good canvas or lights, or a combination of both.

The ground should be deeply-dug or trenched and enriched with manure, as some of the varieties are strong growers and require a rich soil to bring their blooms to perfection. When planting, place the young plants at least 18 in. apart each way; in fact, 2 ft. from row to row

would be better. Water the plants in to settle the soil round them and tie each one to a Bamboo cane.

Subsequent treatment is much the same as that followed when producing large blooms in pots; but, instead of three blooms, from nine to a dozen may easily be carried by most of the varieties now grown for the market. I refer here more particularly to such sorts as *White Countess*, *Cranford Pink*, *Cranford Yellow*, *Cranfordia*, *Soliel d'Octobre*, *Framfield Early White* and *Almirante*.

Generally speaking, the plants only need stopping once, and that just before the break bud appears. After thinning out the growths to the number the plants are to carry the resulting buds are taken and rigid disbudding of all other growths must be followed up if the finest flowers are desired.

In very dry weather watering is necessary after the buds are taken, and this class of early Chrysanthemum will repay growers for the extra time and attention given, as they may be lifted and potted, without much loss in size, if the buds are not too far advanced. They are much appreciated in the Midlands by artisans who gather in small societies, and the rivalry is very keen in producing the best specimens in their gardens for the shows, with only a sheet of glass or canvas over them.

The after-care of the first section, which opens its sprays without any special treatment (though even here partial disbudding is advantageous) in the period of growth, is very similar. These varieties should be struck early in the year, in a low temperature; they must then be encouraged to make healthy growth either by potting on or bedding out in cold pits, for a drawn or attenuated plant will never produce blooms of the quality which all growers desire.

Most of the spray varieties require to be stepped twice, and this work should end not later than the middle of July; but it is not possible to go into this subject with any wealth of detail, on account of space. The varieties are numerous and many possess peculiarities of their own which must be noted before entire success is assured. To appreciate these autumn flowers at their best they should be seen growing as they are handled by large growers and they then form a sight that is not easily forgotten. *W. T. A. Roots.*

## FORESTRY.

### THE GIANT THUYA.

It must be half a century since the late Mr. Peter Lawson, of Edinburgh, an enthusiast in arboriculture, whose name is perpetuated in the Lawson Cypress, told me that he believed that, among all the trees that had been introduced to this country from America, *Thuja plicata* (known at that time as *Thuja Lobbi* or *Menziesii*) would prove to be the most valuable in British woodlands. Very few planters seem to have acted on Lawson's advice, for although there are plenty of fine specimens of this species in most parts of our island, I know of only one place, Benmore, in Argyll, where it has been grown in close forest long enough to develop its quality. At Benmore the late Mr. Hunter planted nearly 2,000 acres of hillside and low ground with a great variety of Conifers between forty and forty-five years ago; and although this *Thuja* has suffered suppression where it was mixed with Douglas Fir, it has proved a rapid producer of straight, fine timber where it was planted pure or mixed with Larch. About the quality of that timber, Professor Sargent reports that it is "very valuable; it is light, soft, and easily worked, and so durable in contact with the ground or when exposed to the elements, that no one has ever known it long enough to see it decay. . . . It is largely used in Oregon and Washington for the interior finish of buildings." A remarkable example of the durability of this timber is given in *Elwes' and Henry's Trees of Great Britain and Ireland* (vol. II, p. 236), where there is shown a photograph of a Western Hemlock (*Tsuga Albertiana*) about 150

years old, grown from a seed germinated on the fallen trunk of a huge *Thuya*, the timber of the latter remaining perfectly sound.

It seems unfortunate that more use of this fine tree has not been made by owners of British woodland. Planted as a specimen, more or less isolated, it gives no right impression of its behaviour in forest, for its lower branches spread wide and root themselves, and the timber is rendered coarse by the persistence of side branches. But grown in close canopy it produces fine, clean boles, and is singularly free from the tendency to form double or treble tops, which is the tiresome habit of the Lawson Cypress. It comes most readily from seed—we raised 70,000 here from fifteen shillings' worth—and in the nursery it forms excellent roots, rendering it very easy to plant out. In two respects only have we found it impatient of our climate; first, it suffers from exposure to wind off the sea; and, second, it is liable to be killed when young if planted in a "frost hole." We planted about 20,000 pure in 7 acres of low-lying peat, and lost them all; whereas those planted in the same season on sound land are now over 30 feet high and growing vigorously.

Introduced by Lobb in 1853, there are already many specimens in the British Isles of a height verging on 100 feet, which is only half the stature it attains in Oregon and British Columbia. Grown in this country under favourable forestal conditions, the timber is probably at the height of its value at 80 or 90 years, before massive buttresses are formed, which often indicate that the centre of the trunk is hollow. *Herbert Maxwell, Monreith.*

## FRUIT REGISTER.

### RASPBERRY PYNE'S ROYAL.

I HAVE grown this fine Raspberry for a few seasons and can highly recommend it for dessert purposes, the fruits being large, dark coloured and of excellent flavour. The variety is practically a continuous cropper from August to October. It has one peculiarity of throwing up numerous growths from the base of the stool to a height of about 2 feet, which crop almost to the ground level, and, after fruiting, die away. At the same time, there are usually 2 or 3 strong canes, which grow about 5 or 6 feet high and show no signs of fruiting until the following season. The flower clusters are continually produced throughout the whole season, and fruit and flowers are seen in all stages on the one cluster. *G. Horne, Craigavad House Gardens, Craigavad, Co. Down.*

### APPLE GRAVENSTEIN.

I HAVE always wondered why this Apple is not more generally planted in counties suited to Apple cultivation.

It is a variety of great utility, either for dessert or culinary purposes. The tree is hardy, healthy, and a good bearer when planted with other sorts. The fruits are handsome and of first-rate quality. This Apple may be grown as a bush, half-standard, or espalier. The fruits are in season until December.

### APPLE NANNY.

THIS variety of Apple ranks in flavour with Cox's Orange Pippin and Margil combined. The growth of the tree is not over strong, therefore, the bush, cordon or espalier methods of training suit it best. The skin is greenish-yellow, streaked with crimson; the flesh is yellow, soft, sugary and very juicy, combining all the qualities of an excellent Apple. The season of this old variety is November, but it is sometimes ripe in October on warm soils. *Pomona.*

### DUAL-PURPOSE APPLES

THE remarks published in your columns under the above heading cause one to reflect, and to ask, whither are we tending? Also, where have we been? Surely a well flavoured Apple is as admissible among culinary Apples as among dessert varieties, and quite as welcome, especially after partaking of a pie, tart, or pudding made with one or other of the nasty-flavoured varieties which have

scarcely any other merit than that of mere size. True, some of the best-flavoured dessert varieties are poor bearers, and their fruits can ill be spared for the oven or the pot; but in that old variety named Reinette Grise we have at once a good and almost constant bearer and a highly flavoured Apple. Dr. Hogg, in the fifth edition of his *Fruit Manual*, published in 1884, says of it: "A very fine dessert Apple of first-rate quality; in use from November to May. The tree is healthy and vigorous and an excellent bearer. One of the finest old French Apples." I can endorse, without qualification, that opinion, which tersely describes its qualities.

In the spring of 1896 I had the privilege of planting in an experimental garden one standard tree of Reinette Grise with twenty or thirty other varieties, and careful records were kept of their behaviour in the matters of flowering and fruiting. The first 4 years were ignored for the present purpose (the report) and given to the tree to make growth. This tree of Reinette Grise flowered during 20 years and produced fruit during 20 years,

### APPLE BUSHEY GROVE.

THIS new Apple has been submitted to the Fruit and Vegetable Committee of the R.H.S. on several occasions recently by Mr. J. T. Good, Bradfield, Bushey Grove Road, Bushey, and on January 31 last it received an Award of Merit. Specimens were exhibited at the meeting on March 14, to show the long keeping qualities of the variety, and one of the fruits shown then is illustrated in Fig. 80.

The variety was raised from Queen crossed with Bismarck, and shows the influence of both the parents, but the shape is somewhat angular and the basal part has four or five slight angles. The fruits are of pale yellow colour, freely marked and spotted with crimson on the side next to the sun. The eye is set in a moderately large cavity, and the segments are almost closed. The stalk is about three-quarters of an inch long in a narrow, conical depression. The flesh is very white, juicy, and of good flavour. The texture is soft, and the variety will appeal to those who prefer a sweet, soft Apple for dessert.

FIG. 80.—APPLE BUSHEY GROVE; A NEW LATE CULINARY AND DESSERT VARIETY.

excluding any produced prior to 1900. The total of the 20 years' crops was 1,466½ lb., or an average of over 73 lb. per year for 20 years, and an average of a trifle less for 21 consecutive years—69 lb. 10½ oz., to be exact.

Among 24 varieties, which include such as Bramley's Seedling, Beauty of Kent, Rymer, Maltster, Queen, Gloria Mundi, Grand Duke Constantine, Lord Grosvenor, Galloway Pippin, New Hawthornden, Greenup's Pippin, Ecklinville Seedling, Lord Sulfield, Lodington Seedling (Stone's Apple), Cox's Orange Pippin, King of the Pippins, Reinette Van Mons, Norfolk Bearer, and Golden Spire, it ranks eleventh in order of cropping. Norfolk Bearer is a good companion to Reinette Grise for cooking and for flavour; but under equal conditions of cultivation, it is not so good for bearing, being twentieth in order in that respect.

One hundred and three varieties of Apples were grown in the small garden mentioned, but not all were planted at the same time. The newest as well as the oldest sorts were represented. If whiteness of the Apple after cooking is considered a *sine qua non*, then Reinette Grise will disappoint in that respect, the fleshy part being yellowish, and it is not very beautiful at any time, except to the eyes of its lover. For dessert it is richer after January than before that month, and is in season until the end of April. *J. Udale.*

## HOME CORRESPONDENCE.

[The Editors do not hold themselves responsible for the opinions expressed by correspondents.]

**Voies** (see pp. 95, 106, 118).—I have read with interest Mr. Mark Hovell's advice on trapping mice and voles. I venture to give an experience I had during the winter 1920-1921. The plants in our earliest Cabbage bed at the south end of the garden, containing about 350 plants, were being continually eaten off. We filled the rows one day; the plants were gone the next. I thought the damage was being done by birds, so had nets put over the bed. The Cabbages, however, were still eaten off. I had traps for mice set along the wall, baited with cheese, but failed to catch any. One day the garden boy saw mice in the potting shed. He set two traps baited with a piece of Potato, and during the day caught ten mice. I changed the bait on the traps by the wall, and put Potato on instead of cheese, with the result that the first night's catch was 12 mice from 12 traps. On the second night I increased the number of the traps to 18 and examined them at 10 at night, when 10 mice were trapped, and next morning I caught another 18. Altogether, or up to date, 250 mice have been caught, including both the short-tailed and long-tailed kinds. Kestrels visited that end of the gar-

den during the day and the birds dived down by the wall very frequently. *D. H. Dunn, Hafod, Devil's Bridge, Aberystwyth.*

**Iris unguicularis.**—So far as my experience goes, *Iris unguicularis* gives a longer season of flower than any other species. Here it usually commences to bloom as early as October and continues to produce an abundance of pale mauve flowers until the beginning of April. I know of no plant which, during this period, produces a better return for the small amount of trouble entailed. I find the best and most serviceable method is to gather the flowers when quite in bud, and if these are arranged in receptacles containing water or moist sand they open perfectly and last for a very long time. *I. unguicularis* grows about 18 inches to 20 inches high and has rush-like foliage, and its flower stems are from 9 inches to 12 inches in length. The best time to divide and replant this beautiful species is at the end of March or early in April. The site chosen should be one receiving the maximum amount of sunshine, and I have proved that the foot of a wall or fence is the best position for the plants. The best medium for planting in is a good loam, with an abundance of old mortar rubbish, ballast or broken bricks added. *R. H. Croxford, Weston Park Gardens, Stevenage.*

**Roofing of Garden "Fruit-cages."**—I should take it as a kindness if you could find space for this note, and should be grateful to any of your readers who would give me their experience of garden "Fruit-cages." There seems to be much difference of opinion as to the effect upon the plants beneath a galvanised wire-netting roof; some gardeners maintain that it is harmful to all fruit, some that it is injurious to Strawberries only, others that it is harmful to none. It is really quite an interesting question, even if it has all been discussed before. Put briefly, the points seem to be these: Injurious or non-injurious? If injurious, is it only so to certain fruits, e.g., to Strawberries? Is the injury due to chemical action? Does the free hydrochloric acid in the damp air, acting upon the zinc, form a chloride which drips injuriously upon the plants? (I have been shown cracks in fruit said to be due to drip from galvanised netting.) Or, again, is it a question of radiation?—i.e., is it possible that temperature is adversely affected, during heat or cold, in an enclosure contained in a large area of small-meshed metallic netting? Netting made of twine—as is well known—excludes frost from wall-fruit; does wire-netting act in the same way? Presumably not. If drip from a galvanised wire-netting roof be harmful (whether to Strawberries or any other fruit), is the growth and bearing-power of the plant affected, or is the damage confined to the actual berry or drupe? Lastly, if the cause of the damage be chemical, does this only apply to galvanised netting in the first year? Does the damage lessen from year to year, and finally cease, as all the zinc becomes converted? *Aubyn Trevor-Battye, Ashford Chase, Petersfield, Hants.*

**Do Plants Know Time?**—The question asked on pp. 31 and 118 requires more explanation than anyone has yet been able to give. The farther one goes and the more often one makes observations the more complicated the subject becomes. A good explanation can be given in some cases, but in others the periodic movements have become hereditary, and not directly dependent upon change of environment. For want of a proper explanation the opening and closing of flowers, particularly those that open during the evening and night, are termed autonomous movements. Probably most flowers that open and close a number of times can only do so while growth is incomplete, and the movements cease with the completion of growth. This would apply to Gentians, Anemones, the Daisy and other Composites. These and many others have anthocyanin on the outer or under side of the petals, and the rays of the rising sun are converted into heat, causing the flowers to open. *Gentiana verna* on the east or south side of a rockery will open widely before those in a northern aspect close by. *G. nivalis* has been observed to open and close repeatedly in

the course of an hour, if the sun shines and gets obscured by clouds alternately. The floral clock constructed by Linnaeus does not hold good for more southern latitudes. At Upsala, *Nymphaea alba* opens at 7 a.m., but thirteen degrees south of that it does not open before 8 to 9 a.m. During the summer the sun rises earlier and sets later in northern than in southern latitudes, and closing is longer delayed. This holds good for Hepaticas in a mountain valley, and at a higher elevation on the mountain, the opening being delayed on the latter. Tulips and Crocuses can be opened at night in a warm room, although they may have been closed all day. The autonomous movements of night-flowering plants are connected with night-flying insects and heredity. *J. P.*

**Carnation Bis Greenfield.**—This variety is undoubtedly the best scarlet Carnation I know. The plants are strong-growing and produce large flowers of good substance, which do not split at the calyx. The stems are long and stiff. As this variety does not seem to be generally known, I should like to know why? *W. J. Carter (Foreman), Leighton Hall Gardens, Welshpool, N. Wales.*

**Violets in Frames.**—I herewith send a photograph [not reproduced—Eds.] and a few blooms of Marie Louise Violets, as grown in these gardens. I often see queries in your paper from correspondents with regard to the cultivation of these flowers, and perhaps my experience may be of use to some. I have tried autumn planting from the open ground, also plants in pots, but I have found that the best plan is to strike the cuttings or side shoots during April, make up the frame, and plant out the cuttings, as soon as they are rooted, direct in the frame. Our frame is made of old 4 inch by 2 inch rafters, fitted up roughly to take a couple of lights, which are used elsewhere when not required for the Violets. Since adopting this plan, I have never experienced a failure. My method of cultivation as regards soil, etc., is the same as advised in your columns from time to time. *W. H. Clark, Bussock Wood Gardens, Newbury.*

**Spraying a Neighbour's Plants.**—Recently a neighbour syringed his fruit trees with Berger's lime-sulphur wash. On my side of the fence I have a nursery bed and plunging ground, in which there are some 800 choice Alpine plants, mostly in pots, which were thoroughly drenched with the mixture, some having the appearance of a slight fall of snow. I spent some hours in trying to wash the stuff off, with not a great deal of success, as it had dried on before I discovered what had been done. Plants with broad foliage are badly marked and look very sorry for themselves. I shall be very glad if you can kindly tell me whether the health of the plants is likely to suffer. The incident may interest your readers, as it is one which might easily occur in other suburban gardens. I know nothing of the properties of winter washes except that some are caustic and some even poisonous, and, while beneficial to fruit trees, it seems to me cannot be otherwise than undesirable when applied to young alpine plants. Is one's neighbour liable for damage resulting from squirting liquids over his neighbour's plants? Their replacement value, at the low average of 1s. each, is £40. But, apart from this aspect of the matter, do you consider that I am unreasonable in suggesting that no man is justified in using materials in such a way that may possibly do damage to another's property, or, for that matter, throwing anything, harmful or not, over his fence into his neighbour's garden? I might add that my neighbour has expressed regret and the hope that no lasting damage has been done, but that is a poor consolation for the loss of plants, many of them the result of hybridising and selection, the value of which to the owner cannot be expressed adequately in terms of money. *S.*

[Your neighbour has committed a trespass in acting as he has done, and if it is your intention to claim damages you should proceed to give him notice accordingly.—Eds.]

## SOCIETIES.

### ROYAL HORTICULTURAL.

MARCH 28 and 29.—A delightful display of spring flowers greeted those Fellows of the Royal Horticultural Society who attended at Vincent Square on the above dates. The attendance was good, and although the exhibits were not so extensive as on some occasions, they were numerous, as may be gathered from the statement that no fewer than thirty-four groups were judged by the Floral Committee. Medal awards were numerous, and Messrs. Sanders were granted a Gold Medal for Orchids. The latter were admirably shown, and included several novelties of considerable merit. Daffodils, Tulips, flowering shrubs, Camellias, and Alpine plants were other subjects prominently displayed.

### Orchid Committee.

*Present:* Frederick J. Hanbury, Esq. (in the chair), Prince Shimadzu, James O'Brien (hon. secretary), J. Wilson Potter, R. Brooman White, Richard G. Thwaites, W. J. Kaye, Chas. H. Curtis, S. W. Flory, Arthur Dye, Frederick K. Sander, Stuart H. Low, T. Armstrong, A. McBean, H. T. Pitt, J. E. Shill, C. J. Lucas, J. T. Barker, and Gurney Wilson.

### AWARDS.

#### FIRST-CLASS CERTIFICATES.

*Odontoglossum Garnet (Lambearianum × eximium Le Papillon)*, from Messrs. J. and A. McBEAN, Cooksbridge. The small plant bore four flowers of perfect form and large size, well showing the influence of Messrs. McBean's strain of *Odm. eximium* as parents. The greater part of the segments is of rich reddish violet, the margins and tips clear white. The lip is broad and finely blotched in front of the yellow crest, the exterior portion being blush white with mauve markings.

*Sophr. Laelio-Cattleya King George (S.-L.-C. bletchleyflora × C. King George)*, from Messrs. FLORY AND BLACK, Slough. A decided advance in size and colour in its section, the flowers being equal to *Laelio-Cattleya*, but with unmistakable evidence of the *Sophronitis*. The sepals and petals are rosy-mauve, with a gold shade; the lip is entirely ruby-purple with light lines at the base.

### AWARDS OF MERIT.

*Dendrobium Perfection (Euryalus rubens × nobile nobiliss)*, from Messrs. SANDERS, St. Albans. A grand *Dendrobium* and a great improvement on *D. nobile nobiliss*, which is in itself a great recommendation. The splendidly flowered plant bore numerous large and finely formed flowers of rosy-mauve tint on a white ground; the broad lip has a deep maroon base surrounded by white, the tip being coloured like the petals.

*Cymbidium Alexanderi var. Imperial Prince*; a superb flower, ivory white tinged with rose and with well-displayed reddish-purple markings on the lip. From Messrs. J. and A. McBEAN.

### PRELIMINARY COMMENDATION.

*Odontoglossum × Llewelyn (amabile splendens × Georgius Rex)*, from H. T. PITT, Esq., Rosslyn, Stamford Hill. Shown with its abnormally large first flower, this new hybrid is of great promise. The segments have two-thirds of their surface coloured claret-red with the white mid-rib showing at the base. The lip is coloured like the petals, but with mottled light rose front.

### GROUPS.

Messrs. SANDERS, St. Albans, were awarded a Gold Medal for a splendid group admirably arranged, the principal plants being elevated and all set in green moss. This tasteful arrangement had much weight with the Committee in giving the highest award to the exhibit.

The main features of the group were finely flowered *Dendrobiums*, all of which had been grown and developed at St. Albans. There was great variety in the various classes and all were good, but the finest and most brightly coloured was the new *D. Enchantress* (*Sybil × nobile nobiliss*) which some preferred to *D. Perfection*, which secured an award. A *Sophr. Laelio-Cattleya*

from *C. Hardyana* × *S.-L.-C. Laconia* is a large and grandly coloured flower, the best of its class; and among the Cymbidiums which were shown in many and fine varieties, *C. Ceres* (*P. Ansonii* × *insigne*) was very good. Many good white Cattleyas and finely coloured Laelio-Cattleyas were also shown, and among species, the singular *Arachnanthe Clarkei*; the rare *Coelogyne Lawrenceana* and some curious smaller species were noticed.

Messrs. J. and A. McBEAN were awarded a Silver Flora Medal for an excellent group rich in specially good *Odontoglossums*, including home-raised *O. crispum* and the best form of *O. c. xanthotes*. *O. Dictyne magnifica* is a finely coloured novelty; *O. Triumphosum*, a very elegant yellow ground *O. cirrhosum* hybrid, and others, with the fine form and shape of their noble *O. Everest*, twenty-six distinct hybrids being shown. Scarlet colour was given by the showy *Odontioda Diana* and others of its class, and among the Laelio-Cattleyas the forms of their *L.-C. Eunice* were attractive.

Messrs. STUART LOW AND CO., Bush Hill Park and Crowborough, were awarded a Silver Flora Medal for an interesting group containing great variety, Cattleyas, Laelio-Cattleyas and *Sophonitis* crosses being specially good. Among the many pretty novelties *Odontioda Ulter* (*Odm. Othello* × *Oda. Charlesworthii*) with rich chocolate-red sepals and petals and yellow lip with red markings; *Brasso-Cattleya Invicta* (*C. Octave Doin* × *B.-C. Digbyano Mossiae*), a charming mauve flower with yellow disc to the prettily fringed lip, and *Sophr.-Laelio-Cattleya Argonaut* (*L.-C. Tunis* × *S.-L. Orpetii*) a very distinct and pretty hybrid, were specially attractive.

H. T. PITT, Esq., Rosslyn, Stamford Hill (gr. Mr. Thurgood), secured a Silver Flora Medal for a group containing examples of most of the showy Orchids of the season. Among the *Odontoglossums*, *Odm. St. James* is a grand example and good in all respects. *Odm. Rossii majus* of the true type brought us back to the best days of the *Odm.* species era; *Odm. Wilkeanum Pittianum*, and others of Mr. Pitt's collection of this hybrid shows that nothing in hybrid *Odontoglossums* has quite passed them, although they have helped to make many superb hybrids. Mr. Pitt always shows an interesting selection of species, the *Chondrorhyncha Chestertonii* being almost perennial, and interesting species of Cymbidiums, now getting rare. Some good *Miltonias* and Cymbidiums were also shown.

Messrs. HASSALL AND CO., Southgate, received a Silver Flora Medal for a pretty group of specially good Cattleyas and allied hybrids. *C. Tityus* var. *The President* is a very good companion to Messrs. Sanders' *C. Tityus Wedding Bells* which worthily secured a First-Class Certificate; seven forms of the pure white *C. Douai*; the rare pure white *C. Luddemanniana* Empress and the pink-lipped *C. L. Stanleyi*, well represented the light section. Some good Cymbidiums and other hybrids were also shown.

Messrs. FLORY AND BLACK, Slough, were awarded a Silver Banksian Medal for an interesting group, consisting principally of novelties. *Odontoglossum Lydia* (*eximilium* × *waltonense*), a pale yellow ground with fine dark markings, and white front to the lip, was a specially good exhibit.

#### OTHER EXHIBITS.

PANTIA RALLI, Esq., Ashstead Park, Epsom Surrey, sent *Odontioda Theresa* var. *Ione* (*Dora* × *Coronation*), a charming flower with strawberry-red inner parts to the segments and white margins.

*Cattleya White Queen* (*Douai* × *Luddemanniana* Empress), a good white variety, was shown by Messrs. FLORY AND BLACK.

#### Floral Committee.

Present: Messrs. H. B. May (in the chair), W. G. Baker, W. B. Crane, Chas. E. Pearson, Chas. E. Shea, H. J. Jones, Arthur Turner, M. C. Allwood, W. B. Gingell, J. Jennings, C. R. Fielder, W. Howe, Amos Perry, W. B. Cranfield, H. V. Warender, W. J. Bean, E. A. Bowles, R. C. Notcutt, Clarence Elliott, Reginald Cory, W. Cuthbertson, C. Williams, J. F. McLeod, W. P. Thomson, and J. W. Barr.

#### AWARDS OF MERIT.

*Eupatorium Raffillii*.—A valuable late winter-flowering plant. It has leaves about 3 inches broad and from 7 to 8 inches long, dark green above, pale green beneath. The leaf stalk, the branches and the undersides of the leaves are all clothed with dark red-brown hairs. The terminal flower head may be six or more inches across, and the colour of the flowers is bright purplish lilac. The origin of the plant is uncertain; it was first cultivated in the Birmingham Botanic Gardens as *E. ianthinum*, which it somewhat resembles, but is of bolder habit and has more spreading heads of bloom. The plant was illustrated in *Gard. Chron.*, January 1, 1910, Fig. 13. Shown by A. BARCLAY WALKER, Esq., Firfield, The Heath, Weybridge.

*Saxifraga hybrida* Gem.—This delightful encrusted *Saxifraga* closely resembles *S. Irvingii* (see Fig. 72), as its round flowers are a lovely shade of pink, and patches of the form of *S. huseriana*, which is evidently one of its parents. When in flower it is barely 1½ inch high and if, as stated, it flowers after *S. Irvingii*, then there is ample room for it in the Alpine garden. Shown by Mr. MAURICE PRICHARD, Christchurch.

*Asparagus Lewisii*.—A distinct ornamental *Asparagus* of light and graceful appearance, and one that promises to be a good pot plant. It is more or less intermediate between *A. plumosus* and *A. Sprengeri*, less broad in its foliar parts, but more dense than the latter, yet deeper in colour and somewhat less feathery than *A. plumosus*. Shown by Messrs. J. LEWIS AND SON, Newtown, near Malvern.

#### OTHER NOVELTIES.

*Eupatorium macrophyllum*, with paler flowers, and without the attractive dark stems of *E. Raffillii* was shown by Mr. A. BARCLAY WALKER. An attractive new rich, crimson-red, semi-double Rose named *H. C. Chandler*, said to be a perpetual-flowering, climbing, *H. T.* variety, was exhibited by Mr. GEORGE PRINCE; this the Committee desired to see again when grown out-of-doors.

#### GROUPS.

A magnificent exhibit of *Eupatorium Raffillii* and *E. macrophyllum* was made by A. BARCLAY WALKER, Esq. The many plants filled a corner of the hall, and each was splendidly grown (Silver Flora Medal). Forced Roses were particularly good in an exhibit by Mr. E. J. HICKS. Of the many sorts on view the large vase of *Madame Butterfly* was perhaps the most admired, though *Columbia*, deep pink, and *Premier*, a still deeper shade of the same colour, were also admirable, and these were deliciously fragrant (Silver Flora Medal).

Long sprays of the yellow Banksian Rose were again shown by Mr. GEORGE PRINCE, who also had a bright vase of climbing *Richmond* and of the beautiful *Fortune's Yellow* (Silver Banksian Medal). Carnations were splendidly shown by several growers. Mr. C. ENGELMANN exhibited Carnations. There were many fine blooms of the dark crimson *Nigger*, which was certificated at last week's show of the British Carnation Society. He also had fine vases of *Carola*, *Tarzan* and the deep flesh pink, *Mrs. Walter Hemus* (Silver Banksian Medal). Large vases of the rich yellow *Marion Willson* and *Jessie Allwood*, a good yellow perpetual-mal-maison, were staged by Messrs. ALLWOOD BROS., who also had many blooms of *Mrs. C. F. Raphael* variety and a large stand of mixed perpetual-mal-maison sorts, as well as a goodly assortment of the choicest perpetual varieties (Silver Flora Medal). Many Carnations were also shown by Messrs. STUART LOW AND CO., who featured their *White Pearl*, flanked by *British Triumph* and the vivid scarlet *Lord Lambourne*. They also showed an interesting selection of *Mimosas*, *Epaerises* and *Azalea indica*, all being especially well-flowered plants (Silver Flora Medal).

A very large collection of excellent Cyclamen was contributed by the ST. GEORGE'S NURSERY COMPANY, who also had a smaller over-flow group in another part of the hall. The plants, which were in 5-inch pots, were all models of cultural skill and bore large quantities of flowers. Of the many sorts, *Queen Mary*, bright rose pink, *Salmon King*, *Mrs. L. M. Graves*, brilliant crimson, and *St. George's*, which also

has beautifully mottled leaves, were perhaps the most attractive in colouring (Silver-Gilt Banksian Medal). Many plants of *Frilled Cyclamen* were shown by Messrs. M. GLEESON AND CO. These were in several sorts, and attracted a deal of attention (Silver Banksian Medal).

Adjoining their exhibit of vegetables Messrs. SUTTON AND SONS set up an attractive group of *Cinerarias*, *Cyclamen* and *Freeseas*. The former included excellent plants of *Sutton's Perfect White*, *Light Blue* and very charming "Pink Shades." Amongst the *Freeseas*, there was a goodly batch of the new rosy-purple flushed *Apotheose* and the rich yellow *Vulcan*. The *Cyclamen* illustrated a good strain of large-flowered sorts, and also included a couple of plants named *Sutton's Sweet Scented*. These nearly approximate to the old *C. persicum* in their perfect form, and they have a pleasing fragrance (Silver Banksian Medal).

A splendid selection of *Primula obconica* seedlings was shown by the CHALK HILL NURSERY COMPANY. The central mass of a ruby-red variety was especially noteworthy by reason of the extra size and good form of the blooms, as well as their exceptionally bright colour. Amongst the lighter-coloured sorts an occasional plant, bearing well-formed flowers with fringed edges, was also noteworthy (Bronze Flora Medal).

A magnificent plant of *Rhododendron Ernest Gill*, bearing many trusses of splendid blooms, was shown by Messrs. R. GILL AND SON. Many vases of *Erica codonodes*, *E. mediterranea* and *Andromeda japonica* were also included in this attractive exhibit (Bronze Flora Medal). Brilliantly coloured sprays of *Cydonia* (*Pyrus*) *japonica coccinea*, with *Wistaria sinensis*, were arranged by Messrs. WALLACE AND CO., who also showed good examples of such *Genistas* as *purpurea*, *praecox* and *kewensis* (Silver Banksian Medal). *Convolvulus Cneorum* and *Coroea virgata*, two silvery foliaged shrubs, were included in an exhibit by Messrs. PIPER AND SON, who also had good examples of *Veronica Hulkeana* (Bronze Flora Medal).

Forced shrubs of many kinds were shown by Messrs. L. R. RUSSELL, LTD., and these included floriferous *Wistarias*, *Laburnums* and many *Clematisses* in small pots and bearing good blooms. Amongst the greenhouse plants there were useful examples of *Clivia* (*Imantophyllum*) and the fragrant *Boronia megastigma* (Silver Banksian Medal). A small collection of *Camelias* by Messrs. SANDER AND CO. included the bright single *Fred Sander*, which received an Award of Merit last year. There were also plants of *Mrs. Wm. Thompson*, a good single white sort, and *Kimberley*, a free-flowering single very like in colour a rich *Rosa Moyesii* (Bronze Banksian Medal).

A small rockery by Messrs. WM. CUTBUSH AND SONS was planted with *Daphne Cneorum* and other appropriate plants (Silver Banksian Medal). *Myosotis Ruth Fischer*, a dainty little variety, was included in an exhibit of Alpines by Messrs. WATERER, SONS, AND CRISP (Bronze Flora Medal). Amongst his uncommon plants Mr. G. REUTHE included *Vaccinium Nummularia* and *Polygala rhodoptera* (Silver Banksian Medal). A batch of excellent *Freesia Excelior* was shown by F. C. STROOP, Esq. (gr. Mr. G. Carpenter), West Hall, Byfleet. These were of unusual size and very fragrant (Bronze Flora Medal).

Amongst many spring flowers shown by Mr. G. W. MILLER there were *Crown Imperials*, *Polyanthuses* and pans of double *Daisies*. Of the last the bright crimson *Rob Roy* and the smaller rosy-pink *Dresden China* were very bright and showy (Silver Banksian Medal). Fragrant *Violets* in several varieties were again shown by the REEDENS SCHOOL OF GARDENING (Bronze Banksian Medal). Messrs. REAMSBOTTOM AND CO. exhibited their *St. Brigid Anemones* (Bronze Banksian Medal). Messrs. J. CHEAL AND SONS included sprays of *Almonds*, *Rhododendron Jacksonii* and many *Conifers* with Alpines (Bronze Flora Medal). Small rock gardens and Alpines in pots were shown by Mr. F. C. WOOD (Bronze Banksian Medal), Messrs. SKELTON AND KIRBY (Bronze Banksian Medal), and the Misses HOPKINS also showed Alpines.

A quantity of *Azalea mollis* varieties of glowing colours was shown by Messrs. R. and G. CUTHBERT (Silver Banksian Medal). Many Saxifragas, including the attractive Russell Prichard, were shown by Mr. M. PRICHARD (Bronze Flora Medal). Messrs. MAXWELL AND BEALE showed Violets and a rock garden (Bronze Flora Medal). Amongst the many Alpines shown by Messrs. R. TUCKER AND SON there were Saxifraga Sundermannii, in quantity, *S. retusa*, a dainty rosy-purple variety, and *S. Stuartii* (Silver Banksian Medal).

#### Narcissus and Tulip Committee.

*Present:* Messrs. E. A. Bowles (in the chair), W. F. M. Copeland, C. W. Needham, H. V. Warrender, F. Herbert Chapman, G. Churcher, John W. Jones, George Monro, W. Poupart, Reginald Cory, W. B. Cranfield, Peter R. Barr, and Charles H. Curtis (Hon. Sec.).

Large Trumpet varieties were a prominent feature of an interesting collection of Narcissi by Messrs. BARR AND SONS, and these were represented by a number of very promising seedlings, as well as named sorts. Of the latter, Adelgar, Alasnam, Mustapha, Princess Juliana and General Joffre were admirable. Along the front of the exhibit there were several vases of attractive Poetaz varieties, including Rembrandt and Triumph, and the tiny, free-flowering canaliculatus. Adjoining the Daffodils there were sprays of *Cydomias* and *Forsythias* (Silver-Gilt Banksian Medal).

An extensive collection of spring bulbs growing in bowls of fibre was again arranged by Messrs. R. H. BATH, LTD. Darwin Tulips predominated, and these included La Tulipe Noire, Princess Elizabeth, King Harold and Prince of the Netherlands. Many excellent Narcissi, and particularly free-flowered *Chionodoxas* and *Scillas*, were also included (Silver-Gilt Banksian Medal). The rich yellow Trumpet Daffodil King Alfred was shown in great quantity by Messrs. CARTER AND CO., and these made a glorious display of colour, as well as illustrating skilful arrangement.

A small collection of choice seedling Daffodils was contributed by Messrs. F. H. CHAPMAN, LTD. Of the few named sorts the bicolor St. Bernard, which has an evenly fringed margin to the trumpet, was very attractive; Ettrick, a giant Leedsii, was also very fine (Silver Banksian Medal).

#### Fruit and Vegetable Committee.

*Present:* Messrs. C. G. A. Nix (chairman), J. Cheal, W. Poupart, Geo. F. Timley, A. H. Pearson, O. Thomas, S. B. Dicks, W. F. Giles, F. Wilson, F. Jordan, G. Reynolds, E. Neal, W. Bates, Ed. Beckett, A. Bullock, W. H. Divers, G. Berry, and W. Wilks.

#### AWARD OF MERIT.

*Apple John Standish.*—This new dessert Apple was shown on several occasions in the autumn of 1921, including the R.H.S. meetings and the Empire Fruit Show at the Crystal Palace. The exhibits then included branches in bearing cut from the trees, and all who saw them were impressed with the prolific cropping of the variety. Because of this quality, the pretty appearance of the fruits, and the late season at which the variety is available, an Award of Merit was recommended as a market Apple. The fruits are of medium size and in appearance somewhat like Worcester Pearmain; they are rich red all over except the eye end, which is a mellow yellow. The eye is closed and set in an even, wide, shallow cavity; the stalk is about an inch long and set in a deep, conical depression. The fruits are solid, juicy and of good flavour for a March Apple—superior to Worcester Pearmain in October. Shown by Messrs. ISAAC HOUSE AND SON, Westbury-on-Trym, Bristol.

#### GROUPS.

Messrs. SUTTON AND SONS were awarded a Silver Knightian Medal for an excellent group of vegetables, arranged in the best exhibition style. The various dishes were all of remarkably high quality, and included baskets of Golden Ball Lettuces, Market Cucumbers, Superb Early White Broccoli, Witloof Chicory, Sea Kale, Harbinger Cabbages, Masterpiece Dwarf Beans,

Perpetual Spinach, Onions, Salsify, Kale, Radishes and Potatos.

Sir MONTAGUE TURNER, Bedford, Havering, Romford (gr. Mr. Barrett), was awarded a Bronze Hog Medal for twenty-eight varieties of Apples of such sorts as Scarlet Pearmain, Beauty of Kent, Duke of Devonshire, Annie Elizabeth, Newton Wonder, Hornmead Pearmain, and Bismark.

## Obituary.

**Professor W. B. Bottomley, Ph.D.**—The death of this distinguished botanist occurred on the 24th ult., at Huddersfield, where he had resided since his resignation last year, through ill-health, of the Chair of Botany, King's College, London, which he had held since 1893. Prof. Bottomley will be known to many of our readers for his investigations in the nutrition of plants, and especially in connection with bacterised peat made by inoculating sterilised peat with nitrogen-fixing bacteria. The advantages the late Prof. Bottomley claimed for bacterised peat were: (1) It adds active nitrogen-fixing organisms to the soil under suitable conditions for nitrogen-fixation; (2) it stimulates the nitrogen-fixers already in the soil; (3) it adds direct plant food to the soil, a large amount of the organic vegetable matter of the peat being rendered soluble in the processes of treatment; (4) it directly promotes the root development of plants; and (5) it improves the mechanical condition of the soil. Prof. Bottomley carried out numerous pot trials of plants treated with bacterised peat, and independent trials were conducted at such places as Eton School Gardens, Kew Gardens and Chelsea Physic Garden. At Chelsea Physic Garden, Radishes watered once with an extract of bacterised peat gave an increase of 54 per cent. over plants untreated. But his work suffered from two drawbacks—he had no funds for proper experimental investigation, and his experiments were handicapped by bad seasons, so that the results were not often so successful as might otherwise have been the case. For some years Prof. Bottomley was science tutor and lecturer of biology at St. Mary's Hospital School, and later became Professor of Biology at the Royal Veterinary College, St. Pancras. He founded the South-Eastern Co-operative Agricultural Society, and was hon. secretary of the Agricultural Banks Association and of the English Land Colonisation Society. He leaves a widow and two sons, to whom we tender our deepest condolences.

## ANSWERS TO CORRESPONDENTS.

#### ARRANGEMENT OF BORDER FLOWERS: R. I. H.

The suggested arrangement for your border A should answer very well, but some of the plants would be better if given a little more space. The Zinnias and White Ostrich-plume Asters should be planted one foot apart, while the Pentstemons, Ray Asters and Giant Comet Asters should stand fifteen inches apart. The Kniphofias (Red Hot Pokers), if strong plants, would do better if planted three feet apart, with the Gladioli grouped between them. Regarding border B., the Phacelia, Eutoca, Anchusa and Nigella should all be sown out of doors as you suggest, as they do not transplant successfully. All annuals, if given plenty of room, last a long time in flower. With most plants the height is a good guide to planting; if a plant is one foot in height, it should be planted about that distance apart from its neighbours; thin growing subjects should, of course, be left a little closer, while some spreading subjects will occupy more ground. If you wish to cover the ground quickly, the distances apart that you suggest should suffice.

**GARDENING BOOKS, ADDRESS WANTED:** Will Mr. George Berbeck please send his full postal address to *The Gardeners' Chronicle* office so that he may be put in touch with a possible purchaser?

**PEACH FLOWERS FAILING TO DEVELOP: F. G.** So far as can be determined from the dried specimens of your Peach shoots, you may rest assured the dressing of Gishurst Compound is not the cause of the flowers failing to develop. The trouble may have arisen from one or more of several causes, such as the tree being slightly overcropped, or allowed to become dry at the roots, but more possibly in your case from the early loss of leaves, as the shoots had much to contend with during the hot season of 1921. It often happens that healthy old trees set such a profusion of blossom buds that it is necessary to thin them severely long before the flowers open. If you had drawn your finger up the back and under-sides of the thickly studded shoots, to remove all the drooping buds, you would still have had a plentiful supply from those pointing upwards, and this removal would undoubtedly have strengthened the remaining flower buds.

**REMARKS.**—The recent cold snap has not been favourable to the increased demand for fruit; but, taken all round, most fruits have been in good request. Arrivals of Cape fruit have been on a large scale during the past week, and have moved satisfactorily. The first shipment of Australasian Apples came to hand in good condition during the week, and sales have been effected at good prices. Fairly large stocks of Newtowns and Winesaps are still on offer, and are quoted lower. Oranges are slightly firmer in price. Lemons show little or no variation in value. Bananas continue a steady trade, with supplies just sufficient for requirements at present quotations. Choice vegetables, such as Asparagus, French Beans, Peas, and New Potatoes, are in moderate demand, any light increase in quantities having the effect of unduly lowering the prices. Canary Island New Potatoes are in better demand, and have hardened in price. Tomatoes from the same source are easier in value. All green vegetables are scarce and costly; Cauliflowers have also advanced in price, and Carrots are quoted at almost prohibitive rates. Onions remain firm. Potato supplies are steady, with no change in quotations.

**AVERAGE MEAN TEMPERATURE** for the ensuing week deduced from observations during the last fifty years at Greenwich, 46.1.

### ACTUAL TEMPERATURE:—

*Gardeners' Chronicle* Office, 5, Tavistock Street, Covent Garden, London, Wednesday, April 5, 10 a.m. Bar. 29.8; temp. 48°.—Weather—Cold and bright.

The retirement of Sir Isaac Bayley Balfour, F.R.S., the King's Botanist in Scotland, Regius Keeper of the Royal Botanic Garden, Edinburgh, and Professor of Botany, University of Edinburgh, marks the close of the official career of the most distinguished horticulturist of modern times. Sir Isaac, indeed, has achieved and deserved fame in many walks of life. He is a distinguished botanist and a great traveller, a remarkably capable administrator, but above all he is a great horticulturist. No one whom we have met understands plants as he does. He comprehends them as individuals, each with its peculiar idiosyncrasy, and he understands them as members of a vast community. Of him it may be said in truth, as in a larger way it was said with irony of Lord Bacon, that he took all plant knowledge as his province. Profundity without pedantry is the characteristic of his knowledge. His mind is a great store of the facts of biological science and of plant life, which it has always been his habit to put freely to the use of his colleagues.

Born in 1853, at a time when botany was under the influence of German inspiration, Sir Isaac pursued his studies both in Edinburgh and in Germany, and became successively Professor of Botany at Glasgow and at Oxford, in both of which places he left proof of his great organising capacity and devotion to botanical science. In 1888

he assumed the offices in Edinburgh which he has now relinquished. Before that date he had already travelled widely. When just of age he was appointed naturalist to the Transit of Venus Expedition to Rodriguez, and in 1880 he explored the Island of Socotra. Among the plants which he brought back from this latter expedition was *Begonia socotrana*, which has played its part in the formation of the now popular winter-flowering Begonias. After many years, his love of travel led him, not so very long ago, to visit China, that Eldorado of horticultural plants. In large measure through his influence, successive explorers have ventured into the innermost recesses of China and its hinterlands and have brought back almost numberless treasures for the enrichment of our gardens. Sir Isaac's wide and sure knowledge has contributed greatly to the description of the plants brought back by recent explorers, and his skill as a cultivator as well as his acumen as a judge of plant possibilities, have enabled him to prove at Edinburgh the garden worth of many of these recent introductions. Prof. Sir Isaac Bayley-Balfour's contributions to botany have been many and distinguished, and it is due to his energy and enterprise that many of the best German works on that science have been translated into English; he also acted for many years as editor of the *Annals of Botany*, which journal has done so much to establish botanical science and botanical research in this country. Few, if any, of his contemporaries have exercised as wide or as beneficent an influence on botanical science and horticulture. For many years he has been an unofficial and final referee in all matters affecting horticulture; the power which he possesses is great and has always been wisely used. His supreme quality is the possession of great resolution combined with the subtle understanding of human nature. Thanks to these gifts he was able easily to get his way, and thanks to the fine quality of his mind, his way was the right way. He touched nothing in botany which he did not adorn and he was able to make even Cabinet Ministers fond of, and generous to, horticulture. Among his many achievements, the formation of the rock garden at Edinburgh deserves special mention. It is a memento of his skill, knowledge, assiduity and judgment; but everyone who has come in contact with Bayley Balfour carries in his heart a yet more precious memento of a man whose whole life is devoted unsparingly and unselfishly to the advancement of knowledge and the helping of those who ensue it. His friends throughout the world will wish him every happiness in the well-earned rest which he is now to take, and will pray that he may long be spared to aid them with his counsel and to serve as an inspiration to them in their work.

—A correspondent sends us the following appreciation of Sir Isaac Bayley Balfour:—The retirement of Sir I. Bayley Balfour from active official life is an event in the course of botanical and horticultural progress which calls for more than mere passing comment. Sir Isaac, even during the earlier stages of his career, when he occupied the Sherardian chair of Botany at Oxford, was one of the central figures in that forward movement in British Botany which marked the closing decades of the last century, and was to prove so fruitful in scientific and economic directions in later years. His was the main moving spirit that led, amid head shaking of older men and scepticism on the part of some contemporary Gallios, to the founding of the *Annals of Botany*, which did much to quicken research in this country, and the periodical itself has from its first appearance occupied a pro-

minent position as one of the leading scientific journals of the world. At Oxford he had scope enough for the exercise of his vigorous energy and his inspiring enthusiasm. Botany in the University had fallen on evil times, and it is no exaggeration to say that, at the time he was appointed to the chair, in 1884, there was hardly anything in existence, but everything to make. He organised the teaching and remodelled the old garden (one of the oldest in Europe), though without destroying its old-world charm. When he resigned the chair in 1888 he had already founded a small, though promising school, infecting all his students with his keenness for his subject, and a recognition of its importance from the economic and scientific standpoints, an importance which escaped the notice of most people at that time. Called to Edinburgh as Professor of Botany in the University, and Regius Keeper of the Botanic Garden, he used the whole weight of his energy, experience and wisdom in grappling with the new problems that lay before him. It was towards the organisation of that great garden, the developing of the facilities it affords for study and research that his future efforts were to be largely directed. It is no exaggeration to say, and all who have followed his great work there will freely admit it, that he has really transformed the place. Gifted with strong artistic perception, coupled with a wide scientific outlook, the result of the many changes he had introduced has been to give to Edinburgh one of the great botanic gardens of the world. The rock garden is one of its famous attractions, the scientific value of which is enhanced by the artistic feeling under which it has been developed. The great collection of Rhododendrons and Primulas is well known, and Sir Isaac himself is the chief living authority on these glories of the vegetable kingdom. Most of the leading botanists of the world have at one time or another been drawn to visit Edinburgh, and none of them will fail to look back with delight on walks through the famous garden with the Professor, who ever had something of fresh interest to tell of every plant. For he adds to an extensive range of botanical knowledge a wonderful appreciation of the many scientific problems that spring from horticultural practice. Perhaps it is this apprehension of the plant in the field, the forest, the garden, the propagating pit, as well as the laboratory that helps to explain the remark of more than one eminent visitor, that a talk with him seemed to open up new views on the fundamental problems of plant life. Whilst his high attainments have deservedly earned for him a widespread admiration, those privileged to closer intimacy have most fully appreciated his real greatness. An acute intellect, coupled with a wide knowledge of men and affairs, is here associated with an individual personal charm that secures sincere and devoted affection, and Sir Isaac carries with him in his retirement from a strenuous scientific and official career the heartfelt good wishes of all his colleagues and friends.

**Midland Daffodil Show.**—Owing to the Easter holidays, the Birmingham Botanic Gardens, at Edgbaston, will be open to the public until late on Tuesday, April 18, consequently the committee of the Daffodil Society is unable to make the necessary preparations for the show originally fixed for Wednesday and Thursday of Easter week. It has, therefore, been decided to hold the exhibition on Thursday and Friday, April 20 and 21, when a fine display is anticipated.

**Memorial to late Professor Trail, Aberdeen.**—Under the presidency of Mr. P. J. Anderson, Aberdeen University Librarian, a meeting of the subscribers to the Trail Memorial Fund decided that the memorial to the late Professor James W. H. Trail, F.R.S., for nearly forty years Professor of Botany in Aberdeen University, should take the form of a portrait plaque, to be placed in the Botany Department of the university, and a memorial volume. The volume will include the late Professor Trail's *Flora of the City Parish of Aberdeen*, as well as certain autobiographical matter, and a complete bibliography of his works. His old students and all those interested in the natural history of

Aberdeen, as well as professional botanists, will appreciate the good fortune of the Memorial Committee in having obtained the permission of the Aberdeen National History and Antiquarian Society, for whom the *Flora of the City Parish* was written, to publish this work as a part of the memorial. The work represents the chief labour of Dr. Traill's later years, and is important not only as a study of the flora as it exists just now, but for its historical aspect, and as an example of the influence of man on his environment. The hope is expressed that publication of the volume may be arranged this year.

**British Horticulture and Quarantine Order No. 37.**—We learn that the Ministry of Agriculture has deputed Mr. W. G. Lobjoit, Controller of Horticulture, to attend a Conference of horticulturists, to be held at Washington on May 15, for the purpose of protesting against the possible extension of the American Quarantine Order No. 37, which, ostensibly set up for the purpose of preventing the importation of insects and other pests, has the effect of excluding horticultural products from Great Britain and other European countries, to the great disappointment of large numbers of garden lovers in the United States, who are anxious to obtain the best British and other plant novelties.

**Ormskirk Potato Show.**—The annual Potato Show, held at Ormskirk, will take place this year on Wednesday and Thursday, November 1 and 2.

**Royal Gardeners' Orphan Fund.**—The annual festival dinner in aid of the Royal Gardeners' Orphan Fund will be held at the Connaught Rooms, Great Queen Street, on Tuesday, May 9, under the presidency of Lionel de Rothschild, Esq., O.B.E., M.P. The fund is fortunate in having secured as chairman of the dinner a member of a family noted for its generosity in assisting all kinds of deserving institutions, as well as being splendid patrons of horticulture. Previous dinners have been presided over by members of the Rothschild family—Baron Ferdinand de Rothschild in 1895 and by Leopold de Rothschild in 1902. We are sure that members of the gardening fraternity and lovers of horticulture generally will give Mr. Rothschild a full measure of support by contributing generously to his list, and thus make the occasion one of the most successful of its kind in aiding the orphans of gardeners.

**Wakefield and Northern Tulip Society.**—References in Sir Daniel Hall's article on the Florists' Tulip (pp. 123, 140, 155) have caused considerable interest in the north and led correspondents to send us a report of the Wakefield Northern Tulip Society for 1921 and a schedule of the classes arranged in connection with the Tulip show to be held on Saturday, May 27, and Monday and Tuesday, May 29 and 30, at the Brunswick Hotel, Wakefield. We understand that Tulip shows were held at Wakefield all through the war period. In November, 1919, a silver challenge sup. value £14 14s., was subscribed for, and this was offered for the best stand of nine Tulips in 1920, when it was won by Mr. Jesse Hardwick. Mr. Hardwick was an enthusiastic cultivator of the old Florists' Tulip, and for twenty-five years was secretary of the Wakefield Society. In November, 1907, he retired from the position of secretary and became chairman, a position he held for several years. A tailor by trade, he was a most regular attendant at the society's monthly meetings, making his last appearance on December 5, 1920; he passed away on December 15 of that year. Mr. C. W. Needham, a veteran Tulip fancier and vice-president of the society, won the challenge cup in 1921. The president of the society is another famous florist, Mr. J. W. Bentley, Stake Hill, Castleton.

**Jubilee of the National Auricula Society.**—The fiftieth annual exhibition of the National Auricula Society (Northern Section) will be held on Saturday, May 6, at the Coal Exchange, Market Place, Manchester. An interesting schedule has been arranged, with seventeen classes for show Auriculas, thirteen for alpine Auriculas, ten for gold-laced Polyanthuses, and five for other Polyanthuses, Primroses, and Anri-

culas. It is interesting to observe that this society has held its exhibitions every year for fifty years, and that its first show was held in the old Town Hall at Manchester on April 29, 1873, when the Rev. F. D. Horner was hon. secretary. The present secretary is Mr. J. Tonge, 22, Booth Street, Manchester.

**Glasgow International Flower Show.**—The schedule of the International Flower Show, to be held in the Kelvin Hall, Overnewton, Glasgow, on Wednesday, Thursday, Friday, and Saturday, August 30th, 31st, September 1st and 2nd has been issued. The show is promoted by the Corporation of the City of Glasgow, in conjunction with the Glasgow and West of Scotland Horticultural Society. A sum of over £1,500 is offered in prizes and trophies in the various classes, which number no fewer than 340. The schedule is divided into numerous sections and embraces classes for pot plants; cut flowers, including Roses, Sweet Peas, Carnations hardy herbaceous flowers, Dahlias, Gladioli, Violas and Pansies; decorative classes and classes for fruits, vegetables and allotment holders' produce. The show is under the patronage of the Royal Horticultural Society, which is sending a deputation of its Council to the show, and will award R.H.S. medals in accordance with the merits of the various exhibits.

PROFESSOR SIR ISAAC BAYLEY BALFOUR, F.R.S.  
(See p. 161.)

Displays of fruits and Dependencies of Great Britain, and suitable trophies and certificates will be awarded to exhibitors of all meritorious displays in this section. In some of the classes the prizes are exceptionally liberal; thus for a group of miscellaneous stove and greenhouse plants arranged for effect the first prize includes the President's cup, together with £40; the second, third and fourth prizes being £40, £30 and £20 respectively. For a decorated table of fruit, comprising twenty-four dishes, the first prize is a silver cup or rose bowl, valued at £50, together with £25 in money, and the other prizes are £25, £20, £15 and £10 respectively. A sum of £28 is offered as prizes in a class for a collection of vegetables, divided into £10, £8, £6 and £4 for first, second, third and fourth prizes. Copies of the schedule may be obtained from the Secretary, Mr. H. M. Mackie, 124, St. Vincent Street, Glasgow.

**North of England Horticultural Society.**—This northern Society, which was founded in 1911, was compelled to suspend operations from 1915 to 1921, and five trustees were appointed on February 18, 1921. The trustees have been asked to resume the activities of the Society, and if sufficient support is forthcoming it is

proposed to hold an educational fruit show in the Winter Gardens at Harrogate in October, 1922. In September, 1913, the Society consisted of 520 fellows and members and twenty affiliated societies, and it has a small balance at the bank, two cups and valuable medal dies. An appeal is being made for a prize fund of £100 toward the expenses of the proposed show. The policy of the Society will be to work in co-operation with the Royal Horticultural Society and northern horticultural societies; at the same time preserving its independence and its definite North of England character. The President is Col. Sir Edward A. Brotherton, Bart., M.P., the chairman Mr. J. S. Brunton, and the secretary the Rev. J. Bernard Hall, B.A., Farnham Vicarage, Knaresborough.

**Legacies to Gardeners.**—The late Sir Thomas Sutherland, who died on January 1, 1922, leaving a large fortune to his lady secretary, Miss Marjory McKay, also bequeathed the sum of £1,000 to his head gardener at Coldharbour Wood, East Liss, Hants, Mr. J. Lintott. Mr. Lintott is still at Coldharbour, and is now in the service of Sir William Dingwall Mitchell Cotts, Bart. The late Mr. George Charles Parr, of Ballygunge, Kent Gardens, Ealing, solicitor, who died on January 15, left the sum of £250 to his gardener, Mr. Joseph Bryant.

**Forestry at Aberdeen University.**—The Aberdeen University Senatus has agreed, in order to bring the course of study for the degree of B.Sc. in Forestry into line with the scheme of study recommended by the Inter-Departmental Committee on Imperial Forest Education, that courses in Plant Physiology (one term), Forest Engineering (one term), and Forest Policy (one term) should be added to the curriculum.

**Blinded Soldiers as Garden-net Makers.**—The late Sir Arthur Pearson's proud boast that blinded soldiers and sailors who had been retrained for a life of usefulness at St. Dunstan's, Regent's Park, could hold their own, as regards the work they produced, with sighted workers, has many times been justified. The making of netting for all garden and other purposes, as organised at St. Dunstan's, is an industry which was initiated in 1915 with wonderful success. This handicraft now gives employment to over 500 blinded soldiers in their own homes. Every description of garden, farm and sports nets is made by the men. Particular attention is directed to the golf driving nets, made of heavy, tanned hemp of three-quarter inch mesh, and the durable tennis nets and tennis boundary netting. It is only fair to emphasise the fact that orders are not asked for *only* on the ground of sympathy and interest in the way these gallant fellows are "making good." That the work they produce commands attention on merit alone is proved by the fact that contracts are often secured in open competition.

**Wart Disease of Potatos.**—The proposed new regulations for the control of wart disease in Potatos, which were to have been brought into operation by the Ministry of Agriculture and Fisheries at the conclusion of the 1922 planting season, are still under consideration by the Minister's Advisory Committees. It is unlikely that any decision will be arrived at in time to issue fresh regulations which may affect the distribution of the 1922 crop, or, therefore, that any change in the 1921 regulations will be made. The Ministry does, however, inform Potato growers that no restrictions additional to those operating in 1921 will be imposed which will affect the distribution of the 1922 Potato crop, or of the entry into England and Wales of seed Potatos produced during 1922 in Scotland or Ireland.

**Iris Conference in Paris.**—The organisers of the forthcoming Iris Conference in Paris are making an urgent appeal to the generosity of professional and amateur growers of irises in all countries for gifts of money or prizes to be awarded to the exhibitors of the best plants and the writers of the best papers, and contributions towards the cost of printing the prize papers. A full list of all prize-givers will be

published, and the principal prizes can, it desired, bear the names of their donors. Mrs. Edward Harding, the generous American lady who has already given several prizes (notably one of 500 francs for a new Iris, which was awarded to the new variety Mrs. Walter Brewster, raised by MM. Vilmorin, Andrieux and Cie.), has just placed another sum of 500 francs at the disposal of the committee. M. Jacques L. de Vilmorin has also offered 500 francs, and M. J. Denis, the raiser of many splendid new varieties, is giving 500 francs, of which 250 francs is to be awarded for the best new variety presented at the Conference.

**Appointments for the Ensuing Week.**—Monday, April 10: United Horticultural Benevolent and Provident Society's Com. meet.; Bath Gardeners' Society's meeting; Purley Horticultural Society's meeting; Reading and District Gardeners' Association's meeting and lecture by Mr. J. Wynn on "Practical Demonstrations in Floral Work." Tuesday, April 11: Royal Horticultural Society's Committees meet (2 days). Wednesday, April 12: East Anglian Horticultural Society's meeting; Sheffield Chrysanthemum Society's meeting. Thursday, April 13: Bristol and District Gardeners' Association's meeting.

**"Gardeners' Chronicle" Seventy-Five Years Ago.**—*Vanda Lowcii*.—This very extraordinary plant has been found in Borneo by Mr. Hugh Low, jun., by whom it has been sent to England. I find the following account of it in a letter from this gentleman, dated Sarawak, January 12, 1846:—"At the time I formerly sent it to you I remember having said that I expected something very magnificent in its flower, and sure I am that when it produces its spikes of flowers in England it will be the admiration of all cultivators, probably beyond any Orchid that has ever yet appeared. As I saw it nothing could have exceeded it in beauty; about 200 of its branches were hanging horizontally from the main stem of a large tree, from each of which depended two, three or four chains of flowers, each ten feet in length, and sometimes twelve feet. The individual flowers are upwards of three inches in diameter. When they first open the ground colour is pale lemon yellow, barred and blotched with bands and spots of the richest cinnamon; as they become older the cinnamon colour gradually diminishes in size; the yellow becomes richer and more brilliant, and takes the place formerly occupied by the more dull, but not less rich tint; the stem and foot-stalks of the flower are covered with a rich, downy coating of moss, similar to that of the Rose; the labellum is shaded cinnamon and purple; the leaves are of a light green colour and leathery texture, similar in shape to those of *Aerides odoratum*, as far as I recollect, but more stiff and erect; the whole habit of the plant is as neat as the rest of those of the same tribe. The roots are large, but by no means so thick as in some of the Continental Indian *Vandas*. It delights in high trees on the banks of rivers, thick forests and other humid places." Mr. Low begged that it might be called *Vanda Lindleyana*, under which name it has already become known to a few persons, but as it has never been before described, Dr. Lindley takes this opportunity of transferring the name of its discoverer, who certainly ought, before all others, to be associated with one of the finest plants which he has discovered in that interesting, but dangerous island in which his researches have been so diligently prosecuted. We have a specimen of this plant now before us, preserved in spirits, and we are thus able to verify Mr. Low's dimensions. The flowers are more than three inches in diameter and spread quite flat, and the space from flower to flower is about five inches. The "rich, downy coating of moss," of which Mr. Low speaks, is formed by curious short hairs, whose sides are studded with irregular microscopical spines, and must add much to the beauty of this most singular plant. *Gard. Chron.*, April 10, 1847.

**Publication Received.**—*Lucerne Growing in the Nelson District*. By T. H. Easterfield and T. Rigg. R. Lucas and Sons, "Evening Mail" Office, Nelson, N.Z. Price 1s.

## NEW OR NOTEWORTHY PLANTS.

### HEDYCHIMUM GREENII.

This is a handsome species of *Hedychium* (see Fig. 81), with flowers of a similar type to those of the well-known *H. coronarium*, but smaller and quite different in colour.

*H. Greenii*, Smith, was described in the *Records of the Botanical Survey of India*, v. 4, p. 272, in August, 1911, and soon after introduced into cultivation in this country. It is stated to grow to a height of from two to six feet, and, among other characters, is well marked by the purple colour of its stems and the undersurface of its leaves. It produces

This species has been thought to be the same as *H. Elwesii*, Baker, which is a native of Assam. But apart from the improbability of these plants from two different regions being the same, *H. Greenii* is distinguishable at a glance from *H. Elwesii*, not only by its purple colouration, which is wanting in *H. Elwesii*, but also by the very much shorter ligule of its much shorter leaves (those of *H. Elwesii* being 16 to 17 inches long, with ligules one inch long), the denser and more floriferous spike, and the shorter corolla-tube, that of *H. Elwesii* being 2 to 2½ inches long and considerably overtopping the bracts. *N. E. Brown*.

[The photograph is from a specimen exhibited by Mr. Elwes.—Eds.]

FIG. 81.—HEDYCHIMUM GREENII.

bulbils freely. The leaves have the petiole sheathing almost up to the blade, with a short and very obtuse pubescent ligule about a quarter of an inch long; the blade is 8 to 11 inches long, and 2¼ to 3¼ inches broad, oblong, cuneately rounded at the base and tapers from above the middle into a long slender point at the apex. The spike is four to five inches long, dense, many-flowered, with broadly ovate acute bracts 1½ to 2 inches long. The corolla has a tube about 1¾ inch long, that does not overtop the bracts, with segments 1¼ to 1½ inch long, the broad, obtusely two-lobed lip being 1½ to 2 inches broad, the two spatulate segments four to six lines broad, and the other three linear. In a wild state the flowers are dark red, but some of the plants in cultivation have yellow flowers. It is a native of western Bhutan, in India.

### CORYDALIS SOLIDA.

DURING the past two or three weeks the young growths of many garden plants, particularly varieties of *Phlox decussata* and plants of *Antirrhinum*, have been severely damaged by cold winds. The stems and petioles of *Corydalis solida* have exhibited an interesting movement, bending over and lying closely adpressed to the soil, so escaping the severeness of the winds. I have not noticed this movement before the present occasion, neither have I observed it in any other plant. The winds have since changed to a more N.W. direction and already the plants have assumed a nearly erect position. I enclose a print (not suitable for reproduction.—Eds.) which shows the change of position. *James W. Bamber, Hoddlesdon*.

## The Week's Work.

### KITCHEN GARDEN.

By JAMES E. HATHAWAY, Gardener to JOHN BRENNAND, Esq., Baldersby Park, Thirsk, Yorkshire.

**Capsicums.**—These plants are both useful and ornamental. The seeds should be sown in 6-inch pots and the seedlings grown in gentle heat. When of a suitable size prick them off singly into small pots, and continue to grow the plants in a warm house through the summer. A keen watch should be kept for green fly. Princess of Wales is one of the best varieties.

**Cauliflowers.**—Plants wintered in frames should be planted out in a sheltered position, and those sown in spring and grown in boxes hardened off. Peas and Beans grown in turves or in pots should be also hardened off and planted out as soon as they are ready.

**Broccoli.**—Sow Self-protecting Broccoli on a warm border. Michaelmas White and Veitch's Self-protecting Autumn are two of the best varieties for early sowing.

**French Beans.**—Make a sowing of French Beans. Place four beans in each 3-inch pot and germinate them in gentle warmth. Harden the seedlings, and plant them in the open as soon as there is no fear of injury by frost, to obtain an early crop out-of-doors.

**Potatos.**—The main crop of Potatos should new be planted in well-manured land, choosing medium-sized sets. Strong-growing sorts should be planted 3 feet apart between the rows and 18 inches between the tubers in the rows. To prolong the season of new Potatos seed tubers of early varieties should have the sprouts rubbed off and be kept in a cool place to be planted in batches every three weeks up to the beginning of July.

**Seed Sowing.**—Seeds of Brussel's Sprouts, Cauliflowers, Savoy's, Turnips, Globe Beet and Radish should be sown in drills made 1 foot apart and 2 inches deep. Cucumbers, French Beans and Tomatos growing under glass require constant attention in watering, airing, and feeding. Water the plants on frequent occasions with liquid manure, and stimulate the roots with a concentrated fertiliser, such as Bentley's Vitaliser or Le Fruiterer.

### THE ORCHID HOUSES.

By J. T. BARBER, Gardener to His Grace the Duke of Marlborough, K.G., Blenheim Palace, Woodstock, Oxon.

**Repotting Vandas.**—*V. suavis*, *V. tricolor*, and other large plants of this interesting family are best grown in pots, whilst smaller plants and species may be grown suspended in pans or baskets. In repotting these plants it will be found that many roots have become attached to the sides of the pots. These may, in many cases, be detached by the aid of a knife, and sometimes it may be desirable to break the pot carefully, and place the roots with the broken not attached to them inside the new receptacle. It is not necessary to repot the plants annually, but it is essential that the potting material should be sweet and in a condition to support healthy growth. In repotting those plants which have become leggy by the loss of their bottom leaves, it is advisable to cut away a portion of the stem at the base, so that the bottom pair of leaves rest just above the compost. A suitable compost is formed of equal parts *Osmunda* fibre and live *Sphagnum*-moss, thoroughly cleaned, and cut up according to the size of the plants; the larger the plants the rougher should the material be. Shade the plants from the bright rays of the sun, but remove the shading material in time to ensure a considerable rise in the temperature by the sun's warmth. Plants that do not need repotting may, if the drainage is perfect, and their pots are sufficiently large enough to carry them through the season, be resurfaced with fresh material. Although these old-world Orchids are

not grown to the same extent as formerly, there are few plants to compare with them when well grown. They vary in their requirements as regards heat, some requiring the hottest position, whilst others succeed in a warm Cattleya house. The beautiful *Vanda Sanderiana* delights in the warmest and most humid position possible whilst making its growth, and all like drier conditions whilst at rest. The same remarks apply to *Aerides* and *Saccolabiums*, which thrive under similar conditions. *Vanda tricolor* and *V. suavis* thrive well in a shady part of a warm Cattleya house or some similar structure.

### HARDY FRUIT GARDEN.

By H. MARKHAM, Gardener to the EARL OF STRAFFORD, Wrotham Park, Barnet.

**Gooseberries.**—The weather having been very favourable for ground operations, the work of manuring and digging lightly amongst the bushes will have been completed; but the hoe should be used freely whenever weeds are seen to be springing up and the land is in a suitable condition to work. Gooseberry bushes are fre-

FIG. 82.—CROCUS SPECIOSUS AS NATURALISED (SEE P. 165).

quently allowed to get in a neglected condition, whereas to obtain the best results they need good treatment, and especially if the land is light and porous. This should be given heavy dressings of rich farmyard manure annually, and repeated soakings of liquid manure when carrying heavy crops, in dry weather.

**Cuttings.**—Cuttings of Gooseberries that were inserted last autumn should be examined, and if found to be loosened by the action of frosts pushed down and made firm again. The same remarks apply to cuttings of Black and Red Currants. Young plants rooted last year that need more room should be carefully lifted and transplanted 18 to 20 inches apart. The heads may need a little pruning to ensure a neat shape. Keep the different varieties correctly named, and, to be on the safe side, make a note of the different sorts where they are growing; it frequently happens that the labels get displaced when the work of hoeing and cleaning is being done. Warrington is one of our best late dessert varieties of Gooseberries at Wrotham.

### PLANTS UNDER GLASS.

By T. PATEMAN, Gardener to Sir C. NALL-CAIN, Bart., The Node, Codscoote, Welwyn, Hertfordshire.

**Seedlings.**—Such plants as *Gloxinias*, *Streptocarpus*, and *Begonias* that were raised from seed sown early in February are ready for pricking off into shallow boxes or pans filled with a light, sandy compost. The pans should be prepared and the soil watered two or three days in advance of planting, and stood in a warm house. In removing the seedlings, great care must be taken not to injure them, and for a few days a little extra shade will be necessary to protect them from bright sunlight. The receptacles should be stood near the roof glass, and the seedlings sprayed overhead several times daily in bright weather.

**Pelargonium.**—Cuttings of Zonal *Pelargoniums* should be inserted now to obtain plants for winter flowering. Select the best ripened growth as cuttings, and insert the latter several together in a 4½-inch pot. They should be rooted in a moderately warm house, and when ready potted off singly into 60-sized pots. The soil for this potting may consist of two parts turfy loam to one part leaf-mould, with silver sand added. These plants should never be allowed to become pot bound until in their final pots, as the *Pelargonium* resents its roots being restricted in its young stage. Keep the plants in a close atmosphere for a few days after potting, but when they are established in the soil admit air on all possible occasions. Pinch the shoots during the growing season to promote a bushy habit.

**Perpetual Carnations.**—The young plants comprising the various batches of perpetual-flowering Carnations should be potted on as they require more root room; it is a great error in cultivation to allow these plants to become pot-bound and starved in their young stage. The soil of plants growing in small pots quickly dries up when the receptacles are filled with roots, and to avoid a too frequent use of the watering-can attention should be given to repotting of the plants. Before this is done the grower should decide what sized receptacles the plants will be flowered in, and use pots of various sizes accordingly. Some growers advocate the use of 7-inch pots for the final shift. I find receptacles of 6-inch diameter quite large enough for most varieties. Carnations resent overpotting, and the small grower would be well advised to keep to the smaller size, and assist the plants with soot water and a suitable Carnation manure, when the pots are well filled with roots. The compost for this potting may consist of good fibrous loam with manure from a spent Mushroom bed, after it has been rubbed through a fine sieve, with a liberal dash of silver sand and fine mortar rubble added. At all stages care should be taken not to pot too deeply, and always see that the receptacles are clean and dry before using them.

### THE FLOWER GARDEN.

By EDWIN BECKETT, Gardener to the Hon. FICHAIR GIBBS, Aldeham House, Hertfordshire.

**Water Gardening.**—At Aldenham we grow a considerable number and variety of waterside plants and aquatics in association with the streams, ponds, etc. At this time of the year the plants are given every attention necessary whereby they may be grown at their best, and form beautiful additions to the garden. Too frequently the banks and edges of ornamental waters are left in a poor, bare condition, whereas much that is beautiful and interesting might be grown on them. Dealing first with the true aquatics, the most important are the many glorious *Nymphaeas*, or Water Lilies, which are most easily grown, but regarded by many as difficult subjects. Some are strong growers and require a good depth of water, and of these *N. alba* and varieties of *N. Laydekeri* and *N. Marliacea*, should be allowed up to 6 feet depth of water, but others do not require so much, being of smaller growth, and are suitable for planting in shallow pools and ornamental basins. Care should be taken with their planting, and the best way to do this is to

**AWARDS TO CROCUSES.**

At the meeting of the Royal Horticultural Society on February 28, 1922, the Council gave the newly instituted Award of Garden Merit to *Crocus Tommasinianus* and to *C. speciosus* (Fig. 82).

Both plants are good doers and will, with ordinary care, increase rapidly in any well-drained British garden. Their only enemies are field mice and pheasants. Both plants produce seed freely and multiply by the formation of so many small corms that so long as their foliage is allowed to remain until it becomes brown (about the end of April) permanence and increase are assured. The only attention they require is an occasional replanting when they become too thick. The one brightens the garden in the early spring, the other tones the browns, reds, and yellows of the dying year.

*Crocus Tommasinianus* flowers, as a rule, just before most forms of *C. vernus* (Fig. 83), and

lavender-violet, which will not interfere in the least with the flowers that are to follow after. It should be planted in August or September, and seed should be sown as soon as ripe in the open to germinate with the growth of the corms in the spring.

*Crocus speciosus* flowers in September and October, and is the most reliable and showy of all the autumn-flowering species, unless it be *C. nudiflorus*, great drifts of which form one of the beautiful autumn features of Wisley, and which, though so abundant in its easily accessible native home, is scarcely known in the nurserymen's catalogues. *C. speciosus* should be planted in July. It will grow in short grass where, as at Wisley, it may be left alone for years, and every year will give stretches of blue among the green of the grass and the brown of the falling leaves without any further care. It will grow under light shade and in the open, and is suitable for the herbaceous border and the lighter shrubbery, the grassy bank, the rock garden, the edge of

FIG. 83.—CROCUS VERNUS, A BEAUTIFUL EARLY-FLOWERING SPECIES. FLOWERS VIOLET, LILAC, WHITE, OR STREAKED WITH WHITE AND VIOLET.

about the time of the old Dutch yellow *Crocus*. It has a slender grace that most of the Dutch forms of *C. vernus* lack, and is, when open, of a clear and delicate colour described by Maw as sapphire-lavender and by Bowles as amethystine-violet. No Dutch *Crocus*, except the one I hold the most beautiful of all, *Margot*, is so tender and pleasing in shade. When closed the flowers of most forms are of various shades of grey.

*Crocus Tommasinianus* is a variable plant, especially perhaps in the colour of the buds, but there is a deep purple variety, a pure white and a particularly pleasing one called "pictus" with flowers marked at the tips with a darker blotch, below an apical white spot.

This beautiful species does well in many places at Wisley, in the open, and in the light shade of shrubs and trees, but does not prove quite so happy as many in the grass. Its best place is on the higher parts of the rock garden, where it may seed down and gladden the early days of dull February with drifts of

the wild woodland walk and the field garden. A strong and vigorous flower, it is calculated to withstand all reasonable buffetings of autumn. In its typical form it is beautifully pencilled with blue on a pale lilac ground, but varies much in colour and size, and numbers of names have been given to more or less distinct forms, the most remarkable of which are the var. *Aitchisonii*, the giant of the species, and flowering later than the type, collected by Mr. H. J. Elwes in the east (for while *C. Tommasinianus* is more western in its distribution, *C. speciosus* stretches away into Armenia and perhaps into Persia); Van Tubergen's var. *Artabir*, intermediate in colour and season between var. *Aitchisonii* and the type; var. *globosus*, a bluer, later-flowering variety; and some white and grey forms which Mr. Bowles has raised which are still rare, but beautiful in their blue pencilling on a white ground, and therefore preferable to the better known pure white form, which is rather starchy in shape. *F. J. Chittenden*.

**FRUITS UNDER GLASS.**

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY M.P., Ford Manor, Lingfield, Surrey.

**Pot Vines.**—The bunches on the earliest pot vines will soon be over the stoning process and the berries commencing to swell freely. The advantage of moderate cropping is seen in the persistent production of laterals; pot vines with roots restricted to a cubic foot of soil may appear weak, yet if the foliage is healthy the berries will finish well. It is too late after stoning to cut off superfluous bunches, but a few berries may be removed where they show signs of crowding. As every new leaf assists the roots, and black Grapes colour best under the shade of healthy foliage, the laterals should still be allowed to grow so long as space can be found for them. Top-dressing should be applied with care for some time to come, and the fertilising properties of the materials well washed down to the roots with warm guano water and soot water on alternate occasions, but when the Grapes get further advanced these stimulants must give place to pure water. At that stage the amount of atmospheric moisture should be reduced and more fresh air admitted. When the Grapes are ripe water should be given the roots less frequently, but on no account should the foliage be allowed to suffer. Reduce the temperature gradually by an increased circulation of dry, warm air. Guard against the roots of *Madresfield Court* variety having a deficiency of water before the berries have attained their full size, as a check from drought, followed by a copious application of water, is almost sure to result in the loss of some of the finest berries.

**Young Vines.**—Vines that were cut back and started in gentle warmth as recommended last month should be ready for their final shift into 11-inch or 12-inch pots. As the healthy roots are essential until the Grapes are ripe, too much care cannot be devoted to this operation. The pots and crocks should be clean and dry when used. The compost should consist of rough, lumpy loam, bones, and old lime rubble, and it should be fairly dry, as it will require firm ramming. If mixed a fortnight in advance so much the better. No animal manure should be used, but bone-meal may be employed rather freely.

**EDITORIAL NOTICE.**

**ADVERTISEMENTS** should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, W.C.2.

**Editors and Publisher.**—Our correspondents would oblige by delaying in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the EDITORS. The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.

**Special Notice to Correspondents.**—The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.

**Local News.**—Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

**Letters for Publication,** as well as specimens of plants for naming, should be addressed to the EDITORS, 5, Tavistock Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

## MR. KINGDON WARD'S SIXTH EXPEDITION IN ASIA.\*

No. 12.—MORE PRIMULAS.

IN my last notes I referred to the great success we had in finding nine Primulas in two days. However, next day, when we set out to cross the range, all previous records were put in the shade. *Primula sonchifolia*, that universal but elusive species of Yunnan and the North-East Frontier, turned up at about 11,000 feet; and then, in the narrow valley leading up to the pass, shut in by frowning cliffs, we suddenly came upon such a mob of Primulas as I would scarcely have thought possible, and certainly had never seen before, either on the Mekong-Salween divide or anywhere else. We simply trampled on *Primula pseudo-sikkimensis*, *P. brevifolia*, and *P. secundiflora*. (I call them by the names of familiar species which they superficially most resemble; they are not necessarily identical.) *P. vincaeflora*, a glorious violet, dotted the slopes, and the sweetly fragrant *P. Giraldiviana* was coming into flower in the woods lining the stream, on the drier slopes beneath the Rhododendrons. So much for known species—if they are known. And no sooner did I see what we had unexpectedly trotted into than I called a halt and there and then had the tents pitched. By the time this operation was completed I had found two more Primulas by no means familiar. The first of this pair was a meal-less bog Primula, sharing the ground with *P. secundiflora*, but selecting even wetter places. It has fine large flowers for its size. It is only 8 or 10 inches high, 6 to 8 in the umbel, purple, lilac, or almost mauve, with white eye, and delightfully fragrant. It was as abundant as the others, some of the boggy ground being coloured with it. With some hesitation I place it in section *Farinosa*—or is it *Auriculata*?

The second was clearly a *sikkimensis*, but such a *sikkimensis* as I, at least, had never seen before. The leaves were glaucous green, with the white veins showing curiously through; the flowers lemon-yellow in nodding umbels. But the unique feature of the plant is that the oblong petals are completely reflexed on the tube and closely adpressed on it, almost touching the calyx teeth. It is a tall, handsome plant, on the shady, wooded slopes beneath the Rhododendrons, where it flourished in considerable numbers. I even secured ancient seed of it, as I did of several of the other species. The roots were bright crimson—apparently it was hant on differing

in every particular from its nearest relations. The only fault I could find with it was the flowers, owing to this doubling up of the petals, being rather small, it ought to have grown in masses; whereas it was quite scattered. But, in fact, it was only just in flower, and a month hence would present quite a different appearance.

We had found eight species of *Primula* in the course of the morning. The afternoon's exploration yielded three more, including the most magnificent of all; and the following day yielded a twelfth.

Of the three found in the course of the afternoon, one was a dear little *Soldanelloides*, with modest drooping, purple bells frilled round the edge. A plant of 2 inches or so, the slender stems rose from a rosette of toothed

FIG. 84.—*FORSYTHIA SUSPENS*A VAR. *ATROCAULIS*.  
(See p. 167.)

leaves on steep, shady, moss-clad cliffs beneath the Rhododendrons.

Another was a wee plant of the crags, with remarkably large purplish mauve flowers, almost flush with the cliff, the tiny leaves being jammed almost into the crevice. These plants were scattered, one flower at a time, over the vast, empty area of the limestone walls. Could it be the lost—or, rather, un-found, for I do not know that anyone has looked for it since it was first discovered—*P. sertulum*? But *P. sertulum* comes from Tatsientu, a good distance north. More likely it is a new species. The solitary flowers and bleached, dead leaves are characteristic.

One might write pages about the glorious *Nivalid* I came across that afternoon. The

colour of the flowers alone—and they are an inch and a half across, no mean size—would send even the most prosaic into ecstasies. The most refined shades of plum-purple, lilac, violet, and strawberry tint, softened with rouge powder, convey but a faint idea of its glory. The velvety surface of the corolla was shot like silk with two different shades, with a central chalice of pure white silver where the meal is concentrated. The flowers, six or eight in the umbel, are nodding, and the upper petals, being slightly reflexed, the corolla is curiously pushed forward, giving an appearance of zygomorphy as in *P. vincaeflora*. Sometimes a second umbel is produced, the stem growing through the first. This splendid plant, which grows 18 inches high, was abundant on the high, wooded ridges between 12,000 and 14,000 feet, and I secured a little of last year's seed for a start. It is easily the finest *Primula* I have ever seen, but I am sure that, however well it is grown in England, it will never look so fine as it did under the Rhododendrons on the limestone crags above Mu-li.

Lastly came another small *Nivalid*, not unlike *P. minor* or *P. pulchella* in fruit and habit. The flowers were practically over, and I could only make a guess at their colour and appearance. It grew in steep gullies between the limestone towers, or rather in a gully, for I found it in one place only.

Thus on the Litang River divide we found twenty-one *Primulas* in three days, and have high hopes of others yet, as soon as we succeed in finding some higher peaks which can be climbed by inexperts, such as we are. For where are the *Bellas*, the *Dryadifolias*, the *Suffruticosas*? Surely there must be some at 15,000 feet and over. But as yet we have only reached 14,000 feet sporadically.

Of the other flowers on this range I must write in my next letter. *F. Kingdon Ward.*

## FORESTRY.

### NATURAL REPRODUCTION OF PLANTATIONS.

RARELY is full advantage taken of Nature's method of re-stocking denuded woodlands, a fact that has been forcibly brought home to me of late when examining some of the grounds from which timber for war purposes was removed, and which are now in the process of natural regeneration. An interesting exception to the rule is that of a plantation of Scotch Pines on Lord Derby's Coworth Park estate, near Sunningdale, in Berkshire, the trees from which were felled and cleared during the war, the site to-day being thickly covered with a healthy crop of self-sown Pines and hardwoods, which have sprung up from seeds of the previous crop. The latter, which mainly included Birch, has appeared in such numbers and grown so rapidly that almost immediate attention will be required in order to prevent the Scotch, Corsican and Weymouth Pines and Larch from being ousted out by their faster-growing and more spreading neighbours. Though the original crop of trees was only felled some five years ago, yet many of the self-sown Birches are fully 5 ft. high and proportionately spreading, the Pines ranging in height up to 30 in., all being remarkably stout and sturdy. The soil all over the plantation is of an unusually kindly nature and peculiarly suited for regeneration purposes, being of a sandy texture with a top surface of rich, black loam, which has produced some of the finest specimens of the Weymouth Pine that are to be found anywhere in this country. In addition to the trees mentioned the undergrowth consists of Gorse, Broom, Heather, and occasional patches of at least two species of *St. John's Wort*, whilst within the damper ground are Willow and Alder. In this particular instance nothing was done to the soil after it was cleared of timber, the original intention being to replant the ground later. However, after a careful examination of the site it was found that seedlings of the Scotch, Austrian, Corsican, and Weymouth Pines, common Larch and several specimens of hardwood, the Birch and sweet Chestnut in particular, were springing up in all

\* The previous articles by Mr. Kingdon Ward were published in our issues of May 14, June 18, July 23, August 20, September 3, October 8, October 29, 1921; January 7, January 21, March 11, and March 25, 1922.

directions over the depleted area, so that replanting was unnecessary, the only positions where Nature might be assisted being along the hard roadways where timber haulage had been engaged in. By timely and careful thinning, a valuable crop of trees, whether for ornament or utility, will be obtained at no cost whatever, save that of weeding out undesirables in order to allow the permanent trees to become fully developed, and the rapidity of growth and freedom from disease in Nature-planted trees are too well known to require comment. In another almost similar case with which I have had to deal on the Holwood property, in Kent, a plantation of Larch and Weymouth Pine was felled owing to the diseased condition of a large number of the trees, which had been brought about by the unsuitable quality of the soil in which they were growing. The whole crop was ultimately cut down in order to make room for self-grown Sycamores that were springing up freely all over the ground, evidently the produce of seeds that had been wafted from old trees of the same kind on the margin of the plantation. The last of the diseased trees were felled five years ago, and to-day many of the seedling Sycamores measure over 10 ft. in height and have completely stocked the cut-over area.

Owing to the excessive cost of labour, scarcity and high price of young trees, and exorbitant land taxes every owner is not prepared to go to the expense of restocking tracts of woodlands that have been cut over for war purposes, the present cost of tree planting being about three times what it was in pre-war days, while the twenty-five or thirty years that must elapse before there is any return for money expended is another deterrent factor. In such cases every advantage should be taken of the natural regeneration of plantations, and assistance given in cases where the ground is not fully stocked, either by the sowing of seeds or insertion of young trees. In some cases little will require to be done to assist in restocking the area, but in others fencing against rabbits and farm stock may be imperative. In the case of rabbits wire netting is to be recommended, while as a fence against sheep or cattle wattle hurdles will prove a cheap protection till the trees are out of danger. Of course, it is not in every position that natural regeneration of woods and plantations can take place, but as a comparatively large amount of timber felled for war purposes was the produce of low-lying, sheltered woodlands that adjoined others in which the trees were of a seed-bearing age, the conditions were in every way favourable for such a method of restocking. One of the few drawbacks to restocking ground with the same species of tree is the liability of the young stock to be attacked by insect pests, as the Pine beetle in the case of the Scotch Fir, which pest has, unfortunately, been greatly on the increase of late years, owing largely to the accumulations of dead and dying wood and branches that have been left in our woodlands as a relic of war times. These, and old tree stumps, form the best of all breeding grounds for the insects that prey on our Coniferous and hardwooded plantations. A. D. Webster.

## TREES AND SHRUBS.

### TWO INTERESTING FORSYTHIAS.

*FORSYTHIA SUSPENS* VAR. *ATROCAULIS*. Mr. E. H. Wilson discovered this distinct variety of *Forsythia suspensa* in Western Hupeh, China, in 1907, where it grows in thickets on moors and cliffs. From the old *F. suspensa*, so long known and valued in gardens, this variety is chiefly distinguished by the dark purple, almost black, young shoots—as indicated by the varietal name. It differs also in the flowers, the four lobes of the corolla being distinctly broader and somewhat shorter than in the typical form; they are also of a paler, more Primrose yellow. Of its free-flowering character our illustration (Fig. 84) gives sufficient testimony, and it makes a pleasing addition to a very valuable group of hardy flowering shrubs.

*F. INTERMEDIA* VAR. *SPECTABILIS*. *Forsythia intermedia* itself is a hybrid between *F. sus-*

*pensa* and *F. viridissima*; its variety *spectabilis* (Fig. 85), was raised in Spath's nursery, near Berlin, and put into commerce about 1906. It is no doubt a seedling from *F. intermedia*. On the whole, it is probably the most beautiful of all *Forsythias*. The flowers are produced in wonderful profusion, and are of a rich, golden-yellow. In habit, too, it is picturesque, being

relied on to give a glowing mass of colour over so long a period. Like the other *Forsythias*, it needs a good loamy soil and should be planted in a sunny spot. It is easily propagated from leafy cuttings struck in gentle heat in July or August. The Floral Committee of the Royal Horticultural Society gave this shrub an Award of Merit on March 30, 1915.

FIG. 85.—*FORSYTHIA INTERMEDIA* VAR. *SPECTABILIS*.

of erect, uneven growth and, when planted in a group, sends up pyramidal clusters of branches that stand well out from the main mass. A large group in one of the shrubberies at Kew has made a beautiful display for several weeks past, in spite of cold winds, frost and occasional snow. In its ability to withstand inclement weather, it offers a marked contrast to other things that came into flower when it did, such as *Rhododendrons* and *Prunuses*. It may safely be said that no shrub flowering in March is better worth planting or can be more surely

### CARYOPTERIS MASTACANTHUS.

ALTHOUGH this plant was introduced from China in 1844, it is not common in gardens. It is generally supposed to be not very hardy; but my experience, at least on warm, dry soils, is that it is hardy over a great part of the country. In any case, it is so beautiful that it is worth a position at the foot of a warm wall; its violet-blue flowers are borne in profusion in September. It is best pruned hard back every spring, just when it is starting into growth. J. C.

## EARLY FLOWERING CHRYSANTHEMUMS FOR GARDEN DECORATION.

EARLY-FLOWERING Chrysanthemums for beautifying the garden and borders are not grown nearly as freely as they should be, therefore a few words concerning the best methods of obtaining a good display in the autumn should be of interest to those who have not yet paid much attention to the cultivation of this desirable class of flowers.

The best way to keep the stock during the winter months is to lift the stools about the end of October, or as soon as the plants have finished blooming, and place them in a cold frame, setting the stools closely together, and putting a little mould about their roots. Afford plenty of air on all favourable occasions, and cover the glass with mats during severe wintry weather. There are two methods of propagation. I prefer to take cuttings about the end of January or early in February, and place them in boxes about 15 inches long, 10 inches wide, and 3 inches deep; each box should hold about fifty to sixty cuttings. Fill the boxes with a mixture of loam, leaf-mould and sand, with a little finely sifted coke ashes. Dibble in the cuttings, make them firm, and give a good watering to settle them in. Then place the cuttings in a temperature of 50°, spray them overhead occasionally, and shade them during bright sunshine.

In about five or six weeks the cuttings should be well rooted, and should then be potted off singly into 60-sized pots. Return them to the frame or greenhouse until the roots have taken hold of the new compost, which should consist of loam, leaf-mould and sand, with a little Clay's fertiliser added. Set the plants in a cold frame, and keep them fairly close for a few days until they are established in their new quarters. If kept well syringed on all bright days they will not require much water at the roots. A great deal of damage is done at this time of the year by over watering. Pinch out the points of growth as soon as the plants are established in the pots. At the end of April the Chrysanthemums should be ready for planting out about 2 feet apart, where they are intended to flower.

The ground for early-flowering Chrysanthemums should be well prepared beforehand, adding some well rotted manure, as all Chrysanthemums respond to liberal treatment.

A simple method of propagation is to select the strongest growths from the old stools, with a few roots attached, and plant them in their permanent quarters not quite so far apart, but by this method they always appear to be a long time before getting a good start. When they are planted out they should be given every encouragement to grow, not left alone to take their chance. By keeping them well sprinkled by means of a fine rose can morning and afternoon, and allowing time for the foliage to dry before night, and also by using the hoe freely to keep them clean from weeds and staking them as soon as they require it, they will grow freely.

A few of the more recent introductions include Goldfinder, an intensely rich golden yellow, height 2 feet, flowering in September; Lichfield Pink, a charming shade, 2½ feet, September; September Glory, brilliant orange-bronze colour, if disbudded gives a very large, well-formed flower; September White, very free flowering, 2½ feet; Golden Goacher, a sport from Goacher's Crimson, 2 feet, September; and Bronze Provence, a light bronze sport of Provence, 2 feet.

Of the older varieties the following is a good selection:—Almirante, orange-bronze, very fine for cutting, 2½ feet, September; Betty Spark, rosy pink, good sprays on long stems, 3 feet, September; Bronze Betty Spark, a sport from Betty Spark, same habit; Bronze Goacher, 2 ft., September; Bronze Normandie, 2 feet; Cranford Yellow, a very fine yellow, if disbudded, 3 feet, October; Crinon Marie Masse, 2 ft., September; Dick Barnes, crimson, fine as a border plant, stiff bushy habit, September; Dolores, terra-cotta, 3 feet, early October; El Draco, orange-amber, very good for cutting, 2½ feet, Octo-

ber; Elsenham White, the best early white if disbudded, 3 feet, September; Etoile d'Or, golden-yellow, 3½ feet, October; Fée Parisienne, rosy mauve, very fine, 3 feet, September; Framfield White, 3 feet, September; George Bowness, crushed strawberry colour, August; Goacher's Crimson, fine for bedding, 2 feet, August; Goldfinch, buff-amber, August, 2 feet; Horace Martin, very fine golden yellow, 3 feet, August and September; J. Bannister, lemon-yellow, with reddish-copper, 4 feet, September; Le Pactole, bronzy-yellow, 2½ feet, October; Lichfield Purple, a very fine, showy garden plant, also fine for cutting, 3 feet, September; Madame Marie Masse, Blac-mauve, 2½ feet, September; Miss K. C. Thorpe, white, faint blush tinge, 2½ feet; Nina Blick, bright scarlet, finishing golden-bronze, 2 feet, August; Normandie, bluish pink, 2 feet, September; Perle Châtillonnaise, creamy white, 4 feet, September; Perle Rose, 2 feet, September; Pink Profusion, this is a lovely pink variety of fine habit; when disbudded it will give a dozen fine blooms, also does well in pots, end of September; Polly, deep orange, flowers large and of fine form, 2 feet, September; Provence, bright rose pink, tipped with gold, 2 feet, September; Ralph Curtis, creamy white, 2½ feet, August; Red Almirante, very fine, 2½ feet, September; Roi des Blancs, pure white, graceful sprays, 2½ feet, August; R. Pemberton, clear amaranth, 2½ feet, October; Sanctiv, one of the best whites, 2 feet, August; Southover Yellow, 3 feet, September; and Verona, bright terra-cotta, fine for cutting, 2 feet, September.

A dozen good sorts for the border are: Goldfinder, Crimson Polly, Polly, Madame Marie Masse, Horace Martin, Sanctiv, Pink Profusion, Dick Barnes, Goacher's Crimson, Almirante, Bronze Goacher, and Framfield Early White. *Wm. Holden, Woburn Place Gardens.*

## NOTES FROM WISLEY.

A VERY striking object in the gardens at present is a scarlet-flowered specimen of *Camellia japonica*, about 12 ft. high, and a mass of blossom. Though this shrub bears a large number of flower-buds each year, they often fail to open, and drop off if the roots are flooded or too dry. There is also a very pretty pink-flowered *Camellia* in the same part of the wood.

In the rock garden some of the dwarfed *Rhododendrons*, such as *R. dauricum* and *R. racemosum* are flowering, and large spaces are covered with *Saxifraga apiculata*, *S. a. alba*, and the bright yellow *S. sancta*.

A fine patch of colour is afforded by the flowers of *Pulmonaria Lawsonii*, the leaves of which are devoid of the spots characterising the common Lungwort; other attractive blue flowers are those of *Anemone Hepatica*, which are springing up under the shelter of a silvery *Eleagnus*.

By the side of one of the rock pools is a very beautiful form of a common wild plant, the Lesser Celandine. The plant in question was collected on Epsom Common, and possesses large cream-coloured petals, which are glossy on the upper surface, and very prettily tinged with green beneath. The leaves are also handsomely marked. By the side of this is the double yellow-flowered form, *Ranunculus Ficaria* fl. pl.

The Alpine house now presents a gay appearance. The eye is at once drawn to a pan of *Ranunculus asiaticus*, the blackish-brown centre of which intensifies the brilliancy of its orange petals. This plant should do better still next year, as it has only been grown from the dried roots recently sent to the gardens.

Among the *Saxifragas* in the Alpine house the *Engleria* section is well represented. This embraces *S. Griesbachii*, which is curious and attractive, with its grey rosette, from which rises the flowering stem covered with crimson hairs and culminating in a red head of flowers.

The Carnation trial, which has been in progress at Wisley, has now been judged, and awards have been made. The number of flowers picked each month since October from the

plants sent in was put before the judges before they made their awards.

Although a large part of the Orchid collection has been disposed of, numbers of Orchids are in flower. A curious plant blooming in the Orchid house is *Crassula arborescens*, which has a small, pinkish white flower, fleshy leaves, and remarkably thick, woody stems, which are 3 to 4 inches thick at the base. The plant itself is only about 3 feet high. *J. E. G. White.*

## ON EDGING WALKS.

AT this season the grass edges of walks need attention, and if this is given now there will be economy of labour during summer, apart from the fact that the appearance of a neatly-edged path or road is attractive. All walks have a tendency to get out of line, more so in light soils than in those of a tenacious character. Should the edges be cut year after year so as to bring parts worn away into line, then there inevitably follows a widened path, usually only observed when some architectural feature such as steps or ends of a wall are obviously out of line with them. To obviate such a state of affairs, the original line must be retained when re-cutting the edges in spring. This means that the worn parts must be brought into line instead of removing the other parts to regain the contour or straight edge, as the case may be. This is effected quickly by simply pressing a spade under the turf in these parts, cutting it with an edging iron in a line with the walk and six or eight inches back from it. The turf is then easily pushed forward by means of either a spade or the edging iron, the vacant space left being filled with pieces of turf removed from other parts of the edging.

There are two methods by which a too wide path may be straightened to the original width. One by introducing a line of turves to the proper width, which, unless the space to be filled is at least nine inches in width, is not to be recommended, being less neat than the other method. The latter consists in bringing forward a piece of turf in width about eight inches and filling the space left vacant by its transposition by imported turves. The principle is exactly the same as recommended for worn patches only on a large scale.

The method is to stretch a line to the breadth of turf required to be moved. Cut along the edge of the line with an edging tool. Press a spade or turfing iron under the turf thus cut to a depth of two inches, after which remove the line to a little beyond the required new edge of the walk, and push the prepared turf forward to the line of its new position. Then pat the sod gently down to level it, cut the edge to the right width, and a perfect piece of turf is provided all along the side of the walk, the cut turves being less conspicuous out of the eye-line.

Young gardeners who may have paths to edge should accustom themselves to taking contours with a line only, using no pegs or sticks. It is perhaps a little difficult at first to obtain just the correct run of the walk, but once the eye is trained to distinguish between the true run of curves and those unpleasing to the eye, the method is vastly superior to that of running the line round a series of sticks not always easy to place in position. If a line is slightly out of the true contour several yards away, it is easy to bring it into position without moving off the spot, and indeed, so rapid and true is this method that I am certain a clever workman would have the edge of a long stretch of walk finished before he could have sticks set and line arranged.

There is just one other important point to be mentioned. Some, indeed many, workmen, in using the edging iron, push the cut turf over the walk; a practice that should not be permitted. Useless material should be lifted and removed without allowing any of it to touch the path. *R. P. Brotherston, Tynninghame Gardens, Prestonkirk.*

**THE FLORISTS' TULIP.\***

(Concluded from page 155.)

THE Tulip is an amateur's flower; it is not so much that it is difficult to grow or exacting as to soil or climate, but it needs personal care, and it has one exasperating habit which puts off the man who gardens vicariously. The marking is inconstant; a bulb may throw a perfect flower one year, and by all rights should come exactly the same in future years. All too often it does not, but the bloom shows some irregularity or some glaring splash of colour which renders it useless on the show bench. It is possible to grow a score of one variety, and not have one flower fit for exhibition. This disgusts the man who has paid a high price for a particular bulb. He thinks he has been badly treated; indeed, as all bulbs are alike at planting time, an unscrupulous seller may put him off with a poor strain of the same variety. If a new Daffodil is bought, there can be no doubt about its being true, and given proper cultivation the flowers will be just as good as those of other people. Still, among florists' Tulips some varieties are steadier than others, and can be counted on to come fine. The newer seedlings are great improvements in this respect upon the older ones, and without doubt we shall breed out this inconstancy like the other faults of the flower.

But some folk may be wondering why bother

like the English, are both breeders and broken, and are divided according to their colour into bizarres (yellow ground), roses (red shades on

freely, much to the disgust of their owners, because the markings possess no quality. One or two of them can be shown among English

FIG. 87.—FLORISTS' TULIPS: SIR JOSEPH PAXTON, FLAMED BIZARRE.

white ground's), and bicolors (purple shades on white ground). Some thirty years ago Krelage, of Haarlem, introduced into commerce a new race of Tulips, which he called Darwin Tulips. They are the outcome of the old stock

breeders, and one or two men have experimented in crossing them with English florists' Tulips, in order to impart their vigour and strength into the more refined race. Undoubtedly the Darwins are among the best garden Tulips, for they will stand up unharmed to hail storms and rough winds.

There is another race of May-flowering Tulips which the catalogues call "Cottage Tulips." This heterogeneous class really embraces all the chance seedlings which have been cast out by the florist, but which, from some excellence of colour or style, have been preserved for garden decoration. The class owes its name to the fact that many of the varieties have been picked up in old cottage gardens, unknown beyond then until some of the great bulb firms multiplied them and gave them a wide circulation. They embrace pre-eminently a number of lovely pure yellow Tulips, and certain delightful varieties, where a yellow or pink flush struggles with the more dominant colour of the flower.

Then there are double Tulips, which are an abomination; and Parrot Tulips, odd creatures of great interest and lovely colour, but rather dependent on a good climate.

I cannot pretend to have touched more than the fringe of my subject; there are still scores of points connected with this fascinating flower that call for elucidation, but I hope I have said enough to introduce some garden lovers to the great tradition that surrounds this lovely flower. For more than six centuries now it has been a labour of love to gardeners in divers countries to elucidate its beauties. I think with rever-

FIG. 86.—FLORISTS' TULIPS: FLAMED FLOWERS SHOWING THE CLEAR BASE. LEFT, TALISMAN; RIGHT, MABEL.

about all these points in the flower—form, purity, marking, and so forth; why not admire the Tulip as a flower which may be beautiful even with pointed petals? Why have artificial rules of excellence at all? This opens an age-long dispute, but it is not merely a question of taste. The so-called artificial rules are the outcome of the tradition and judgment of successive generations of men who have best known and loved the flower; they represent what in their judgment best displays the essential features of the flower.

Premising that we are concerned with a marked Tulip, then it follows that it must open into a cup and must have broad, round-topped petals, for thereby only are the markings properly displayed. Again, the pure base enormously enhances the effect of the markings, which again must be as symmetrical, definite, and finely pencilled as possible. Of course, a long petal or an impure based Tulip may be beautiful in itself, but it is not on its way to the best. It is not making for perfection, and the true florist will have none of it. Some photographs of florists' Tulips, reproduced in Figs. 86, 87, and 88, will assist me in pointing out wherein excellence and defect lies.

Of course, there is a great realm of Tulips other than the florists' flowers, many of them of extraordinary beauty and growing in favour among gardeners every year. I have mentioned the early Tulips and the Dutch florists' flowers, some of which are still in cultivation. They,

which must have been carefully selected for generations, it is rumoured in some old Flemish monastery. Their characteristics are great vigour and size, and tough leathery petals.

FIG. 88.—FLORISTS' TULIPS: FEATHERED FLOWERS. LEFT, SIR JOSEPH PAXTON; RIGHT, MASTERPIECE.

though their shape is somewhat square and ungainly. Among Darwins proper there are no bizarres or yellow grounds, only pink and purple shades, sometimes with white, though generally with blue, bases. Typically, they are all breeders, though, like other Tulips, they freak

ence, almost with tears, of many forgotten men in all these generations who have found, perhaps, their purest pleasure in watching its blooms unfold, and whose achievement in life was to make one step towards the perfect flower of which they dreamed.

\* A lecture delivered by Sir Daniel Hall at a recent meeting of the London School Gardening Association.

## DIETETIC AND MEDICINAL VALUE OF NETTLES.

At this period of the year green vegetables are scarce in many gardens, and especially is this so in southern areas after a season like the one experienced in 1921. It may, therefore, interest certain readers not already acquainted with the fact, to know that the young Nettle tops are good to eat, and that Nettles have also a medicinal value of no mean order.

There is no nicer vegetable, at any season, than boiled Nettle tops, though, generally, spring is the best season when the growths are young, but by cutting down the plants a new crop is soon available at any season, thus making it valuable when Spinach is not easily obtained. Nettles are very like Spinach when boiled, but have more valuable medicinal properties.

Nettles may be used to make a soup, which, properly flavoured, is very agreeable. With Leeks, Broccoli, and Rice, Nettles are used in Scotland to make Nettle pudding, a delicious blending of natural vegetables, the excellence of which is obvious.

No doubt the reason why Nettles are so beneficial, whilst being at the same time so palatable, is the fact that they contain formic acid, a large proportion of phosphates, and a small percentage of iron. Indeed, they have been used in the treatment of consumption, the young tops being mashed, made into a pulp, and mixed with thick cream, pepper and salt.

As a homeopathic remedy Nettles are highly recommended, as, besides being astringent, they serve as a useful tonic. They are used as an infusion of the dried plant, or, when made into a tincture, to stop bleeding from the nose or internally, the juice itself having been used for this purpose. With its astringent properties the Nettle is also valuable as a gargle. For burns, moreover, Nettles may be used in tincture form, with damp cloths.

Nettle tea is perhaps better known than other preparations. For rheumatic complaints, as I can personally testify, the tea is very valuable, and is by no means disagreeable to drink; it may be flavoured and sweetened if desired, though it is quite pleasant without any addition. Other uses to which the tea is put are as cures for Nettle rash and gouty gravel.

Nettle beer is used for gouty complaints and for rheumatism. To make it pluck a quantity of young Nettle tops, wash them well, place in two gallons of water, and add some Dandelion, Cleavers or Goosegrass (also used for beer), and 2 oz. of bruised whole Ginger. The whole should be boiled for three-quarters of an hour over a steady fire. The liquid should be strained, and two cupfuls of brown sugar stirred in. As soon as the liquor is lukewarm, place on the top a slice of toasted bread, with an ounce of compressed yeast spread on it, after being stirred till liquid with a teaspoonful of sugar added. If kept warm for six or seven hours, skimmed, and a teaspoonful of cream of tartar is stirred in, it is then ready for bottling and forms a good substitute for ginger beer.

Nettle juice is used as rennet to curdle milk, the Nettles being boiled; the juice may also be used to make tubs waterproof. Nettles may be used in dyeing, producing a yellow dye, for yarn, and a green dye for wool. It is also a good substitute for Flax, the stems being very fibrous, and in this connection it has been used largely in Scotland for coarse household cloths. It was used in Germany during the war in place of Flax, on a large scale, and the company formed to exploit it is, I believe, still in existence.

In indicating many of the good properties of so common and despised a plant as the Nettle, I have only given one example of how valuable herbs are, not only as an article of food in so many unexpected cases, but for so great a variety of other purposes, besides their medicinal properties. *A. R. Horwood, Leicester.*

## CYANIDING VINES WHEN IN GROWTH.

HAVING failed to exterminate mealy bug in a viney when the vines were dormant, after serious consideration I decided to cyanide the house just as the vines commenced to grow. I had intended to do this before the buds had made more than a quarter of an inch of growth, but, owing to the weather being unsuitable, the cyaniding was deferred until a fortnight after this, and a few of the shoots were an inch long. I am happy to say that the result justified the experiment, for beyond a few of the shoots that were extra advanced being damaged, the rest did not suffer, and all the mealy bugs were destroyed. Of about 2,000 other plants in pots in the viney, comprising some thirty-five varieties in all stages of growth and flower, a few tips of the young growths of Chrysanthemums and Pelargoniums were damaged, but neither the mature leaves nor the blooms suffered any ill effect. Young Tomatos in the seedling pots with their second leaves were, however, nearly all killed. I used 2½ ounces of sodium cyanide, which is half an ounce less than is recommended for dormant vines. At the time of the vine leaves falling I have used as much as 3½ ounces, but that quantity of cyanide damages many kinds of plants, and is no more effective than 3 ounces, which is a safe quantity to use for the majority of plants with mature foliage.

A Muscat house was cyanided just as the leaves commenced to fall, and the bunches all gathered; better results were obtained than when the vines were quite dormant, and with the result that it hastened the falling of the leaves. Some growers maintain that vines thrive better after they have been subjected to cyaniding, and the vines I have referred to have certainly improved in four years from very poor quality to first-class; but that I attribute to change of treatment rather than to cyaniding. Where vines are grown solely in a house by themselves it is an easy matter to keep them free from mealy bug, but when numerous other plants are brought into the house, it is very difficult to keep this pest in check. Ants are active agents in spreading mealy bug in houses, acting as distributors, and I would recommend all growers to see that ants are not allowed to exist in plant houses. With regard to the ants, even cyaniding at the 3½ ounces strength will not kill them, neither will it kill wood-lice or the larvæ of leaf-mining insects, but it kills the adult form of the leaf miner. The risk of injury to the vines with cyanide of potassium is certainly less than with gas tar; I know of some vines that have been badly damaged by the latter material; in fact, nearly killed, and yet the mealy bug was not exterminated.

In *Gard. Chron.*, December 24, 1921, it was stated that ½ ounce of cyanide was sufficient to kill white fly. I put it to the test at once, with complete success, and I also tried its effect on red spider, but it was useless for this pest; indeed, the spider was more lively. Besides being a great pest of Tomatos, white fly seems to threaten disaster to all the members of the Brassica family. It seems to be very abundant in gardens, and I know of no means of checking it on crops in the open. White fly has been prevalent in this locality for some time. *G. Abbey, Stonerwood Park Gardens.*

## CULTURAL MEMORANDA.

### THE TRAINING OF PEACH TREES.

In some gardens the manner in which Peach trees are trained is most deplorable; many gardeners do not appear to have the time or the desire to train their trees in an intelligent manner.

I do not say that an ill-trained tree will not produce fruits equally as good as one with its branches regularly spread and straightly trained. It is not that crooked shoots will not bear good fruit, but appearance should certainly be studied. Under certain conditions—such as crowding of the branches—faulty training is responsible for unsatisfactory crops. Of all fruit trees none is more adversely

influenced by crowding of the branches than the Peach and Nectarine. Maturity of the current season's growth from whence the subsequent fruit crop is obtained is an absolute essential to success, and in no way is the ripening process affected more than by depriving each shoot of its due share of light and air. Trees in the open are, perhaps, more affected by overcrowding than those growing under glass, especially during a wet and cold season.

Trees under glass have the advantage of being shielded from incessant moisture, and under glass the air is warmer, more buoyant, and more helpful to maturity than the outside atmosphere during wet, cold weather.

Old-time gardeners were wont to say that the leaves of a Peach shoot should not overlap those of its neighbour, and I am inclined to agree with them, as it is a safe practice to adhere to. Many present-day gardeners are so exacting in their crop expectations that they train the branches of their trees much more thickly than did the older practitioners.

I cannot see the advantage of this method, because a heavy crop of fruit may be obtained with a greater certainty from trees more thinly trained, for the reason that the wood has a better chance of ripening. Trees with ill-ripened shoots never produce fruits of high quality, and, if the thickly trained trees give a greater number, they are not so good in size, colour, or flavour.

Nowadays there is too great a tendency for growers to fill the available wall space in the shortest possible time, and pruning to produce shapely trees is not studied. It is the practice of some gardeners to secure the whole of the shoots to the trellis or wall, the first and subsequent years after planting, in order that the space may be quickly covered and much fruit gathered in a short time. It is in such trees as these that faultily trained branches are common as the years go by. I am strongly in favour of a rather close system of pruning the first and second year after planting, to ensure a well-balanced tree, which is easy to train afterwards. Trees that are not well furnished about the base with branches cannot ever become perfect specimens. Even the merest novice in fruit growing knows that the sap flows direct to the extreme point of each shoot and accelerates the growth in that portion of the tree more than in another, and it is in consequence of this that the lower or basal buds remain dormant, and, if they do so the first season, they seldom start into growth afterwards, unless a severe method of pruning is practised the following and subsequent years.

How much better a tree is in appearance when the branches are trained quite straight—necessarily in a slanting direction when fan-shaped—than where they have bends and abrupt crooks, as is too commonly seen. The extreme point of a branch, no matter how long it is, should be in a straight line from the base of the tree, or where the branch or branchlet starts from. In my younger days we were taught to use a line in laying out all the main branches. It is a simple matter to train the smaller branches and shoots from the main branches on the same principle; not one should show a curve, but should run quite straight from its base; if it cannot be made quite straight, then remove it. The crossing of two shoots was never allowed under any circumstances in the garden I refer to, but at the present day it is all too common. The training of a shoot on a bare branch to hide the latter is not bad practice if the shoots are kept quite straight, but it is only in extreme cases that I would advise even that.

It is difficult to say how far apart the branches should be trained, as so much depends on circumstances, such as size of tree, individual shoots, and requirement; but as a guide, four inches may be regarded as sufficient in a general sense. If the shoots are extra stout, allow more space, as it is far better to err on the side of liberality for the benefit of the tree and its future crop than to overcrowd the growths. *M.*

## FRUIT REGISTER.

## RUSSET APPLES (See pp. 46, 94).

It surely matters little whether that most excellent Apple St. Edmund's be called pippin or russet, though the latter is preferable as being descriptive, whilst pippin has no such attribute. Better still, perhaps, would it be to follow the American system of abbreviation and simply call it St. Edmund's. Rosemary Russet has rather puzzled me, as the character of russetting has been slight or even absent in the specimens I have received and grown; for those who like a somewhat sharp Apple in the late season it is worthy of trial. This evidently makes it clear that its origin is not the *Romarin rouge*, for Leroy distinctly says that this is likely to be appreciated by those who do not like acidulous fruit. With regard to selling power, I was much impressed some years ago by the purchasers at a street barrow, which was laden with a smallish, "dirty" russet (? Golden Knob) and a bright red Apple (? Baumann's Red Reinette). I watched for some minutes and many purchasers bought bags full of russets, but I saw none of the taking red ones sold. Given the chance I think that people will get the better flavoured sorts, but the salesman likes to try and attract with bright coloured ones, however poor or "boxy" the flavour. Lately a very large fruit grower said to me: "May heaven put off the evil day when the public acquires a palate! We shall be ruined!" But Duke of Devonshire variety will hardly save the situation; specimens from the Midlands and from Kent seemed to me to be not higher than third class. Lodgemore Nonpareil seems to me to be one of the best, but I have no experience as to its cropping.

In the recent appreciation in these pages of Messrs. Bunyard's Nurseries, the point about them which has struck me much and to which no reference was given, is the wonderful collection of varieties of all sorts of fruits, extending, indeed, to the original wild stocks.

## APPLE COURT-PENDU-PLAT.

SOMEHOW a curious error has crept into my note (on p. 94) and a circumflex accent is placed over the u; none of the half-dozen French authors I have consulted accentuate the letter. The abbreviation Capendu, with several variants, seems to be used indefinitely for several varieties. Leoeur (*Pomone Nouvelle*, 1914) gives the "rouge" as the sole synonym; Truelle curiously puts down *pas de synonymes*; the former gives it both as a table and vintage fruit. I gather from Leroy (*Dic. de Pomol.*) that Lindley more or less introduced the terminology in this country identifying the rouge with the plat; Mas also follows this. The Apple called plat in this country must evidently be the rouge. Of the two modern authoritative works *Les Meilleurs Fruits*, 1907, of the Soc. Nat. d'Hort. de France, gives only the Court-pendu-gris as the accepted title, with C.-p. plat as synonym; the flesh character being *cassante* and *assez juteuse*, neither of which could be applied to the red variety called plat here. The *Catalogue descriptif* (1906) of the Soc. Pomol. de France, however, lists both the gris and the rouge, and makes the latter synonymous with plat, so that the confusion between the two still exists. When writing before I had relied on Leroy and the *Meilleurs Fruits*, and it is noteworthy that the latter does not admit the red variety grown here under the name "plat" amongst the "best fruits." The cross, Cox's Orange Pippin x Court-pendu-plat (W. Watson), of Messrs. Laxton Bros., has a very marked improvement on flesh texture over the latter parent, though it still retains the peculiar musky flavour to some extent. In regard to history, I may add that Sir J. Cotterell, Bt., and Mr. Wootton have kindly given me evidence of one importation of the Court-pendu (*Journal of Pomology*, Vol. II., p. 123), the original name of which—was it rouge or plat?—was lost, and the Apple was renamed Garnon's Pipping. H. E. Durham.

## VEGETABLES.

## A GOOD CROP OF SPRING CABBAGES.

OWING to the abnormal drought last year winter Green crops have been almost a failure in the south, and in most gardens even the Spring Cabbage crop is none too promising. It is with great pleasure therefore that we publish an illustration (see Fig. 89) of a successful plot of 3,600 plants of Cabbage Flower of Spring on a small holding at Taplow, Buckinghamshire. The photograph has been sent us by Mr. Edward H. Pike with the following note: "I thought the enclosed photograph might interest you and your readers, especially coming from an amateur, an employee of the Great Western Railway Company. I think you will agree, having regard to the difficulties experienced last summer and autumn, owing to the drought, that to obtain such results is very gratifying. The seeds were sown at the extreme end of July, and the photograph taken on Wednesday,

grown by this method as under the old, and certainly at a greatly reduced cost as regards labour and also with the added advantage of immunity from damage and disfigurement of the Celery by slugs—an important consideration. The only question remaining in doubt appears to me to be whether the quality of the Celery is not better, when blanched with earth, than when blanched with paper. Quality should after all be the crucial test, so far as private and home consumption is concerned. Some growers contend that the Celery is sweeter, more crisp, brittle and toothsome, when blanched in the old way than when blanched with paper? Owen Thomas, F.M.H.

## HORSERADISH.

How often one sees this useful plant relegated to an odd, out-of-the-way corner in the garden and left to take care of itself, with the result that the root grows small, ill-shapen, and with often a black streak in the middle! I have known gardens where a plantation of Horseradish has existed for years, and the ground re-

FIG. 89.—CABBAGE FLOWER OF SPRING AT TAPLOW; PORTION OF A CROP OF 3,600 PLANTS.

March 22." Mr. Pike is to be congratulated on his excellent results which many professional gardeners may well envy. Flower of Spring Cabbage is usually very early in hearting and not prone to bolting, so that it is a popular variety for planting.

## ECONOMY IN THE GROWTH OF CELERY.

SOME little time ago, when visiting a notable old kitchen garden, I espied in the distance an unfamiliar and a rather weird-looking crop. On nearer approach, it turned out to be a fine crop of Celery, blanched with paper collars, but not earthed up, grown in an open quarter, the same as a crop of Brussel Sprouts or any other ordinary vegetable might be grown. There is nothing new about this method of growing and blanching Celery, as it has been practised for considerably more than twenty years to my knowledge; but generally on a limited scale. Now, the method is practised on a larger scale evidently.

Provided the ground has the same depth of tillage, the same generous application of manure applied at planting time, and liquid manure given the roots during the season of growth—as would have been applied under the old system, there is no reason why as heavy crops cannot be

planted with small pieces of roots where the plants have been dug up for use. Horseradish repays for good cultivation, and should be planted in rich, light soil, selecting stout thongs, or sets, about fifteen to eighteen inches long and from one and half to two inches in circumference. Before planting all rootlets should be rubbed off by drawing the root through the hand covered with a piece of sacking taking care not to injure the skin of the thong, or there will be a large cankered area when the root is lifted. The best way to plant Horseradish is to dig a trench or, if on a large scale, to use a plough, and lay the sets on the slant so that the top part is covered about two inches deep. Planting with a plough is done very quickly, and with children to place the sets in position at one foot apart, a large area of ground is soon planted. In the late summer it pays to scrape the soil from each plant and rub the hands, covered with an old glove or a piece of sacking, up and down and around the roots, so that when they are dug up they will, if well grown, be seven or eight inches round and fifteen inches or more long. James Page, Atvidaberg, Sweden.

## HOME CORRESPONDENCE.

[The Editors do not hold themselves responsible for the opinions expressed by correspondents.]

**Drought Effects.**—A noteworthy feature of this season about here is the appalling state of the winter and spring Brassicas. A small percentage of Cabbage has escaped, but Broccoli of all sorts have succumbed; at most we shall not have half a dozen of the latter; even the Purple-sprouting, which one regards as fairly hardy, have nearly all gone. The shoots from Brussels Sprouts and Savoy stumps seem to be the only source of spring greens available for the table. It looks as if the drought delayed growth so long that, when it did take place, the tissues were too immature to withstand the slight frosts we have had. Old-established plants of Simpson's Nine Star have gone as well as the more recent sowings of other sorts. It would be interesting to have records from other parts of the country. Gardens and allotments about Hereford all tell the same tale so far as I have seen. *H. E. D.*

**Raising Seedling Rhododendrons on Moss.**—Having a quantity of Rhododendron seedlings grown by a method which has thus far proved very successful, I think perhaps a few notes relating to the method may be of interest to the readers of the *Gard. Chron.* Having often noticed Rhododendrons self-sown on mossy banks in the woods growing in profusion, it occurred to me that the close growing moss which grows in the woods here would make a good medium for seed sowing. This moss grows in cushion-like tufts, and is made up of stems closely packed together, which draw up moisture from below by capillary action. Mr. G. Webster, of York, gives me the name of the moss, *Leucobryum glaucum*. I collected some of these tufts and fitted them into 5-inch feeders, after knocking a hole in the bottom of each, and sowed the seed on the surface, using a fine sprayer to settle the seeds in the moss. The feeders were then dropped into a 6-inch pot, over which a square of glass was laid. The pots were then put into a larger feeder, which was kept filled with water, and all were placed in a warm house, with a temperature of about 50°-55°. The seeds soon germinated, and in every case came up as thick as the proverbial Mustard and Cress, as the enclosed photograph (Fig. 90) shows. They were sprayed overhead occasionally, and if the moss showed signs of being at all dry, water was poured round the edge of the feeders. When dry this moss takes on a glaucous hue, hence its name, but when kept moist it is a beautiful green. By sowing the seeds on this moss, I find uniform moisture is maintained. As soon as the seedlings were well through the glass was removed, and they were gradually hardened and taken to cooler quarters. When the first leaf developed I pricked out the seedlings into small pans in a mixture of loam, peat, and sand. When the small seedlings are removed from this mossy seed-bed, the moss may be pulled in pieces, stem by stem, thus enabling one to get out all the fine silky roots intact, which is almost an impossibility when lifting seedlings from a seed-bed of soil. Those pricked out about a month ago are making very satisfactory progress. The seedlings shown in the photograph were raised from seed sown on January 6th. *G. Taylor, Bulstrode Gardens, Gerrards Cross.*

**Paeonia Mlokosewitschi.**—On page 149 Mr. Arnott questions my statement that this is the best yellow Paeony and wonders if I had compared it with *P. Whitmanniana*. I have grown the latter for a great many years, yet I have found no difficulty in its culture, and though I think it a very pretty plant, its flowers are more fugacious than those of any other I know, and so pale in colour that there is no question in my mind which is the best. I have a white Paeony, also from the Caucasus, which is very closely allied to, if yet not a variety of it, but this again has very short-lived flowers and is not so floriferous or robust as the golden *P. Mlokosewitschi*. The only fault I find with the latter is its name. *H. J. Elwes Colesborne.*

**R.H.S. Daffodil Show.**—This morning (April 1) I thought I would see what chance I had to make an entry for the London Daffodil Show on the 11th inst., so took a stroll round my beds, and then came in to fill up the entry form, but found that I was out of time, as Regulation 1 provides:—"All entries must be made on the prescribed forms, which may be obtained from the Secretary, Vincent Square, Westminster, S.W., and which must be returned to him not later than Friday (*sic*) April 1." The success of a well organised show depends on the strict adherence to regulations, which have been carefully drawn up. This, I am told, is the secret of the success of the National Sweet Pea Society. A show schedule without an entry form must be unique. I noticed in your issue of the 13th ult. a report of a meeting to consider the desirability of forming a National Daffodil Society. The schedule for this year's Daffodil Show is a strong argument in favour of such a proposal—or a British Bulb Society. I understand Capt. Hawker, at the meeting, described the alterations made in the R.H.S. schedule this year as too drastic, the increase in the number of vases and stems should have been notified last year, prior to planting time, and the cutting out of all the single classes he considered a mistake. Mr. Dykes, I am told, gave the point of view of his Council, which was against single-bloom exhibits, and cited, in support, his experience with seed-

FIG. 90.—RHODODENDRON SEEDLINGS RAISED IN MOSS.

ling Irises. Yet immediately following the Daffodil schedule in *Notices and Arrangements for the Year 1922*, p. 45, I read, in connection with the Special Iris Show, there will be three separate competitions:—(1) For three spikes of one seedling. (2) For one spike each of three seedlings. (3) For one single spike. I suppose *Punch* would make something humorous out of the situation, but I content myself by setting out the facts, and wondering how many more were caught on All Fools' Day, 1922. *C. R.*

**Do Plants Know Time** (see pp. 31, 47, 95, 118, 158).—I have been very interested in the correspondence on "Do plants know time." Mr. Lynch infers that an introduced plant follows its season or time and period of flowering and growing when introduced elsewhere. *J. F.*, on p. 158, would have us to believe that anthocyanin and the rays of the sun are the causes of flowers opening, but is this true in all cases? When I flowered *Dracaena Goldiana* in the hothouse, it was completely and heavily shaded from the sun's rays, and I am wondering if 3.55 p.m., when the flower opened, would be the same period of the day in its own natural habitat in West tropical Africa; according to Mr. Lynch, it would be so. Again, our native *Tragopogon pratensis*, Yellow Goats-Beard, commonly known as John-go-to-bed-at-noon, closes its flower soon after 12 o'clock noon to 1 o'clock. Would *J. F.* claim that the same agencies govern the closing of the blooms of this plant? *Mark Mills, Coombe House Gardens, Croydon.*

## SOCIETIES.

## ROYAL HORTICULTURAL.

## Trial of Winter-Flowering Carnations at Wisley.

THE following awards have been made to Carnations at Wisley by a joint committee of the Royal Horticultural Society and the British Carnation Society.

The judging was solely on the productiveness of the plants during the winter, and upon their habit, and the colour and form of the flowers.

## AWARDS OF MERIT.

Nos. 1 and 2, *Wivelsfield White*, sent by Messrs. ALLWOOD BROS. and Mr. C. ENGELMANN; No. 10, *White Pearl* (see Fig. 69, p. 141), sent by Messrs. S. LOW and Co.; Nos. 21 and 22, *Maine Sunshine*, sent by Messrs. ALLWOOD BROS. and Mr. C. ENGELMANN; No. 132, *The Herald*, sent by Mr. C. ENGELMANN; No. 141, *General Joffre*, sent by Mr. C. ENGELMANN; No. 154, *Aviator*, sent by Mr. C. ENGELMANN; No. 221, *Toreador*, sent by Messrs. ALLWOOD BROS.; No. 228, *Jazz*, sent by Mr. C. ENGELMANN.

## HIGHLY COMMENDED.

No. 12, *Whiteall*, sent by Mr. STOKES; Nos. 35 and 36, *Mrs. Walter Hemus*, sent by Mr. C. ENGELMANN and Messrs. ALLWOOD BROS.; No. 84, *Cupid*, sent by Mr. C. ENGELMANN; Nos. 86 and 87, *Enchantress Supreme*, sent by Messrs. ALLWOOD BROS. and Mr. C. ENGELMANN; No. 88, *Lady Northcliffe*, sent by Mr. C. ENGELMANN; No. 107, *Lady Inverforth*, sent by Messrs. STUART LOW and Co.; No. 121, *Mary Allwood*, sent by Mr. C. ENGELMANN; No. 149, *West Hall Scarlet*, sent by Mr. G. CARPENTER; Nos. 158 and 159, *Triumph*, sent by Messrs. ALLWOOD BROS. and Mr. C. ENGELMANN; No. 164, *Pocahontas*, sent by Mr. C. ENGELMANN; No. 183, *Mrs. Hamilton Fellowes*, sent by Mr. C. ENGELMANN; Nos. 194 and 195, *Countess of Wilton*, sent by Mr. C. ENGELMANN and Messrs. STUART LOW and Co.; Nos. 211 and 212, *Wivelsfield Beauty*, sent by Messrs. ALLWOOD BROS. and Mr. C. ENGELMANN; No. 236, *Iowa*, sent by Mr. C. ENGELMANN.

## COMMENDED.

Nos. 3 and 4, *White Wonder*, sent by Messrs. ALLWOOD BROS. and Mr. C. ENGELMANN; No. 115, *Boadicea*, sent by Mr. C. ENGELMANN; No. 145, *Nebraska*, sent by Mr. C. ENGELMANN; Nos. 205 and 206, *Benora*, sent by Mr. C. ENGELMANN and Messrs. ALLWOOD BROS.; No. 223, *Fancy Carola*, sent by Mr. C. ENGELMANN; No. 229, *Marion Willson*, sent by Mr. C. ENGELMANN.

## BRITISH MYCOLOGICAL.

A MEETING of the British Mycological Society was held at the Botany School, Cambridge, on Saturday, March 18. Before the meeting members were taken through the building by Mr. F. T. Brooks, President of the Society, and Professor A. C. Seward.

The first paper was by Mrs. M. N. Kidd, who gave an account of some work that is being done at Cambridge under the Food Investigation Board on the diseases of Apples in storage.

A survey has been made during the last two seasons of the moulds attacking Apples in storage and of the amount of loss caused by each. The result shows a definite sequence of mould attack, the moulds which attack Apples early in the season being different from those which appear later.

Physiological diseases of Apples are of considerable importance in Apple storage. A disease which Americans have named Apple Scald causes considerable loss under certain conditions in this country. Newton Wonder is particularly susceptible to it. It can, however, be completely controlled by wrapping the fruit in specially prepared paper. Evidence was also given that the spotting of Apples, so prevalent last season, was probably of physiological origin, and also capable of control.

The next paper was by Mr. J. Line on *Nectria cinnabarina* as a parasite.

Mr. K. C. Mehta followed with an account of his observations on the occurrence of Wheat rusts near Cambridge. Black rust (*Puccinia graminis*) cannot overwinter either through the uredospores or the mycelium inside host plants, which may get infected early in autumn and before the winter cold sets in. There was no black rust observed on Wheat last season, but it was noticed on Barley and Couch Grass within a few yards from the infected bushes of Barberry, which showed complete aecidia about three weeks earlier. The recurrence of this rust can be explained only through fresh infection by aecidiospores produced on Barberry. In orange (*Puccinia triticina*) and yellow (*P. glumarum*) rusts it is not very difficult to find viable uredospores during the greater part of winter. There is conclusive experimental evidence that both these rusts can overwinter also by means of mycelium inside the host plants. This recurrence can therefore be most satisfactorily explained through infection of young seedlings of winter Wheat by the uredospores found in plenty on self-sown plants by autumn time. Following the infection there is a comparatively long incubation period, the exact duration of which is determined by weather conditions, particularly those of temperature. Fresh outbreak of yellow rust on winter-sown crop of Wheat was observed as early as January 20 in 1921. The orange rust appeared a few weeks later.

The President finally gave an account of his work, in connection with Mr. C. G. Hansford, on "Mould Growths on Cold-store Meat."

During the latter part of the war meat coming from the southern hemisphere was not infrequently affected by mould fungi. At the request of the Department of Scientific and Industrial Research an investigation into the causes of this contamination was carried out. The results show that some of these fungi, particularly *Cladosporium herbarum*, the cause of meat "Black Spot," can develop at — 6 deg. C., so that the abnormally long periods of storage during the war largely accounted for the undue prevalence of this trouble. Other moulds grow readily at temperatures round about freezing point, hence if the refrigerating plant breaks down at any time during storage opportunity is given for the development of mould spores lurking on the surface of the meat. At several degrees above 0 deg. C. bacterial growth is so active as to suppress the moulds. These fungi are only superficial, and unless accompanied by putrefactive bacteria do not render the meat unfit for food. During the course of the investigation two new species, *Sporotrichum carnis* and *Torula botryoides*, and one new genus, *Wardomyces anomala*, have been discovered. Other fungi which commonly occur on cold-store meat are *Thamnidium chaetocladioides*, *T. elegans*, *Mucor* spp., *Penicillium* spp., and *Saccharomyces* spp.

In the course of this work it has been shown that many so-called species of *Cladosporium* are merely strains of *C. herbarum*, and that *Hormodendron cladosporioides* is also one of the spore forms of this fungus produced at low as well as at high temperatures.

The very common occurrence of the Coral Spot fungus on the dead portions of Red Currant bushes has led to an investigation into the exact cause of the die-back observed.

A characteristic wilting of apparently healthy branches was found to be associated with the presence of a brownish-green region in the stem, the wood of this portion being choked up with fungal hyphae. This fungus was shown to be *Nectria cinnabarina*, which is found to appear on the whole stem affected during the following autumn. It was observed that the fungus had apparently originated in a small dead side branch or at a wound, and this view of the method of infection was borne out by experiments. Pure cultures of the fungus were found to be incapable of establishing the fungus in living wood or cortex, but when the experiments were repeated on portions killed artificially when still attached to the main stem it was found that the fungus made headway, and was finally able to pass over into the healthy wood.

There was a magnificent series of exhibits, illustrating points in the papers, and a large collection of interesting specimens was arranged in one of the laboratories.

After lunch the party visited the new Moltano Laboratory of Parasitology, where Professor G. F. H. Nuttall explained the points of the well-appointed building; Mr. F. R. Petherbridge then showed the party round the Agricultural School. Many places of non-scientific interest were then visited. The President entertained the members to tea in the Botany School, after which Miss E. R. Saunders took the party over Newham, and Dr. F. Kidd showed the John's Combination Room.

All the members who read papers are Cambridge workers. It is pleasant to find that the school founded by the late Professor Marshall Ward is in such a flourishing condition, and Mr. F. T. Brooks is to be congratulated on his many-sided mycological activities displayed.

#### READING AND DISTRICT GARDENERS.

At the meeting held on the 20th ult. Mr. H. H. Cook presiding, the subject for discussion was "Sweet Pea Culture," and this was introduced by Mr. H. Wynn, The Gardens, Quern's House, Goring Heath, who read an excellent practical paper on this popular flower. He gave full details on the preparation of the soil, seed-sowing in T.P. Raisers and in the open ground, planting, feeding, staking, training, thinning, shading, and in conclusion dealt with diseases and pests, such as mildew, rust, streak, greenfly, slugs, mice, and sparrows.

There is certainly a diversity of opinion as to the best methods of cultivating the Sweet Pea, and a lengthy and animated discussion followed, sustained by Messrs. Cook, Blackwell, Waite, Martin, Falke, Townsend, Young, M. Goddard, Butcher, Cox, Dore, Woolford, and Carter.

In a competition for one vase of Violets, not more than fifty blooms, the first prize was awarded to Mr. F. H. Bratten, The Oaks, Shinfield Road, and the second to Mr. G. Sired, The Grove, Shinfield. In the non-competitive section Mr. W. Broomfield, The Gardens, Cliffe House, Mapledurham, staged six magnificent plants of Cyclamen, carrying numerous blooms of splendid quality. The judges unanimously awarded the association's First-class Certificate of Cultural Merit to this exhibit. Mr. D. Turner, The Gardens, Coley Park, showed five dishes of well-kept Apples, Annie Elizabeth, Lane's Prince Albert, Bramley's Seedling, and Sturmer Pippen, being exceedingly fine for so late in the season. Mr. Pratten, in addition to his prize blooms, showed excellent flowers of Princess of Wales (picked from the open) and the double Marie Louise Violets.

#### CARDIFF GARDENERS.

The annual general meeting of this Association was held March 23 at the Queen's Hotel, St. Mary Street, Cardiff. The Patrons, President and Vice-Presidents were re-elected *en bloc*. Mr. P. Meyers was elected chairman, and Mr. H. Wilkins vice-chairman. The committee was also elected. Mr. Toy, the retiring chairman, gave an inspiring address on the year's working of the Association. Mr. R. Mayne, who has held the offices of hon. secretary and treasurer for 14 years, did not seek re-election, but subsequently consented to hold these offices again. The balance-sheet showed a balance in hand. A honorarium of three guineas was voted to Mr. Mayne. It was decided to hold an annual outing as in former years, to take the form of a char-à-banc trip to some garden to be decided on by the committee.

#### ANSWERS TO CORRESPONDENTS.

APHELANDRA AND EXACUM: *A. R. D.*. Regarding your inquiry for *Aphelandra tetragona*, you might try Messrs. L. R. Russell, Sheen Road, Richmond; also M. Louis Van Houtte, Gentbrugge, Ghent, Belgium. Since Messrs Veitch and Sons gave up business *Exacum macranthum* has not been offered in any home or Continental catalogue. You

might obtain seeds from the Supt. of the Botanic Gardens, Peradeniya, Ceylon. It is indeed a pity that so many choice stove and greenhouse plants excite so little attention at the present day.

BURNT BONES AS MANURE: *H. E.* The highest grades of superphosphate of lime are prepared from burnt bones. By burning them, however, you drive out the small remaining quantity of nitrogen boiled bones contain, as well as most of the carbonate of lime. The nitrogen would be valuable, if the bones were reduced to bone-meal by grinding. Under the circumstances, that is impossible for you. What remains consists almost entirely of phosphate of lime, which cannot be destroyed nor driven into the air by burning. If large bones can be kept at a red heat for some hours in the rubbish fire, you can pick them out when sufficiently cool, and they can be pounded to a fairly fine powder by means of a hammer on a stone or piece of iron, laid in a box to keep the ashes from flying about. The finer you can crush them the more valuable the manure will be, because the sooner the ingredients will be available as plant food. They contain phosphorus and calcium (lime) and can be used instead of phosphate of lime, or basic slag, at the rate of one to two ounces to the square yard. This is not a complete manure, but contains only the two elements of food named. You can spread it over the ground where Sweet Peas are to be grown, and scratch it in lightly with a hoe or hand fork. There is no need to bury it deeply.

ESTABLISHING MISTLETO: *C. R.* Mistletoe grows parasitically on various trees, and so cannot be successfully grafted. It must be established by seed. All that is necessary is to squeeze a few berries on to the moderately young bark of the selected host trees, when the sticky nature of the fruit will cause it to adhere. Sometimes an incision is made in the bark and the seed is pressed into it; but this procedure is not necessary. From fairly recent extensive correspondence in our columns it is abundantly clear that Mistletoe will grow on a great variety of trees in this country, though the commonest hosts are probably the Apple and the Lime. The seed may be "sown" at any time during the winter.

FRAMES AND NURSERY BEDS: *J. P.* Regarding positions for frames and nursery beds, we imagine there would be very little difference in the temperature, and, if any, it would possibly be only about 2°. But, as you suggest, you could easily test it by taking the night temperatures of both positions, for a period of a few weeks. For meteorological records for shade readings the thermometers are placed in a special screen, at about 3 ft. from the ground. For what is known as a grass temperature, a special registering minimum thermometer is used; this is not mounted on a frame, but generally laid on two forked sticks about three inches above the ground level, and in an open position. This is the type of thermometer you could use, but for your purpose any self-registering thermometer would do; it is, of course, important to ascertain that both glasses read alike under the same conditions. For meteorological purposes the readings are usually taken at nine o'clock in the morning, when the thermometer should be set for the next twenty-four hours.

MUSHROOM MALFORMED: *A. R.* The malformation of the stem of the Mushroom is due to parasitic mould, *Mycogone perniciosa* major. The insects present between the gills are *Achorutes purpureus*, which is not infrequently found on the larger fungi, but apparently does not cause any damage. As a preventive against *Mycogone* the house should be fumigated with formaldehyde gas; bearing beds should be sprayed with a 2½ per cent. solution of Lysol.

NAMES OF FRUIT: *H. S. W.* A and B. decayed; C. Radford Beauty.

NAMES OF PLANTS: *A. J. H.* *Cephalotaxus drupacea*, Nat. Order, Taxaceae.—*W. M.* 1. *Pinus Coulteri*; 2. *P. austriaca*; 3. *Abies*

Obituary.

Luke Collins.—The American horticultural Press records the death of Mr. Luke Collins, florist, of Chicago. Mr. Collins was a native of Salisbury, and settled in the United States when he was about twenty years of age. He had been some fifteen years in private gardens in that country when he took up the commercial side of horticulture and eventually established a successful retail flower business at Chicago.

TRADE NOTE.

THE Commercial Flower Growers of Chicago have adopted co-operative advertising with a view to increasing the sales of their products. The Society's scheme of advertising, on a basis of one half per cent. of the amount of the gross sales of each grower, was altered to one per cent. at the last monthly meeting of the Society, the proposition, receiving the support of every grower who was present.

MARKETS.

COVENT GARDEN, Tuesday, April 4, 1922.

Fruit: Average Wholesale Prices.

Table listing various fruits and their prices, including Australasian Apples, Oranges, Lemons, and various berries.

Vegetables: Average Wholesale Prices.

Table listing various vegetables and their prices, including Artichokes, Asparagus, Beans, Carrots, and various greens.

REMARKS.—The severe weather has adversely affected the demand in several departments, as well as curtailed supplies. South African fruits have been available in larger quantities lately, a good inquiry being encouraged by the moderate prices. Forward shipments are lighter, and values will probably harden for the Easter trade. The first shipment of Australasian Apples is cleared. Two boats are due at the time of writing carrying approximately 37,000 cases of Apples and a few of Pears. English Apples are now practically finished, the last of some excellent Bramley's Seedling from cold storage having come to an end. Fair stocks of North American Apples are still held, and prices have an easier tendency. Oranges are inclined to advance in price, but there is only a poor demand for Lemons. Bananas are a better trade, and have advanced in price. Canary Island Tomatoes are cheaper, but Potatoes from the same source are firmer in value. Asparagus is in good demand. Forced Beans are slightly cheaper, due to increasing quantities. Forced Marrows are available, but there has been little

demand for them so far. Salads are a fairly good trade. Forced Mushrooms advanced slightly in price, due to colder weather restricting quantity. Forced Rhubarb has weakened in supply. All green vegetables are scarce and costly. Potatoes have eased in quotation with ample supplies on offer.

Plants in Pots, etc.: Average Wholesale Prices.

Table listing various plants in pots and their prices, including Adiantum, Aralia, Asparagus, and various flowering plants.

Cut Flowers, etc.: Average Wholesale Prices.

Table listing various cut flowers and their prices, including Acaia, Adiantum, Anemone, and various other floral varieties.

REMARKS.—Supplies from all sources appear to be getting shorter, and prices generally are rising, especially for white blooms; a further advance in value is anticipated during the next fortnight. A large quantity of cut blooms will be required for the Palm Sunday festival in Wales this week-end. Richardias (Arums), Stocks, Allium (Stars) and white and yellow Roses being the chief subjects in demand. Cut blooms will be required in quantity for the Easter festival in the following week-end; supplies are already affected by the severe weather, and consignments promise to be very short, which may cause a rapid rise in prices during the next fortnight, for flowers of all grades.

GARDENING APPOINTMENT

Mr. F. W. Wise, for the past fourteen years Gardener to Mrs. F. C. LONGBOURNE, Loseley Park, Guildford, as Gardener to Col. H. SOTHEBY, Ecton Hall, Northampton.

SCHEDULE RECEIVED.

Welsh National Agricultural Society.—Horticultural show to be held on the Racecourse, Wrexham, on July 26, 27, and 28, 1922.—Secretary, Thomas Welsby, 14, Charles Street, Wrexham.

nobilis; 4, Pinus Pinaster; 5, P. Strobus; 6, Abies Nordmanniana; 7, A. grandis; 8, Cunninghamia sinensis; 9, Libocedrus decurrens; 10, Picea excelsa; 11, Abies lasiocarpa; 12, A. brachyphylla; 13, A. Veitchii.—L. H. Picea orientalis.

PLANTS FOR LOGGIA: H. B. The most suitable Ferns for the shady loggia would include the Hart's Tongue and any of its interesting varieties, Blechnum spicatum plumosum, Adiantum Capillus-Veneris, Polypodium vulgare and varieties, any of the three British Polystichums, Woodwardia radicans, and Lomaria magellanica. For the corners we suggest a pair of Arundinaria nitida, Ceanothus Veitchianus or Fatsia japonica.

SAND TENNIS COURT: W. M. M. Full particulars with regard to the construction of sand tennis courts were given in our issue of August 8, 1914, p. 124.

TENDRE OF ALLOTMENTS: W. M. A departmental committee has made certain recommendations with regard to allotments, and these are being embodied in a Bill to be brought before Parliament. You will find reference to this matter in our issue of March 4, 1922, page 97.

NEW HORTICULTURAL INVENTIONS.

LATEST PATENT APPLICATIONS.

- 7249.—Harvey, J. N.—Plant container. March 11.
7182.—Peter, J.—Apparatus for sorting seeds, etc., according to length. March 19.
7071.—Southall, J.—Garden rollers. March 10.
6466.—Du Vallon, H. C. de J.—Fertilisers, insecticides, etc. March 4.
6097.—Templeman, G.—Traps for slugs, snails, etc. March 1.
5905.—West, C. E.—Plant labels, etc. February 28.

SPECIFICATIONS PUBLISHED LAST MONTH.

- 175,757.—Potter, H. S.—Tool for binding or tightening wire or wire clips on rubber hose or other flexible tubing for securing same on the spigot end of a hose union or other connection.
175,933.—Hopkins, M.—Handle for scythe tree.
175,338.—McDougal, L. and Howles, F.—Apparatus for spreading or distributing powder insecticides upon trees, plants, and the like.
175,343.—Alver, O. P.—Instrument for determining the sex in plant life and incubative matters.
175,521.—Jardine, C. A.—Pruning shears.
175,550.—Knight, S. C.—Garden rule or spacing device for plants.

ABSTRACT PUBLISHED LAST MONTH.

Hand hoes. Patent No. 174,246.—A new type of blade-holder for a hoe having a reversible and interchangeable blade has been patented by Mr. D. Shepherd, of Stracathro, Brechin, Forfarshire. It comprises a transverse bar curved and slotted longitudinally to receive the blade. A bar has downwardly extending ends, and is connected to the handle by means of a socketed shank, which is cranked or bent into proper shape for a push hoe. The blade consists of a flat plate sharpened on both edges. It is fixed by being driven tightly into the slot, or by pressing the sides of the holder together after inserting it.

Messrs. Rayner and Co., will obtain printed copies of the published specifications and forward them, post free, for the official price of 1s. each.

This list is specially compiled for The Gardeners' Chronicle by Messrs. Rayner and Co., registered patent agents, of 5, Chancery Lane, London, from whom all information relating to patents, trade marks, and designs can be obtained gratuitously.

**AVERAGE MEAN TEMPERATURE** for the ensuing week deduced from observations during the last fifty years at Greenwich, 46.1.

### ACTUAL TEMPERATURE:—

Gardeners' Chronicle Office, 5, Tavistock Street, Covent Garden, London, Tuesday, April 11, 10 a.m. Bar, 29.6; temp, 51°.—Weather—Sunny.

### Do Plants Know Time?

The question asked by Mr. R. Irwin Lynch in his interesting article on p. 31 is one which in the present state of knowledge does not admit of confident answer. Before anyone could even attempt to answer the question—Do plants know time?—he would have to spend no inconsiderable amount of time in preliminary considerations. These would of necessity be somewhat tedious, and that is probably the reason why, as observed by Mr. W. H. Divers, this and other similar problems of plant life often find but scant mention in text books of botany. At the risk, however, of tediousness an attempt may be made at all events to state the problem and to enumerate some of the considerations which have to be taken into account before an answer to the question can be enunciated. It may be conceded at once that rhythmic change is common and probably universal in plants. The broad facts of Nature proclaim it and detailed investigations confirm general experience. Broadly speaking, each plant brings forth its fruit in due season, and as illustrated by the remarkable example cited by Mr. Mark Mills, of *Dracaena Goldieana* opening its flowers punctually by the clock at 3.55 p.m. each day, the rhythmic behaviour of plants may be and often is amazingly constant. That such rhythmic behaviour should occur in plants is perhaps not surprising when the periodic changes of environment to which they are subject—of day and night, of summer and winter—are remembered. Among ex-

amples of periodic rhythm, that is, of a change of behaviour attained in time to an external condition, those of the Runner Bean and of *Convolvula* may be mentioned. As everyone knows, the leaves of the Runner Bean exhibit well-marked movements. During the day they are spread out, and at night they are folded together. Even though the plant be kept in darkness the diurnal and nocturnal movements continue for some time as though the plant had some internal monitor of the sequence of day and night. The case of *Convolvula Roscoffensis* is no less wonderful. This animal is a minute green worm which lives in vast colonies on the sea shore between tide marks. It sinks below the surface as the rising tide inundates the zone of the beach in which it lives and ascends again as soon as the waning tide has receded from that zone. If a patch of *Convolvula* with sand and sea water be scooped up into a saucer and brought away from the shore the *Convolvula* continues to ascend to the surface of the sand punctually as each making tide reaches the zone from which it was taken and as punctually descends below the surface as each waning tide falls away from that zone. These movements up and down continue at their proper times for some eight days and then become irregular. There are many other examples of such periodic movements; particularly among the floating plant population (plankton) of the seas, which may ascend to the surface at one period of the day and descend at another. It is possible that the following considerations may throw some little light on these facts of periodic movement. Every plant process is governed by many factors—the opening of a flower, for example, depends on temperature, degree of illumination, water supply, supply of oxygen and also on internal factors bound up with the structure and internal state of the plant. It is a well-established fact, and one which requires only to be stated to be accepted, that any one of the several factors on which a process depends may become a limiting factor, and in that case no change in the rate of the process will be produced by making the other non-limiting factors more favourable. A classical example of the operation of limiting factors is provided by two sets of experiments made, one in Ceylon and the other in Japan, by two different observers on the rate of growth of Bamboos. In one set of observations it was concluded that the rate of growth of Bamboos is determined by temperature, and with each increase of temperature the rate of growth was found to increase by a definite amount. In the other set of observations, it was as certainly proved that the rate of growth of Bamboos is determined by water supply; in this case fluctuations of temperature made no difference to rate of growth, but on the other hand each increase in amount of water supplied to the plant was followed by a proportionate increase of growth. The reconciliation of these apparently contradictory results is easy when the doctrine of limiting factors is applied. In the first experiment examination of the data showed that the supply of water was ample for all the growth which a Bamboo growing its fastest could accomplish. Temperature, on the other hand, was limiting; that is, not enough for a maximal growth, and therefore whenever it increased, growth increased. In the second experiment the conditions were reversed. The temperature throughout the experiment was high enough for more growth than was actually accomplished, but the water supply was limiting. If, therefore, it fell off so did growth, and if water supply increased growth also increased. This question of periodicity is of such great interest that we propose to pursue it further in our next issue.

**Sale of Claremont** (see Supplementary Illustration).—The announcement that Claremont, Esher, which has been for many years the residence of the Duchess of Albany, is to be sold by Messrs. Knight, Frank and Rutley, marks another stage in the history of this fine old property, the gardens of which are celebrated for their extent and beauty. Claremont will always have a special interest to horticulturists, owing to the fact that McIntosh, of Dalkeith, at one time had the management of the gardens. The mansion, which is seen in the upper part of our supplementary illustration, was built by Lord Clive and has been the home of other distinguished personages, including the Duke of Newcastle, Princess Charlotte, daughter of George IV., and her husband, Prince Leopold; Queen Victoria, Louis Philippe and his Queen; Princess Louise, and in recent years the Duchess of Albany. The bottom picture shows the imposing herbaceous borders with the sundial where the paths intersect, a nearer view of which was given in Fig. 74 in our issue for October 14, 1916, when illustrations of the long border of Pentstemons and the Lily basin draped with Dorothy Perkins Roses were also given.

**A Tasmanian Visitor.**—Mr. F. Walker, who has a nursery and seed and florist's business in Launceston, Tasmania, arrived in England a few days ago and called at our office to "get his copy of *The Gardeners' Chronicle*." So hale and hearty is Mr. Walker it is difficult to understand that nearly fifty years have passed since he left England to engage in business in Tasmania, after serving at home in such famous gardens as those of Abbots Wood and Melchet Court. In addition to being a nurseryman and seedsman, Mr. Walker is also an extensive cultivator of fruits and has about 65 acres under Apples, Pears and Plums in the Tamar Valley. It is especially in connection with the distribution of Tasmanian fruits that Mr. Walker is visiting England. He is an enthusiast and speaks very highly of the value of selected areas in Tasmania for the cultivation of fruits for export, and especially for Sturmer Pippin, Cox's Orange Pippin and Jonathan Apples.

**Gifts of Douglas Fir Seeds to France and Great Britain.**—The President of the American Forestry Association, Mr. C. L. Pack, is presenting the French Government with 700 lb. of Douglas Fir seeds for the reforestation of the area devastated during the war. This gentleman is also sending 300 lb. of Douglas Fir seeds to this country to assist in replanting the forests that were felled to supply the pressing need for timber during the war period.

**Centenarian Widow of a Gardener.**—Mrs. Isabel Watson, wife of the late Mr. Peter Watson, who was for over forty years gardener at Dell Lodge, Nethybridge, Inverness-shire, has attained the age of one hundred years. Her husband was also a centenarian and his death is recorded in *Gard. Chron.*, October 8, 1921, his age being 103 years. That both husband and wife should live to be more than one hundred years old is indeed remarkable, and it is more so in the case of Mr. Watson, who, in his early manhood was extremely delicate and advised by his doctor to choose an outdoor occupation. Mr. Watson lived to celebrate his 70th wedding anniversary.

**Royal Society of Arts.**—The Royal Society of Arts, which has been in existence for over a century and a half, has purchased the freehold of its house in John Street, Adelphi. An anonymous donor has contributed £30,000 to the fund of £50,000 required, and others have subscribed £12,000, so that it is hoped that the whole of the amount will soon be forthcoming. The Society of Arts, like most other institutions of its kind, has grown from a modest beginning. Its first meetings were held in a coffee house in Henrietta Street, Covent Garden, and subsequently the meetings took place in Crane Court, Fleet Street, and Harcourt Buildings, Strand. The brothers Adam, who were members of the Society, built the premises in John Street, Adelphi, but up to now the Society has only been tenants. The interest on a trust fund of about £20,000 is devoted to the provision of lectures. The society's examinations in con-

mercial subjects and in modern languages are very popular, and 50,000 candidates sat for these examinations last year. As the Society will become the proprietor of the property, it will be possible to make alterations that have long been desired and to reseat the lecture hall. The membership is between three and four thousand.

**Agricultural Problems.**—The Stackyard field at Woburn, which was held by the Royal Agricultural Society of England for many years, has been taken over by the Rothamsted Experimental Station, which will continue the experiments on Wheat and Barley in close association with the work at Rothamsted. The Agricultural Society will in future carry out its experiments on the farms of the members, and has set up a research fund and formed a committee to initiate or receive schemes for investigation. The Society will, in the first instance, concern itself with the investigation of four problems: (1) The value of ground mineral phosphates, more particularly in the improvement of pasture; (2) the use of various forms of lime on grass and tillage crops; (3) the use of wild White Clover, wild Red Clover, Bird's Foot Trefoil, etc., in laying down grassland; (4) the profitable utilisation of Whey.

**Retirement of Mr. J. G. Wilson.**—After serving as head gardener to Sir Thomas and Lady Pilkington for twenty years, Mr. J. G. Wilson is retiring from the charge of the gardens at Chevet Park, Wakefield. Mr. Wilson is taking up the position of sub-postmaster at New-millerdam, Wakefield, but hopes before long to engage in commercial horticulture.

**Legion of Honour.**—Among recent nominations in this order we notice the names of Mme. Philippe de Vilmorin, widow of the late M. Philippe de Vilmorin, who was well known and who had many friends on this side of the Channel; and M. Leloup-Grimoux, the Comisary-General of the International Horticultural Show at Le Mans—both being appointed to the rank of Chevalier. M. Pinguet-Guindon, the well-known nurseryman of Tours, has been promoted to the rank of officer.

**Golden Wedding of Mr. and Mrs. J. B. Stevenson.**—On Tuesday, the 4th inst., Mr. and Mrs. J. B. Stevenson celebrated their golden wedding at New Milton, Hampshire. Our readers will remember that Mr. J. B. Stevenson spent the greater part of his life at Bournemouth, where he had charge of the parks and gardens, many of which he laid out and planted. It is due chiefly to Mr. Stevenson's zeal and skill that Bournemouth enjoys such a high reputation for its beautiful public gardens and open spaces. We hope there are many more years of happy and well-earned retirement for Mr. and Mrs. Stevenson.

**Motor-car for Aberdeen Parks Superintendent.**—The City Corporation of Aberdeen has provided Mr. Clark, superintendent of the city parks, with a motor-car in order to enable him more expeditiously and more comfortably to visit the parks under his charge.

**Silver Leaf Disease.**—According to the *Journal of the Ministry of Agriculture*, Silver Leaf Disease is attacking Apple trees in this country, particularly the varieties Early Victoria, Lord Grosvenor, Lord Suffield and Newton Wonder. Mr. E. T. Brooks, who has been conducting investigations, states that he has found the disease on Pear trees, which have hitherto been considered to be immune from attack. Mr. Brooks, in conjunction with Mr. Hatton, Director of the East Malling Research Station, has undertaken experiments to determine the relative susceptibility of the Plum when worked on different stocks. In one orchard, Victoria Plums worked on the Myrobalan stock were considerably infected, whereas the remaining trees, grafted probably on the common Plum, appeared to be highly resistant. It has also been found that while the Pershore Plum can be readily infected with the disease by inoculation, there is a high percentage of natural recovery. Mr. Brooks draws the attention of growers to the importance of cutting out and burning all infected wood and covering the wounds with grafting wax, tar or similar material. The fungus

attacks other trees beside fruit trees, and where Poplars are planted as a wind screen to orchards their dead stumps often constitute centres of infection.

**Mr. Clarence Elliott.**—Few among those who specialise in alpine plants have so wide and intimate an acquaintance with their subject as Mr. Clarence Elliott, of Six Hills, Stevenage. Moreover, Mr. Elliott knows many of his plants in their native habitats, hence he converses about them in a most entertaining manner and writes about them with the enthusiasm of a collector and the restraint of an experienced cultivator. When at school at Giggleswick, in the Craven Highlands, Mr. Elliott admits he preferred rambles to studies; but, fortunately, Dr. Marshall Watts, the science master, and author of a School Flora, took young Elliott under his care out of school time, and with the help of the fine local flora, assisted him in his botanical studies. Mr. Elliott is ever ready to acknowledge his indebtedness to his old teacher. After leaving school and spending a short period with Messrs. T. S. Rivers and Son, Sawbridge-worth, Mr. Elliott entered the service of Messrs. J. Backhouse and Son, of York, where for several years he was employed in the alpine and herbaceous department. The roaming instinct

MR. CLARENCE ELLIOTT.

would not be denied, however, and so three years were spent in fruit growing in South Africa, where Mr. Elliott was almost persuaded to settle down for life. Returning home, he was invited by Messrs. George Routledge and Sons to edit John's *Flowers of the Field*, and by the time this work was accomplished he had "taken root" again. About fifteen years ago he went to Stevenage, purchased land there, and commenced business as a specialist in alpine and herbaceous plants, and in the designing, construction and planting of rock gardens. On one occasion he paid a visit to Corsica to collect *Morisia hypogaea*, and there he found the Caraway-scented Thyme (*Thymus Herba-barona*), which was new to cultivation. He undertook a special expedition to the Falkland Islands to obtain *Oxalis enneaphylla*, and was able to introduce to cultivation the pink-flowered form of this charming plant. On this occasion he also brought home plants of *Sisyrinchium filifolium*, which had also gone out of cultivation in this country, but is now fairly widely distributed in British gardens. *Azorella caespitosa* was found during this visit, and two other Falkland Islands plants introduced were *Myrtus nummularia* and *Veronica elliptica*, as well as the rare and handsome *Senecio canescens*. Other collecting trips have been made by Mr. Elliott to Switzerland, the Maritime Alps, Savoy Alps, the Dolomites,

the Pyrenees and Bavaria, including a long expedition with the late Mr. Reginald Farrer. Mr. Elliott's introductions include plants of his own raising, and among his hybrids, *Pumila Zuleika* Dousson is one of the best known; and he has obtained no fewer than fifteen Awards of Merit from the Royal Horticultural Society for hardy plants and a First-Class Certificate for *Lilium centifolium*, one of Mr. Farrer's Kansu plants, which first flowered at Stevenage.

**American Roof Gardens.**—*The Florists' Exchange* for March 25 publishes an illustration of a remarkable roof garden on the Union Club building at 54th Street and Fifth Avenue, New York. The garden covers an area of 150 feet by 50 feet, and is entirely surrounded by trellis work. It includes a large summer-house with additional seats under a pergola leading to it. The plants are grown in boxes varying in width from one foot to three feet, the depth being about one foot. Annuals are largely employed and such subjects as Cosmos, Stocks, Portulaca and Asters are freely planted, while *Convolvulus* and *Tropaeolums* are used as climbers. The roof garden also contains a greenhouse forty feet long. The illustration of the roof garden in *The Florists' Exchange* presents a pretty picture with a great wealth of flowers.

**Chamber of Horticulture Annual Meeting and Dinner.**—The annual meeting of the Chamber of Horticulture will be held at 18, Bedford Square, on Wednesday, May 3rd, at 3 p.m. The meeting will be followed by a dinner, which will be held in the Richelieu Room, Hotel Cecil, at 6.30 p.m. Advantage will be taken of this occasion to present Mr. George Monro, the first president of the Chamber, with his portrait in oils. The Minister of Agriculture, Sir Arthur Griffith-Boscawen, has signified his intention of being present. Applications for tickets should be made at once to the Secretary.

**Entertainment Tax at Flower Shows.**—Mr. Hilton Young stated in the House of Commons on Wednesday, April 5, that Section 7 of the Finance Act, 1921, authorises the Commissioners of Customs and Excise to grant exemption from entertainment duty in respect of allotment flower shows, which are shown to their satisfaction to be provided by a society established solely for the purpose of promoting the interests of horticulture, and not conducted for profit, and to consist solely of an exhibition of the products of horticulture. A member pointed out that local bands often played free at shows held for the purpose of encouraging allotment holders, and many such shows have been stopped owing to the imposition of the tax. Mr. Young stated that under the existing law, a show must consist solely of an exhibition of the products of horticulture if the tax is to be remitted, and that a band is not one of the products of horticulture.

**The Flowering of the Almond.**—Mr. H. Teatherton writes to inform us that the Almond tree on Wandsworth Common, the date of flowering of which the late Mr. R. Hooper Pearson recorded for many years in these pages, opened its first blossoms this spring, on March 6, as compared with February 22 last year, February 13, 1920, and March 14, 1919. Although it has been a comparatively mild winter in the Wandsworth district, the tree is thus fifteen days later in flowering this year than last.

**American Gooseberry Mildew.**—At this time of year Gooseberry-growers should be taking all possible precautions against American Gooseberry Mildew. The disease attacks shoots, leaves and berries, and renders the latter of less value commercially. It first shows itself in glistening, white patches on the bush which, later, turn brown. The Ministry of Agriculture recommends that as a preventive measure the bushes be sprayed with lime-sulphur, of which the first application should be made in the early part of April, and two further applications at intervals of three to four weeks. The spray should be mixed in the proportion of one gallon of lime-sulphur to 29 gallons of water. The lime-sulphur should be of 1.3 specific gravity; and a spraying machine having copper parts should not be used. In spraying, the object should be to wet the inside of the bush.

to cover both sides of the leaves with the spray, and to coat the berries where these have appeared. The solution recommended is suitable for most commercial varieties of Gooseberry, but in the case of the more delicate Gooseberries, Berry's Early (Keepsake), Cousin's Seedling, Lancashire Lad, and Crown Bob, a wash of one-half of the strength named should be used. In the case of the Golden Drop (Yellow Rough) and other berries of the Sulphur varieties, lime-sulphur cannot safely be used at all. It is difficult to suggest a satisfactory fungicidal wash for varieties which have very tender foliage. It is, however, quite safe to use a pure lime wash, and it may be applied just as the buds are bursting. The proportions are as follows:—0.15 lb. good lime (90 per cent. CaO = quick lime) in ten gallons of water. The lime should be strained through a piece of rough sacking. It should be noted that the American Gooseberry Mildew Order, of 1919, requires persons who raise Gooseberries or Currant bushes for sale, to notify the Ministry of the presence of this disease upon their premises.

**Appointments for the Ensuing Week.**—Wednesday, April 19: Hertford Horticultural Society's meeting. Thursday, April 20: Manchester and North of England Orchid Society's meeting; Midland Daffodil Society's exhibition (two days). Friday, April 21: Paisley Florists' Society's meeting; Eastbourne Horticultural Society's meeting; National Rose Society's spring show at London Scottish Drill Hall.

**"Gardeners' Chronicle" Seventy-Five Years Ago.**—*Calceolarias.*—As the Calceolaria, when well managed, forms one of our finest ornaments for the drawing-room, conservatory, and greenhouse through May, June, and July, its culture should by no means be neglected. When the flower stems begin to fade in May or June, cut them off, place the plants in a cool shady greenhouse and be very careful in watering, for if they are allowed to become too wet the evil will probably be insurmountable. In about a month's time they will have made young shoots, which must be taken off as soon as possible, and propagated in sand under hand-glasses in a cold pit or frame. If attended to they will be well rooted in a month, when they should be potted off into 3-inch pots in a compost of three-parts turfy loam, and one of leaf-mould and sand; place them in a cold frame for a few weeks, until they fill the pots with roots, when you may give them another shift into 6-inch pots, in a rather stronger compost, but still keep them in the frame, of course shading regularly in sunny weather. Should they require another shift before winter (which some of them will do), you may pot with a very porous compost, and not quite so strong as for the second shift. In these pots, say, 8-inch pots, they may stand all the winter in the pit or frame if the weather should not be too severe; if severe, put them into a cool, well ventilated greenhouse, and let them stand in this state until the middle of January, when you may keep the house closer and moister; and keep on in this way until the middle of February, when you may give them their final shift, say, into 11-inch pots. Still keep the house moist and rather close until the end of March, when you may put them into cold pits or frames, where they grow very rapidly until they begin to send up flower stems, when they must be removed into a cool greenhouse, shaded and aired when required. After this time tying up and watering will be all that will be required. *Alfred Moore, Henderson's Nursery, Pineapple Place, April 13. Gard. Chron., April 17, 1847.*

**Publications Received.**—*Tomato Cultivation Under Glass and Outdoors.* By R. V. Giffard Woolley; *Potatoes: How to get the Finest Crops.* By Edwin Beckett. ## HARDY FLOWER BORDER.

### LYSIMACHIA.

THE genus *Lysimachia* includes several valuable garden plants. One great point in their favour is that they do not call for a great deal of attention on the part of the cultivator. They do not, it is true, rank as among the choicest of garden plants, but they have a character of their own and a value which are distinct assets in the garden. They are easily increased by division and form capital border or wild garden plants, their flowers, mostly on spikes, looking well among the other blooms of their season. *L. barystachys* is a useful border plant, and produces good spikes of Veronica-like white flowers in June and July. It grows about 18 inches high. *L. clethroides* is a bigger-flowered species, also with white flowers, but with rather curling spikes, and blooms about the same time as *L. barystachys*. A species of some worth, not at all well known,

half-shaded situations. The bright yellow blooms are developed in summer.

All these plants may be increased readily by division and some are easily raised from seeds sown in the spring. *S. Arnott*

### NICOTIANA

THERE are several useful species of *Nicotiana* which should be sown now. *N. sylvestris* and *N. colossea* are large, handsome plants, suitable for furnishing large lawn beds, or utilising in mixed bedding, where a sub-tropical effect is desired. *N. colossea* var. *variegata* is a very beautiful plant for a large bed, but this plant needs to be propagated by means of cuttings. *N. affinis* is always popular, on account of its delicious fragrance during the evening; on this account, where suitable situations can be found, it should be planted near the dwelling-house, remembering that it should not be used in any conspicuous way, as its flowers remain closed during the day. *J. Coult.*

FIG. 91.—*GEUM REPTANS* IN ITS NATURAL HABITAT AT 7,000-8,000 FT. ALT.

is *L. dahurica*, which has good spikes of sulphur or light yellow flowers in close spikes. The plant grows about 2 feet high. From China we have *L. Henryi*, which is about nine inches high and has clusters of golden flowers each about the size of a sixpence, and rather hard foliage. A useful August and September flowering Loosestrife, also from China, is *L. Fortunei*, which has drooping spikes of white flowers about two feet high. It is tendered more valuable by the scarlet autumn tints which the leaves assume late in the season. *L. Nummularia*, the Golden Moneywort, or Creeping Jenny, is too well known to call for much description. Its trailing branches are clad with roundish leaves and set with pretty yellow flowers. There is a variety named *minor*, which is much smaller in size than the type, and *aurea*, with brilliant golden foliage, all these plants being valuable for carpeting.

*L. thyrsoiflora*, which blooms in May and June, is not so pleasing as some of the Loosestrifes. It has small spikes of yellow flowers borne in the axils of the leaves, and grows about two feet high. A species not commonly grown, *L. velutina*, grows fully two feet high in moist,

## THE ALPINE GARDEN.

### GEUM REPTANS.

IN *Gard. Chron.*, February 11, 1922, p. 66, Mr. Clarence Elliott gave some interesting particulars of this plant as it grows in the Alps, and the methods he adopted to collect specimens, which is no easy matter, owing to the depth to which the thick, woody root stock grows. Fig. 91 shows a plant growing in its native habitat in the Alps at some 8,000 feet altitude. The late Mr. Reginald Farrer, in his interesting work on Alpines, entitled, *The English Rock Garden*, describes *Geum reptans* as the special glory of the highest moraines and shingles on non-calcareous Alps, where it grows in plummy masses 9 inches high and several feet across, often spreading into colonies several yards wide. His description of the flower is in his usual enthusiastic style when writing of plants that appealed to him, "they are borne singly on stems that may be as much as 6 inches high, and are enormous golden suns that would make two of montanum's, to be succeeded by a similarly reduplicated splendour of silkier, fluffier, more wild and catherine-wheelish whirls of silver."

# The Week's Work.

## THE KITCHEN GARDEN.

By JAMES E. HATHAWAY, Gardener to JOHN BRENNAND, Esq., Baldersby Park, Thirsk, Yorkshire.

**Marrows.**—The main crop of Marrows should now be sown to have plants ready for putting out-of-doors next month. The seed should be sown in 3-in. pots, placing two seeds in each pot. Where a frame is available, a slight hot-bed should be made, and a frame placed on it, putting soil about 6 in. deep in the frame. Plant three plants in each light, and by the time the plants have filled the frame, the latter may be removed altogether, and the plants allowed to run. Where frames are not available, bell glasses may be used for protecting the plants, removing them during the day in very sunny weather. A good method, where there is no glass, is to make a trench four feet wide and three feet deep, and three parts fill it with litter, leaves, and similar materials. Place some good soil on the top of the litter in which to plant the Marrows, and by placing laths across the trench, the plants may be protected from frosts with mats. Long White and Long Green are the best varieties for show purposes.

**Endive.**—If a constant supply of Endive is required, small sowings should be made every fortnight. Sow the seeds in drills made 15 in. to 18 in. apart. As soon as the seedlings are large enough, thin them from 12 inches to 15 inches apart. Batavian Endive requires more space than the curled type.

**Seakale.**—Cuttings of Seakale inserted as advised on p. 53 are ready for planting out in rows made three feet six inches apart, allowing two feet between the plants in the rows and setting them in threes, about six inches apart, to form a triangle. Crowding is often the cause of poor results with this crop. The tips of the crowns should just be seen after planting and, to prevent slugs damaging them, they should be protected by a covering of sifted ashes, and a dressing of lime. No attempt should be made to force Seakale in the first year of planting.

**Celeriac.**—A sowing of Celeriac should be made in pans, and the seedlings treated similarly to Celery.

## THE ORCHID HOUSES.

By J. T. BARKER, Gardener to His Grace the DUKE OF MARLBOROUGH, K.G., Blenheim Palace, Woodstock, Oxon.

**Vanda.**—Plants of *Vanda teres* and *V. Hookeriana*, also their hybrids, *Miss Joachim* and *Marguerite Maron*, will soon commence to grow again. These plants, having been resting under comparatively dry conditions for some considerable time, should now be placed in the warmer end of the hottest house. It is advisable to place them in a position where they may receive uninterrupted sunlight, shading them only during the hottest days of summer, or whenever scorching of their terete leaves is to be feared. From the present time syringe the plants overhead on all bright days at least once, and keep their surroundings moist at all times. If the growths are strong enough they should, under these conditions, produce large spikes of good flowers.

**Vanda coerulea.**—The lovely blue *Vanda coerulea*, which to many is a source of trouble, should be grown where it may receive liberal supplies of fresh air at all seasons. The re-potting of this species should be done at this season. A light spraying overhead on fine days will be of great assistance to the plants in recovering from root disturbance, and prevent the loss of the lower leaves. Whilst in full growth the house in which this plant is growing should be shut up sufficiently early, so that the temperature rises considerably, afterwards opening it again later to allow the atmosphere to become sweetened. In the admission of air at all times, night or day, cold draughts must be prevented.

**Odontoglossum.**—The *Odontoglossum* house will now be gay for some time. Many of these plants suffer considerably during the flowering season when the spikes are allowed to remain on them too long. A strong, large-bulbed and thoroughly rooted specimen may be permitted to carry its spike for a long season, but it is a different matter with weak or poorly rooted plants. When the pseudo-bulbs show signs of distress before the flowers begin to expand, the spike should be cut off as soon as it is partially open. The present is a suitable time to afford more root-room to such plants as are not flowering, but none should be disturbed unless re-potting is absolutely necessary.

## HARDY FRUIT GARDEN.

By H. MARSHAM, Gardener to the EARL OF STRAFFORD, Wrotham Park, Barnet.

**Strawberry Beds.**—The soil should be kept well hoed between newly-planted Strawberries to eradicate weeds and prevent the soil from cracking in dry weather. The hoeing should be followed by the application of a good mulching of manure on light land, to encourage the plants to grow freely; but on deep, fertile soil suitable for the growth of these plants mulchings are not so much needed. See that the roots are made firm in the ground where they have been loosened by frosts, and this is best done when the soil is moderately dry.

**Peaches and Nectarines.**—The cold weather has been very trying to these fruit trees, and has had a retarding influence on their growth. With a change to more genial weather, growth will be rapid and disbudding will need prompt attention. It is advisable not to disbud them too severely on the first occasion, but to reduce the number of small growths gradually at intervals, till only just those needed for filling the space and for fruiting next year are left. Disbudding is one of the most important details in connection with the building up of evenly balanced trees, and should not be left to an inexperienced person. An effort should be made from the commencement to have every portion of the walls devoted to fruit culture covered with fruit-bearing wood from the bottom to the top, and not crowded with a quantity of small, weakly shoots. It is a good practice when disbudding to retain at least one good shoot as near the base of last year's wood as possible, and on the upper side. Others may be left at intervals alternately, and a good leader also, if there is room for further extension of the tree, but if not, pinch out the points at the third or fourth joint. Guard at all times against wholesale thinning, but thin freely where the shoots are crowded, so that by the time the fruits are almost full sized the shoots will have been reduced to the number that is required for fruiting next year.

**Orchard and Bush Trees.**—Sparrows sometimes destroy many of the flower buds on Apple and Pear trees, ruining the crop. A thorough syringing overhead with a mixture of Quassia Extract, or soapsuds, followed with a good dusting of soot and wood ash, will sometimes keep the birds in check. Pear and other trees on walls are best protected against damage by placing netting over them. In some gardens voles are very troublesome and destructive, by eating the buds of Pears and other fruits.

**American Blight.**—Trees that were badly infested with this pest last season, and which have not yet been thoroughly cleansed, should have all the infested parts well dressed with nicotine, sufficiently strong to be effective. Paraffin emulsion is another capital remedy for this pest, and should be well brushed into the parts affected. I use an ordinary painter's brush for the purpose.

**Fruiting Plants.**—Strawberry plants that were put out last year and those older in bearing are not strong, especially certain varieties. The crowns are small and the foliage weak. If not done already a good mulching of straw manure may be placed amongst the plants. This will be washed quite clean by the time the fruits are ripe.

## PLANTS UNDER GLASS.

By T. PAYMAN, Gardener to Sir C. NALL-CAIN, Bart., The Node, Codicote, Welwyn, Hertfordshire.

**Stopping Carnations.**—Perhaps the best time to stop the plants is when the roots are getting well established in large 60-sized pots. The tips may then be pinched out at the fifth or sixth pair of leaves. The object of this is to induce the plants to make side growths and to increase their size. After stopping pay careful attention to watering until growth is active again.

**Cyclamen.**—Young plants of greenhouse *Cyclamen* should be ready for transference to 54-sized pots. The soil should be of a light, rich, open nature, and contain a liberal sprinkling of old mortar rubble after it has been passed through a fine sieve. After potting, stand the plants near the roof-glass to prevent them becoming drawn. *Cyclamen* at this stage may be given a much cooler treatment. Water the roots carefully at all times, and spray the foliage on frequent occasions when the weather is bright.

**Chrysanthemums.**—The latest batch of *Chrysanthemum* cuttings may be inserted. The plants will make fine decorative specimens if grown on in 6-inch pots. The cuttings will root readily in a cold, airy, light frame.

**Lilium.**—Pot Lilies plunged in ashes or leaf mould should be examined occasionally, and those found to be making growth should be removed to a cold frame, afterwards introducing them into gentle warmth as required. If space was left in the pots to admit of top dressing, the material should be applied immediately the young roots form at the base of the young growth. Good fibrous loam, enriched with manure from a spent Mushroom bed and lightened with sand, forms a suitable compost for use as top dressings.

**Asparagus plumosus.**—Seedlings of this decorative foliage plant and also of *Asparagus Sprengeri*, raised from seed sown as previously advised, are ready for transferring singly to small pots. Rich open loam, with a little peat and sand added, forms a suitable rooting medium for these plants. After potting them, the young plants may be grown in a Cucumber house or other house in which a warm moist atmosphere is maintained. Older plants requiring larger receptacles should be re-potted, using good fibrous loam with broken charcoal and sand added. The stock may be increased by dividing the plants, but in my opinion they are best when raised from seed. Old-established plants will be improved by stimulating the roots with a reliable *Asparagus* fertiliser.

## THE FLOWER GARDEN.

By EDWIN BECKETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Hertfordshire.

**Herbaceous Borders.**—From now onwards careful attention should be devoted to the borders, and occasional hoeing will be of benefit in assisting the growth of the plants. Caution should, however, be observed not to damage the young growths, as a Dutch hoe very easily causes harm in this way, unless properly used. A watch should be kept for plants requiring support in the shape of stakes or brushy twigs, in order to keep them in good shape. Oftentimes an otherwise fine border has a spoiled appearance owing to the growths falling all ways, and not being restrained by proper staking.

**Bamboos.**—Where ponds and streams exist Bamboos look fine by the water side. These graceful plants may also be employed to great advantage around shrubberies, and, where space permits, they form a most interesting plantation by themselves. Where it is desired to make a plantation the very best way in which this can be done is to lift, or obtain, medium-sized plants now, and place them in receptacles of sufficient size, using a rich compost. They should be grown on in a house having a moist atmosphere, such as a late vinery, where the temperature is about 60° to 65°, with a view to planting out in their new quarters in May. By this method growth becomes very active, and the plants, after a careful hardening off, are thus planted out in their full vigour.

which permits of them growing away freely with a minimum of check from the onset. The situation for a plantation of Bamboos should, if possible, be where it is possible to flood the land during dry, hot weather. Where this is not feasible much may be accomplished towards retaining moisture at the roots, by thoroughly mulching the plants with long stable litter or similar material. Established clumps of Bamboos should be carefully attended to each season; the three-year-old canes should be cut out and the plants trimmed to shape if required. We have at Aldenham such a plantation as this, and the contrast between the fifty odd species and varieties makes this feature of the garden a most interesting one.

**Summer Bedding Plants.**—These should now be carefully looked to as many require cooler quarters preparatory to hardening them off. Any that are already in cold frames, such as hardy annuals, should be stood out in the open where they can be protected if required, and other plants may take their places in the frames. Plants in boxes should have the soil stirred frequently around them, and the plants in frames freely aired on all fine, bright days. Such plants as Pelargoniums and Fuchsias should be pinched or pruned to obtain well-shaped, bushy specimens.

### FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

**Potting Young Vines.**—If a close, warm potting shed is not available, the work of potting should be done in the pit, and the vines plunged in bottom-heat to give them a good start. But little water will be needed for a time, especially if the plunging bed is moist and the young vines syringed lightly once or twice daily. Shading should only be used when absolutely necessary after the roots are established in the fresh soil, in order to obtain short-jointed shoots quickly. As growth proceeds, each lateral should be pinched at the first joint, but guard against the main lead being injured until it is some 6 feet to 8 feet in length, when it should be stopped to throw strength into the lower parts and plump up the buds. Feed the roots with weak guano water and clear soot water occasionally, when the roots have taken a good hold of the soil, and syringe the vines once or twice a week with soot water, removing the plunging material by degrees.

**Peaches.**—The fruits of pot Peaches in the early houses are stoning, if they have not already passed that stage, and the fruits to all appearances are making very little progress. It is impossible to say how many Peaches a pot tree should be allowed to ripen, but of two evils it is better to crop lightly. Disbudding having been done conjointly with thinning of the fruits, superfluous shoots should now be few. Vigorous trees will require constant attention in pinching the first shoots and laterals, to obtain perfect pyramid or bush specimens well set with triple buds for next season's crop. Excessively cropped trees will make only weak or medium growths, many of them with not more than two wood buds, the removal of which will render the shoot useless as a fruit producer next year. To throw strength into these shoots, others inclined to draw an undue share of the sap should be pinched when about 10 inches long, the laterals and sub-laterals at the first or second leaf. By adopting this method and cropping moderately, the same set of trees may be forced successfully for a great number of years; provided their potting, watering and feeding receive careful attention. A top-dressing should be applied as soon as the fruits are set, and fresh material applied as often as the roots appear on the surface, until the fruits are nearly ripe. Rough loam, bone-meal and a little vine manure will supply all the food that the wood, foliage and fruit require, whilst weak manure water, guano and soot water are invaluable for washing the fertilising properties down to the roots. Damping the house and trees little and often, and watering the roots abundantly should be done, as dry conditions are fatal to pot fruit trees.

## CHINESE SHRUBS AT ALDENHAM.

(Continued from p. 137.)

**LIGUSTRUM.**—The new Chinese Privets include two fine evergreen species, *Ligustrum acutissimum* and *L. Delavayanum* (see Fig. 92), and both have made splendid specimens of rounded habit; 8 feet high, and as much in diameter. The dark, glossy green foliage of both species persists during the winter, and I anticipate that these two species will prove of much value for hedge planting. In *Plantae Silesianae*, in connection with *L. Delavayanum*, another species, *L. ionandrum*, is referred to as having been discovered by Diels in Yunnan, and the authors suggest that it is possibly only a form of *L. Delavayanum* with stunted flowering branchlets and short, dense panicles. Having seen both the plants growing near each other at Aldenham, I am inclined to

is of special interest on account of its chocolate-coloured stems. It has white flowers that are succeeded by orange-scarlet coloured fruits.

**RUBUS.**—Of the numerous Brambles introduced by Wilson, some of which have only a botanical interest, and take up too much room to be worth their place in any moderately-sized shrubbery, *R. Giraldianus* and *R. lasiostylus* *diszygos* are noteworthy additions to those shrubs which are at their best during the winter months. Though quite distinct in foliage and fruit, they both make stout canes from six feet to eight feet in height, clothed with a conspicuous white covering or tomentum. They are seen to the best advantage when planted in masses in company with such bright stemmed shrubs as the scarlet Dogwood and golden Willow.

*Rubus Irenaeus* is quite distinct from, and has none of the faults of, those scrambling, weedy Brambles which are unfitted for a small and trim garden. It is quite dwarf, has the

FIG. 92.—*LIGUSTRUM DELAVAYANUM* AT ALDENHAM HOUSE.

doubt strongly this assumption. To my mind *L. ionandrum*, which has been introduced to cultivation by Mr. George Forrest, is probably the most refined and smallest-leaved Privet known, and its healthy, dainty habit of growth appears to be quite distinct, even though related to the other species, and may be confidently recommended for any rock-garden.

**ROSES.**—One of the best of the numerous Chinese species of *Rosa* is the fine, single-flowered *Rosa Moyesii*. It is a most attractive garden plant, and one of the showiest of shrubs in fruit. It grows freely and makes a fine, spreading bush ten feet high, and when clothed with its dark red, single flowers, or its remarkable fruit, has few superiors in beauty. Though *R. Moyesii* stands undoubtedly first among the recently introduced Chinese Briar Roses, yet *R. Wilmutiae*, with its freely-produced, delicate blooms, is a good second, and where the plant is allowed a free run for its straggling growths, as in the woods at Aldenham, it is very charming. There are many other Chinese Roses of great charm, both in flower and fruit, including the white-flowered *R. Helenae*, which has a wonderful fragrance and develops large bunches of red fruits; *R. Gentiliana*, a strong grower with single white flowers made more conspicuous by the golden anthers; and *R. longicuspis*, which

merit of enjoying dense shade, and its large, nearly circular leaves have a lovely bronzy metallic colour in their young state. This Bramble should prove of value as a carpet under trees where turf will not grow satisfactorily. The fruits are described by Mr. Bean in *Trees and Shrubs Hardy in the British Isles* as large and red; at Aldenham it has been found that they are by no means freely produced.

**SALIX.**—No Willow can approach *Salix magnifica* in beauty, indeed, it is one of the finest shrubs introduced from China. At Aldenham it has proved perfectly hardy, and of free growth. In addition to those grown in bush form, a standard tree with a clean stem of twelve feet is of more than usual interest, it being found only in a wild state as a bush. The handsome foliage, often from eight to ten inches long, and fully half as broad, is pale green above and glaucous beneath. The female catkins are remarkable, being almost a foot long. In winter the red buds and young stems are conspicuous. The tree succeeds at Aldenham planted close to water. As this Willow gets older and tends to assume a tree form, the striking character of the foliage disappears, as the leaves lessen in size. *A. B. Thatcher.*

(To be continued.)

**EDITORIAL NOTICE.**

**ADVERTISEMENTS** should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, W.C.2.

**Editors and Publisher.**—Our correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the EDITORS. The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.

**Special Notice to Correspondents.**—The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.

**Local News.**—Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

**Letters for Publication,** as well as specimens of plants for naming, should be addressed to the EDITORS, 5, Tavistock Street, Covent Garden, London. Communications should be written on ONE SIDE ONLY OF THE PAPER, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

**AN ITALIAN BROADSIDE, 1612.**

**A** CURIOUS as well as an interesting botanical and horticultural problem, which has baffled many botanists in London, has arisen over an Italian broadside (12½ in. by 8½ in.), which came into my possession some little time since. Both the name of the plant, Maranto, and the plant itself, in spite of the elaborate descriptive text and its accompanying illustration on the broadside, constitute a puzzle which some reader may be able to solve. The name, Maranto, has not been found in any Italian dictionary, botanical or general. It, of course, suggests a commemoration of Bartolommeo Maranti (sometimes written Maranta or Marantha), an Italian doctor and botanist, a contemporary and correspondent of the more distinguished P. A. Mathioli (1500-77). Maranti wrote several treatises, which were published in Italy from 1559 to 1572, whilst one, *Lucullianus Questiones*, appeared at Basel in 1564; he died in March, 1571, and the first adequate memoir of him to appear, with a number of his letters, was contributed by Prof. G. B. de Toni to the *Proceedings of the Reale Istituto Veneto* 1911-12 (pp. 1505-1564). He is commemorated in the genus *Maranta* by Plumier in his *Nova Plantarum Americanum Geneva*, Paris, 1703; from one of the species, *M. arundinaceum*, we get the arrowroot, whilst many of the species and varieties are familiar in British gardens. But the Maranto of 1612, and the Maranta of about a century later, are not the same.

Whilst the figure of *La Nobil Pianta chiamata Maranto* is clearly conventional (Fig. 93), yet it bears no sort of resemblance to the Maranta. The broadside is dated 1612, and the plant is expressly described as *Nouamente portata dall' Indie*, a somewhat vague geographical expression in those days, which might have meant the East Indies or the West Indies, possibly the latter. The broadside was evidently an advertisement of this "*cosa inestimabile*," until then unknown in Italy, although nothing is stated as to where or from whom it could be obtained. The seed is described as a little larger than that of the Melon, with a harder husk, blackish in colour and with a bitter taste. The plant is stated to grow to the height of two yards, and in the manner of the Canna ("*agroppata a modo della Canna*"), which was a well-known plant in Italian gardens at the time. The smooth leaves are described as beautiful and as streaked with red, whilst the flower is like that of the Lily—"il suo fiore assomiglia a quello del Giglio, delli maggiori, che se ritrovi in Italia," and in colour, "*giallo, verde, rosso e bianco*." Not only is the Marante a beautiful plant, but it has also wonderful medicinal virtues, such as blood-stanching and as a purgative!

It will be noticed that the writer of the broadside refers to the plant as having a habit like the Canna and a flower like the Lily. Dr. B. Daydon Jackson suggests that a species of *Lilium*—perhaps a form of *L. Martagon*—may possibly have inspired this broadside. The Maranto, as will be seen from the reproduction, on a very much reduced scale, is a crowned

may be seen from Professor R. G. Hatton's perennially delightful *Craftsman's Plant Book*—the varied interest of which is obscured by its unhappy title—the *L. Martagon* was figured by Fuchs in 1542, and some years later by Lobel, so that that plant could not have been new in 1612.

Strangely enough, after an oblivion of over three centuries, the problem of the Maranto has cropped up from two totally different and independent quarters within a few weeks of one another. Among the papers of John Goodyer (1592-1664), at Magdalen College, Oxford, now being edited for immediate publication by Mr. R. T. Gunther, is a drawing by Lobel of this same Maranto plant. A photograph of this was sent to Dr. B. Daydon Jackson at the Linnean Society quite recently for identification. Evidently Lobel saw this broadside and sent or gave a drawing of it to Goodyer, and it has remained undisturbed at Magdalen until now. My copy of the broadside came from an Italian library of many thousands of pamphlets and books which my friend, Mr. W. M. Voynich, purchased in Italy some years ago; Mr. Voynich sold it with other books to Messrs. Dulau, through whom it came to me.

The broadside has a typographical as well as a botanical interest. The imprint reads: "*In Barcellona, in Venetia & poi in Ferrara. Per Vittorio Baldini*," from which it might be assumed that Baldini printed it successively at Barcelona, Venice and Ferrara. But I can find no record that Baldini ever had a printing press either in Barcelona or Venice. It may mean that the plant was first brought from overseas by the Spaniards on one of their expeditions to the West Indies, and that it may have been first grown at Barcelona, finding its way thence to Venice and then to Ferrara. For many years Vittorio Baldini, who variously describes himself as "*stampatore ducale*" and "*stampatore camerale*," was the leading printer of books and pamphlets at Ferrara; my notes of his activities show that in 1587 he printed an *Orazione* of Leonardo Salviata, an eight-leaf affair, and in 1616 a substantial book of 248 pages by G. Fuligatti, the Jesuit mathematician, with numerous diagrams, not to mention a long list of publications which appeared in the intervening twenty-nine years. He died in 1618, was himself a man of letters, writing at least one historical work, which he also printed, had a neat hand at turning a sonnet, as well as engraving on wood; so we may reasonably suspect that he may have had a share in both the text and in the illustration on our broadside. Most of the books he printed were illustrated with woodcuts.

But his only claim on our notice to-day in these columns is this disquieting broadside concerning an unidentified plant with a name which seems to have escaped Italian lexicographers. W. Roberts.

**PRIMULA SINENSIS.**

FIG. 93.—CONVENTIONAL ILLUSTRATION OF THE "MARANTO" PLANT, REPRODUCED FROM THE ITALIAN BROADSIDE.

with a solitary head which, at the first glance, suggests a plant of the Umbelliferae or Compositae; whilst the flowers of the *L. Martagon* are in a terminal raceme. There was no room for a raceme, so perhaps the Italian engraver thought it would serve the purpose if he gave a single flower—a kind of artistic licence necessitated by lack of space! But, as

winter, the seed should be sown now. The seed pans should be clean and dry before filling them with prepared soil, which should be of an open nature, and thoroughly moistened an hour or two before the seed is sown, so that very little, if any more water will be needed until germination takes place. Do not cover the seeds deeply, and shade them from bright sunshine. P.

## TREES AND SHRUBS.

## PINUS PATULA.

THERE is a considerable variety amongst the species of *Pinus*, due chiefly to the varying length of the leaves, the number in a cluster, and their relative stoutness or otherwise. The leaves of *P. patula* are long, slender, light green, produced three together in a sheath, and hang down over the branches with greater smoothness and regularity than a horse's mane. There is a tree of this species on the rockery at Wisley about 8 ft. high, and broadly pyramidal, with horizontal branches, as the specific name would imply. The direction of the branches enables the leaves to hang perpendicularly, and this gives the whole tree a distinctiveness which I have seen in no other member of the genus. Were one to have seen the tree during the drought of last year its habit would have suggested that it was flagging. The pleasing light green of the foliage at the present time indicates that it is in the best of health. The tree is a native of Mexico, and was first described in 1838. It is reputed not to be hardy, but there is no indication of tenderness so far. *J. F.*

## INDOOR PLANTS.

## GREVILLEA ASPLENIFOLIA.

*GREVILLEA asplenifolia* (syn. *G. longifolia*), of which a flowering spray is well illustrated in Fig. 94, is now coming into the market from the South of France. Although not the most showy member of the genus, it is a free grower, and its long, elegant shoots, with their slender foliage and reddish-pink flowers, are excellent for decorative purposes in the cut state.

The plant is a native of New South Wales, and the genus includes many beautiful species—all natives of Australia, with the exception of some species native of New Caledonia—which are poorly represented in gardens at the present day. In common with many other members of the natural order Proteaceae, many of the species, in the absence of seeds, are by no means easy of increase. Propagation, by means of cuttings, is slow and uncertain, and many cuttings, even if they can be rooted, do not grow at all freely. At Kew we graft such species on seedling stocks of *Grevillea robusta*, on which they take readily and grow freely.

The subject of this note grows well and makes a fine specimen if planted out in a bed or border, in a cool conservatory or greenhouse. Other beautiful greenhouse species are *Grevillea thelemanniana*, *G. preisei* and *G. punicea*, the last named being the best of them all in respect of colour and freedom of flowering. It is a pity there is so little interest taken in this class of plants at the present day. *J. Coultis, Kew.*

## FUCHSIA SPLENDENS.

In general appearance *Fuchsia splendens* is widely removed from the numerous garden varieties, forming as it does a free growing, rather loose-habited bush, clothed with heart-shaped leaves of a soft texture. The flowers, which are about 1½ inch in length, are of a tubular shape, but somewhat inflated in the middle. They are deep scarlet in colour, while the sepals and petals are green. The sepals do not reflex in the same manner as in most other *Fuchsias*. A very pretty variety, of which *Fuchsia splendens* was one of the parents, was shown at a spring meeting of the Royal Horticultural Society in 1912. It was raised at the nursery of Messrs. W. H. Rogers and Son, Southampton, as the result of crossing *F. splendens* with a Continental kind—*Gartenmeister Bonstedt*. The variety, known as *Benita*, did not gain any recognition from the Floral Committee, but at the same time it seemed to be very distinct, pleasing, and exceedingly floriferous. The blossoms, which hang in clusters at the ends of the shoots, are about an inch long, and supported by pedicels of the same length. The stout tube of the flower, and the sepals which do not reflex, are of a rosy scarlet colour, while the petals are bright orange scarlet. *T.*

## MARKET FRUIT GARDEN.

MARCH was a cold month almost throughout, with much strong wind, mainly from the east and north-east. Conditions were very unpleasant for work in the open, but were all that could be desired for the welfare of the fruit trees. Buds made such slow development that not even Plums were in bloom at the end of the month. Last year the earliest-blooming varieties were open on the 15th, and most of the Plums,

1.82 inch, which is under the average. Thus there was little interruption to soil cultivation. Every plantation received its first stirring with either horse or motor cultivator, and a start was made with hoeing. It is seldom that the land works so well at the first spring cultivation. The surface did not get panned down so hard as usual during the winter.

## PLUM APHIS.

Winter spraying having been finished early in March, I am now waiting to catch the Plums

FIG. 94.—GREVILLEA ASPLENIFOLIA.

Pears, and Cherries bloomed during the latter part of March. Thus fruit trees are quite three weeks later than they were last year. This is a good thing, because we may reasonably hope that they will now experience favourable weather for blooming. It is time now, however, that they pushed on, and it would be well if we could have a warm, showery April, which would take us quickly over the blooming period. The longer the bloom hangs fire in the advanced bud stage the greater the risk of damage by insect pests.

The rainfall of March at my place was only

when the earliest bloom is on the point of opening. They will then be sprayed with nicotine and soft soap to kill the mother queens of the leaf-curling Plum aphid (*Aphis pruni*). I have usually waited until immediately after the fall of the bloom, but that is not always soon enough to prevent damage. No aphid multiplies so rapidly as this, nor so quickly and effectively protects itself by curling the leaves. Therefore, it is better to spray before blooming, in spite of the fact that only the most exhaustive search can discover any of the mother-queens on the trees at that time. I have almost given up

looking for them, but spray as a matter of routine, because there is hardly a season when some harm is not done by this pest, and often it is very serious indeed. A bad attack of *A. pruni* ruins the crop and may half kill the trees. Some growers find spraying with limewash just before blooming an effective means of prevention. There will be a wonderful display of Plum blossom; so it is worth while to give the crop every attention this year, particularly as Apples are likely to be scarce.

Since writing the above I have found several of these stem-mothers and spraying has been started. They are large aphides and almost exactly the same colour as the young Plum wood—purplish brown.

#### DEAD BRANCHES.

Whilst pruning during the winter a good many mysterious dead branches were found on Apples. There is no appearance of any fungous disease; and an expert mycologist failed to find the cause. The trouble was worst in some trees of Beauty of Bath, which with me is usually a very healthy variety. I am inclined to think that it is simply a result of last year's drought, particularly as it was most serious in a grassed orchard, which showed more signs of distress during the dry season than did cultivated plantations.

#### SMALL FRUITS.

During the war large areas under small fruits went out of cultivation, or were devoted to other food crops. The agricultural statistics show that growers are making up the acreage. During the winter of 1920-21 it increased by 15,800 acres, bringing the total up to 72,600 acres, or about the same as in 1916. Of this increase Strawberries accounted for 3,768 acres. It will, of course, be several years before supplies of small fruits return to normal; and by that time it is to be hoped that the duty on sugar will have been reduced so that manufacturers can produce jam to sell at a reasonable price, and thus greatly increase the consumption.

#### MANURES FOR FRUIT TREES.

Experiments in the manuring of fruit trees have given such conflicting results that we may be said to possess no reliable information as to the needs of the different crops. No doubt they all require nitrogen, phosphoric acid, potash and lime; but we do not know in what proportions. In this respect fruit growers are much less fortunate than farmers, for the manurial requirements of farm crops have been established by repeated experiments.

Mr. G. E. Colby, chemist to the Californian Department of Agriculture, who has been studying the chemistry of fruits for some years, has worked out the amount of the vital soil ingredients removed by the various fruit crops. He obtained the following results per 100 lb. of fresh fruit:—

	Phosphoric			
	Potash	Lime	Acid	Nitrogen
	lb.	lb.	lb.	lb.
Apples ...	1.40	0.11	0.33	1.05
Cherries ...	2.77	0.20	0.72	2.29
Pears ...	1.34	0.19	0.34	0.90
Plums ...	3.41	0.25	0.75	1.81

Now it has been found in the case of farm crops that the composition of the plant does not indicate the most successful manurial treatment, because it does not take into account the plant foods already present in the soil, nor the feeding or rooting habit of the crop. For instance, an analysis of Swedes shows that the crop withdraws from the soil about 150 lb. per acre of nitrogen, 30 lb. of phosphoric acid, and 120 lb. of potash. Yet field experiments have proved beyond doubt the phosphatic fertilisers are by far the most important for this crop. The Swede is so shallow-rooting that it fails to obtain the small proportion of phosphoric acid it needs unless this is supplied in the form of manures.

However, we may perhaps learn a little about the needs of fruit crops from the figures quoted above. It is noticeable that potash is the ingredient which occurs most largely in each case, but specially in the stone fruits, Plums and Cherries. Phosphoric acid, generally considered so important for all fruit-bearing subjects, ap-

pears in the smallest quantities. Nitrogen does not assume so much importance as one would expect, considering that in practice organic nitrogenous manures prove the most useful of all, but there is a reason for this. The figures refer only to the fruit, but the tree has to make leaves and wood as well, and nitrogen would occur largely in these.

The practical lessons of the figures seem to be that the stone fruits require more generous feeding in all respects than Apples and Pears, whilst they also make special demand for potash and lime.

#### NON-RETURNABLE PACKAGES.

We have a satisfactory non-returnable package for Apples and Pears in the British standard box, and for certain of the soft fruits chip baskets with handles are much in favour; but we have nothing really satisfactory for Plums, Cherries, and such of the soft fruits (*e.g.*, Currants) as are not choice enough to market in small chips. The best thing available is the chip "bonnet," which holds the same amount of fruit as the wicker half-sieve. This is an excellent package for quite small consignments, but it has decided drawbacks for general purposes. It does not stack or load well on vans, lorries, or in railway trucks. The small, slightly rounded bottom makes it roll about. Moreover, it is not strong enough to stand roping, which is essential with big loads on a van or motor lorry. Some of the Continental chip non-returnables of half-bushel capacity are superior, because, although the fruit is held in a bonnet-shaped receptacle, there is a square outer casing which has rigid wooden corner-pieces, so that the packages stack better and are altogether stronger.

It has occurred to me that thin wood, such as the round cheese boxes are made of, would be excellent material from which to make non-returnable packages; but I do not know whether this is made in England or if it is cheap enough for the purpose. The ideal package must be clean and rigid, and it should, if possible, be available in the flat, like the Apple box, or capable of nesting, like the bonnet, so that it may not require too much space for storage. Strength is essential now that so much fruit is carried on motor lorries, big loads being the rule. Thin chip packages are really too flimsy.

The existing wicker half-sieves are quite suitable for Plums and soft fruits, but non-returnables are certainly desirable. There are buyers of fruit, such as the large stores and multiple shops, which will not be bothered with packages that have to be returned, and therefore purchase imported fruit only. *Market Grower.*

## ANNUAL FLOWERS FOR NORTHERN GARDENS.

THERE is a general apathy amongst gardeners in regard to the merits of annuals, yet if the area devoted to their cultivation by some of the leading seed firms could be filmed when the plants are at their best, and shown on picture screens throughout the country, it would be a revelation in colour, and an object lesson of the utility of these easily raised flowers.

There need be no hesitation in employing the usual summer bedding plants in geometric beds, and allotting borders to annuals, thereby saving valuable time and labour without in any way reducing the effect. Annuals generally are seen to the best advantage when employed in an informal manner, and a border of them hacked with Sweet Peas and associated with a selection of plants which, though not strictly annuals, bloom profusely when treated as such, is a fine feature in summer, and one that may be had with a minimum of labour and expense.

Many kinds of annuals are also suitable for associating with hardy perennials and may be employed to fill in vacant spaces in the herbaceous borders. The foreground of shrubberies may also be brightened considerably with the aid of the more robust-growing kinds, and there are dwarf annuals as attractive as alpine for the rock garden. In addition, many kinds are valuable

for supplying cut blooms, and a plot of ground devoted to annuals for this purpose is well and usefully employed.

No hard and fast rules can be laid down as to the sowing and raising of annuals; to limit the sowings to the months of March and April is to reduce their utility to the minimum. Up to March they should, in all but the most favoured parts, be sown in pots, and the protection of frost-proof frames provided. Several kinds are useful for conservatory decoration in April and May, and those planted out will furnish a display in June, and onwards, according to the date of sowing.

Ground intended for annuals should be prepared some time in advance of sowing in order that the soil may have time to settle, as when newly turned up it is too loose to favour the growth of strong, self-supporting plants. It is not a case of lavish manuring with the majority as it is of providing a fair depth for the roots, and a fine surface tilth, especially for seeds to be sown direct in the open. Many hardy annuals do not transplant readily, except when raised in pots, owing to the tap-like character of their roots, and are therefore best sown where they are intended to bloom. It is essential to thin the plants before they crowd one another in order that their lateral development be not retarded. Supports, where necessary, are easily fixed while growth is upright, and for all medium growers a few short twiggy sticks are all that is required. Mention may be made of a few leading sorts for this mode of treatment. *Godetias* might well head the list, and some idea of their importance may be realised when it is seen that over twenty named sorts are available, embracing all the leading colours in single and double blooms, and varying in height from 1 foot to 3 feet. The *Stock-flowered Larkspurs* are also divided into tall and dwarf varieties, the former having a just claim for notice for cutting. Amongst *Lupins* the *Hartwegii* varieties are a great improvement on the old type. *Lavateras* or *Mallows* provide valuable material for the background of borders, and the plants should be allowed a space of 2½ feet apart. *Sutton's Loveliness* is a splendid variety. *Clarkias* have attained some fame as conservatory plants, and the effect of groups in the open is no less charming. Others with an equal claim to notice as being suitable alike for sowing in the open and for sowing in pots to be kept in reserve for putting out where vacancies occur, include *Cornflowers*, *Sweet Sultan*, *Nigellas*, *Annual Chrysanthemums*, *Coreopsis*, *Eschscholzia*, *Candytuft* and *Antirrhinum*. For edging purposes dwarf *Nasturtiums*, *Cupid Sweet Peas*, *Viscaria*, *Linarias* and *Virginian Stocks* are suitable. For all the *Poppies*, and especially the *Shirley* type, there are countless uses which need not be referred to.

*Shirley Poppies* should be sown on several occasions at intervals of three or four weeks to obtain a display throughout the season until late in the autumn, and the seedlings should be thinned as early as possible to not less than one foot apart. There are also beautiful varieties of *Panapar somniferum*, which grows some two feet high, and the colours range from white to intense crimson.

Amongst half-hardy and tender annuals there is an equally wide choice. *Asters* and *Stocks* alone are capable of creating an effect quite equal to that obtained from the usual type of bedding plants, and with less labour and inconvenience. Under each heading there is a greater variety than is often realised. There are types admirably fitted by rigid selection for use in formal beds in case of need, while others have a marked value in the mixed borders and for cutting. *Marigolds* are also worthy of more notice—the double French and African kinds for general purposes, and the dwarf, single French *Marigolds* for beds. The fragrance of *Nicotians* is acceptable almost anywhere. *Sabiglossis* has become very popular in late years, and a bed of this annual in July and August is a fine feature. All these, and there are others too numerous to deal with now, should be sown under glass in April, and the seedlings subsequently pricked off into frames or boxes, and gradually hardened off for planting out early in June. *Yorkshire Gardener.*

## ORCHID MYCORRHIZA.

ONE of the most interesting phenomena in biology, and at the same time one of the most puzzling, is the living together of two organisms in intimate association. Symbiosis, as it is called, is generally assumed to be of mutual benefit, though probably it is never more than a compromise. Orchids have long been known to show fungal hyphae in their roots and, next to Lichens, are the most frequently cited examples of symbiotic union in plants. Link (1840) first observed the hyphae in the young seedlings of *Goodyera* without realising what they were, but Reissek (1847) recognised their nature, worked out their universality in Orchids and their distribution in the plant, and attempted to extract the fungi. Since his day much has been learned about fungus roots (mycorrhiza) and they have been found to occur very widely spread throughout the plant kingdom. This does not mean, however, that the relation between the green plant and fungus is always the same and what is said below must be taken as referring only to Orchids.

The fungus is best seen in the young roots. A transverse section just above the root cap (Fig. 95) shows the balls of hyphae in the cortical cells. The epidermal cells are not usually infected and the fungus does not enter the endodermis. One, two, or more layers of the cortical cells

FIG. 95.—SECTION OF YOUNG ROOT OF HABENARIA JUST ABOVE THE ROOT CAP, SHOWING FUNGUS MYCORRHIZA IN THE OUTER CORTICAL LAYERS;  $\times 36$ .

may contain the fungus, though the distribution is remarkably constant in any species. All Orchids so far investigated possess mycorrhiza with the single exception of the saprophytic *Wulfschlaegelia aphylla*. Apart from this anomalous case the amount of fungus present in the root seems to bear relation to the amount of chlorophyll—plants like *Listera* and *Epipactis*, which have dark green leaves are irregularly infected, whereas, when there is little chlorophyll, as in *Limodorum* and *Corallorhiza*, the fungus is well developed. It is interesting to note that aerial roots are not infected, except when they are in contact with the soil and without chlorophyll.

Part of the charm of Orchid growing is the satisfaction in overcoming the difficulties met with in germination. The trouble in obtaining seedlings has been one of the bywords of horticulture. Seedlings are apparently rarely found in nature—and half a century ago were rarer still in cultivation. The method of sowing seeds on the soil of the parent plant led to a different state of affairs. The known constancy of the presence of fungi in Orchid roots and the fact that the only means of securing germination was by sowing the seeds on soil which contained, or had contained, these roots, led many to believe that there was some relation between the mycorrhiza and the seed. As most people know, Noël Bernard eventually put

this to the test by extracting the fungus and inoculating seeds with it; when the appropriate fungus is present and the proper cultural details attended to, practically every seed germinates. The seeds of Orchids are very small, the embryo being frequently only just visible to the naked eye. They possess a single integument, which is in the form of a characteristic network. On sectioning the seed (Fig. 96) there is seen to be no differentiation into cotyledon, stem and radicle as is almost universal in flowering plants. In cultivated Orchids the cells at the suspensor end, that is the end by which the seed is attached, are generally somewhat larger than those at the upper end, though *Cymbidium* and others show no such differentiation. Seeds taken from the capsule under sterile conditions and sown on ordinary substrata where no fungus is present, do not as a rule develop. Generally, they merely swell and become green. The only case so far known in which any considerable development can take place under these conditions is that of *Bletia hyacinthina*, where Bernard found that thin, slender seedlings developed with distinct leaves.

The food reserve of Orchid seeds is most frequently oil, part of which becomes transformed into starch. The reserve food comes to its end just as the seed begins to become green. This is usually after three or four months; if no fungus infection take place then, the seedling dies. It is somewhat surprising that after the

FIG. 96.—LONGITUDINAL SECTION OF SEED OF ODONTOGLOSSUM, SHOWING THE SLIGHT DIFFERENTIATION IN THE CELL STRUCTURE. THE INTEGUMENT HAS BEEN RUPTURED IN SECTIONING;  $\times 215$ .

production of chlorophyll death should occur rather than autonomous growth by aid of photosynthesis; the seedling appears to form chlorophyll as a sort of despairing effort. If, however, the appropriate fungus be added, now at the latest, an extraordinary change takes place. The fungus seems to give an impetus to development. What, however, is the appropriate fungus? So far as we know at present it must be the fungus normally in the roots of the parent plant or of some near-ally. *J. Ramsbottom.*

(To be concluded.)

## ORCHID NOTES AND GLEANINGS.

### TWO NEW WHITE HYBRIDS.

BRASSO-CATTLEYA Albion, raised in Baron Schröder's gardens, The Dell Park, Englefield Green (gr. Mr. J. E. Shill), between *B. C. Thorntonii* alba and *Cattleya Trianae* alba, is a grand addition to the large white hybrids which will never be too plentiful. It is impossible to imagine a better flower in any respect, for it is perfect in form, pure white, and of fine substance, with broad, circular fronted, fringed lip. The disc of the lip is coloured chrome yellow. *B. C. Albion* was shown at Manchester on March 16 by T. Worsley, Esq.,

Haslingden, who obtained a First-Class Certificate for the novelty.

*Cattleya Minnehaha*, obtained by crossing *C. Trianae* alba and *C. Lady Rowena* (Suzanne Hye de Crom  $\times$  *Warneri* alba), also a Dell hybrid, shows the advantages of *C. Warneri* alba in crossing, and gives evidence of the desired effect being secured by thoughtful work. The flower is broad in all its parts, pure white, with an orange yellow blotch in the centre of the lip.

### CYMBIDIUM HYBRIDS.

W. WATERS BUTLER, Esq., Southfield, Edgbaston, sends an interesting selection of *Cymbidium* flowers raised in his garden, two of which are new crosses.

*Cymbidium Pyrhus* (*Wiganianum*  $\times$  *Holfordianum*) is a very desirable novelty, as it is quite distinct in colour from the bulk of hybrid *Cymbidiums*. The sepals are gamboge-yellow tinged with red; the petals are rather paler in colour and with a clearly defined red line down the middle. The lip is similarly coloured externally, but is white inside, and has the front beautifully marked with red spotted lines. The upper side of the column is red. *Cymbidium Vedic* (*Lowginum*  $\times$  *insigne*) is sent in three varieties, two having the white and rose tints of many other kinds, but No. 4,420 is a very distinct form with Primrose yellow colour. The sepals and petals, and the white lip are spotted with claret red.

Others sent are *Cymbidium Fortima* (*eburneum*  $\times$  *Schlegelii*), a superb white, recorded for Mr. Waters Butler last year; and *C. Venus*, Southfield variety (*insigne*  $\times$  *Holfordianum*), also previously noted.

### SCALE INSECTS ON ORCHIDS.

CATTLEYAS, Laelio-Cattleyas, Brasso-Cattleyas, Sophro-Cattleyas and other Orchids of this class are very susceptible to attacks of scale insects, which secrete themselves beneath the dry skin of the old pseudo-bulbs. In addition, therefore, to dipping and sponging the leaves and plants in a solution of nicotine, the skin of the pseudo-bulb should be removed to make sure of destroying all the insects. *J. T. B.*

### PROMENAEA.

THREE species of this interesting genus are in cultivation, viz., *P. xanthina*, *P. Rollissonii*, and *P. stapelioides*, and when these plants are in good health they produce plenty of bloom, especially the yellow *P. xanthina*. The plants are best grown in shallow pans and suspended about two feet from the roof rafters of the intermediate house, or the cooler end of the *Cattleya* division. Frequent disturbance of the roots is not advisable, and if due attention is paid to watering, the rooting medium will remain in good condition for several seasons.

### TRICHOSMA SUAVIS.

THIS sweetly fragrant Orchid blooms during the winter and should be grown in a cool house throughout the year. Any necessary repotting or top-dressing should be done when the new growth is a few inches high, employing the usual mixture of peat, partly decayed Oak leaves, and *Sphagnum*-moss. This Orchid should be kept more or less moist at all times in accordance with its condition of growth.

### BRASSAVOLA.

At one time *B. Digbyana* was in great demand for hybridising purposes, but now it is rarely seen, a remark which also applies to *B. glauca*. Both are interesting plants, the former being noteworthy for its large, fringed lip. The plants require similar treatment to that afforded *Cattleyas* and *Laelias*. *B. nodosa*, *B. cucullata*, *B. venosa* and *B. lineata* are quite distinct species, having terete leaves, which grow in a downward direction. On account of this peculiar habit the roots should be made fast to Teak wood rafts which have previously been covered with *Sphagnum*-moss and peat. During the growing season the plants should be suspended from the roof rafters of a warm house and the roots kept well supplied with water. A sunny position should be chosen and the plants should receive plenty of light at all seasons. When at rest a cooler temperature will suffice, and the plants may be kept slightly drier at the roots. *B.*

## HOME CORRESPONDENCE.

[The Editors do not hold themselves responsible for the opinions expressed by correspondents.]

**Roofing of Garden Fruit Cages** (see p. 158).—About ten years ago I built a fruit cage here 100 ft. by 50 ft., beneath which I planted Gooseberries, White Lion, Trumpeter, Green Ocean, and Lancashire Lad; Currants, White Dutch, Versailles, and Boskoop Giant. One line of Loganberries was planted, and Strawberries, Royal Sovereign and Waterloo, put between the rows of other fruits. The Strawberries did not succeed. Lettuce Holborn Standard in their place was a great success. I have not seen any of the other fruits injured by drip from the galvanised netting. Boskoop Giant Black Currant became badly infested with big bud, and although the big buds were removed by hand-picking last year the big bud became worse than ever; the bushes were therefore grubbed up and burned. The ground has been trenched and Raspberry Lloyd George planted. It will be interesting to see if, after ten years, Strawberries will succeed, and I shall plant a few runners from pots in July or August to test them. *William Currell, East Cliff Lodge Gardens, Ramsgate.*

—The point raised by Mr. Aubyn Trevor-Battye in your issue of April 1 is interesting and important. For many years I grew good crops of Strawberries in a "cage" surrounded with wire-netting and fish-netting over the top. When I made a new garden here I set up a complete "cage" with wire-netting over the top. As I now have a much better soil for Strawberry cultivation, I was very disappointed to find that the plants not only refused to bear, but some kinds, such as Royal Sovereign, absolutely died out. This went on for some years, while every endeavour was made to obtain improved results. In the meantime it was observed that runners cultivated in a bed outside the enclosure did remarkably well, but failed when transplanted inside. Consequently the Strawberry bed was removed to a plot previously occupied by Potatoes, and the plants have flourished exceedingly since. In addition to Strawberries there were grown in the "cage" Raspberries, Gooseberries, Currants, Cherries and Plums. Gooseberries were unaffected and did very well. Raspberries also succeeded, but not quite so well as those outside the cage. Currants behaved similarly. Plums and Cherries did very badly indeed. As a wire-netting surround appears to be harmless I think it most probable that the injury is due to the harmful action of zinc salts dissolved from the galvanised netting over the top, and not to any influence on the temperature. Perhaps in suburban and seaside gardens the effect would be more noticeable than in an open, inland district, as the smoke and salt would favour a more rapid solution of the zinc. If in other gardens harmful effects are not observed this might be the reason. Mr. Trevor-Battye asks if the damage only applies to the first year. It certainly continues for years; I suppose so long as any zinc remains, and very soon after all trace of galvanising is gone the netting rots and the cage becomes useless. *F. T. Paul, Cloudestee, Caldby, Cheshire.*

—There is little doubt that Mr. Trevor-Battye's letter of inquiry (page 158) will evoke widely different opinions. It is a very decided conviction with many gardeners that the drip from the roofing wire is inimical to the fruits beneath, but it is always a difficult matter to draw from them information which is the direct outcome of personal knowledge—it is usually based on hearsay, never a reliable post on which to lean for support. In a long experience I have never known evil results to be associated with properly constructed wire cages. That there is a deleterious effect when the growths of fruits and Roses are directly attached to galvanised wire, is perfectly well known, and it appears usual for the trouble to commence during very hot sunshine on wires wet after a shower, but contact seems to be an essential to the injury, since I have not seen the slightest damage due to drip from roofs on Strawberries, Raspberries, Currants or Gooseberries. The

fault in many fruit cages lies in the fixed roof which excludes birds when they are wanted, equally as effectively as when they are not wanted. The roof should, of course, be sound, but it must be removable at will, with ease, and immediately the crops from the enclosed plants have been harvested it should be taken off off for careful storage until such time as it is required again. *H. J.*

**Heavy Rainfall in Central Wales.**—In your issue of March 25, page 142, and March 11, page 116, *Mr. Wiggins* and *Market Grower*, respectively, give the rainfall record for January and February of this year. *Market Grower* also gives the record for the first two months of 1921. It may interest your readers to have the record for Central Wales, taken 580 feet above sea level. In the first six months of 1921 we had—January, 8.26 inches; February, 0.92; March, 7.31; April, 2.69; May, 2.75; June, 0.82. For 1922 the record is—January, 6.74; February, 7.17; and March, 3.20 inches. There were twenty-eight rainy days in January, and the heaviest rainfall occurred on the 16th, when 1.60 inch was recorded. In February we had twenty-two rainy days, and the heaviest fall, on the 4th, was 0.71 inch. March gave seventeen rainy days, with the heaviest fall of 0.64 inch on the 6th. The total rainfall for the first two months of 1922 was 13.91 inches, and, up to March 31, 17.11 inches. *D. H. Dunn, Hafod, Devil's Bridge, Aberystwyth.*

**Voles.**—The subject of dealing with voles, discussed in the *Gard. Chron.* for some weeks, is of interest here, as we are surrounded by woods. I have been troubled with the pests, and have tried all manner of traps to catch them. One plan is to dig a circular hole in the ground one foot in diameter at the top, about a foot deep and 18 inches diameter at the bottom. I have caught so many as eight voles in one night in a trap of this kind, using Peas, Beans or bread as bait. During my first winter here we caught 180 voles on half an acre of fruit plantation. We also used what are known as figure-four traps; but as your correspondent, *G. H. Hollingworth*, has 50 acres of fruit trees to deal with, the only trap that would serve his purpose would be a more or less permanent one, as I think the one-trap one-vole business would be too expensive. I also advise the encouragement of hawks, owls, and weasels, especially the last, as the small amount of harm done by the birds and weasel is far outweighed by the number of mice and voles they destroy. *W. H. Clark, Bussock Wood Gardens, Newbury.*

**Aristolochia gigas Sturtevantii.**—Since stove plants have undergone such reduction in this country, it is surprising to find this plant outside a botanic garden. It flowered recently in the nursery of Messrs. L. R. Russell, Ltd., Richmond. Much taller plants have been grown and admired for their curiously shaped and strangely coloured flowers. Even the hardy *A. Siphon* grows much more rampantly, and is admired or esteemed for the shade cast by its large leaves, when used for covering arbours. *A. gigas Sturtevantii* excites surprise on account of the great size of its flowers, which are purple, downy, and netted with veins on the face, while the exterior is strongly ribbed. One of the three lobes of the perianth is also furnished with a long tail. The species is a native of Guatemala, and is figured in the *Bot. Mag.*, t. 4368. The variety is finer in colour, and larger than the type. *J. F.*

**Mr. John Gray** (see p. 134).—Mr. Divers may like to know that my father, Mr. John Gray, is still at Brantingham Thorpe, Brough. They were both in the bothy there together in 1872. My father was awarded a First-class Certificate in fruit and vegetable culture from the Society for the Encouragement of Arts, Manufacture and Commerce, which was held in Hull at that time. There were no late trains from Hull to Brough, so he walked the distance of 12 miles to be ready for work the next morning at 6 o'clock. He walked this distance on three different occasions. Later, he married, and started in business as a florist and seedsman, still working in the gardens at Brantingham

Thorpe. I was appointed gardener in the same gardens at the age of 22 in the year 1905, which post I held for five years. Then the place was sold. I am pleased to state that my father is still enjoying good health. *Bernard Gray, Stotham House Gardens, Stotham, Brough, East Yorkshire.*

**Carnation Bis Greenfield.**—Having read with interest the remarks of Mr. W. J. Carter on Carnation Bis Greenfield (page 158), I would add that I have known it for several years. We have it in these gardens, and I have often remarked how strange it seems that this splendid Carnation is so rarely seen in collections. Bis Greenfield is one of the best Carnations with which I have had anything to do. It sends up strong cuttings which root very freely. The variety also has very dark green foliage. I should like to know when it was first brought out, and by whom. *H. Hills, Fawke Wood Gardens, Sevenoaks.*

**Forced Hyacinths.**—This year again many of the forced Hyacinths have developed four or five spikes of bloom from the one bulb, and especially those of blue shades, instead of one well-developed spike. *La Grandesse*, one of the best white Hyacinths, has in some cases, sent up two or three spikes; pink and red sorts have proved the most satisfactory in sending up one extra fine inflorescence. This multiple flowering has been very common in recent years in the case of bulbs which appear to be first-class for pot culture. In the case of Hyacinths used for bedding this defect is often overlooked, yet it is annoying when plants are grown especially for exhibition purposes. The cause may be due to one or more reasons, such as lifting the bulbs too early before they have had sufficient time to mature, or not allowing them a sufficiently long resting period. It is just possible that the varieties lose their vigour after they have been propagated for a number of years in succession, as the trouble is more noticeable in the older varieties, pointing to a weakened constitution; indeed, many of the bulbs rot off when they are started into growth. This all points to the need of raising new varieties by hybridisation to maintain the true type of flowering Hyacinths. *F. Pollintine, The Gardens, Rosemere, Wylde Green.*

**Kalendarium Universale, or The Gardiner's Universal Calendar, etc., by Benj. Whitmil.**—If any reader of *The Gardeners' Chronicle* possesses a copy of the first edition of this little book, which was published about 1726, I should be very grateful if he would send me a copy of the list of Roses mentioned in it. At the end of the later editions there is a list, entitled "A Collection of the best sorts of Flowers." No doubt the first edition has a similar classified list, and a copy of the names of the Roses there mentioned would be of great service in clearing up a point upon which there is at present some doubt regarding Rose history. Will readers please observe that references to other editions are not wanted? *C. Harman Payne, 195, Wellmeadow Road, Catford, S.E.6.*

**Iris unguicularis.**—It can scarcely be too widely known that this winter-flowering Iris, which commenced unfolding its blossoms here early in October, was producing flowers at the end of March, having in the meantime provided an abundant supply of spikes without a break. There still appear growths with flower sheaths that will carry the flowering well into the present month. It should, however, be stated that the plants have a warm and favoured position against a south wall, and this, coupled with the fact that the clumps are well established and large, will in some measure account for so continued a display. Three things are apparently necessary for success—suitable position, a certain amount of moisture, and exposure to sun and air. Generally, the best time for planting this species is after flowering—early in April, the best position being under a south wall though I do not advocate planting under a fence. When planting this Iris the rhizomes should never be buried under the soil, but kept at the surface. Almost any soil which is not of a heavy nature will suffice. *James A. Paice, Elstree.*

## FRUIT REGISTER.

## APPLE JOHN STANDISH.

In our description of this new, late market Apple, we referred (see p. 160) to the extraordinary cropping qualities of the trees; in Fig. 97 we illustrate a portion of one of the long branches crowded with Apples, exhibited last autumn by Messrs. Isaac House and Son, showing the freedom with which the fruits are borne on the spurs. Those who saw these branches were impressed with the enormous crops they bore, even in a year when Apples were unusually plentiful, and one of the reasons why the variety received the R.H.S. Award of Merit was because of its prolific nature of bearing. A description of the fruit was given on page 160; a specimen we have before us is still plump and fresh-looking, and promises to keep for much longer. The fruits even now are very juicy, and all these qualities, combined with the very attractive appearance, should cause the variety to find favour with growers, especially as a late market dessert variety.

FIG. 97.—APPLE JOHN STANDISH, R.H.S. AWARD OF MERIT, MARCH 28.

## APPLE ROSEMARY RUSSET.

This variety is one of the best to follow Cox's Orange Pippin, and has been exceptionally useful this winter, as Cox's Orange Pippin has deteriorated. It is at its best about January, but keeps well into March. The tree is a free grower and requires frequent root pruning to bring it into full bearing, especially cordon trees. The cordon method of training is the best form to adopt for this variety and our plants are free from canker at present. I send a sample of fruits, which are of a medium size, just suitable for the dessert table. The variety is a free bearer, as the blossoms set freely. The fruits are highly flavoured and have a bright yellow skin. They grow close to the wood, and the leaves cluster round them, affording protection from heavy rains, which is an advantage as the skin is very thin. A. B. Wadds, Englefield Gardens, Reading.

## APPLE WINTER PEARMAN.

This Apple is well known in some parts, but little known generally, yet the variety is such an excellent one it should be more generally grown. The tree is an abundant bearer, the fruit being large, richly coloured and of good flavour. Recently a sample was brought for my inspection and naming, which gave me great delight. Its synonyms are Great Pearmaine, Duck's Bill

Pearmain, and Old Pearmain. The fruit is of large size, being three inches and a quarter wide, and three and a half inches in height. It is of true Pearmain shape, with five ribs towards the crown. The skin is smooth and shining, coloured deep yellow, streaked with flesh colour on the shaded side, but of a beautiful clear, deep crimson on the side next the sun, and strewn all over with russet dots. The eye is large and open with short segments and set in a deep and prominently plaited basin. The stalk is about a quarter of an inch long and inserted in a deep, funnel-shaped cavity, which is lined with russet. The flesh is yellowish, firm, crisp, juicy and sugary, with a brisk and pleasant flavour.

This Apple is useful for cooking and dessert purposes, and is available late in the season. It is believed to be one of the oldest known varieties, and was cultivated in Norfolk as early as 1200. In those days the word Pearmain was spelled Pearemaine, which signified Great Pear Apple, in allusion no doubt to varieties known by that name bearing a resemblance to the form of a Pear. *Pomona*.

## VEGETABLES.

## RUNNER BEANS.

The drought last year proved exceptionally trying for this very important crop, and more especially were they a failure on light, porous land. Our best supply is usually gathered from plants that are grown in well prepared trenches, two feet wide. The soil is worked deeply, and an abundance of well decayed manure thoroughly incorporated with it, as the digging proceeds. Ample room should be allowed for the plants to grow sturdily, and to produce a long supply of large, fleshy beans. In dry weather, when Runner Beans are grown in trenches, mulchings of manure may be placed over and about the roots, and water supplied in quantity at intervals whenever needed. The water will wash down the manurial properties direct to the roots, and greatly benefit the plants when in full bearing. It is of great importance to gather the pods as fast as they become ready, so that others to follow may have a better chance of developing quickly.

Long, stout Pea sticks form the most useful supports, or tall, stiff stakes, inserted deeply in the soil by means of a crowbar, may be used. The plants offer a great surface to the winds of autumn, and at such times they are also very heavy at night with dew. H. M.

## SOCIETIES.

## MANCHESTER AND NORTH OF ENGLAND ORCHID.

MARCH 16.—*Committee present*:—The Rev. J. Crombleholme (in the chair), Messrs. R. Ashworth, Dr. F. Bedford, J. Birchenall, A. Burns, A. Coningsby, D. A. Cowan, J. C. Cowan, A. G. Ellwood, J. Evans, W. Giles, Dr. R. N. Hartley, J. Howes, A. Keeling, J. McNab, D. McLeod, F. K. Sander, E. W. Thompson, and Hillier.

## Awards.

## FIRST-CLASS CERTIFICATES.

*Cattleya Dupréana alba*, a pure, white flower with yellow throat; *Odontoglossum crispum majesticum*, a large flower of fine shape, blotched deep red and with a white margin; *O. crispum Astraee*; *O. Pescatoreii Rex*, a large flower with broad white petals and sepals, the latter slight rose colour and a very broad lip with deep purple blotch. From P. SMITH, Esq.

*Potinara Juliettae* (S.-L.-C. Marathon × B.-C. Ena), the broad sepals and petals are finely coloured and with intensely dark lip; *Lycaste plana Measuresiana*, sepals greenish-brown, petals and lip cream coloured. From Dr. F. BEDFORD.

*Odontoglossum crispum Brunhilda*, and *Laelio-Cattleya General Allenby* (L.-C. Lucasiana × C. Fabia), from S. GRATRIX, Esq.

*Dendrobium Dr. Hartley* (chessingtonense × illustrissimum), a fine yellow flower with dark brown centre in the lip; *Odontoglossum Thwaitesii Hartley's var.* (Rossii × Harry-anum), a very distinct variety with a white lip. From Dr. R. N. HARTLEY.

*Cymbidium Castor, Bridge Hall var.*, a large cream coloured flower. From Mrs. BRUCE and Miss WRIGLEY.

*C. Castor, St. Mary's var.*, with large white flowers. From the Rev. J. CROMBLEHOLME.

*Odontioda Juno* (eximium × Coronation), the ground colour is rose, heavily spotted bright red. From A. HANMER, Esq.

*Cymbidium Alexanderi, Bolholt var.*, the sepals and petals are white, the lip spotted and lined with deep red. From Capt. W. HORRIDGE.

*Odontioda Alcantara, Beardwood var.*, a fine, reddish-brown flower with white margin. From Col. Sir J. RUTHERFORD, Bart.

*Brasso-Cattleya Albion* (B.-C. Thorntonii alba × C. Triana alba), a white flower of very good form. From T. WORSLEY, Esq.

*Laelio-Cattleya Aquitania, Sanders' var.* (C. Enid × L.-C. Britannia), a large flower with mauve sepals and petals and deep purple lip. From Messrs. SANDERS.

## AWARDS OF MERIT.

*Lycaste Skinneri Goliath* and *L. S. Delight*, from Mrs. BRUCE and Miss WRIGLEY.

*Odontoglossum crispum West Point Monarch*; *Odta. Brighteye*, from S. GRATRIX, Esq.

*Odontioda Joyce var. Milky Way*; *Odontoglossum crispum Marlind* (Marie × Lindeni). From P. SMITH, Esq.

*Cymbidium Alexanderi var. Rajah*. From Capt. W. HORRIDGE.

## GROUPS.

Mrs. BRUCE and Miss WRIGLEY, Bury (gr. Mr. A. Burns), were awarded a large Silver-Gilt Medal for a group of *Lycastes* of the Skinneri section; *Cypripediums* and *Cymbidiums*. S. GRATRIX, Esq., West Point (gr. Mr. J. Howes), was also awarded a large Silver-Gilt Medal for a group in great variety. Capt. W. HORRIDGE, Bury, was awarded a Silver Medal for a group.

Messrs. SANDERS, St. Albans, were awarded a Gold Medal for a magnificent group in which *Cymbidiums* were an especial feature.

T. WORSLEY, Esq., Haslingden (gr. Mr. J. Sandwell), was awarded a Silver-Gilt Medal for a group of choice *Cypripediums*. A. HANMER, Esq., Buxton (gr. Mr. W. Giles), was awarded a large Silver Medal for a general collection. Col. Sir J. RUTHERFORD, Bart., Blackburn (gr. Mr. J. Lupton), staged a group for which a large Silver Medal was also awarded. The Rev. J. CROMBLEHOLME, Clayton-le-Moors (gr. Mr. E. Marshall), and Dr. R. N. HARTLEY, Wigan, were awarded Silver Medals for groups.

## ROYAL HORTICULTURAL.

APRIL 11 AND 12.—The hall at Vincent Square was well filled on these dates with an exhibition that was beautiful, interesting, and greatly admired by a large number of Fellows and visitors. Daffodils, Orchids, Roses, Carnations, flowering shrubs and Alpines were the leading features.

## Orchid Committee.

*Present*: Sir Jeremiah Colman, Bart. (in the chair), Prince Shimadzu, Messrs. James O'Brien (hon. secretary), Gurney Wilson, R. Brooman White, Frederick J. Hanbury, the Rev. J. Crombleholme, H. G. Alexander, J. E. Shill, J. Cypher, S. W. Flory, H. T. Pitt, A. McBean, W. J. Kaye, E. R. Ashton, Pantia Ralli, T. Armstrong, J. Wilson Potter, F. K. Sander, C. J. Lucas, and Chas. H. Curtis.

## AWARDS OF MERIT.

*Cymbidium Castor var. claytoniense* (insigne × *Woodhamsianum*), from the Rev. JOHN CROMBLEHOLME, Clayton-le-Moors. A very fine hybrid, forms of which have been exhibited before, but the specimen now shown, a fine example of high cultivation bearing a noble spike of nineteen flowers, represented it at its best. The wax-like flowers are blush white, with ruby-red markings on the front of the lip and the face of the column.

*Odontoglossum eximium var. Mabel*, from PANTIA RALLI, Esq., Ashted Park, Surrey (Orchid grower, Mr. Farnes). *Odontoglossum eximium* results from crossing *O. crispum* and *O. ardentissimum* (crispum × *Pescatorei*), and the present novelty was obtained by crossing two fine varieties of the original type, the result being a flower of greatly improved shape and form. The bloom is coloured deep claret red, with white lines between the blotches, and it has pure white margins.

*Oncidioda Stuart Low* (*Oncidioda Cooksoniae* × *Oncidium macranthum*), from Messrs. STUART LOW AND CO., Bush Hill Park, Enfield, and Crowborough, Sussex. This is the second use of the yellow *Oncidium macranthum* in the combination which produced *Oncidioda Cooksoniae* (*Cochlioda Noezhiana* × *Oncidium macranthum*), and the result is a good stride towards obtaining a crimson hybrid of the size of *O. macranthum*, as noted in *The Gardeners' Chronicle*, April 1, page 149. The flowers are purplish red, with yellow on the tip of the labellum and margins of the petals.

## PRELIMINARY COMMENDATION.

*Odontioda Pittiae* (Oda, Juliet × Odm. St. James), from H. T. PITT, Esq., Rosslyn, Stamford Hill (gr. Mr. Thurgood). A pretty novelty shown with its first flower, which was of good size and broad proportions, the greater part of the segments being closely blotched with magenta-crimson, with relieving lighter lines, the yellow crest of the lip being a prominent feature.

## GROUPS.

MESSRS. SANDERS, St. Albans, received a Silver Flora Medal for a finely arranged group of both hybrids and species, the *Odontoglossums*, *Odontiodas* and *Dendrobiums* being specially well displayed. Novelties were *Odontoglossum Royalty* (Rollae × Royal Monarch) a very dark and distinct hybrid; *Odontioda Majestic* (Oda, Coronation × Odm. majesticum) of the Oda, Coronation class, but larger and deeper in colour. The middle of the group was of the yellow *Laelio-Cattleya Golderest* with scarlet *Odontiodas*, and among interesting species noted were *Dendrobium chrysanthum*, *D. aggregatum* and many forms of *D. nobile*, *Cirrhopetalum picturatum*, some singular *Bulbophyllums* and *Masdevallias* and *Odontoglossum cirrhosum*.

Messrs. STUART LOW AND CO. were awarded a Silver Flora Medal for a varied and excellently well-arranged group consisting chiefly of *Odontoglossums*, *Odontiodas* and *Laelio-Cattleyas*. Among the *Odontoglossums* was the perfectly formed Odm. *harvengtense* Low's variety. Other choice plants were *Cattleya Schröderae* *Achilles*, *Oncidioda Stuart Low*, *Laelio-Cattleya Arca* (L.C. General Maude × C. Enid), a very pretty and well-formed flower and L.C. *Topaz* (L.C. *Smilax* × C. *Mossiae*), a good yellow variety.

H. T. PITT, Esq., Rosslyn, Stamford Hill, was awarded a Silver Banksian Medal for an interesting group, in the centre of which was a grand plant of the rare *Eulophiella Elisabethae* of the original importation, which has been in Mr. Pitt's collection for nearly twenty-nine years. The plant, which was in the most perfect health, bore a spike of thirteen wax-like white flowers. *Miltonia Venus* var. *Dulcinea*, the very rare *Epidendrum Endressii*, *Cirrhopetalum Colletii* and other pretty species were also shown.

Messrs. FLORY AND BLACK, Slough, were awarded a Silver Banksian Medal for a neat group, the central plant in which was a fine specimen of *Cattleya Empress* Frederick var. *Vesuvius*, the richest in colour of its class; with it were L.C. *Princess Mary*, *Odontioda Prince Albert*, the white *Cattleya The Bride*, and some pretty *Sophranitis* crosses.

## Floral Committee.

*Present*: Messrs. Henry B. May (in the chair), W. P. Thomson, C. Williams, E. A. Bowles, G. Reuthe, H. V. Warrender, Sydney Morris, R. C. Notcutt, Jas. Hudson, J. W. Barr, Donald Allan, John Heal, Andrew Ireland, C. R. Fielder, W. Howe, W. B. Gingell, J. Jennings, J. P. McLeod, M. C. Allwood, A. Turner, H. R. Darlington, Hugh Dickson, D. B. Crane, W. G. Baker, Reginald Cory, Amos Perry, H. J. Jones, W. B. Cranfield, Clarence Elliott, and Chas. E. Pearson.

## AWARDS OF MERIT.

*Rose Souvenir de Claudius Pernet*.—A *Pernetiana* Rose, broad petalled, of good form, but none too substantial. The colour is lovely light golden yellow, with buff and cream-white shading on the upper part of the outer petals. Slightly fragrant; long stemmed; glossy foliage. Shown by Messrs. W. EASLE AND SONS.

*Bougainvillea Mrs. Butt*.—A distinct variety, shown as a young plant, which apparently had been subjected to considerable heat, hence the bracts were limp. The colour is fiery red, with rose shading on the inner surface. Shown by Messrs. STUART LOW AND CO., Enfield.

## GROUPS.

A good variety of Roses was displayed by Mr. E. J. HICKS, Madame Butterfly, Columbia, Mrs. Elisha Hicks, Premier and M. Ed. Herriot amongst the many sorts so well shown were especially valuable (Silver Flora Medal). Allen Chandler, a new perpetual flowering climbing Rose of crimson colour, was included in a group by Mr. G. PRINCE, with vases of Padre, Lady Plymouth and C. E. Shea (Silver Banksian Medal). *Souvenir de Claudius Pernet*, a magnificent deep yellow *Pernetiana* Rose, carried on long, stout stalks, was well shown by Messrs. W. EASLE AND SONS. *Hoosier Beauty*, Columbia and Premier were also excellent (Silver Banksian Medal).

Coloured *Freesias*, of nearly every possible variety, were shown by Messrs. SUTTON AND SONS, and this formed an interesting feature of the meeting. Of the many sorts so well shown, mention can only be made of *La Charmante*, orange-flushed throat margined with rose, *Robinetta*, rosy mauve, *Buttercup*, rich yellow, *Apogée*, large, deep primrose, and *Mouette*, fragrant, lilac tinted (Silver Flora Medal). A collection of well-grown *Hippeastrums* was contributed by the Hon. Mrs. SKEFFINGTON-SMYTH (gr. Mr. G. Marchan), Stockton House, Wilts (Silver Banksian Medal).

Brightly coloured *Rhododendrons*, such as *R. Aucklandii rubrum*, *R. arboreum Kermesium* and *R. barbatum* were included by Mr. G. REUTHE in his exhibit of uncommon trees, shrubs and alpines. The fragrant *Berberis Bealei* and *B. hyenalis* and *B. hakeoides* were other interesting items (Silver Banksian Medal).

Such interesting plants as *Olearia stellulata*, *Osmanthus Delavayi*, *Draba imbricata*, *Saxifraga cochlearis minor*, and other alpines were shown by Messrs. SKELTON AND KIRBY (Silver Banksian Medal). Various alpines with elegant little plants of the miniature Irish Juniper were shown by Messrs. W. H. ROGERS AND CO. (Silver Banksian Medal). An attractive little collection of coloured *Freesias* and spring flowers was arranged by Messrs. BARR AND SONS (Bronze Banksian Medal). Alpine plants were displayed

by the Misses HOPKINS (Bronze Banksian Medal).

Carnations were shown in excellent condition by several specialists. Messrs. ALLWOOD BROS. had a large stand of beautiful blooms of Mrs. C. F. Raphael, which, for effect, was equalled only by a collection of mixed sorts of the same type, including a seedling very much of Marian Willson appearance, but larger, and rather more plentifully striped with rose colour. Jessie Allwood, another perpetual-Malmaison, was richer in colour, and so even more effective than earlier in the season. Many useful perpetual varieties were also shown (Silver Flora Medal). Amongst the many good Carnations displayed by Messrs. KEITH LUXFORD AND CO. were *White Wonder*, *Carola*, *White Benora*, *Maine Sunshine*, *Coquette* and *Rose Sensation* (Silver Banksian Medal). *Violet Mond*, a fragrant bright purple Carnation of good habit, was prominent in an exhibit by Mr. C. ENGELMANN, who also showed good vases of *Peerless*, *Circe*, *Cupid*, *Laddie* and *Nigger* (Silver Banksian Medal).

A particularly interesting collection of Acacias in perfect condition was made by Messrs. STUART LOW AND CO. Besides such fairly well-known sorts as *Acacia Riceana*, *A. armata* and its variety *pendula*, there were several plants of the uncommon *A. lineata* bearing long, graceful sprays of tiny, deep golden balls of flowers. *Hippeastrums*, *Anthurium Scherzerianum* varieties, and several distinct *Epacris* were also admirable (Silver Flora Medal). Adjoining their exhibit of Acacias and other greenhouse plants, Messrs. STUART LOW AND CO. showed many vases of especially good Carnations. In a corner space Messrs. L. R. RUSSELL, LTD., displayed to great advantage *Wistarias*, *Cestrum elegans*, *Viburnum Carlesii*, *Azalea indica*, excellent forms of *Clivia miniata*, *Hippeastrums* and *Brunfelsia eximia* (Silver Banksian Medal).

The beautiful soft, pink-coloured *Azalea Hidomanyo*, bearing a profusion of flower, was extensively shown by Messrs. G. G. WHITELEGO AND CO., and this made a particularly effective display. At one end of the little informal, yet pleasing, rockery, there were many plants of the fragrant *Iris pumila formosa*. Amongst a selection of Alpines *Morisia hypogaea*, and *Aethionema Warley* Rose were very attractive (Silver Banksian Medal). Bold effect was made by Messrs. J. PIPER AND SON with large, well-grown plants of Japanese Maples, batches of *Viburnum Carlesii*, *Daphne Cneorum*, various *Clematis*, and a beautiful breadth of *Lithospermum Heavenly Blue*. Other good features included *Veronica Hulkeana*, and a splendid plant of *Convolvulus Cneorum* (Silver Flora Medal).

A very convincing little rock garden was built by Messrs. WM. CUTTUSH AND SON. The plants included various *Aubrietias*, *Saxifragas*, *Alyssum saxatile* varieties, and *Primulas*, with bushes of *Azaleas* and *Brooms* (Silver Banksian Medal). Spring-flowering shrubs, such as early *Rhododendrons*, forced *Laburnums* and *Viburnums*, with *Azalea mollis* and Japanese Maples were arranged by Messrs. WALLACE AND CO., who also showed a few alpines (Silver Flora Medal).

Amongst a collection of choice alpines by Messrs. R. TUCKER AND SONS were plants of the tiny, rose-coloured *Saxifraga retusa*, *Androsace pyrenaica*, *A. argentea* *Cheiranthus Harper* *Crewe*, and *Daphne arbuscula*, as plants only a few inches high and crowned with sweet-scented mauve flowers. The tender *Daphne indica*, and several pots of *Fritillaria Meleagris* were also shown (Silver Flora Medal). A bright, spring display was made by Messrs. WATERER SONS AND CRISP with *Brooms*, *Bulbocodiums*, *Muscari*, *Violas* and a dwarf *Forget-Me-Not* (Silver Flora Medal).

*Polyanthuses* in great variety and all of merit were displayed by Mr. G. W. MILLER, and of these, several gold-laced varieties were very attractive. Other spring flowers included red *Crown Imperials* in quantity, *Muscari Heavenly Blue* and a small collection of *Saxifragas*, with a few *Sempervivums* (Silver Banksian Medal). Miniature alpine gardens were again exhibited by Mr. E. G. WOOD, and this time they were in

handy shallow trays, which had a cross-handle, suitable for easy transport. A small rock garden was appropriately planted with Iberis, Morisias, Aubrietias, and the like (Bronze Banksian Medal). Seasonable alpine were effectively displayed in an informal rock garden by Messrs. MAXWELL AND BEALE (Silver Banksian Medal).

#### Narcissus and Tulip Committee.

*Present:* Messrs. E. A. Bowles (in the chair), G. W. Leak, G. H. Engleheart, A. R. Goodwin, J. Jones, F. Barchard, H. V. Warrander, Reginald Cory, George Montro, F. Herbert Chapman, Herbert Smith, Rollo Meyer, W. F. M. Copeland, W. Poupard, Geo. Churcher, Peter R. Barr, W. Backhouse, G. Renthe, J. W. Pearson, W. B. Cranfield and Chas. H. Curtis (Hon. Sec.).

There was an excellent display of Daffodils and Tulips.

#### AWARDS OF MERIT.

*Narcissus Silver Chimes.*—One of the most delightful Daffodils we have seen for a long time. It is the result of crossing a Tagetta variety with *N. triandrus*. The growth is robust, stems erect and stout, bearing from five to seven semi-drooping flowers. The latter are about two inches wide, perianth white, slightly reflexing; cup round, citron yellow. The flowers are fragrant and beautiful and this variety had many admirers. Shown by Mr. J. C. MARTIN, Bosvigo Gardens, Truro.

*Narcissus Golden Pedestal.*—A shapely giant Leedsii variety that is practically a golden counterpart of the white variety named Pedestal. Perianth and trumpet are alike of good form and colour. Shown by Mr. J. L. RICHARDSON, Waterford.

*Narcissus White Nile.*—A refined giant Leedsii variety, with frilled, pale primrose-yellow trumpet and regular, white perianth. Shown by Messrs. H. CHAPMAN, Rye.

*Narcissus Magog.*—A bold Trumpet Daffodil of large size, evidently of *N. maximus* ancestry. It was shown as a market variety and got its award as such. The colour is soft golden yellow; the trumpet is deeply and evenly frilled and the perianth segments very slightly twisted. Shown by the DONARD NURSERY Co., Newcastle, Co. Down.

#### GROUPS.

A particularly meritorious collection of Narcissus was staged by Messrs. BARR AND SONS. It was fairly representative of all sections, and the very many blooms were of great merit. Pax, a beautiful Leedsii, Midüre, Barrii with a brilliant corona, Pixie, Ornament, Jasper, and Michael Angelo of similar type, were also very attractive. Of the Trumpet varieties, Alara, King Harold, Thackeray, Adejar, Estrella, Titymus, Frantin, Labour, Mustapha, and Achilles were especially noteworthy. This exhibit was also strong in such Poetaz sorts as Triumph, Jaure d'Merveille, Intermediate Sunset, Helios and Rembrandt (Gold Medal).

The central feature of a large exhibit by the DONARD NURSERY Co., was a handsome mass of King Alfred, Gog and Prospector: two other large, rich yellow Trumpet varieties were also shown in quantity. The new Magog was also largely shown. The richly-coloured coronas of Torch, Carnival and Brilliancy made them very conspicuous. The double-flowered Copeland's Seedling and several new seedlings were also of merit (Silver Gilt Flora Medal).

A comprehensive collection was shown by Messrs. CARTWRIGHT AND GOODWIN. Sunrise, Lemon Star, Marigold, Lady Boscawen, Henrietta, The Fawn and White Lady, are the names of only a few of the many good varieties (Silver Banksian Medal). The ANGLESEY BULB GROWERS' ASSOCIATION had a decorative exhibit of such sorts as Princess Victoria, Coryn, Cedys and Dafal.

A small, but choice collection of Narcissus was arranged by Messrs. F. H. CHAPMAN, LTD. This was mostly of unnamed seedlings, Trumpet and Incomparabilis varieties, but also included Fortune, which may be termed a Sir Watkin with an orange cup, Sunrise, Barri and Dactyl, a good Poeticus (Silver Banksian Medal). The decorative value of Silver Chimes was fully illustrated in an exhibit of Daffodils by Mr. J. C.

MARTIN. Such double-flowered varieties as Carnation, Conquest and Gullock and the Barri sort Little Gem, with unnamed seedlings, were also of more than average merit (Silver Banksian Medal).

Messrs. R. H. BATH, LTD., again displayed Darwin Tulips growing in fibre. On the present occasion Petrus Hondius, Moralis, Mrs. Potter Palmer, Clara Butt and Prof. Suringar were particularly grand. Many pots of the old double mauve Primrose were also of interest (Silver-Gilt Banksian Medal). Useful plants in 5-in. pots of such Dutch Tulips as Enchantress, White Beauty Beauty, Jauve Aplaité, Moncheron, Rising Sun and Pink Beauty were well shown by Messrs. R. and G. CURTHERT (Silver-Gilt Banksian Medal). A collection of useful Darwin Tulips, associated with Japanese Maples, was shown by Messrs. CARTER AND Co. Of the many sorts, Bartigon, King Harold, Psyche, from WILLIAM PITT, were particularly attractive (Silver Banksian Medal).

#### Fruit and Vegetable Committee.

*Present:* Messrs. C. G. A. Nix (chairman), J. Cheal, A. H. Pearson, Geo. F. Tinley, S. B. Dicks, W. Jefferies, E. Merryweather, G. Reynolds, F. Jordan, W. Poupard, A. Metcalfe, T. Pateman, E. Neal, J. C. Allgrove, E. Harriss, A. Bullock, P. C. M. Veitch, W. Bates, W. H. Divers, F. G. Treseder, G. Berry, W. Wilks, E. A. Bunyard and Prof. W. L. Howard, pomologist of the University of California (visitor).

A seedling Apple raised from a pip of the Old Nonpareil variety, and named Devonshire Cream, was shown by Mr. MARTIN, Market Gardener, Pinhoe, Exeter. The skin is light, clear yellow, flushed with citron on the sunny side. The fruit is of small to medium size. The flesh is juicy and very sweet. It was recommended that a deputation of the Committee inspect the tree next autumn. The same exhibitor showed another very sweet Apple, raised from Cox's Orange Pippin, and named Martin's Favourite. It is a pretty red fruit, but not so good in quality as the other.

Messrs. BUNYARD AND Co., Maidstone, showed thirteen varieties of late dessert Apples, viz., Claygate Pearmain, American Mother, Wagener, Allen's Everlasting, Heusgen's Golden Reinette, Roundway Magnum Bonum, Sturmer Pippin, Norman's Pippin, Easter Orange, Lord Hindlip, Galvalva, Duke of Devonshire, and Mannington Pearmain. The best flavoured were Claygate Pearmain, Wagener, Roundway Magnum Bonum, Sturmer Pippin and Easter Orange.

Messrs. R. F. FELTON AND SONS, Hanover Square, showed splendid fruits of Doyenné du Comice Pears imported from South Africa. The quality was superb in every respect.

#### The Daffodil Show.

Owing to adverse weather this was the smallest Daffodil show that has been held for a long time. It was only in the more favoured parts of the country that the blooms are sufficiently advanced for exhibition purposes, while the exhibits were few, the general quality was very high and augurs well for a good season at a later date.

The only exhibit of a collection of 36 varieties fairly representing the different divisions was by Mr. J. L. RICHARDSON, Waterford, Ireland. This was quite a good exhibit and well worthy of the First Prize it received. Of the Trumpets, Van Waverins' Giant and Cleopatra were the best of the named blooms; Black Prince and Acme (poeticus) and Red Lady (Barri) were also especially noteworthy. Mr. RICHARDSON was similarly placed in the class for 18 varieties, and here he also showed many unnamed seedlings, with similar sorts to those in the larger class, and of equal merit.

There were three entries of 12 varieties, not in commerce, but only two were forthcoming. The Engleheart Challenge Cup was won by the DONARD NURSERY Co., Newcastle, Co. Down, with an excellent collection of seedlings. These were mostly of the large Trumpet and Incomparabilis type. Mr. F. CHAPMAN, who was second, included his new white Nile, Neris, a

beautiful creamy-sulphur Trumpet sort, and St. Bernard, a Bernardino seedling with orange tinted, frilled lip.

Of the two exhibits of 12 varieties, three stems of each, the better was by Messrs. BARR AND SONS, who included in Stornoway Warwick, Latona and Tresskerz, very good trumpet varieties. The DONARD NURSERY Co. were second.

#### HUNTINGDONSHIRE DAFFODIL.

IN spite of the wintry weather a very successful show of spring flowers and Daffodils was held at Huntingdon on Wednesday, the 5th inst.

Messrs. Barr and Sons had a very tastefully arranged exhibit of Daffodils from their Cornish nursery. Among Trumpet sorts, King Alfred, Mustapha, G. P. Haydow, Peter Barr and Victoria were in fine form, while other groups were well represented by Barrii cuspicus, Blackwell, Incognita, Lucifer, and the cyclamineous hybrids.

Messrs. Allwood Bros. contributed a fine stand of Carnations; Wivelsfield Scarlet, Wivelsfield Claret, Edward Allwood, Mrs. Raphael, Benora, Apricot, etc., and the usual hybrid border varieties, all merited the admiration they received.

Mr. G. W. Miller, Wisbech, had a capital exhibit of Polyanthus, Primroses and Alpines.

There was a very good attendance. The judges were Messrs. S. F. Staffurth and J. Mallender.

#### Obituary.

**W. Waghorn.**—We very much regret to learn of the death of Mr. W. Waghorn, fruit foreman of Messrs. G. Bunyard and Co., Maidstone, in whose employ he had been since he was eighteen years old. Mr. Waghorn, who was 68 years of age, was well known to exhibitors at the principal London and Provincial shows, which he attended with the fruit exhibits of his firm.

#### TRADE NOTE.

A largely attended Conference, presided over by Mr. Alfred W. White, was held under the auspices of the Chamber on the 6th instant, Mr. W. G. Lobjoit, Controller of Horticulture, and Mr. H. V. Taylor, Deputy Controller, being present.

The question under discussion was that the Destructive Insects and Pests Order of 1921, as far as bulbs are concerned, had brought more disadvantages than advantages. It was contended by several speakers that the inspection in Holland was of little use, but that considerable delay in transit was thus caused and consequent damage. There was also the question of the additional expense, and that once the certificate was given the importer had no redress in the event of damage. Further, the risk of damage by delay was feared ten times more than the risk of disease. On the other hand, the Order had admittedly done good as regards auction sales, and generally it was agreed that an efficient and speedy inspection was the ideal to aim for.

The Controller pointed out that the Order entirely met the forcers' case. Bulbs could come in without a certificate, and the Customs would notify the Ministry as to where they were destined. Forcers could thus register with the Ministry and go ahead and use the bulbs, but could not distribute them until after inspection. This seemed to clear the position of forcers, and discussion was resumed as to the position of dealers, and it was agreed to take advantage of the forthcoming visit to Holland of the deputation to the International Horticultural Conference, on the 20th instant, from the Chamber, the Horticultural Trades' Association, and the British Florists' Federation, to interview leading Dutch exporters as to the possibility of speeding up or, if necessary, altering the form of certificate or inspection. Mr. H. V. Taylor, Deputy Controller, promised to accompany the deputation and give his assistance.

## ANSWERS TO CORRESPONDENTS.

**AZALEA LEAVES DISEASED:** *J. R.* The gall-like condition of your Azalea leaves is caused by a fungus, a species of *Exobasidium*. Later in the season the swollen leaves develop a "bloom" which consists of the spore-bearing organs of the fungus. Be careful to remove all the diseased leaves before this stage is reached and burn them. It is an old complaint of *Rhododendrons* and *Azaleas* and was described in these pages so long ago as July 19, 1879, p. 119.

**EARLY-FLOWERING CHRYSANTHEMUMS IN POTS:** *R. R.* June is really too late a date for propagating *Chrysanthemums* for cultivation in small pots. Five-inch pots are rather small; six-inch pots will give you much better results. If you particularly want plants in pots of the size you mention, you can propagate as you suggest, and from young stock rooted earlier in the season. To obtain fine examples in six-inch pots, propagation should be commenced during April; grow one plant in a pot, and stop the plants until the number of shoots required is obtained. Such plants require high cultivation and strict attention as regards watering, for neglect in this respect results in the loss of the bottom leaves, without which they look very poor specimens. For this reason all varieties are not suitable for your purpose, for, although many have good flowers, not all make good plants. Taking them all round, there are few better varieties for this method of cultivation than the *Caprice du Printemps* set, the best of them being *Yellow Cap*, *White Cap*, and *Kathleen Thompson*. The colour of the flowers of *Caprice du Printemps* is not pleasing to everyone. All these varieties flower towards the end of October. Other varieties worth trying for October use are *Uxbridge Pink*, *Mrs. Roots*, *Lucie Louppe*, *Mlle. M. Fabre* and *Blanche de Poitou*. To follow them, try *November Gold*, *Sorcerer*, *Felton's Favourite*, *Market Red*, *Rosalind* and *Pourpre Poitevine*. For December, *Ivy Gay*, *Niveus*, *Framfield Pink*, *White* and *Yellow Money-maker*, *December Pink*, *December Gold*, *December Bronze*, *Baldock's Crimson*, *Heston Pink* and *Heston White*. Some of the singles of good habit are also well suited for this purpose, *Ladysmith* being a good type, the small-flowered varieties being best, although *Caterham Bronze*, rooted late and well grown, is very fine. It is well to try a few fresh varieties each year, and thus find out those best suited for your particular purpose.

**HIPPEASTRUM SEEDLING:** *J. E.* The flower was somewhat faded when we received it, but we do not think it is so fine as some of the crimson varieties already in cultivation. However, as the variety is very vigorous and has produced a spike of four fine blooms, it is well worth perpetuating for decorative purposes in the greenhouse and conservatory.

**NAME OF FRUIT:** *Rez.* 1, *Catshead*; 2, *Graham* or *Kentish Deux-Ans*; *Catshead* is probably the parent tree, and at some time the *Graham* variety has been grafted on to it.

**NAMES OF PLANTS:** *T. S.* 1, *Juniperus chinensis*; 2, *Thuja orientalis*; 3, *Cupressus pisifera* var. *plumosa*; 4, *Cunninghamia-sinensis*; 5, *Pinus austriaca*; 6, *Picea excelsa*.—*A. M.* *Grevillea asplenifolia* (see Fig. 94).—*T. O. C.* *Salvia fulgens*.

**PROPAGATING BRUNFELSIA.**—There is no difficulty in propagating any of the *Brunfelsias* by means of cuttings inserted in a sandy compost and plunged in a warm propagating case over bottom heat. They may be propagated from young growths sufficiently firm to prevent damping, or from cuttings of the previous year's wood. You do not state what species you have, but it appears to be *B. latifolia*, which is a native of Brazil; but there are several other species native of South America. *Brunfelsia calycina* used to be common in gardens; the variety *macrantha* has much larger and deeper coloured flowers. You may be able to obtain plants from Messrs.

*L. R. Russell*, *Richmond Nurseries*, *Sheen Road*, *Richmond*.

**QUICKLIME:** *E. H. W.* There is no gas evolved when water is added to calcium oxide. Energy is liberated in the form of heat, and calcium hydrate ( $\text{Ca (O.H.)}_2$ ) is formed. If this is exposed to the air for a few weeks the carbon dioxide of the air enters into combination, and calcium carbonate is produced. The oxide is certainly very useful in ridding the soil of many insect pests.

**RASH FROM DAFFODIL BLOOMS:** *M. G.* It is very likely that the rash is caused through handling the *Daffodils*, as there are numerous cases of a similar nature on record. When the flower stems are gathered the cut end of the stem exudes a quantity of sap which is highly charged with microscopic needle-like crystals of calcium oxalate. These crystals gain a ready entrance into the skin and act as an irritant to people with tender skins. The rash on the face may be explained by the person rubbing or touching that part with the hands. The affected parts should be treated with carbolic or zinc ointment, and if the hands are dressed with vaseline before the flowers are picked the crystals cannot enter the skin so readily. It is also advisable to wash the hands directly after handling the flowers is completed.

**ROMNEYA COULTERI AND DOUBLE HOLLYHOCKS:** *M. B.* *Romneya Coulteri* may be pruned about the beginning of April; except in favoured places in the south and west, there is usually not much choice except to cut the plants right down to the ground. If there are any strong shoots unharmed by frost the dead tips should be cut off and the weak and soft shoots cut clean out. Luckily *Romneya Coulteri* usually flowers freely on strong current year's shoots thrown up from the base. *Double Hollyhocks* from good selected strains come true from seed, both as regards colour and doubleness. For the last ten years we have been raising two fine varieties every year from seed, and they always come true.

**SOWING BARE PATCHES ON A LAWN:** *C. R.* Before sowing lawn grass seed on the bare patches, it would be advisable to well dig them and to incorporate some decayed manure with the soil. The soil should then be made thoroughly firm, raked level, and sown at the earliest opportunity. A calm day should be selected for the sowing, and the soil should be sufficiently dry not to adhere to the boots when it is trodden upon. The best quality grass seed should be procured—economy in this direction is a fatal mistake with a feature which, to all intents and purposes, is to be permanent. At so late a time in the season the seed should be sown rather more thickly than need have been the case earlier— $\frac{1}{2}$  oz. per square yard would be a suitable quantity to use. After sowing the seed lightly rake over the surface, taking care not to bury the seed deeply, or the finest grass seeds will not germinate. Generally some protection from birds is necessary, and this may best be afforded in small areas by covering with garden netting raised above the surface by one of the methods usually adopted with *Strawberry beds*. If netting is not available, fowl's wing feathers will be found exceedingly effective. These should be suspended on strong threads criss-crossed at about 2 ft. from the ground; one feather to each 20 in. run of thread will be sufficient to scare the birds.

**TETRACHLORETHANE:** *R. S.* This chemical may be obtained from Messrs. *Murphy and Sons, Ltd.*, *Horticultural Chemists*, *Mortlake*, *London, S.W.14*, who also supply full particulars regarding its use in controlling white fly.

**TOMATO PLANTS DISEASED:** *P. T.* The trouble appears to be due to an early infection by *Phytophthora infestans*, but the specimens were so dried up when they reached us that it was almost impossible to find a bit of leaf. Spray with weak *Bordeaux* or *Burgundy* mixture.

**TREATMENT OF OLD VINES:** *J. B. D.* Cut out the rods which have died and train young shoots from the base to take their places. After the *Grapes* have stoned, or as soon as the first tinge of colour appears in the berries, give dressings of vine manure in alternate weeks, in addition to the manures you have given. Your *Grapes* will not colour better by the vines being started earlier, but by reducing the atmospheric moisture and increasing the ventilation. After colouring commences always admit a little air by means of front and top ventilators at night from the end of June onwards, allowing a gentle warmth in the pipes during damp weather.

**WEEDY LAWN:** *W. W. F.* The cause of the lawn drying out very quickly is the sub-soil of clay with only a thin veneer of good soil on the surface. You should endeavour to stimulate the growth of the grass by rich top dressings, such as old potting compost or good garden soil mixed with well-decayed farmyard or stable dung. The application of sulphate of ammonia will have the effect of stimulating the growth of the grass, but it will not give body to the turf. Your best plan would be to mark out the lawn into suitable areas and apply the top dressing evenly over each portion. Nitrogenous manures may be mixed with the fine soil, and bone meal may be added as well. After a lapse of a week or so the lawn should be raked both ways and stones or other rubbish removed. In dry weather a light roller drawn over the sward will serve to ensure an even surface and press the soil well about the roots of the grass.

**Communications Received.**—*J. W. S.*—*C. C.*—*H. A.*—*P. R.*—*W. W.*—*F. T. P.*—*W. C.*—*D. H. D.*—*J. C.*—*H. T.*—*C. D.*, Thanks for Is. for R.G.O.F. Box—*K. W. P. T.*

## THE WEATHER.

## WEATHER IN MARCH.

MARCH commenced with a spell of open, unsettled, south-westerly weather. A great change then occurred in the pressure-distribution over this part of the world, and from the 10th day dry, light winds from the colder half of the compass prevailed, with scarcely any intermission, to the month's close. The most frequent direction was due east, and the next frequent due north. A number of days were cold, and many nights extremely so, being fine and dry starlit to an unusual extent. Fortunately, practically throughout these last three weeks, the weather was exceptionally calm for March in Southport. The most easterly period occurred about the middle of the month, and was very hazy; but at all other times ozone was abundant. For the complete month, the mean temperature was barely 40°, being half a degree below normal. There were, however, 126 sunny hours, or four more than usual. The total rainfall amounted to only 1.36 inch in *Hesketh Park*, 1.23 inch near *Birkdale Station*, and 1.04 inch near *Woodvale Ainsdale*; the deficiency at *Hesketh Park* was 0.86 inch. There were 77 fewer miles of wind per day than the average at *Marshside*. Frost occurred in the shade on 6, and upon the grass on as many as 18 nights; the lowest reading in the open was 18° on the 22nd. Small quantities of snow fell on the 21st and 24th, and an inch on the early morning of the 31st. Fog was restricted to one night and one morning. There were no gales. *Joseph Barendell, The Fenley Observatory, Southport.*

## THE WEATHER IN SCOTLAND.

A few mild days towards the beginning and middle of the month gave March a mean temperature slightly above the normal, but on the whole, the month was a cold one. While the rainfall showed a deficit of fully one inch below the normal, March was exceptionally dull with occasional fogs. Rain fell on 17 days to a total of 2.05 inches, the wettest day being the 6th, with 0.62 inch. Of bright sunshine 106.4 hours were registered for 25 days, giving an average of 3.4 hours per day and a percentage of 29. The mean temperature was 40°, with a mean maximum of 47° and a mean minimum of 33°. The highest maximum of 56° was on the 11th, and the lowest minimum of 25° on the 23rd. On 10 nights the temperature fell below the freezing point. The mean minimum on the grass was 38°, with a lowest of 17° on the 23rd; there were 22 nights of ground frost. At 1 ft. deep the soil temperature rose from 38° on the 1st to 42° on the 15th and the five following days, and then fell to 39°. With a mean of 29.84 inches, the barometer varied from a highest of 30.52 inches on the 13th to a lowest of 29.98 inches on the 8th. Snow fell on 3 days, the heaviest fall being that of the 31st. The prevailing winds were westerly; there were no gales. *John Davidson, Director of Studies, St. Andrews Provincial Training College Gardens, Kirkton-of-Mains, near Dundee.*

### Do Plants Know Time?

The conception of limiting factors referred to in our leading article on p. 175 is due to the distinguished plant physiologist, Mr. F. F. Blackman, of Cambridge. It is of great value not only to botanists, but also to horticulturists, and some of its applications will be dealt with on another occasion; but for the moment attention must be confined to an attempt to apply it to periodic movements. Take the case of Mr. Mill's *Dracaena Goldiana*. The several days on which its flowers opened punctually at 3.55 p.m. doubtless varied considerably both as to temperature and light. These factors were not limiting. The opening of the flower depends also on internal factors. The cells of the floral tissues have to make or absorb sugar, this sugar has to accumulate to a certain amount before growth is sufficient to force the flower open. The suggestion is, therefore, that the structure of the flower—that is, of the tissues concerned with causing it to open—provided a limiting factor. The cells of which that tissue is composed could grow no faster even though external conditions became more favourable. They had their labourers' strike;

so much and no more could they grow, and hence each day the same length of time was taken by them in accomplishing their work. It is not pretended that this application of the doctrine of limiting factors solves all difficulties or offers a complete solution of the problem. It is put forward in the hope that those who have shown by their observations that plant life teems with mysteries which plant-physiology has as yet by no means solved, may find it useful in thinking over the significance of their observations. The idea may be extended thus. Daybreak ushers in a series of operations which are arrested at night. As soon as sunlight falls on a plant, its stomata, which were closed during the night, begin to open. With the opening of the stomata—the breathing pores of leaves—oxygen necessary to active life is free to diffuse into the leaf more rapidly than it could when the stomata were closed. Thus chemical processes dependent on relatively large supplies of oxygen would resume activity with daylight, to fall off again as the stomata close in the early afternoon. Hence the whole life of the plant would tend to be divided into two shifts, a day and a night shift, and some kinds of work would go on actively during the one period and either be knocked off altogether or limited during the other. In this way it is possible to imagine that the business of the opening of the flowers of *Dracaena Goldiana* is an affair of the day shift. This work begins at daybreak and though the plant does it as fast as it can, the earliest moment it can be completed is at 3.55, for the limiting factor of the process is by assumption not one of the external factors, light or temperature, but an internal factor independent of external factors. Of course, it is possible by artificial means to make some other factor limiting. For example, if temperature be lowered plant processes slow down. In some cases it has been shown that the rate of a plant process depends in a very definite manner on temperature, the rate of the process being doubled (within limits) by an increase of 10° C. Thus it may be understood how complex is the problem of understanding the behaviour of the growing plant. For it is subject to both external and internal factors, each of which may in turn be limiting so that the marvel of periodicity becomes the greater when it is realised how out of such a welter of circumstance the plant contrives stability and orderliness of behaviour. One other conception may prove helpful to those who take pleasure in cogitating upon the ways of plants. All vital activity of whatsoever kind means the production of waste products, and mechanism, if it is to act continuously, must have means of disposing of these products. Cut off the exhaust from an internal combustion engine and the waste products of combustion accumulate in the mechanism, the engine labours and finally ceases to run. So with living organisms; plant activity is a form of combustion. It results in the production of waste substances. The plant's means of riddance of waste substance is less perfect than the animal's, but it suffices. It is probable that periodicity of the kinds here considered is not unconnected with the accumulation of waste products of activity escaping from a tissue at a certain rate, but more slowly than they are formed. The mechanism, after a definite time, is clogged by the products of its own activity, slows down, and stops, only to become active again after the lapse of a definite interval of time, when sufficient of the waste products has been removed to admit of resumption of work by the mechanism. These conceptions applied to the Runner Bean and to *Convolvula*, and cognate cases of periodicity have

helped to form a picture of how these strange happenings might occur. We would not, however, have offered these speculations for the consideration of others had it not been for the fact that the recent correspondence in these columns has shown that the problems which have vexed our mind so much and so often are of such general interest that even uncertain suggestions, such as are here put forward, may prove of service, and perchance set others thinking to better effect.

**New Regius Keeper of the Royal Botanic Garden at Edinburgh.**—It is announced that Mr. William Wright Smith is to succeed Sir I. Bayley Balfour in the offices of Regius Keeper of the Botanic Garden at Edinburgh, Regius Professor in the University of Edinburgh, and King's Botanist in Scotland, which Sir I. Balfour vacated on the 8th inst. It has come to be a tradition that these high offices should be held by a Scotsman, and it is a matter for general congratulation that it should have been found possible on this occasion to maintain the tradition by so happy an appointment. Mr. Smith, who was born in 1875, has spent a considerable part of his official career on Sir I. Bayley Balfour's staff at Edinburgh, for in 1902, after taking his degree at the University of Edinburgh, he was appointed assistant and lecturer in the department of Botany, having charge of the laboratory and superintendence of research work. In 1907, Mr. Smith was appointed Keeper of the Herbarium in the Royal Botanic Garden at Calcutta, so that his election to the Edinburgh posts adds another link to the chain of association between that well-known garden and the mother country. In 1908 he was appointed Acting Superintendent of the Calcutta Garden and at the same time officiated as Director of the Botanical Survey of India. In the course of his duties in connection with the Survey, Mr. Smith had the exceptional good fortune to undertake the botanical exploration of little known regions in Sikkim, and on the borders of Nepal, Tibet and Bhutan. In particular he explored the Lonakh valleys north of the Kangchenjunga glaciers, at an elevation of over 14,000 feet. Subsequently he worked the High Himalaya between Chumbi and Eastern Sikkim. Mr. Smith is, therefore, one of the few living botanists with personal experience of exploration in the Eastern end of the Himalaya. After four years in India, Mr. Smith returned to Edinburgh as Deputy to the Regius Keeper of the Garden, a post he only now relinquishes. Mr. Smith's work in connection with the systematic botany of Eastern Asia and particularly of India, Burma, Tibet and the Western Chinese Alps is well known, and his contributions to the literature of the subject, both in collaboration with Sir I. Balfour and from his own pen, are numerous and important. As Deputy to the Regius Keeper, a not inconsiderable share of the administrative and teaching duties have fallen on Mr. Smith. In view of the unique relations prevailing at Edinburgh between the University and the Garden, the presence at the head of affairs of a systematist is of the utmost importance. The promotion of his deputy may be taken to foreshadow a continuance of the wise and enlightened policy which has prevailed at Edinburgh under the retiring Regius Keeper. Mr. Smith is a Fellow of the Royal Society of Edinburgh and of the Linnean Society, and for many years has been secretary of the Botanical Society of Edinburgh.

**Potato Trials at the Royal Show.**—Amongst the plots of growing agricultural produce which will be displayed by the National Institute of Agricultural Botany at the Royal Show, Cambridge, next July, the portion allotted to Potatoes is likely to create much interest. This portion will take the form of a comparative yield trial, and will consist of a checker-board made up of plots of the newer first early varieties, and those which have already won public approval. The following varieties will be represented:—America, Colonist, Di-Vernon,

Dunottar Castle, Dunvegan, Immune Ashleaf, Sharpe's Express, and Duke of York. Planting is now completed, and in order to equalise possible effects of soil irregularity, each variety is represented by six plots scattered throughout the checker-board. For demonstration purposes it has been decided to lift a small portion of each variety daily during Show Week, and an assistant will be in attendance daily to furnish the necessary explanations and to answer inquiries. When mature, the remaining plots of each variety will be lifted; the produce weighed; and the results, with explanatory notes, will be supplied to the agricultural and horticultural Press.

**Catalogue of Plant Names.**—Mr. Harlan P. Kelsey informs us that the pre-publication price of \$3.50 (\$3.75 west of the Mississippi River, in Canada and abroad) holds good for all orders for the "Official Catalogue of Standardised Plant Names," accompanied by cash and received by May 1, 1922. This extension of time was made necessary as it was found impossible to get out the prospectuses to organizations in time for members to avail themselves of the special pre-publication price.

**National Institute of Agricultural Botany.**—At a meeting of the Council of the National Institute of Agricultural Botany, held on the 23rd ult., one hundred and twenty-five candidates were elected, among whom were the following: The Duke of Devonshire, the Marquis of Salisbury, the Rt. Hon. the Earl De la Warr, the Earl Cawdor, the Earl Fortescue, the Earl of Macclesfield, the Rt. Hon. the Lord Ailwyn, Lord Glentanar, Lord Lee of Fareham, Lord Leigh, the Rt. Hon. Viscount Burnham, the Hon. A. E. Parker, the Hon. I. M. Campbell, the Rt. Hon. Walter Runciman, Sir Herbert Brown, Sir Malcolm McAlpine, Brig.-Gen. Sir Walter Ross, Professor F. E. Weiss, Dr. N. W. Michahelles, Mr. A. Birch, Mr. W. Hasler, Mr. A. E. Humphries, Mr. A. W. McAlister, Mr. A. McAlpine, Mr. Robert McAlpine, Mr. W. H. McAlpine, Mr. G. P. Miln and Mr. J. E. N. Sherwood.

**Dahlias in America.**—The American Dahlia Society will conduct trials at two stations during the coming season, a northern one at Storrs, Connecticut, and a southern one at College Park, Maryland. The Society will hold its annual show in the roof garden of the Pennsylvania Hotel, New York, on September 26, 27 and 28. According to the *American Florist*, the Society is making highly satisfactory progress and the membership is increasing daily.

**Home-grown Sugar.**—The Minister of Agriculture, Sir Arthur Griffith Boscawen, states that the Government has decided to remove the excise duty from home-grown sugar, and is making provision to remove the existing duty permanently in the coming Finance Bill. The concession will doubtless result in a stimulus to Sugar-beet growing in this country, and the British Sugar-beet Growers' Society proposes to offer farmers contracts for Beet sugar grown during the coming season.

**The Paris Iris Conference.**—The Committee of the Paris Iris Conference has drawn up a list of classes open to exhibitors from any country during the flowering period of Irises. The classes are as follows:—(1) The most important and finest collection of Irises of any kind exhibited either at the International Iris show at the Jardin d'acclimatation, or at the meetings of the Conference, 84, Rue de Grenelle; (2) a collection of 50 varieties of garden Irises (Germanica group); (3) a collection of Iris Kempferi; (4) a collection of bulbous Irises (Xiphium); (5) a collection of twenty-five varieties of garden Irises exhibited by an amateur; (6) 10 varieties of garden Irises exhibited by an amateur. The amount of the prizes awarded to successful exhibitors in these classes will be determined by the amount of money collected for this purpose. The American Iris Society has kindly offered its silver medal for 1922 as an award. A prize of 500 francs is offered by Mons. F. Denis for the finest new Iris (I. Kempferi excepted) submitted to the Conference. A prize of 250 francs is offered by MM. Cayeux

et Leclerc for the three finest new varieties of German Irises. Large collections of Irises must be staged on May 20 or 26 before 10 a.m., but small exhibits, or plants of special interest, or those useful to illustrate any point raised at the Conference, may be staged in the Society's rooms on the day of the Conference May 27. Exhibitors should state the number of flowers they intend to stage, the room required, and the number of vases needed, and applications should be sent as soon as possible to the President of the Society, 84, Rue de Grenelle, Paris. Exhibitors are requested to advise the President of the Conference of their intention to exhibit at least a fortnight in advance of the meetings. There will be no meeting on May 25—Ascension Day. A wrong interpretation of Mons. Denis' gift was conveyed in our note on p. 163, the whole amount of his prize of 500 francs is to be awarded for the finest new Iris.

**Mr. N. E. Brown.**—Mr. N. E. Brown is one of our oldest and most valued contributors, and he has described in this and other periodicals so many species of plants suitable for cultivation that, like his old colleague, the late Mr. J. G. Baker, he may be described as a gardeners' botanist. Through his long connection with Kew he is known personally to

MR. N. E. BROWN, A.L.S.

many gardeners in all parts of the world, and his quiet, unassuming manner has endeared him to a still wider circle of acquaintances. He was born at Redhill, Surrey, on July 11, 1849, and as he himself facetiously remarks, at death's door, for his home was only a few yards from the churchyard. After attending two private schools and one public school, he finished his education at Reigate Grammar School, where his career was decided for him. The first year he was at the Grammar School, Mr. W. Wilson Saunders, of Reigate, offered a microscope as a first prize for botany. Young Brown was then only some thirteen or fourteen years old, and a microscope was the one thing above all others which he wished to possess. Even at that early stage he had an inclination for the study of natural history, and made a special hobby of insects, but he knew absolutely nothing of botany. However, he decided to win the microscope, if possible, studied hard and succeeded, and he remarks that the possession of that instrument made him a microscopist, as well as a botanist, and microscopy is still his favourite hobby. After leaving the Grammar School he acted as curator to Mr. Saunders, who had a very large collection of insects and other natural history objects. He stayed with that gentleman for six years, and at the end of that period he competed for a vacancy in the Herbarium at

Kew, and succeeded in obtaining the post. That was in February, 1873, and he remained at Kew until 1914, when he retired; but he continues his work amongst plants in a private capacity, and how thoroughly he still pursues his botanical studies is seen in his erudite monograph of the genus *Mesembryanthemum*, which is appearing in these pages.

**Food of the Teredo.**—At a meeting of the Philosophical Society of Cambridge, on February 6, Mr. F. A. Potts dealt with the food of teredo, the ship-worm. The minute fragments of wood excavated by this mollusc pass through the alimentary canal and are in part digested by it. The stomach has an enormous coecum, which retains a quantity of wood, but digestion takes place in the so-called "liver," some of the cells of which are gorged with particles of wood.

**Lincolnshire Flowers for Easter.**—We learn that about fifty tons of flowers, chiefly Daffodils and Tulips, were despatched from Spalding railway station, Lincoln, to London and other large centres, for the Easter market.

**Extension of Wimbledon Common.**—Wimbledon Common, the beautiful public open space on the south-western outskirts of London, has been enlarged by some forty-two acres on the Putney Vale side. The additional land was acquired as a memorial to the members of the Army units belonging to the districts around the common or of families resident in or connected with those districts who have fallen in the war. The land has been formally handed over to the conservators of the common by the executive committee of the Wandsworth and Wimbledon Memorial Fund. The ground has been laid out under the direction of Miss Agar, of the Metropolitan Gardens Association, but nothing in the way of landscape gardening or floral displays has been attempted, and there are no formal paths or flower beds, but suitable trees and shrubs have been planted at intervals.

**The Bulb Farms of Holland.**—Mr. Anthony C. van der Schoot informs us that the best time to see the Hyacinths, Tulips, and Narcissi in full bloom at the bulb farms of Holland will be from about April 25 until the end of the first week in May.

**A New Tree Gentian.**—Dr. N. L. Britton, Director-in-Chief of the New York Botanical Garden, records in the *Bulletin of the Department of Agriculture, Trinidad and Tobago*, the discovery of a plant new to science, a member of the Gentian family which he has named *Chelonanthus arboreus*. The tree was found growing at the top of the precipitous northern slope of Mount Tucuche, a short distance from the summit. Dr. Britton states that the plant does not suggest a member of the Gentianaceae at first sight, and it was only after he had broken off a flowering branch and examined a blossom that its relationship became apparent. The tree grows to some two or three times the height of a person, and has a few nearly upright branches and a smooth trunk, which is three or four inches in diameter near the ground; the leaves are broad, dark green, and of leathery texture. The inflorescences form terminal clusters of yellow, bell-shaped flowers, each about one inch long.

**Legacies to Gardeners.**—The late Mr. Richard Thomas Prowse, C.B., of Howton, Bushey Heath, Hertfordshire, who died on December 17 last, aged 87 years, bequeathed £100 stock, £50, and all out-door and garden effects, poultry and live stock to his gardener, Mr. Fred Daniels, and £50 and his garden seats to his under gardener, Mr. A. J. Young.

**Flowering Plants of South Africa.**—Part 6 of Volume 2 of the *Flowering Plants of South Africa* contains descriptions and illustrations in colour of ten interesting plants. The first one described is *Gazania subulata*, a handsome, yellow-flowering member of the family known as "Gousblom" in South Africa. Then follow *Pelargonium crassicaule*, a woody stemmed species with small umbels of white fragrant flowers;

*Androcymbium melanthioides*, a low-growing Liliaceous plant which has large, purplish bracts that are far more showy than the cluster of small flowers they enclose; *Mesembryanthemum aloides*, a stemless native of Bechnanaland, with a rosette of fleshy, white-dotted leaves, and sessile, lemon-yellow flowers; *Aloe striata*, a showy plant bearing a panicle inflorescence of tubular, coral-red, yellow-tipped flowers; *Polyxena haemanthoides*, another Liliaceous subject of lowly growth, bearing a cluster of yellowish flowers set amid white bracts; *Dimorphotheca spectabilis*, a poisonous plant bearing large, mauve, Daisy-like flowers, which would be much appreciated for home decoration if they could be produced easily in British gardens; *Mimetes capitulata*, a curious Protead, with white capitula surrounded by narrow, orange-coloured bracts and set in the axils of the closely-set leaves towards the ends of the branches; *Erythrina caffra*, known in the Cape as the "Kaffir Boom" and to the children of Natal as "Cockie Doodles," a tree of moderate height with trifoliate leaves, spiny stems and many flowered dense raceme of pendulous, scarlet flowers; and *Sparaxis grandiflora*, a slender Irid with dull, bluish-purple flowers.

**Appointments for the Ensuing Week.**—Tuesday, April 25.—Royal Horticultural Society's Committee meetings (two days); Bath and West and Southern Counties Society's Council meeting. Wednesday, April 26.—Irish Gardeners' Association meeting; Elgin Horticultural Society's meeting. Thursday, April 27.—Bristol and District Gardeners' Association's meeting; Royal Botanic Society's meeting.

"Gardeners' Chronicle" Seventy-five Years ago.—*The Warratah* (*Teloepa speciosissima*). In the vast colony of New South Wales, which is so abundant in floral beauties, none attracts the traveller's attention more than the Warratah, its splendour being second to none. The rich crimson blossoms, elevated on an erect stem, are discernible at a great distance, and large tracts of it form indeed a gay sight in the months of August and September (spring months there). The *Teloepa speciosissima* of botanists, Warratah of the Aborigines, and Native Tulip of the colonists, is found in greatest perfection in shaded valleys of very sandy loam, containing decayed vegetable matter, the accumulations of ages. In such situations it will attain the height of 5 and 6 feet, each shoot producing one and often two flowers, and each stool from one to three and four flowering stems. The roots are large in proportion to the top, with few fibres, but nevertheless very tenacious of life, a great advantage in point of carriage, as the plants may be dug up, the top cut clean off, and packed in casks or boxes, in very dry mould. In this way I have conveyed them to England with pretty good success. The points to be attended to, are, to pack them dry, and to keep them in that condition. When subjected to artificial cultivation in this country, too much stress cannot be laid on the necessity of securing thorough drainage, and on the judicious application of water; for months in winter scarcely any watering will be necessary; should a plant become sodden, however, at this season, through careless watering, I should prefer turning it out of the pot, reducing the ball, and replacing it in the same pot, or one of a smaller size, using very dry soil. *Alex. Burnett, March 8, Gard. Chron. April 24, 1847.*

**Publications Received.**—*Investigations of the White-Pine Blister Rust.* By Perley Spaulding. Bulletin No. 957; *Meade Cotton, an Upland Long-Staple variety replacing Sea Island.* By G. S. Meley and C. B. Doyle. Bulletin No. 1030; *Commercial Control of Citrus Scab.* By John R. Winston. Circular 215; *Inventory of Seeds and Plants Imported by the Office of Foreign Seed and Plant Introduction During the Period from January 1 to March 31, 1917.* All published by the U.S. Department of Agriculture, Government Printing Office, Washington. *Empire Forestry.* Vol. 1. Journal of the Empire Forestry Association, Imperial Institute, London. Macmillan and Co., Ltd., St. Martin's Street, W.C. Price 4s. net.

## DRY WALL GARDENING.

A DRY wall furnished with a variety of plants in flower is an exceptionally pretty feature in the garden, and there are usually suitable situations in most gardens where a wall of this kind may be formed. The wall may be either very dwarf or tall as is desired, and suited to the environment. It is necessary that the soil used should be of a rich and lasting nature, in order to supply the plants with adequate nourishment, and to retain the necessary moisture. The compost should be mixed and got in readiness for use as the wall is formed, and the plants should be inserted at the same time as the stones are placed in position. Good, solid pieces of stone of all sizes are suitable, and the best shape is flat or oblong, as this form admits most readily of firm packing. The stones should be about eighteen inches long, with smaller pieces, some five to eight inches in length and width. In localities where sandstone abounds this type of stone may be used with every advantage, and the plants will cling to the stone, seed and

*Thymus*, especially *T. citriodorus*, *T. Serpyllum* and *T. S. album*; *Sedum Ewersii*, *S. kamtschaticum*, which flowers from July to September, *Phloxes* in variety, *Lithospermum*, *Linaria*, *Hypericum*, *Iberis* Little Gem, and others. *Erigerons*, *Dianthus* in variety, *Cerastium*, *Arenarias*, *Acaena*, *Arabis*, *Aquilegia*, *Antirrhinum*, and *Polyanthus*.

Certain bulbs may be associated with the plants on the top, such as *Crocuses*, miniature kinds of *Narcissi* and *Tulip* species. These give a fine spring effect before the general mass of plants are in flower. With the selection of plants I have given the wall will be an object of beauty (see Fig. 98) for six months of the year. In dry weather the wall should be sprayed each morning and evening, and when it is hot and very dry the hose or water can should be requisitioned to give the plants a good soaking at the roots. When the various subjects have finished flowering the seed pods should be removed, the plants trimmed, and those that have made excessive growth restricted by pruning. *W. A. Cook, Drynham Gardens, Walton-on-Thames.*

FIG. 98.—EXAMPLE OF THE BEAUTIFUL EFFECT WHICH MAY BE OBTAINED FROM THE SUCCESSFUL CONSTRUCTION AND PLANTING OF A DRY WALL.

reproduce themselves, but any type of stone may be used except such as has a glazed surface.

In building the wall commence by laying some of the flattish stones on the base and allow them to lean slightly inwards, say an inch in every two feet. This will prevent the wall from falling outwards should much rain fall, and the moisture will be directed into the interior part of the wall. When the bottom layer of stones has been laid and fitted, the soil should be filled in as high as the stone, pressing it down firmly to prevent it sinking. Continue this method layer by layer, putting in odd shaped stones here and there to give a more natural effect, taking care, of course, that they are well wedged in at the back so that they are not easily displaced.

Allow each plant plenty of room to develop according to its size, and when the wall is completed finish the surface off level and plant the top with suitable subjects. Amongst plants which are adapted for this method of gardening are *Aubrietias* in variety, *Campanulas* and especially *C. muralis*; *Cheiranthus Allionii*, *Alyssums* in variety, *Saxifragas*, *Sempervivums*,

## HARDY FLOWER BORDER.

### CARDAMINE ROTUNDIFOLIA.

With comparatively little to recommend it compared with many other flowers, *Cardamine rotundifolia*, the round-leaved Lady's Smock, has the great merit of very early blooming, to induce many to give it space in their gardens. It has been familiar to me for very many years, and some time before I acquired it I was rather surprised to observe it in bloom in what was then one of the best collections of good rock and border plants in the United Kingdom. It did not appear good enough to warrant its inclusion, but its owner expressed his high appreciation of the plant on account of its very early flowering. I have grown it for many years since that time, and, although I do not claim that it ought to be numbered among the elite of plants, I like to have it and appreciate to the full its precocity of flowering. It sometimes blooms in February and in a sheltered place, its heads of small, white flowers are valued in the garden, and it is also possible to pick a few flowers for the home at a time when other outdoor subjects are not available. With a little

greenery they form no mean ornament for those who have no glass, and have to depend upon their outdoor flowers for this purpose. *C. rotundifolia* is not difficult to grow on the lower parts of the rock garden or in the border. A sunny, sheltered place is best, as it will bloom there sooner than in a colder aspect. Ordinary garden soil will suit it, but the best rooting medium is a mixture of light loam, sand and a little leaf-mould. The plant may be propagated freely by division.

#### CORYDALIS NOBILIS.

THE noble *Fumitory*, *Corydalis nobilis*, is one of the border or rock garden plants which has accorded to it less favour than it deserves. It is quite ornamental in the border and its only garden fault appears to be that of slowness of increase. It is not too plentiful in nurseries, and this may be due to this fact, which makes it a less profitable plant than those which are readily multiplied. It is a handsome plant of some ten or twelve inches high. The leaves, like those of practically all the other *Fumitories*, are graceful, and the flower stems, which are clad with foliage to the top, carry a good head of bright golden-yellow flowers, each tipped with a little reddish-brown dot in the centre. The effect of the whole plant when in bloom is such that few pass it by without admiring it. It is by no means particular as to soil, but it should, if possible, be grown in a light but rich rooting medium. It is one of the many desirable plants which bloom in early summer. A.

### THE ALPINE GARDEN.

#### AQUILEGIA STUARTII.

It is now many years since the late Dr. Stuart, of Chirnside, sent me a young plant of the Columbine which bears his name, *Aquilegia Stuartii*, a flower which I never see now, as my specimen met the untimely fate all plants of this hybrid seem to do. So beautiful, however, was it I wish that I could see it again. I do not think it is obtainable from nurserymen, as I have not observed it offered for sale for a long time. It is said to be a hybrid between *Aquilegia glandulosa* and *A. olympica*, but for various reasons, which cannot be discussed here, there are grave doubts of the truth of this statement. The plant is more like a miniature *A. juncunda*, and it has the same large flowers, though, perhaps, a trifle smaller, and the same lovely colouring of white sepals, and corollas of the most charming shade of blue imaginable. The plant is a gem for the rock garden, as its height is rarely more than six or eight inches. I should be glad to know if any reader possesses the true *Aquilegia Stuartii*. I fear, however, that it is likely to be unusually rare, and that it may not even exist in gardens at the present time.

#### TWO GOOD ANNUALS FOR THE ROCK GARDEN.

*SEDUM CAERULEUM* is a charming little, low-growing annual with somewhat succulent leaves and small, starry flowers of a delightful soft shade of blue. The plant grows only a few inches high. It flowers for a long time in summer and autumn, and will be found very useful for furnishing places on the rockery where bulbous flowers have bloomed and ripened their growth. Some sow the seed in pots in March and plant the seedlings out in May, but I think better specimens are produced by sowing the seeds very thinly at the end of April or the beginning of May where the plants are to bloom, thinning the seedlings to about six inches apart. In this way charming little groups of the starry, blue flowers, that are almost lace-like in appearance when in a mass, are produced.

The Violet Cress, *Ionopsidium aculea*, is another dwarf annual of high charm, and of much value for the rock garden where it covers what might otherwise be bare spaces with its neat leaves and charming, pale violet flowers, the whole plant being only an inch or two high. It may be associated in perfect harmony

with the choicest of alpine. It is best when sown where it is to bloom, and the end of April or early May is a good time to sow, taking care to sow the seeds sparsely and to thin the young plants before they become crowded. This is one of the best annuals for furnishing bare spaces on the rock-work. A point in its favour is that it likes a little shade. *S. Arnott.*

### FLORISTS' FLOWERS.

#### SWEET PEAS.

THE recent wet, cold weather has delayed various operations in the garden, including the planting out of Sweet Peas raised in pots, from seed sown during the autumn. As soon as the weather is more favourable and the soil in a condition for working, and for the reception of plants, the planting should be undertaken. All growers do not agree with this method of raising Sweet Peas, but I strongly adhere to it, inasmuch as I am of opinion that it results in hardier, more healthy plants than those raised in heat in the spring, and obviates the risk of having blank spaces in the rows which often occur when spring sowing in the open is depended on, whilst the flowers are certainly earlier. Spring sowing in the open should, however, be followed in addition, to prolong the season of flowering, and this is the more important if the summer is very hot and dry.

The ground for Sweet Peas should be as carefully prepared as that for culinary Peas, for the Sweet Pea revels in a good, carefully prepared root run, and to this end the soil should be well and properly trenched in the autumn, incorporating at the same time a liberal quantity of well-decayed manure.

If the planting is to be done in rows, it is well to first stand the pots in position, each sort by itself, in a double row, leaving about a foot to 15 inches between the two sides of the row. Crowding of the plants should be guarded against, and a space of about 10 inches should be allowed between the plants in the rows. At one period it was considered inadvisable to disturb the roots when planting them out of pots, but this is not the generally accepted idea nowadays, and, provided the roots are not damaged, the plants may be carefully divided to permit of planting without crowding. Plant carefully with the aid of a trowel, and make the soil moderately firm.

After planting, draw the soil up carefully around the stems of the young plants to protect them from frost, and, should keen east winds prevail, it is well to provide some slight protection for the young plants, such as by inserting a few boughs of Spruce or similar material along the rows. I have found it beneficial to make a shallow trench for Sweet Peas, as this greatly helps when watering the roots later in the season.

Stake the plants as soon as they are planted, as there is less risk of root disturbance when this is done early, and the necessary support is available as soon as it is required. Good Pea sticks are the best supports for carrying the long growths of Sweet Peas, although many other devices may be employed.

At a later period the side shoots should be tied to the stakes, when they become long enough.

To prolong the flowering season the seed pods should not be permitted to remain, for they draw much of the energy of the plant, with the result that flowering rapidly finishes. When good growth is made it is advisable to afford the plants extra food, in the form of liquid manure; a light mulching of suitable material will also be of much benefit to the roots during dry weather, but, above all, give the plants plenty of water at the roots in hot summer weather.

Sweet Peas may also be planted in circular patches, and a good effect may be attained in this way in the herbaceous border, if it is sufficiently large to accommodate them, and requires additional furnishing; they may also be grown in a row at the back of a border devoted solely to annuals, making a pretty and effective background. *E. Beckett*

### CYMBIDIUMS AT WESTONBIRT.

RARELY has the horticultural world been so excited over a new race of garden plants as it has been this year over the beautiful-hybrid *Cymbidiums* raised at Westonbirt, Tetbury, Gloucestershire. Even as Orchids these splendid plants have deserved and received the keenest interest of specialists, but it is as long-lasting, graceful plants, of easy cultivation in a warm greenhouse, and of the highest value for the decoration of a warm conservatory and the drawing-room that this new race presents such wonderful possibilities. Hybrid *Cymbidiums* may be had in flower from December to May, commencing with *C. Doris*, a little before Christmas, and concluding with *C. Butterfly*, or a similar *C. Lowianum* hybrid, in May.

Sir Geo. Holford and his able Orchid grower, Mr. H. G. Alexander, commenced to raise hybrid *Cymbidiums* in 1907. The first hybrid from *Cymbidium insigne* was *C. Gottianum*, raised by Messrs. Sander, who used *C. eburneum* as the second parent. But only a few days after the flowering of *C. Gottianum*, *C. Alexanderi* flowered at Westonbirt, and this was the result of crossing *C. eburneum-Lowianum* with *C. insigne* Sanderi. Since then a large number of primary and secondary crosses have been effected at Westonbirt, with the result that six greenhouses are now filled with *Cymbidiums*, and on the occasion of a recent visit about one thousand spikes of flowers were to be seen. The famous group shown by Sir Geo. Holford at Vincent Square on the occasion of the R.H.S. meeting of February 28, was wonderful, but a visit to Westonbirt revealed the fact that "the half had not been told." Our visit was made on March 30, and consequently hundreds of spikes had already been cut; but, as indicating the longevity of the flowers of certain hybrid *Cymbidium*, blooms on one plant of *C. Doris*, which opened a few days before Christmas, 1921, were still in good condition. No fewer than thirty new *Cymbidiums* have been raised and named at Westonbirt, and the majority have been given the names of birds.

Very naturally the question may arise—If Sir Geo. Holford and Mr. Alexander commenced work on *Cymbidiums* in 1907, how is it that little has been heard of the results until 1922? The answer may be given in one word—War! However, during 1921 and 1922 one Gold Medal, one Silver-gilt Lindley Medal, five First-class Certificates, and seven Awards of Merit have been granted to the Westonbirt *Cymbidiums* by the R.H.S.; so the honours have been won in bulk instead of being spread over several years, as would have been the case had there been no war.

In all cases *Cymbidiums* have elegant, grassy foliage, which looks well at every season of the year. Cultural difficulties, such as many Orchids present, do not arise in connection with these hybrids; indeed, they are among the easiest of pot plants to cultivate and flower successfully. The hybrids show a considerable variation in colour and in the style of the inflorescence. Some, as in *C. Dryad*, have erect spikes, but the extreme end of the inflorescence is gracefully arched. In *C. Redstart*, arching spikes are produced, while in these hybrids which approximate most closely to their *C. Lowianum* parent, the spikes are semi-drooping rather than arching. But whatever the style, all are graceful, and whatever the colour of the flowers, all are beautiful. As cut flowers for floral decorations of all kinds *Cymbidiums* are extremely serviceable, often lasting from two to six weeks when placed in water. A plant in a 6-inch pot will produce one and often two spikes of bloom each year, and be an object of grace and beauty for two or three months—a record few other flowering plants could attain. One plant of *C. Pauwelsii* noticed had five spikes; it was in a 10-inch pot and carried an aggregate of 83 flowers. What plant could compare with such an example for grace, beauty, and its long period of usefulness?

*C. Alexanderi*, the first Westonbirt hybrid of this group, usually bears white-ground flowers, with a few reddish-purple markings on the lip, but some have a lemon-yellow tint, others have pink shading, and one form is notable for the prominent yellow crest on the lip. *C. Redstart*

(Dryad × Pauwelsii) is the most wonderfully varied of all the hybrids (Fig. 99), and it may have erect, semi-erect or arching spikes. Most of the varieties have lovely rose-pink flowers, with yellow disc and crimson markings; others are of a deep, old rose colour, which brings the yellow crest into greater prominence; and still others show in their colouring and in the markings on the lip the influence of *C. Lowianum*, which was one parent of *C. Pauwelsii*. *C. Martin* (*Lowio-grandiflorum* × *Parishii Sanderæ*), has drooping spikes, and shows the *C. Lowianum* characters in a marked degree, but the flowers are nearly all cream-coloured, often with a green tint, and with the red or crimson markings either as blotches, bars, or spots.

*C. Landrail* (*Dryad* × *Lowianum*) is a hybrid in which the yellow colouring has been developed considerably, but this shade is often suffused with pink. The yellow and crimson markings on the lip render the flowers of this variety conspicuous among all others. *C. Yellow Hammer* (*Gottianum* × *Lowianum*) has flowers of soft yellow or fawn shades of colour, and in many instances the lip shows the prominent horseshoe-shaped red-brown mark, which is such a conspicuous feature of *C. Lowianum*. *C. Kittiwake* (*Dryad* × *Gottianum*) has flowers of exceptionally good form (Fig. 99) with, usually, a white ground, although some have pink colouring, and in the latter the pencillings and dottings are

*C. Merlin*, the result of crossing *C. Dryad* with *C. Alexanderi*, has white or blush flowers, with deep violet-rose markings on the lip. *C. Cygnet* (*Pauwelsii* × *Parishii Sanderæ*) varies from pure white to deep rosy-purple, and the lip is usually blotched and barred with deep velvety crimson or crimson-purple; it is a strikingly beautiful hybrid. *C. Garnet* (*Lowianum* × *Parishii Sanderæ*) has pinkish-bronze flowers with vivid, velvety maroon mark at the apex of the lip.

Other hybrids not here described have been given the names of Pipet, Brownie, Jasper, Linnet, Eider, Ostrich, Widgeon, Bullfinch, Ringdove, Gannet, Petrel, and Cornerake; all these possess their own peculiar points of beauty and attraction.

Although *C. Pauwelsii* was first raised on the Continent, it has been re-raised at Westonbirt, where it is extensively cultivated. Most lovers of Orchids are familiar with its strong, arched spikes and its handsome flowers, all of which show the mark of *C. Lowianum* on the labellum. Thirty-five flowers were counted on one spike of *C. Pauwelsii* at Westonbirt, and one specimen carried six spikes, with an aggregate of one hundred and four flowers. *C. Gottianum* has also been re-raised at Westonbirt, where it produces on an average from three to seven flowers on each of its erect spikes; the big white flowers, with their yellow crest and red-brown markings are extremely beautiful.

ing chapter, "On Laying Our Flower Gardens," and one may ask the question: Might not the outburst of Loudon be caused by the unknown one treading on his toes? If Loudon was an advocate for the make-believe, natural style of gardens, one must own he did get rather a dressing down.

Anyhow, after Loudon's review had appeared another edition of the same work, *The Flower Garden*, appeared the very next year (1839), in which the objectionable part is replaced by a short "Floricultural Calendar" and both the frontispiece, the title, and the little bunch of flowers on the title page are all altered.

*The Flower Garden with selected lists of Annual, Biennial and Perennial Flowering Plants* has become "*The Flower Garden, its Cultivation, Arrangement and General Management*," and underneath is added, "A new edition carefully revised," and the date at the bottom of the page 1839. The only trace of revision is the very skillful alteration already mentioned, for after page 8, the two editions are exactly the same so far as I have compared them. I am wondering if Mr. Brotherton knows of these two editions, as he does not allude to them in his able summary of the contents of the work on p. 30. I wonder, too, if the binder has cut into the plates as much in his copy as he has in both of mine. From the identity of the covers

FIG. 99.—THREE NEW HYBRID CYMBIDIUMS RAISED AT WESTONBIRT. LEFT *C. KITTIWAKE*; CENTRE, *C. MIRANDA*; RIGHT, *C. REDSTART*. THE FLOWERS ARE REPRESENTED ABOUT TWO-THIRDS THE NATURAL SIZE.

reddish-brown or crimson. In *Wagtail* (*Parishii Sanderæ* × *Gottianum*) the long yellow crest or disc is a conspicuous feature of the narrow-lipped, white-ground flowers. *C. Curlew* (*Butterfly* × *Alexanderi*) has white or blush-coloured flowers, and in every case the lip is heavily marked, and has a prominent yellow crest.

*C. Dryad* (*insigne Sanderi* × *Parishii Sanderæ*) is one of the loveliest hybrids, and one which shows very little variation. It flowers very freely, and its spikes are carried erect until they arch towards the extreme end. One hundred spikes of this hybrid were counted, and few of these were less than 4 feet high. One plant carried four spikes and a total of forty-four flowers.

*Cymbidium Miranda* (*Lowio-grandiflorum* × *Alexanderi*), illustrated in Fig. 99, is one of the most variable of the hybrids, the colour ranging from pale cream to a deep bronze hue, as in the case of the variety named *Bronze Beauty*. It forms an excellent contrast to some of the lighter and brighter coloured hybrids. *C. Seaneu l'Ansonii* × *Parishii Sanderæ*) has large, purple-bronze coloured flowers, with crimson markings broken up on the buff or whitish lip. In *C. Thrush* (*Schlegelii* × *Holfordianum*) the flowers are pale coloured, sparingly spotted on the grandiflorum-like lip. *C. Warbler* (*Gottianum* × *Holfordianum*) is fairly constant, the flowers being a pale creamy green with a waved lip on which the yellow crest and markings are prominent.

This is not the first time that Westonbirt has achieved fame in connection with one particular family of flowers, but notwithstanding its high reputation in connection with Orchids in general, with trees and shrubs, with *Clivias*, and its wonderful collection of *Hippeastrums*, it is doubtful whether its owner has ever accomplished quite so great a success in horticulture as the raising of this splendid new race of hybrid *Cymbidiums*. *C.*

### "ORR'S FLOWER GARDEN."

I HEAD this note Orr's *Flower Garden*, although Orr is only the publisher and not the compiler. This is, I think, a more accurate word than author, for so much of the book is only, as we say, scissors and paste. For example, opening the book at random at page 284, which happens to be about Pinks, I read: "Hogg begins," "Paxton says," "Mr. Ibbett begins," "Mr. Revell and others consider it," and "Mr. Ibbett adds." which is not bad for one page. This characteristic of the work is mentioned because I cannot help thinking that Loudon's review in the 15th volume of his *Gardeners' Magazine* is a little unfair when he states that the compiler wrote in a "controversial, ill-natured spirit." The only controversial part in *The Flower Garden* is the open-

of the two editions, it would appear that the perpetrators of this barbarism were Orr's own binders, and to allow it to be done to Baxter prints!

I have one more comment to make on Loudon's review. He takes the compiler to task for not producing a better copy of Le Blond's original in the plan he has given of a French Parterre. I have compared them, both and I do not think there is much wrong with it if we take into consideration the necessary reduction in size. It would not be possible to show all the distinctions of the beds and the cut "greens" in their boxes in such a small space, any more than Loudon himself was able to say all that could have been said about a French garden in the few pages of original writing that he gave to *The Flower Garden*, and to Mr. Ferris's Parterre in his rather drastic reviews of these two works, which for a proper understanding of Loudon must be read together as they follow one another in the *Gardeners' Magazine*. Joseph Jacob.

**Salvia.**—Various kinds of *Salvias* should be potted on as they become ready. It is not wise to allow these plants to become pot-bound until in their final pots. They will be safe now in a cold frame where protection may be given when the weather is frosty. P.

## The Week's Work.

### THE ORCHID HOUSES.

By J. T. BARBER, Gardener to His Grace the Duke of Marlborough, K.G., Blenheim Palace, Woodstock, Oxon.

**Coelogyne cristata.**—I have recently had brought under my observation the hardness of this plant, and am thoroughly convinced that it will even withstand a much lower temperature whilst at rest than most growers realise. The plant to which I refer had passed the whole of the past winter in a house where there had been no fire heat whatever, and at the present time is pushing flower spikes, which show every signs of developing satisfactorily. Now is the best time to repot any overgrown specimens, or to break up those that may be in an unhealthy condition, remarking them up into smaller plants as desired. Unless repotting is absolutely necessary, do not disturb the roots in any way, but rather, if in good health, allow the plants to remain as they are, as they invariably suffer when disturbed. In repotting those that require it, use good fibrous loam, chopped Osmunda fibre, and Sphagnum-moss, in equal proportions, with plenty of drainage. The various materials should be used in a rough condition, according to the size of the pans used. Moderately deep pans form the best receptacles; cover the crocks with a thin layer of Sphagnum-moss to prevent the compost working down amongst them. Arrange the compost so that the centre of the plant is higher than the edges of the pan, and direct the young growths to the centre, pressing the compost moderately firm.

### THE FLOWER GARDEN.

By EDWIN BECKETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Hertfordshire.

**Hollies and other Evergreens.**—The present is a suitable time of the year for transplanting evergreens. When moving them take every care to maintain as good a ball of soil around the roots as possible. Showery weather should be selected, and the plants well mulched when placed in their new positions.

**Border Carnations and Pinks.**—Plants raised from layers rooted last autumn and wintered in frames may now be planted out. Carnations do best in ground that has been well worked and manured, and where a large area is devoted to their growing, they should be planted out in straight rows, allowing an alleyway between, say, every half-dozen rows, for convenience in getting at the plants to attend to them in tying, etc., and to assist the surface water to drain from the beds. Support the young plants as required by looping the growths to stout stakes, and when planted dust the soil with soot and apply a similar dressing occasionally in showery weather. Pinks should be planted in groups or colonies on the front of the flower borders in a little prepared compost, and will soon make good headway and form beautiful patches.

**Plants for the Water-side.**—Water gardening is increasingly popular, and many beautiful flowers may be planted along the banks of streams or sides of ponds and lakes. For floral beauty, Japanese Irises—the *Iris Kaempferi* group—should be included, whilst for early effect *Caltha palustris* and other varieties. The Marsh Marigolds, sometimes known as King Cups, have few to equal them with their wonderful golden flowers. *Myosotis palustris semperflorens*, the large-flowered water Forget-Me-Not has a quieter beauty, but is none the less effective. *Senecio Clivorum*, *S. Veitchii*, and *S. Ledebourii* comprise a fine group of golden-flowering plants suitable for growing by the water's edge, whilst pretty, pink-flowered *Lythrum*s, *Astilbes*, and *Funkias* are all worthy of a place. There are many other subjects deserving mention, including certain shrubs and trees, chief of which are the various Willows with their finely coloured barks,

so beautiful in the dull winter months. Alders, also, are most effective, whilst Bamboos for the most part revel in well-soaked ground on the swampy side, and thrive exceedingly well under such conditions.

**Annuals.**—About this period the sowing of various annuals should be undertaken, leaving any that are of a tender nature until, say, a week or fortnight's time. Virginian and Ten-week Stocks, *Ageratum*, *Candytuft*, *Dianthus*, *Eschscholzia*, Indian Pink, Marigold, Mignonette, Clarkias, Cornflowers, *Godetia*, *Nigella*, Scabious, and Sweet Sultan are all well worth growing, where space permits, and their wealth of colour and sweet perfume make them some of the delights of a well-kept garden. Seeds of annuals should always be sown thinly, and the seedlings thinned early, so that the plants are never crowded. Where space is available, a very beautiful effect may be obtained by reserving a border solely for annuals. With their varying heights and brilliant colours, such a border proves a source of wonder and pleasure, and by judicious successful sowings, the various items may have their seasons prolonged, besides providing big quantities of cut flowers for decorating vases indoors.

### PLANTS UNDER GLASS.

By T. PATEMAN, Gardener to Sir C. NALL-CAIN, Bart., The Node, Codicote, Welwyn, Hertfordshire.

**Grevillea robusta.**—Seedlings *Grevillea*s raised from seed sown in February, are ready for transferring to small pots filled with a rich compost, of an open texture. After potting the plants stand them in a moderately warm house until they are well established in the new soil, when they may be grown under cooler conditions. The plants will be found most useful for decorating purposes.

**Regal Pelargoniums.**—To be successful with these plants it is necessary to keep them free from Aphis by vaporising or spraying. Plants sprayed with *Quassia* extract occasionally will keep free from this pest. Good results follow feeding the plants with a concentrated fertiliser. Grow them in a light position until the bloom commences to open, when they should be shaded from bright sunshine.

**Hippeastrums.**—As these plants pass out of flower top dress them with rich soil, and place them in a house having a temperature of 65° to 70° to encourage them to develop healthy growth and thus build up the bulbs for next season's blooming. Much of next season's success with these plants will depend on the cultivation afforded at this stage. Later, the plants may be transferred to a house having a lower temperature, but they should be given a sunny position in order that the bulbs may ripen thoroughly.

**Euphorbia jacquiniæfolia.**—Stock plants of this *Euphorbia* that were introduced into heat, as advised in a previous calendar, are breaking freely. When the young shoots are about 3 inches in length they will be suitable for use as cuttings. The latter are best made with a heel of the old wood; immediately they are severed with a sharp knife they should be stood in powdered charcoal to prevent bleeding. The receptacles should be prepared in advance of the potting, in order that the cuttings may be inserted before they flag in the least degree. After they are potted place them at once in the propagating frame. If it is intended to grow them on as large specimens in 7-inch pots, insert three cuttings in a small pot; the plants may then be potted on without any unnecessary disturbance of the roots. I am not in favour of growing this beautiful plant in too large a pot; receptacles 6 inches in diameter are the largest size we use at The Node, while for the latest batch of cuttings 3½-inch pots are used. These latter plants are a useful size for table decoration. This plant delights in a stove temperature until well established in its flowering pot, when it may be grown in a little lower temperature. It requires careful watering at all times, but the roots should never be allowed to become excessively dry.

### FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

**Peach Trees in Borders.**—Attention should be given to trained trees in the early house; the fruits should be thinned to about 12 inches apart, according to the age and vigour of the trees. Tie the shoots to the trellis as they advance in growth, taking care that the stems are covered with foliage to afford them partial shade from the sun. Do not crowd the trees with young growths; 6 inches to 8 inches apart is not too much space for the young shoots. Stop the strong growths in order to regulate the flow of sap over the whole tree. If the weather is mild the temperature may range from 60° at night, and 75° to 80° at closing time with sunheat and moisture. For syringing use pure soft water, or water free from lime, as water containing lime leaves a deposit on the fruits. Twice a day is not too often to syringe; a little clear soot water syringed over the trees twice a week will impart a healthy hue to both fruit and foliage.

**Succession Houses.**—Attend to the disbudding and thinning of Peach trees in succession houses as they advance in growth. See that the roots do not suffer for want of water. Late houses containing trees in bloom should have a little fire-heat at night, with ventilation. During dull weather exclude currents of frosty air during the period of fertilisation, and keep a sharp watch for insect pests, which generally appear at this stage.

**Frame Melons.**—Now is a good time to commence the cultivation of Melons, either in heated pits, or frames heated with manure, or in frames without heat. Many amateur and some professional gardeners find it necessary to utilise fermenting material for forcing purposes, and as frame Melons cannot be produced in fewer than twelve to fifteen weeks from seed sowing, any one requiring more than one crop should employ fire-heat. From seeds sown now, good Melons should be forthcoming from the end of July to the end of September. The months devoted to their growth provide the heat so essential to success, with a minimum of labour. Assuming that fresh stable manure and leaves in equal parts have been turned two or three times, that beds large enough for the frames have been solidly built, and seeds sown singly in 3-inch pots the day the beds were made, the plants will be ready for planting by the time the excessive heat from the fermenting materials has subsided. Upon these beds small cones of soil may be placed 15 inches high, as Melons should be planted well above the line of watering. Perhaps a better method is the formation of a continuous ridge of compost, the same height, upon which the plants may be placed 18 inches apart, irrespective of the lights or rafters.

**Compost.**—The most suitable rooting compost for frame Melons is turfy loam of a calcareous and somewhat heavy nature, with old lime rubble or charcoal added, and a little soot. The soil should be mixed some time before it is wanted, and placed where it will become dry and warm, otherwise, when firmly packed in the ridge, heat will be a long time penetrating it. A little bone-meal may be added in preference to rotten manure, if the soil is poor, as manure encourages worms as well as gross growth, and, later, becomes sour when the fruits are swelling. Too light or too rich a compost fills a frame with rampant growth, and plenty of fruit will set; but, later, the plants almost invariably become barren, or go off under attacks of canker.

### THE KITCHEN GARDEN.

By JAMES E. HATHAWAY, Gardener to JOHN BRENNAN, Esq., Baldersby Park, Thirsk, Yorkshire.

**Onions.**—Seedling Onions in pots and boxes should be planted out on ground which has been well trenched and manured. Break up the surface, apply a good dressing of wood ash, rake the surface level, and plant the seedlings in rows made 15 inches apart, allowing 1 foot between each plant in the row. For convenience in

watering a 2 feet wide alley should be made at every twelfth row. The soil on the roots should be disturbed as little as possible, and the plant made very firm in the bed. Water the seedlings if the weather is dry, and syringe them two or three times daily. Strong plants are benefited by tying them to a small stake. Leeks raised indoors should also be planted out in trenches made similar to Celery trenches, in single rows, 1 foot apart.

**Cauliflowers.**—Plants raised from seed sown last autumn and wintered in frames should be planted out in rows made at a distance of 2 feet 6 inches apart and 2 feet between the plants in the rows. The robust variety Autumn Giant should be allowed 6 inches more each way. Those sown in boxes are also ready for planting out of doors. As much soil as possible should be retained at the roots. After setting out the plants water them overhead with a rose can.

**Lettuce.**—Seedling Lettuces raised in boxes should be planted out one foot apart in a sheltered part of the garden. A sowing of Lettuce should be made every fortnight to maintain a constant supply.

**Cabbage.**—Seedling Cabbages growing in boxes should be planted out of doors. The smaller varieties, such as April, should be planted in rows made 15 inches apart, and 12 inches asunder in the rows; larger growing varieties should be allowed 3 inches more space each way.

#### HARDY FRUIT GARDEN.

By H. MAREHAM, Gardener to the EARL OF STRAFFORD, Wrotham Park, Barnet.

**Wall Fruit Trees.**—Make a thorough examination of the roots of all wall fruit trees, especially those that have been in position for several years. If the soil is dry, which it may be after last year's long spell of drought, the roots should receive a thorough watering either with clear water or weak liquid manure. First point over the surface soil, and loosen it to allow the water to penetrate freely. If the weather should prove dry after the water has been applied the soil surface may be lightly stirred with a hoe or rake to prevent rapid evaporation; a suitable mulching will also prove useful in this respect. The borders of wall trees are apt to become hard and solid for some distance from the walls if once thoroughly dry, and a heavy rainfall is needed for moisture to penetrate deeply.

**Plums.**—Whether dessert or cooking varieties it is wise to grow only the best and most useful varieties of Plums, and endeavour to select those which will extend the season so far as possible. Grafting may be successfully accomplished during the present month, and should be practised on healthy trees that are not pleasing the grower. I strongly object to cutting back the branches too near the trunks in accordance with the practice frequently observed, but advise cutting back to branches not exceeding 2 or 3 inches in diameter. On these place one or two grafts. On these smaller shoots, not only will the union be more certain, but the fruiting heads will be more rapidly produced. A few good dessert varieties are Early Transparent, Oullin's Golden Gage, Saint, Jefferson's Gage, Transparent Gage (old), Late Transparent Gage, Washington Gage, Green Gage, Coe's Golden Drop, and Coe's Violet. Cooking Sorts: Victoria (equally good for dessert, jam and bottling), Pond's Seedling, Sultan, Gisborne, Cox's Emperor, Archduke, Prince of Wales and Monarch.
