**Old Plum Trees.**—Trees that are becoming unproductive may be greatly improved if good top dressings of fertile loam, manure, lime, and old brick mortar are applied over the root area. Heavy dressings of manure and lime during the summer growth, well washed down to the roots, will prove very beneficial to those trees that bear heavy crops, and all such trees should be given every attention at the right time, so as to assist them in maintaining sufficient vigour to crop the following season.

### THE BULB GARDEN.

#### NARCISSUS CYCLAMINEUS AT EDINBURGH BOTANIC GARDENS.

AMONG the comparatively limited number of outdoor flowers in bloom in the Edinburgh Royal Botanic Gardens, Edinburgh, in the first week of April were several pretty groups of *Narcissus cyclamineus*, mainly at the base of the rockwork, and close to and on the level of the path. They presented this interesting Daffodil at its best: sturdy, healthy-looking, and bright and well-displayed, against the deep-coloured rocks of which the rock garden is composed. Next to a setting of grass, in which *N. cyclamineus* is delightful, a background of dark rocks, such as those at Edinburgh, is about the best for displaying the golden yellow blooms of *N. cyclamineus*, with their long trumpets and reflexed outer segments. S. A.

We can imagine also that, given suitable soil, it would look well in the rock garden. So far, we believe, it has only been cultivated in Cornwall, therefore it remains to be seen whether this exquisite hybrid will thrive in the less pleasant conditions of the Midlands and the bleaker climate of northern counties. *Narcissus Silver Chimes* indicates a line of progress that might well be pursued further in connection with the raising of Daffodils, as at present raisers appear to direct most of their attention towards increasing the size and deepening the colour of trumpet varieties, and extending the season of the poeticus sorts.

#### TRITELEIA UNIFLORA.

THIS pretty, hardy, dwarf, bulbous plant is not commonly known or met with as frequently in gardens as its merits deserve, for when well grown its unique, pretty, mauve-coloured

FIG. 100.—NARCISSUS SILVER CHIMES. R.H.S. AWARD OF MERIT, APRIL 11. SHOWN BY MR. J. C. MARTIN, BOSVIGO GARDENS, TEURO

#### NARCISSUS SILVER CHIMES.

THE exquisite and altogether beautiful *Narcissus Silver Chimes* (see Fig. 100), shown so freely and finely by Mr. J. C. Martin at the meeting of the Royal Horticultural Society on the 11th inst., has the very great advantage of having a beautiful and appropriate name. Of sturdy growth, this result of crossing a form of *N. tazetta* with *N. triandrus* promises to become useful for cultivation in pots, for cutting, and for market use, and the hope has been expressed that it may increase with freedom without losing any of its robustness. The individual flowers are of excellent form, about 2 inches wide, with a white perianth in which the segments are just a trifle reflexed. The cup is rounded and of a light citron yellow colour. As from five to seven of these fragrant flowers are carried on one stem, it will be understood that *Silver Chimes* is a desirable *Narcissus* from the market point of view.

flowers, which are borne on slender stems, present a charming appearance. There is also a whitish form, but this is not nearly so pleasing.

*Triteleias* flourish best when planted on a warm sunny border or, better still, at the foot of a warm wall. Propagation is carried out by separating the bulbs and taking away the offsets, when the plants are at rest.

The most suitable soil for this plant is a light, sandy loam enriched with a little leaf-mould. The bulbs should be planted about three inches deep; when the foliage turns yellow the ground should be kept as dry as possible in order that the bulbs may ripen thoroughly; they will then produce much finer flowers and better foliage, which will repay for the slightly extra trouble entailed. When once established in a suitable position the plants will not fail to flower abundantly during April and May year after year. *Richard H. Crookford, Weston Park Gardens, Steepleage.*

**EDITORIAL NOTICE.**

**ADVERTISEMENTS** should be sent to the **PUBLISHER, 5, Tavistock Street, Covent Garden, W.C.2.**

**Special Notice to Correspondents.**—The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.

**Letters for Publication, as well as specimens of plants for naming, should be addressed to the EDITORS, 5, Tavistock Street, Covent Garden, London.** Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

**DONALD BEATON.**

**T**HIS one time well known gardener was also remarkable as an individual. He was born in the county of Ross in 1802, shortly previous to his father commencing business in Inverness-shire as a breeder and dealer in horses, in which he failed while the son was a boy at school, this episode altering his prospects for the future. He spoke no English till he attained the age of seventeen. The factor on Lord Lovat's estate of Beaulieu seems then to have taken an interest in the lad, taking him into his house and in due course sending him with his own boys to Inverness Academy, where the quarterly fee charged was five shillings! I have read somewhere that a Scottish boy at the period in question might secure a first-class education, equal to what would cost in England hundreds of pounds, for £10, so that there is nothing remarkable in the above charge. Beaton's academic career was prematurely terminated on account of an outburst of spleen or other equally disreputable scholastic effervescence on the occasion of an examination, and at the age of twenty he had to look out for something to do other than the leisurely life he anticipated in one of the professions.

Finally, Beaton found himself in Beaulieu Gardens, where for some time he was the butt of the other men, partly on account of his previous training and perhaps largely because of his awkwardness in handling tools. Like most young gardeners of that age, he took to field botany, and went a step beyond the others in studying plant physiology. At the age of 23 he commenced crossing plants, and I am not sure if he was not the first person who used "cross fertilisation" to indicate its difference from hybridisation. He left Scotland for good in 1831, the sea voyage to London occupying thirteen days, and he found work in Mackay's Clapton Nursery, Mr. Low, who shortly afterwards became proprietor, then being foreman, with whom he contracted a friendship of long standing. A few weeks only there, and he was appointed gardener to Mr. Gordon, Haffield, near Ledbury, a small estate interesting as having been the property of Jacob Tonson, the famous bookseller and publisher of the early eighteenth century, and where he cultivated vines on a slope and made his own wine from the Grapes. Master and servant had congenial tastes, and the young Highlander experimented on plants to his heart's content, consulted authorities from the former's bookshelves, and travelled at his expense wherever he chose in pursuit of knowledge in gardening. He commenced writing in 1835, and an interesting article on crossing Fuchsias sent to Loudon's *Gardeners' Magazine*, at once obtained for him Loudon's appreciation. An outstanding contribution to that periodical is a long review of Lindley's *Theory and Practice of Horticulture*, long regarded as a standard work. The best of his reviews, however, is that on Dean Herbert's *Amaryllidaceae*, a piece of work that placed Beaton in a foremost position. The last article he wrote for Loudon was in 1841, the cessation being due probably to some misunderstanding between the two. We find him writing in Paxton's *Magazine of Botany*, in 1836, of Orchids, but he does not seem to have contributed to the cheap magazines at all.

Following the death of Mr. Gordon, in 1838, Beaton engaged with Mr. Harris, Kingbury, originally a farm house, on the Edgware Road, where that gentleman erected greenhouses, Orchid houses, and stoves, and gardening was pursued regardless of expense. The whole of the plants were sold three years afterwards on the death of the proprietor, and this was said to be the first collection of plants put to the hammer by Stevens, of Covent Garden. Sir W. Middleton, of Shrubland Park, then engaged Beaton, and there he became famous as a flower gardener and raiser of bedding plants from seed, Geraniums especially, and of these the Nosegay section. He contributed in 1841 to an early number of *The Gardener's Chronicle*, and many of his experiments were noted from time to time in the pages of this journal. He left Shrubland Park in 1852, and settled in Surbiton, where he continued his experimental work among a variety of plants, but Geraniums always received the preference. There he designed and had erected some cottages, but the arrangements were not appreciated by the tenants.

In 1848 Mr. G. W. Johnson, author of a *History of Gardening* and other books devoted to gardening, instituted *The Cottage Gardener*, afterwards better known as *The Journal of Horticulture*, and in its fourth number Beaton appeared on its staff as writer on the Plant House department. On his retirement in 1852, he became reporter, and I think there can be no doubt that his contributions had a very important effect in raising that weekly to the high position it attained as an exponent of practical gardening. But Beaton was no reporter simply of gardening efforts. Anything that attracted his attention at shows was duly recorded; the most remarkable of these instances arose from the visit of the Emperor and Empress of the French, in company with the Queen and Prince Albert, to the Crystal Palace, on April 20, 1855. None of the Press reporters were able to get near the royalties, but Beaton, who spent five hours in examining the plants and exhibits, somehow found himself close to them, and thinking that his young readers would be as much gratified to read what he had to say of the royalties as the horticultural productions, he set down his observations. They are much too lengthy to copy, but these brief extracts will show their quality. Of the Empress he remarked, "You would call her handsome without being a showy woman. She was not the best nor the second best dressed lady there, but she evidently understood the art of wearing and carrying her dress properly. She swept round the Crystal Fountain late in the afternoon, just as if she had that moment been turned out of a mould." Then he described her dress, the colour of her hair, and the style of her coiffure. Of Napoleon he wrote, "There is not a single line in his face, nor a glance in the eye from which you could infer decision of character." His dress and general appearance are also detailed, and equally appropriate remarks on our own royalties. The wonder was great that the reporter of an obscure weekly should have been qualified and fortunate enough to give these descriptions, when the dailies had almost nothing to say. On the occasion of the great frost of 1854-5, when all but the hardiest vegetation was destroyed, Beaton's name also became prominent, and in this way. In an article in the previous autumn he forewarned gardeners to expect a long and severe winter, and prepare accordingly. Afterwards when requested to tell how he had been able to foresee so disastrous a period, he would not be drawn to say anything.

I have no information of his having produced anything in book form other than giving assistance in the production of Johnson's *Gardeners' Dictionary*, the nomenclature in which he was responsible for. He died of paralysis, October 26, 1863, the last article of his writing being published subsequently. It referred to the colour of cross fertilised Peas, and was an explanation to Mr. Charles Darwin, with whom he had a controversy regarding the value of Gaertner's theories and experiments.

As a writer Beaton was extremely profuse, evidently setting down his thoughts without any

effort at condensation, and with advancing years he became more long-winded. At the same time he was original; his observations on cultivation, cross fertilisation and other subjects being always worth attention. In his plain speaking one might almost think him harsh, but there was the saving grace of humour to mollify the sting. His reports were like no other, as this extract from one will show: "Cut Tulips were very numerous, but I do not happen to know one Tulip from another. I began and finished my Tulip fancy in May, 1852, at a show in Manchester, where four or seven hundred blooms were staged, and I think Mr. Mowbray, of the Botanic Garden there, and I had to pay 5s. each, or between us, to get to see them. When I reached Chatsworth next week, I told Mr. Paxton about our entrance fee, and he told me 'the greater fools, etc.'" And that is all he reported of Tulips! In an obituary notice, Dr. Hogg gave the highest estimate of his personal worth, and the only word of detraction I ever heard of him was that he was somewhat conceited. His writings, however, do not bear that out, for though they give the impression of the work of an opinionated individual, yet whenever he found he had committed a mistake, it was at the first opportunity admitted or corrected. R. P. Brotherston.

**MR. KINGDON WARD'S SIXTH EXPEDITION IN ASIA.**

NO. 13.—THE VALLEY OF BEAUTIFUL FLOWERS.

AFTER four days spent in the monastery at Yung-ning, on the edge of Chinese Tibet, we started for Mu-li, in the interior, and almost due north.

"Chinese Tibet" is not a good name for the Tibetan Marches, since the country is so little Chinese that the authorities cannot guarantee the traveller's safety once amongst the Mantzu, and indeed can scarcely protect themselves in such border regions as they hold; witness the sack of Chung-tien early in the present year. But the huge territory of which I speak is painted "China" on atlas maps, so let it stand.

I was warned against penetrating far into this wild region and promised to go no further than the chiefs would protect me; and on June 2 we set out. The first stage took us over a low, wooded range of hills, their southern slopes covered as usual with Pines and scrub Rhododendron; and we met with no plant that was not already familiar to us.

Descending the northern flank, however, we noticed many plants coming up in the woods—crimson *Androsace*, *Spiraea*, *Rodgersia*, *Arisaema*, and other large-leaved shade plants. It was here that *Primula lichiangensis* turned up. Next morning we reached a village at the foot of the main range, and, passing through a cultivated valley, began the long ascent of the divide, which parts the water flowing to the Litang river from that which flows more directly to the Yangtze.

In the lower part of the valley, which was well wooded, flowers familiar to us abounded for many days; but several small Orchids, new to me, were met with. A *Lonicera* already hung out its translucent red berries, and looked so pretty, decorated with hairy fruit as large as Gooseberries, that I collected seed; it must be a very early-flowering species.

As we got higher up into the woods, the valley contracting to a ravine, other flowers came into prominence. Masses of golden *Caltha* carpeted the open glades and a purple *Aquilegia* was common. More unusual was a charming pink Rose, deliciously scented, and a *Strobilanthes* in the dim, damp forest; for a minute I was reminded by this find of the North-East Frontier, but it was only a passing thought. That quartet of North-East Frontier plants—*Strobilanthes*, *Begonia*, *Chirita* and

\* The previous articles by Mr. Kingdon Ward were published in our issues of May 14, June 18, July 23, August 20, September 3, October 8, October 29, 1921; January 7, January 21, March 11, March 25, and April 8, 1922.

*Aeschynanthus* haunts me yet. However, it must be confessed that there are far more *Rhododendrons* on the North-East Frontier than there are in this country.

To resume. We camped in the evening high above the torrent on a steep grassy slope sulphur with *Roscoea*; all round was the Pine and Oak forest draped with lichen. High above were barren limestone crags. The woods were fringed with masses of bright yellow *Daphne calacola*, which formed wonderful patches of colour and scented the whole region. It grows both in the woods, where it forms a large bush, and on the open cliffs, where it is a dwarf shrub. I have never seen so many flowers to the cubic inch as this species displayed.

I decided to spend the next day in camp and see what the limestone towers had in store. Accordingly we set out next morning, and plunged straightway into the woods. Here the going was by no means so easy as it had looked from the outside, for there was an undergrowth of Bamboo we had not reckoned with. However, we got through to the ridge, and then began a steep climb, continually interrupted by sheer cliffs. A tiny *Campanula* looked interesting, but was not yet in bloom, and the same with a *Meconopsis* with prickly leaves, a *Lychnis* and an *Adenophora*. A speckled *Fritillaria* was, however, in flower and a snow white *Rhododendron* with little, trumpet-shaped flowers.

At last we reached the crags, and here flowers were more abundant—a lemon-yellow *Caragana* as prickly as a hedgehog, two *Primulas*, the fragrant *Daphne*, and a very fragrant purple flower, *Cardamine*. On the steep earth slopes *Androsace spinulifera* was in bloom, and there were many small *Cruciferae* on the cliffs, besides *Lloydia* and other items. However, the weather was so bad—slashing rain and thick mist—that it was not safe to be clambering about these limestone cliffs, so we returned to camp with the spoil. The results were by no means discouraging on this, the first day of serious plant hunting; we ran to earth some fifteen or twenty species, several of them suitable for cultivation.

On June 5 we continued our march northwards, passing at first through forest very similar to that met with in the A-tun-tzu region, but much poorer in deciduous-leaved species, and also in shrub undergrowth. The only big trees were *Picea* and *Oak*; amongst the shrub growth were *Potentilla fruticosa*, several species of *Lonicera*, *Berberis* and *Rosa*, and scattered species of *Deutzia*, *Ribes*, *Rhododendron* (*Azalea*), etc. Presently Bamboo undergrowth reappeared, and a beautiful, violet-flowered *Meconopsis*, with shimmering, satiny petals was met with on fallen limestone boulders in deep shade. This was evidently the plant met with in an adolescent condition on the previous day. Later we met with it all over the country, though July had come before it really opened out. Though we found it on the slate ranges it was much more partial to limestone, where it was as common as it was beautiful.

*Primula sonchifolia* turned up under the Bamboos—it was over, by the way—and a white-flowered *Thalictrum*. Then, as we continued to climb, the forest became entirely *Abies* with thickets of *Rhododendron*, and the flowers we had found the day before appeared in large numbers; *Androsace spinulifera*, purple *Morina*, violet *Nivalis*, *Primula*, and so on. Here, too, *Incarvillea grandiflora* coloured the slopes, with its vile magenta-purple. As a matter of fact, we found a few white-flowered specimens, which were much more pleasing.

Another species of *Incarvillea* grew here, a great gawky thing, some four feet high, with dull yellow flowers, no more beautiful than its rival. Yet it was a handsome plant in other respects, and might be turned into a fine garden plant if it could be induced to strike its colours in favour of something more pleasing.

A large shrub *Rhododendron* with lemon-yellow flowers in moderate-sized trusses was here much in evidence on the steep hillsides. It was of the *R. Wardii* type, with very regular, bell-shaped corollas. We found it in the woods on the other side of the divide in abundance, a very pretty sight, mixed with *Oak*, *Birch*, *Maple*, etc. *F. Kingdon Ward*.

## SPRING BEDDING SCHEMES.

The illustration reproduced in Fig. 101 shows several of the permanent, formal beds on the terrace at Aldenham House, Elstree, grouped around a small fountain and basin and furnished with spring bedding plants. Along the full length of the terrace on the north side, and parallel to the beds shown in the foreground, runs a long, narrow border, the counterpart to which can be seen in the illustration on the far side. The terrace lies to the east of the residence, at slightly higher level than the last-mentioned border, and contiguous to it is a long, wide grass belt, which passes along the southern side of the building. In this are cut four large oblong beds, the short sides of which curve slightly inwards, and these are separated from each other by circular beds. Two other small beds lie near by, at the foot of the wall of the house, whilst the long border first mentioned above also has an annexe, being divided therefrom by a flight of stone steps.

On the terrace itself are four circular beds

FIG. 101.—BEDS OF SPRING FLOWERS AT ALDENHAM HOUSE, ELSTREE.

filled with *Polyanthuses*, and the same subject is used in planting four shaped beds, the companion four to which are furnished with *Myosotis Royal Blue*. Two other circular beds are planted with *Wallflower Fire King*, a vivid orange-coloured variety, and two with *Wallflower Cloth of Gold*, bright yellow.

The long northern border is furnished solely with the fine deep red *Wallflower Blood Red*, whilst its counterpart on the south side of the terrace is planted with *Polyanthuses* only. The annexe is rather more elaborately planted with *Wallflower Eastern Queen*, apricot, changing to pink, for the main part, but for the front rows *Wallflower Ivory White* is used, and the bed, being much higher than the others, is edged with *Polyanthuses*.

The oblong beds on the grass belt are planted with *Polyanthuses* only, but the round ones are furnished with two kinds of plants—No. 1 with *Tulip Inglescombe Pink* bedded with *Aubrietia J. S. Baker*. No. 2 with *Tulip Inglescombe Yellow* and *White Arabis*, and No. 3 with *Tulip La Merville* (old rose-flushed buff), with *Aubrietia Perkinsii* as a groundwork. The two small pieces, close to the house are bedded with variegated *Arabis*, and planted in one case with *Tulip Picotee* (recurved petals of white, edged rose), and in the other with *Tulipa gesneriana spatulata* (bloom crimson, with bright blue base).

The planting of the beds for a spring display usually follows the finish of the summer-bedding period—i.e., about mid-October—and, once the work is completed, careful watch is kept as to the progress of growth, and, should any plants fail, they are made good so far as is possible. Also, after frosty spells, they are examined to see if the roots have been loosened in the soil, owing to the action of frost. Later, the soil is frequently stirred to assist growth, an operation that greatly benefits the plants. When once in flower, the whole scheme presents a delightful picture with a variety of beautiful colours.

The preparation for this work calls for skilled attention in the matter of raising the plants. The *Aubrietias* are obtained from cuttings inserted about July, or early in August, in well-drained pots of sandy compost, and struck in cold frames. The *Wallflower* seed is sown in shallow drills in cold frames, about the middle to the end of June, whilst the *Myosotis* is similarly sown about a fortnight later, and, when the seedlings of both are large enough, they are pricked out into beds until required. *Arabis* is generally lifted and

divided at the time the work commences, and put in the beds direct, the portions soon taking root.

Perhaps more attention is devoted to the raising of the *Polyanthuses*, of which we have a fine strain. During the flowering season very careful selection is made of the best of the plants—i.e., those showing good, free-flowering habit and beauty of flower and colour—and these are marked as seed parents, the others being destroyed later. When the seed on the chosen plants is ripe, the pods are gathered, and the ripening and drying completed under glass. This method of selection is responsible for the fine improvement that has been effected in the strain. The seed is sown in pots or boxes filled with a sandy compost, about the end of February or the beginning of March, germinated in cold frames, and the seedlings, when large enough, are pricked out into shady beds to grow on until wanted; the care devoted to them is amply repaid by their beauty.

At the end of the spring-bedding season, the *Tulips* are lifted and ripened carefully for storing. The *Aubrietias* and *Arabis* are transplanted to other quarters, whilst the *Polyanthuses* are lifted carefully and replanted as and where required, special care being taken with the best plants marked for seed purposes.

*E. Beckett*

## NOTES ON THE CONTROL OF NURSERY STOCK AGAINST CROWN-GALL.

It is generally acknowledged that the presence of the insidious tumours, known as Crown-gall, on young trees is undesirable, and although direct experimental evidence of the deleterious effect of the disease on nursery stock is at present lacking for this country, observations made by investigators in America show that the galls impair the general vigour of young trees, a result which is not unexpected when it is realised that the galls absorb a considerable amount of foodstuffs which would otherwise be utilised in building up normal healthy tissues. As badly galled nursery stock is unsaleable, it is to the interests of the nurserymen to produce trees as free from the disease as possible.

Certain types of "Paradise" (layered) Apple stocks grown at the Fruit Research Station, East Malling, prove to be very susceptible to Crown-gall, and provide excellent material for field observations and experiments. Observations on young trees as they were being lifted for transplanting showed that in the majority of cases the galls originated at obvious wounds; they were particularly noticeable at the basal end where the stock had been severed from the parent "stool." This fact suggested that methods which reduce to a minimum the areas of the injured surfaces would reduce gall formation, while careless handling which produced unnecessary wounding would induce ready development of galls. It also suggested the possibility of preventing infection of the injured surfaces by covering them with a protective layer of some antiseptic substance.

Field experiments are being carried out, therefore, at East Malling in order to obtain information respecting the factors which favour gall development, and to ascertain whether there is any practicable method of controlling gall formation on layered Apple stocks grown in infected soil. The experiments are still in progress, but a brief outline of results already obtained may be without interest.

The object of these experiments was to determine:—

(1) Whether cutting (with a clean cut) the stocks from the "stool" is preferable to tearing the stocks away with a rough "heel."

(2) Whether covering the cut surface with a protective layer before planting up the stocks reduced the number and size of the galls.

(3) Whether rough treatment at the time of planting increased gall production.

The stocks used in the experiments were removed from the stools as one-year-old rooted shoots, then subjected to the particular treatment, and planted in infected soil in March, 1920. They were left undisturbed until February, 1922, when they were lifted and the size and situation of the galls noted.

The results may be summarised as follows:—The galls occurring on the base of the stock were distinctly larger where the stocks had been roughly torn from the stools than where they had been smoothly cut with a knife; and on both these groups the galls were larger and more frequent than on stools cut with a knife where the wound had been covered before planting with either Stockholm tar or grafting wax. Of these two materials, Stockholm tar appeared to reduce the disease more than grafting wax; but it also appeared to injure the roots of the stocks to some extent, more of the stocks treated with it having died than those untreated, or treated with grafting wax. This may be attributed entirely to the fact that the types of stock used are often poorly rooted, and frequently have, when planted, no more than two or three roots close to the base of the stem. It seems probable that more freely rooted types of stock would have shown little if any injury.

A further experiment on the effect of injuries, such as bruising the bark and cutting the roots before planting, also gave a significant result. Stocks planted with their bark severely bruised showed after two years' growth a considerable proportion (nearly half) with galls on the main stem above the base; whilst similar stocks

injured as little as possible were very nearly free from such galls. Many of the cut roots gave rise to small galls at the cut end.

These preliminary results suggest that on "Paradise" Apple stocks:—

(1) Cutting the shoots with a knife gives rise to smaller galls than tearing them from the stool.

(2) Covering the cut surfaces at the base of the stocks with a protective layer, e.g., Stockholm tar or grafting wax, reduces the number and size of the basal galls.

(3) Galls on the stem above the base, and root-galls, may be largely prevented by careful handling and planting, so as to avoid unnecessary injuries. *H. Wornald, South-Eastern Agricultural College, Wye; and N. H. Grubb, East Malling Research Station.*

## MESEMBRYANTHEMUM AND SOME NEW GENERA SEPARATED FROM IT.

(Continued from page 151.)

Conophytum, N. E. Br.

VERY small succulent plants, stemless or developing stems with age, with several or numerous growths in a clump. Roots very short. Each growth formed of two leaves fused into one fleshy body, globose, obovate, ovoid, subcylindric or oblong in shape, convex, flat, depressed, notched or two-lobed at the top, with a small orifice resembling a closed mouth at the centre of the top or between the lobes. Flower solitary, growing up from the interior of the growth through the central orifice. Calyx with a distinct slender membranous tube above the ovary, 4-6-lobed at the top, more or less included in or partly or entirely exerted from the body of the growth. Corolla with a distinct slender tube as long as or longer than the calyx-tube; petals numerous or occasionally few, spreading or recurved, in one to several series, the inner series at the mouth of the tube sometimes much smaller than the others and differently coloured. Stamens few or many, erect, not collected into a column, included in the corolla-tube or partly exerted from it. Ovary flat or convex at the top, with a marginal, crenulate, glandular ring, 4-6-celled. Style long or short (rarely almost absent), with 4-6 filiform stigmas at its apex. Capsule small, 4-6-valved, 4-6-celled, with or without cell-wings covering the seeds.

The generic name is formed from the Greek words *konos*, a cone, and *phyton*, a plant, in allusion to the form of the growths, which in many species resemble an inverted cone in shape. I have adopted this name from Haworth's suggestion in his *Revisiones Plantarum Succulentarum*, p. 82, where, under his Section Minima, he writes, "If this section proves to be a genus the name *Conophytum* would be apt." But he does not himself actually propose to consider it generically distinct from *Mesembryanthemum*, as he does in the case of *Glottiphyllum* and *Gibbaeum*. Yet, as I consider that these plants are generically distinct from *Mesembryanthemum*, I have accepted his suggestion for a generic name for them by modifying it into the Latin form.

The plants included in this genus are all distinguishable at sight from *Mesembryanthemum* by their form, and technically by their calyx and corolla, each having a distinct tube, by the presence of a distinct style (in two or three species, however, this is almost absent), and by their peculiar mode of growth in both the seedling and adult stage, being, together with those of the genus *Lithops*, the only known plants that are almost alike in form in both the cotyledonary and adult stages, the only practical difference between the two stages being that of size, as I have described, and illustrated in the *Gardeners' Chronicle*, 1921, vol. LXX, p. 207, fig. LXXXIV., M-O, and p. 223, fig. 97.

A peculiarity of these plants is (as stated in vol. LXX, p. 290) that they have very short roots, rarely more than about an inch or an inch and a half long, and they often grow in a very

shallow layer of soil (from half an inch to one inch thick) that has accumulated upon the surface or in crevices of rocks. How they manage to exist in the dry, hot climate of South Africa in such situations is a mystery that cannot be solved in Europe.

The plants of this genus, together with those of the genus *Lithops*, are popularly known as the "Sphaeroid *Mesembryanthemums*," and of this group in the most recent monograph of the genus *Mesembryanthemum*, published by Berger in 1903, only 17 species are enumerated, of which he appears to have seen only six, yet at that date I had at least thirty species in cultivation. In the following enumeration 58 species are described, so that with the addition of the ten species of *Lithops* already described, the number of Sphaeroids at present known amounts to 68, and I have a few others that I expect to be new species that have not yet flowered. Over a hundred years ago Haworth (*Synopsis*, p. 236) records that he asked Masson (who introduced a vast number of these plants) if he had sent home all the species there were in South Africa, to which Masson replied, "No, nor half of them." And I very much doubt at this period if half the species of Sphaeroids have yet been discovered.

During my botanical career I have worked at a large number of genera of plants, and have generally been able to make some sort of a key to the species, but this genus *Conophytum* defies all my efforts, for there are so few characters to make use of that can be defined by words. These plants do not possess the evident parts that other plants have; no stem, no leaves, no angles, no stipules, no prickles or spines from which differentiating characters can be derived, only an obovate, globose, obovate or two-lobed fleshy mass and a flower. And as the size of the growths of the very same plant in different years under cultivation varies considerably, there is nothing but a difference in colour and markings, and perhaps a very slight difference in form by which to distinguish different closely allied species when out of flower, and these are not characters that can be clearly defined by words, and are sometimes variable. The flowers often differ likewise in small but constant characters that cannot be described, for colour cannot always be relied upon to separate allied species, since different plants of the same species may vary from white to rosy in the colour of their flowers. Haworth and others have thought that the exertion of the ovary from the body of the growth or its inclusion within it is a good specific character, but I find that the exertion or inclusion of the ovary and calyx-tube varies in different years upon the very same plant, so that it cannot be implicitly relied upon. Therefore, only good coloured drawings with dissections accompanying the descriptions can really enable anyone to correctly discriminate between the closely allied species of this genus, and such illustrations I have been for some years preparing for a future work. Meanwhile, I have done the best I can to classify the species by grouping them in accordance with the character of their surface, form and markings.

There is one point that it is very important to note, and that is the difference in size and appearance between newly imported plants and those very same plants after being in cultivation a few years. The behaviour of different species in this respect varies, however; some do not alter at all, while others alter greatly. For example, the growths of the beautiful little *C. minusculum* are no larger to-day, after 13 years' cultivation, than they were when first sent to Kew in 1903, while the growths of *C. globosum*, when introduced at Kew, were about half an inch in diameter, yet a portion of the plant given to myself developed in two years growths 1-1½ inch in diameter, and in subsequent years varied from ¾-1¼ inch in diameter, a size that it probably never attains in nature. The most remarkable change that I have noticed has been in the case of the very distinct *C. pilosulum*, which has altered its form from obovately obovate to an elongated ovoid shape, pointed at the top. *N. E. Brown.*

(To be continued.)

## THE TREE BOX AT BOXHILL.

THOSE who are interested in our rarer native trees and their timber should pay a visit to Boxhill, in Surrey, which is distant from London about twenty miles. Though this is the only place in Britain where the Box is found in a truly wild state, yet in several other parts of England, and in a few stations in Ireland, this so-called shrub grows in considerable quantity, and has attained to quite tree-like dimensions, some of the tallest specimens exceeding thirty feet in height.

Perhaps the largest and finest of the Boxhill trees are to be seen close to the main road, bordering the private grounds of the Burford Bridge Hotel, and in company with the Yew, Beech and other trees and shrubs that favour a chalky formation. Here the average height of the Box is 35 feet, and the clean, smooth-barked trunks are from six inches to eight inches in diameter at breast high, though one unusually large specimen that was measured had a diameter of 25 inches. Some of the stems have assumed a curious, flattened shape, probably owing to their being top heavy and bent over, several, though 18 inches wide, being only three inches thick.

Though all the trees are of somewhat small diameter, yet the stem thickness is carried well upwards, the girth at 20 feet being, in some cases, little less than near ground level. On other parts of the hill the Box is of much smaller dimensions, being found of all heights from a few feet up to the full-grown tree. Not a few of the trees have assumed a semi-procumbent mode of growth, which is largely owing to overcrowding and consequent hending of the stems; indeed, the whole plantation would be improved by careful thinning and pruning, especially towards the lower fringes of the woodland.

Such thinning, if judiciously carried out, would not interfere in the least with the natural appearance of the wood as a whole, but add greatly to the health and value of the remaining specimens. The timber produced here is of excellent quality, and it is recorded that in 1815 the sale of Box-wood from this plantation exceeded £10,000.

Later sales of Box-wood in this country were those on Lord Gladstone's Dane End estate, in 1917, and about the same time twenty tons were offered for sale in Ireland. Small quantities have also been sold in Kent and Sussex.

Box-wood is of a pleasing, delicate yellow colour, hard, dense and compact, and one of the heaviest of our home-grown timbers, a cubic foot weighing fully 80 lb. It is the best timber that has been discovered for wood engraver's blocks, while in the making of mathematical instruments it is largely employed. For thermometer scales, gauging rods, foot-rules, and wherever figures have to be cut on wood, Box timber has no rival, as it cuts smooth and evenly, without splitting or tearing, and every line is clear and perfect.

For the manufacture of shuttles Box-wood was also at one time mainly in use, but the falling off in supplies led a Liverpool firm to try several substitutes, the most successful being that of the Cornel and Persimmon. The timber of the Phillyrea has, likewise, been employed as a substitute for Box-wood. The Box has a somewhat restricted range in southern Europe and Asia Minor, and the finest timber is sent from the Black Sea forests and Caspian shores. West Indian Box-wood is, in many respects, similar to Turkish, and to some extent satisfies the manufacturer of carpenter's rules and like articles.

It is probable that the Boxhill trees were in the past of larger dimensions than is at present the case, and it was provided in a lease of the land, dated August 25, 1602, that the tenant should use his best endeavours for preserving the Yew, Box, and all other trees growing thereupon; as also to deliver, half-yearly, an account of what had been sold, to whom, and at what price. The Box trees cut down in 1603 when the sheep walk on this hill realised £50. *A. D. Webster.*

## CHINESE SHRUBS AT ALDENHAM.

(Continued from page 179.)

*PHOTINIA DAVIDSONIAE* promises to be a most useful evergreen, as it is perfectly hardy at Aldenham. A handsome specimen there is now 7 feet high, and nearly as much in width. The young shoots are quite red, and offer a fine contrast to the glossy green foliage. Wilson states that the fruits are orange red, and describes the plant as one of the handsomest evergreens in China. The Aldenham specimen—of which an illustration is given in Fig. 102—has not yet fruited.

*SYCOPSIS SINENSIS* is an interesting evergreen member of the Wych Hazel family, which also flowers during the winter. The most conspicuous parts of the flowers are the yellow stamens. The species bear neat, dark foliage, and makes an attractive shrub or small tree. A

been previously introduced from India in 1881. In severe winters the plant is liable to suffer from damage by frost at Aldenham. *V. dasyanthum* forms a deciduous shrub with long, dark green, tapering leaves and corymbs of white flowers. The large, red fruits are showy. *V. Davidii* is a distinct, low-growing evergreen, having blue fruits, which make a pleasing contrast to the dark-green foliage. *V. Henryi* is particularly fine when in fruit. The berries are produced in pyramidal panicles, and are red at first, changing to black. The species is evergreen, and makes an upright bush from six to eight feet tall. *Viburnum ovalifolium*, a fine, deciduous species, has made a shapely bush seven feet high. Those who have seen it in autumn assure me of the beautiful show made by its bright red fruit. *V. propinquum* is a neat-growing evergreen bearing blue-black fruits. In winter the dark green leaves contrast well with the red leaf stalks.

*V. rhytidophyllum*, which is now fairly com-

FIG. 102.—*PHOTINIA DAVIDSONIAE*.

good specimen at Aldenham is seven feet high.

*SYRINGA*.—The new Lilacs include *Syringa Komarowii* with deep, rosy-pink flowers; *S. reflexa*, which has a long, pendulous inflorescence of carmine-red flowers, that are most attractive before they are expanded; and *S. Wilsonii*, which has made a fine bush ten feet high, bearing white flowers tinged with lilac.

*VIBURNUM*.—The various Chinese plant-collecting expeditions have contributed a large number of *Viburnums*, many of which have proved totally distinct from the kinds hitherto known. Both the evergreen and deciduous species contribute to our gardens some very handsome shrubs, the most noteworthy of which are the following:—*V. buddleifolium*, a deciduous shrub, with long, narrow foliage, covered on the underside with white down. It forms a well shaped bush, about six feet high, and has black fruit.

*Viburnum cylindricum* (syn. *V. coriaceum*), is a strong-growing evergreen, the Aldenham specimen being nine feet in height and the same in diameter. It has large, dull green foliage, with a waxy surface, which is most plainly seen when the leaves are rubbed. The white flowers, produced in midsummer, are succeeded by black fruits. This plant was raised from Wilson's seed, being introduced by him from W. Hupch in 1907, but the species had

mon in gardens, often develops into a fine bush, ten feet high, and is one of the most distinct and best known of the new evergreen *Viburnums*. The leaves, some six or seven inches long, are dark green above and covered with a dense tomentum on the under-surface. The flowers are not conspicuous, but the red fruits, produced in large trusses in September, are very handsome. Unfortunately it cannot be counted upon to fruit regularly with any profusion; probably if the plants were massed instead of being isolated this defect would be remedied. All who saw them in mass in the Coombe Wood Nursery were impressed with the brilliant display of fruit. *V. theiferum* forms a distinct, erect-growing shrub with fine foliage, six inches long, two and one-half inches wide, and dark green in colour. It has large egg-shaped, red fruits. *V. utile* is a pleasing evergreen of somewhat slender growth; a good specimen at Aldenham is six feet high. The dark green foliage is covered on the underside with a dense white down; the blue-black fruits are attractive. *V. Veitchii* in general resembles the common *V. Lantana*, and is one of the finest of all in fruit, which is red at first, changing to black. It has proved particularly good at Aldenham when trained as a standard. *A. E. Thatcher.*

(To be concluded.)

## ORCHID MYCORRHIZA.

(Concluded from page 183.)

THE method of extracting the fungus from the root calls for a certain amount of skill. Perhaps the greatest difficulty, however is met with in ascertaining whether the desired fungus has really been extracted, and not the fungus of one of the numerous saprophytic or even parasitic fungi present in the houses. To sow seeds on these would be worse than useless as, unless a seedling has got to the rooting stage, such fungi as *Penicillium* will kill off even well germinated seeds. The characteristics are well shown in Fig. 103. Sclerotia, small hard masses about the size of a pin's head, are formed in some cases, in others these are absent—but the swollen chains of "spores" are always seen on the glass of the containing vessel; it is from the massing of these that the sclerotia arise. Sections of seeds which have been sown on the requisite fungus (Fig. 104) show after a week or so that the fungus has entered through the suspensor end and passed into the larger cells. These are invaded by degrees, the hyphae becoming twisted into a ball in each cell before passing on to the next. Almost immediately the smaller cells at the opposite end of the seed undergo division. Here the meristem of the stem is laid down. The fungus never enters these cells; in fact, the only cells capable of division which ever harbour the endophyte appear to be those of the seed where it first enters. Eventually the developing seedling takes on a swollen shape being most frequently more or less tubinate. Bernard called this swollen tubercle a protocorm from its similarity to the protocorm in Lycopods. The fungus remains restricted to the larger cells—and follows in the wake of their division.

FIG. 103.—FUNGUS ISOLATED FROM ODONTOGLOSSUM ROOTS AND BEGINNING TO FORM SCLEROTIA.

Meanwhile, the rapid division taking place in the smaller cells at the anterior end of the seed gives rise to the young stem and the first leaf (cotyledon). About the time this young leaf becomes visible to the naked eye the cell division has extended along the axis and the beginning of the central stele is seen (Fig. 105). In this manner the young root is formed and begins to absorb its way through the tissues of the protocorm. Finally it passes into the soil. It is a remarkable fact that apparently in none of the cultivated Orchids does the developing root when passing through the tissues enter the fungal zone, nor do the hyphae of the fungus pass into the root. When the root enters the soil, therefore, it is absolutely free from infection: in none of the usually cultivated Orchids does the root obtain its fungus from the swollen protocorm. Infection takes place from the soil most frequently when the root is about a quarter of an inch in length, the hyphae entering the root hairs a little behind the region of greatest growth. It is somewhat unexpected to find that the root is infected in this way and not by the fungus already in the plant, but a somewhat similar state of affairs is again encountered in Orchids with tubers which do not retain

their roots; tubers never harbour the endophyte and the new roots receive their fungus from the soil. Only in one Orchid so far studied, the saprophytic *Neottia*, does constant infection obtain. Here, according to Bernard, the fungus progresses gradually from the widely infected protocorm into the body of the plant, gains the rhizome and infects successive roots; the region of infection is continuous throughout the plant.

What has happened meanwhile to the fungus? Bernard pointed out that after a fungal hypha has passed through the suspensor end of the seed, entrance is forbidden to any other hyphae. There appears to be an attraction, though feeble, towards the place of entry. When a "wrong" fungus is used it may proceed in a more or less straight line and invade the whole of the seed, but in successful germination, the fungus, after seed entry, follows the development of the cells and forms mycelial balls in all the posterior portion of the seedling. According to Bernard, when the fungus reaches the cells bordering on the meristematic region, digestion takes place. This is regarded as being analogous to phagocytosis, such as occurs in animals, where the white corpuscles of the blood attack, engulf

FIG. 104.—SECTION OF AN ODONTOGLOSSUM SEED NINE DAYS AFTER IT WAS SOWN ON A FUNGUS CULTURE. THE MYCORRHIZA HAS ENTERED THE LARGER CELLS AT THE POSTERIOR END.

and digest any invading micro-organisms; the cells in which digestion takes place are the phagocytes.

The same phenomenon is seen in roots. Many observers hold that here the cells containing the fungus may be divided into two kinds, those in which the fungus is digested and those in which the fungus is allowed to thrive and continue until its liberation from the plant to invade other roots. Bernard, likewise considered, that whereas eventually the more deeply lying cells of the protocorm absorb the fungus the cells of the external layers act as host cells. This is an attractive theory, but hardly more. There can be no doubt that the fungal hyphae are disorganised in the cells of the developing seedling, but all the cells containing the fungus appear to act in this way. It is also noteworthy that host cells seem absent from the roots in most cultivated Orchids.

The question arises as to how far it is possible to replace the action of the fungus in bringing about germination by making use of chemical stimulation. Bernard concluded from a consideration of the way in which the endophyte can act at a distance, that is, bring about changes in cells to which it has not access, that there is a general modification of the physico-chemical properties of the sap which can reach all the tissues. He tried the effect of solutions of salep and saccharose in increasing concentrations on seeds of *Bletilla*, *Cattleya* and *Laelia*. Seeds of *Bletilla*, as seen above, germinate under ordinary conditions with the formation of slender seedlings, whereas in high concentrations the seedlings show thickened protocorms and short internodes comparable with seedlings infected with the fungus. The seeds of *Cattleya* and *Laelia* at low con-

centrations of the medium swell and become green. With higher concentrations development is much slower than when the fungus is present, but seedlings of quite normal appearance can be obtained. Thus it appears that augmentation of the culture medium can, in certain cases, supply the place of fungus action. In fact, Bernard states that under the conditions of his experiments it was more certain and easier to germinate certain seeds by the action of concentrated solutions than to have recourse to fungal infection. Germination was slow, but very regular, the protocorms had a normal appearance and the seedlings when fairly developed could be transplanted.

These results are of great theoretical importance as suggesting the manner in which the fungus acts. There are interesting similarities to experimental parthenogenesis in invertebrates, and the activation necessary for the germination of the spores of certain cryptogams. Very recently Knudson (*Botanical Gazette*, 1922, p. 1), has suggested that the fungal stimulation is somewhat of a myth, or at least that it has not yet been conclusively proved, the fungus only being necessary under the conditions of pure culture employed by Bernard and Burgeff. His experiments were, however, conducted with *Cattleya*, *Laelia* and *Epidendrum* (!) where the phenomenon of chemical stimulation is already well known and where, moreover, it is often rather difficult to find fungi in the roots of

FIG. 105.—LONGITUDINAL SECTION OF ODONTOGLOSSUM SEEDLING SHOWING THE STEM GROWING POINT AND THE BEGINNING OF THE FORMATION OF THE VASCULAR STRANDS. MOST OF THE FUNGUS IN THE TISSUE IS DIGESTED.

cultivated plants. He shows that sugars are apparently the necessary chemicals, fructose being more favourable than glucose. It is probable that the work of the fungus is to introduce carbohydrates into the seed, but so far as I am aware, no one has yet succeeded in chemically stimulating the seeds of *Odontoglossum* and similar plants. It is with these that the late Mr. Joseph Charlesworth, of Haywards Heath, had as uniform a success as is possible. Usually in one of the culture flasks as many seeds germinate as can find room, germination even taking place on the sides of the flasks. No one who has seen such a culture flask, the transplanted seedlings, the growing and then flowering plants, can doubt for a moment that the natural type of germination is occurring; and further, no one with experience of fungi would imagine that they could be harnessed under such conditions unless it was their natural mode of life. When the appropriate fungus is obtained and the ordinary methods of Orchid culture are grafted on to the laboratory methods, the numerically insignificant results obtained in the epoch-making test tubes of Noel Bernard become the millions of seedlings appearing like a green sward in the houses of Messrs. Charlesworth and Co. *J. Ramsbottom.*

## THOMAS AND EW KNIGHT AS A POMOLOGIST.

THE recent decision of the Council of the R.H.S. to award the Knightian medal to exhibits of vegetables, and the Hogg medal to fruits, must not be taken to infer Knight was not so great a pomologist as Hogg, for he raised numerous varieties of fruits, but, unlike Hogg, his activities were not restricted to pomology, but extended to all branches of gardening, and the vegetables he raised marked a great improvement on those of his time. The name of Thomas Andrew Knight, squire of Downton Castle and owner of land around Tillington, will always occupy a high place in horticulture, if only for the reason that he was one of the founders of the Royal Horticultural Society, and one of its most brilliant presidents. Some of the work which Knight accomplished in fruit-raising may be gathered from the following interesting notes contributed to us by *Pomona*, but a fuller list is given in *Gard. Chron.*, Feb. 10, 1877, p. 170:—

Mr. Knight gave much thought and attention to the raising of Apples, Pears, Cherries and Strawberries, obtaining many choice varieties that are still in cultivation, although a century has elapsed since the work began.

Lord Scudamere, of Holme Lacy, whilst Ambassador at the Court of France in Charles I.'s time, is said to have collected in Normandy cuttings or grafts of cider Apples, which he afterwards had grafted and planted in Herefordshire. Mr. Knight followed somewhat on the same plan, and to-day the selected seedlings of his raising may be found in the orchards that once belonged to him. Among these, are the Tillington Seedling, an Apple of Pearmain shape, of beautiful colour, a fair cropper, and very good quality. The tree is not a strong grower on the Crab stock, but is robust on the Paradise stock. The season of this variety is November to January. Wormesley Pippin, named from Wormesley Grange, a country seat where Mr. Knight once resided, is a fruit of medium size; the stalk is long; the skin pale green with brown next to the sun; the flesh white, crisp, with a rich vinous juice. Red and Yellow Ingestre varieties are twin productions raised from seeds of the same fruit, the parents being Orange Pippin crossed with Golden Pippin. This is a fine instance of the value of crossing, and had Knight achieved no other triumph of his skill and patient industry, this result would have been sufficient to hand down his name with honour to posterity. Bringewood Pippin, a variety he raised by crossing Golden Harvey with the pollen of Golden Pippin, is a nearly globular fruit of middle size with short stalk and bright gold coloured skin, dotted with white specks and russety next to the sun. The flesh is firm, crisp, juicy, sweet and highly perfumed. The season is November to April. Downton Pippin, originated with Mr. Knight, who crossed Orange Pippin with the pollen of Golden Pippin, this latter variety being a favourite for hybridisation purposes; Mr. Knight's aim was to raise a variety as near the colour and shape of an Orange as possible, and probably to ensure a prolonged season. The fruit of Downton Pippin is larger than that of its parents, the skin is yellow and covered with numerous specks; the flesh is yellowish. It is a very excellent Apple, and the tree a good bearer.

Mr. Knight also raised Strawberry Elton, a valuable late variety; Nectarine Downton, a fruit of luscious quality; Pear Knight's Monarch, and Cherries Waterloo, Knight's Elton, Black Eagle and Early Black, all of which are excellent varieties, still in cultivation.

## FRUIT REGISTER.

### APPLE WINTER QUOINING.

This variety is synonymous with Winter Queening, Winter Quinin, and Calleville d'Angleterre. The flesh is greenish-yellow, tender, soft, sugary, rich and aromatic. Several large trees of this useful Apple may be found in some districts of Herefordshire.

Early in the season the colour does not "take the eye," for the skin is pale green, covered with stripes of deep red and marked on the shaded side with a thin coat of russet. The eye is small and closed, and set in a narrow angular cavity. The stalk is slender, half an inch long, and inserted in a narrow angular cavity. At this season of the year it is a dessert Apple of merit. *Pomona*.

### APPLE LAXTON'S PEARMAIN.

This excellent dessert Apple (see Fig. 106), received the R.H.S. Award of Merit on January 31 last when shown by the raisers, Messrs. Laxton Bros., of Bedford. It is a seedling raised from Wyken crossed with Cox's Orange Pippin, and another interesting case similar to the one referred to by *Pomona* in his article on this page dealing with Apples raised by Thomas Andrew Knight. A second pip from the same fruit gave a variety of first-class merit, Laxton's Superb, which also obtained the R.H.S. Award of Merit. Laxton's Pearmain greatly resembles Cox's Orange Pippin in appearance, but is of duller red, and has a longer stem; the eye, however, is almost identical with that of Cox's Orange Pippin. The quality of this late Apple is excellent, but it is somewhat past its best at the end of January, being in its

agencies at work. I use three or four rabbits' tails tied neatly on to fairly long cane, so that all branches may be easily reached. With this, when the pollen is dry and free, I brush carefully over the anthers until the brush is covered with pollen, and when this is the case, another variety is treated. Stigmas are touched, and cross pollination effected. If this method were adopted generally, I am sure more fruit would set, thus proving that bad weather is not wholly responsible for poor crops.

I notice Mr. A. N. Rawes states that Coe's Golden Drop pollinated with Jefferson did not set, neither did President pollinated from Late Orange, which shows that incompatibility must be taken into account. In general practice it seems desirable to cross pollinate with varieties which produce an abundance of pollen. *R. H. Crockford, Weston Park Gardens, Stevenage.*

## VEGETABLES.

### CELERIAC.

I HAVE often wondered why Celeriac or, as it is called here in Sweden, "roots Celery," is not more cultivated in England, as it is very easily grown. Seed should be sown in March in boxes

FIG. 106.—APPLE LAXTON'S PEARMAIN.

finest condition about Christmas. The tree is said to be of very vigorous growth, upright in habit, and very prolific in cropping.

## HARDY FRUIT GARDEN.

### SELF-STERILITY IN PLUMS.

Plum blossom will soon be opening, hence a reminder that certain varieties of Plums are self sterile may be opportune. Those who have read in the R.H.S. *Journal* issued last May, the account of the tests carried out among Plums at Wisley during 1919, will understand how greatly gardeners are indebted to the director and staff at Wisley for the most valuable information given.

Three varieties of Plums proved self fertile, and these were Denniston's Superb Gage, Monarch and Czar. Varieties partly self fertile are Early Rivers, President and Prince Engbert, and those self sterile are Coe's Golden Drop, Decaisne, Grand Duke, Jefferson, Kike's Blue, Late Orange, Transparent Gage, Pond's Seedling, Comte d'Althaus's Gage, and Washington. As most Plum blossom is fully open within a period of two weeks, I advise cross pollination, especially should the weather prove dull and cold, with few bees and other pollenising

or in a warm frame, and the seedlings pricked out later in frames, if possible with warm manure underneath; in fact, the same culture as is applied to Celery should be adopted until May, when the plants should be ready to plant out in the open. Choose a piece of land that has been manured for a previous crop, or dig in well-rotted cow manure. Twelve inches between the rows and seven inches between the plants is a very good distance to plant. During dry weather Celeriac should receive copious supplies of water at the roots and be kept free from weeds. Liquid manure should be supplied when the roots begin to swell. In September it is a good plan to begin to take away some of the leaves; here we take away all the lower leaves first, and three weeks later strip off most of those remaining, leaving only two or three in the centre. This removal of leaves greatly assists the roots to swell and become a better shape, and if done carefully saves a lot of work when the time comes to lift the roots.

The best place in which to store Celeriac in the winter is a cold frame, setting the roots closely together in soil or sand. Here they will keep quite fresh and plump until spring. I have seen "roots Celery" in England quite dry and almost wizened in winter, and, of course, under these conditions the vegetable

loses its flavour, as well as its commercial value, especially if sold by weight, as is often the case in Sweden.

I presume the reason that this useful and easily grown vegetable is not so much used in England as on the Continent is that more Celery is grown in Great Britain. From a commercial point of view Celeric is much cheaper to cultivate than Celery, and it may be used for many purposes in the kitchen instead of Celery. I have sold roots of Celeric here at from three-pence to sixpence or more each, which I consider is a good return for the labour and room allowed them. I am not sure that there is a great demand in England, but I well remember a greengrocer in a fairly large way of business telling me twelve years ago it was a pity more of this vegetable could not be grown at home, as supplies were mostly imported from the Continent. *James Page, Adelsnäs Trädgård, Atvidaberg, Sweden.*

## HOME CORRESPONDENCE.

[The Editors do not hold themselves responsible for the opinions expressed by correspondents.]

**Do Plants Know Time?** (see pp. 31, 47, 95, 118, 158, 172).—It is only necessary for me to reply to the questions asked by Mark Mills, seeing that the subject is much more widely discussed on pp. 175 and 189. I did not state nor infer that all flowers were made to open by anthocyanin and the rays of the sun. Indeed, I stated that a good explanation could be given in some cases, and that other movements were connected with night-flying insects and heredity. Every movement of plants has to be judged on its own merits. The closing movements of the flower heads of *Tragopogon pratensis* are not due to the heat of the sun, for the heads close before the maximum temperature has been reached. The closing is autonomous and hereditary. The bracts of the heads close and press the receptive stigmas of the older florets against the pollen of the younger ones, and thus effect cross-fertilisation. That is the object of the closing. *J. F.*

**Thompson's "Gardeners' Assistant."**—In answer to *Quez*, the prices given apply when sets are out of print. "Recent," in my notes, should have been "older," as the early issues of the enlarged book are the more valuable. There have been a number of editions issued at various times, including several of the one-volume work, which, by the way, is not much wanted now and worth very little to collectors. *A Book Collector.*

**Musa Cavendishii.**—I was interested in reading Mr. Snell's and Mr. Hill's notes on Banana growing in the *Gard. Chron.* of March 25. It causes me to wonder whether Bananas are grown as much in private gardens as they were, say, twenty-five to fifty years ago by the old school of gardeners. When at Wimbledon House fifty years ago Sir H. Peck's gardener, Mr. James Ollerhead, grew bunches averaging 100 to 112 pounds, and continued producing them annually up to 1895; the bunches had to be supported from the rafters by chains. The Banana house was about 24 feet long and 20 feet high in the centre. The bed was 5 feet wide, divided by a brick wall, which made two borders 2 feet wide and 2 feet deep; the borders or beds were filled up with good Banstead loam with plenty of  $\frac{1}{2}$ -inch bone added. There was ample piping for providing bottom heat, also plenty for maintaining a warm temperature in the house. Mr. Ollerhead also grew a smaller variety in the Aquatic House, in tubs, which carried bunches of 20 to 30 pounds weight. When I read of 36-pound bunches, it occurs to me that modern gardeners have much to learn from the old school about Banana growing. *Thos. E. Furnell, Quakers Hall Nursery, Sevenoaks.*

—I was much interested in the correspondence in your issues of March 4 and 25 on this fruit. I fruited three plants last year, with an average of 100 fruits to each bunch, the one shown in the photograph [not suitable for reproduction—Eds.] having 130 fruits, and was carried by a two-year-old plant, having a height

of 8 feet, with a stem 24 inches in circumference. The plants were grown in tubs, with a night temperature of 65°, and 70° by day, rising 10° with sun heat, when a little ventilation was given. These Musas were grown in a light structure 25 feet high. The manures used were Le Fruitier and liquid cow manure. I quite agree with Mr. J. Snell when he writes that Bananas may be fruited and ripened easily in eighteen months to two years from suckers. My employer spoke of the very fine flavour of the fruit grown. *F. Capp, Nostell Priory Gardens, Wakefield.*

—I was interested in the correspondence of Mr. J. Snell and Mr. H. Hills on the cultivation of *Musa Cavendishii*, especially as Mr. Hills mentioned that this Musa was grown at Colwood during his service there. We have at the present time a fine bunch of 144 fruits on a plant growing in a box on the Palm house stage. This bunch developed last October, and has been growing in an average night temperature of 55°. The fruits are fine and well developed. There is also another growth with a bunch just showing, and a fine bunch was cut from a plant growing in the same box last year. I may add that the plants have been grown in the same soil for several years, but liberally fed with manure and soot water. If possible, I will have a photograph taken and will send a print to you, in the hope that it may be suitable for reproduction in *Gard. Chron.* *Alfred Swann, Colwood Gardens, Warninglid, Haywards Heath.*

**Blinds for Glasshouses.**—In your issue of March 25, Mr. Pateman observes, "The blinds should now be fixed." Is it not much better to have such blinds as the wooden chain-lath blind that may be kept in its place all the winter and let down at night to conserve the heat and keep the glass protected, and are thus always ready for use, summer and winter, rather than have to "refix the blinds" or "the summer"? *F., Crandon, Hadley Green, Barnet.*

**Ipomaea rubro-coerulea** (p. 135).—This blue-flowered *Ipomaea* may be, as stated by Dr. Robertson Prochowsky, the most pure sky-blue coloured of flowers; but it is not sufficiently hardy for general outdoor cultivation. Of all blue flowers there are few to equal that of the long introduced, but seldom grown, *Commelina coelestis*. Poets have sang of it, and of the many myths which cluster round it, it will suffice to recall one, mentioned in your columns by *Cornelius Senex* in his monthly notes (see *Gard. Chron.*, Vol. XXVIII., 1900, p. 81). "The Daughter of the Year." Of it we are told that "a seed adhered to the foot of the flower angel as she returned to heaven after visiting her charge below. It gazed on the celestial blue until heaven's azure passed into its tiny frame, when it returned to emulate the empyrian hue on earth." *Fred. W. Jeffery, Dalsrif, N.B.*

**Roofing of Garden Fruit Cages.**—A most important and interesting point has been raised by Mr. Trevor Batye in your issue of April 1. About twelve years ago a fruit cage was built here, covering half an acre, and it is still in good condition. It has one wire door at each end, and was planted with Raspberries, Black Currants, Red and White Currants, Gooseberries and Strawberries; since the Gooseberries were grubbed up (owing to mildew) Strawberries have been planted between the other subjects. I have also a piece of ground within the cage set aside for Strawberries only. I have not discovered any damage due to zinc salts from the wire overhead, as we have good results every year with Strawberries within the cage, but I quite believe that the temperature acts adversely at times, but not sufficiently to cause harm if the crop is planted between rows of taller fruits. Of Raspberries and Currants we have good crops. There is not the slightest damage done through drips from the roof. *F. J. Wren, Wittersham House Gardens, Wittersham, Kent.*

—When I took charge of these gardens thirteen years ago my employer had just built and planted a fruit cage, with Red Currants and Gooseberries, which have been a great success, as the bushes crop well every year, whilst

others in the near neighbourhood have failed to bear owing to late frosts, which usually occur in this district. Last year the Gooseberries gave a record crop; I was obliged to string the branches to the roof of the cage to support the weight of the fruits. The bushes are still healthy. I found the first two years I was here that the Red Currant fruits were a little discoloured, but by deferring the summer pruning a little this defect was not apparent afterwards. I have never grown other fruits in cages, so do not know how they would do here. Our greatest trouble is when we get a heavy fall of snow, as we are exposed to the north-east, with no protection whatever. The soil is a dark loamy clay, on a subsoil overlying rock. *George Gilbert, The Grange Gardens, Farnborough, Banbury.*

## SOCIETIES.

### ECONOMIC BIOLOGISTS.

PROFESSOR E. B. POULTON, president, occupied the chair at a meeting of the Association of Economic Biologists, held in the Imperial College of Science on Friday, March 31. Dr. Wm. B. Brierley showed some fine original photographs of Dr. Erwin F. Smith, the most eminent living plant pathologist, of Professor Richard Owen and of Herbert Spencer. A paper on "Advantages and Disadvantages of Team Work in Economic Biology" was read by Dr. W. Lawrence Balls, of the Fine Cotton Spinners' Association. The paper was an attempt to enunciate certain principles governing the increasing development of team work between different scientists and sciences, particularly on the industrial and economic side. Three union principles were formulated as follows:—(1) The team leader must administer research, and not merely administer; (2) the "scientific management" of scientific research must be considered; (3) every new problem needs a new method. Of major principles, apart from the self-evident essential of sincerity, two were enunciated:—(1) The specialist in an applied science must be a "Jack-of-all-trades." (2) The scientists' code of "individualism in effort and credit; communism in results" must not be contravened. It is amazing that a subject of such vital importance to the immediate welfare and future progress of science should have had so little attention paid to it, and the attempt of Dr. Balls to bring it to the forefront for discussion is much to be commended. That team work in research must be adopted on an ever-increasing scale there is no doubt, but its detailed technique is a matter of much controversy, and in the discussion which followed the paper the following took part:—Professor V. H. Blackman, Dr. Wm. B. Brierley, Mr. A. B. Bruce, Dr. E. J. Butler, and the President.

A second paper was read by Dr. Franklin Kidd on "Problems of Fruit Storage," in which he described the uses of fruit storage in commerce, and gave an outline of the quantities of fruit imported into this country as compared with what is grown by ourselves. The speaker dealt more particularly with Apples as one of the most important crops, and showed how behind we are in this country in the matter of storage of these fruits. He gave a *resumé* of experiments carried out to test the efficacy of "gas storage" a cheaper method than cold storage. The possibility of "gas storage" was first suggested by some purely scientific research carried out by Dr. Kidd on the effect of carbon dioxide and oxygen upon germination and growth. It is another instance of results of the great practical value arising almost directly from research of apparently a purely theoretical significance. The interesting fact in the present case is that the original pioneering research and its application to an immediately practical end are both by the one person.

Finally, Dr. Kidd in his paper dealt with a series of recent experiments on the respiration of Apples during their storage life after gathering. At each of three temperatures tested.

2.5° C., 10° C., and 22.5° C., the rate of respiration changes with age in similar manner, first rising, then falling. The age changes in the respiration curves are, however, not related to the amount of respiration. Apparently while the respiration rate has a temperature relation of 1:2.5:3, the age factor has a temperature relation of the order of 1:4:30, and, consequently, at analogous points on the age respiration curves, more carbon dioxide has been produced at a temperature of 2.5° C. than at 10° C. or 22.5° C.

The value of the work that Dr. Kidd and his colleagues are carrying out on this problem of fruit storage cannot be overestimated, either in its scientific or its practical aspects. Money is needed in order to carry out research, and fruit growers and merchants who will surely benefit from these researches should make it a point of personal honour to see that all support possible is given to ensure that no avenue of investigation is left untried from a mere lack of a few hundred pounds income.

In the discussion following Dr. Kidd's paper the following took part:—Dr. West, Dr. Brierley, Mr. Bruce, Professor Percival, Professor V. H. Blackman, Mr. Lamb, and Mr. Taylor.

### READING AND DISTRICT GARDENERS'.

THE final meeting of the winter session, held in the Recreation Club-room, Abbey Hall, under the presidency of Mr. H. Cook, was set apart for demonstrations in floral work, and Mr. H. Wynn, The Gardens, Hammonds, Checkendon, gave various examples of this art suitable for private households, such as bowls for the dining-room and drawing-room, and a design for a dinner table, large or small. Daffodils, Schizanthus, Carnations, Statice, Richardias, Amaryllis and Cinerarias were the flowers used. Great interest was manifested in the work, and at the close Mr. Wynn was heartily congratulated and thanked.

There were two excellent exhibits in the non-competitive section, and both were awarded the Association's First-class Certificate of Cultural Merit, viz., two dozen Lane's Prince Albert and Seeding Apples, the fruits being remarkable for colour and sound condition for so late in the season, shown by Mr. E. BLACKWELL, The Gardens, Foxhill, Reading; and six excellent plants of Cineraria stellata staged by Mr. A. H. FULKER, The Gardens, Elnhurst, Reading.

In the competition for three plants of Polyanthus grown from seed during 1921, there were only two entries, owing, no doubt, to the excessive drought of last year. The first prize was won by Mr. H. WYNN, The Gardens, Queen's House, Goring Heath, and the second by Mr. W. SHARPE, The Gardens, Sidmouth Grange, Reading.

It being "hospital night," a goodly collection of cut flowers was brought to the meeting, not solely for exhibition purposes, but to be sent for the use of the patients at the Royal Berkshire Hospital. Those contributing were Messrs. Dore, Fulker, Harvey, Jones, Reeves, Sopp, Townsend, Tovey, H. Wynn and J. Wynn. A collection taken in the room enabled the Association to send a sum of £2 10s. to the funds of the hospital.

### ROYAL CALEDONIAN HORTICULTURAL.

APRIL 4.—The ordinary monthly meeting of this Society was held at 5, St. Andrew Square, Edinburgh, Mr. David King, president, in the chair.

Mr. R. Glode Guyer, of Messrs. Duncan Flockhart and Co., manufacturing chemists, Edinburgh, who started a very successful drug farm in Edinburgh some years ago, gave a lecture, illustrated by lantern slides, on "Edinburgh Physic Gardens, Past and Present." Mr. Guyer gave a historical account of the physic gardens which had been successfully formed in Edinburgh, commencing with that of George Heriot's Hospital, the Governors of which instructed their gardener to have their eastern yard planted with all sorts of "physical and medicinal plants"

in 1661, exactly forty years after the establishment of the physic gardens at Oxford, the first of its kind in Britain. Early in the eighteenth century there were three physic gardens in Edinburgh, at North Yards, Trinity Hospital (the site of which is now occupied by the part of the North British Railway Company's Waverley station lying to the east of the present North Bridge), and Kirk o' Fields (adjoining the site of the present Old University Buildings). Mr. Guyer traced the subsequent changes which took place in connection with these physic gardens, and concluded his address with a description of his firm's drug farm at Warriston, of which he exhibited a number of slides showing fine crops of Belladonna, Henbane, Foxglove, Monkshood, etc.

The exhibits were *Primula obconica grandiflora rosea*, from Mr. R. B. WHITE (awarded a cultural certificate; Violet Princess of Wales, from Mr. D. M'LEOD, Yester (awarded a cultural certificate); and *Richardias*, from Miss BURTON, New Saughton Hall (awarded a cultural certificate).

### ROYAL HORTICULTURAL OF IRELAND.

APRIL 5 AND 6.—With no break in the long spell of chilling conditions, which has held spring flowers in abeyance, the show held by kind permission of the Earl of Iveagh, K.P., in the covered court, Earlsfort Terrace, Dublin, was small, but generally bright and pleasing.

The absence of trade groups due to the same cause, and possibly others, was less conspicuous than it might have been owing to the large floor group set up by Mr. F. STREETER, gardener to B. H. Barton, Esq., D.L., Straffan House, Co. Kildare, and this practically saved the situation. For this the Society's Gold Medal was unanimously awarded, and in recognition of Mr. Streeter's work in contributing highly meritorious groups both to the shows and to Council meetings, he was made an honorary member of the Society.

Alpines and hardy flowers were judged by Messrs. J. W. Desant, Rialtas Sealadach na Heirann (late Royal) Botanic Gardens, Glasnevin, and P. Reid, St. Anne's Gardens, Clontarf. In the premier class for twelve pans, not exceeding 12 inches diameter, distinct, Mrs. BUTLER, Priesttown, Co. Meath, won the challenge cup presented by Mrs. Greer. For a dozen pots or pans, not exceeding 5 inches diameter, distinct, Lady Nutting's challenge cup was won by MURRAY HORNIBROOK, Esq., Abbeyleix, Queen's Co., with Miss HART, Woodside, Howth, and Mrs. BUTLER 2nd and 3rd respectively.

For two dozen vases of hardy bulbous, tuberous, or rhizomatous plants in competition for the challenge cup presented by Capt. S. Anketell Jones, Kilkenny, Capt. RIALL, D.L., Old Conna, Bray (gr. Mr. T. Webster), won first prize; Mrs. BUTLER 2nd. In the class for twenty-four vases of hardy cut flowers, shrubs not excluded, Capt. RIALL won Mrs. Geo. Mitchell's challenge cup. For a similar class of 12 vases, the Rt. Hon. ANDREW JAMESON, P.C., Sutton House, Co. Dublin (gr. Mr. G. Osman); Wm. ROBERTSON, Esq., Hermitage, Dundrum (gr. Mr. C. Kempton); and Mrs. McENNERY, Dalguise, Monkstown (gr. Mr. Wm. Taylor), were placed in this order. In the smaller class, for 6 vases, Major SEAGRAVE, Killymon, Co. Wicklow (gr. Mr. J. Gilleran), was first prize winner, his exhibit including a grand bunch of *Pieris japonica*.

In a class for hardy shrubs, 12 vases, distinct, the prizes presented by Messrs. Wm. Watson and Sons, Ltd., Killiney Nurseries, Co. Dublin, the Hon. A. E. GUILNESS, Glemmaroo, Co. Dublin (gr. Mr. W. Stevens), led; 2nd, the Rt. Hon. ANDREW JAMESON. In a similar class for 9 vases, Wm. ROBERTSON, Esq., won first prize; 2nd, Mrs. McENNERY; and for 6 vases of Rhododendrons, distinct, G. VAUGHAN HART, Esq., Waltersland, Stillorgan, was placed first, and R. K. A. KENNEDY, Esq., Kilmacurragh, Rathdrum, Co. Wicklow, second.

Ed. D'OLIER, Esq., Knocklinn, Bray, had

the only exhibit in the class for 12 Roses; while for 6 vases of Carnations, distinct, the prizes presented by Messrs. Chas. Ramsay and Son, Royal Nurseries, Ballsbridge, Dublin, Mr. STREETER had the only exhibit. Several classes for hardy Primulas and Polyanthuses were not a strong feature, the winners being Mrs. BUTLER, C. WISDOM HELY, Esq., Oakland, Rathgar (gr. Mr. J. H. Orr), T. RAY, Esq., Thornfield, Stillorgan (gr. Mr. H. Cousins), and Captain RIALL.

Daffodils were not yet at their best, although Mr. J. L. RICHARDSON'S Waterford blooms, included such good varieties as Lord Kitchener, Michael, Bernardino, Sir John French, Silver-spring, Van Waveren's Giant, Duke of Bedford, Mermaid, Incognita, Lemon Star, Mrs. Sydenham, Lord Roberts, Mrs. Gamp, Kingcup, Queen of the North, J. T. Bennett Poë, Sirdar, Buttercup, Avalanche, Red Lady, White Queen, Homespun, and some of his own remarkable unnamed seedlings, in the important class for 30 vases, distinct, and secured the Lord Ardilann perpetual challenge cup. For 12 large trumpet Daffodils; distinct, and for 12 medium cupped varieties, distinct, Mr. RICHARDSON was also the winner; C. W. PARR, Esq., Athboy, Co. Meath; Mrs. BUTLER and Mr. PARR won other honours.

The 21 classes for plants were but sparsely filled. For 6 *Primula obconica*, C. WISDOM HELY, Esq., won first prize; 2nd, Major KELLY, Montrose, Dennybrook. For 6 plants suitable for table decoration, Wm. ROBERTSON, Esq., led; 2nd, Mrs. McENNERY. The best three *Deutzias* were shown by Major KELLY; 2nd, C. WISDOM HELY, Esq. (both excellent). Prize winners in other plant classes were: W. ROBERTSON, Esq., Major KELLY, Mrs. McENNERY, Miss CUNNINGHAM, Trinity Hall, Dublin; T. RAY, Esq. For Hyacinths, the prizes presented by Messrs. M. Rowan and Co., Capel Street, Dublin, Mr. T. RAY won the premier award.

Fruit and vegetables provided few entries, but high quality ruled. The class for baking Apples included superb examples of Newtown Wonder, and the prize winners were Lord CLONCURRY, Lyons, Co. Kildare (gr. Mr. W. Hall), Capt. RIALL, and Ed. D'OLIER, Esq., as placed. For baking Pears, the 1st and 2nd prizes were won by Lord CLONCURRY and Wm. ROBERTSON, Esq., respectively. Other prize winners were: Broccoli, Lord CLONCURRY; Cabbage, T. N. ATKINSON, Esq.; Lettuce, Mrs. McENNERY; Onions, Major SEAGRAVE; Parsnips, Lord CLONCURRY; Potatoes, new, Lord CLONCURRY; Potatoes, old, Major KELLY; Rhubarb, Wm. ROBERTSON, Esq.; Seakale, C. WISDOM HELY, Esq. For a collection of vegetables, 6 kinds, the prizes presented by the firm of Sir Jas. W. Mackey, Ltd., Dublin, Lord CLONCURRY was placed first with fine examples of April Queen Broccoli, Scarlet Model Carrot, New Success Potato, Canadian Wonder Beans, white Artichokes, and Early Snowball Turnip. In a similar but smaller class, Mrs. McENNERY led.

A Silver Medal was awarded to Mr. MURRAY HORNIBROOK for an extensive collection of miniature alpines, among which were *Anemone Halleri*, *A. intermedia*, *Jeffersonia dubia*, *Saxifraga Sundermanni*, *Sedum Palmeri*, *S. Stahlii*, *S. confusum*, *S. adenotrichum*, *S. cupressoides* and *S. moranense arboreum*, with *Sempervivum Ballii*, *S. Thomassii*, *S. pulchellum*, *S. violascens* and *S. hirtum*. The collection comprised nearly a hundred distinct species and varieties of the three genera. Mr. HORNIBROOK was also awarded a F.C.C. for *Thymus citriodora tricolor*. By common consent the most attractive shrubby subject in the show was a good plant of *Pieris taiwanensis* (see Fig. 68, March 25, 1922), raised by Mr. W. E. Trevithick, gardener to the Marquis of Headfort, Headfort House, Kells, Co. Meath, from seeds sent from China by Wilson in 1918 (First-Class Certificate).

### Awards.

A First-Class Certificate was also awarded to Mrs. LA TOUCHÉ, Kilmacurragh, for *Magnolia Campbellii*. Thirty fine bunches of Daffodils in 70 distinct varieties, considerably helped the limited Daffodil display. An Award of Merit was awarded to Major KELLY for a goodly group of well-grown *Cinerarias*.

## UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.

The monthly meeting of this Society was held in the R.H.S. Hall on Monday, April 10, Mr. Chas. H. Curtis in the chair. Nine new members were elected, Six members withdrew interest amounting to £20 8s. 10d.; one lapsed member withdrew his deposit of £11 12s., and three members over the age of 70 years withdrew from their deposit accounts sums amounting to £17 5s. 7d.

The death certificates of four deceased members were received and the sums of £28 10s. 2d., £26 12s. 4d., £21 10s. 7d. and £41 13s. 1d., were passed for payment to their respective nominees. The sick pay for the month on the Ordinary Side amounted to £99 2s. 1d., and on the State side to £90 11s. 6d., while maternity benefits came to £6.

The question of appointing agents all over the country was discussed and referred to the next sub-committee meeting.

## ANSWERS TO CORRESPONDENTS.

**BEGONIA HAAGEANA:** H. A. Begonia Haageana is easily propagated by means of cuttings any time during the spring or summer, and these root readily in a warm propagating case. Rooted during April or May, they make excellent plants by the following winter. If grown on for a second year, they make fine specimens in ten-inch pots.

**DARK CRIMSON PHLOX:** C. N. We do not know of any variety of Phlox, the flowers of which may be correctly described as crimson, but Charles Davis and Imperator are catalogued as such. Your best plan is to inspect a good trade collection in flower, such as is grown by Mr. H. J. Jones, Ryecroft Nurseries, Lewisham.

**MELON PLANT DISEASED:** A. J. S. An abundance of fungus mycelium and also bacteria were found to be present in the decaying roots and base of the stem. The specimen, however, was insufficient to determine the exact nature of the disease; if you will send a fresh specimen, carefully packed in a tin box, we will endeavour to assist you further.

**NAMES OF PLANTS:** M. G. 1, *Viburnum Tinus* (Laurustinus); 2, *Cornus Mas*.—J. H. S. A fine form of *Scilla sibirica*.—H. A. *Begonia Haageana*.—A. G. 1, *Saxifraga apiculata*; 2, *Saxifraga apiculata alba*; 3, *Saxifraga scardica* var. *obtusa*; 4, *Sedum acre variegatum*; 5, *Sedum album*; 6, *Sedum rupestre*.

**PEACH TREES DYING:** J. S. and J. T. The trouble is not due to organic disease caused by a fungus, but most probably results from some error in cultivation or unsuitable conditions at the roots. Do not keep the borders excessively dry in autumn, and if there is any sign that the drainage is imperfect, this should be seen to when the trees are in a dormant condition.

**PEACH AND NECTARINE LEAVES DROPPING:** H. V. There is no fungus present in the leaves sent. You should have forwarded a whole branch, as the trouble may probably be due to disease in the wood. Exercise great care in watering. When the trees are defoliated in the autumn, lift the roots of one of the trees and ascertain if the drainage is perfect.

**POTATOS DISEASED:** E. P. D. The tubers are severely affected with the disease known as "internal rust spot," which is believed to be caused by a bacteria. Such tubers should not be used for seed purposes, but should be destroyed by burning.

**TOMATO PLANTS FAILING:** C. J. M. A critical examination of the stem does not reveal the presence of any fungus mycelium, but the material you sent was insufficient for a correct determination of the complaint. It does not appear to be typical foot rot, a disease caused by the fungus *Phytophthora cryptogaea*.

**Communications Received.**—J. P.—F. W. J.—M. W. G.—L. G. C.—J. W. B.—A. D. F.—W. B. B.

## MARKETS.

COVENT GARDEN, Tuesday, April 18th, 1922.

We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Tuesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general average for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—Eds.

REMARKS.—The improvement in business, due to the Easter demand, tended to harden values all round, but the usual post-Easter reaction is ruling at the time of writing, and prices are easier. Australasian Apples are selling freely, the latest shipments from New Zealand being in first-rate condition. Fair supplies of Californian and Oregon Newtowns are still available, at firm values. Cape fruit generally have been a good trade, except for Red Haaneport Grapes which were slightly watery, but the last arrivals have been in excellent condition. The cold weather has had a deterrent effect on the demand for Oranges, Lemons have also suffered from the adverse climatic conditions, and values are easier. Forced Strawberries and Figs are in better supply, but the demand is not very firm at ruling prices. Rhubarb is selling slowly owing to a more restricted demand for both forced and natural supplies. Cucumbers are now in full supply, and prices are considerably easier. Tomatoes from Worthling and Guernsey are increasing in quantity almost daily, and the first arrivals from the Lea Valley are also reported. Lettuce is more plentiful, supplies from France being augmented by arrivals from Holland and home grown produce. Forced Beans from all sources are quoted lower, as are Peas and new Potatoes. All green vegetables continue scarce, and comparatively costly. The Potato trade is quiet, and prices tend to fall.

REMARKS.—Business in this department continued good up to Saturday morning. White blooms were in most demand, and there was a further rise in prices, as anticipated. Carnations were a limited supply, and Roses were not over plentiful, the later arrivals being very irregular. Richardias (Arums) and Lilium longiflorum met with the usual brisk demand; Lily-of-the-Valley was also in request. There were ample supplies of Daffodils from home growers, and also from the Channel Islands, the blooms arriving here in excellent condition. Good supplies of white Narcissus came from Guernsey; the flowers were in great demand. White and coloured Tulips found a good market. Small consignments of blue and mauve Spanish Irises are arriving in excellent condition. The quantities of good Sweet Peas available are much below the present requirements. Violets have been checked by the severe weather. With the exception of Smilax, other foliage was fairly plentiful. Smilax realised six shillings per bunch of six trails.

### GARDENING APPOINTMENT.

Mr. E. Hodgson, for the past fifteen years Gardener to NEVILLE FONDS, Esq., Godden Green, as Gardener to W. SMART, Esq., Lisburn, Sevenoaks.

### SCHEDULE RECEIVED.

Bradford Hospital and Convalescent Fund.—Second annual flower and vegetable show, to be held in Lister Park, on Friday and Saturday, August 4 and 5, 1922.—Secretary, 44, Horton Lane, Bradford.

**AVERAGE MEAN TEMPERATURE** for the ensuing week deduced from observations during the last fifty years at Greenwich, 46.7.

**ACTUAL TEMPERATURE:**—  
Gardeners' Chronicle Office, 5, Tavistock Street, Covent Garden, London, Wednesday, April 26, 10 a.m. Bar. 29.4; temp. 43°.—Weather—Dull.

The tributes on p. 161 to Sir I. B. Balfour, at the moment of his retirement from official life, were necessarily, to a great extent, of a personal nature, and did not refer in detail to his administration of the Garden during the 34 years he held the post of Regius Keeper. When, in 1888, Professor Balfour, as he then was, vacated the Sherardian Chair of Botany at the University of Oxford, to succeed Dickson, who in turn had followed Professor Balfour's father, John Hutton Balfour, as Regius Keeper, the Botanic Garden at Edinburgh was under the dual control of the Treasury and the Commissioners of Works. As is so often the case where control is in two pairs of hands, the arrangement, which had been in existence for a long time, did not make for efficiency, and one of the first of the many changes of Professor Balfour's administration was the abolition of joint control. Hence it came about that, in April, 1889, less than a year after Professor Balfour's assumption of office, the Commissioners of Works assumed sole control of the Garden.

Like the holders of all political offices, First Commissioners of Works come and go; there have been no fewer than thirteen of

them during Sir I. Balfour's tenure of office, and those who appreciate the working of Government departmental machinery will realise that the maintenance of consistently harmonious relations with official headquarters in Whitehall during 34 years of political change, is a great tribute to Sir I. Balfour's administrative ability. It is probably true to say that this friendly co-operation between the Office of Works and the Regius Keeper has been responsible to a greater degree than anything else for the unique position held by the Edinburgh Garden to-day, for the spirit of co-operation carried with it that continuity of policy which is of such inestimable value where the policy is sound. One of the immediate consequences of the change in the official control of the Garden was of a nature to which—so have the times changed—but slight importance would be attached nowadays, though in those days it assumed an almost epoch-making importance. We refer to the opening of the Garden to the public on Sundays. Looking back on it now it is difficult to appreciate the nature and extent of the controversy to which the proposal gave rise or of the bitter feeling that was aroused by it. The question was ultimately raised in the House of Commons, and though eventually those who were working for the Sunday opening carried the day, it was not without strenuous opposition. Ample justification of the saneness of their view was not long in coming, but it is not generally known that for the 24 years following the Sunday opening in 1880, the attendance on all Sundays was well in excess of that on all weekdays.\*

For some years before the date of Professor Balfour's appointment, the expenditure annually voted by Parliament for the upkeep of the Garden had not been liberal, and it had not been possible to maintain the place in a manner worthy of a great National Garden. A splendid opportunity, too, had been lost by the refusal of the University Authorities of an offer made by the Treasury for the maintenance of the Garden as a National Research Institute in which students of the University of Edinburgh would have a privileged place. When the Commissioners of Works assumed control of the Garden, however, work long deferred was taken in hand. The Garden was remodelled, old boundary walls, representing areas absorbed at different periods, being removed. Construction of the now famous rock garden was commenced and worn-out plant houses rebuilt. Later, an Alpine house—model to all the world—was added, and apparatus (including refrigerating machinery) provided for the propagation of plants on the lines with which Sir I. Balfour has made us familiar in the classic “Some Problems of Propagation.” The remarkable results obtained by the staff propagator in the propagation of plants at the Inverleith Garden is convincing proof of the soundness of Sir I. Balfour's tenets.

During the late Viscount Harcourt's enlightened rule as First Commissioner of Works, the long-deferred reconstruction of laboratory and teaching accommodation was commenced, and though not yet complete, the buildings already erected provide opportunities second to none in this country, for research and study. The University of Edinburgh is singularly fortunate in having to its hand a great National Botanic Garden maintained by the Government, in which students can receive the practical and scientific training they desire and apply themselves to research, and no other university in Great Britain is so happily situated. The

Garden provides educational advantages in other directions, for it includes a flourishing school for the practical education of foresters, gardeners and nurserymen. This had its origin in a grant from the Board of Agriculture in 1892, and was the first systematised effort in Scotland to provide scientific instruction to practical men in forestry and gardening. It is generally known that of late years the task of marshalling and elucidating the mass of material sent home from Western China by Forrest, Farrer, Ward, and other explorers, as well as that included in the herbarium of Leveillé, has devolved on the ever-willing shoulders of Sir I. Balfour and his staff. But few realise the immensity or the arduous character of the task, or the importance of it to the present and future generations.

No sketch of the administration of the Edinburgh Garden during the past thirty years would be complete without reference to the important part it has played in the advancement of practical horticulture, and particularly in the encouragement of the amateur. The enlightened views of the late Keeper on the relation of a National Garden to horticulture in general are well known, and it cannot be doubted that the giving of practical effect to those views has had a most stimulating effect on the progress of horticulture. Generosity in the distribution of plants is an attribute of gardeners, but assuredly few have practised it so spontaneously, impartially and to such excellent national purpose as the late Regius Keeper.

As British Botanic Gardens go, that at Edinburgh is of respectable antiquity, though hardly so old as the first of them all—the Oxford University Garden, which is within ten years of its tercentenary. For the beginning of the Edinburgh Garden we must go back to the latter part of the seventeenth century, when two eminent physicians of the time, Andrew Balfour and Robert Sibbald, leased a small piece of ground south of Holyrood Palace, on which they cultivated medicinal plants, placing one James Sutherland in charge of it. That was in 1670, and a year or two later the doctors moved their plants to the Royal Garden at Holyrood, which then became a Physic Garden. In 1699, Queen Anne created the Royal office of King's Botanist in Scotland, Keeper of the Royal Garden and Professor of Botany, the aforesaid James Sutherland being appointed to all three offices. From the first, Sutherland had used the Royal Garden for giving instruction in Botany to the lieges, and except for an interval of twenty-five years following the death of Queen Anne, when Sutherland ceased to hold them, the concentration of the three offices in one pair of hands has continued to the present day. After a century of use as a Physic Garden, the Royal Garden at Holyrood became overcrowded and in 1763 the contents were transferred to more roomy quarters on a site below that occupied by Haddington Place, where they remained for sixty years. Once more the ground proved too small for the purpose and a hundred years ago, when Robert Graham was Regius Keeper, fourteen acres of the Park of Inverleith were purchased by the Exchequer. Those fourteen acres formed the nucleus of the Garden on the present site, assuredly one of the most beautiful and appropriate in the world. Subsequent purchases increased the area of the place, till, in 1876, while John Hutton Balfour was Regius Keeper, it attained its present dimensions.

We take this opportunity of publishing on the next page a portrait of the new Regius Keeper of the Garden, Professor W. Wright Smith.

\* Notes from the Roy. Bot. Garden, Edinburgh, No. XXXV., p. xvi.

**Messrs. Alex. Dickson and Sons' Dublin Premises Raided.**—The entire seed business in Southern Ireland of Messrs. Alex. Dickson and Sons, Ltd., has been confiscated by the Boycot Department of the Irish Republican Army. On the afternoon of Tuesday, April 11, armed raiders took possession of the metropolitan establishment of the firm, situated at 61-63, Dawson Street, Dublin, carrying away all the books of the company, and ordered the business to be closed down. Orders in course of execution were not even allowed to be completed, and all the company's book debts and stock-in-trade are at the disposal of the Republican Army. The business is completely paralysed, and in a state of absolute chaos at the moment. Under these trying circumstances Messrs. Dickson ask for the kind indulgence of their customers in England, Scotland and Wales, and request that all communications pertaining to the Dublin House should be directed to the northern headquarters at Hawkmart, Belfast. A claim has been lodged with the authorities for damages, amounting to £50,000.

**Flower Show Abandoned.**—The Lichfield Floral and Horticultural Society, the second oldest of its kind in the country, has decided not to hold its annual exhibition in August this year owing to the financial losses experienced at the last two shows.

**Royal Botanic Society's School of Gardening.**—Miss M. Williamson has resigned the post of principal of the School of Practical Gardening for women under the auspices of the Royal Botanic Society. Miss Williamson was the first student to join the school when it was commenced in 1898, and in 1901 she was appointed assistant instructor. From the time when she was appointed principal, in 1913, she had the entire charge of the school. Miss Williamson has considerable artistic abilities and designed the medal of the National Sweet Pea Society, the certificate of that Society and also the Dean Memorial Medal of the National Dahlia Society.

**Darwin, May-flowering and Cottage Exhibition of Tulips.**—At the meeting of the Royal Horticultural Society, on May 9 and 10, collections of Darwin, May-flowering and Cottage Tulips will be considered by a special jury, and the Council will make awards according to merit on their recommendation. The undermentioned classes have been arranged by the National Tulip Society, which will make awards as in 1914. The Tulip Society will welcome exhibits of Tulip species or Tulip seedlings, to which suitable awards will be made if of sufficient merit. Class 1: Darwin Tulips, 12 varieties, 5 blooms of each; class 2, Darwin Tulips, 6 varieties, 5 blooms of each; class 3, Rembrandt or Broken Darwin Tulips, 3 varieties, distinct, 5 blooms of each; class 4, May-flowering or Cottage Tulips (not Darwins) self-coloured or Breeders, 12 varieties, 6 blooms of each; class 5, May-flowering or Cottage Tulips (not Darwin's), self-coloured or Breeders, 6 varieties, 5 blooms of each; class 6, May-flowering or Cottage Tulips, variegated or "Broken" varieties, 6 distinct varieties, 5 blooms of each; class 7, English Florist Tulips, 12 varieties, 5 blooms of each, Breeder or Broken. Entries should be forwarded to Mr. W. Peters, Farcet House, Cambridge, on or before May 2, 1922.

**"Review of Applied Mycology."**—The first four parts of a new publication issued by the Imperial Bureau of Mycology and entitled the *Review of Applied Mycology* have been issued. The work consists of abstracts and summaries of work published in all countries on the diseases of plants and various other aspects of economic mycology. Though the chief object of the new journal is to give an up-to-date summary of work bearing on the practical application of the study of plant diseases to the reduction of the wastage due to such diseases in agriculture, the fundamental researches on which most progress in this direction is based have a wider appeal. The *Review* will enable all those who are interested in the progress of science to follow

the development of one of its youngest branches; the student of pure science will, it is hoped, find many side-lights on the wider problems on which he is engaged; while the practical grower will be able to learn the experience in other countries with improved methods for controlling plant diseases. The subscription to the *Review* is 12s. per annum post free, payable in advance, while single parts will be sold at 1s. 4d. each. Subscriptions, orders and all communications respecting the publication should be sent to the Editor, Imperial Bureau of Mycology, Kew, Surrey.

**Ghent Quinquennial Exhibition.**—The Royal Horticultural and Botanical Society of Ghent will hold a great exhibition in Ghent in 1923, opening on or about April 15. We publish this information, given us at The Hague, on the authority of M. Emile Spaë, and we do it with the greatest of pleasure, as a Ghent Quinquennial Show is a great exposition of horticulture and an unique opportunity for an international gathering of horticulturists. We congratulate our Belgian confreres on their decision, as we are aware how greatly they suffered during the war and how small has been their opportunity of recovering since the war ended.

PROF. W. WRIGHT SMITH, M.A., F.R.S.E., F.L.S.  
THE NEW REGIUS KEEPER OF THE ROYAL BOTANIC  
GARDEN, EDINBURGH (SEE PAGES 189 AND 205).

**A New Park for Derby.**—Darley Abbey Park, consisting of some twenty acres on the outskirts of the town of Derby and adjoining the River Derwent, has been presented to Derby by Mr. L. G. Curtis. The gift is subject to the interest of the existing life tenant, Mrs. Walter Evans, on whose death Mr. Curtis inherits the estate under the will of the late Mr. Walter Evans, of whom he is a relative. Mr. Curtis was formerly private secretary to Lord Milner and has no interest in Derby apart from his inheritance. This is the second time within two years that the town has benefited from a private benefactor, the previous gift being one of £10,000, bequeathed by the late Mr. H. M. Gray for the purchase of a park or allotment gardens.

**Annual Inspection of Edinburgh Parks.**—The annual inspection of the parks and open spaces of the Edinburgh Corporation took place on April 13. There was a good attendance of the committee, including Mr. Philips-Smith, the convener; Mr. J. W. M'Hattie, the superintendent, was also present. An inspection of the different parks, bowling greens and sports grounds was made, and general gratification was expressed at the works carried out and the many

improvements effected during the year or still in progress. New bowling greens, tennis courts, cricket grounds, and improved golf courses showed that the committee had carried through much excellent work during the year, while in many other respects the condition of the parks was greatly improved. The committee had done, also, a good deal to lessen unemployment, as some 500 of the unemployed had been given work during the winter. Mr. M'Hattie and his staff are to be congratulated on the condition of the parks generally.

**National Tulip Society.**—The annual meeting of the National Tulip Society will be held in connection with the fortnightly meeting of the Royal Horticultural Society on May 9, at Vincent Square, Westminster, London, S.W. If the season permits, the usual exhibition will also be held in the committee tent of the Chelsea Show of the Royal Horticultural Society on May 24 and 25 next.

**Appointments for the Ensuing Week.**—Tuesday, May 2: Royal Caledonian Horticultural Society's meeting; Bournemouth Gardeners' Association's meeting. Wednesday, May 3: Royal Agricultural Society's Council meeting; National Viola and Pansy Society's exhibition. Thursday, May 4: Linnean Society's meeting at 5 p.m. Friday, May 5: Paisley Florists' Society's meeting. Saturday, May 6: National Auricula Society's show (Northern Section) at the Coal Exchange, Manchester.

**"Gardeners' Chronicle" Seventy-five Years Ago.**—*Torenia asiatica*.—There is now in bloom here at H. Bevan's, Esq., place, Twickenham, though rather past its best, a magnificent specimen of the comparatively new *Torenia asiatica*, a small plant of which was shown for the first time at Chiswick last year. It is upwards of three feet in height, and quite as much in diameter, trained over a wire trellis, but so that the latter is quite concealed. By this means the plant is rendered symmetrical in form, without appearing to be artificially supported, and being regularly covered all over with beautiful blossoms, which stand well up above the rather copious pale green foliage, has a very handsome appearance. This fine plant is not yet a twelvemonth old; it was raised from a cutting last summer, and was grown in a close frame without artificial heat till October, when it was placed in a stove whose temperature ranged between 55° and 60°, and in this situation it has been blooming all the winter. It was repotted in February last, and, with very little intermission, has been in bloom ever since. It strikes freely from cuttings, flowers well in a small state, and patiently bears cutting for bouquets, for which the pale blue dark purple blotched blossoms are very suitable. *Gard. Chron.*, May 1, 1847.

## INTERNATIONAL COMMERCIAL HORTICULTURAL CONFERENCE.

As each spring comes round it becomes more and more evident that the Conference of the *Fédération Horticole Professionnelle Internationale* is becoming an increasingly important function to those horticulturists who have international commercial relations. This evidence is to be found in the larger number of delegates attending and the keen attention they give to the many matters brought forward.

This year, Mr. Ernest Krelage being the president, the conference was held in Holland, at the Hotel Wittebrug, The Hague. This hotel occupies a delightful position in the woods on the environs of The Hague, on the tram route to the fashionable seaside resort of Schevening. Here the majority of the British, French, Belgian and Luxemburg delegates, and some of the Dutch also, stayed, consequently there was little difficulty in commencing the conference sessions according to the programme.

The personnel of the conference is a matter of general interest. The officers present were Mr. Krelage, president; M. Turbat (Orleans), general secretary; M. Sauvage (Paris), treasurer; and M. Barbier (Orleans) and M. Arluison (London), national secretaries.

Holland was represented by Messrs. E. H. Krelage (Haarlem), H. C. Valetton (The Hague), H. de Lange (Rotterdam), J. C. Mensing (Aalsmeer), D. Frets (Boskoop), P. Visser (Naarden), F. Kakebeeko (Goes), B. Ruys (Dedemsvaart), Jac. Smits (Naarden), T. Wezelenburg (Hazerswoude), W. F. Wery (The Hague), J. M. Van Til (Lisse), W. Warnaar (Sassenheim), T. Van der Koog (Haarlem).

The Belgian representatives were Messrs. Spaë (Ghent), E. Praet and D. Kerkevoorde (Wetteren), while little Luxemburg sent Mr. J. Bintner and Mr. Ketten, the former an old Kewite, formerly representing his Government on horticultural matters, and now starting in business on a large scale.

The British delegates were Mr. H. V. Taylor, specially sent by the Ministry of Agriculture; Mr. George Monro, Mr. W. E. Wallace, Mr. J. S. Brunton, Mr. E. A. Merryweather and Mr. C. M. Matthews (secretary) from the Chamber of Horticulture; Messrs. E. A. Bunyard, G. W. Leak, Chas. E. Pearson and C. G. L. du Cann (secretary), from the Horticultural Trades' Association; and Messrs. Alfred W. White (president), and C. H. Curtis (secretary), from the British Florists' Federation; and Messrs. J. Arluison, J. K. Ramsbottom and Wardle.

France was strongly represented by Messrs. H. Graindorge (Vitry-sur-Seine), N. Levavasseur (Ussy), E. Turbat (Orleans), René Barbier (Orleans), L. Sauvage (Paris), Lecolier (St. Cloud), G. Royer (Versailles), L. Levasseur (Angers), R. Leclerc (Vitry), F. Cayeux (Paris), Emile Boullet (Bourg-la-Reine), Raverdeau (Paris), C. Souchet (Vitry), and F. Fauque (Orleans).

The representatives of each country sat together and occupied the same seats throughout the conference. The proceedings opened with an address of welcome from Mr. Ernest Krelage, the president, which was followed by an address of welcome from His Excellency the Minister of Agriculture for Belgium, and a lengthy address by Professor Treyselhuys, President of the National Horticultural Society of Holland, who made special reference to the trading difficulties which have arisen by reason of the imposition of Quarantine Order 37 by the United States Government, and expressed the hope that there might be free trade for plants between all countries.

A letter from the Queen of Holland was read wherein Her Majesty welcomed the conference to the Hague, and expressed her intention of receiving the delegates at the opening of the exhibition during the afternoon, an intention she could not, unfortunately, fulfil owing to the sudden illness of the Prince Consort's mother. A message of respect and appreciation was sent to Her Majesty by the conference.

Messrs. Arluison, H. Valetton and René Barbier were appointed secretaries to assist M. Turbat. Then the minutes of the conference held in London in 1921 were considered and accepted. Next came the reports of the Secretary and Treasurer, and these were accepted without much comment. It appeared that Italy, while not expressing a desire to remain outside the F.H.P.I., had not answered any letters forwarded by M. Turbat, nor had she paid her subscription, consequently the Conference regarded Italy's membership as ineffective.

Several minor alterations of rules were suggested, principally designed to allow application for membership. Thus, Germany is not in the F.H.P.I., and there has been some difference of opinion as to whether she should be asked to join; the alteration of rules renders invitation unnecessary, but makes application necessary. The H.T.A., through Mr. Bunyard, claimed the right to direct representation to

only eight subjects had been registered, and these represented registrations from France (Roses), Belgium (Azaleas) and England (Apples). The Conference appeared to be somewhat surprised that raisers had taken so little advantage of the Bureau to obtain international registration for their novelties. In answer to a question with regard to publication, it was stated that as so few plants had been registered, publication had not seemed worth while. The British delegation pointed out that publication was the most important part of the business, and would be the means of encouraging further registrations. Moreover, it was hardly fair to expect the British horticultural Press to publish long accumulated lists; indeed, it would be better for all concerned if publication took place at brief intervals, and to this suggestion the conference agreed, and, further, agreed that Mr. Sauvage's expenses for stationery, books, etc., be defrayed from the funds of the F.H.P.I.

Hitherto matters had progressed very smoothly; but when the next item on the agenda was reached, relating to placing trade discounts for cash on an international basis, the Dutch growers found themselves unable to agree to the proposals which the British delegation made, and only after long conferences with their own countrymen and the use of much persuasion did Belgium agree to come into line as soon as possible. Mr. Leak urged the Dutch traders to agree to the method proposed, but it was only after they had gone into committee and slept on it that they agreed, subject to confirmation by their respective associations.

The vexed question of transport was discussed with some spirit by the French and Belgian delegates, but the British section of the conference was so apathetic that the Continentals were surprised, until Mr. Leak, the British unofficial spokesman, stated that the British trade had this matter always with them, and were almost always fighting the great railway transport monopolists. He suggested every country should do its best to secure suitable facilities for the transport of horticultural produce, and, having obtained these, the international question would settle itself.

Before proceeding with the next item on the agenda, Mr. Krelage read a telegram from the Swiss horticulturists, in which regret was expressed that they found themselves unable to send delegates this year, but they sent their good wishes. M. Turbat was requested to send a suitable reply from the conference. In this connection, we may add that Sweden has not yet joined the F.H.P.I., but, nevertheless, expressed a wish that the conference should be held in Sweden in 1923, and that the official language for that year be English. In effect, the conference's reply was that Sweden should first join the F.H.P.I., and so obtain a *locus standi*. Moreover, according to rule, French is the official language of the conference.

And now a breeze arose and ruffled the placid surface of the proceedings. It was a pleasant breeze, however, because the majority of those present have met and conferred before on several occasions, hence they know how much allowance has to be made for the excitability of a Frenchman, the enthusiasm of a Belgian, the persistency of a Dutchman, the ardour of a Luxemburger, and the dear insistence of an Englishman. The subject was an international system of arbitration for the settlement of differences among horticulturists. The Dutch delegates had placed a somewhat lengthy proposal before the conference, and wanted the latter to agree out of hand. To this the British opposed a solid front, and neither the persuasiveness of Mr. Van Til nor the forcible humour of Mr. Jac. Smits—the Peter Pan of the conference—could move them. This matter occupied the conference for the remainder of the session; finally, after the breezes, came the calm, and the conference very sanely agreed that each country should have the matter discussed by its affiliated associations; that the results of such discussions should be circulated among all associations having representation to the F.H.P.I. for consideration and report; and that a committee should tabulate and reduce the several proposals for presentation to the conference of 1923.

FIG. 107.—MALE CONES OF CERATOZAMIA MEXICANA (SEE P. 209).

the F.H.P.I.; but this point was referred to the Britishers to consider. We understand the claim was made because, before the war, the H.T.A. dealt directly with the International Conference then existing, but which died of inanition several years ago.

The work of the F.H.P.I. grows yearly, and the conference, fully appreciating the amount of time M. Turbat must give, readily agreed with the suggestion of the French delegates that the secretaries, MM. Turbat and Barbier, be allowed to pay for secretarial assistance as necessary—a small matter, yet one of considerable importance, which was also a reminder of the energy M. Turbat has given unsparingly to those international matters since the F.H.P.I. was instituted in 1919.

M. Sauvage reported that the Bureau of Plant Registration was now in working order. In reply to a question, it transpired that so far

ORCHID NOTES AND GLEANINGS.

ORCHIDS AT THE WARREN HOUSE.

Mrs. B. BISCHOFFSHEIM's collection of Orchids at The Warren House, Stanmore, includes both species and hybrids in about equal proportions, and at times, as at the present season, the species are the more interesting. The Odontoglossum house is gay with a fine series of *O. crispum*, of several importations, and the plants show interesting variety of form. *O. luteo-purpureum* of the best type; *O. Hallii*, now scarce; forms of *O. Andersonianum*, from almost wholly pale yellow to densely spotted flowers; the very fragrant *O. gloriosum*; *O. Wilckeanum* and *O. Pescatorei* have all a great show of bloom, rendered more effective by the scarlet *Sophranitis* suspended overhead. Some fine specimens of *Dendrobium nobile* and other species are also well in bloom, and the scarlet *Renanthera lmschootiana* is beginning to flower.

Among the hybrids a large batch of *Cymbidiums* is bearing strong spikes, one specimen of *C. Alexanderi* having nine sprays; *Brassolaelio-Cattleya* Queen of the Belgians, a fine white form; and good *Laelio-Cattleyas* were also noted.

EPIDENDRUM ENDRESII.

THE charming little specimen of this extremely rare and beautiful species of *Epidendrum*, shown by H. T. Pitt, Esq., Rosslyn, Stamford Hill (grower, Mr. Thurgood), at the meeting of the Royal Horticultural Society on April 11, is another instance of the many frail species saved from passing out of cultivation by the skill and care given to them at Rosslyn.

The plant, which is only a few inches in height, and bears a relatively large spike of pure white flowers with blue markings on the lip, was discovered by Endres when collecting for Messrs. J. Veitch and Sons in Costa Rica in 1873, but the plants died in transit. Five years later F. C. Lehmann sent plants to Europe, but only one or two plants reached their destination alive. Subsequently other collectors made the attempt to introduce the species, but with small success. Mr. Pitt's plant must have been in his collection for many years, being one of Pfans' collecting.

It was described by Reichenbach in *Gard. Chron.*, 1883, p. 432, and illustrated in *Gard. Chron.*, April 18, 1885, Fig. 91. It was used by Messrs. Veitch in crossing with *E. Wallisii* and others, and gave several pretty hybrids.

RESTING ORCHIDS.

REST is an essential to plants, as it is to animals, therefore it is advisable to give all plants a period of rest at the proper season. The resting of Orchids is a large subject, too large to be dealt with in the space at my disposal; but it will suffice for the moment to state that *Odontoglossums* usually require a short rest after flowering. Water should not be withheld entirely, but only sufficient should be given to prevent the plants shrivelling. On all bright days the newly potted plants may be sprayed lightly, only applying sufficient water to give a dew-like appearance on the foliage, which will assist the plants to become re-established quickly. These remarks also apply to *Cochlidodas*, *Odontodas*, and similar Orchids, which for cultural purposes may be treated almost precisely the same as *Odontoglossums*. B.

NEW HYBRIDS

(Continued from March 25, page 140).

Name.	Parentage.	Exhibitor.
Brasso-Cattleya Conqueror ...	B.-C. Oberon x C. Maggie Raphael alba ...	Baron Schroder.

Sophr-Laelio-Cattleya Prince of Orange ...	S.-L.-C. Eros x L.-C. Thyone ...	Flory & Black.

LILIES FOR GREENHOUSE DECORATION.

THE practice that so generally prevails of retarding the bulbs of several kinds of Lilies enables them to be had in bloom at nearly all times of the year. The additional cost, however, and the fact that some species, especially *Lilium auratum*, are less reliable from old bulbs than from freshly imported ones, leads many to depend upon these last named for greenhouse decoration. *Lilium longiflorum* is a general favourite, and for this purpose is treated in a variety of ways, either potted singly in six-inch pots, or three bulbs arranged triangularwise in a larger pot, while clumps or masses may be grown in pots or tubs by putting several bulbs together.

*Lilium speciosum* is a Lily of remarkably good constitution, and an equal favourite with *L. longiflorum* for retarding purposes. Very desirable qualities possessed by this Lily for greenhouse decoration are the readiness with which it responds to pot culture, the fact that under normal conditions it blooms towards the latter part of the summer when many of the occupants of the greenhouse are on the wane, its comparative freedom from insect pests (for aphides have to be sharply looked after in the case of *L. longiflorum*), and also in the fact that the blossoms are not powerfully scented, hence they can be employed in more confined places than certain other Lilies.

As *Lilium speciosum* is a typical example of a stem rooting Lily, as large a space as possible should be left in the pot to admit of accommodating a top dressing of good soil as the plants grow. When the bulbs are potted they may, with advantage, be stood in an ordinary garden frame, just giving them enough water to keep the soil slightly moist, the object being to encourage a steady, yet vigorous root action from the base of the bulb. In the event of severe weather, the frame may be just protected from the frost, but if mild, air should be admitted. This, of course, applies to the individuals that are required to bloom at the normal season, when their value in the greenhouse is so great, as if needed earlier, they may, when well rooted, be given a little artificial warmth. When the cold weather is past, these Lilies may, with advantage, be plunged out of doors in a bed of Coconut refuse, or some other moisture-holding material. As the pots become filled with roots, the latter are greatly benefited by an occasional application of liquid manure and soot-water mixed. They should be taken under glass just before the earliest blossoms expand.

There are several varieties of *Lilium speciosum*, but two of them, markedly distinct from each other, can be confidently recommended. They are *Kraetzeri*, a regularly reflexed, white flower with a greenish centre, and *Melpomene*, the richest coloured of all, the segments being deep carmine with a narrow white border. The difference in habit, foliage, and other particulars, of these two Lilies is remarkable. In *Kraetzeri*, the bulb is yellowish and produces, as a rule, but a single stem, whereas in *Melpomene* it is reddish, and very apt to break up into two, three, or more crowns, each of which pushes up a stem of its own.

*Lilium auratum* is exceedingly capricious in its behaviour, and some individuals are much later in flowering than others. A magnificent Lily though it be when at its best, the strong perfume is in a confined space far too powerful for many people.

Of the Tiger Lily (*L. tigrinum*) there are several forms, one of which succeeds in pots much better than any of the others. This is the variety *splendens* or *Leopoldii*, characterised by a smooth, dark coloured stem, and upright coloured flowers, with unusually large dark tinted blotches. Beside those above mentioned, the two Burmese species—*L. nepalense* and *L. sulphureum*—may be regarded as greenhouse species, for usually some of the blossoms develop so late that glass protection is necessary for their safety. As a rule, *L. sulphureum* is the earlier of the two, and it has adapted itself to our climate better than many other Lilies. T.

## TWO USEFUL VERONICAS,

THERE are many fine varieties of *Veronica speciosa* which are more or less hardy in the south-west; they are all very useful for cultivating in pots for the autumn furnishing of the greenhouse or conservatory. With judicious stopping they make compact flowering subjects for growing in six-inch pots.

Plants rooted from cuttings inserted this spring will be ready for potting on in the first week of June, and are subsequently best grown in cold frames until they are established in their flowering pots, when the lights should be removed entirely, or the plants may be stood on an ash bed in the open. They are strong-rooting subjects and require an abundance of water at all stages; the roots should be stimulated with a concentrated fertiliser when they have filled their pots.

*Veronica diosmifolia* is a very dainty plant for the stages of the greenhouse, making compact little bushes, which are very pretty when covered with the pale lilac-coloured flowers. The plants should be trimmed when they have finished flowering to obtain shoots suitable for use as cuttings, which are best rooted under a bell glass in a cool propagating case in June. Compared with the *speciosa* forms, this is a slow growing plant, taking some three years before it attains a useful size. But with proper attention it lasts for many years, maintaining its compact habit without increasing much in size. *J. C.*

## BEGONIA DREGEI.

THIS old South African species of *Begonia* is more often referred to as one of the parents of the ubiquitous *Gloire de Lorraine* than for its own intrinsic merit. It is, however, well worth consideration for its simple cultural requirements, neat, compact habit, and its great profusion of white blossoms, borne during the latter part of the summer, throughout the autumn, and well on into the winter. Another hybrid of *Begonia Dregei* is *B. Weltoniensis*, which forty years ago was a popular market plant, and to-day is well worth cultivation for its continuous flowering qualities. *Begonia Weltoniensis* has a good deal of the upright, compact habit of *B. Dregei*, but the flowers are of a pleasing shade of deep pink. *W.*

## NEW OR NOTEWORTHY PLANTS.

### CERATUZAMIA MEXICANA.

SEVERAL plants of this interesting Cycad have borne male cones during this spring at Kew.

In the illustration (Fig. 107) one large and two smaller cones are shown clustered together on one plant. Development is rather slow; but just before the sporophylls (stamens) mature the cone elongates rapidly, and the scales separate from one another showing the numerous microsporangia on their lower surfaces.

*Ceratuzamia mexicana* has a very short trunk. Its leaves are carried erect for some distance, and then they gradually droop in a very graceful manner. Small, sharp spines are borne on the petioles. Other species of *Ceratuzamia* are represented at Kew.—*E. N., Kew Gardens.*

### A NEW HEDYCHUM.

WITH reference to the plant illustrated on p. 163, Fig. 81, as being *H. Greenii*, it seems I have fallen into a trap concerning it, for Mr. Turrill has very kindly informed me that there are two similar plants in cultivation, which, unknown to me, had both passed through his hands.

Unfortunately I had no specimen of the plant nor any information concerning it, only the reduced photograph for identification, which was said to have yellow flowers and was named "*H. Elwesii*."

This I found it certainly could not be, and so far as I could judge from the photograph

it seemed to agree with specimens of *H. Greenii*, one of which was named "*H. Elwesii*," but quite wrongly. Mr. Turrill, however, has shown me specimens of another plant, sent to Kew by Mr. Elwes, which differs from the red-flowered *H. Greenii* by the lip of the yellow flower being broad and cordate at the base instead of wedge-shaped, and by the stamen being longer than the lip instead of about equaling it in length. These specimens I had not compared with the photograph, but now that I have seen them I agree with Mr. Turrill that the photograph represents that plant and not *H. Greenii*, as I had supposed. When comparing the photograph I had noticed that the lip of *H. Greenii* seemed to be more wedge-shaped

garden hybrid, yet it seems that it ought to have a distinctive name, therefore I give the following description of it, made from the dried specimens of Mr. Elwes' plant above-mentioned.

*HEDYCHUM DECEPTUM*, N. E. Br. Leaves of the specimens seen with the petiole sheathing close up to the blade, with an obtuse pubescent ligule 9-10 lines long; blade 8-8½ inches long and 1½-1¾ inch broad, lanceolate, rounded at the base, tapering from about the middle into a long, slender point. Spike 4-5 inches long, compact, many-flowered, pubescent on the axis, with oblong-ovate convolute acute or subacute bracts about 1½ inch long, pubescent at the tips. Corolla yellow, with a tube about 1¼ inch long and shorter than the bracts, with segments

FIG. 108.—*HEDYCHUM DECEPTUM*.

than shown in the flowers of the photograph, but as the upper right-hand flower in side view shows a wedge-shaped base, I mistook the more obvious cordate base of the lips of the other flowers as due to the pose or infolding of the sides of the lip. There are also differences in the size of the leaves and ligules, which I should have noticed at once if I had possessed a specimen, but which the photograph does not show.

The description given on p. 163 is correct for *H. Greenii* (which is in cultivation), except that the base of the lip should have been described as wedge-shaped.

As the plant represented by the photograph (which is reproduced in Fig. 108) cannot be identified with any known species, and as its origin is unknown so that it may even be a

about 1¼ inch long, the broad obtusely 2-lobed lip being about 1½ inch broad and somewhat cordate at the base, the two spatulate segments 5 lines broad, and the three narrower and linear. Stamen about 1½ inch long, longer than the lip.

This plant completely differs from *H. Elwesii* by its much shorter and narrower leaves, a ligule about a quarter of an inch shorter, a dense and broad instead of a lax and narrower spike, and the corolla-tube shorter than the bracts instead of much longer than them.

From *H. Greenii* the yellow flowers, narrower leaves, cordate based lip and longer stamen distinguish it so far as the dried specimens and photograph show, but probably living specimens in flower seen side by side would show other distinctions. *N. E. Brown.*

## The Week's Work.

### THE ORCHID HOUSES.

By J. T. BARKER, Gardener to His Grace the Duke of Marlborough, K.G., Blenheim Palace, Woodstock, Oxon.

**Repotting Odontoglossums.**—Many consider August and September the best months for potting these delightful Orchids, and they are right in so far as it concerns species that flower in the early spring and summer, but in an up-to-date collection of Odontoglossums there are always some of the plants in flower during most months of the year. That being so it is obvious that all the plants cannot be ready for potting at one time. I do not infer that those which were not ready for potting in the early autumn are ready now, but there are not many weeks in the year when some of the plants are not in the right condition, thus enabling the potting to be done as and where it is required. When the new growths are about three or four inches long, according to the strength of the plants, is the time to repot, irrespective of season. When the young growths are about to push forth new roots the least possible harm will accrue from disturbance. The material for repotting should consist of equal parts peat and A1 fibre, thoroughly cleaned, sphagnum-moss and Bracken rhizome, with sufficient small crocks to render the mixture porous. The pots should be well drained, for although Odontoglossums need plenty of water whilst growing actively a stagnant soil is injurious to them. After repotting afford the roots water with great care, for any excess of moisture at that stage would cause the old roots to perish, the pseudo-bulbs to shrivel, and a general deterioration of the plants. Specimens which have flowered recently should be afforded but little water at the roots; if kept too moist they will start into growth prematurely.

**Seedling Odontoglossums.**—Seedling Odontoglossums should, so far as is possible, be kept growing, as a seedling does not stay long in one condition; it is either improving or going back. The general requirements of these small plants are precisely the same as for the larger ones, with the exception that the material they are grown in should be cut up finely and that they are best placed in the warmest position in the house.

### THE FLOWER GARDEN.

By EDWIN BECKETT, Gardener to the Hon. Vicary Gibbs, Aldenham House, Hertfordshire.

**The Shrubberies.**—Most shrubs and trees are making a fine show this year with flowers, doubtlessly owing to the effects of last year's hot, dry summer, which caused the wood to become thoroughly ripened, even though it did not favour a free growth. Forsythias have been lovely, and are not yet finished; special mention should be made of *F. intermedia*, and its wonderful variety (probably the very best of them all), *F. intermedia spectabilis*, *F. suspensa*, *F. suspensa decipiens*, and *F. viridissima*. Any, or, where room permits, all of these Forsythias should be planted in the shrubberies, for during the early spring their fine golden yellow flowers always prove a welcome sight. Other groups that are doing well are the flowering Plums and Cherries, *Prunus* species. Commencing with *P. pissardii*, and its beautiful varieties, these are followed closely by such as *P. pilosiuscula barbata*, and *P. pilosiuscula media*, two charming and dainty varieties introduced by Mr. E. H. Wilson from China; *Prunus subhirtella* is just opening its blossoms, and soon will follow those beautiful Japanese varieties, such as *Prunus serrulata flore luteo pleno*, *P. s. Hisakura*, *P. s. Shirofugen*, *P. s. Veitohiana*, and *P. s. shidare-sakura*. All these are very charming varieties, and should be selected for planting in prominent positions as flowering trees. *Prunus Cerasus Sargentii* (Sargent's Cherry) is also a beautiful tree, and there are many others, including *P. tenuiflora*, that are worthy of cultivation.

*Cydonias* are bursting into flower, and *C. japonica*, or, as it is sometimes known, *Pyrus japonica*, is simply smothered with flower buds this season. There are many beautiful forms of this shrub, and, perhaps, the richest coloured of any is the variety Knap Hill Scarlet, whilst running this very close is the variety *Simonii*. A white form, named *nivalis* promised much beauty; but, unfortunately, frost badly caught this in the bud stage, with the result that the flowers are considerably marred. *C. Maulei* is closely allied to *C. japonica*, but of much dwarfier growth, and of this there is a very pretty white form named *alba*. Various *Pyruses* are showing excellent promise, and *P. chinensis*, which makes a magnificent tree, has been literally covered with its white flowers for some time past.

**Violets.**—A commencement should now be made with a view to obtaining full supplies of Violets during the winter. The site for the plants should be chosen, preferably with a northern aspect, where the soil has been well trenched and enriched with well-decayed farmyard manure. After the surface has been broken down, rake it well to reduce it to a fine tilth, and, after dividing the old plants, select the strongest and healthiest crowns, planting them in rows, allowing a foot apart for the stronger growing single varieties; for double varieties, which make smaller plants, the distance may be lessened somewhat. Stir the soil occasionally, give the roots copious supplies of water, and dust the rows occasionally with a concentrated fertiliser and soot. The plants should be well syringed in the mornings and evenings, especially in very hot weather, in order to keep them from red spider. Only the best varieties should be grown, and the plants, during the whole of their career, should never be coddled.

### HARDY FRUIT GARDEN.

By H. MAKHEM, Gardener to the Earl of Strafford, Wrotham Park, Barnet.

**Planting Vines.**—As young vines are usually sent from the nursery in pots, they may be planted much later than most other fruits, with, probably, the exception of Figs. To be successful with Grapes in the open, a warm situation and a sweet, fertile soil are needed. Thin training of the shoots is also necessary to have the wood well ripened, also the timely disbudding and removal of any useless young shoots, as the season advances. The borders need not be very wide—between 4 feet and 6 feet is ample. Good drainage is essential, and a somewhat dry, rather than a damp, position is preferable. In preparing the border for the reception of the roots, dig out the soil two feet deep and break up the bottom to allow water to pass away freely. Over the bottom layer place 6 inches of broken bricks and cover them with turves, grass side downwards. Fill the trench with a mixture of turfy loam, wood ash, old mortar, a little crushed bones and a small quantity of decayed manure. The soil should be made rather firm and allowed to settle before planting is done. If the weather is wet, a covering should be placed over the border to prevent the soil from becoming sodden. In planting, first soak the ball of roots in water, and then turn the plants out of the pots. Shake the soil from amongst the roots very carefully, prepare the stations and spread out the roots evenly and at different angles, finally covering them with some of the finer soil, which should be made firm. Spread a mulching of strawy manure over the soil, and if the latter is dry when planting, afford water to settle it, but guard against an excess of moisture until the roots are more active. In suitable situations the varieties Black Hamburg, Black Cluster, Royal Muscadine, and Sweetwater should give satisfactory results.

**Protecting Fruit Blossom.**—All fruit trees are very backward this season, but on warm walls the blossom of many kinds has already expanded and care must be taken to protect it from injury by frost. Tiffany hung from the top of the wall over the face of the tree will answer the purpose, or double-fish netting may be used if preferred.

### FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

**Melons in Frames.**—Melons cannot have too much sun and light throughout the whole stage of their development. It is best to set the plants about 2 inches higher than the level to which the top dressing of soil will reach when the final earthing up is finished. Two plants to a light are sufficient for a 6 feet light, and three breaks from each plant will be ample. Top dress with 2 inches of warm compost as soon as the roots push through the soil, and afford water to the roots as necessary, at a temperature of 85°. Linings may be added later if the heat declines too much, and the frames should be covered with mats at night during the early stages of growth. Admit a little air when the temperature reaches 75°, and increase the amount until the maximum of 85° is reached. Do not shade the plants unless bright sunshine, after a dull period, causes the foliage to flag, and then only lightly and for a short time. Close the frames early and syringe the Melons with water at 80° to 85°, care being taken when syringing or watering to keep the small mounds upon which the plants are standing dry.

**Cucumbers.**—Spring-sown Cucumber plants are in full bearing, and require attention every other day or so in stopping and tying the shoots. Nothing is more wasteful or injurious to the plant than to allow the young shoots to grow after the points can be pinched at the first leaf beyond the fruit intended to swell to maturity. To secure an abundance of straight fruits with the flower attached, all crooked or imperfect specimens should be removed before the flowers open, and on no account should the fruits be allowed to attain their full size, a length of 14 inches being ample for all purposes. Some growers keep their houses closed, no matter how hot the weather may be, but 70° at night with a little air, 80° to 85° by day, and 90° to 95° after closing with sun heat and moisture is sufficient warmth for this crop.

**Summer-Fruiting Cucumbers.**—As the weather improves, pits and frames intended for Cucumbers should be cleared, cleansed, and made ready for planting healthy young plants which have been carefully raised for the purpose. If a little fire-heat can be utilised, much labour through May and June may be saved, but the main source of heat should be from fermenting materials. The warmth of the bed, of course, fluctuates more or less, but the soft, moist heat economises syringing on fine mornings and dull days, whilst covering the lights with mats at nights ensures an atmosphere in which the plants revel. Train the main growths outwards, pinch them before they reach the sides of the frame, and stop the laterals at the first joint beyond the fruit. Increase the supply of tepid water as the plants gain strength, ventilate the frame early on fine mornings, and close it again early in the afternoons with sun-heat and moisture in time for the temperature to rise to 90°. The soil should be of a rich nature, but practically free from manure and leaf-mould, as the roots may be fed with stimulants when the plants actually require nourishment.

### THE KITCHEN GARDEN.

By JAMES F. HATHAWAY, Gardener to JOHN BRENNAND, Esq., Baldershy Park, Thirsk, Yorkshire.

**Parsley.**—Plants raised in boxes should be set out in rows made 1 ft. apart, on ground that has been trenched deeply. Water the seedlings if the ground is dry, and dress them overhead every fortnight with soot.

**Beetroot.**—The main sowing of Beet should be made on ground that has been trenched deeply but not manured. Fork the land, level it with a wooden rake, and sow the seed in drills made 18 in. apart and about 1½ in. deep. Dell's Dark Red and Blood Red are two of the best varieties. A watch must be kept for sparrows, which are sometimes troublesome to

this crop, and also for slugs. To prevent damage by the birds use nets, whilst for combating the slugs dust the roots with soot after rains. To procure extra fine roots make holes 3 ft. or more in depth with a crowbar and fill them with a rich compost consisting of old potting compost, horse droppings, leaf-mould, wood ash and lime rubble, sifted through a fine sieve.

**French Beans.**—Make a sowing of French Beans in a sheltered position. Plant the seeds in rows made 2 ft. apart and thin the seedlings, as soon as they are large enough to handle, to 6 in. apart. Canadian Wonder, Carter's Perpetual, and Sutton's Superlative are three of the best sorts.

**Maize.**—Seed of Indian Corn should be sown in small pots to raise seedlings for planting out next month. This crop must be raised in gentle warmth as Maize is very tender; it should not be planted out-of-doors until it has been well hardened and there is no fear of frost.

**Herbs.**—Sweet Basil, Marjoram and Chervil should be sown in rows made 1 ft. apart. As soon as the seedlings are large enough thin them to 9 in. apart.

**Dandelion and Chicory.**—Sow these salads in rows made 12 in. apart on ground that has been well manured the previous year. As soon as the seedlings appear thin them to 1 ft. apart.

**New Zealand Spinach.**—Sow this vegetable in rows made 3 ft. apart in a sunny position on a light soil. Thin the plants to 2 ft. apart as soon as they are large enough to handle.

#### PLANTS UNDER GLASS.

By T. PATEMAN, Gardener to Sir C. NALL-CAIN, Bart., The Node, Codicote, Welwyn, Hertfordshire.

**Cuttings.**—Rooted cuttings of such plants as Codiaenum (Croton), Dracena and Saintpaulia that were propagated in February require to be potted singly in small pots. Care must be taken not to break the young roots, which are very brittle. For putting use rich, open loam mixed with leaf-mould or a little peat, adding sharp sand and broken charcoal to ensure a free drainage. After potting, plunge the plants in a mild hotbed and shade them from bright sunshine for a short time.

**Campanula pyramidalis.**—For furnishing a cool greenhouse and for other decorative purposes, the elegant Chimney Campanula is well worthy of cultivation in pots. By introducing a few plants now into a little warmth and allowing others to remain in the cold frame, plants may be had in bloom over an extended season. There are both white and blue forms of this Campanula, and under good cultivation they make most useful plants for grouping purposes. To maintain a good stock of these plants, it is necessary to sow a few seeds annually, and now is the most suitable time to perform this operation. Sow thinly in well-prepared pots or pans, cover the seed lightly with soil, and place the seed pans in a warm greenhouse. Shade the receptacles until the seeds have germinated, and, when the seedlings are large enough to handle, prick them off into boxes. When suitably hardened, they may be planted out-of-doors in well-prepared soil and allowed to remain there until the autumn, when they should be lifted and placed in their flowering pots. Plants in pots intended for flowering this season will be greatly assisted by frequent applications of liquid manure.

**Coleus thyrsoideus.**—Stock plants of this Coleus may be grown in a brisk temperature with a view to obtaining cuttings for raising flowering plants for next winter. This Coleus is very easily grown, and produces its flowers in the dullest months of the year. It is useful either for supplying cut blooms or grouping purposes. As soon as cuttings become available, they may be inserted three or more in a small pot, and later either potted singly or grown on intact.

#### SPRING FLOWERS.

THE beauty of a flower border may easily be marred by want of forethought in the arrangement of colours. I speak advisedly, having suffered rude shocks as the result of my own inveterate habit of sticking in plants wherever there is room for them, without reckoning upon the colour or season of the bloom on their established neighbours. For instance, only two years ago, when moving some bulbs of Habranthus pratensis, I dumped them right in front of a large bush of Buddleia globosa. In the following May, when the bush and the bulbs burst into flower together, the effect was excruciating, so cruel was the clash between the flaming vermilion Habranthus and the orange of the Buddleia. Equally harsh was the discord between Berberis Darwinii, rising to a height of ten feet, alongside a crimson Rhododendron two feet higher. As they persisted in blooming simultaneously, and as each was too big to transplant, the Barberry had to be cut out. A third example out of many which might be recounted will suffice. A liberal

FIG. 109.—CROCUS VERNUS IN COLONIES IN THE GRASS.

space in the front of a border having been dressed with lime was filled with Pasque Flower (Anemone Pulsatilla), which responded with what should have been a delectable display, had not neighbouring masses of Aubrietia been overlooked, whereof the stronger purple utterly eclipsed the delicate tones of the Anemone and nullified the effect. The colours of spring flowers are so vivid, and their effect is so greatly heightened by leafless woods and naked fields, that it is well to take note of felicitous harmony, and contrast with a view to future arrangement. Here are a few early combinations which have afforded pleasure during the present spring. Winter Aconite with Scilla bifolia. These bloom together early in February. 1. Tulipa praestans (scarlet) among a wide scattering of Narcissus Bulbocodium citrinus (the pale Hoop Petticoat). 2. Narcissus Queen of Spain springing amid breadths of purple Aubrietia. The yellow of this graceful Daffodil, which is said to be a natural hybrid between N. pseudo-narcissus and N. triandrus, is of a peculiarly soft, yet luminous,

quality. 3. Anemone Pulsatilla, with Tulipa Kaufmanniana. 4. Anemone fulgens (scarlet) with Muscari conicum Heavenly Blue. 5. Bloodroot (Sanguinaria canadensis), with Grape Hyacinth (Muscari botryoides). 6. Narcissus cyclamineus with Chionodoxa Luciliae. 7. Narcissus Bulbocodium (the deep yellow Hoop Petticoat) with Scilla sibirica. 8. Erythronium Dens-canis (Dog-tooth Violet) with Ornithogalum nutans. 9. A very choice association of delicate colours is presented by the Queen of Spain Daffodil beside Primula denticulata.

Modest combinations such as these will not satisfy those who aim at regular spring bedding with gaudy breadths of Tulips, Hyacinths, etc., adapted for public parks and formal gardens, but they contribute much charm and interest to humbler parterres.

After all, I have seen nothing during this spring of such lavish beauty as the lawns round a Scottish manse, which were sheeted from end to end in February with the soft purple of Crocus vernus (see Fig. 109). The effect was enhanced in March when the common Daffodil (N. Pseudo-narcissus) came through the carpet in scattered groups. It implies no disrespect to the opulent Dutch varieties of Crocus if I extol the natural C. vernus above them. The pity is that, so far, I have failed to find any nurseryman that stocks it. *Herbert Maxwell, Monreith.*

#### THE ALPINE GARDEN.

##### DIANTHUS SPENCER BICKHAM.

DIANTHUS SPENCER BICKHAM, raised by the gentleman whose name it bears, and who is an authority on the genus, is an exquisite plant with close, yet graceful growth, making a pretty mat on the soil, and in summer decorated with bright crimson flowers that are borne on short stalks and look exquisite on the rock work or moraine. It is a gem for a moraine of whinstone intermixed with lime and looks exceedingly well against the grey chips, the cool green of the leaves and the bright crimson flowers presenting an object of great beauty. The plant is hardy and may be increased by means of division.

##### SAXIFRAGA CORIOPHYLLA.

In the Royal Botanic Garden of Edinburgh there are two fine masses of two Saxifrages bearing the above name. One is marked *S. coriophylla* of gardens and the other *S. Rocheliana* var. *coriophylla*. Both plants are very beautiful, though the latter is the prettier, with its close-set, spiny, dainty margined foliage and good white flowers. It was delightful in early April. As with many Saxifrages there is some confusion regarding the nomenclature of these plants. The late Mr. Reginald Farrer dealt fairly thoroughly with the Saxifrages in the *English Rock Garden*, but even his views as formulated in that great work leave us in some doubt regarding the precise plants which should bear the name of *coriophylla*. In the first place, Mr. Farrer referred *S. Rocheliana* to *S. marginata*, and stated that "*S. coriophylla* is a marked form, being a high-alpine development of *S. marginata*, with smaller flowers on stems of an inch, which usually carries only two. The leaves also are much smaller and rounder, packed in tighter, more densely-overlapping rosettes, so that their silver margin becomes more conspicuous." Mr. Farrer also states that it is distinct from *S. marginata*, but that "there is no abiding character to distinguish them." According to Mr. Farrer the plant offered in catalogues as *S. coriophylla* or as *S. Rocheliana* *coriophylla* is only a slightly divergent form of *S. marginata*, but that the true *S. m. cordifolia* is sometimes sent out as *S. scardica*. All this is very unsatisfying to those who desire to have their plants correctly named. The plant labelled *S. coriophylla* of gardens at Edinburgh seems a trifle earlier than the other, which is in all probability the true *S. m. coriophylla*, and is very charming indeed. *S. Arnott.*

**EDITORIAL NOTICE.**

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, W.C.2.

Special Notice to Correspondents.—The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.

Letters for Publication, as well as specimens of plants for naming, should be addressed to the EDITORS, 5, Tavistock Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

## TREES AND SHRUBS OF SAVOIE HAUTE SAVOIE AND ISERE.\*

THE densely-wooded valleys of that Highland country are of special interest, as almost all the species of trees and shrubs indigenous to Central Europe are to be found there.

In the streets, gardens and squares of the

branches had been broken off by their weight. In England the tree only produces its handsome purple flowers in the best climates of the south, and that only after a mild winter, as it sets its flower buds in the previous autumn.

In Savoy, *Sophora japonica* is the most beautiful of planted trees, and is often completely covered with its creamy blossoms, beloved of bees; *Ailanthus glandulosa* also flowers and sets seed freely (see Fig. 110). Roadside avenues of *Gleditschia triacanthos* and of the silver-leaved Lime (*Tilia argentea*) are frequent. The latter, the habitat of which is south-east Europe, I noticed had suffered more in Savoy from the drought of last summer than the two native species, *T. platyphyllos* and *T. parvifolia*. The black Walnut of North America (*Juglans nigra*) is occasionally planted, and at Moutiers I noticed a fine specimen planted in the middle of the town. The Nettle-tree or "micoculier de Provence" (*Celtis australis*) is planted occasionally; at Anney by the side of the lake it was bearing its small black fruits profusely. I know of no trees of it in England, and the other member of the genus, *Celtis occidentalis*, from eastern North America, is a very rare tree with us.

only made from Pear wood and evergreen Oak (*Quercus Ilex*), though the latter is not native in the district. Sweet Chestnut (*Castanea sativa*) is not thought so highly of as Oak for furniture-making or other purposes, but is regarded as valuable timber. Trees of this species are not grown so frequently as on the Italian side of the Alps, and I saw none that would compare with the great sweet Chestnuts of England.

As one ascends from the valleys to 1,500 feet and over, in all parts of Savoy, pedunculate Oak forms the scrub forest growth, often mixed with and gradually giving place to Hornbeam. During the drought of last summer these species became so withered on much of the shallower soil overlying the limestone that I fear they have been killed outright.

Walnut and Robinia, though, of course, not natives, may be seen coming up from natural regeneration in many of the lower woodlands. Higher still the natural woods are so varied in the number of species they contain, and, in the case of certain forests, such as those of the valleys of the Grande Charreuse, the timber itself is so superb as to

FIG. 110.—FOLIAGE AND FRUITS OF *AILANTHUS GLANDULOSA*.

principal towns, such as Chambéry, Aix-les-Bains and Anney many exotic trees grow to greater perfection than in the most favoured parts of Great Britain. At Chambéry I saw the finest Maiden-hair tree (*Salisburia adiantifolia*) I know of in Europe, larger even than the examples in the old Botanic Garden of Montpellier in Provence. It grows behind the old citadel, and is a female tree which last summer was covered with fruit. Specially fine specimens of Paulownia, Catalpa, *Gleditschia* *Sophora*, *Ailanthus*, *Tilia argentea*, *Acer* *Negundo*, Chinese Persimmon, *Morus alba*, and others of the more uncommon broad-leaved species are also to be seen. There are many remarkable avenues of Planes, notably that at the north end of the Lake of Anney, and near Anney an avenue of Walnuts. By the way, why is it that in Great Britain, so far as I am aware, there are no Walnut avenues, despite the many merits of the tree? I saw Paulownias at Chambéry and Brides-les-Bains of great size, and so laden with fruits that

\* Reprinted, with permission, from the *Journal of the Royal Scottish Arboricultural Society*.

The fields and lower hillsides are dotted with Walnuts, the wood of which is used throughout the country for the making of better-class furniture; the shop fronts and their variously panelled shutters are invariably of Walnut, often of considerable antiquity. I found that it commanded a higher price than the wood of "cerisier" and "merisier," though these are much in request for such articles as the small tables of restaurants and shop counters. So far as I can find out "cerisier" is the name given loosely to the timber of cultivated Cherries, and "merisier" to that of the wild Gean (*Prunus Avium*), though I think the latter name is also applied to the woods of *P. Mahaleb* and *P. Padus*. I found in Savoy, as in other parts of France, that the material used for such special purposes as joiners' adjustable "plough" planes and sash-fellisters, where great hardness, rigidity and closeness of grain are required, is the wood of "sorbier" (*Sorbus domestica*); I wonder why this admirable tree is so seldom planted in Britain. "Jack," "trying" and hand-planes as used in Savoy are most com-

recall the wonderful and fast-diminishing virgin forests of Arkansas. Of the broad-leaved species I saw in these valleys, Beech, Ash, Lime (*Tilia platyphyllos*), Sycamore and Wych Elm were the finest, while, except for the Yew, the only Conifers were Silver Fir and Spruce. The last two are felled carefully and peeled before being hauled out of incredibly difficult and inaccessible places. At the roadside they are loaded, six or eight to the timber wagon, generally drawn by a string of five to six mules, and taken down to the nearest railway. Each stem is from 75 feet upwards long, and has less taper than any timber I have seen except in western America.

The woods are largely owned by the peasants, though there are extensive state and communal forests; in consequence, the peasantry of the better timbered districts are exceedingly well off, and are only partly dependent on their tillage.

Of the rarer trees I saw in the woods of Savoy, two Maples, neither of which is in common cultivation in this country, were frequent, these being *Acer Opalus* and *A. mons-*

pellulanum. The grey Alder (*Alnus incana*) is commoner in the woodlands than our own Alder (*A. glutinosa*), though both are general in the river valleys. The White-beam (*Sorbus Aria*) is thoroughly at home on the limestone of Savoy, but the Rowan (*S. Aucuparia*) I did not often see. The two Limes, *Tilia platyphyllos* and *T. parvifolia*, our only British species, Norway Maple, field Maple, commonly used for vine-posts, and Aspen-Poplar all occur frequently. Tree Willows of many species, accompanied doubtless by many natural hybrids, flourish by the streams. The most distinct is *Salix incana*, often wrongly but not unnaturally called *S. rosmarinifolia*. The dwarf-creeping Willows, *S. reticulata*, *S. herbacea*, *S. repens* and *S. retusa*, may be found among the rocks above timber-level. Birch of the warty-twigged weeping form (*Betula verrucosa*) is frequent but local; at a distance it is often difficult to distinguish its white stems from those of the Aspen (*Populus tremula*). The woolly-twigged Birch (*B. pubescens*) and intermediate forms also doubtless occur, though I did not see them.

Of the smaller trees the following are universal—Hawthorn, Hazel, "Scotch" Laburnum (*L. alpinum*), Prunus Mahaleb, Blackthorn (*P. spinosa*), the Wayfaring Tree (*Viburnum lantana*), and Guelder Rose (*V. Opulus*). The commonest shrubs are Dogwood (*Cornus sanguinea*), Privet (*Ligustrum vulgare*), common Elder (*Sambucus nigra*), and scarlet-berried Elder (*S. racemosa*), a shrub which has become our worst forest weed in Tweeddale, though it is not a native of Great Britain. On the hill-sides below the denser woodlands Juniper and Box mix with the scrub Oak and, like it, were often dead or moribund this summer.

In the higher valleys of the Isère and Doron, which take their rise in the Alpine range of the Vanoise, Larch woods cling to the rocks at timber-level of 6,000-7,500 feet. Scots Pine is usually at a somewhat lower altitude, and, though *Pinus Cembra* occurs, I saw none but scattered trees. Much of the Larch appeared to be of great age, though I saw no really large trees. From many of the mountains of Savoy *Pinus montana* appears to be absent; further south, in Dauphiny, I believe the erect form (*P. uncinata*) is found. In the higher country the Alpine Elder (*A. viridis*) flourishes as a bush on the margins of the woods, often mingled with the two Alpine Rhododendrons (*R. hirsutum* and *R. ferrugineum*).

Several shrubs, seldom seen in British gardens, abound in the sub-alpine regions; two shrubby Honeysuckles (*Lonicera coerulea* and *L. alpigena*), the former with purple fruit and the latter with its scarlet Cherry-like fruits are common; neither has flowers of much merit.

*Cotoneaster vulgaris*, whose native habitat in Great Britain is confined to the Great Orme's Head, its near relative *Cotoneaster tomentosus*, *Rosa alpina*, *R. rubrifolia*, *Rhamnus alpina*, and, at about 5,000 feet, *Rubus saxatilis*, which bears its scarlet fruit in great profusion and replaces the Raspberry (*R. Idaeus*), common at lower altitudes; these are perhaps the shrubs best worth mentioning, though I know my list is incomplete. In the valleys among river boulders the common Barberry (*Berberis vulgaris*) and Sea Buckthorn (*Hippophaë rhamnoides*) are laden in August with their berries, and "Old Man's Beard" (*Clematis Vitalba*) festoons the underwood.

It is curious that while on the western side of the Little St. Bernard Pass pure Spruce forms the timber-level at nearly 7,000 feet, on the eastern or Italian side of the pass Larch is the only tree to be seen at the corresponding altitude. Larch, however, is usually absent from calcareous rock formations, while Spruce is found on both calcareous and granitic rocks, and the great line of demarcation between the two is in this region.

To those who delight in Alpine plants Savoy offers, perhaps, the best field in Europe. The limestone mountains at the head of the Val d'Isère are particularly rich in Gentians, Saxifrages, Sedums and many other Alpine genera. *F. R. S. Balfour.*

## THE MONTEREY CYPRESS.

Nowhere is the Monterey or large-fruited Cypress (*Cupressus macrocarpa*) to be seen in better condition than at Point Lobos, a rocky promontory that extends into the Pacific from the mainland of California. There, growing amongst broken granite rocks interspersed with dark brown earth and fully exposed to the long-continued and fierce ocean storms, this beautiful Cypress is to be seen at its best. Where fully exposed, as on the summit of the peninsula, the tree assumes a dwarf, tortuous appearance, the stems grow Carrot-shaped and buttressed, and the branches and foliage become strangely arranged in flat, shelf-like tiers. Many of the exposed trees have the appearance of being centuries old, the stems twisted and gnarled, the branches shortened and directed away from the prevailing wind and assuming sharp, angular forms, as if to offer the smallest amount of resistance to the storm.

Further inland, where the tree is found in quantity, this Cypress may be seen of perfect shape and with foliage of the richest shade of green.

The noble specimens at Penrhyn Castle, in Carnarvonshire, growing on broken shale

## CHINESE SHRUBS AT ALDENHAM.

(Concluded from page 199.)

*RIBES LAURIFOLIUM* (see Fig. 111) is a very distinct evergreen with fairly large, dark green foliage. It is most interesting in early winter, when the flower buds commence to expand, these being of a beautiful ruby-red colour. When this low-growing evergreen is out of flower I know of no plant which less resembles a member of the Currant family. Mr. Gibbs informed me that when Mr. Wilson paid a visit to Aldenham several years ago—when the seedlings of Wilson's collection were just beginning to show their characters—Mr. Gibbs was himself completely deceived by this plant. Calling attention to a box of these seedling Ribes he invited Mr. Wilson to admit that seeds of some completely different plant had been sent in error under the name of Ribes. Another evergreen Chinese Ribes grown at Aldenham, which bears considerable resemblance to this one, is *R. Henryi*. Another remarkable shrub is *R. longeraemosum*, one foot to eighteen inches long, which has racemes of fruits like Black Currants. *R. Maximexiczii* is a strong-growing bush, which flowers and fruits abundantly; the berries are bright red when ripe and are said

FIG. 111.—*RIBES LAURIFOLIUM*.

rock, are as perfect in shape and beauty of foliage tint as any that could be found amongst the forests of the tree that may be seen within a short distance of the mission of San Carlos di Rio, on the mainland of California. Cones are abundantly produced by this Cypress after middle age is attained, and seedlings spring up freely wherever shelter and soil are provided.

It is to be regretted that this Cypress is in England only suited for seaside sheltered situations and that it is readily uprooted by the wind. *A. D. Webster.*

## GIANT LARCHES.

As you have published numerous notes from correspondents concerning very fine specimens of *Cedrus Libani*, it occurred to me that there must be some very fine specimens of the Larch in this country. It is supposed that the specimens at Dunkeld were among the first to be planted in Scotland. We have several specimens on this estate and I have just completed the measurements of two. No. 1, at 3 ft. from the ground, is 8 ft. 11 in. in circumference with a branch spread of 65 ft.; height 85 ft. No. 2 has a circumference of 8 ft. 4 in., a spread of 66 ft. and height of 106 ft. Can any of your readers give me any idea when such trees were planted? *Mark Mills, The Gardens, Coombe House, Croydon.*

to be edible. A fine specimen at Aldenham is ten feet high and eight feet in width.

*SARCOCOCCAS*.—Although one cannot claim that these plants are of special value at Aldenham, as they suffer during hard winters, there are many gardens in which they would prove useful for planting in shady places, and produce the same general effect as the Butcher's Brooms. The white flowers are not showy, but those of *S. humilis* and *S. ruscifolia* are desirable on account of their fragrance. The bright, evergreen foliage is very pleasing where it remains in good condition. It is very interesting to know from Mr. Bean that the Chinese form of *S. saligna*, sent home by Wilson, has proved "quite hardy and a vigorous grower."

*STRANVAESIA DAVIDIANA* is a handsome evergreen, similar to a Photinia, with large dark green foliage, and corymbs of white flowers. The blossoms are succeeded by brilliant red fruits, which remain in good condition well into the winter. The tree is particularly good when grown as a standard. There is a variety at Aldenham that bears yellow fruit; it has no advantage over the type except that of rarity. *S. undulata* is another fine species which makes a spreading bush about eight feet across and almost as much in height. The leaves are smaller and lighter in colour than those of *S. Davidiana*, but the bright red fruits are produced in greater abundance, and in autumn few shrubs are more beautiful. *A. E. Thatcher.*

**MESEMBRYANTHEMUM AND SOME NEW GENERA SEPARATED FROM IT.**

(Continued from page 198.)

In the descriptions which follow it will always be necessary to take the smaller dimensions given as more nearly indicating the size of the growths as they occur in South Africa. The time at which the flowers are stated to expand is Greenwich time, not the so-called "summer-time."

As in the case of the genera previously dealt with, the name *Mesembryanthemum* is indicated by the letter M in the synonymy.

The groups under which I have arranged the species in most cases are purely artificial, and do not admit of a proper sequence of the nearest allied species.

In the descriptions the breadth of the growths is the greater diameter, and the thickness the lesser diameter across the top.

**CONOPHYTUM.**

**KEY TO THE GROUPS.**

I. Growths globose, ovoid, obovoid, obconic, obcordate, or rarely subcylindric, not compressed as if pinched between the finger and thumb and two-lobed at the top. Types A to Q of Fig. 112. Species 1-49.

Surface pubescent, minutely puberulous or covered with minute points scarcely amounting to hairs, as viewed with a lens.

A, Species 1-5.

Surface glabrous except at the minutely puberulous orifice. C. oviforme is minutely tuberculate all over, and a few species have raised dots, all the others are quite smooth. AA, Species 6-49.

Growths uniformly green or more or less tinted with purple, without dots or markings, except sometimes in 8, C. jucundum; 11, C. Wettsteini; 12, C. minutum; 14, C. saxetanum; and 15, C. viridicatum (see also 18, C. translucens). B, Species 6-15.

Flowers yellow C, Species 6-7

Flowers of some shade of red or perhaps whitish in 14, C. saxetanum. Colour unknown in 10, C. subrisum. CC, Species 8-14.

Flowers white (see also 14, C. saxetanum. and 18, C. translucens). CCC, Species 15.

Growths marked with dots or lines.

BB, Species 16-49.

Dots all scattered and separate (see also 14, C. saxetanum; 27, C. Nevillei; and 30, C. parvipetalum). D, Species 16-22.

Some or all of the dots confluent into lines or the growths marked with lines not formed of confluent dots.

DD, Species 23-49.

Top of the growths flattish or with a broad and shallow, trough-like transverse depression, or slightly excavated and shallowly cup-shaped (see also 33, C. leviculum, and 37, C. signatum). E, Species 23-31.

Top of the growths more or less convex (flattish in species 33 and 37), or convex on each side of the central notch, which does not spread out over the whole of the top as in some of those under E. EE, Species 32-44.

Top of the growths obcordate, with or without a slight ridge or keel extending from the orifice to the top of the convex lobule on each side of it. Types O-Q of Fig. 112. EEE, Species 45-49.

II. Growths two-lobed at the top, and the lobes or top of the growth compressed and keeled as if pinched between the finger and thumb, with flat sides to the notch separating the lobes, except in 57, C. turrigerum, which has cylindrical lobes, convex or subtruncate at the top. Types R to T of Fig. 112.

Surface covered with minute points viewed

with a lens, slightly and harshly puberulous to the touch. F, Species 50-51.

Surface quite glabrous, smooth to the touch. FF, Species 52-57.

I.

Growths globose, ovoid, obovoid or obconic in form, circular, elliptic, or rarely slightly angular on outline, viewed from above, and not compressed as if pinched between the finger and thumb at the upper part, with the top convex, flat, depressed, obcordately notched so as to form two very short and broadly-rounded lobes, or with a broad V-shaped trough extending from margin to margin all across the top, as represented in the outlines Fig. 112. Types A-Q (Species 1-49).

A.

Surface either distinctly pubescent or (as seen under a lens) minutely puberulous or covered with minute points scarcely amounting to hairs. (Species 1-5).

I. C. PILOSULUM, N. E. Br. Growths obcordately obovoid (type N) in nature, but under cultivation with me becoming elongated-ovoid and more or less pointed at the top (type B),  $\frac{1}{2}$ - $\frac{3}{4}$  in. in diameter, softly pubescent with fine outstanding hairs, dull purple where exposed to the sun, uniformly light green on other parts, without spots or markings. Flowers not seen, but

FIG. 112.—OUTLINE SECTIONS OF TYPES OF GROWTH OF CONOPHYTUM. (SEE TEXT.)

according to a photograph the flower is about eight lines in diameter with about thirty recurved-spreading petals, and stated to be bright purple. M. pilosulum, N. E. Br. in *Journ. Linn. Soc. Bot.*, Vol. 45, p. 98. Ladysmith Div. near Touwsberg Mountains, in a clayey subsoil covered with sand, flowering in May, Pole Evans, 6927.

2. C. LEIPOLDTII, N. E. Br. (Fig. 113). Growths globose (type C), about a quarter of an inch in diameter, covered with an adpressed pubescence of fine hairs all pointing downwards, pale brownish, tinted with reddish, not dotted. Flower not seen, stated to be magenta and not to close when once expanded until it withers.

Clanwilliam Div., near Clanwilliam, Leipoldt. I have much pleasure in naming this very distinct species after Dr. C. L. Leipoldt, who has discovered a considerable number of interesting South African plants. The flower is probably usually more symmetrical than represented in the figure, which is from a photograph sent to me by Mr. Leslie.

3. C. FIBULIFORME, N. E. Br. Growths obconic, flattened at the top, slightly pubescent, whitish or hoary, without spots. Flowers unknown. M. fibuliforme, Haw, *Misc. Nat.*, p. 22 (1803), and *Rev. Pl. Succ.*, p. 83.

Locality unknown. Introduced by Masson in

1795, but soon died out of cultivation, and does not appear to have been rediscovered.

Haworth states that it is of the size of *M. truncatellum* and resembles that species in form, but is more depressed and more evenly truncated. The description given by Sonder (*Fl. Cap.*, Vol. 2, p. 393) is evidently partly based upon Haworth's description and partly upon a plant collected by Zeyher. It is certainly a mixed description of two species, and must, therefore, be discredited. The above account contains all that is known of the plant at present.

4. C. FIMBRIATUM, N. E. Br. Growths obconic, apparently flattish or slightly convex on the top, minutely puberulous. Calyx five-lobed, gland-dotted. Corolla with a tube about  $\frac{1}{2}$  line long, and narrowly linear acute petals about  $2\frac{1}{2}$  lines long, marked (in the dried state) with numerous linear immersed glands along their entire length. Style short, with five filiform stigmas, gland-dotted like the petals.—*M. fimbriatum*, Sond. in *Fl. Cap.*, Vol. 3, p. 393.

Near the Ganika River in either Beaufort West Div. or Prince Albert Div., Burke! Zeyher 693!

The gland-dotted flowers distinguish this from every other species known to me. Sonder describes the species as glabrous, from specimens collected by Zeyher. I have not seen Zeyher's specimens, from which Sonder described, but as Burke and Zeyher travelled together, and in most cases collected the same species, the specimens collected by Burke at the same locality are probably identical with those of Zeyher, and are decidedly minutely puberulous, as in Zeyher 693, which Sonder wrongly quotes as being *M. minutum*, Haw.

Photograph by T. N. Leslie.

FIG. 113.—CONOPHYTUM LEIPOLDTII, N. E. BR. NATURAL SIZE.

5. C. PISINNUM, N. E. Br. Growths obconic or subglobose,  $2\frac{1}{2}$ - $3\frac{1}{4}$  lines in diameter, convex on the top (type E), slightly velvety to the touch from being covered with very minute points, scarcely amounting to pubescence, only visible under a lens and best seen on the old withered sheaths, of a slightly greyish-green, often more or less tinged with purple on the sides, and inconspicuously marked with scattered dots on the top. Flowers unknown. Locality unknown. Karoo, Marloth.

M. pisinum, N. E. Br. in *Journ. Linn. Soc. Bot.*, v. 45, p. 98.

AA.

Surface glabrous, except at the orifice, which is usually minutely puberulous, minutely tuberculate all over in *C. oviforme*, and in a few species with the dots raised and tubercle-like, but in all the others quite smooth. (Species 6-49.)

B.

Growths uniformly green, or green with the sides or sometimes the top or around the orifice purple, usually without dots or markings, but in *C. jucundum*, *C. minutum*, *C. saxetanum*, *C. viridicatum* and *C. Wettsteini* there are sometimes a few indistinct dots on different plants or even on the same plant in different years. (Species 6-15.) N. E. Brown.

(To be continued.)

## THE GRAPE VINE.\*

It is the general belief that the vine was introduced into England by the Romans, A.D. 10, in the reign of Emperor Augustus. At an earlier period the Romans planted great vineyards in Italy. They trained the vines to tall trees, and it is said that the vines out-topped the highest Elms. There are various records of vineyards in different parts of Britain, attached to castles and monasteries, but, owing to our moist climate, little progress was made with the vine in this country until it was cultivated under glass. Since that time no branch of horticulture has received more care and attention than the cultivation of the Grape, and in no country in the world do Grapes compare in flavour, at least—with those grown in this country.

The construction of vineries, like all horticultural buildings, made great progress during the latter half of the nineteenth century, and although the details of a vinery must be left largely in the hands of the builder, there are certain things which must be considered essential. The elevation, exposure and shelter, must be considered in choosing the site, and the situation should be high enough to ensure perfect drainage in all seasons. The aspect should, for preference, be due south, in order that the vines may receive the full benefit of the sun's rays from dawn to dusk. All the protection required is from the east. The best protection of all is provided by raised ground some distance away, so as not to obscure the morning sun, failing this a fairly high wall or belt of trees will afford the necessary shelter from cold east winds. Some growers object to the early morning sun reaching the vines, but this is, I consider, a mistake, for I would rather have one hour of sunshine in the morning than two in the afternoon. The best type of vinery for all purposes, in Scotland at all events, is what is known as the "semi-span." This is to be preferred to the "lean-to"—except, perhaps, for early forcing—more especially for mid-season and late varieties, because colouring and ripening of the fruit is aided considerably by the sun reaching the bunches through the back or hip roof.

A liberal heating system must be provided; the more heating surface the better: one foot of four-inch piping is required for every twenty-five cubic feet of space in the house. For early forcing and houses in exposed positions this amount may be increased, for it is false economy to fire so hard that the water in the pipes comes near to boiling point when the temperature is low outside, besides, the heat given off from very hot pipes parches the atmosphere of the house, and a dry atmosphere is detrimental to all plant life. What should be aimed at is to have enough heating surface to ensure the desired temperature in the house without overheating the pipes, even in severe weather. It is also an advantage, when a central heating arrangement is in use, to have the feeding pipes inside (return and flow) instead of outside, as is often the case, by which a considerable amount of heat is lost.

A trellis for training the vines is best made of galvanised wire, fixed not less than thirty inches from the glass and nine inches between the wires, running from end to end of the house and supported below each rafter by light iron bars. At one time, ten inches was considered the most suitable distance between the wires and the glass, but during the past forty years, it has been the practice to keep the leaves further and further away from the glass to prevent them becoming chilled by sudden changes in the weather and from being scorched by strong sunshine.

Thorough ventilation—top and bottom—is essential; the ventilators should run the full length of the house and be hinged at the top to open outwards, with suitable gearing or levers attached, so that the ventilators may be

opened either an half inch or a foot, as desired. Fresh air plays an important part in keeping the vines in health.

Drainage is of paramount importance, for the vines cannot thrive in a stagnant border. The bottom of the border should be concreted and have a gentle slope from the back to the front of the house, say a fall of a quarter of an inch to the foot. Formerly, the roots were allowed to work through arches into a border made outside the vinery, but this is not suitable for growing good Grapes in Scotland.

In the south of England, where the growing season is longer and cold in winter less severe, this practice is quite sound, but in the north, where heavy frosts are experienced in the late spring and early autumn—causing a big difference in the temperature between the outside and inside borders—making it impossible for the roots in the different temperatures to work in harmony, the vines break unevenly in the spring and the fruit do not finish well in the autumn.

In 1918 we planted a vinery at Scone Palace, details of which may be of interest. Muscat varieties were planted. The soil of the old border was taken out to a depth of three feet. A thin layer of concrete was laid on the bottom and the arches in front built in, leaving a single drain pipe just under the level of the concrete. The border was divided into compartments by building a single brick wall from back to front seven feet apart, which makes the wall on an average two feet four inches in height. (Building from the concrete to the height of the border.) A drain-pipe was laid in the centre of each division, connected with a pipe going through the front wall and taken into the main drain in front of the range. There were also a few short tiles laid at each side of the centre pipe in each division. The great advantage of this system of separate compartments in a vine border is that the roots of the individual vine are entirely under control and may be given the treatment most suited to the requirements of the different varieties. Water may be given to one vine and withheld from another; stimulants may also be given or withheld at will—which is impossible when the roots of all the vines in the border are allowed to ramify amongst one another; moreover, a vine may be taken out and replaced without interfering in any way with the others.

The drainage material consists of rough stones and brick-bats with coarse lime rubble on the top, to the depth of six inches in all. The lime keeps the fine particles of soil from washing into the drainage.

The soil used for making up the border consists of good, stiff loam taken from land under fairly old pasture; the grass, or as much as possible, was removed from the turf before it was lifted, to the depth of six inches. The turf was chopped up into squares of three inches and it was mixed with about equal parts of rough charcoal, rough lime rubble, old brick-bats—broken with a hammer into pieces about the size of road metal—and wood ash to the extent of one-third to the whole.

To make the soil more calcareous I gave a light dressing of carbonate of lime—air-slaked ground lime.

I am not in favour of having too much fibre in the soil for making up permanent vine borders, or any kind of organic matter which only lasts a limited period at the best, and when used up or washed away there is little left to sustain the plant, if what is left does not run together and become, more or less, a sour, sodden mass. Fibrous loam is undoubtedly the best rooting medium for growing pot plants, as the soil is renewed periodically, at a limit of two or three years, but a vine border is required to furnish food for the vines for a period of at least forty years. The compost recommended is sufficient to keep the vines growing in health and vigour for years.

The roots of the vine ramify through rough material and nothing seems to suit it better than an old stone and lime wall. All soils, or almost all soils, have iron present in sufficient quantity to meet the needs of all fruit-bearing plants but, like all other soil constituents, it is not always present in a suitable or available form. This want may be made good by apply-

ing sulphate of iron periodically; every four years is generally sufficient.

One hundredweight of vine manure was added to every five tons of compost in all the divisions of the border except one. In this division I gave a slight dressing of basic slag instead of vine manure, and strange to say, it has produced the best vine in the house so far, though the others are excellent.

In making up the border place a layer of thin turf grass downwards over the drainage, and use turves for building the retaining wall. Do not complete the border forthwith; a width of four feet is quite sufficient to begin with and should suffice for three or four years. It can be added to as the roots extend. With these additions the drainage should be a foot or so beyond the border. When adding to the border, remove the turf wall, and also the drainage down to the floor; add fresh drainage and extend the border three to four feet in the same way, and with similar material to that used for the original border. Have no scruples about cutting the roots of young vines, or vines of any age, for in a year's time there will be ten roots for every one cut. As the soil is being placed in the border, see that it is made firm, and it should be in position a month before planting in order that it may have time to settle. A depth of twenty inches of soil is ample above the drainage. The plants I used and those which I prefer are green canes, struck from eyes inserted in February, and grown on in the usual way in a warm house until the first of June. By that date, those planted were about six feet long; young vines grow with more vigour once they reach the trellis and are past the eaves of the house. One cane was planted in each division, two feet from the front wall, taking care not to injure the roots, which were made firm and copiously supplied with warm water. The house was kept close until growth was apparent. Should the weather be very hot soon after vines are planted, it may be necessary to shade the house during the middle of the day; this may be done by placing mats over the glass above the plants. As soon as the growth has fairly commenced admit air freely, using both top and bottom ventilators, thereby encouraging the development of strong, healthy leaves and firm wood, and insuring a good break for the following year. The leading shoot should be stopped, also all the side laterals except two, one at either side about 2½ feet from the ground; these again should be pinched at four feet to make the laterals break strongly, then allowed to grow on for the season. The temperature in the house was not high at any time, the top and bottom ventilators were practically always in use day and night, the air being reduced late in the evening, the temperature falling to 60° at night during August and 50° in September with very little heat in the pipes. Water was supplied to the roots as required. By the end of September the vines had made splendid growth and the wood was well ripened. In the winter, when the leaves had fallen, the centre shoot was taken out and the two—one at either side—cut back to a joint or two below where they were pinched, and a little above the first wire on the trellis. Care should be taken in the pruning of young double rods that the two rods on each vine are cut to the same level, otherwise the higher of the two will break into growth first and, as a rule, strongest.

(To be continued.)

## THE BULB GARDEN.

### GALTONIA CANDICANS.

It is usual to lift the bulbs of *Galtonia candicans* in the autumn and replant them in the spring, but in late districts it is not wise to do so, as the opening of the flowers is too long delayed. Planting the bulbs permanently necessitates a thorough preparation of the soil and attention to efficient drainage. Light, annual mulchings of rich manure, applied in spring, are beneficial to plants in permanent beds, and liquid manure may be applied to the roots freely in summer. *S. L.*

\* A lecture delivered by Mr. Malcolm Macnaughtan, Scone Palace Gardens, Perth, in the Technical College, Dundee, before the members of the Dundee Horticultural Association.

## HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

**Do Plants Know Time?**—The article in last week's issue, "Do Plants Know Time?" is very instructive and also, from the botanical side, very useful. Yet the explanations given are more or less on the floral organs and their cause of opening and closing. *J. F.* is quite correct when he states the more observations made the more complicated the subject becomes. We will consider *J. F.*'s explanation on Gentsians, Anemones, Daisies, and other Composites; this correspondent concludes that the opening and closing of the flowers of these types are due to incomplete growth, and he particularly refers to anthocyanin acted upon by the sun's rays. The opening and closing of the flowers of *Tragopogon pratensis*, he says, are autonomous (i.e., "self-governing") and also hereditary. Do not all flowers open through heredity? *J. F.* must admit that the incomplete growth must refer to the flower only, not to the plants of the four types; a plant has not completed its growth immediately the flower is closed or opened. That only applies to the gaiety of the petals or the beauty of the flower. Then it either drops, fades, or withers. There must be time for re-production in most cases. When I flowered the first specimen of *Dracaena Goldieana* I propagated several offsets that had sprung from the base of its cone-like inflorescence and raised a useful stock of plants. The second specimen that flowered belonged to this stock, and this would at once suggest heredity, for *Dracaena Goldieana* did open its flowers, whether the day was bright or dull. A few years ago I made some observations of an Evening Primrose (*Oenothera biennis*), growing under the shade of a large Horse Chestnut tree. On a dull day several flowers would remain open all day; again, on bright days, occasionally one or two flowers would remain open. In this case the "day and night shifts" must have been greatly disorganised and not working correctly. The probability is that the heavy shade of the tree was a false indication to the plant that twilight was near. Still, the plant was not out of time in ripening its seed and dying down. I do not take it that because a flower opens at a given time that the plant (as we understand it) knows the time of day, but rather that the plant has a limited time to develop all its functions and understands that, whatever the conditions may be, it must either retard or hurry growth accordingly. *Mark Mills, Coombe House Gardens, Croydon.*

**Roofing of Garden "Fruit Cages."**—For some thirteen or fourteen years I have had personal experience in the cultivation of soft fruits in a wired-in enclosure. For ten years only Currants and Gooseberries were grown under that system, and I am quite certain that there were no detrimental effects on the Gooseberries or Currants in either their growth or cropping. This particular fruit cage was completely wired in, and the only means of access for birds was through two small gates, one at either side. In these gardens, during my first year here, a fruit cage was erected in which Gooseberries, Currants, Raspberries and Cherries are grown, and during that season Cauliflower and Lettuce were planted between the rows of fruit bushes and did remarkably well. Whether zinc salts are dissolved or not, I have nothing to show that anything harmful has happened, but rather the contrary, for all bushes have cropped well, and their growth is all one can desire. I do not like the method of a complete enclosure, for these reasons: (1) That there is not sufficient access for birds; and (2) not enough air is admitted after the crops are gathered. This, to me, seems to confirm the idea that temperature in the cage is affected. The method I have adopted here is to have a fixed wire-netting roof with the sides open, so long as it is safe to have them so, then a string netting is suspended from the roof frame-work by means of hooks screwed in at frequent intervals. It has the desired effect, is easy to manipulate, and just as easy to dismantle. *G. H. Preece, Heathlands Gardens, Kinner, Staffordshire.*

## SOCIETIES.

## NATIONAL ROSE.

APRIL 21.—The spring show of this society, which was held in the London Scottish Drill Hall, Westminster, attracted the customary large number of enthusiasts that attend all the society's functions, and, as usual, the new Roses were the chief objective. These were not so numerous as usual, nor were they of such high quality as at most of these spring shows, so only three Certificates of Merit were awarded. But the general quality of the show was very good, and it is pleasant to be able to record that the very best Roses were shown by amateurs.

The Silver Medal for the best bloom in the nurserymen's classes was won by Mr. A. T. GOODWIN with one of his magnificent blooms of *Maréchal Niel*, while Mr. HAMMOND won the honour in the amateurs' section with a beautiful bloom of *G. Amédée Hammond*.

Besides the competitive collections there were groups of excellent *Polyantha* varieties by Messrs. W. H. CUTBUSH AND SON, and H.T. varieties by Mr. W. EASLEA; Carnations by Messrs. ALLWOOD BROS. and Mr. C. ENGELMANN; Alpines by Messrs. J. CHEAL AND SONS; and St. Bridgid Anemones by Messrs. REAMSBOTTOM AND CO.

## CERTIFICATES OF MERIT.

**Sovereign.**—This is a gorgeous *Pernetiana* seedling of rich golden yellow colour, heavily flushed with dull carmine on the buds and half-open flowers. The blooms are fully double, of flattish, globular shape, and have a pleasing fragrance. The foliage is luxuriant and of lustrous rich green colour. It is recommended for general garden purposes. Shown by Messrs. B. R. CANT AND SONS.

**Elsie Beckwith** (see Fig. 114).—A deep rose-pink H.T. variety, much resembling *Richmond*, and, like that variety, it produces long, moderately stout stems that are so valued for decorative purposes. The foliage is good, and it seems a variety that will have a great future as an early market Rose, as well as in the private garden. Shown by Messrs. G. BECKWITH AND SON.

**Mrs. Hornby Lewis.**—A dwarf, vigorous, H.T. Rose that carries its blooms well above the luxuriant, dark-green leaves on stout, erect stems. It is a globular, fully double bloom of chrome-yellow colour, shaded with Malmaison pink in the centre. Shown by Mr. ELISHA J. HICKS.

## OTHER NOVELTIES.

**Dorcas**, a floriferous *Wichuraiana* seedling, stated to be a cross between *Minnehaha* and *Orleans*, was shown by Messrs. ENGLISH AND SON. It bears large trusses of rather more than semi-double flowers that are midway in colour between *Blush Rambler* and *Mrs. W. H. Cutbush*. The soft pink blooms have a pale, nearly white, eye. *Mrs. T. English*, shown by the same growers, is a vigorous H.T. variety of apricot-fawn colour, shaded with salmon pink. The foliage was good, but the variety was scarcely of certificate quality.

## NURSERYMEN'S CLASSES.

The only group of Roses in Class 1 was by Mr. ELISHA J. HICKS, and this was awarded the first prize. He confined himself to pot plants, and of these the young examples of *Gorgeous*, *Mrs. E. Hicks*, and *Columbia* were very good. Of the taller plants *Paul's Scarlet Climber* and *Ophelia* were the best. Mr. HICKS was also the only exhibitor in the classes for sixty Pillar Roses and for a group of *Polyantha* Roses, and in each case he was awarded the first prize. He included good examples of *White Tausendschon*, *Orleans*, and *Ellen Poulsen*.

There were two groups of cut Roses on staging, and these made admirable displays. The first prize was won by Messrs. B. R. CANT AND SONS with a good representative collection, which included beautiful vases of *Sovereign*, *Phoebe*, and an unnamed seedling of rich yellow colour, shaded with orange buff. Amongst the tall

stands *Goldinch*, *Paul's Scarlet Climber*, *Constance Cassoon*, and *Covent Garden* were excellent. In the second-prize exhibit by Mr. GEORGE PRINCE, there were tall stands of *Sadie* and *C. E. Shea*, and beautiful vases of *Mrs. C. Lamplugh* and *Muriel Wilson*.

Although the competition was limited, the exhibition Roses were very good indeed. The first prize was won by Mr. E. J. HICKS with a very even collection of such sorts as *Gladys Holland*, *Mrs. Foley Hobbs*, *Crusader*, *Mrs. E. J. Hicks*, and *George Dickson*. In the second-prize collection of Messrs. B. R. CANT AND SONS there were splendid blooms of the *Rev. F. Page Roberts* and *Mrs. Edward Mawley*, but this high quality was unfortunately not sustained. Mr. A. T. GOODWIN staged a dozen magnificent blooms of *Maréchal Niel*, which was deservedly awarded the first prize.

In the class for three baskets of cut Roses there was only one exhibitor—Mr. E. J. HICKS and he was awarded the first prize; *Mrs. Curdock Sawday* and *Lady Hillingdon* were very handsome varieties. Mr. A. T. GOODWIN showed super-excellent *Maréchal Niel* Roses in the class for one basket, and Mr. PRINCE was second with very good blooms of *The Padre*. The open class for a decorated dinner table did not induce much competition, but *Mrs. A. R. Bide*, who won the first prize, arranged a very beautiful table with *Columbia* Roses and sprays of *Japanese Maple* and *Asparagus plumosus*. *Mrs. L. R. Max*, *Waltham Cross*, was second with a tasteful arrangement of *Sunburst* Roses and *Japanese Maple* foliage.

The bowls of Roses in this section were not very noteworthy. Mr. HICKS was placed first with a bowl of *Joanna Bridge*, which was very thin and had over-much foliage; while *Mrs. A. R. Bide* was second with a rather formal arrangement of *Madame Butterfly*.

New Roses put into commerce since the beginning of last year were limited to an exhibit of six varieties by Mr. E. J. HICKS, who received the first prize for good blooms of such sorts as *Earl Haig*, *Premier*, *Crusader*, and *Glory of Steinfurth*.

## AMATEURS' CLASSES.

The two groups of cut Roses arranged on staging were highly creditable. Mr. E. J. HOLLAND, *Sutton*, was first with an excellent collection which included beautiful blooms of *Wm. Sheau*, *Mrs. Foley Hobbs* and *Caroline Testout*. Mr. G. A. HAMMOND, *Burgess Hill*, was second, and he had very good vases of *Rev. F. Page Roberts* and *Mrs. Foley Hobbs*.

The twelve exhibition blooms with which Mr. E. J. HOLLAND won the first prize formed the best collection in the show, and were equal in quality to the premier blooms at a summer show. His chief varieties were *Louise Crette*, *Mrs. Foley Hobbs*, and *Wm. Sheau*. Mr. G. A. HAMMOND was an exceedingly good second, and he only lost first place by the slightly more even quality of his competitor's blooms. Mr. HAMMOND had splendid examples of *J. L. Mock*, *Mrs. Foley Hobbs*, *G. Amédée Holland*, and *Mrs. R. K. McClure*.

The first prize six exhibition blooms, by Mr. H. L. WETTERN, *Oxted*, were also of high quality. His best blooms were of *Melanie Soupért*, *Mrs. E. Mawley*, and *Wm. Sheau*. With a pretty arrangement Mr. WETTERN was also first in the class for a basket of mixed varieties, while Mr. HAMMOND was placed similarly with an excellent basket of *G. Amédée Hammond*, a delicately perfumed Rose like a pale *Maréchal Niel*.

The amateurs' decorative classes were particularly successful, and there was a great competition of dinner tables, where the first prize was won by *Mrs. OAKLEY FISHER*, *Sudbury*, with a pretty table of *Sunburst*, and *Mrs. CHARLTON*, *Viewsley*, was second with *Madame Butterfly*. The best bowl of cut Roses was by *Mrs. CHARLTON*, who used the variety *Richmond*. *Miss ETHEL JAMES*, *Abingdon*, beat four competitors with a beautiful vase of *Madame Butterfly* Roses.

## MIDLAND DAFFODIL.

APRIL 20, 21.—The extent of this society's annual show, held at the Birmingham Botanical Gardens on the above dates, suffered much from the very cold—almost arctic—weather experienced over the greater part of these isles during the past few weeks. It was, therefore, not to be wondered at that Midland and Northern growers were only sparsely represented, the biggest number of the seventeen competitors coming from the warmer parts of the country and Ireland. Nevertheless, the large exhibition hall and adjacent glass-roofed building were well filled with flowers of good quality. It was a show of Daffodils only, there being no other flowers or exhibits of any sort on this occasion. J. LIONEL RICHARDSON, Esq., a new exhibitor from Ireland, is to be congratulated upon his first appearance at Birmingham. His flowers were of first-rate quality.

At the annual general meeting, held during the afternoon of the first day of the show, Dr. N. Y. LOWER, an enthusiastic amateur grower and regular exhibitor, was elected president for the ensuing year; the other officers and committee were re-elected. Later in the day a number of Daffodil lovers met at the Grand Hotel, Birmingham, under the genial chairmanship of the Rev. T. BUNCOMBE, and took part in an impromptu discussion on eel worm, improving the Society's schedule of prizes, and other matters. Mr. and Mrs. W. CAREY-HILL, of Christchurch, New Zealand, visited the show, and in the evening Mr. CAREY-HILL gave his impressions of the show and referred to the improving position of the Daffodil in New Zealand. It was arranged to send a letter of sympathy to the Rev. JOSEPH JACOB, chairman of the Society, in his long and serious illness, together with an expression of joy at his steadily improving health. This is the first Midland Daffodil Show Mr. Jacob has missed since the inception of the Society. We were glad, however, to see Mr. Jacob at the meeting of the Royal Horticultural Society on Tuesday last.

## OPEN CLASSES.

The biggest class in the open division was for 36 varieties, representing the different types of the Daffodil. The schedule called for one vase of three stems of each variety. There were two exhibits, and the first prize was awarded to J. LIONEL RICHARDSON, Esq., Waterford; 2nd, the Rev. T. BUNCOMBE, Black Torrington, Devon. The flowers in the first-prize collection were beautifully fresh and well set up. A few of the best varieties were Firetail, Macebearer, Glorious, Whitewell, Cleopatra, Noble, Victory, Herod, Lord Kitchener, Bernardino, and Mrs. Robert Sydenham. The Rev. T. BUNCOMBE's best flowers were Noble, Coeur de Lion, Bernardino, and Great Warley.

The DONARD NURSERY Co., Newcastle, Co. Down, won first prizes in classes for (1) 12 *Trumpet Daffodils*, with splendid blooms of White Emperor, Comely, Everest, Mrs. Robert Sydenham, and Lady Primrose; (2) 6 *white Trumpet Daffodils*, with grand examples of Everest, White Emperor, Mrs. Krelage, and White Knight; 2nd, Mr. F. H. CHAPMAN, Rye; (3) 6 *bi-colour Trumpets*, in which Moira O'Neill, Selina Malone, and Florence Pearson were of outstanding merit; 2nd, Rev. T. BUNCOMBE; and (4) 6 *yellow Incomparabilis* with good blooms of Leonte, Croesus, Noble, Donax Dingo, and 283; 2nd, Rev. T. BUNCOMBE.

Mr. F. H. CHAPMAN excelled in the class for 6 *yellow Trumpet varieties*, with uncommonly good flowers of Regal, Roughcast, Apotheosis, Millennium, Rampart, and Cinema. The Rev. T. BUNCOMBE and the DONARD NURSERY Co. were bracketed equal 2nd, with Mr. J. MALLENDER, Scrooby, 4th. Mr. F. H. CHAPMAN also won first prizes in classes for (1) 6 *yellow Barrii varieties*, (2) 6 *bi-colour Barrii varieties*, and (3) 6 *Leedsii 4a*. J. LIONEL RICHARDSON, Esq., was placed second in each of the two last-named classes, and first for (1) 6 *bi-colour Incomparabilis*, with choice flowers of Pedestal, Whitewell, Great Warley, Bernardino, Victory, and Lady Boscawen, and (2) 6 *Poeticus varieties*. The Rev. T. BUNCOMBE won the first prize in the class for 6 *Leedsii 4b*.

## SINGLE BLOSSOMS.

*Yellow Trumpet*.—1st, H. G. HAWKER, Esq., Ivybridge, with a magnificent bloom of Cleopatra; 2nd, J. LIONEL RICHARDSON, Esq., also with Cleopatra. *White Trumpet*.—1st, J. L. RICHARDSON, with White Knight; 2nd, the DONARD NURSERY Co., with White Emperor. *Bi-colour Trumpet*.—1st, the DONARD NURSERY Co., with Lady Primrose. *Yellow Incomparabilis*.—1st, Mr. W. A. WATTS, St. Asaph, with Brightling. *Bi-colour Incomparabilis*.—1st W. F. M. COPELAND, Esq., with a seedling, No. 1,015. *Barrii*.—1st, F. H. CHAPMAN, Esq., with 3 G.17. *Bi-colour Barrii*.—Mr. J. MALLENDER, with Jessie.

of his own raising were of great merit, particularly Nero, Mrs. Lower, Beauty of Radnor, Ingot, and Clarion; 2nd, F. H. CHAPMAN, Esq., who had exquisite flowers of Spellbinder, Eminent, and Postmaster.

The Cartwright Challenge Cup was offered for twelve varieties, but the schedule did not require them to be raised by the exhibitor. The first prize was won by Mr. CHAPMAN, with grand flowers of Robin Redbreast, Fortune, Salcote, Robin Adair, Magnolia, and Pilgrim Father; 2nd, the DONARD NURSERY Co., with beautiful specimens of Festive and Leontes; 3rd, Dr. N. Y. LOWER.

FIG. 114.—ROSE ELSIE BECKWITH; SEE AWARDS OF THE NATIONAL ROSE SOCIETY, P. 216.

*Leedsii 4a*.—1st, the DONARD NURSERY Co., with Tenedos; 2nd, F. H. CHAPMAN, Esq., with Magnolia. *Leedsii 4b*.—1st, J. LIONEL RICHARDSON, Esq., with Ivorine; 2nd, H. G. HAWKER, Esq., with Roster. *Triandrus hybrid*.—1st, W. F. M. COPELAND, Esq., with T.25; 2nd, the DONARD NURSERY Co., with Harvest Moon. *Cyclamineus hybrid*.—1st, F. H. CHAPMAN, Esq., with 1. E.15. *Jonquilla hybrid*.—1st, J. LIONEL RICHARDSON, Esq., with Glorious. *Poeticus*.—1st, H. G. HAWKER, Esq., with Snow King. *Double*.—1st, W. F. M. COPELAND, Esq., with a seedling, No. 1,011; 2nd, Miss HINCHCLIFF, with Golden Rose.

## SEEDLINGS AND NEW VARIETIES.

There was a good competition in the class for the Bourne Challenge Cup, and last year's winner, Dr. N. Y. LOWER, Presteign, retains the cup for another season. The twelve varieties

The Walter Ware Challenge Cup, offered for three varieties of Daffodils bunched for market was won by the DONARD NURSERY Co., which showed large rather loose bunches; 2nd, W. A. WATTS, Esq., with smaller and more compact examples.

The "White" Daffodil Trophy was offered for six varieties of white Trumpet Daffodils. First, the DONARD NURSERY Co., with delightfully fresh flowers of Mrs. Robert Sydenham, Mrs. Krelage, Everest, White Emperor, White Knight, and 73; 2nd, F. H. CHAPMAN, Esq.; 3rd, Dr. N. Y. LOWER.

The following exhibitors were awarded first prizes in small classes for seedling Daffodils, viz.: MESSRS. WATTS, THURSTAN, RICHARDSON, and the DONARD NURSERY Co.

[Our remarks on the Amateurs' Classes will be published in the next issue.—EDS.]

## EXHIBITION AT THE HAGUE.

NOTWITHSTANDING the lateness of the season in Holland, an exhibition of considerable size and beauty was arranged in connection with the meeting of the Fédération Horticole Professionnelle Internationale, at the Zoological-Botanical Gardens, The Hague, where a large and handsome concert hall with wide stage, spacious galleries and several annexes was filled with plants, flowers and horticultural sundries.

As in the case of so many other Continental exhibitions, the individual exhibitor had to fall into line with the conditions laid down by the director of the exhibition, and did so for the sake of assisting to make the exhibition a beautiful picture. We believe that if the council of the Royal Horticultural Society would provide a design for one of its fortnightly shows, and allow its exhibitors to fill certain spaces under a few general conditions, the appearance would be so vastly improved that the long rows of tabling would seldom be requisitioned again.

The show at The Hague presented a picture designed by an artist and executed by horticulturists. The width of the hall did not permit the breadth of design characteristic of Ghent and Antwerp, but, nevertheless, the view on entering the main hall was a perfect one of its kind. Vantage points were occupied by great vases of Lilac, pillars were draped with tall palms and big Rhododendrons and Azaleas, while down the centre a restful lawn of grass led the eye between masses of Hydrangeas and great groups of Lilacs, to the gorgeous colouring of Anthuriums and the grace of Orchids, and beyond, to a garden of delight on the ample stage, where, in a setting of greensward, Rhododendrons, Azaleas, Cherries, and other early flowers were grouped in the most charming manner possible.

Daffodils and Hyacinths were conspicuous by their absence in the general scheme and only two or three exhibits of the former were to be found in the galleries.

We make no pretence to report all the exhibits, and refer only to those which appealed to us by reason of their beauty of form or colour, their rarity or their novelty.

The mention of novelties brings us at once to consider the exhibit from Messrs. JAN BOER AND SON, Boskoop. This filled the side entrance lobby with banks of Rhododendrons, Pyrus, Cerasus, Thorns, Wistaria, and Guelder Roses, most charmingly and harmoniously displayed. But of even greater interest was the semi-circular group of new Hydrangeas. Of these, the one with the deepest rose coloured heads of fringed bracts was named Elmar, and it is a grand variety, and wonderfully distinct; Lorely has larger heads and bracts of rose-pink colour; Helga has pink, white-centred "flowers"; Westfalenkind has enormous heads of immense "flowers" of a pink shade, often tinged with green when young; Parsifal is of intense rose colour, small as to individual bracts and deeply fringed, but making up big heads of bloom. This was probably the most striking novelty exhibited, but we cannot agree with the exhibitor's colour description of "blood red." Messrs. J. BOER AND SON received numerous awards.

THE DUTCH PLANT EXPORTERS' ASSOCIATION (Mr. W. F. WERY), The Hague, showed a rich salmon-orange coloured Mollis Azalea named Herr G. Van Noordt; a most effective variety. Larger flowered and more in accord with British tastes was the one named Legaticraad Greist. He also displayed two big vases of a new white Lilac named Jan van Tol, which has longer segments than is usual with individual flowers; the latter are borne in very large thyroid panicles. Mr. WERY also filled one annexe with an elegant and brilliant display of Mollis Azaleas associated with Japanese Maples in variety, Rhododendrons, Ghent Azaleas, Cytisus praecox, Pyrus floribunda, Laburnums, Viburnum Carlesi, Cerasus Hisakura and very fine (but we beg leave to doubt the correctness of the name), Wistarias, and the bright polyantia Rose Jessie, the whole backed by columnar Yews. A group of Rose Jessie in a big earthenware vase occupied a prominent position and was a centre of admiration.

Two of the handsomest groups in the great hall were staged by Messrs. BEIR AND ANKERSMIT, Ghent, and consisted of well grown plants of hybrids of *Cymbidium insigne*, of the Paulwelsi, Gottianum and Dryad types (Gold Medal). This firm also exhibited an enormous specimen of *Cymbidium Lowianum*, and one, we believe, we have seen before at Ghent and Antwerp. It carried about thirty spikes of its green and red-marked flowers. Four large groups of white Hydrangeas, each plant a large specimen and one carrying 36 heads, were at the corners of a small lawn; these were edged with Ferns, chiefly *Nephrolepis*, but the display also included two beds of *Selaginella Watsoni* and two huge vases of white Lilac. This contribution was set up by Mr. R. EGGINK, Voorschoten.

It was pleasing to discover two groups of the graceful *Adiantum Farleyense* var. *Roem van Moordrecht*, shown by Mr. J. BIER, Moordrecht, Close by were two oval beds of superb Lily-of-the-Valley, from Messrs. C. J. SPEELMAN AND SONS, flanked by banks of finely-flowered plants of the best broad-spathed forms of the Scarlet *Anthurium Scherzerianum*, shown by Mr. G. J. BIER, Nieuwerkerk, for which a Gold Medal and other awards were granted.

A gigantic *Alsophila Scheidei*, a big *Cycas revoluta* and a huge specimen of *Philodendron odoratum*, with a few well flowered *Vanda suavis* served to fill a big corner near the stage; these were set in a little lawn, with a very few *Gloxinias* and *Primula obconica* to give a touch of colour. In the opposite corner, a huge *Pandanus*, another *Philodendron*, various *Nidulariums* and other *Bromeliads* and *Vandas* were grouped, and each group was presented by the DIRECTOR OF THE BOTANICAL GARDENS.

Lovers of succulent plants and particularly those of our readers who are following Mr. N. E. Brown's articles with close intent, would have been greatly interested in the collection staged by Mr. T. JANSEN, The Hague, in the gallery. The various species of *Opuntia*, *Euphorbia*, and *Pilocereus* and even the fine, flowering example of *Cereus flagelliformis*, may be passed over without further comment, because for us interest centred in the collection of stones flung together—apparently without purpose—in the centre of the group. We confess that some moments had elapsed ere we grasped the true design of Mr. Jansen, but presently we espied a little plant of *Mesembryanthemum Lesliei*, almost like the stones around it; and then, interest awakened, we searched for and found we specimens of *M. Bolusii*, *M. pallidum*, *M. pusillum*, *M. karasmontanum*, and *M. pseudo-truncatellum*. A little later Mr. Jansen became interested in our close scrutiny of his bit of stony desert, and in conversation with him we found he was a correspondent of Mr. N. E. Brown, and indeed, it was from the collection of the latter that Mr. Jansen received his examples of *M. Lesliei*—so we have been to The Hague to see some of the interesting South African species Mr. Brown has written about, whereas half an hour's walk from our home would suffice to bring us to Mr. Brown's private collection!

Mr. A. J. STEMERDING, a Hague florist, filled the back of the wide stage in charming fashion. Rhododendrons, chiefly Pink Pearl, were set in front of big *Kentias* and *Phoenix Roebelinii*, while two groups of pink Azalea occupied positions on the lawn. At one corner Ghent Azaleas were grouped with pale mauve Irises of the pallida type, and at the opposite corner there was a somewhat similar arrangement, with *Cinerarias* and *Cherries* in perfect harmony. A semi-circular lawn filled the front part of the stage, leaving ample room to promenade between it and the group just referred to. Here, however, Azaleas were disposed in a couple of groups, whilst red-leaved *Cordylines* with *Azalea indica* and *Aralia Veitchii* rising over a ground work of *Saxifraga sarmentosa variegata* were other fine features. The whole stage was thus occupied by Mr. STEMERDING, and a Gold Medal was deservedly awarded.

A glorious exhibit of forced Lilac from Mr. W. G. TAS AND SON, Aalsmeer, arrested the attention of the Britishers. The Lilac was

arranged in three bold masses, each from 8 to 12 ft. wide, set in a ground work of *Azaleas*, *Genista fragrans* and giant *Mignonette*. Some of the Lilac plants carried eighteen splendid heads of bloom. White, blush and deep mauve-purple varieties were exhibited and a Gold Medal was one of the several awards granted.

Numerous presentations of floral art were made, and a combination of *Ophelia* Roses and deep mauve Lilac in a big basket was capital, but Tulips with the three outer segments turned back were monstrous. Floral designs, with flowering and foliage plants, set so as to show their usefulness in certain positions and colour surroundings, were made a feature by M. W. de HAAN, The Hague. The Scarlet *Cineraria Matador* was grandly shown by M. A. MAARSE, Aalsmeer, who also showed small *Azaleas* finely flowered.

A fair sized and somewhat thinly arranged group of Orchids from Mr. J. W. VAN DE GRAAF, Bennekom, contained an assortment of *Odontoglossum* hybrids, and *Odontodas*, with a few examples of *Odontoglossum crispum xanthotes*, but the whole display would have secured only a small award at an ordinary R.H.S. meeting.

The only exhibit of Carnations was the one submitted by Mr. H. V. CLINGENAALSCHIE, Kweekerij, and it included good flowers of such well-known British grown sorts as White Pearl, Nigger, Saffron, Circe, Mrs. Raphael, Jessie Allwood, Laddie and Eileen Low. The RYSWYK SCHOOL OF HORTICULTURE sent a capital selection of early vegetables and salads, some forced Strawberries, and some of the finest spikes of white and mauve Stocks we have ever seen.

Daffodils were represented by two small groups in one of the galleries, arranged respectively by Messrs. MELOCK HOUSON AND Co., Zierikzee, and Mr. G. TUNBE, Oegstgees. Icicle, Pharaoh, Cygnet, and Mount Everest, were a few outstanding varieties. In addition to these, Messrs R. H. BATH, Wisbech, showed a few dozen very fine and brilliant coloured flowers of Bath's Flame, which attracted considerable attention.

An interesting exhibit of winter-flowering Sweet Peas set up by Mr. H. CARLEE, Kweekerij, contained fair-sized, bright blooms of varieties named Glitters, Lavender King, Father Christmas, Fire King, Early Blue and Enchantress. The same firm showed a few coloured *Freesias*, but these were eclipsed by the vases of splendid flowers of *Apothécose*, and of Daffodil, a large-flowered yellow, orange-yellow throated variety, exhibited by Mr. C. J. VAN TUBERGEN. The alpine gardening exhibits were not especially good, if we except M. REISER's group, but somewhat regular planting rather spoiled the general effect.

Near the tea room, Messrs. H. WARMENBOON AND SON, Hillegom, showed a grand lot of *Hippeastrums*, including a splendid strain of rich orange-scarlet flowered forms; some pure white; white, feathered with pink; and white grounds, flamed with orange-scarlet. This was a most effective and satisfying display and gorgeous in the extreme.

Altogether we have to congratulate our Dutch friends upon the attendance at the show, its interesting horticultural features and, particularly, upon its delightful arrangement.

## ROYAL HORTICULTURAL.

APRIL 25 AND 26.—A very fine exhibition was held on these days, and those who could not find ample interest in it, and especially in the large number of novelties which gained awards, would be hard to please. It was also a bright display wherein Daffodils, Rhododendrons, Roses, flowering shrubs, Orchids and Carnations were leading features. In addition to the Orchids, there were about four dozen groups in the hall.

## Orchid Committee.

Present: Sir Jeremiah Colman, Bart. (in the chair), Messrs. James O'Brien (hon. secretary), R. Brooman White, Arthur Dye, C. J. Lucas, Fred. K. Sander, H. T. Pitt, Thomas Armstrong, A. McBean, W. J. Kaye, E. R. Ashton, Pantia

Ralli, Gurney Wilson, Richard G. Thwaites, C. H. Curtis and S. W. Flory.

## AWARDS.

## AWARD OF MERIT.

*Aëranthus (Angraecum) Leonis* from Sir HERBERT LEON, Bart., Bletchley Park, Bucks. A fine specimen of the plant originally illustrated in *Gard. Chron.*, July 18, 1885, pp. 80-81, from one of the earliest importations from the Comoro Islands, and which received a First-Class Certificate when shown by Sir TREVOR LAWRENCE and other exhibitors at the R.H.S. meeting on August 25, 1885, as *Angraecum Humblotii*, a more generally accepted name commemorating the discovery by the collector Humblot. The plant is unique in form, with hard, compressed, equitant foliage, and sprays of fragrant white flowers with remarkable long and twisted spurs.

*Catasetum Trulla, Dovercourt variety*, from Dr. F. BEDFORD, Esleforde, Marden, Kent. A remarkable variety, differing from the type in having flowers with sepals and petals coloured entirely dark maroon purple, and trowel-shaped, fleshy, yellow lip.

*Brasso-Laelio-Cattleya Truffautiana, Low's variety (B.-C. Mrs. J. Leemann × L.-C. luminosa)*, from Messrs. STUART LOW AND Co., Bush Hill Park, Enfield, and Crowborough, Sussex. A fine and distinct hybrid, with large flowers having yellow sepals and petals, tinged with emerald green, and a broad, magenta-rose coloured lip, with light yellow lines from the base.

## GROUPS.

Messrs. SANDERS, St. Albans, were awarded a Silver Flora Medal for an artistically arranged group with a fine specimen of *Vanda suavis* in the middle, *Cymbidium insigne Sanderi*, *Phalaenopsis amabilis* and *Rimestadiana*, and many showy *Dendrobiums*, *Odontiodas* and *Odontoglossums* being displayed on either side. Among the rare species noted were *Trias picta* with its singular red flowers nestled among the little pseudo-bulbs, the true *Xylobium leontoglossum* and various *Coelogynes*. Messrs. STUART LOW AND Co., Crowborough, Sussex, were awarded a Silver Flora Medal for a good group, in which *Odontiodas*, *Odontoglossums* and *Laelio-Cattleyas* were the principal features. The new *Brasso-Cattleya Medea (C. Dusseldorfei Undine × B.-C. Digbyano-Mossiae Queen Alexandra)* had good, rosy-lilac tinted flowers, which did not, in this instance, carry on the albino characters of the parents. A choice selection of species included *Saccolabium ampullaceum*, *Dendrobium triphyllum*, various *Cirrhopetalums* and *Bulbophyllums*, the charming white *Disa sagittalis* and a selection of *Cattleya Schröderae*. Messrs. J. and A. McBRAN, Cooksbridge, were awarded a Silver Flora Medal for a pretty group, in which their charming *Laelio-Cattleya Eunice* varieties were prominent, with splendid, branched-spiked white *Odontoglossum Pescatorei*, and many richly coloured hybrids, the best of which was the deep claret-red *Odm. Lambesuanum var. Mars*, and *Odm. Theo. (Otbello × Queen Alexandra)*. The finest dark *Odm. Harryanum* and a good *Odm. Waltoniense* were also shown. H. T. PITT, Esq., Rosslyn, Stamford Hill (gr. Mr. Thurgood), was awarded a Silver Banksian Medal for a small, but very select group, including the famous *Miltonia vexillaria* Princess Elizabeth, *M. Bleuana Hesse* variety, two grand forms of *M. Venus* and some pretty species. Messrs. FLORY AND BLACK, Slough, were awarded a Silver Banksian Medal for a group of fine hybrids, including the handsome *Sophras-Laelio-Cattleya Joseph Charlesworth* and the new *Laelio-Cattleya Wiswynne (C. Mossiae × L.-C. Bellatrix)*, rose coloured with claret lip.

## OTHER EXHIBITS.

Dr. F. BEDFORD, Esleforde, Marden, Kent, showed the extremely rare *New Guinea Dendrobium Ashworthiae*, originally imported by Messrs. Sanders through their collector, Micholitz. It is of the *D. atro-violeaceum* class, the sepals being primrose yellow and the lip and petals white, the lip having small purple lines at the base. RICHARD G. THWAITES, Esq., Chessington, Streatham Hill, showed the clear white *Cattleya Mary Sander*, Thwaites' variety.

## Floral Committee.

Present: Messrs. H. B. May (in the chair), H. V. Warrender, W. P. Thomson, Sydney Morris, R. C. Notcutt, W. B. Gingell, Arthur Turner, J. F. McLeod, H. J. Jones, W. Howe, G. Harrow, W. J. Bean, G. Reuthe, Donald Allan, John Heal, C. R. Fielder, Chas. E. Pearson, Thos. Stevenson, John Dickson, Hugh Dickson, Chas. E. Shea, D. B. Crane, W. R. Dykes, J. W. Barr, Clarence Elliott, W. B. Cranfield, Reginald Cory and James Hudson.

## NOVELTIES.

## AWARDS OF MERIT.

*Azalea Fraternelle*.—This and the following varieties represent a new strain known as the Kersbergen Azaleas. They are characterised by flowers of large size and exquisite shades of colour; in short, they are somewhat glorified *Mollis* sorts. *Fraternelle* has light salmon-coloured flowers with yellow markings on the upper segment.

*Azalea Thomas More*.—Flowers of wonderful size, light salmon pink, with fawn suffusion, and yellow markings on the upper segment and on the upper halves of the next segments. A very fine Azalea.

*Azalea Chicago*.—The deepest coloured variety shown; rich orange-copper, with deep orange markings on the upper segment.

*Azalea Frederick Engels*.—Not so shapely as other sorts, but of rich salmon-rose colour suffused and marked with orange. The above four varieties were all shown by Messrs. R. WALLACE AND Co., Tunbridge Wells.

*Rhododendron Souv. de D. A. Koster*.—A free-flowering and brilliant variety bearing large trusses of rounded flowers. The colour is light crimson scarlet, with spottings of crimson brown on the upper segment. Shown by Messrs. WM. CUTBUSH AND SON, Highgate.

*Rhododendron Aurora*.—A grand hybrid obtained by crossing *R. kewensis* with *R. Thomsonii*. The wide-spreading flowers are of a bright and rich rose-cerise shade, the buds being deep red; thus the influence of *R. Thomsonii* is seen in the colour (and also the leaves), while the form of the flower is more like that of *R. kewensis*. Shown by Mr. LIONEL DE ROTHSCHILD, Exbury, Hants.

*Aubrietia Maurice Prichard*.—In this large-flowered variety the yellow-edged flowers are of a pleasing shade of lavender-mauve. Shown by Mr. MAURICE PRICHARD, Christchurch.

*Streptocarpus Sutton's Giant Blue*.—The flowers, of enormous size, are of fine form and carried erect on stiff stems. The colour is a pleasing shade of medium blue, with white throat. A truly giant flower, and most effective. Shown by Messrs. SUTTON AND SONS, Reading.

## GROUPS.

A large and interesting collection of alpines of the type suitable for growing in a cool house was shown by the VISCOUNTESS NORTHCLIFFE, Brickthorn Hill, Crowborough. The many different sorts included useful plants of *Saxifrages*, *Sedums*, various alpine *Anriculas* and *Primulas*, *Armeria caespitosa* and *Gentiana verna*, and all illustrated good cultivation (Silver-Gilt Banksian Medal).

Many Polyanthuses of great merit and attractively arranged with moss in the form of a gentle sloping bank were contributed by Mrs. BERKELEY, of Spetchley (Silver Flora Medal). The REDEN'S SCHOOL OF GARDENING and Mr. G. W. MILLER also showed many Polyanthuses. Mr. Miller included various other spring flowers, including *Crown Imperials* (Silver Banksian Medal).

Alpines were contributed by Mr. M. PRICHARD, Messrs. R. TUCKER AND SON (Silver Banksian Medals), Messrs. B. LADHAMS, LTD., Messrs. SKELTON AND KIRBY (Bronze Flora Medals), Messrs. MAXWELL AND BEALE, and Messrs. WATERER, SONS AND CRISP (Bronze Banksian Medals), while small informal but pleasing rockeries, suitably planted, were exhibited by Messrs. WM. CUTBUSH AND SON, and Messrs. G. G. WHITELEGG, who included varieties of *Iris Bucharica* (Silver Banksian Medal).

A very large and attractive group of flowering shrubs was arranged on a floor space by Messrs. WALLACE AND Co. *Rhododendrons* were very prominent, and included excellent examples of

Princess Juliana, a bluish variety, which has pretty crimped margins, and *Hugo de Vries*, said to be a cross between *Pink Pearl* and *Doncaster*, but it favours the former greatly and is very handsome. *Mollis* and *Ghent Azaleas* were also largely shown (Silver-Gilt Banksian Medal).

Some early hybrid *Rhododendrons* and other shrubs were included by Mr. G. REUTHE with his customary exhibit of new and rare plants. The border plants included some interesting hardy *Cyclamen*, *Anemone fulgens* and *Crown Imperials* (Bronze Flora Medal).

In a corner space Mr. R. C. NOTCUTT had a charming group of spring-flowering shrubs, including standard *Cytisuses*, profusely-flowered bushes of *Double Peach*, many *Azaleas* of the *Kaempferi* type and other spring-flowering shrubs (Silver Banksian Medal).

With various other shrubs Messrs. J. PIPER AND SON showed flowering examples of *Corokia virgata*, which attracted much attention. The massed plants of *Azalea Hinomayo (Kaempferi variety)* were exceedingly effective. Amongst many border plants there were examples of *Aethionema Warley Hybrid* and many long-spurred *Aquilegias* (Silver Banksian Medal).

Various *Prunuses*, *Azaleas* and *Rhododendrons* with excellent little plants of *Pieris floribunda* were well arranged by Messrs. J. CHEAL AND SONS, who, in another place, had many interesting alpines (Bronze Flora Medal). Well-flowered sprays of *Forsythia spectabilis* with other shrubs and alpines were staged by Messrs. W. H. ROGERS AND SON (Bronze Flora Medal), while Messrs. REAMSBOTTOM AND Co. showed their *St. Brigid Anemones* (Bronze Banksian Medal), and Mr. CLARENCE ELLIOTT had a good batch of *Polyanthus Scarlet Bedder*.

Just inside the entrance Messrs. WM. CUTBUSH AND SON arranged a charming group of *Polyantha Roses*. The principal varieties so well disposed were *Glory of Steinfurth*, *Greta Klaus*, *Ellen Poulsen*, *Echo* and *Pink Delight*. Adjoining the *Roses* were several pot plants of three new *Rhododendrons*, *Souvenir de D. A. Koster* (see Awards), Mrs. T. Wezenberg, a slightly smaller and darker coloured flower, and *Barnet Glory*, which is much like *Doncaster* (Silver Flora Medal).

Excellent cut *Roses*, similar to those shown at the recent spring show of the National Rose Society, were displayed by Messrs. B. R. CANT AND SONS and Mr. E. J. HICKS (Silver Flora Medal). The new varieties, *Elsie Beckwith* (see Fig. 114) and Mrs. Hornby Lewis, were again excellent, while *Paul's Scarlet Climber*, *Una* and *Phoebe* were also very beautiful.

Carnations, equal to the high quality of some time past, were again exhibited in generous quantities by Messrs. ALLWOOD BROS. (Silver Flora Medal), Mr. C. ENGELMANN (Silver Flora Medal), and Messrs. STUART LOW AND Co. (Silver Flora Medal).

An excellent group of *Schizanthus Dr. Baxter's Strain* was contributed by Messrs. DOBBIE AND Co. The plants were all perfect broad pyramids and carried enormous quantities of large blooms in a great variety of colours (Silver-Gilt Banksian Medal).

*Mimosas* in variety, and associated with *Epa-crises*, *Anthuriums* and other stove and greenhouse plants, were arranged by Messrs. STUART LOW AND Co. on a table space adjoining their Carnations. A small collection of *Hippeastrums* with spring-flowering shrubs was shown by Messrs. L. R. RUSSELL, LTD. (Bronze Banksian Medal). *Gloxinias* and *Streptocarpus*, illustrating excellent strains, were displayed by Messrs. SUTTON AND SONS (Bronze Banksian Medal).

## RHODODENDRONS.

The special show of *Rhododendrons* attracted a number of enthusiasts, but for the most part their exhibits were arranged in a very elementary manner and the names of the varieties were difficult of access. A special committee inspected the exhibits and made awards.

An exception to the above remark was the large collection by Messrs. R. GILL AND SON, which was exceedingly attractive. This contained a large number of the beautiful half-hardy sorts that Messrs. GILL AND SON annually bring from the Falmouth district, and of these such brilliant varieties as *Ernest Gill*, *Shilsoni* and *Gill's Triumph* found many admirers. Various ar-

boreum seedlings, *R. ciliatula* and *R. cilicalix*, with a central mass of *Azalea amoena*, were delightful (Silver Flora Medal).

Many *Rhododendrons* in large pots were sent by Mr. T. H. LOWINSKY from Tittenhurst, Sunninghill. For the most part, these were very beautiful hybrids of *R. Aucklandii*, but all were shown under their seedling numbers (Silver-Gilt Flora Medal).

To the enthusiast the exhibit of single trusses of a large variety of *Rhododendrons* by Mr. E. J. P. MACOR, Lanellan, St. Tudy, Cornwall, was full of interest, and there were some very beautiful flowers amongst them. The sparkling white, erect bells of *R. calophytum*, each containing a crimson-lake spot, were very charming, as also were the blooms of *R. barbatum* and *R. Blood Red arboreum*. *R. Smithii* was interesting on account of the densely barbed leaf stalks. Along the front there was a collection of the pigmy blue-flowered species, which are so valuable when massed. Of these, *R. hippophaëoides*, *R. fastidii*, *R. prostigiatum* and *R. impeditum* may be quoted. This valuable exhibit received a Certificate of Appreciation (Silver-Gilt Flora Medal).

From Exbury, Mr. Lionel de Rothschild's Hampshire garden, some attractive *Rhododendrons* were exhibited. In the front of the collection there were good trusses of the bright ruby-red *Horsham*, with their characteristic long styles extending beyond the blooms. *R. nepalense*, *R. Iverianum* and *R. Queen Wilhelmina* were also very showy sorts of very bright colour. A cross between *R. kewensis* and *R. Thomsonii* (see Awards), raised by Mr. Gill, is a most beautiful rose-pink bloom (Silver Flora Medal).

A smaller collection was shown by G. W. LOBER, Esq., Ardingley. The blooms of *R. eximium* and *R. oreodora*, as well as several seedlings, attracted a great deal of attention. Sir JOHN RAMSDEN, Bulstrove, Gerrard's Cross, exhibited such species as *R. niveum*, *R. Thomsonii*, a pink form of *R. Falconeri*, *R. campylocarpum* and several interesting crosses from it, and other sorts (Silver Banksian Medal). A few trusses of bloom, from LADY ABERCONWAY, Bodnant, Tal-y-cafn, were displayed on table.

#### Narcissus and Tulip Committee.

*Present*: E. A. Bowles (in the chair), Miss Willmott, Messrs. G. W. Leak, W. Poupard, H. V. Warrender, F. Barchard, J. de Graaff, Peter R. Barr, W. B. Cranfield, C. Fowler, J. Jacob, H. Smith, G. Reuthe, Reginald Cory, J. W. Jones, W. F. M. Copeland, F. H. Chapman, J. W. Pearson, W. R. Dykes and Charles H. Curtis (Hon. Secretary).

There were several splendid groups before this Committee, and no fewer than seven *Daffodils* were granted Awards of Merit.

*Narcissus Orange Glow*.—A glorious incomparabilis variety with shapely, soft yellow perianth of large size and a rich orange gold, heavily frilled short trumpet. A handsome novelty, and one of the many brilliant seedlings raised by the late Mrs. Backhouse. Shown by Messrs. R. H. BATH, LTD.

*Narcissus Magnolia*.—A striking Giant Leedsii variety of large size and with solid white perianth segments, which have suggested the varietal name. The trumpet has the faintest possible tint of buff and has a frilled margin. Shown by Messrs. GEORGE MONRO, LTD.

*Narcissus Rob. Berkeley*.—One of the most refined of the white Trumpet *Daffodils*. The overlapping segments of the perianth stand out well in a fully opened flower, but have a tendency to point forward in younger blooms. Shown by Mrs. BERKELEY, of Spetchley.

*Narcissus Chinita*.—This showy poetaz variety promises to be very useful for garden and cutting purposes. Two or three flowers are borne on each stem, and they are straw-yellow, with a red-edged crown. Raised by Mr. F. H. Chapman. Shown by LIONEL DE ROTHSCHILD, Esq., Exbury.

*Narcissus Xenophon*.—A very large-flowered *Tazetta* form, the yellow flowers being almost as large as those of a *Barrii* form. The cup is vivid orange. This also was raised by the late

Mrs. R. O. Backhouse, and it usually has two flowers on a stem. Shown by the ANGLESEY BULB GROWERS' ASSOCIATION.

*Narcissus Brightling*.—An incomparabilis variety with an almost perfect pale sulphur yellow perianth and a short crown, of richest orange and finely frilled. Raised by the late Mrs. R. O. Backhouse. Shown by the ANGLESEY BULB GROWERS' ASSOCIATION.

*Narcissus Mountaineer*.—A bold and shapely Trumpet *Daffodil* of fine substance and rich golden yellow colour. It was raised by the Rev. G. H. Engleheart, and has a deeply frilled recurving rim to the large trumpet. Shown by Mr. W. B. CRANFIELD, Enfield.

#### GROUPS.

A large and very comprehensive collection of *Narcissi* was arranged by Messrs. BARR AND SONS. Of the many sorts on view it was those with brightly coloured coronas that attracted most attention, and these included *Best Man*, *King's Pirate*, *Nyssa*, *Ruby* and several very promising seedlings. The large Trumpet *Daffodils* were also prominent in this good exhibit, and of these *Polemon*, *Adelgar*, *Anteope*, *St. Gawain* and *Tityus* are the names of characteristic varieties. Along the front there was a vase of the dainty *Lavender*, a *Barrii* flower, which has a pale apricot corona (Gold Medal).

Incomparabilis and *Barrii* varieties, with exceptionally bright coronas, were also a feature in the collection by Messrs. R. H. BATH, LTD. The central place was given to a large quantity of excellent blooms of *Flame*. Near by there were vases of *Orange Sir Watkin* and *Bernardino*. Other noteworthy varieties were *Scarlet Gem*, a *Tazetta* variety of rich colour, *Lady Superior*, a *Barrii* with a fiery orange rim to a golden corona. A number of seedlings of various types were of more than average merit (Silver-Gilt Flora Medal).

The great decorative value of *Daffodils* was well illustrated by Messrs. SUTTON AND SONS in a delightfully arranged exhibit. For the most part the varieties used were those in general cultivation, such as *Acme*, *Dixie*, *Olympia*, *St. Vincent* and *Rosalie* (Silver-Gilt Banksian Medal).

A smaller exhibit by Messrs. F. H. CHAPMAN, LTD., was composed largely of seedlings, but of the named sorts, *Acme* (poeticus), *Corregio*, an incomparabilis with a large orange-flushed corona, and *Robin Redbreast*, an orange-cupped incomparabilis, were particularly handsome (Silver-Gilt Banksian Medal).

Such decorative varieties as *Bernardino*, *Melyn*, *Derwin* and *Lucifer* were displayed in wicker-covered jays by the ANGLESEY BULB GROWERS' ASSOCIATION, and a small collection of seedlings of merit was arranged by Mr. W. F. M. COPELAND.

#### Fruit and Vegetable Committee.

*Present*: Messrs. J. Cheal (in the chair), E. A. Bunyard, Geo. F. Tinley, S. B. Dicks, W. F. Giles, G. Reynolds, A. Bullock, P. C. M. Veitch, E. Neal, Ed. Beckett, W. Bates, A. Metcalfe, W. H. Divers and G. Berry.

There were only a few exhibits in this section. Fruits of the *Madras Citron* were shown by Mr. HOWARD FOX from his garden at Grove Hill, Falmouth.

Messrs. SUTTON AND SONS exhibited seeds of a number of seedling French Beans, to show the great variation in the colour of the seed coats. The varieties *Evergreen*, with light dun-coloured testa, and *Satisfaction*, with brown and white coloured testa, when crossed, gave rise to a Bean with a mottled coat, and seedlings from this gave progeny with seeds, some pure white, others mottled or striped, and through all shades wholly brown to deep mahogany colour.

### Obituary.

**Osgood H. Mackenzie**.—Our readers will learn with regret of the death, on April 15, of Mr. Osgood H. Mackenzie, of Inverewe, Poolewe, Ross-shire, where he died. Mr. Mackenzie was the owner of a remarkable garden in

a favoured district on the west coast of Scotland, where he succeeded in cultivating with success many rare shrubs, trees, and other plants which gardeners much further south could not establish. At Inverewe the mild sea air and the shelter of the trees give opportunities for the cultivation of tender plants—opportunities seized with profit by Mr. Mackenzie, who had formed a collection of many rare and beautiful subjects from many parts of the world, and which succeeded splendidly under the genial conditions of this favoured district, enhanced by the skilful planting of Mr. Mackenzie. His notes were always interesting and frequently highly informative to others interested in such plants. Mr. Mackenzie, who was in his eightieth year, was the youngest and only surviving son of the late Sir Francis Mackenzie of Gairloch, and the uncle of the present baronet, Sir Kenneth Mackenzie. Gardening was Mr. Mackenzie's chief pursuit, but he took a deep interest in county and parish affairs, and was held in high esteem as an able member of several public bodies. He was also keenly interested in the antiquities of the Highlands, as was evidenced by a volume from his pen which was published last year. It was entitled *A Hundred Years in the Highlands*, and besides much other information, contains numerous references to his garden and the plants which grow there. His funeral took place at Gairloch on the 19th inst.

**Walter Cobb**.—With extreme regret we have to announce the death of Mr. Walter Cobb, Normanhurst, Rusper, at the advanced age of 86 years. Mr. Cobb, who was a keen business man and great lover of Orchids, retained his faculties to the last, and had attended recent meetings of the Orchid Committee of the Royal Horticultural Society, of which he has been a member for a great number of years. At Silverdale, Sydenham, and later at his home at Normanhurst, Rusper, Mr. Cobb made his garden his chief hobby, and took especial interest in his excellent collection of Orchids. In business and in horticultural circles Mr. Cobb was generally much esteemed, and was always ready to place his great experience at the service of other horticulturists. A number of fine species are named in his honour.

### ANSWERS TO CORRESPONDENTS.

**DAHLIAS FOR GARDEN DECORATION: J. H.** The following varieties in their respective sections will be suitable for your purpose: Decorative—*Delicé*, pink; *Crimson Flag*, crimson; *Queenie*, golden amber; *Reginald Cory*, crimson, tipped white; *Apricot*, salmon-apricot; *Brentwood*, yellow. *Collette*: *Admiral*, maroon, white collar; *Bonfire*, orange-scarlet, scarlet collar; *Dora Fisher*, pink, white collar; *Scarlet Queen*, scarlet, yellow collar; *Ustane*, salmon-scarlet, yellow collar; *Mrs. O. M. Courage*, deep carmine, white collar. *Cactus*: *Mary Purrier*, rich crimson; *Mrs. F. Paton*, scarlet; *Richard Box*, yellow; *Rose Queen*, rose; *Coral*, coral red; and *Mrs. Landale*, yellow, edged rose.

**NAMES OF FRUIT: C. D.** 1, Schoolmaster; 2, *Hambledon Deux Ans*.—H. W. A. Allen's *Everlasting*.

**SHAMROCK: T. A. S.** The specimens you send are those of *Trifolium minus*, the species that has been adopted in Ireland within the last thirty years or so as the true Shamrock. It is only an annual, and if it did not flower last year it had been prevented from doing so by the drought. On the contrary, it may have bloomed, and the present plants would be seedlings from the original. It is showing its flower heads now, the colour being yellow. You can grow the plant in the garden if you firmly tread a piece of ground for it. The Shamrock is common to the British Islands, and you could doubtless find it not far away if you look on banks or pastures where the grass is not very rank.

**AVERAGE MEAN TEMPERATURE for the ensuing week** deduced from observations during the last fifty years at Greenwich, 49.6.

### ACTUAL TEMPERATURE:—

*Gardeners' Chronicle* Office, 5, Tavistock Street, Covent Garden, London, Wednesday, May 3, 1922. Bar, 30.0, temp. 54°. Weather—Dull.

From observation of the vegetation in different parts of the country, it would appear that plants generally are in a very backward state. The cold winds and low temperature of the past month are, of course, mainly responsible for the delay of growth, but the heavy rains which fell recently on successive nights have doubtless also helped to increase the backwardness; for the rains have helped to chill the slowly-warming earth, and root action has been retarded. In exceptionally sheltered spots in well-worked gardens ground crops are fairly forward, but in exposed situations they are behind-hand. Fruit trees in particular are slow in breaking into flower. The buds of Pears in a fairly advanced state remained stationary or almost so for nearly two weeks and even the Sloe of the hedgerows came into flower only grudgingly. It has been suggested that last season's drought is producing its aftermath in this slow development and that the long persistence of the leaves last autumn was an indication that ripening of the wood was checked by the abnormal season. It may be so, but for our part we are inclined to wait and see. The blossom buds of fruit trees are there in plenty—so far as the gardens under our observation show, whereas had last year's wood failed to ripen, failure and not belatedness of blossom would have been expected. At the same time, it seems to be true that plants, such as Roses, which flourished exceedingly last year in heavy soils, were as early as usual in showing growth. Too early, indeed, and in low-lying

ground they have suffered from frosts. Those—if any there be—who were too hasty with the pruning of these plants partially have cause to regret it. It is indeed curious how slow some amateurs are to learn the value of late pruning for Roses as well as other things. Needless to say it is too early yet to make any confident prediction as to garden crops. The lateness of the season is all to the good so far as top fruit is concerned, but the yields must, of course, remain for some weeks at the mercy of the weather. If late frosts do not spoil the setting it seems at all events likely that the fruit crops may prove good. Of small fruit, Raspberries, as was to be expected, have suffered severely from last season's drought. Except in well-established gardens, the canes have an impoverished appearance and do not bid fair to produce much of a crop. Any comments on season are apt to be belied by sudden weather changes and the still air and warm sun which have followed the boisterous and chilly Easter have already caused vegetation to assume a less wintry aspect. The trees already "in the fire of spring, the winter garment of repentance fling"; the mauve haze of commencing growth envelops the tops of the Larches and over the Oaks a yellow orange hue heralds the verdure that is to be. It is generally supposed that after the enforced, and, as may be said, deliberate arrest of growth to which plants subject themselves in autumn and early winter, vegetation in spring awaits passively favourable external conditions and this corresponds to them automatically, but this can scarcely be the truth, for after a period of enforced idleness, as, for example, that through which vegetation checked by bad weather has recently passed, a few warm days makes such a wonderful transformation as to compel the belief that the energies of plants pent up during untoward days find exuberant expression when the sun at last shines upon them. Vegetable physiology is as yet a long way from explaining to us all the fine details of plant behaviour.

**Experiments and Demonstrations at Kirton.**—From Mr. Wallace, Secretary to the Holland County Council's Agricultural Education Committee, we have received a copy of the *Guide to Experiments and Demonstrations*, on the Agricultural Institute Farm, Kirton, during 1922. We find these are trials of nineteen varieties of Spring Cabbages—to test earliness, yield, and hardness—of new varieties of Barley, of Potatoes and of Peas, in addition to manual experiments and an experiment on the preparation of seed land for Potatoes. Arrangements are made for visitors to be shown the experiments at Kirton on Thursday afternoons and evenings; other days by appointment only. Reports of the Kirton experiments are issued from time to time and may be had free of cost on application to the Institute Farm.

**The Ramparts of Ypres.**—All lovers of trees and shrubs will be pleased to know that the famous "Ramparts" at Ypres have now been replanted with trees and shrubs. The work of grubbing out and removing the old shell-shattered trunks has been no easy task, and the Ypres town authorities are to be congratulated on getting the place ready for planting at such an early date, taking into consideration the fact that for a considerable time no labour could be spared for such purposes as planting ornamental trees. Now, out of the ruins and debris has arisen a new Ypres. The Belgians are fond of their trees and realise their value for beautifying the country. Mr. E. H. Biggs, Superintendent of War Graves at Ypres, informs us that from the Porte de Menin to the Porte de Lille, on the Ramparts, have been planted such well-known favourites as *Fagus purpurea*, Acers in variety, *Liquidambar styraciflua*, *Liriodendron tulipifera*, *Robinia hispida*, *Robinia pseudacacia*, *Quercus palustris*, *Quercus coccinea splendens*, Limes in

variety, Laburnums, Poplars in variety, Elms, Weeping Ash and Willows, and, amongst Conifers, Abies, Taxus, Ginkgo biloba and *Taxodium distichum*. These have been advantageously planted, some in bold clumps, others as specimens the whole length of the Ramparts, finishing up at the Porte de Lille with an avenue of *Tilea argentea*. A few of the more common shrubs still exist and are quite restful to the eye after so much new brick and mortar; these include the old Ribes, which is now in full flower, *Berberis vulgaris*, *Symphoricarpos*, *Lycium formosum*, a few clumps of *Castanea sativa*, and the cut-leaved Elder, *Sambucus tennifolia*, which covers the deeper slopes. It is also interesting to learn that the famous Menin Road has also been planted, from the Menin Gate, past Hell Fire Corner, to Hooge Crater, while beyond, miles of avenue trees, chiefly Limes, Oaks, Acers and Elms, are being planted on this route.

**Royal Gift of Flowers to a Hospital.**—The King and Queen have forwarded to the patients of the Royal Northern Hospital, Holloway, a magnificent supply of fine Daffodils from the Royal Gardens, Windsor.

**Destruction of Charlock by Spraying.**—The University College of North Wales, Bangor, in association with the County Councils of Anglesey, Carnarvonshire, Denbighshire and Flintshire, has conducted experiments to test the effects of spraying Charlock with a solution of sulphate of ammonia. Experiments were conducted on three stations and both copper sulphate and sulphate of ammonia were used. It was found that the copper sulphate is more rapid in its action, and whereas the sulphate of ammonia solution mainly attacks the leaves and only to a less extent the flowers, copper sulphate destroys the leaves, flowers and stems. It was also found that a strong solution of sulphate of ammonia checks the corn just as much as copper sulphate, and destroys Beans, which are hardly affected by copper sulphate. Moreover, it was found that the use of sulphate of ammonia is much more expensive than copper sulphate, although there is considerable value in the ammonia salt as a manure; but the corn would not be benefited by a nitrogenous fertilizer at a time when the Charlock was sufficiently advanced for spraying, as it would prolong the growing period too much, and, in the case of a dry season, it would have little or no effect on the corn crop and would be washed out of the soil in the autumn.

**Horticultural Show at Darwen.**—For the first time in its history the Darwen and District Agricultural Association is including a horticultural section in its annual exhibition, which will be held this year on Saturday, June 3, at Darwen. The secretary has forwarded us a preliminary list of the prizes in the horticultural section; but other classes and prizes will probably be added, and the secretary, Mr. Richard Leach, 26, Railway Road, Darwen, will be pleased to send copies of the complete schedule when it is ready to those who make application to him. Medals and diplomas will be placed at the disposal of the judges for awards to non-competitive exhibits.

**Taxation Concessions.**—The reduction in the taxation of land announced in the new Budget will, according to the Chancellor of the Exchequer, put the agricultural industry on the same footing as the other industries in this country in considering the proper burdens which they ought to bear. The basis of taxation on land before the war was one-third of the annual value, but, during the war, when profits on farming rose very considerably, the basis of assessment was raised to twice the annual value. The present Budget makes provision for a reduction of this assessment to the annual value. This concession is estimated to entail a loss to the Treasury on amenity lands in the present year of £150,000 and £200,000 in a full year; in the case of agricultural land the loss to the State will be about £950,000 and £2,150,000 in a full year. Farmers will thus obtain a substantial relief from taxation, but it is recognised that in the present unsatisfactory condition of

agriculture the land owning and agricultural industry is entitled to some relief. The removal of this large amount of taxation on land, together with the reduction in income tax, should indirectly benefit horticulture and give a greater stimulus to trade generally.

**British Horticulture and Quarantine Order No. 37.**—The much discussed Quarantine Order No. 37, imposed by the United States Government as a measure for preventing the importation of plant diseases and pests into America, will be considered at a Plant Conference to be held at Washington on May 15. At the request of British horticultural traders the Ministry of Agriculture has sent its Controller of Horticulture, Mr. W. J. Lobjoit, to the conference to protest against a proposed extension of the Order. Mr. Lobjoit sailed from Southampton on Friday, April 28, by the s.s. Lapland; among those who gathered at Waterloo Station to wish him *bon voyage* and success in his efforts to secure free exchange of horticultural produce between Great Britain and the U.S.A., were Mr. H. V. Taylor, Deputy-Controller of Horticulture, and Mr. C. H. Curtis (*Gardeners' Chronicle*). Belgium will be represented at the Washington Conference by Mr. Chas. Pynaert, of Ghent, and Mr. L. Sander, of Bruges; and Holland's delegates are Mr. Van Poeteren, of the Dutch phytopathological service, and Dr. Slogterem. It is hoped, as a result of this Conference, that Quarantine Order No. 37 will be so modified as to allow the admission of plants from Europe without those restrictions which at present amount to prohibition, and which are so adversely affecting the horticultural trade of our own land as well as of Belgium, Holland and France. Moreover, there is considerable evidence to show that many horticulturists in the United States would welcome imports of many kinds of plants from the British Isles.

**Jubilee of the Netherlands Horticultural and Botanic Society.**—On the occasion of its fiftieth anniversary, on September 27, 1923, the Netherlands Horticultural and Botanic Society will hold an International Horticultural Congress at Amsterdam. Papers will be read on such subjects as Horticultural Education, Landscape Architecture, Plant Breeding, and Scientific Research in Horticulture. The Organising Committee, of which Jhr. G. F. van Tets is president and Dr. M. J. Sirks, 55, Bergweg, Wageningen, Holland, the secretary, proposes to arrange visits to the more important centres of horticulture in Holland in connection with this conference, while the Amsterdam section of the Society will organise a great horticultural exhibition.

**Royal Gardeners' Orphan Fund.**—The annual festival dinner of the Royal Gardeners' Orphan Fund, which is to be held on Tuesday next, and at which Mr. Lionel de Rothschild, O.B.E., M.P., will preside, promises to be one of the most successful of the series, and it only needs the hearty co-operation and support of all interested in the Fund to make the receipts a record for these gatherings. The Connaught Rooms, where the dinner will be held, is very central and not far from Covent Garden; these public rooms have become very popular for the holding of social functions, and many notable gatherings have been held in them in recent times. We strongly urge the claim of this excellent gardening charity to the notice of our readers. The Secretary is Mr. B. Wynne, 19, Bedford Chambers, W.C.2.

**Birds in Town Gardens.**—The amount of damage that birds cause in the garden compared with the amount of good they do is often a subject of debate by gardeners, but our experience this season is that they are an unmitigated nuisance. We know of one town garden in which birds, principally sparrows, have destroyed almost the whole of the buds of Gooseberries, Red and White Currants and Plum trees. Besides this damage, they also ruined the fruit blossom of Pear trees wholesale before the trusses expanded. At first sight, the small amount of growth and blossom on the Plum trees was put down to the effect of last summer's drought, as most of the branches have the appearance of being dead, but an examination

proved that the bark is quite green and that almost the whole of the buds have been picked out by birds.

**Mr. Ernst H. Krelage.**—As head of the firm of Messrs. E. Krelage and Son, of Haarlem, Mr. E. H. Krelage is widely known in the horticultural world, and especially in that section chiefly concerned with the cultivation of bulbous plants. He is recognised among bulb specialists as an expert in all that pertains to Tulips and Tulip history, and many book lovers are aware that he is the fortunate possessor of a wonderful library dealing with floricultural matters. A week or so ago Mr. Krelage concluded his year of office as president of the *Fédération Horticole Professionnelle Internationale*; but this is only one of the very many high positions he has held or holds, and it is of interest to observe that he is president of the General Bulb Growers' Society, president of the Central Bulb Committee of Holland (a committee composed of the presidents, vice-presidents and secretaries of three great bulb organisations in Holland), vice-president of the Netherlands Horticultural Federation, president of the Chamber of Commerce of the Haarlem district, and hon. secretary of the board of directors of the private phytopathological laboratory at Baarn. In pre-

MR. ERNST H. KRELAGE.

vious years he has been president of the Dutch Bulb Exporters' Association and of the Dutch Horticultural Trades' Association, and has held the position of president of the Dutch committees at the horticultural exhibitions held at Berlin, 1909; London, 1912; and San Francisco, 1916; while he has been an official delegate or member of the jury at nearly all international horticultural shows since 1893. Mr. Krelage has strong literary tastes and instincts, and from 1895-1900 was co-editor of the *Florilegium Hartense*, and until the year 1889 he was co-editor of *Sijdschrift voor Tuinbouw* (a Dutch monthly magazine). In 1910 he produced the Jubilee Book of the General Bulb Growers' Society, and a year later, on the occasion of the centenary of his firm, he wrote *A Century of Bulb Growing*, which was published in Dutch. Mr. Krelage has received many honours from his own and other countries, including that of Officer of the Orange-Nassau Order, and Knight of the Order of the Prince of Orange. Officer of the Order of the Crown of Belgium, and Knight of the Russian Order of St. Stanislaus. Mr. Krelage is a frequent visitor to this country, and is a splendid English linguist; but his visits are invariably of very brief duration, as his business interests are so wide that he cannot absent himself for long from his beloved Holland.

**Prizes for Potatoes.**—Taking time by the forelock, Messrs. W. Cotter and Co., Corporation Market, Dublin, have offered to provide three classes for Potatoes at the spring show of the Royal Horticultural Society of Ireland, to be held in 1923. These classes are respectively for fifty, twenty-five and twelve tubers of Mahon's Fingallian Potato, and in each of the classes three of the tubers must be boiled. The prizes for fifty tubers are £4, £3 and £2 respectively, and proportionate amounts are offered in the other two classes.

**A Bird's Method of Obtaining Nectar.**—Mr. P. M. Debbarman, of the Royal Botanic Gardens, Sibpur, Calcutta, in a communication to *Nature*, records that the flowers of *Castanospermum australe* are visited by a nectar-sipping bird, *Mirafra assamica*, in India. As the beak of the bird is not sufficiently long to reach the nectar in the calyx, it has adopted the practice of biting off the fleshy petals which obstruct it. The tree is a native of Australia, and not of India, so that the bird probably plays no part in the pollinisation of the flowers.

**Appointments for the Ensuing Week.**—Monday, May 8.—United Horticultural Benefit and Provident Society's meeting; Purley Horticultural Society's meetings. Thursday, May 9.—Royal Horticultural Society's Committee meetings (two days); Royal Gardeners' Orphan Fund festival dinner at the Connaught Rooms, Great Queen Street, W.C.2. Wednesday, May 10.—East Anglian Horticultural Society's meeting; Sheffield Chrysanthemum Society's meeting. Thursday, May 11.—Manchester and North of England Orchid Society's annual meeting; Bristol and District Gardeners' Association's meeting; Hornsey and District Chrysanthemum Society's Committee meeting. Saturday, May 13.—Ringwood Society's meeting.

**"The Gardeners' Chronicle" Seventy-five Years Ago.**—*Tropaeolum Lobianum*. To those who cultivate plants for floral display during the winter months this *Tropaeolum* may be regarded as a plant of the greatest importance, whether the easy mode of its cultivation, the great beauty of its flowers, the peculiarity of their structure, or the prodigality with which they are produced, be taken into consideration; they form, too, an article of some use as an ingredient for mixing into, or ornamenting a dressed salad. Last midsummer a cutting was taken from a plant growing on a verandah in the open air, where it failed to produce its flowers; it was struck in a cold frame, and shifted and pinched in the usual way until it reached a twelve-inch pot and covered a pyramidal trellis some four feet high; it was then placed in a cool stove, where the night heat seldom exceeded 60 deg., when it began to flower in the early part of December, and continued a dense mass for upwards of four months, forming a striking contrast to the Orchids and other plants then in a state of hibernation. *James Duncan, Basing Park, May 1. Gard. Chron., May 8, 1847.*

**Publications Received.**—*The Painted Hickory Borer*. By E. H. Dusham. Bulletin 407; *Decomposition of Green Manures at Different Stages of Growth*. By Thomas Lysons Martin. Bulletin 406; *An Economic Study of Farm Tractors in New York*. By W. I. Myers. Bulletin 405; *The Inheritance of Salmon Silk Colour in Maize*. By E. G. Anderson. Memoir 48; *Typha Insects; Their Ecological Relationships*. By P. W. Claassen. Memoir 47; *The Botrytis Blight of Tulips*. By Edwin F. Hopkins. Memoir 45; *Attachment of the Abdomen to the Thorax in Diptera*. By Benjamin P. Young. Memoir 44; *Variations in Bacteria Counts from Milk as Affected by Media and Incubation Temperature*. By G. C. Snipple, W. A. Whiting and P. A. Downs. Memoir 43; *Bean Anthracnose*. By Mortier F. Barrus. Memoir 42; *Lygimeter Experiments*; records for tanks 13 to 16 during the years 1913 to 1917 inclusive. By T. Lyttleton Lyon and James A. Bizzell. Memoir 41; *Liberation of Organic Matter by Roots of Growing Plants*. By T. L. Lyon and J. K. Wilson. Memoir 40. All published by the Cornell University Agricultural Experiment Station, Ithaca, New York.

## NOTICES OF BOOKS.

## Rose Annual, 1922.

THE National Rose Society is to be congratulated on being able to publish such a splendid volume, comprising the *Rose Annual* for 1922,\* on Rose matters, and the editor, Mr. Courtney Page, is to be equally congratulated on the excellent choice of subjects dealt with. The work forms a valuable addition to Rose literature and is freely illustrated, some of the pictures being in colour. It is a wise policy on the part of any society which is able to afford it to make its "annual" as complete and variable as possible, for publications of this kind are valued by those members who are unable to attend the exhibitions and serve to keep them in touch with events concerning the particular flower in which they are especially interested. For instance, the excellent notes dealing with the spring show, the metropolitan exhibition at Regent's Park, the provincial show at Ipswich, and the autumn show at Vincent Square, by Messrs. H. Oppenheimer, H. H. Thomas, A. C. Bartlett and the Rev. J. Jacobs respectively, are not merely catalogues of the prize winners and the varieties shown, but chatty articles touching on special features and noteworthy varieties as they appeal to Rose lovers.

The frontispiece is a portrait of Mr. Samuel McGredy, one of the most successful raisers of new Roses in Great Britain; he raises about 17,000 seedlings each year. Mr. McGredy has won fifty-two medals and twenty-nine certificates for new varieties and each exhibition adds more to the number. A useful article by the President, Mr. E. J. Holland, entitled "Roses in Pots," gives first-hand experience of growing the plants indoors. The compost recommended by this amateur grower is good loam enriched with a small quantity of thoroughly well-decayed manure from a spent hot-bed and a little bone meal, with sufficient sand or grit to render the mixture porous. Mr. Holland recommends that the soil should be on the light side rather than heavy, and he states that in stodgy or over-rich soil pot Roses are a failure. It may be useful for amateurs to know that excellent results may be obtained by potting the plants in ordinary, light, sweet garden soil, and if the medium lacks sufficient nourishment, stimulants may be easily supplied at a time when the plants are best able to make use of them.

Another valuable contribution is on "Bedding Roses" by Mr. H. R. Darlington. As only a select few cultivate Roses specially for exhibition, this article will appeal to the majority of Rose growers, as a knowledge of the best varieties for garden purposes is very valuable. Mr. Darlington has enlisted the services of Rose growers living in the west and east coast of Scotland respectively; the Thames Valley and West Surrey; the Surrey and Kent border; and Sussex, while in addition he gives his own observations from his garden on the borders of Middlesex and Hertfordshire, about fifteen miles from London. It is interesting to know that all the contributors included the yellow variety, Mrs. Wemyss Quin, in their lists of the best varieties; General McArthur, Lady Pirrie, and Ophelia were recommended by six out of the eight contributors, while four each recommended Lady Hillingdon, Los Angeles, and Red Letter Day, and three Mme. Abel Chatenay, and Mme. Edouard Herriot. These nine varieties may therefore be said to represent the pick of the Roses for garden purposes, while those who live in the special district of the special contributor will be able to select other equally beautiful Roses for their gardens. A lengthy description of each of the nine premier varieties is given, and there are a few notes dealing with the merits or any defect of each of the other varieties mentioned by the contributors. Mr. Darlington's list should be studied in conjunction with an article by Mr. J. Parkin on "The Imperfection of Modern Roses with Special Reference to Bedding Varieties." Mr. Parkin's ideal bedding Rose is one "which is in constant bloom from June until put to rest by winter's frosts," and with regard to floriferousness Mr. Parkin states

that the hybrid Teas and hybrid Austrian Briars greatly excel the older hybrid perpetuals, also, taking the Rose bush throughout the flowering season, the H. T. habit of growth is on the whole better adapted for bedding than that of the H. P. Those who wish for fragrance in Roses, which some of the modern varieties lack, are recommended to include General McArthur in their collections. Mr. Parkin's article is a very complete one, and deals not only with form, colour, fragrance, floriferousness, habit, and the flowering season, but also with the Rose as a cut flower and varieties especially prone to attacks of insect pests and diseases.

A useful article on Climbing Hybrid Tea, Tea and Noisette Roses is contributed by Mr. Walter

by the Editor; and New Roses at Bagatelle Trials by Madame Charles Siret. Descriptions of the new Roses of 1921 and the Rose Analysis for 1921, both by the Editor, show the direction in which progress is being made and the most popular sorts for the exhibition table.

The numerous black and white illustrations are exceedingly well reproduced.

## Orchard Fruit Tree Culture.\*

THE title of this book suggests that it deals generally with the commercial culture of hardy fruit. This is misleading. Though the author does offer a few remarks on planting, pruning, and marketing, his main object has evidently been to describe the propagation of fruit trees

FIG. 115.—ROSE SOVEREIGN; CERTIFICATE OF MERIT, N.R.S., APRIL 21 (SEE P. 216).

Easlea, who regrets the loss of some of the beautiful old climbing Roses, such as Climbing Devoniensis, Celine Forestier, Lamarque and Jaime Desprez. The present-day tendency is to plant the Wichuraiana varieties extensively and neglect the valuable old climbers which were the former pride of gardens and still to be found in some of the old Rose nurseries. Many of our most beautiful Tea and hybrid Tea varieties, including Mme. Abel Chatenay, Ophelia, Lady Hillingdon, Richmond and Caroline Testout have given climbing forms as sports and, as Mr. Easlea states, there is a very rich collection to select from. Other articles include notes on the History of the Moss Rose by Major Hurst, Chemical Manuring with Inorganic Fertilisers by Major A. D. G. Shelley, Budding of Roses

and bushes and their treatment whilst in the nursery. Even so, it is difficult to see what object the book is intended to fulfil. The experienced man will find nothing in it that is new to him; and it does not go sufficiently into detail to teach a beginner budding and grafting. Two methods of propagating trees are dealt with—shield budding and whip grafting; but these operations are not actually described in words. The reader is referred to the illustrations. The raising of bush fruits by cuttings is treated rather more fully, but there are omissions. *M. G.*

## PASSPORTS FOR PLANTS.\*

HORTICULTURE has suffered a great deal from war conditions, but another evil is troubling and handicapping its development nowadays. This consists of regulations and rules which different countries have adopted for the importation of nursery stock, seeds, bulbs, etc., so as to minimise the carrying of fungus parasites and insects from one country to another.

The passport, which to-day a plant needs to travel from one part of the world to the other, is more complicated and requires more work and trouble to secure than does that for a human being. The control or disinfection, and the inspection of its growing district, involve a large amount of work and give rise to many difficulties. However, anyone studying phytopathology knows that many of these rules are comprehensible.

We all know that many plant parasites have travelled from the U.S.A. to Europe, from Europe to the U.S.A., from Asia to the U.S.A., from Asia to Europe, and so on. We know that the Phylloxera and the American Gooseberry Mildew came over here; that the White Pine Blister Rust and the Brown Tail Moth went from Europe to the other side of the Atlantic; and that the San Jose Scale was a passenger from China to the U.S.A. We know that sometimes diseases obtain a different aspect in another climate, but as to this matter, we are all in the same condition on this and on the other side of the Atlantic, or anywhere.

The transport of the above mentioned examples happened when we knew very little of phytopathology; when this science was in its childhood, and when hardly any phytopathological control existed. However, these questions have taken quite another aspect, because of the broader knowledge and the better control of the different diseases, therefore, now we are more able to separate the dangerous from the harmless, and the more refined our methods of disinfecting are, then the import restrictions should diminish. Instead of this, we see different countries reinforcing and strengthening their quarantine regulations; Western Europe is beginning in the same way as the U.S.A., the movement takes a more hysterical aspect, and the end will be an isolation of each country's plant products.

The scientists acknowledge that there is a danger of transporting parasites. Science and practice have to work hand in hand concerning these problems, but they must never lose touch with each other. But the scientists are also aware that the danger is on both sides, in Europe as in America. I think that this fact has not had sufficient attention drawn to it.

I want by this address to try and answer two questions for you:

1. What are the immediate and possible dangers for Western Europe if it does not quarantine products from the U.S.A.?

2. Are the dangers as large, with our modern methods of control, as the quarantine laws from the U.S.A. indicate?

I shall restrict myself to the fungal and bacterial diseases as my time is limited and the insects are not quite in my line of work.

In answering the first question, I would point out the diseases which, up to this time, have not been found in Western Europe, and which may be brought over from America. I will also refer to diseases already known here, but which are commonly found on American products, because the U.S.A. also quarantines against diseases which are already spread in their own country. However, in my opinion, some of these American conclusions go too far. We must put the "possibility" case of diseases changing their force, as the U.S.A. does, but we must avoid falling into speculations with regard to harmless saprophytes becoming parasites under other conditions, or of host plants changing their susceptibility. We hardly know anything of the scientific basis of such changes.

We do not know whether the host plant of the fungus is changed; we only know that their relations have a different aspect.

We accept the possibility that fungi and bacteria which cause severe trouble in the U.S.A., may cause as severe an epidemic here in Western Europe.

I propose to follow the lists of plant products imported into Rotterdam harbour, for my conclusions, and to refer to the parasites of plant products for propagation as well as for consumption.

The importation of fruit is becoming larger and larger. Apples were imported into the harbour of Rotterdam: 5,000 kg. in 1920, 208,000 kg. in 1921; Nuts increased from 238,000 kg. in 1920 to 590,000 kg. in 1921.

A severe Apple disease, the Bitter Rot, caused by *Glomerella cingulata* (syn. *Gloeosporium fructigenum*) exists in America. This fungus also lives in Europe, without doing harm. But we also know by the researches of Krüger, that in Europe the strain (as we call it in mycology) of the fungus is different from the American strain, as well in morphology as in virulence. It is possible that the virulent strain will be carried from America as small spots on the Apple, and it may possibly cause epidemics here as severe as in the U.S.A. I would also draw your attention to a disease of Nuts, common in California, the Walnut Blight, caused by *Pseudomonas juglandis*. When young, the Nuts are exposed to a severe rot, and an attack actually kills them. But the late infections (after the researches of C. O. Smith and H. Ramsay) only give "a very shallow, superficial development of the disease." I am well aware that these Nuts imported are not used for propagation, but they may carry the bacteria, and this case is comparable to the many cases of the American pathologists.

As to seeds, we know that Clover seed has always been imported from the U.S. to Western Europe (15,000 kg. in 1920, 11,000 kg. in 1921). In scientific phytopathological publications the question of parasite importation on this seed is often mentioned, as we know that American Red Clover seed is mixed with European in the market. Merchants generally advertise their seed as being unmixed with American varieties, as they know it is often attacked by *Anthraxnose* (*Gloeosporium caulivorum*). I do not think it was quite proved on a scientific base, though it is highly probable that it has been imported. In Germany it has been found often on crops from American seeds, and the general opinion is that American varieties are more susceptible.

The importation of Wheat, Maize, Rye, Barley, Oats and Buckwheat is of the greatest importance, especially as foodstuffs. Through the latest agricultural quarantines of the U.S.A. we know that America is afraid of importing fungus parasites through grain seeds "imported for consumption." Quarantine Order No. 37 is an example. It demands a certificate that the seeds imported were grown in a place free from *Ophiobolus graminis* ("take-all" disease), which they find mentioned in Japan, Australia, France, Italy, Germany, Great Britain, Ireland, Belgium and Brazil. This "take-all" disease is caused by a soil parasite, *Ophiobolus*, which attacks the plant at the stem base, and which has no flying conidia which might infect the seed. The ascospores of the fungus are liberated during the winter or early spring, and remain in the soil until the required amount of moisture and temperature induces germination. Mangin observed the germ tubes enter the Wheat plant through the root hairs. I do not think it possible that seeds could carry or transmit any propagating organisms of the fungus. If they were carried, it could only be by the straw, though it will probably remain in the stubble, but certainly not with the seed, even in an uncleaned state. Americans state that the disease is not yet widely prevalent or distributed within and throughout the U.S. Are they sure that it is "prevalent" in the countries mentioned above? I know that our knowledge of the *Ophiobolus* is very small indeed, and that there is more than one *Ophiobolus* disease. The economic importance of the disease is not large, it has been studied insufficiently, and the

transmission of the disease by seed is highly improbable. Besides, the disease *does* occur in the United States. In recent American phytopathological literature another disease of grains in the U.S.A. is mentioned, which, unfortunately, has the same name, "take-all," but of which the cause is undetermined. It is described in *Farmers' Bulletin* 1226 of the U.S. Department of Agriculture. In 1920 it was found in Illinois. It is supposed that a *Helminthosporium* is connected with it. If Europe is going to be afraid of this "unknown" disease, we will probably get into a muddle about the name "take-all," and before we really know what it is. As Quarantine Order No. 37 was established in 1919, and the new "take-all" disease only appeared in 1920, this name should be abolished by scientists. We cannot yet make out what the danger is of the "Illinois take-all" for Europe. The large shipments of cereals, even when used as a foodstuff only, will probably put European agriculture on the look-out.

(To be continued.)

## NOTES FROM WISLEY.

As a consequence of the cold weather the flowering of fruit trees and of ornamental varieties of Plum, Pear and Apple has been considerably delayed in most parts of the country; Wisley shares the common experience.

One of the most beautiful sights to be seen at the R.H.S. gardens is the flowering of the large, weeping, Chinese Cherry (*Prunus Cerasus pendula*), and it is remarkable how profusely this and the smaller specimen on the rock garden blossom every year.

Another striking but less graceful tree is *Pyrus Niedzwetzkyana*. The wood is very dark in colour and shows up the reddish shoots and reddish-pink flowers. *Pyrus floribunda purpurea* is also fine. Another ornamental fruit tree deserving particular mention is *Prunus subhirtella autumnalis*, which has been in blossom for a considerable time. It should have flowered in the latter part of last year, but the drought is probably responsible for its present behaviour. The flowers are very pale pink and their delicacy is enhanced by the tender green of the young shoots.

All the aforementioned are to be seen in the newly formed shrub borders in "Seven Acres," which promises to be a successful and highly interesting addition to the gardens. Large numbers of the shrubs planted here are comparatively unknown, and we can only make guesses as to their future value. A shrub now in flower, and one that seems likely to be a good thing, is *Prinsepia uniflora* with white flowers and a habit reminding one of *Spiraea arguta*.

In the American garden there is plenty to be seen, including *Rhodora canadensis* and *Vaccinium pennsylvanicum*; the latter is very conspicuous in dark places in the woods at this time of the year, as the foliage and stems are light yellow-green.

*Narcissus triandrus* is exceptionally good this year, and occurs in large patches in the grassy glade near the round ponds. After flowering, the stems bearing the seed vessels are cut down with the grass, which is deposited so that the seeds may drop out wherever it is wished to establish this charming plant.

In the rock garden *Arabis* and *Aubrietias* are chiefly in evidence. By the side of one of the rock pools, what appears to be *Aubrietia* Mrs. Lloyd Edwards, on closer examination, however, proves to be partly *Primula Juliae*.

At the present time there are quite a number of little shrubs flowering in pans in the Alpine House. Amongst others there is a dwarf specimen of *Amelanchier canadensis*, barely a foot high, but with normal sized flowers. There is also *Veronica Hulkeana*, a loose growing plant with pale lavender flowers; the bluish-flowered *Rhododendron fastigiatum* and *Azalea amoena*. Perhaps the prettiest plant to be seen in flower in this house is *Asperula suberosa*, with its silvery-pink cascade of trumpet-like flowers and its downy foliage.—J. E. G. White.

\* An address given by Prof. (Miss) Westerdijk, of Utrecht and Baarn, at the Conference of the Federation Horticole Professionnelle Internationale, at the Hague, on April 21.

## THE BULB GARDEN.

## A NEGLECTED BULB.

THE delicate beauty of *Ornithogalum nutans* entitles it to more esteem than it appears to receive, judging from the infrequency with which one sees it in cultivation. This may be owing to want of experience of its merit as a cut flower, whereof I confess to having been in ignorance till lately. A couple of the flower spikes were placed in water just a fortnight ago, when half the blossoms were expanded; the others have now opened and the earlier blooms remain perfectly fresh, and the spike is a column eight inches high, of a dozen stars, each two inches across. The texture of the blossoms is satiny, their colour milky-white streaked outside with grass green, the segments of the perianth opening star-wise round the close column of anthers, whereof the silvery-white filaments are flattened into the semblance of petals, adding much to the richness of the flower. I feel sure that this *Ornithogalum* would be more frequently planted if the quality of its blossoms was more generally known, for it is as hardy as a Dandelion, the bulbs are very cheap and thrive as vigorously when planted out in grass as when grown in a border. This *Ornithogalum* does not conform to the provoking habit of the common Star of Bethlehem (*O. umbellatum*), which closes its flowers punctually at 4 p.m. (Greenwich, not summer, time). That species reminds one of the trap into which the translators of the authorised version were led in the narrative of the siege of Samaria. We are told in 2 Kings, vi., 25, that the famine in the besieged city was so severe that "an ass's head was sold for four-score pieces of silver and the fourth part of a cab of dove's dung for five pieces of silver." Now it is conceivable that the head of an ass might form stock for tolerable soup; but, for the life of me, I never could comprehend what nutriment could be had out of dove's dung, until the late Dr. Tristram, of Durham, Oriental traveller and author of *The Land of Moab*, solved the mystery for me. He explained how in spring the plains of Syria are sheeted with the white blossoms the Star of Bethlehem. The Arab name for this flower signifies "dove's dung," which the Greeks more elegantly rendered as "ornithogalum"—bird's milk. The bulbs, being commonly used in normal times as an article of food, naturally brought a high price during the siege. In the Revised Version of the Old Testament, the only alteration made in the passage in Kings consists of "cab" being changed to "kab." *Herbert Maxwell, Monreith.*

## PLANT NOTES.

## SOME OLD FAVOURITE GARDEN PLANTS.

THERE are a few old plants that I have lost sight of that are worth noting. One is *Eranthemum pulchellum*, an inmate of the stove, which produces its pretty blue flowers in profusion during the dull months. It roots readily from cuttings at this season, which make good specimens if grown in five-inch pots in a loamy medium and stopped once or twice to make them bushy. Requiring similar treatment with the addition of a neat stake for support is *Thysanacanthus rutilans*, which produces long, drooping sprays at the same season. The colour is dull red. *Clerodendron fallax* is better known, and strong plants throw brilliant racemes which make quite a glow for some months. Seedlings

like a Fuchsia at all, but though the flowers are almost minute, it is, notwithstanding, a plant to be desired. It is hardy in some parts, but here it has to be lifted annually and stored during winter. The best way to increase it is to pull an old plant in pieces, as it is so slow in growth from cuttings that it is a long time before these form decorative material. *Fuchsia Riccartonii* is another fine variety, hardy here, where the plants grow to a height of 10 feet.—*R. P. Brotherton.*

## EPIGAEA REPENS.

THE Mayflower of North America was introduced to this country in 1736, and a red-flowered variety exactly a century later; yet little success has attended the cultivation of either. I have seen *Epigaea repens* flowered in a pan of peaty soil, but never so freely as in the gardens of the Royal Horticultural Society at Wisley. It

FIG. 116.—NARCISUS EVEREST: AWARD OF MERIT, MIDLAND DAFFODIL SOCIETY. (SEE P. 234.)

## THE ALPINE GARDEN.

## SAXIFRAGA ASPERA.

IT cannot be said that this Saxifrage is a general favourite, and it remains unrepresented in numerous gardens, where the Saxifrages are highly cherished. It is a member of the mossy section, but is distinct-looking in its foliage. It makes spreading mats of bristly green leaves, on branches which spread about in a manner likened to those of some of the Mossy Phloxes. They are quite distinct, however, and those who have once seen *S. aspera* are not likely to forget its general appearance. Its one fault with me has always been its shyness of flowering. It is a disappointment to grow it for some years and to be rarely ever rewarded with a sight of its delicate bronzy stems and butter-yellow flowers, growing deeper in colour towards the centre and freckled with orange. The allied *S. bryoides* is quite as deserving of growth, but with me had always the same tantalising shy-flowering habit as *S. aspera*. It comes from higher altitudes than *S. aspera*, and has a denser habit of growth. Its little shoots and close habit give it a strong resemblance to some of the Mosses. It also has yellowish flowers, brighter than those of *S. aspera* and more deeply freckled. Both these Saxifrages are easy to grow in ordinary rock garden soil. *S. Arnott.*

produce the best flowering material, the seeds to be sown early in the year and the plants potted finally into six-inch pots in loam. Cut-over plants form larger flowering specimens, but in my experience the heads of flowers are not nearly so fine, and it is perhaps better to keep a plant or two to bear seed than to preserve them over one year for flowering.

All the above plants require a stove temperature, and flower in the winter and spring months. *Fuchsia Mme. Cornelliison*, on the contrary, is a summer and autumn flowering plant, good alike for the greenhouse and the open-air border. It is a very old variety, perhaps 70 years old, of a peculiarly straight growing habit and producing quantities of red and white flowers of medium size, being probably one of the first white corolla Fuchsias to be distributed. I have not seen it for many years, but it is hardly possible so desirable a variety should have gone out of cultivation. *Fuchsia minimus* is scarcely

seems perfectly happy on the side of a shallow ditch, facing north, but shaded on that side by trees. The soil of these gardens is naturally peaty and that is entirely to the plants' liking, as in the case of many shrubs belonging to the Ericaceae. The shade and the congenial medium for the healthy growth of mycorrhiza are, no doubt, the principal reasons for the success of this desirable little shrub. April is the average month for flowering, but it was in bloom for some time at Wisley before the end of March. One factor that helps for the continued success of the plant is a cool position that will delay growth till the worst of the late frosts are no longer to be feared; while a mild winter is liable to start the plant into growth too soon. It is perfectly hardy while at rest, but the young growth is tender. I have proved this in the case of *Salix myrsinites*, which grows at high elevations on the mountains, and a mild spring will start it into growth, while a late frost will completely blacken the leaves. *J. F.*

## The Week's Work.

### THE ORCHID HOUSES.

By J. T. BARBER, Gardener to His Grace the Duke of Marlborough, K.G., Blenheim Palace, Woodstock, Oxon.

**Cymbidium.**—The large, ivory-white *Cymbidium eburneum* still holds its own amongst this most popular family of Orchids, and is deserving of a place in any collection. Plants that require more root room should receive attention as they pass out of flower. The thick, fleshy roots of these Orchids require a larger space to ramble in than is generally afforded them. The pots should be well drained, and the compost consist of one half good turfy loam, the other half fibrous peat, or *Osmunda* fibre and moss, to which may be added a little leaf-mould and broken crocks in sufficient quantities to render the compost porous. These plants should be potted in much the same manner as ordinary plants, keeping the soil at least half an inch below the rim of the pot. During the growing season water should be given the roots freely, and at other times in sufficient quantity to keep the roots moist. *Cymbidiums* do not appreciate dryness, either at the root or in the air, as it causes loss of foliage, greatly to the disfigurement of the plants. Other species to which the above remarks apply are *C. elegans*, *C. Mastersii*, *C. affine*, *C. aloifolium*, *C. ensifolium*, *C. chloranthum*, *C. longifolium* and *C. insigne* (*Sanderæ*). *C. Lowianum* does not require so large an amount of pot room as *C. eburneum*, and, when properly potted and well cared for, may be allowed to remain undisturbed for many years, for it produces its long, arching spikes more freely when kept in a pot-bound condition. The whole of these plants, both species and hybrids, produce flowers more freely when the roots are cramped. An occasional dose of weak liquid cow manure will greatly benefit the plants when they are throwing up their flower spikes.

**Other Species.**—*C. Traceyanum*, *C. giganteum*, *C. pendulum* and *C. Hookerianum*, should be treated as advised for *C. Lowianum*. *C. Devonianum* produces its pendulous racemes from the base of the young growths, and is best grown in a wooden basket. All the above-mentioned *Cymbidiums* grow well in a cool, intermediate house. One of the great features of these interesting plants is the length of time their flowers last, either on the plants or in a cut state. These plants should be sprayed overhead occasionally to help keep down attacks of red spider, and other insect pests.

### THE FLOWER GARDEN.

By EDWIN BECKETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Hertfordshire.

**Herbaceous Borders.**—Examine the plants in the borders now, and where the growth is congested remove some of the shoots in order to give those that remain plenty of space to develop, as this will result in finer flowers. This attention is particularly necessary in the case of plants that have been in the same position for more than one season, such as *Michaelmas Daisies*, *Heleniums*, *Amellus Asters*, *Phloxes*, and similar close-growing subjects.

**Annuals.**—The more tender kinds of annuals may be sown with comparative safety in the open, remembering the previous caution to sow thinly. Also, to maintain a succession of those sown as previously directed, further batches should now be sown. The *Mignonette* is one of the greatest favourites amongst annuals, and we endeavour at Aldenham to ensure as long a season for this fragrant plant as possible. The earliest plants are raised in pots in a cool house, where they are safe from frost. We raise a later batch in 60-sized pots in cold frames for planting out to bloom early in borders, and again later, from the first week in May, we

make three sowings at intervals to carry on the succession. *Matchet* and *Miles' Spiral* are the two principal varieties employed, as we find these sorts very reliable for all kind of work. *Mignonette* does best in well-dug, enriched ground, into which a good quantity of mortar rubble has been worked. Thin the seedlings out in stages until they are finally left from 4 inches to 6 inches apart.

**Mildew on Roses.**—Mildew is one of the unsightly pests to which *Roses* are subject, and various causes are assigned for its appearance, but the general view now held is that it is caused by quick variations in the temperature. If the disease is observed it should be treated at once with a spray containing sulphur, and one of the best I have used is "Seeride," which destroys it very effectively.

FIG. 117.—A PYRAMIDAL ELM AT ALDENHAM (SEE P. 227).

**Weeds on Gravel Paths.**—After April rains weeds appear rapidly on gravel walks, paths and drives, but are easily destroyed with weed killer. Weed killers should be most carefully handled and used. The utensils employed for mixing the solution and for applying it should be reserved solely for such work, and not employed for general operations, otherwise serious results may occur and other plants may be seriously damaged, if not killed.

### PLANTS UNDER GLASS.

By T. PATEMAN, Gardener to Sir C. NALL-CAIN, Bart., The Node, Codicote, Wolwyn, Hertfordshire.

**Humea elegans.**—This plant should be ready for the final potting. Use rich, open loam, mixed with manure from a spent mushroom bed, and grit. I do not favour the use of very large receptacles for *Humeas*, pots of 7 inches diameter being the most suitable

size. After potting the plants, water them carefully until the roots become active again.

**Coleus Seedlings.**—These should be potted on into larger receptacles as required. Rich, open loam, with leaf mould and sand added, forms a suitable compost for these plants. When these are well established in their final pots, a little concentrated fertiliser will be very beneficial to them. Pinch the growths to induce them to form bushy specimens.

**Celosia pyramidalis.**—Seeds of this *Celosia* and also of *C. cristata* may be sown now to raise plants for summer flowering. To be successful with these plants, it is necessary to obtain a quick growth; it is a mistake to allow them to suffer from lack of root space in their early stage. The soil should be of a rich, open nature. Red spider is one of the worst pests of these plants, therefore it will be necessary to syringe the growths frequently to keep the spider in check, but not so heavily as to cause the surface soil to become sour.

**Clivia.**—It is not necessary to repot these plants each year, but where they have been allowed to remain in large pots for several seasons and the growths have become crowded it will be necessary to overhaul them now that the flowering season is over. Rich, open loam, to which leaf-mould, bone meal, and grit have been added, will provide a suitable compost. Do not use very large receptacles for these plants, as they produce flowers more freely when the root space is restricted.

**Acalypha.**—Old plants of *Acalypha* that have become leggy may have their tops taken off and inserted in small pots. Place one cutting in each pot, and plunge the latter in the propagating frame, using a good open compost as a rooting medium. The old plants may be pruned as desired and grown on again for another season if necessary.

### THE KITCHEN GARDEN.

By JAMES E. HATHAWAY, Gardener to JOHN BRENNAN, Esq., Baldersby Park, Thirsk, Yorkshire.

**Potatoes.**—Early planted *Potatoes* are pushing their shoots through the soil. The haulm should be covered for so long a time as possible by drawing fine soil over it with the hoe every evening. When the growths are too big for this kind of protection, use old tiffany or Bracken Fern if the weather is still very cold.

**Brussels Sprouts.**—Early plants of *Brussels Sprouts*, raised in boxes, should be planted in ground that has been well manured. Allow plenty of space for these plants—not less than 3 ft. between the rows, and 2 ft. 6 in. between the plants in the rows. Where land is scarce, *Potatoes* planted 4 ft. apart, with dwarf tops, may have *Brussels Sprouts* planted between the rows. If the *Potatoes* are lifted early they will not affect the *Brussels Sprouts* to any extent.

**Cardoon.**—This vegetable should be grown in trenches made 18 in. wide and 2 ft. deep, and filled with well-decayed manure to within about 4 in. of the surface, covering the dung with about 3 in. of soil. Sow about four seeds in stations about 18 in. apart, and as soon as the seedlings are large enough thin them to one. The trenches should be 4 ft. 6 in. apart.

**Celery.**—The early batch of *Celery* should be hardened off ready for planting out. Plants comprising the main batch are ready for pricking out 3 in. apart in a good mixture of loam, leaf-soil and sand. The seedlings should be kept close and shaded for a few days after they are transplanted, and well syringed.

**Salsafy.**—Grow this crop in light, sandy soil that was well manured last year and has been deeply trenched. Sow the seed in drills made 18 in. apart. *Salsafy* is a useful vegetable, but if sown too early the plants run to flower and become useless. As soon as they are large enough, thin the seedlings to 10 inches apart. *Scorzonera* requires similar treatment.

## FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

**Strawberries.**—Peach houses and vineries will now be clear of the early batches of pot Strawberries, and the shelves should be washed carefully to prevent spider or mildew attacking the vines when syringing is discontinued. The later stock of pot Strawberries may be placed together in a light, roomy, and well-ventilated house or pit to set and ripen their fruit, where the different batches may be regularly syringed and watered until the plants come into flower, as healthy plants set their berries freely, the flowers may be well thinned before they open. After the fruit is set, syringing should be resumed and clear, weak liquid manure used at every watering. As strawberries will swell in the hottest plant stove, batches may be forced if it is necessary to do this to keep up the supply, but not otherwise, as Strawberries grown in a temperature ranging from 60° to 65° at night, and 75° to 80° by day, are superior in quality, if not quite so large as those grown in very hot houses. Most forced Strawberries, like early Grapes, are consumed before they are absolutely ripe, yet the berries may be kept in an improving condition on the plants in a dry, airy house for a week or ten days after they have coloured.

**Young Figs in Pots.**—Young trees growing in pots and intended for forcing later should be pinched when 1 ft. in height, to favour the formation of side shoots. The trees should be potted on before the roots become too pot-bound. The pyramid being the best type of tree, the leaders should be trained and pinched as often as they require it. It is not necessary to keep the roots in bottom-heat; the pots may be raised by degrees to the surface and the trees grown on in a warm, well-ventilated house or pit where plenty of heat and light are available.

## HARDY FRUIT GARDEN.

By H. MARRHAM, Gardener to the EARL OF STRAFFORD, Wrotham Park, Barnet.

**Late planted Fruit Trees.**—Young Peach and other trees that were planted very late in the season, and which, so far, have been left unpruned and not finally secured to the wall or trellis, should now receive attention. First tread the soil firmly about the roots, and then prune the shoots, more or less, according to their length and strength. If the shoots are of medium size and thoroughly matured, little, if any, shortening will be necessary. Spread out the branches at equal distances to form an evenly balanced head, and, as the young growth extends, preserve those best situated for filling bare spaces and gradually remove any that are ill-placed or too numerous. This work should be carefully carried out throughout the growing season, so that a well-formed head is obtained the first season after planting. Keep a watchful eye on the small, tender shoots for insects, such as green and black aphids, which may be expected at any time now, and, if not immediately checked, would cause much harm. A nicotine insecticide, Quassia extract, or Abol will destroy the pests, and the trees should be syringed with one or other of these specifics in the afternoons, and again with clean water applied with moderate force the following morning.

**Roots of Fruit Trees.**—A careful examination should be made of all kinds of fruit trees to ascertain whether the roots have been buried too deeply, and especially where the soil is rather heavy and cold, for nothing is more detrimental to the welfare of the trees than burying the roots far below the surface. In the vegetable garden and on borders the soil is apt to get shifted and placed over the roots from time to time, until the stems of the trees are covered with soil several inches higher than they should be. If this is found to be the case, shift some of the top soil from the roots, so that the warmth of the sun may reach them.

## TREES AND SHRUBS.

## ULMUS CAPESTRIS PYRAMIDALIS.

IN Mr. Bean's admirable work, *Trees and Shrubs Hardy in the British Isles*, he mentions that he has never come across a fastigiata form of *Ulmus campestris*, although, as anyone who has studied Elms knows, it is comparatively easy to find such varieties of *U. montana*, and *U. stricta* *Wheatleyi* with its stiffly erect branches is also fairly well known under its popular name of the Jersey Elm. The passage in Mr. Bean's book to which I refer reads as follows: "The fact that fastigiata as well as weeping trees originate only as seedling variations will explain the absence of any fastigiata common Elm" (Vol. I, p. 66).

When Mr. Bean wrote thus, his attention had not been called to a fastigiata form of the common Elm at Aldenham (see Fig. 117), which, in spite of his dictum, did not originate as a seedling variation, but was undoubtedly a "bud" sport! When I call it "fastigiata," I mean that its branches all grow vertically, and not at right angles to the trunk, as is the normal way of broad-leaved trees, but as this word usually suggests trees that are more or less the same size all the way up, like the upright form of Black Poplar, commonly called Lombardy, I prefer to describe it as "pyra-

The ultimate result has, however, proved eminently satisfactory. The tree, deprived of any other outlet for its energies, devoted itself exclusively to the development of the sport, so that in a few years this latter grew rapidly both in height and girth, and before long any marked difference in girth between the top of the stem and the bottom of the sport disappeared, and we now possess a striking and shapely tree of a height of 85-90 feet, in which anyone standing on the ground can hardly detect any break of continuity, or could guess without being told that the tree had ever had any other form than the one which it now presents. I should add, in conclusion, that at the time when I operated on it so drastically and successfully, I also removed any adjacent trees.

On the same page of Mr. Bean's book he mentions that he has never seen a fastigiata Linden or Lime tree, but since he wrote that I have had the pleasure of showing him one at Aldenham, which I obtained about a dozen years ago from a foreign nurseryman. *Henry Gibbs, Aldenham.*

## RHODODENDRON SUTCHUENENSE.

THE photograph reproduced in Fig. 118, taken on March 23, 1922, shows a fine plant of *Rhododendron sutchuenense* with 80 trusses of bloom, each carrying about 20 flowers 3 inches across.

FIG. 118.—RHODODENDRON SUTCHUENENSE IN A SCOTTISH GARDEN.

midalis," for the base of this variety is materially broader than the apex, and in outline it more resembles a deciduous Cypress than a Lombardy Poplar.

The origin of this variety is curious, and well illustrates how much can be done by judicious surgical operation entirely to transform, and vastly to improve, the outward appearance of a tree.

Some thirty years ago, when I first noticed this specimen, it was a mean, ill-grown example of the common hedgerow Elm, which with us, as in most parts of southern England, is by far the commonest field tree. It was then, I should judge, about thirty years old, and having been dominated by a big neighbour, it had, at about 15 feet above the ground, bent away in search of light, and carried an ill-shaped, rather starved crown. It would have been remorselessly condemned had I not observed that it had sent up a small, upright shoot, then, I think, between two and three feet high, just at the point where the trunk began to turn from the vertical. Accordingly, instead of ordering the tree's removal, I got the woodman to behead it just above the point where the abnormal growth started, and further, to remove all boughs below the said growth. No doubt the immediate effect was grotesque, and such as would have raised a great outcry if a tree in a public park had been in question.

The blooms are lightly speckled on the inside and of a good pink colour. The leaves are long and leathery. *R. sutchuenense* is a woodland species from China. Owing to its early habit of flowering this *Rhododendron* does best planted where the morning sun does not reach it. Here, on the west coast of Scotland, it has flowered regularly in March for some years past, and is now a specimen over 5 feet high and 9 feet through. *Kenneth McDonall, Logan, Stranraer.*

## PINUS PATULA.

This beautiful Mexican Pine closely resembles *Pinus longifolia* in general appearance, but being more hardy than *P. longifolia*, it is most suitable for planting in the warmer counties of England and the south of Ireland. The horizontal growth of the branches and the dense, fringe-like growth of the leaves gives the tree a very attractive appearance. It has principally been planted in the south-west of England and the south of Ireland, but I have also found specimens of it in Sussex. *Pinus patula* is not always found planted in suitable positions, but it is worthy of a place where its distinctive beauty can be seen to advantage. One may frequently see examples of errors in planting, and fail to understand why some trees are so planted; there is often no consideration for what such trees may become thirty or forty years hence. *Paul More.*

**EDITORIAL NOTICE.**

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, W.C.2.

**LILIES IN 1921.**

FEW gardeners seem to regard the most remarkable year of the present generation—1921—in quite the same light. So much depends upon the point of view, and that in turn depends on local conditions of aspect and soil, humidity of the atmosphere, and, above all, water supply.

The gardener whose camp is pitched—shall we say—in an arid country in East Anglia, with a water supply which ceases to be adequate when the rainfall is much below the normal, would not take the same view of 1921 as the individual whose garden is on generous land in a valley among the Welsh hills. But there seems a general agreement that by the end of August more than a few gardeners had come to the conclusion that it was possible to have too much of a good thing.

A point that emerges from a consideration of experiences is that, where the water supply held out, as it did in a surprising number of places, and was used intelligently, garden vegetation was almost sub-tropical in growth. It has to be recognised, however, that in the ordinary way there is so little need for irrigation of gardens in this country that only the enthusiast will go to the trouble of it on the chance of a deficiency of rain now and again.

In such a season as that of last year, the grower of Lilies who is able to irrigate the ground has an immense advantage over those who have to take things as they come. In the case of the mere difficult species, which need a higher summer temperature than our climate normally affords them, but dwindle in sun-baked places, the effect of a cool and moist root-run in a parching time is remarkable. The amount of water needed for subterranean irrigation is trifling and out of all proportion to the beneficial effect.

The record drought will not have taught the systematic cultivator of Lilies very much he did not know before, but the year was not barren of lessons. The almost total absence of Botrytis, for instance, was very marked. The scourge made an appearance during the sharp spell of inclement weather of the third week in April, and for a few days made characteristically rapid progress. But with the return of fair weather towards the end of the month, the disease was checked and made no further progress in the year. Plants which had been attacked, too, made a wonderful recovery.

The conditions which predispose certain forms of plant life to the ravages of this disease, for which there seems as yet no prophylactic and no effective cure, are doubtless known to scientists. To the gardener it seems tolerably clear that the sun has a definite bearing on the matter, for in 1911, and again last year, there was a marked absence of the fungus. An epidemic is to be expected at any season of the year, in moist, sunless weather, whether the temperature is high or low, and, though the hurt caused by spring frosts to plants susceptible to Botrytis seems to lay them especially open to the initiatory attack, it may come at any moment when atmospheric conditions are favourable to it.

Another feature of the year was the bountiful harvest of seed yielded by the June and July flowering species in general, and the later flowering species where they were not crippled by the drought, as well as the satisfactory condition of the seed.

The fruiting of cultivated forms of *L. candidum* was reported in many directions, and that is testimony to the exceptional nature of the season, for, as is well known, these forms of the Lily do not produce seed in the normal British summer. In this respect, the behaviour of the plant differs materially from that of the wild form of *L. candidum* from Salonica, distributed by Mr. Bowles a few years since, for that produces a rich crop of seed with annually astonishing regularity. This Lily is a real drought-resisting species,

for it remained green and imperturbable throughout the season in places where all around was burnt and browned. It seems to be remarkably resistant to Botrytis, too.

Another noticeable feature of the year was the revelation of the drought-resisting powers, hitherto unsuspected in a stem-rooting species, of *L. Henry* (see Fig. 119); except for a slight curtailment of stature in very arid places, plants of this species also remained green to the end.

No lengthy retrospect of the season is needed, for it must be long before the recollection of it will fade from the memory. Suffice it to say that, except for the check due to a wintry spell in the third week of April, there was nothing to mar the smooth progress of Lilies from the turn of the year till the opening of the season a few days earlier than usual.

There is usually a definite gap between the June Lilies—*L. pyrenaicum*, *L. monadelphum*, *L. rubellum*, *L. tenuifolium*, and *L. Hansonii*

FIG. 119.—LILIAM HENRYI.

—and those which flower in July, just as there is between the latter and the late flowering species; but last year broke the sequence which had been maintained with remarkable regularity over a period of twenty years. *L. regale* was in bloom before the petals of *L. Hansonii* had fallen, and the buds of *L. Henryi* opened on a date earlier than any whereof the writer has a record.

It is a commonplace that Lilies are plants of the sun, but that does not mean that they will tolerate the parched situations in which so many found themselves last year. In many places the early flowering Lilies flourished amazingly, because in June there was still a sufficiency of moisture below the crust of the earth, and, as we know, the bulbs of many species push their roots far and wide in search of moisture. The writer has often noticed wandering roots of *L. Leichtlinii*, for instance, four feet away from the bulb.

By July, however, the absence of rain was beginning to tell, and the water content of the earth had been seriously depleted. The late-flowering group, consisting almost entirely

of stem-rooting species, depends for the exuberance of its growth and bloom on a sufficiency of surface moisture, and, as in the majority of gardens this was non-existent by the middle of July, the group was generally stunted in growth and deficient in bloom. Newly planted imported bulbs, and especially those of the Japanese species, such as *L. auratum*, *L. speciosum*, and *L. tigrinum*, must have been slaughtered in thousands.

Of the newer Lilies, there is not much to be said from the gardener's point of view which has not been said already. The pair sent home by Farrer during his first exploration of Kansu—*L. centifolium* (see Fig. 120) and *L. Farreri*, the "Marble Martagon," which seems to grow more and more like *L. Duchartrei*—have still to prove themselves satisfactory garden Lilies. Of the hundreds of seedlings of *L. centifolium* raised in this country since 1915, there cannot be more than fifty flowering plants at the present time, many of them under glass, and, though the scarcity of the plant in the hands of enthusiasts may be due to errors of cultivation or mishaps, one cannot yet couple this Lily with *L. regale*, for instance, as a good garden plant. Nor is it possible at present to write more hopefully of *L. Farreri*.

At the R.H.S. show on July 27, 1920, *L. centifolium*, then identified by the number F. 316, was awarded a First-Class Certificate when exhibited as *L. Brownii kansuense* by Mr. Clarence Elliott. In a summary of the characteristics of the Lily in the Royal Horticultural Society's *Journal* (Vol. XLVI., p. lxviii.) it is stated to be practically scentless. In point of fact, it is deliciously fragrant. At the instance of Mr. Elwes, in August of last year \* the specific position of this fine Lily was dealt with provisionally by the authorities at Kew, who named the plant *L. centifolium*, Stapf., placing it in the *L. Brownii* phylum. If bulb characters have any taxonomic value, however, those of the bulb of this Lily point to a relationship with *L. sulphureum* rather than *L. Brownii*.

Schenkel's hybrid between *L. sulphureum* and *L. regale*, shown at Holland House in July, does not seem an improvement on either parent, or to combine the good points of each. Its sole claim to fame at present is that the flowering season is intermediate between the parents. Hybrids between these parents may prove of use, however, in the consideration of the specific position of *L. Sargentiae*, which is so variable in many of its characteristic features as to lead one to the conclusion that it is not quite sure of itself as a fixed species.

The so-called Formosan variety of *L. philippinense* is as elegant and refined a trumpet Lily as anyone could wish to see, but in this country it is for the cold house rather than the garden. That is not to say that Price's alpine form of it in particular will not grow and flourish in the open in certain places.

When any trouble is taken with it, E. H. Wilson's *L. Willmottiae* is one of the most satisfactory garden Lilies of recent introduction. The only drawback to it is the unusual one that it often sets more sail in the way of bloom than it can carry, and so needs support for about two-thirds the height of the stem.

Far less floriferous, but equally elegant, is another Wilson Lily, *L. Thayerae*, which, in the opinion of its author, is no longer separable from the older *L. Davidii* of Franchet. The latter is known only by the beautiful plate of Faquet (t. 24) in *A Monograph of the Genus Lilium*. It is the sole figure in that remarkable work not drawn from the living plant, and, as is made clear in the text, the drawing is a reconstruction based on the dried specimen of David. This is not the place for a consideration of the reasons which have led to the conclusion that *L. Davidii*, as presented by Faquet, does not exist, and never has existed, but one may confess to a feeling of regret that such a beautiful Lily should have proved so entirely elusive.

*L. Davidii*, as Wilson considers his *L. Thayerae* should now be known, was regarded

\* *Gard. Chron.*, August 20, 1921, p. 101.

for some time after its introduction as a calcifugal plant; but more extended experience shows that this is not so.

The drought thinned out the ranks of Lilies in many gardens, but the bulbs of those which weathered the visitation will have been thoroughly ripened. In the southern half of England there were none of the heavy early winter rains which usually catch the bulbs when they are dormant and drown so many. From the Lily grower's point of view, everything in the late autumn was for the best, and the prospects for the present year are excellent.

It is satisfactory to know that the synonymy of the Martagon group of Western Chinese *Lilium* has been investigated during the year at the Edinburgh Botanic Garden, and that it is hoped before long to make the conclusions arrived at available for students and others interested, in a paper from the pen of the Regius Keeper. *A. Grove.*

## MR. KINGDON WARD'S SIXTH EXPEDITION IN ASIA.

### NO. 14.—MORE TREASURES FROM THE VALLEY OF BEAUTIFUL FLOWERS.

So few are the species of *Rhododendron* in this region—at least, as compared with the Mekong-Salween divide, and perhaps even with the Mekong-Yangtze divide; anywhere west of the Yangtze, in fact—so few, I say, are the *Rhododendrons* in the Yung-ning Mu-li region that each one deserves special notice. Between Yung-ning and Mu-li I have come across scarcely fifteen species. But I think this must be partly due to the fact that I have not been able to get high enough. I feel sure there are more species on the snowy range; and yet perhaps not many more. There are vast slopes of mountain here covered with dwarf *Rhododendron*, but all of two, or at most three, species. Tree *Rhododendrons*, in the proper sense of the word, there are none; at the altitudes where they would normally occur it is too dry for them. This is emphatically not a *Rhododendron* country, and we may confidently recognise the Yangtze river gorge as the eastern boundary, beyond which the genus rapidly diminishes in variety. Certainly there is nothing like so many species in the Mu-li area as there are on the Mekong-Yangtze divide, for instance. But this is not the whole story, for if we go northwards, to the region of Tatsienlu, where Wilson found so many species, they increase again. It would, therefore, appear that the *Rhododendrons* follow two streams—one from the north-west, the other from the north-east, which unite somewhere about the Mekong-Salween divide. Into this absorbing topic, however, I cannot enter now.

Now we approached the pass by a narrow valley, girt with gloomy cliffs. A stream tinkled over the precipice on our left, and splashed amongst boulders. Quite suddenly flowers seemed to spring up on all sides, and we found ourselves tramping over fields of *Primula pseudo-sikkimensis*, *Meconopsis pseudo-integrifolia*, *P. brevifolia*, *P. secundiflora*, and other delights. We waded through them, knee deep; and I stood spellbound. It was impossible to continue further up the ravine with the flowers beckoning to us to stay, and the cliffs crying aloud their welcome. So I gave the order, and the tents were pitched then and there—in a bog! From the door of my tent I could count six species of *Primula*. A bushy *Rhododendron*, with leaves brightly silvered beneath, and trusses of pink flowers, looked promising. Another species, with leaves rusty red beneath, and compact trusses of tubular white cups, suckled inside with purple, accompanied it; this last was one of the *Irrotatum* series, perhaps. Were we in the *Rhododendron* zone after all? Alas! they were the last bush *Rhododendrons* met with. The day was still young, so after a quick lunch we set out to climb the

\* The previous articles by Mr. Kingdon Ward were published in our issues of May 14, June 18, July 23, August 20, September 3, October 8, October 29, 1921; January 7, January 21, March 11, March 25, April 8 and April 22, 1922.

cliff over which the stream cascaded. I soon found myself in a lovely alpine valley, where rare *Primulas* grew like *Daisies* on an English lawn. Turning the corner, I came to a marsh, which was a sheet of brilliant lavender blue, thanks to a small bush *Rhododendron* in full bloom; and a more exquisite sight I have rarely seen—the colour was so refined, so unusual. Between the trickles of dark, peaty water, masses of *Iris* were springing up, and of this I secured an advance guard of seed—last year's.

On the rocky slopes above this bog were a few shrubs growing thickly—two small *Rhododendrons*, *Juniper* and *Lonicera*, the last with large, straw-yellow, pendent flowers, in pairs. There was little variety in the shrub belt.

FIG. 120.—*LILIUM CENTIFOLIUM*, STAPP.

Very steep earth slopes, which, facing south, were at present almost bare, led up to the crags. A species of *Philomis* was the only obvious thing on them. Ascending to the crest, we found *Abies* and *Rhododendron* sp. growing on the sheltered side, and straggling over the broken crest, in nooks and crannies. Everywhere the whitened rock was weathered into fantastic needles and pitiless knife blades. The whole world was on edge—never have I seen so perpendicular a country. The precipices were agonising to look at, cruel, but grand beyond belief. White *Rhododendrons* (two species) flecked the tree-clad slopes with foam. Down below were sheets of purple and lavender, where the dwarf species carpeted the slope; and every stream was embroidered with *Primulas*.

The limestone region which we had been

traversing now for ten days' journey—ever since we left Yung-pei, in fact—seemed to reach its apogee here. Comparatively clear as the atmosphere was, no obviously higher peaks were visible in any direction, though westwards the view was much restricted. As a matter of fact, the nearest snowy peaks lay a few miles to the west, though whether they were of limestone or not, I had no means of judging, even when I observed them later, from no great distance.

On the following day, June 6, after a cold night, with heavy dew at dawn, we climbed the western ridge again, exploring many a peak and valley. One of the most extraordinary plants found was a *Crucifer*, a species of *Solms-Laubachia*, I think; extraordinary for a mere *Crucifer*, that is, and at the same time beautiful. There are many *Cruciferae* high up on these ranges—species of *Draba*, *Cochlearia*, *Cardamine*, *Sisymbrium*, etc., which, like *Uriah Heep*, are very umble, contenting themselves with a meagre subsistence on screes, and such-like places, where no self-respecting plants grow. Very few of them are worthy of cultivation. But this was an exception. The flowers were pale violet, delicately veined with a darker shade, and extremely fragrant. But it was the habit—almost that of a *Suffruticosa Primula*—woody stems more or less clothed with the bases of old leaves, that was so surprising. This year's leaves were crowded at the ends of the stunted stems, and the whole formed a compact cushion. It was very floriferous and would look well on a rockery, though no doubt requiring some years to establish itself. One of the jolliest plants was a dwarf *Meconopsis*, with deep violet flowers. It grew scarce six inches high, on open grassy slopes, a modest little flower hanging its head and hard to find. It appears to belong to the *Primulinae* series, having three or four flowers on the scape, and only four (sometimes five) petals. The region is certainly not rich in this genus, though doubtless there are others to be found; but this little tot, with its almost glabrous leaves and shy, half-opened flowers, was a sheer joy, with none of the gawkiness or perky pride common to so many of its race. On the shaded cliffs grew a little white-flowered *Pinguicula*—not *P. alpina*, the pretty egg-yellow species of *A-tun-tzu*; and bunches of the graceful *Isopyrum grandiflorum*—rather pale of complexion—hung from dark crevices.

It was early yet for *Saxifragas*; they come late in the summer with the *Gentians*, when the *Primulas* and *Rhododendrons*—those early birds of the alpine regions—are thinking of scattering their seeds. Still, there was one *Saxifrage* in bloom on the shaded precipices, a cushion plant starred with white flowers. Other plants noticed in this region include *Potentilla peduncularis*, species of *Corydalis*, *Lloydia*, *Cassiope* (*myosurioides*?) yellow-flowered *Cremanthodium*, *Pedicularis*, *Myosotis*, etc. After a climb up to the screes, on June 7, where we found even those apparently barren rock chutes chequered with plants, notably a *Fritillaria*, *Saussurea*, and several *Cruciferae*, we returned to camp and packed up, starting down in the afternoon. From the pass we plunged straight down into forest, all the trees—*Abies*, *Oak* and *Rhododendron* being heavily draped with lichen. Presently *Larch* trees appeared—*Larix tibetica* probably, a beautiful sight in its fresh green foliage—and then we came to a patch of dwarf *Rhododendrons* in full bloom, bright lemon yellow.

As we got down into warmer regions, the banks were smothered with pink-flowered *Androsace spinulifera*, a variable species, growing at all altitudes and in very different situations, between about 8,500 feet and 13,000 feet. Presently we entered a beautiful forest of *Oak*, *Larch*, *Birch* and *Picea*, where the tree *Rhododendron* with large, pale yellow, bell flowers, grew to perfection. In a grassy clearing appeared a dwarf *Iris* with dark purple, glossy flowers, looking like velvet.

The descent became steeper, and we soon left the mixed forest behind and entered the lowest forest belt—that of *Pines*. In these dry regions (it seems silly to write "dry regions" while listening to the rain which has been falling for

some days now!) the Pine woods are always thin. A few scattered shrubs grow beneath them, chiefly Rhododendrons. Next morning, June 8, we descended through a belt of shrubs to the bottom of the ravine, and ascending the far slope, presently reached Mu-li, just above the Litang river. A very pretty *Arisaema*, with white spathe like an "Arum Lily," grew by the way-side. Our arrival at Mu-li, which was to be my home for a few months, was sensational. We were expected, as I had sent the heavy baggage on from camp, and the roofs of the vast monastery were lined with spectators. But for the stony silence, I might have imagined myself the new Lord Mayor riding down Lombard Street at the rear of my little procession. However, the silence was not to be taken as indicating a cool reception, but simply as Oriental. On the contrary, my reception was a warm one, the welcome accorded me hearty; for scarcely was I inside the house when one of the head lamas came round with messages from the grand lama, bringing presents of butter, tea, fowls, eggs, rice (*tamba*), and a sheep, hoping I would be comfortable, and bidding the owner of the house do everything he could. The good man, too, promised me every assistance in my work, transport, interpreters, collectors; and in this wise we settled down at Mu-li, under the shadow of the monastery, a village in itself. *F. Kingdon Ward.*

## INTERNATIONAL COMMERCIAL HORTICULTURAL CONFERENCE.

AFTER the somewhat strenuous business session on the first day of the Conference of the Fédération Horticole Professionnelle Internationale held at the Hague (see p. 207), the representatives lunched together in the Hotel Wittebrug. Then they went to see the exhibition arranged by the Netherlands Horticultural and Botanical Society in the Zoological Gardens. This fine exhibition was opened with due formality and is referred to in some detail on page 218. In the evening the Burgomaster, on behalf of the Municipality of The Hague, gave a reception to the delegates at the beautiful municipal offices in Java Street, where the City fathers have their splendid council chamber.

About 9.10 a.m. on the second day, April 21, the second session of the Conference began. Mr. Krelage presided again and read a gracious reply from Her Majesty the Queen of Holland to the letter sent her the previous day. Then came the surprise of the Conference. Mr. Krelage introduced Miss Westerdijk, a pathologist and professor of Utrecht University, who discussed the problems raised by the American Quarantine Order No. 37, in so far as these were of phyto-pathological interest. Her address, written and read in English, was listened to with profound interest. That she was voicing in scientific fashion the feelings of the practical men present was evident from the ejaculations of her audience as she made her various points, and also by the round of applause she received at the conclusion of her address when she observed that "prohibition was a sign of weakness." We have much pleasure in publishing Prof. Westerdijk's address, in part, on p. 224.

Mr. H. V. Taylor, the British Deputy-Controller of Horticulture, after thanking Miss Westerdijk for her address, stated that the United States authorities formerly considered a certificate of health sufficient warrant for allowing European horticultural produce into their country, but now evidently they did not regard such a certificate as of any value, hence Quarantine Order No. 37. He pointed out that the United States had some grounds for fear seeing that since 1912 their officers had found pests of some kind in 1,000 consignments of plants from Holland, 600 from France, 500 from Belgium, and 154 from England, but, he added, many of the insects discovered were already well known in the U.S.A., and in one instance it was the

common house fly which was reported as a sinister! His view was that America ran very little risk with regard to fungous and insect pests conveyable by European horticultural produce, and he pointed out that prohibition of the importation of horticultural produce would spoil trade and would not necessarily prevent the importation of disease. It was, however, necessary that the various European countries trading with America should do their utmost to ensure the health and cleanliness of the goods they wished to export to America, and so encourage trading, which is the outcome of civilisation.

The President congratulated Mr. Taylor upon his observations, and both he and Mr. Turbat urged that the Professor's address and Mr. Taylor's observations should be translated and published in the several countries represented. Mr. Leak brought matters to a practical issue by asking what each country was doing to support its own representatives at the Washington Plant Conference in May; he felt that it was very necessary the delegates to Washington should have the very strongest possible support in combating Quarantine Order No. 37. He stated that Mr. W. J. Lobjoit, the Controller of Horticulture, would represent Great Britain. The Dutch delegates stated that Mr. Van Poeteren and Dr. Slogteren would represent Holland and were being supported by the various trade committees and a special branch of the Dutch Legation at Washington. Belgium reported that it would be represented by Mr. C. Pynaert and Mr. L. Sander, nurserymen, but did not propose to send pathologists. France appeared to consider that direct representation by means of horticulturists or scientists would serve no useful purpose, and so they would be represented at Washington only through the Diplomatic Service.

Mr. J. Smits, in a very racy address, emphasised many of the points made by Prof. Westerdijk and Mr. Taylor, and as he has travelled extensively in America, his remarks were of considerable interest. He stated that in 1919 a Dutch Deputation agreed to establish a quarantine house in America and to provide all necessary means for ensuring the cleanliness of horticultural subjects sent from Holland, but Dr. Marlott wanted 100 per cent. of safety, and was not prepared to accept the offer made by the Dutch officials, but, instead, desired to set up his own quarantine arrangements. Mr. Smits contended that the majority of the horticultural traders in America desired free importation of European horticultural products and that the Quarantine Order No. 37 was nothing less than a prohibition order. The only means of fighting this Order was to set up somewhat similar quarantine regulations against the import of American produce into Holland. Several other delegates spoke, and eventually, on the motion of Mr. E. A. Bunyard, it was agreed:—

"That this Conference, considering that every country has the right and duty to prevent plant diseases and parasites being introduced; considering, too, that the Quarantine system, as enforced by the United States, would in time result in complete prohibition, which is not justified; considering that European countries would have to adopt the same measures against U.S. agricultural and horticultural products (including fruits), if the present system is maintained; and further, considering that in such a case International Horticultural Trading would be so reduced as to be in danger of extinction; urges that the importation of produce from countries which have a phyto-pathological service should be free and guaranteed between these countries, which would reserve the right to issue rules concerning the importation of certain products; invites affiliated associations to communicate this resolution to their respective Governments and pledge themselves to press it with all their power; and decides that this resolution be communicated to the American Government by the F.H.P.I. Bureau."

Mr. Spaer referred to the Rome convention and urged that traders in every country should endeavour to secure the ratification of the arrangements and thus make them effective. He

suggested also that cut flowers should not require a certificate of health.

In connection with another item on the agenda the British delegates protested strongly against the proposed duty on British flowers sent to France. In defence, the French delegates stated that the French duty on flowers was imposed to prevent Italian produce from flooding the Paris market, and they considered that a duty of two francs per kilo. would not seriously affect the English trade, as flowers sent from England were always of such high quality that the small duty would not affect their sale. The Belgian delegation and also the Luxemburgers were equally strong in their protest against the French duty on flowers. Mr. Monro pointed out that enormous quantities of French flowers were exported to England; they had spent almost the whole of the morning in endeavouring to secure freedom of horticultural trade with America, and yet France was now proposing to impose a duty on the comparatively few British flowers which she received. Mr. Turbat stated that the French growers wanted protection against the "dumping" of Italian flowers, but when a question of imposing a duty arose, the French Government could not set it up against one nationality only. Finally, after a very spirited discussion, a resolution of protest was passed by all the delegates, except, of course, those representing France.

The third session of the Conference, held in the early part of the afternoon of April 21, was concerned chiefly with the question of dumping. Mr. Westenberg said that he was sorry the Dutch Ministry of Agriculture had not yet decided to consider legislation against the dumping of Dutch horticulture produce in England. Mr. Leak stated that the British representatives had hoped for a favourable report to the protest made prior to the Conference because British traders felt the effect of this dumping very badly. In his own district there had been four sales of Dutch produce, and in as many weeks; five Roses were sold for 6d., an altogether impossible price and far below the cost of production, consequently the British traders, being the largest buyers of Dutch produce, protested very strongly against the practice of dumping. He moved that the Dutch Ministry of Agriculture be asked to put suitable regulations into force to prevent it. Mr. Westenberg replied that all growers, great and small, had the same right to export, but numbers of small growers in Holland did not belong to the Dutch Exporters' Association, a body which was doing all it possibly could to prevent dumping, indeed, no member of that Association was allowed to sell produce at auction under a penalty of £400. Mr. Leak's motion was adopted, and supported by the Dutch delegates.

Reverting to the subject of plant diseases and quarantine arrangements, the Conference agreed that all countries with a pathological service should work out a method of procedure which might find general adoption.

A report on the condition of horticultural trade in Great Britain was presented by the Chamber of Horticulture, and, though brief, its contents appeared to be of great interest to the whole of the delegates present.

Arrangements for the conference to be held in 1923 next came under consideration, and Mr. Spaer, on behalf of Belgium, invited the Fédération Horticole Professionnelle Internationale to hold its conference at Ghent next year in connection with the great Ghent International Quinquennial Exhibition, on or about April 15. The conference accepted the invitation, and expressed the hope that the Ghent Exhibition would be a great success. Mr. C. Pynaert, of Ghent, was elected president for the ensuing year, and Mr. Ruys, Holland, vice-president. The president (Mr. Krelage) and the general secretary (Mr. Turbat) were heartily thanked for their services, and Mr. C. E. Pearson expressed the thanks of the British delegates for the courtesy extended to them and for the hospitality they had received throughout the conference proceedings. In a brief concluding speech Mr. Krelage returned thanks for the honour extended to him last year, and his pleasure in presiding over so large and representative an attendance.

**MESEMBRYANTHEMUM AND SOME NEW GENERA SEPARATED FROM IT.**

(Continued from page 214.)

C. FLOWER YELLOW.

6. *C. calculus*, N. E. Br. Growths globose (type D), 7-10 lines in diameter, light glaucous-green or chalky-green; the old withered skin is very tough and of a pale brown, becoming blackish-brown with age. Calyx 5-6-lobed. Corolla 7-8 lines in diameter, expanding at night, closed during the day; tube 3½-4 lines long; petals 40-50 in 3-4 series, 3½-4 lines long, filiform—linear, yellow. Stamens exerted about 2 lines from the corolla-tube, whitish, with yellow anthers. Top of the ovary dome-like. Style very short; stigmas 6, filiform, greenish.—*M. calculus*, Berger, *Mesemb.*, p. 289 (1908), Marloth, *Fl. South Afr.*, v. 1, p. 201, t. 49, f. B.

Van Rhynsdorp Div. Near Nieuwerust, Pearson 5515; near Bakhuis, Pearson 5471; Hardeveld, Marloth 4573; Mrs. Rood.

7. *C. Pageae*, N. E. Br. Growths 4-5 lines high and 3-5 lines in diameter, obconic, flattish at the top (type F), with the orifice sometimes slightly depressed, sometimes (in the very same plant) uniformly bright green, at others bright apple-green, with the sides and around the orifice of a rich purple. Flowers not seen, but figured in a drawing as being 4-6 lines in diameter and yellow, with the tips of the petals tinted with red.—*M. Pageae*, N. E. Br. in *Journ. Linn. Soc. Bot.*, v. 45, p. 86.

FIG. 121.—*C. NOPHYTUM GLOBOSUM*, N. E. BR. NATURAL SIZE.

Little Namaqualand. Near Garies, Burke.

The manner in which this species changes its colour in different years under cultivation (at least with me) is very remarkable. When the rich purple colouring around the orifice is present it is an exceedingly attractive plant, yet sometimes this is entirely absent; for example, in 1919 and 1920 the purple was present on my plants, yet during the hot sunny year of 1921 it was entirely absent on the very same plants.

CC. Flower of some shade of red, or perhaps whitish in *C. saxetanum*, colour unknown in *C. subrisum*. (Species 8-14.)

8. *C. globosum*, N. E. Br. (Fig. 121). Growths of introduced plants originally globose and about 5-6 lines in diameter (type B), becoming under cultivation slightly globose-obcordate (type M), and sometimes 1-1¼ inch in diameter, of a slightly bluish-green colour. Corolla ½-1 inch in diameter, expanding in the morning, closing in the afternoon, scentless, funnel-shaped, with 40-50 petals in 3 series, white at the lower part and light pink at the apical part. Anthers yellow. Style 3-5 lines long, slender, with 4 filiform stigmas.—*M. globosum*, N. E. Br. in *Kew Bull.*, 1913, p. 119. *Lycoperidistrum soboliferum altius radiculatum*, etc. Burmann, *Rar. Afr. Pl.*, p. 22, t. 10, f. 2, probably belongs here.

Little Namaqualand. Near Garies, Pearson 5582, Pillans.

9. *C. jucundum*, N. E. Br. Plant forming branching stems with age. Growths pear-shaped in side view (type D), subglobose seen from above, glaucous-green, occasionally with a few dots of darker green when young, which disappear with age. Calyx 3-4-lobed. Corolla 8-11 lines in diameter, opening in the daytime; tube 4-5 lines long, apricot-coloured, petals 30-40 in 2-3 series, bright rosy-magenta. Anthers yellow. Style 4-5 lines long; stigmas 4-5, about 1 line long, greenish, equalling or

FIG. 122.—*C. NOPHYTUM MINUTUM*, N. E. BR. NATURAL SIZE; FLOWERS SMALLER THAN USUAL.

exceeding the stamens.—*M. jucundum*, N. E. Br. in *Journ. Linn. Soc. Bot.*, v. 45, p. 93.

Little Namaqualand. South of Bethany Drift, Pearson 6067.

The formation of stems with age is a marked character of this and the next species. Under cultivation the stems of *C. jucundum* spread over the ground, but under natural conditions are probably buried under drifting sand.

10. *C. subrisum*, N. E. Br. Plant developing branching stems with age. Growths 9-12 lines long, 7-8 lines in diameter, obconic, truncate at the top (type I), with the orifice depressed and somewhat resembling a smiling mouth, with a small dimple at each end, uniformly whitish-green. Flowers unknown.—*M. subrisum*, N. E. Br. in *Journ. Linn. Soc. Bot.*, vol. 45, p. 100.

Van Rhynsdorp Div. Near Atty's, Pearson 5466.

Of this very rare species a single plant was sent to Kew in 1911 by Prof. H. H. Pearson, which under cultivation increases very slowly. It is readily recognised by its habit of forming stems, and the resemblance of the depressed orifice to a smiling mouth.

11. *C. Wettsteinii*, N. E. Br. Growths 6-10 lines long, 6-13 lines in diameter, very broadly obconic, with the flat circular top often overhanging the sides (type II.), uniformly light bluish-green or rarely with a few scattered darker green dots. Calyx 3-5 lobed, whitish or pale reddish. Corolla 8-11 lines in diameter, remaining open irrespective of cloud or sunshine, scentless; tube longer than the calyx, dull orange-pink; petals of two kinds, the outer 17-38 in two series, widely spreading, bright rich magenta, becoming white at the base, shining; the inner erect at the mouth of the tube, 1½-2 lines long, linear-filiform, very acute, yellow or orange. Stamens all included in the corolla-tube below the inner petals. Style ½-1 line long; stigmas 4, erect, minute, about ¼ line long.—*M. Wettsteinii*, Berger, *Mesemb.*, p. 285 and 288, fig. 11. (1908). *M. truncatellum*, Othner in *Gartenwelt*, 1907, vol. 11, p. 301, with fig., not of Haw.

Van Rhynsdorp Div. Near Bakhuis, Pearson 5469.

12. *C. minutum*, N. E. Br. (Fig. 122). Growths forming short branching stems with age, clothed with old sheaths; each growth about 5-6 lines long and 2½-5 lines in diameter, obconic or subglobose-obconic, slightly convex at the top (type E.), with the orifice in a slight central depression, light bluish-green or some-

what glaucous-green, with or without a few inconspicuous scattered darker green dots. Calyx 4-lobed, whitish. Corolla 6-11 lines in diameter, expanding in the daytime irrespective of cloud or sunshine, scentless; tube slender, dull orange, or sometimes pale yellowish-white; petals of two kinds, the outer 3-5 lines long, widely spreading or recurved, bright rosy-magenta, shining, and the inner 1-1½ line long, ascending or spreading from the mouth of the tube, yellow, or some with magenta tips. Stamens included in the corolla-tube and hid from view by the inner petals. Style ½-1 line long; stigmas 4, up to ¼ line long, greenish.—*M. minutum*, Haw. *Misc. Nat.*, p. 21 (1803); *Bot. Mag.*, t. 1376; Berger, *Mesemb.*, p. 285 and 288, f. 65, 1., copied from the *Bot. Mag.* *M. thecatum*, N. E. Br. in *Bot. Mag.*, t. 8595 A. Van Rhynsdorp Div. Near Bakhuis, Pearson 5470, Pillans. Introduced by Masson in 1795.

When I described *M. thecatum* I considered it to be distinct from *M. minutum*, because the tube of the corolla was not exerted from the calyx, in the manner represented in the figure of *M. minutum*, and in the case of the latter, the formation of sheath-clad stems is neither represented nor described; but my plants of *M. thecatum* have now produced flowers with a corolla-tube nearly or quite as long and as much exerted from the calyx as is represented in the *Botanical Magazine*, and when the plant is more deeply set in the soil the stem-formation is not evident. Other characters being apparently the same, I have now no doubt that

FIG. 123.—*C. NOPHYTUM OVIFORME*, N. E. BR. NATURAL SIZE.

Photo by Dr. Pale Evans.

*M. thecatum* is identical with *M. minutum*. The extent of the exertion of the corolla-tube probably depends upon the temperature and amount of moisture received during the formation of the flower, as I have found a variation of these conditions to produce similar results in other species.

13. *C. oviforme*, N. E. Br. (Fig. 123). Growths subcylindric-ovoid or narrowly obovoid, 4-6 lines long and 2-3½ lines thick, very convex at the top (type A.), grass-green, minutely tuberculate or papillate all over, soft and pulpy, often enclosed in their old whitish or pale brownish skins. Calyx 6-7-lobed, included, or only the tips of the lobes exerted from the old skin. Corolla about 7 lines in diameter; petals about 30, stated to be pale magenta, but not seen in a fresh state. Style none; stigmas 6, about 1½ line long, filiform. Capsule 2-3 lines in diameter, 6-valved, 6-celled, with small call-wings, and broad marginal valve-wings.—*M. oviforme*, N. E. Br. in *Journ. Linn. Soc. Bot.*, v. 45, p. 95; and in *Gard. Chron.*, vol. LXX., p. 207, fig. 84, 1-1.

Van Rhynsdorp Div. Hardeveld, Marloth; Mrs. Rood, 655.

I think it quite probable that the flowers of this species are sometimes white. The minute papilla-like tubercles on this plant readily distinguish it from all other species. *N. B. Brown.*

(To be Continued.)

## THE NETTLE AS A FOOD.

THOUGH it is certain that your correspondent (see p. 170) is correct in stating that the Nettle was used for food in Scotland, I imagine few eat it in this year of grace. If we give credit to the astute Andrew Fairservice Nettles were forced 200 years ago, and the verse—

Cowe\* the Nettle, stow\* the Nettle,  
Cowe the Nettle early.  
Cowe it by the castle wa's,  
Cowe it where the dew ne'er fa's.  
Cowe the Nettle early—

is assurance that it was in common request long ago. It is also known to have been in repute as an assured specific along with Mugwort (*Artemisia vulgaris*) for girls in an anaemic condition. Moreover, I well remember how the matrons in my native village fed their pigs when food was scarce on boiled Nettles mixed with miller's dust and an occasional meal of brewer's grains. But in olden times it was as a herbal preparation that the Nettle, or, rather Nettles, for the Roman (*Urtica pilulifera*) and two varieties of *N. urens*, of which that with dark stems was held in the greater esteem, was used. That collection of ancient recipes, *The Garden of Health*, gives no fewer than 121 in which the Nettle either alone or in conjunction with other herbs is mentioned. The gathering and preparation of Nettle "crops," as the young shoots were called, might be a difficulty with many, but the verse of a 17th century poem shows how easy it is:—

Tender-handed touch a Nettle  
And it stings you for your pains;  
Grasp it like a man of mettle  
And it soft as silk remains.

The Nettle is one of the ingredients in the "herb pudding" prepared and eaten in some parts of the North of England at Easter, the leaves of the Bistort (*Polygonum Bistorta*) being another. The latter is there known as Easter Ledges, which carries one back to the days when the Bistort was described as *Aristolochia rotunda* and which through many changes, of which Oister loyte is one, became the Easter Ledges of the present day. These are probably long forgotten substitutes for the bitter herbs eaten at the Passover season by Jews. The Mercury of Lincolnshire (*Chenopodium Bonus Henricus*) has similar laxative properties, and was certainly cultivated as the Flowery Docks in Scotland, old garden sites still being evidenced by plants in the vicinity. Spinach has in our time superseded these, but Spinach is probably not a whit better, and, indeed, I have frequently, when the crop has been overmuch gathered, substituted Scotch Kale, a vegetable possessed of similar properties, for Spinach. Purple Sprouting Broccoli is another valuable spring vegetable, less laxative than the above. The Scot up to a very recent period ate the pith of Cabbage stalks. Hereabouts it was called Casties, the Castocks of Burns:

Gif the Castocks, sweet or sour,  
Wi' joetelegs they taste them.

Up to about 40 years ago the working-class in this locality decocted *Artemisia maritima* and drunk it in spring as a prophylactic, and for its tonic properties, and another common herb in use particularly among vagrants was *Agri-monia Eupatorium*, which they infused like tea and consumed when bilious. Those who know Thoreau's *Walden* are aware how he lived for a time, annually, on what he produced by his own labour in six weeks, and made a satisfactory dinner on Purslane alone on one occasion. One need not experiment as he did and yet find a vegetarian diet competent to meet all the wants of the body alike for food and physic. One of the most distressing afflictions that overtake old men may be kept, if not away, at least under, by a purely vegetable diet in which decocted barley, and if one cares for them, Dandelions, form a daily portion. Whether so much meat as is now usually consumed has anything to do with the origin of the above functional disease it would be rash to say, but the resort to a vegetable diet has certainly a great effect for good. *R. P. Brotherston.*

\* Cowe and stow are old Scots for "cut."

## THE GRAPE VINE.\*

(Continued from page 215.)

THE pruning should be done at least a month before starting the vines into growth, as soon as the wood is ripe and when the leaves are down. Cut away all the current year's wood to one or two buds, and thus keep the spurs within reasonable limits. One bud is sufficient for the production of a good bunch on most varieties; but there are others, so called "shy bearers," which do not always throw a bunch from the basal bud. Duke of Buccleuch is particularly shy in this respect. This difficulty may be got over successfully by leaving eight inches of the current year's wood instead of one-quarter inch, and then removing all the buds except one or two at the base. This means that all the reserve food in the last season's wood will be available for the buds left. In the spring, when the sap rises, these shoots are tied firmly to the wires. The young shoots can be trained to these the following spring, and by putting on a base tie after the shoot is about four inches long it saves a lot of work when tying down the laterals later. During the following season this reserve food is all used up by the plant. By the end of the season, when pruning time comes round again, this wood is thin and starved. It is then cut flush with the current year's wood, and the wound will heal over completely the following season, whereas in the short method the wound seldom heals or calluses over properly. None of the varieties in cultivation are shy bearers in their young state, because the whole of the vine is of recent growth and can be pruned to a single bud.

The spurs should never be closer than twenty inches apart on alternate sides of the stem. It is impossible to get large, well-finished bunches without large leaves, and this cannot be accomplished with spurs every few inches. For instance, we have some old rods of Black Hamburgh, with spurs two feet apart, on which I have seen leaves measuring seventeen inches when the vines were in flower, and the leaves easily cover the space when at full maturity.

Only one shoot should be allowed on a spur, and each of these shoots should be capable of carrying a bunch. It is only when there is plenty of room between the spurs that fully developed leaves are found, without overlapping each other. Though reserve food is found in the spurs, it is not readily available. This is proved by the fact that a bud rising from the spur takes a year or two to fruit, while a bud from the current year's wood will fruit the following year.

When the rods have been pruned, they should be thoroughly cleansed and dressed with Gishurst compound; at the same time the woodwork, glass, and all bare surfaces in theinery should be scrubbed with hot soapy water, with a little paraffin added, to destroy any vermin lurking in the crevices.

Remove about one inch of soil from the surface of the border. At all events, sweep away all loose particles of inert soil and the loose bark taken from the rods. Give the border a dressing of some suitable fertiliser: the strength of the vines the previous year is a good guide to the quantity required. Fork this material in lightly, and add about one inch of fresh, finely chopped loam to the border. The soil in the border should be tested periodically to see if it is sour, and, should it be found to be acid, dress the border with lime.

In starting the vines into growth, keep the front ventilators closed, using the top ventilators only. The night temperature should be about 45°, with a rise of 10° during the day, when fire heat is used, but it may be allowed to rise more with solar heat. The rods may be syringed with tepid water in the mornings till the buds burst evenly over the vine. If there is danger of the top buds in young canes developing far in advance of the

\* A lecture delivered by Mr. Malcolm Maenaughton, Scene Palace Gardens, Perth, in the Technical College, Dundee, before the members of the Dundee Horticultural Association.

others, let down the cane to a horizontal position, remove all superfluous buds as they appear, and reduce the buds to one on each spur.

As soon as growth is fairly started, raise the night temperature from 50° to 55°, with a gradual increase to 65° in the daytime. I discontinue syringing and damping as soon as the vines are breaking evenly. When there are enough leaves beyond the bunch to cover the trellis, without the leaves touching one another in the space between the rods, pinch out the points of the shoots; also pinch the leading shoots on young rods when they have made four or five feet of growth. The bunches should be removed from this shoot as soon as they are seen. Pinch out all laterals and tendrils and also long, straggly shoulders from the bunches, leaving nothing but the primary leaves. This directs the sap to the leaves and bunches. This stopping does not affect the growth of the vine. The leaves are larger and better able to do their work; at the same time root action is steadied, causing short, branchy rootlets to develop instead of long, spongy, soft roots, which generally die off at a critical time.

Many shoots will develop two bunches, and the better one should be retained.

Care and patience are required when tying the shoots to the trellis, for they are easily removed from the sockets at this stage. It is better to draw them down a little at a time till they are in position.

When the vine comes into flower, admit air carefully during the day, especially in the morning. No harm will accrue if the temperature rises to 90° with top air admitted. Guard against a sudden lowering of the temperature during the forenoon, even for a few minutes, by the sun disappearing behind a cloud, the reason being that, when the temperature falls suddenly, the stomata of the leaves close, and growth is practically arrested for the day. A check of this kind is not good for vines at any time early in the season, but it is fatal so far as the setting of the flowers is concerned.

In pollinating the flowers, a little jerk will occasion the dislodgment of the cap or covering of the flower, causing the pollen to be dispersed. With some free setting varieties this is effected naturally, aided only by the proper atmospheric conditions. The flowers of other varieties are more difficult to set, and this difficulty has to be overcome by artificial impregnation of the flowers. This is best accomplished at mid-day by gently tapping the rods and holding a piece of glass under a bunch of a free setting variety to catch the pollen while the bunch is being shaken. The pollen is then taken directly to the six setting varieties and blown lightly over the bunches on to the stigma, these bunches having been shaken previously to remove the cap from the flowers, leaving the pistil exposed. If this is done two or three times, it generally proves efficient.

In bright weather, and if the atmosphere is dry, daup the house down after the flowers have been gone over. It is sometimes necessary to thin the bunches, especially when the rods are too close together, or where there are too many spurs on the rod. It is not the number of shoots the grower has to consider, but the number of leaves or amount of leaf surface, in deciding the number of bunches the vine is able to carry. If the rods are three feet six inches apart and twenty inches between the spurs it is quite safe to leave a large bunch on each shoot, provided the vines are in good health.

### THINNING THE BERRIES.

As soon as the flowers are set thin the berries before they are as big as Radish seeds. Free setting varieties I have thinned before the flowers opened with the best of results. Clip out what may be termed side berries and those in the centre of the bunch, starting at the lower end of the bunch and working to the shoulders, taking care not to damage or rub the berries. A tiny mark made at this time may develop into an ugly blemish.

At this stage everything should be done to help the bunches to develop rapidly. Keep the

temperature on the high side during the day, with a little top air admitted, and damp the house several times daily for a week after the berries have been thinned, so that the bunches will spread themselves out and the stalk of the berries lengthen and strengthen as much as possible, for there is no use having big bunches if half the berries have to be removed. Aim at having a bunch that will retain its firmness and shape when finished and placed on the table. It is best if the thinning can be done at one operation, so that the berries can place themselves in position as they grow. We do not tie up the shoulders of the bunches unless they are very heavy, but prefer to cover the bunches occasionally and ease the berries with a smooth, round-pointed stick or penholder. Commence at the top of the bunch and work the berries upwards, regulating them as much as possible; this helps them considerably in swelling, care being taken not to rub the bunches with the hands or the hair, as this often spoils the bloom and may disfigure the fruit. As the berries begin to swell, reduce the temperature and give an abundance of air, using both top and bottom ventilators, leaving them open a trifle during the night, even in dull, cold weather, when fire-heat has to be used. Discontinue damping theinery, unless in the forenoon, if the air gets very parched.

(To be Continued.)

## FRUIT REGISTER.

### APPLE RUSHOCK PEARMAIN.

THIS Apple is of the russet family and it is surprising to me it is not more generally grown, as I feel certain it would find a ready and profitable market.

The fruit is about medium size, some two and three-quarter inches in width, and about the same in height; conical and handsomely formed. The skin is a deep yellow colour, almost entirely covered with cinnamon-coloured russet, with a brown tinge on the side next the sun. The eye is large and open, with broad, flat segments, which fall off as the fruit ripens. The stalk is short and stout and inserted in a deep cavity. The flesh is yellowish, firm, crisp and juicy, with a brisk sub-acid and sugary flavour.

It is a dessert Apple of first-rate quality, keeping sound until the end of April. It was raised by Chas. Taylor, a blacksmith, at Rushock, in Worcestershire, about the year 1821. *Pomona*.

### APPLE WINTER PEARMAIN.

*Pomona's* note on this Apple on p. 185 confuses two totally distinct varieties. Old Pearmain, which, according to the *Fruit Manual*, dates back to the year 1200 is now almost extinct. A few specimens of it were shown at one of the Royal Horticultural Society's meetings four or five years since, from the neighbourhood of Orpington, Kent; possibly the trees from which they came are still in existence. I know of only two other trees, which are now getting very weak. This variety is far superior in quality to Duck's Bill or Winter Pearmain, also called Sussex Scarlet Pearmain, and does not keep so long in condition, the end of October being about the limit of its season. It is a pity such a good flavoured Apple should have been allowed to pass out of cultivation. Duck's Bill is very much inferior both in flavour and texture, but has the merit of keeping several months longer than Old Pearmain. *W. H. Divers, V.M.H.*

## HOME CORRESPONDENCE.

[The Editors do not hold themselves responsible for the opinions expressed by correspondents.]

**Chorleywood Cedars.**—I read with great interest Mr. Stacey's note, on p. 56, about the Chorleywood Cedars, and the correspondence arising from it on pp. 81 and 111. These trees were under my observation from 1887 till about three years back. I am afraid I cannot contribute any information as to their age. Several times during the past thirty

years attempts have been made to arrive at the ages of these particular trees. As Sir Herbert Maxwell points out, there is no certain evidence of the exact year that the Cedar of Lebanon was introduced to the British Isles, and, no doubt, the old writer, John Evelyn, was about the first to bring this tree to the notice of planters in Britain. It is my opinion that batches of plants were raised about that time, and that they were distributed to some of the great landowners of the period, and possibly the oldest and largest trees in exist-

wood trees are of greater age than 155 years. The feature of the largest Chorleywood Cedars are the huge limbs, forming straight boles, say, from 10 feet to 12 feet from the main trunk. I quote a description taken from J. C. Loudon's *Arboretum et Fruticeum Britannicum*, 1838, Vol. IV., page 2426, as follows:—

"REMARKABLE EXISTING TREES.

"At Chorleywood, near Rickmansworth, on an estate of the Duke of Bedford, are, near the house, eight remarkable Cedars, the largest of which has a trunk 18 feet in circumference,

FIG. 124.—ONE OF THE LARGEST SPECIMENS OF CEDRUS LIBANI AT CHORLEYWOOD CEDARS.

ence are from that particular distribution. I mention this as Mr. Baker, Bayfordbury, refers to the Cedar seed planted at Enfield in or about 1670. Mr. Baker also mentions the Cedars at Bayfordbury, one of which has a girth of 20 feet and is 97 feet in height, and this in the short time of 155 years. I think 300 years from the time of planting quite covers the time of any tree of Cedar of Lebanon in this country. The soil and sub-soil make a great difference in the growth of Cedars, as of other trees not native of the country. For instance, Mr. Baker has mentioned a height of 97 feet in 155 years. This exceeds in height any of the Chorleywood Cedars, the highest of which in 1907 was 92 feet. It is quite certain the Chorley-

wood trees are of greater age than 155 years. The feature of the largest Chorleywood Cedars are the huge limbs, forming straight boles, say, from 10 feet to 12 feet from the main trunk. I quote a description taken from J. C. Loudon's *Arboretum et Fruticeum Britannicum*, 1838, Vol. IV., page 2426, as follows:—

"REMARKABLE EXISTING TREES.  
"At Chorleywood, near Rickmansworth, on an estate of the Duke of Bedford, are, near the house, eight remarkable Cedars, the largest of which has a trunk 18 feet in circumference, dividing into 12 large limbs, from which spring 32 branches of a size fit to be measured as timber and containing 613 solid cubic feet."  
This is, I think, the tree referred to by Mr. Stacey as measuring 25 feet in girth 3 feet from the ground. This tree, at 4 feet from the ground, I think, measures 30 feet, as it bulges out at that part. The Chorleywood trees have suffered much from heavy snows during the past 50 years. The great snowstorm of January, 1881, did much damage to them, and huge limbs have come away in snowstorms since. Very great expense has been incurred in past years in trying to preserve these splendid trees by chains laced high up amongst the limbs and iron hoops to keep them from snapping by the weight of snow.

My opinion is it would have been better to have left them alone, as the chains and hoops have tightened and cut into the bark, so that, when snow falls, they prevent the huge limbs from swaying and releasing the snow. I have seen the branches break many times, just where the chain and the hoop clasped the limb. The heights of seven of the large Cedars at Chorleywood in 1907 were 92 feet, 82 feet, 87 feet, 85 feet, 81 feet, 84 feet, and 70 feet respectively. *William Waterman, Hollydene, Elsenham, Essex.*

I have been greatly interested in the various letters concerning *Cedrus Libani*, many of which have really been answers to my original enquiry. I have not ventured to give the age of our big Cedars, but I wanted particulars, so far as possible, of large specimens and some data that might lead to reliable information concerning the introduction and planting of the finest specimens in the country. I am greatly obliged to you for your help and for the help of your correspondents. I enclose a sample twig to show the slow rate of growth of *Cedrus Libani*, and another photograph (see Fig. 124) showing the largest of our original seven trees (a four and a three). The height of the big specimen is from 100 to 110 feet, and this tree is visible from miles around. Our soil dries quickly, as we are on gravel and chalk. If you can find space to illustrate our giant, I shall be grateful, and it would seem to be a fitting end to the discussion. *Geo. W. Stacey, Chorleywood Cedars, Herts.*

**Greenhouse Blinds.**—In your issue for April 22, p. 202, Mr. F. Crandon asks whether it is not much better to have such blinds as the wooden chain lath blind, that may be kept in its place all the winter, to save the little extra time that it takes to refix the cotton-canvas blind. The lath blind is undoubtedly a great protection during severe weather, where a high temperature is required in the houses, but beyond that it has very little to recommend it. I much prefer the thick cotton-canvas blind for the flowering-plant house and stove during the summer, as it gives, in my opinion, a much better shade and a cooler temperature, when the plants need it. *T. Patman, The Node Gardens, Welwyn.*

**Summer Time.**—In your issue of April 1, page 145, the Minister of Agriculture states that there is no obligation on farmers or their labourers to revise their customary hours of work according to the sun. May I point out that they all have to fall into line with the other workers, for various reasons. Cows have to be milked an hour earlier for the farmers to catch the trains, as both the retailer and the public require milk an hour earlier. Butter and eggs have to be taken to market by the clock, and the market gardener has to have his goods in the market or at the shops by the clock, not by the sun. All workers on farms, market gardens, and private gardens have to make their after-work arrangements by the clock if they wish to play cricket, go by train or to any place of amusement. My experience is they do not like to be at work after other people have finished labour. They quite realise that they have to work late in the hay and corn harvests. From what I gather, the grievance is that on farms, market gardens, and private gardens there is always work to be done after the usual working hours, especially on Saturday afternoons and Sundays. The one hour on these days makes a lot of difference to the farmer and private gardener. In large gardens, where there are men in the botany, it does not matter so much. *A Derbyshire Gardener.*

**Effect of Last Summer's Drought on Hardy Bulbs.**—Never do I remember the spring bulbous plants to have flowered with greater freedom than this season. The stems, and particularly those of Narcissi and Daffodils are much longer and stronger than usual, and the flowers very much larger and more beautiful, which clearly proves what a good effect the great drought of 1921 and long rest the plants enjoyed had in thoroughly ripening

the bulbs, as no manuring or other assistance has been given them. I also notice that *Amaryllis Belladonna*, *Habranthus*, bulbous Irises, and other bulbous plants are commencing to grow with far greater vigour than usual, and promising very fine flowers during 1922. *R. H. C., Weston Park Gardens, Stevenage.*

**Musa Cavendishii.**—Are we to understand correctly from the note by Mr. Thos. E. Furnell on p. 202 that the bunches of fruits produced by Mr. James Ollerhead, weighing as much as 100 to 112 lb., were of *Musa Cavendishii*? It appears to me to be more likely that the species was *Musa sapientum*, and that the smaller variety alluded to was *Musa Cavendishii*. Sir Joseph Paxton observed that bunches might be produced from 15 to 30 lb. I admit that larger bunches are likely to be produced when the Bananas are planted out than when grown in tubs. The weight I quoted was of fruits only—"120"—and did not include the stem. *J. Snell, Sunderland.*

**Blanching Celery.**—Mr. Owen Thomas' remarks on blanching Celery with paper collars (see p. 171) prompts the query: "Is it possible to produce well blanched, sweet, crisp, nutty-flavoured Celery from August to May with paper collars instead of the usual earthing up?" Celery is very susceptible to frost, and a paper collar is a thin garment against the frequent attacks of 20° to 30° of frost in winter. Celery in many gardens is a most important and expensive crop to cultivate. Information on this matter should interest many growers and readers. *John Bates, Meaford Gardens, Stone.*

**Aquilegia Stuartii.**—In Mr. Arnott's note (p. 192) upon *Aquilegia Stuartii*, he observes that it is said to be a hybrid between *Aquilegia glandulosa* and *Aquilegia olympica*, and suggests that there are grave doubts as to the truth of this statement. There need be no doubt at all as to the parentage of this lovely Columbine. I had the privilege of acquaintanceship with the late Dr. Stuart, and often visited his garden at Chirnside. He told me the parentage of *A. Stuartii*, and its history is confirmed in the paper upon "A Few Notes on Reproduction in Hardy Plants," which he contributed to the International Conference on Hybridisation held in London in 1899 under the auspices of the Royal Horticultural Society. His paper is published in full in the "Hybrid Conference Report" (*Journal R.H.S.*, Vol. XXIV.), and deals fully with the story of *A. Stuartii*. The parentage is *A. Witmannii* × *glandulosa*. I have seen several stories of the history of *A. Stuartii* in various gardening journals, all of which have been wrong. Every student of hardy plants can obtain the true history in the *Journal* to which I have referred. That is surely authoritative, and should settle the matter once and for all. Many writers, however, seem to copy each other without any verification of the statements that are made, and errors are perpetuated in consequence. Like Mr. Arnott, I have lost my stock of *A. Stuartii*, and I am afraid it is not now to be procured true from nurserymen. The cross, however, might be repeated in the hope of creating, *de novo*, the hybrid again. It was the gem of the blue and white *Aquilegias*, and its great sapphire blossoms with their snowy settings were flowers to be remembered. *George M. Taylor, Edinburgh.*

**Carnation Bis Greenfield.**—Mr. W. Carter wonders why this variety is not more widely grown (see p. 158), and I agree with him. I have grown it since it was first introduced by Messrs. Peed and Son, and consider it the best Scarlet Carnation yet introduced. The plant has a wonderful constitution; it makes strong growths and long, stiff stems, whilst the calyx does not split. The flowers are as large as those of a Malmaison variety and they have a lovely Clove scent. Although this variety does not flower quite so early as some of the Enchantress type, it blooms at a time when Carnations are most needed. I am sure when this variety is better known it will be found in every collection of good perpetual Carnations. *F. J. Cubberley, Tatton Park Gardens, Knutsford.*

## SOCIETIES.

### MIDLAND DAFFODIL.

(Continued from page 217.)

#### AMATEURS' CLASSES.

The collection of twenty-four varieties of Daffodils, which gained for Miss HINGCLIFF, Inston, Messrs. BARR AND SONS' Daffodil vase, offered as first prize, was a particularly praiseworthy one, not only for the quality of the flowers, but also for their pleasing arrangement. A few of the best varieties were M. M. de Graaf, Madame de Graaf, Barrii, Bullfinch, Poeticus Horace, Mermaid, and Tazetta Grand Monarque; 2nd, R. H. DARLINGTON, Esq., Potter's Bar; 3rd, Rev. R. H. WILMOT, Worcester.

Mr. DARLINGTON won first prizes in classes for (1) 6 Trumpet varieties, (2) 6 Incomparabilis varieties, (3) Barrii varieties, (4) 6 Leedsii varieties, and (5) Poeticus varieties.

Messrs. Cartwright and Goodwin's silver vase, offered for six varieties of Daffodils, was won by Miss V. WARREN with a choice half-dozen flowers.

The Birmingham Botanical and Horticultural Society's medals were awarded as follows:—Classes 1-30: Silver medal to Mr. J. LIONEL RICHARDSON, with 112 points; bronze medal to the DONARD NURSERY Co., with 89 points. Classes 16-30 and 31-40: Silver medal to Mr. J. LIONEL RICHARDSON, with 66 points; bronze medal to the DONARD NURSERY Co., with 64 points. Classes 16-30 and 41-49: Silver medal to Mr. DARLINGTON, with 71 points; bronze medal to Mr. W. F. M. COPELAND with 42 points.

#### AWARDS OF MERIT.

**Magnolia.**—A beautiful Eucharis-like Giant Leedsii of great purity, with a prettily frilled cup. Exhibited by Messrs. GEORGE MUNRO, LTD., Covent Garden, London.

**Poeticus Coronation.**—A charming flower, with a pure white flat perianth and a rich crown, edged with orange. Exhibited by Messrs. BARR AND SONS, Covent Garden.

**Glorious.**—A robust Tazetta variety of good size, pure white, with a bright orange-coloured cup. Exhibited by J. LIONEL RICHARDSON, Esq., Waterford.

**Brightling.**—A strong growing Incomparabilis variety, with a pale yellow perianth and a very deep orange-coloured cup. Exhibited by the ANGLESEY BULB GROWERS' ASSOCIATION, Llanfair, P.G., Anglesey.

**Sunrise.**—Delicate white perianth and a rich orange-coloured crown. Exhibited by the ANGLESEY BULB GROWERS' ASSOCIATION.

**Mrs. Percy Neale.**—A bi-colour Incomparabilis. Exhibited by W. F. M. COPELAND, Esq., Southampton.

**Everest** (see Fig. 116).—A refined, delicate white Trumpet variety. Exhibited by the DONARD NURSERY Co.

**Orange Glow.**—An Incomparabilis, with a broad, flat perianth and a deep orange-frilled cup. Exhibited by Messrs. R. H. BATH, LTD., Wisbech.

#### HONORARY EXHIBITS.

Gold medals were awarded to Messrs. BARR AND SONS, Covent Garden, for an extensive display of Daffodils, including many new varieties, and the DONARD NURSERY Co., Newcastle, Co. Down, for a large group of Daffodils, consisting principally of Trumpet varieties.

Silver gilt medals were awarded to Messrs. R. H. BATH, LTD., Wisbech, for Daffodils, and the ANGLESEY BULB GROWERS' ASSOCIATION, Llanfair, P.G., Anglesey, for Daffodils.

Silver medals were awarded to J. LIONEL RICHARDSON, Esq., for Daffodils; W. F. M. COPELAND, Esq., Southampton, for Daffodils; and Messrs. CARTWRIGHT AND GOODWIN, Kidderminster, for Daffodils.

A bronze medal was awarded to H. G. HAWKER, Esq., Ivybridge, Devon, for Daffodils.

**MANCHESTER AND NORTH OF ENGLAND.**

APRIL 6.—*Committee present*:—The Rev. J. Crombleholme (in the chair), Messrs. R. Ashworth, B. J. Beckton, J. Birchenall, A. Burns, A. Coningsby, D. A. Cowan, J. C. Cowan, J. Cypher, Dr. R. N. Hartley, J. Evans, W. Giles, J. Howes, A. Keeling, J. Lupton, D. McLeod, J. McNab, L. W. Thompson, and H. Arthur (secretary).

**AWARDS.**

**FIRST-CLASS CERTIFICATES.**

*Odontoglossum crispum Royalty*. A remarkable variety of the Premier type; the sepals and petals are very broad and beautifully fringed; the large lip is also fringed. *Dendrobium Cybele, West Point var.* A fine variety of the type. *D. Cybele album magnificum*. A large white flower of fine shape. *Brassolaelio-Cattleya Lady Rachel* (B.-C. Queen Alexandra × B.-L.-C. Veitchii). A large flower with white sepals and petals; the lip is white, with the lower half coloured deep purple. *Odontoglossum crispum Iron Duke*. A large white flower of grand shape, heavily blotched deep red. From S. GRATRICK, Esq. *Odontioda Alcazar* (*Odontioda Hippolyta* × *Odm. L'Empeur*). A deep claret-purple coloured flower of perfect shape. *Odontoglossum crispum Athertoniae*. A very fine variety. *Odm. Duke of York* (percultum × *illustrissimum*). A flower of fine shape; the sepals and petals are deep reddish-brown and the lip of the same colour with a white tip. From Mrs. GRATRICK. *Odontioda Cilleham Flammea*. A very pretty variety deep scarlet in colour. *Odontioda Laura superba*. Deep reddish-brown flower of fine shape and substance. *Odm. Llewellyn var. Mrs. Hanmer* (*amabile splendens* × *Georgius Rex*). A large reddish-purple flower with rose-coloured margin. From A. HANMER, Esq. *Cymbidium Castor var. claytoniense*. A large flower of fine shape. *Cymbidium Alexanderi Imperial Prince*. A large, rose-coloured flower of fine shape. From the Rev. J. CROMBLEHOLME. *Cypripedium Alcar* (*Alciadiades illustris* × *Carola*). A large well-shaped flower, the dorsal sepal showing a preponderance of white. From Dr. CRAVEN MOORE.

**AWARDS OF MERIT.**

*Cattleya Irene, West Point var., Odm. crispum Cygnet, Dendrobium Mrs. S. Gratrick, Cypripedium Gold Mohur*. From S. GRATRICK, Esq. *Sophro-Laelio-Cattleya Adelina var. Dorabella*. From Mrs. BRUCE and Miss WRIGLEY. *Cypripedium Thais, Edgemoor var.* From A. HANMER, Esq. *Cypripedium Olympus The Secretary*. From Dr. R. N. HARTLEY. *Cymbidium Elfin* (*Parishii Sanderac* × *Pauwelsii*). From Col. Sir J. RUTHERFORD, Bart.

**AWARDS OF APPRECIATION: FIRST-CLASS.**

*Odontoglossum crispum May Blossom*. From S. GRATRICK, Esq. *Miltonia Sanderac var. Painted Lady*. From Capt. W. HORRIDGE.

**GROUPS.**

MESSRS. ARMSTRONG AND BROWN, Tunbridge Wells, were awarded a Gold Medal for a magnificent group of Orchids in great variety.

Mrs. BRUCE and Miss WRIGLEY, Bury (gr. Mr. A. Burns), staged a group for which a large Silver Medal was awarded.

The Rev. J. CROMBLEHOLME, Clayton-le-Moors (gr. Mr. E. Marshall), was awarded a Silver Medal for a group of Cymbidiums in variety.

Col. Sir J. RUTHERFORD, Bart. (gr. Mr. J. Lupton), was also awarded a Silver Medal for a group. MESSRS. CYPHER AND SONS, Cheltenham, staged a collection for which a large Silver Medal was awarded.

**NATIONAL PRIMULA AND AURICULA.**

(SOUTHERN SECTION.)

APRIL 25.—The annual show of the Southern Section of this old-established Society was held in conjunction with the R.H.S. fortnightly meeting. Time was when this function was an important horticultural event, but for many years past the show has assumed very small proportions and with the apparent apathy shown

by the executive, there are but small prospects of any return of the Auricula to its former position as an exhibition flower. The few exhibitors staged were really beautiful specimens of the fascinating Auricula, but they were painfully few. A great number of the many visitors to the hall came, in due course, and inspected the exhibits, but there was nothing to assist them, except the very meagre statement on the entry cards of a few classes, in their evident anxiety for enlightenment.

**FIRST-CLASS CERTIFICATES.**

*Auricula Glow*.—A very beautiful Alpine Auricula of rich crimson-carmine colour and golden centre. Shown by Mr. JAMES DOUGLAS.

*Primrose Clarkson*.—This is a free-flowering, rather dwarf single Primrose of medium size and rosy-lake colouring with an orange eye. This and the two following were shown by Mr. G. W. MILLER.

*P. George*.—Similar in habit and type to the foregoing. The colour is a clear lilac, and it has a small orange eye.

*P. Lingwood Beauty*.—A larger single Primrose of attractive rosy-purple colouring.

**COMPETITIVE CLASSES.**

The principal exhibitor of Auriculas was Mr. JAMES DOUGLAS, Great Bookham, who won the first prizes for (a) 12 Fancy, (b) 12 Alpine, (c) 12 Show, and (d) 6 Show varieties. His outstanding plants were (a) Lothario, Jupiter and Annot Lyle, a beautiful Rose; (b) Day Dream, Picotee, and Glow (see awards); (c) and d) Blue Eyes and Gleam, a gorgeous golden flower with a broad white eye.

Mr. J. T. BENNETT-POE won first prizes for (a) 6 Alpines, (b) 4 Alpines, (c) 1 white-centred Alpine, showing a good specimen of Argus, and (d) 1 gold-centred Alpine, with Muriel. His Alpines were of high merit and included extra good plants of Argus, Muriel and Golden Dustman.

The only collection of Primulas and Auriculas was by Mr. G. W. MILLER, and he was awarded the first prize for an interesting and comprehensive exhibit. Mr. MILLER was also awarded all the first prizes for Primroses and Polyantheses. He showed exceedingly good plants in all the classes, his 6 double-flowered Primroses and one plant of Clarkson Gem, a rich yellow, with orange centre, were all very beautiful.

**DEESIDE FIELD CLUB.**

UNDER the general presidency of the Marquis of Aberdeen and Temair, who was accompanied by the Marchioness, the annual meeting of this club was held in the Town Hall, Banchory Ternan, Kincardineshire (a pretty little town situated on the bank of the Dee, and some 18 miles from Aberdeen), on Saturday, April 15. Despite the tempestuous weather, there was a magnificent attendance, and the greatest enthusiasm prevailed. Mr. W. Murdoch, Logie Mar, Banchory, secretary and treasurer, submitted the annual report. Substantial progress, it was pointed out, had been made during the past year—the membership had doubled, activities had developed, enthusiasm had grown, the financial position had improved, the club's policy and methods had stood the test, the main difficulties had been overcome, and they had now no fear for the future. Such was the gist of the second annual report.

In his opening remarks, Lord Aberdeen reviewed the principal events of the past year, and made special reference to the Bay of Nigg, a beautiful spot situated near the entrance to Aberdeen Harbour. His lordship characterized the bay as a delightful and attractive asset to Aberdeen and warmly praised the work of those now making an effort to make this magnificent asset more popular and its beauties and charms better understood and developed. On the motion of Miss Burnett Ramsay, Banchory Lodge, seconded by Mr. J. S. Davidson, O.B.E., Currie, Cults, the report was unanimously adopted.

Office-bearers were then appointed, and were their names given here, it would simply include members of the leading families in Aberdeen-

shire and Kincardineshire, scientists, university professors and lecturers. Baron Bentinck, seconded by Mr. J. C. Thom, proposed the appointment of Mr. Alex. Macdonald, M.A., Aberdeen, as recorder and editor. The summer excursions were fixed to take place on the second Saturday of each month, with the exception of July and August, when the date will be the second Wednesday. Lord Aberdeen suggested an excursion to the old castle of Coull and Craigievar, and the secretary mentioned a suggestion by an absent member in favour of the old castle of Birse and Finzean, the residence of Mr. Joseph Farquharson, R.A. Both suggestions were favourably received, and will be included in the itinerary.

After tea, members took advantage of the opportunity given by Miss Burnett Ramsay to visit the beautiful grounds and gardens at Banchory Lodge. Regret was expressed at the absence, through indisposition, of Dr. Bremner, Aberdeen, who was to have given a geological demonstration.

**EAST ANGLIAN HORTICULTURAL CLUB.**

AT the April meeting of this club a very instructive and lucid paper on "Cyclamen Culture" was given by Mr. F. J. Endersby, gardener to J. H. Gurney, Esq., Keswick Hall, Norwich. Mr. Endersby has gained much local reputation as a successful cultivator of this flower and for the numerous prizes he has won with them at local shows. There was no one point from seed sowing to flowering and then growing the plants on again that he did not touch upon.

One great point Mr. Endersby emphasised was that at no stage in their culture did he believe in drying off the corms; experience had taught him that such a method was not the way to secure the best results.

As an evidence of his cultural skill Mr. Endersby brought to the meeting a wonderful collection of plants of varied ages, and showing diversity of colour and form in their flowers. The best of the collection was a variety with flowers of a deep, crimson self colour; the plant was eighteen months old from seed sowing and yet measured over two feet in diameter and carried over a hundred fully developed flowers. Mr. Endersby received a Cultural Certificate for his plants and a hearty vote of thanks for his paper.

**FALMOUTH SPRING SHOW.**

A FLOWER show in Cornwall, and especially a spring flower show, differs considerably from any held elsewhere in this country. At Falmouth, on April 19 and 20, in a collection shown by HOWARD FOX, Esq., of that town, Citrons, Oranges, Bananas (*Musa japonica*) in bud, Bamboos 25 feet long, large fragrant branches of *Cytisus elegans*, *Viburnum rugosum*, *V. Carlesii*, *Eriostemon ericoides*, and similar plants were a striking contrast to the subjects to be seen at meetings of the Royal Horticultural Society.

Australian plants have been grown for years, and it is not necessary to go to Cornwall to see these, as the beloved "Wattle" of the Australians flourishes in sheltered spots in other parts of the country, *Acacia Baileyana*, and *D. dealbata* sometimes measuring 15 feet or more in height and presenting a fine picture when in blossom in the open.

At Falmouth some half dozen private exhibitors sent *Acacias* from their gardens, while the local nurserymen, Mr. RUSE and Messrs. GILL AND SON, showed *Rhododendrons*. *Acacias* and other plants which flourish out of doors in the neighbourhood; a fine specimen of the white Himalayan *Rhododendron ciliolatum*, which opens flushed with rose, was a very fragrant attraction.

The garden lover in Cornwall is encouraged by climatic conditions, but cultivation is not superior in the case of Roses and fruit trees. Certain growers, however, exhibited some of the finest flowers of *Anemones* imaginable. The Cornish gardener is very conservative; for instance, while the classes for rare flowers were

fairly well filled, not a single competitor came forward for the £4 offered in prizes for Carnations. Amateur growers of Carnations here, as elsewhere in the country, do not bring out their blooms, and even at the British Carnation Society's show, held at the Horticultural Hall in March, some £25 worth of prize money went begging.

In the class for decorative pot plants, arranged on a space of 100 square feet, the winner, Mr. J. C. BURROW, gardener at the Falmouth Hotel, had a magnificent specimen of *Iris japonica* in full flower, with a promise of ample blossom to follow; *Schizanthus*, *Diplacus*, *Abutilons*, and *Senecios*, flanked by *Phoenix rupicola*, were other subjects employed. Mr. R. GILL, gardener to the Falmouth Corporation, won second prize, his group including *Schizanthus*, *Primula malacoides*, and *Rhododendron Pink Pearl*.

Non-competitive exhibits were a feature of the show. These included a choice lot of new Narcissus from Mr. J. C. MARTIN, who recently secured an Award of Merit for Silver Chimes; his spikes exhibited here carried 6 or 7 flowers each. Messrs. R. VEITCH and SOX, Exeter, brought plants which flourish in Cornish gardens, noticeably, the brilliant *Correa splendens*, *Viburnum Carlesii*, *Prostanthera rotundifolia* with purple bell-like flowers; and *Tremandra verticillata*. Roses from the Devon Rosery, Torquay, and Carnations of the Perpetual varieties, which do so well in the open here as elsewhere in England, came from Messrs. ALLWOOD, BROTHERS, Hayward's Heath, and Messrs. STUART LOW and Co., Enfield.

Hybrid Orchids were also shown by the latter firm.

The exhibition was opened by the Rev. BOSCAWEN, an enthusiastic horticulturalist, who in his opening address advised his audience to take up gardening as being a hobby which returned better value than any other. He suggested they should work themselves, advice which elicited droll remarks from a few gardeners present, one asking what jobs would be left for the professional gardeners; to which another replied that it was but a diplomatic way of calling attention to the value of gardeners, because if amateurs did their own work they would more readily appreciate the value of the professional and soon want his assistance.

## Obituary.

**Samuel Thomas Wright, V.M.H.**—No name in horticulture is better known, no figure was more familiar, than that of S. T. Wright. And though we shall often hear his name, we shall never again see that familiar figure, for he passed away quietly early on Friday morning, April 28, at Matlock, where he had gone to recuperate after his recent severe illness, and where, as the latest reports had told us, he appeared to be getting on well. His body is laid to rest in the parish churchyard of Snelston, near Ashbourne, Derby, hard by the garden where he began his life's work, and among his father's people. Born on October 21, 1858, he began his gardening career at Snelston Hall Gardens in 1870, and went thence to the famous gardens of Alton Towers in 1875. Leaving there, he became foreman at Woodseat, Rochester, and then head gardener at Ednaston Lodge, Bailsford, and, later, head of the gardens at Glewston Court, Ross, and manager of the well-known fruit plantations there. He had served a good apprenticeship, and this stood him in good stead, for while at Glewston he had opportunities of exhibiting fruit, flowers and vegetables, and he made such good use of them that over 700 prizes were won by him at various exhibitions in England, Scotland and Wales. There, too, he became practised in the use of his pen, and contributed a good deal to *The Gardeners' Chronicle*, *The Gardeners' Magazine* and other papers. His book, *Fruit Gardenina for Amateurs*, has passed through many editions and has set many on the right methods. His triumphs on the exhibition table, his record at Glewston, and his writings combined to bring him before the horticultural public, and he became a member of the Fruit

and Vegetable Committee of the R.H.S. while at Glewston. But, perhaps, what did most to establish his position in those days was his admirable essay on "Hardy Fruit Culture," which gained the Royal Horticultural Society's prize in 1896. In that year he was appointed to succeed the late Mr. A. F. Barron as superintendent of the R.H.S. Gardens at Chiswick, and he has remained superintendent of the R.H.S. Gardens ever since. He saw Chiswick when it had scarcely recovered from the dire straits into which it had fallen in the 'eighties, and he helped its growth until another site was found, less cramped, and altogether more favourable, at Wisley. Wisley was largely rough corn land around a beautiful wild garden in 1905, and no one will ever know how much Wisley owes to the hand, that is stilled for ever, in its development to what it has become to-day. For a long period Mr. S. T. Wright was the Society's adviser, and those who know the Society most intimately know best how greatly his advice and knowledge were valued by garden owners up and down the country; and this work he relinquished only when Wisley became too large for him to do both. He was secretary of the Fruit and Vegetable Committee until his death, and superintendent of the shows, first at the Drill Hall, Buckingham Gate, then at Vincent Square, as well as the Temple, Chelsea, and Holland Park. In 1919 the coveted Victoria

THE LATE MR. S. T. WRIGHT.

Medal of Horticulture was conferred upon him, and perhaps no single thing in his whole life gave him greater pleasure than to be selected to join that small company of medallists. So much for his career. He had many things to do, but what, perhaps, distinguished him most, what endeared him to so many, was the geniality that was his unerring attribute. Every questioner at the shows, every visitor to Wisley, every exhibitor with a grievance, found him a sympathetic listener, and—as with those whose gardens he visited—able and willing to do his utmost to help them with advice and in other ways. All these, the staff and students at Wisley, and the old members of that staff and school, will miss his pleasant greeting, which to receive almost constituted one a friend, and none can quite fill the place he filled, and filled with such effect. He died as he would have wished, still in the offices he had held so long, and our sympathies are with his widow and family, who will miss him even more than we of the horticultural world.

An impressive memorial service, conducted by the Rev. C. Hamilton, was held in the little church at Wisley on Tuesday morning, May 2, and it was attended by the entire Wisley staff and numerous gardeners and garden lovers in the district.

**Michael H. Walsh.**—The American horticultural papers record the death of Mr. Michael H. Walsh, of Woods Hole, Massachusetts, one of the most prominent of American rosarians. He was a native of Wrexham, South Wales, and served an apprenticeship for five years in a

private garden; later he was appointed undergardener to Sir Watkin William Wynns, of Wynnstay, Ruabon. In 1863, Mr. Walsh emigrated to the United States and secured a position as foreman on the Samuel R. Payson estate at Belmont. Five years later he was appointed manager of a nursery firm at Brighton, Mass., of which he subsequently became the proprietor. In 1877 Mr. Walsh was appointed superintendent of the estate of Mr. J. Fay, of Woods Hole, Mass., and it was while he was there that he raised many new Roses, several of which were awarded prizes by the Massachusetts Horticultural Society. The introduction of *Rosa Wichuraiana* from Japan gave Mr. Walsh material for crossing with various hybrid teas, and eventually he obtained a new type of rambler Rose of which *Lady Gay*, *Hiawatha* and *Excelsa* are well known and extensively cultivated; he was also the raiser of *Delight*, *Débutante*, *Wedding Bells*, *Evangeline*, *Paradise* and *Minnehaha*. Mr. Walsh was not only a skilful raiser, but also a clever grower of Roses, and the huge specimens which he exhibited won many gold medals and other awards at exhibitions in the United States.

## ANSWERS TO CORRESPONDENTS.

**BOOK:** *A. D. F. Cactaceous Plants*, by Messrs. Brittain and Rose, comprises four volumes, two of which have been published, price £6 and £7 10s. respectively. These may be obtained from Messrs. Dulau and Co., 34-36, Margaret Street, Cavendish Square, W.1.

**BOWLING GREEN:** *M. S.* If the bowling green has been well laid and rolled the grass should by this time have become well matted together and the green in a suitable condition for use when the season opens. The rainy weather will have greatly benefited the turf, and if the greens have been rolled carefully on dry days the turf should be settled well in position and suitable for reasonable use almost immediately.

**ELM SHOOT WITH GRUBS:** *T. C.* The Elm bark is attacked by the Elm Bark Beetle, *Scolytus destructor*. The beetle itself is fairly easily recognisable by its black thorax and light brown abdomen. The beetles appear about the middle of June and the female begins to bore into newly felled or unhealthy trees. Shortly after she has begun boring the male appears and pairing takes place in the primary burrow. After pairing the female starts the burrow proper. In this she lays eggs to the number of from 100 to 160. The larvae are white, fleshy, footless grubs with strong chitinous heads to take the powerful muscles necessary for boring into hard material. Towards the end of July some become full fed, and perfect beetles may be found, which may emerge from holes cut from the ends of the larval galleries to the open air. Many larvae, however, take longer to mature, and so larval stages may be found in winter, as in your case. It is important, where possible, that all sources of infestation should be removed. Search should be made in the vicinity for any fallen Elms, as they will probably be strongly infested. They should either be completely removed, or better still the bark removed and burnt. In extreme cases it may be necessary to fell badly attacked trees in order to remove these sources of infection from other healthy ones in the neighbourhood. First, however, care must be taken that no infested felled tree is acting as a source of infection. The pest is a serious one and often does much damage unless checked.

**NAMES OF PLANTS:** *W. G. A. 1.* Narcissus Barrii conspicuus; 2. *N. Burbidgei* type; 3. *N. incomparabilis* Autocrat; 4. *N. i. Stella*; 5. *N. Leedsii* Duchess of Braborne; 6. *N. Leedsii* type.

**Communications Received.**—*F. T.*, Auckland (thanks for 1s. for R.G.O.F. Box.—*Ens.*)—*W. B.*—*T. C.*—*R. I. H.*—*A. R.*—*W. G. A.*—*R. J. C.*—*A. B. H.*—*W. H. C.*—*L. D.*

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 51.5.

### ACTUAL TEMPERATURE:—

Gardeners' Chronicle Office, 5, Tavistock Street, Covent Garden, London, Wednesday, May 10, 10 a.m. Bar, 30.3; temp, 54°. Weather—Dull.

### Importance of the Horticultural Industry.

There was a time when the horticultural industry was regarded as the Cinderella of commerce. That time has passed, we hope never to return. The regular meetings of the Royal Horticultural Society and the seasonal exhibitions of the National Rose Society, National Chrysanthemum Society, National Sweet Pea Society, National Dahlia Society and the British Carnation Society give ample evidence of the keen interest which is being taken in horticulture and especially in floriculture, while the activities of the several trade associations, with the Chamber of Horticulture as the co-ordinating organisation, have demonstrated the importance of commercial horticulture. The concentration of people in large towns has resulted in a largely increased demand for fruits, vegetables and flowers. To meet this demand, a new type of grower has come forward, and with intensive systems of cultivation and thorough business organisation the industry has been raised in importance, until now the value of horticultural crops produced each year in this country is estimated to be not less than £50,000,000. But, large as the production is, it does not entirely meet the demand. It is believed that about one-third of the food consumed by the British people consists of fruits and vegetables, consequently the home supplies are insufficient, and in 1920 were supplemented by imports of Apples valued at nine and a half millions of pounds; other fruits (excluding Bananas and Citrus fruits), six and a half millions; Potatoes, five millions; Onions, three and a half millions, and Tomatoes, four and a half millions. The total value of the imports of fruits, vege-

tables, flowers, plants and seeds during that year was 30.8 millions of pounds sterling, of which only about nine million pounds worth came from our overseas dominions. These figures, put forward by Sir Arthur Griffith Boscawen, Minister of Agriculture, at the annual dinner of the Chamber of Horticulture on May 3, show that there is ample room for a wide expansion of the horticultural industry at home and in the colonies if the idea of a self-sustaining Empire is to be attained. Success in horticulture means something more than high cultivation and clever organisation; it includes the prevention of diseases and insect attacks, consequently measures are taken by the Government to restrict or prevent the spread of such troubles as Wart Disease, Silver Leaf, and American Gooseberry Mildew. Most civilised countries have now a phytopathological service, but with the increase of knowledge of diseases and insect pests, there has grown up the fear that one country may import diseases from others, through the medium of horticultural products, to its own disadvantage. This fear has led to the setting up of quarantine laws, which, unless sanely considered, will lead to the shutting down of that international interchange of horticultural produce which is one of the wonders of our times. In referring to this matter at the annual dinner of the Chamber of Horticulture, of which a report is given on p. 248, Sir A. Griffith Boscawen considered there were three lines of policy which might be adopted by the Government; the first is the *laissez-faire* policy, under which no restrictions are placed on any categories of plants and the risks of importing new and dangerous diseases and pests are entirely ignored; the second is the extreme policy of allowing no plants at all to enter the country; the *via media* is that which has been adopted by the Ministry, namely to secure that the fullest possible safeguards are taken to ensure the health of all imported plants by demanding their inspection by a responsible Government official in the country of origin.

Organisation for protecting and furthering the interest of various branches of horticulture has been in existence for many years, but it is only in recent times that it has been developed to a degree at all comparable with the progress of the industry. With this development there arose a distinct need for some co-ordinating body that would serve the interests of all when all interests were concerned, and so the Chamber of Horticulture, founded in 1919, began its career of usefulness mainly owing to the enthusiasm, energy and generosity of Mr. George Monro. The Chamber of Horticulture is in close touch with the Ministry of Agriculture—as shown by the presence of Sir A. Griffith Boscawen and Sir Daniel Hall at the annual dinner—and the Ministry has found in it that direct contact with the whole horticultural industry which could not be found previous to its inception. At present the Chamber of Horticulture is being subjected to considerable criticism; doubtless its methods and its usefulness may be improved, but the wisdom born of experience is not the monopoly of its critics, who, we hope and believe, will find it more advantageous to the horticultural industry to build up rather than to pull down the Chamber. In the words of the Minister of Agriculture, "the aims and objects of the Chamber are to promote the best interests of horticulture, to watch over all measures affecting horticulture both in and out of Parliament, and to link up all sections, and generally to promote horticultural organisation and reform." These aims and objects can only be attained when personal and sectional

jealousies are forgotten and when all horticulturists "pull together," to use the words of the new President, Mr. G. W. Leak, whose advice at the meeting referred to was, "aim high and be satisfied with nothing but the best."

**The Late S. T. Wright.**—The announcement of the death of Mr. S. T. Wright, which was made in last week's issue of *The Gardeners' Chronicle*, has come as a great shock to his many friends. They had hoped that after his many years' service to horticulture and to the R.H.S., he might be spared to enjoy a well earned period of rest, to pursue those country sports of which he was so fond, and to inspire in others the love of gardening which was so conspicuous in himself. The late Mr. S. T. Wright was a great gardener. Few had such a wide knowledge or so keen an appreciation of the garden value of plants, and none had in greater degree the power of imparting knowledge and communicating enthusiasm. The debt which the R.H.S. owes to Mr. Wright is great. He made Wisley a happy garden. The charm of his welcome none could resist, and to walk round the garden in his company was at once a liberal education and a unique pleasure, which led hundreds of visitors in the course of each year to make many pilgrimages to Wisley. It is high praise to give to any man to say that he had qualities of greatness; yet this praise is due in full measure to Mr. Wright, for he possessed—in a degree which we have not seen equalled—urbanity of manner, a quality as rare as it is distinguished, and one which men of little minds can never acquire. Courtesy, consideration for others, and unselfishness are some of the ingredients which go to the compounding of this quality. Thanks to it, Mr. Wright was able to suffer fools gladly and to win the deep, lasting regard of those who knew that in the scale of human attributes urbanity stands high; far above intellectual attainments and far above cleverness. This quality stood the Society in good stead, for, thanks to it, many members were led to a greater loyalty and to a deeper interest in the Society. As a colleague, Mr. Wright was perfect. Not that he lacked imperfections; he was too much a man for that; but because he had the rare gift of loyalty, when he believed in a man he gave him frankly, and without reserve, the full measure of his confidence, and that is the secret of successful co-operation. It is a great sorrow to realise that that jovial figure, bright eyed, and full of cheeriness, may be seen no more, and that the walks we used to take with him about the grounds of Wisley must now be solitary.

**Kew Guild: Annual Meeting and Dinner.**—The annual general meeting of the Kew Guild will be held at the Imperial Hotel, Russell Square, on Wednesday, May 24th, at 6.30 p.m. The annual meeting will be followed by the annual dinner at 7.15 p.m., when the President-elect of the Guild, Mr. Ernest H. Wilson, M.A., V.M.H., will preside. Mr. Wilson recently arrived in England after a trip round the world undertaken on behalf of the United States Government in connection with the Harvard University and the Arnold Arboretum.

**Manchester Parks Horticultural Debating Society.**—This Society was formed about a year ago for the purpose of furthering the horticultural knowledge of the employees in the Parks and Cemeteries Department of Manchester, and also for the purpose of increasing the opportunities for social intercourse among the members of the staff. There are seventy parks and open spaces in the city, and some of these are so much as ten miles apart, and when it is remembered that the permanent staff consists of about 450 members, it will be recognised that such a society is extremely useful. The Society has a membership of 110, and has held fortnightly meetings throughout the winter session; during that period the superintendent of the department, Mr. W. W. Pettigrew, has very actively interested himself in the proceedings, while the chairman and deputy-chairman of the

Manchester Parks and Open Spaces Committee have also given their support. So far as we are aware, this is the only society of its kind in the country, and we congratulate the Manchester Park staff on the success of its venture.

**Trial of Salpiglossis at Wisley.**—The Royal Horticultural Society will carry out a trial of Salpiglossis for flowering in the spring of 1923, under glass, at Wisley. Those desiring to send varieties for trial should post them to the Director (from whom the necessary entry forms can be obtained), R.H.S. Gardens, Wisley, Ripley, Surrey, so as to reach him by May 31, 1922.

**Insects Beneficial in the Garden.**—The Ministry of Agriculture has recently published a pamphlet under the title of "Beneficial Insects," having for its object the wider recognition of some of the more common of those insects which are the farmers' and the gardeners' friends, but which too often are destroyed in error. The letterpress is brief, and is written in simple language. Great care has been taken to ensure that the illustrations, which are very well reproduced by the four-colour process, shall be scientifically accurate. The pamphlet, "Miscellaneous Publications No. 37: Beneficial Insects," may be obtained from the Ministry of Agriculture and Fisheries, 10, Whitehall Place, London, S.W.1, price 4d., post free.

**Flowers in Season.**—From Mr. D. Chaplin, Froggnal Gardens, Sunninghill, Ascot, we have received blooms of what he considers to be sports from *Viola gracilis*, but the size and improved form of the flowers suggests that they are seedlings having a blue garden *Viola* as one parent. No. 1, now in full bloom, is earlier than *V. gracilis*, and has flowers of light, violet-blue colour, with a few purple blue lines radiating from the yellow eye. No. 2 is much larger, with blooms  $2\frac{1}{2}$  inches across at the widest part, and rich violet-blue in colour with dark violet-blue lines radiating from the soft yellow eye. The flowers in each case are of charming colour and elegant form, and if the plants flower profusely, the varieties should have considerable value.

**Silver Leaf in Apple Trees.**—The number of cases of silver leaf on Apple trees is now on the increase, and the Inspectors of the Ministry of Agriculture report that the disease is more abundant in Apple trees where large branches have been cut off during pruning, or where the trees have been headed back for the purpose of top grafting. The fungus, *Stereum purpureum*, is a wound parasite, and, as our readers are aware, wounds left exposed during the winter may lay the tree open to infection by the disease. No remedy is known for silver leaf; but, by covering each wound made by pruning, or by heading back, with Stockholm tar or grafting wax, the spores are prevented from entering and the tree is protected. The greatest danger is with the trees which have been headed back, as large wounds are exposed during the winter and spring months of the year. If the wounds are not covered at the time of cutting, then one foot more of the branches should be sawn off at the time the grafts are inserted, so as to remove any wood which may have become infected. Needless to add, all wounds should be covered with grafting wax as soon as the graft has been inserted. Silver leaf disease is one of increasing danger to fruit growers with each succeeding year.

**Association of Economic Biologists.**—A general meeting will be held at 2.30 p.m. on Friday, May 19, in the Botanical Lecture Theatre of the Imperial College of Science, South Kensington, London, S.W.7, when Mr. Wilfred Rushton (St. Thomas's Hospital, Medical School) will lecture on "Further Contributions to the Biology of Freshwater Fishes (see *Annals, Appl. Biol.*, IX., 1); and Professor J. H. Priestley (Leeds University) will discuss the "Toxic Action of Illuminating Gas on Plants," with a demonstration. The Council will meet on the same day at 2 p.m.. The annual field meeting of the Association will be held on Friday, June 30, at the Royal Horticultural Society's Gardens, Wisley, by kind invitation of the Director.

**Royal Gardeners' Orphan Fund Festival Dinner.**—All our readers will be glad to learn that the annual festival dinner held at the Connaught Rooms on May 9, was one of the most successful ever held on behalf of that most deserving charity, the Royal Gardeners' Orphan Fund. The Chairman, Mr. Lionel de Rothschild, M.P., a great lover and patron of gardening, made a strong appeal on behalf of the Fund, which does such splendid work in the interests of the orphans of gardeners. Mr. Lionel de Rothschild—whose portrait we have great pleasure in presenting—is, as most horticulturists are aware, a great lover and student of Rhododendrons, and has a wonderful collection of those shrubs, including many new and rare species and varieties, at Exbury, near Southampton. He brought flowering specimens to the dinner and suggested that some growers might like to make him a good offer for them, as grafts, on behalf of the Fund. Similarly, he offered pollen of a fine strain of *Hippeastrum*, but apparently there were no Rhododendron or *Hippeastrum* enthusiasts present, as no offers were made even when Mr. Rothschild offered a layer of any of the Rhododendrons if the grafts failed. The appeal was made on the high ground of gratitude to those who made gardens so attractive and interesting to their owners, and who, cut

MR. LIONEL DE ROTHSCHILD, O.B.E., M.P.

off in early manhood, left children unprovided for. It was to assist such orphans the Fund existed. Mr. Rothschild's appeal was most successful and resulted in a subscription list of £1,623, to which the chief contribution were the Chairman, and Messrs. N. M. Rothschild and Sons, £100; Messrs. Hurst and Son, per Mr. E. Sherwood (Treasurer of the Fund), £100; Messrs. Sutton and Sons, £100; Covent Garden friends, per Mr. David Ingamells (Chairman of Committee), £230; Sir Harry J. Veitch, £26; Mr. W. Nutting, fifty guineas; Mr. J. B. Bridgeford, £55; Mr. Anthony Waterer, £25; Messrs. R. and G. Cuthbert, £21; Messrs. G. Bunyard and Co., £20; Mr. Dixon (Hurst and Son, collected), £22; and Mr. H. J. Jones £21. Mr. E. Sherwood responded in his usual able manner to the toast of "The Royal Gardeners' Orphan Fund," proposed by the Chairman. Mr. George Monro proposed "The Visitors," and to this Mr. G. P. Berry, of the Horticultural Department of the Ministry of Agriculture, responded; while "The Chairman" was very pleasantly proposed by Lord Aldenham, who observed that though all other pastimes of youth and manhood might lose their attractiveness with advancing years, gardening never failed. The Festival dinner was wholly successful, the attendance was large, the tables were charmingly decorated with *Ophelia* Roses

and a capital programme of music was rendered under the direction of Mr. Turle Lee.

**Royal Horticultural Society's Committees and Chelsea Show.**—The various Committees of the Royal Horticultural Society will meet on the first day of the Chelsea Show to adjudicate on plants, fruits and vegetables submitted for awards. The Fruit and Vegetables, Floral, Orchid and Narcissus Committees will meet at 10.30 a.m. outside the Secretary's tent. On the second day of the show Dr. A. Rendle will deliver a lecture on "Plants of interest exhibited."

**Birmingham Flower Show.**—Although the annual show of the Birmingham Horticultural Society in Cannon Hill Park last year proved a failure financially, the committee, encouraged by promised support, has decided to hold a show in the Victoria Park at Handsworth on July 21 and 22, 1922.

**Horticultural Club.**—The Horticultural Club has made arrangements with the Hotel Belgravia to have the exclusive use of a room for the Club on the Mondays and Tuesdays in the weeks when the Royal Horticultural Society holds its fortnightly meetings and also on any other occasion when important horticultural functions are held in the metropolis. The room will be available for the members on the three days of the Royal Horticultural Society's Show at Chelsea, and the Club has arranged with the Hotel for the members to obtain accommodation on special terms. The Hotel Belgravia is situated in Grosvenor Gardens, Victoria; it is quite close to Victoria Station and within easy access of Vincent Square. Since the hotel was relinquished by the Government, it has been entirely renovated by the new proprietors, and all the latest modern improvements added to make it a first-class hotel. The Annual General Meeting of the Club will be held on May 24, the second day of the Chelsea Show. A house dinner will also be held on this occasion, and after the dinner, Mr. E. A. Bunyard will give a lecture, illustrated by lantern slides, on "Impressions of Algeria; mainly horticultural."

**Profits from Shrewsbury Flower Show.**—The total receipts in connection with the Shropshire Horticultural Exhibition, held at Shrewsbury on August 17 and 18 last, was £13,954, while the expenditure was £11,380, leaving a net profit of £2,573. The committee has offered the town £2,000 towards erecting a suspension bridge over the Severn to connect the suburbs of Port-Hill and Copthorne with the Quarry. This has been accepted by the corporation, and the work will be proceeded with at an early date. At the annual meeting of the society, held at Shrewsbury on the 3rd inst., Lord Howard de Walden was elected president for the ensuing year.

**National Dahlia Society.**—The schedule of the National Dahlia Society's exhibition, which is to be held on September 6, 1922, includes a list of varieties certificated in 1921 after trial in the R.H.S. Gardens at Wisley. The number of varieties certificated is twenty-eight, and includes Single, Collette, Paony-flowered, Decorative, Camellia-flowered, Show, Pompon, Star and Cactus varieties respectively. There are also lists of varieties which were highly commended and commended, as judged by the R.H.S. trials. The number of classes in the Society's exhibition is 53, and there are sections for all types of this popular autumn flower. We are glad to notice that the Society is endeavouring to make the Dahlia as valuable for garden purposes as for exhibition, and to this end the trials in the R.H.S. gardens should provide a suitable guide as to the best garden sorts. The Dahlia is, together with the *Chrysanthemum*, one of the most valuable of autumn garden flowers, and there is unlimited scope for development both in the raising of new types and varieties for garden decoration. The National Dahlia Society is one of the oldest horticultural societies, and is worthy of the support of all gardeners. The Secretary is Mr. A. C. Bartlett, 318, Kew Road, Kew, who will be pleased to forward a copy of the schedule to those interested.

**Appointments for the Ensuing Week.**—Wednesday, May 17: Hertford Horticultural Society's meeting; Somerset County Agricultural Association's Horticultural Show at Bridgwater (2 days).—Friday, May 19: Paisley Florists' Society's meeting; Association of Economic Biologists' meeting; Eastbourne Horticultural Society's meeting.

**"The Gardeners' Chronicle" Seventy-five Years Ago.**—*Exhibition at the Horticultural Society's Gardens, Chiswick.*—The first exhibition at Chiswick has had the misfortune to fall upon the last day of winter—a fitting conclusion to a most uncomfortable season. The dawn was wet, the morning damp, the forenoon gloomy, midday cheerless, and the afternoon a deluge. Under these circumstances, we have nothing to record beyond the good humour of the visitors, the patience of the exhibitors, and the magnificence of the plants. If anything could have increased our respect for the unrivalled skill of English gardeners, it would have been this exhibition, which, with two or three exceptions, consisted wholly of plants displaying the most admirable cultivation. We

## PLANTS NEW OR NOTEWORTHY.

### RHODODENDRON FARGESII, FRANCHET.

At the meeting of the Royal Horticultural Society, held on April 25th, a very fine form of this Chinese species (see Fig. 125) was shown by Mr. G. W. E. Loder from his garden at Wakehurst. Like nearly all these species from Western China *R. Fargesii* varies a good deal in the quality of the individual plants. Mr. Loder's was, perhaps, the best form that has flowered in this country up to the present time. *R. Fargesii* is a shrub originally found in Eastern Szechuen by Père Farges, but introduced by Mr. E. H. Wilson from Western Hupeh in 1901; when he was collecting for Messrs. J. Veitch and Sons. He describes it as occasionally 18 feet high, the flowers varying from white to deep rosy-red. The leaves are  $2\frac{1}{2}$  to  $3\frac{1}{2}$  inches long, with a rounded or slightly cordate base, dull green above, rather glaucous beneath. Six to eight flowers occur in a terminal truss, the corolla widely funnel shaped, seven-lobed and  $2\frac{1}{2}$  inches wide, the ground colour sprinkled more or less freely with darker spots. The stamens and style

## RAISING SPRING BEDDING PLANTS FROM SEED.

MANY of the spring bedding plants may be propagated from seed, and the work of raising the plants may be put in hand immediately.

Forget-me-nots make an admirable carpet for Tulips, and in most districts there is no question as to their hardiness. *Myosotis dissitiflora* is an old species which is still valuable. The plant branches freely, attains a height of about 9 in., and produces its blue flowers very early. Amongst the many varieties of Forget-me-nots Royal Blue is of very rich colour, and a little taller than the last-named. Star of Love, sky blue, is one of the best sorts for edging purposes. Attractive also are the blue, white, and pink flowered strains which most seed firms now offer. The seed should be sown on a shady border of finely prepared soil, and the seedlings pricked out into nursery beds 6 in. apart. *Arabis alpina* is one of the earliest of white spring flowers; the plant is compact in growth and free in flowering. Rather taller, but brilliant in the mass, is the

FIG. 125.—RHODODENDRON FARGESII.

should hope that those who have obliged us to regard them as exceptions will have read a lesson last Saturday which they will not fail to remember. Out of 11,580 tickets which had been issued, only 1,479 were presented, the whole number of visitors and Fellows of the Society having been 1,644. The number of medals awarded was 24 gold and 85 silver, their value being £409 15s. The judges added to their award the opinion that "the appearance of woody plants is greatly injured by the excessive use of stakes, as employed in some collections," in which we fully concur. *Gard. Chron.*, May 15, 1847.

**Publications Received.**—*Water-stress behaviour of Prima Cotton in Arizona.* By C. J. King. Bulletin No. 1,018. *Comparison of Corn Oils obtained by expeller and Benzol extraction methods.* By A. F. Sievers. Bulletin No. 1,054. *The Sugar-Beet Nematode in the Western States.* By Gerald Thorne and L. A. Giddings. Farmers' Bulletin, 1,248. *The Sunflower as a Silage Crop.* By H. N. Vinall. Bulletin No. 1,045. All published by the United States Department of Agriculture, Government Printing Office, Washington.

are quite smooth, but the ovary is always furnished with glands. The species is quite hardy, and thrives best in a semi-shaded spot. Flowering in April, its blossoms are liable to be injured by spring frosts, but, on the whole, it is one of the most attractive of the earlier-flowering Chinese species that are really hardy in our average climate.

### RHODODENDRON OREODOXA, FRANCHET.

This species (see Fig. 130) was also shown in flower at the same time by Mr. Loder. It is very closely allied to *R. Fargesii*, and has leaves similar in size and shape, and the arrangement of the flowers is the same. The best ready distinction between the two is furnished by the ovary: in *R. Fargesii*, as stated above, it is covered, often densely, with glands; in *R. oreodoxa* it is perfectly smooth. The corolla in both is seven-lobed, and in *R. oreodoxa* is rosy pink tinged with lilac. Even more than *R. Fargesii* it needs protection from hot sunshine. It was introduced by Wilson from Western Szechuen about the same time as *R. Fargesii*, and Wilson gives the height of the plant in its natural habitat as 9 feet or 10 feet. Both these Rhododendrons are valuable additions to gardens. W. J. B.

golden yellow *Alyssum saxatile compactum*. Sutton's Silver Queen is a pale lemon form of equal merit. All these plants are raised readily from seed. Associated with bulbs, Double Daisies, which are available in a variety of pleasing colours, produce some of the most attractive displays, while for edging purposes few plants are more suitable. The seedlings require a certain amount of shade and moisture, conditions which are easier afforded if boxes are used in the first stage. The summer position, too, should be on the shady side, and growth is most rapid in soil containing leaf mould. Perhaps few plants are more valuable for spring bedding than Aubrietias. Desirable as are the modern varieties, it takes time to work up a bedding stock from cuttings, and seed sowing offers a ready method of increase. A small percentage of the plants may fail to come true, but the exceptions are seldom conspicuous enough to be an eye-sore. Of the named varieties obtainable from seeds, *A. Leichtlini*, bright rose, *A. purpurea*, dark purple, and *A. graeca*, a rich blue, are noteworthy. The seed should be sown in boxes, and the plants pricked out in fine soil, although it is an advantage if they can be potted, and the pots plunged in ashes.

Polyanthuses are invariably in demand for the furnishing of formal beds, since few plants are more brilliant. On the principle of better late than never, seed may still be sown in frames, and if the plants are well treated afterwards, the majority will have reached the required size for putting out in autumn. They may be procured in separate colours, but where a pleasing mixture is required the Munstead strain leaves little to be desired. Primroses and Auriculas, especially the Alpine section of the latter, are also useful, and the season is not yet too far advanced to commence working up a stock. Of Violas there are numerous named varieties. Yet there are possibilities of raising good plants from seeds, a method of increase to be recommended where large numbers are required on the grounds of economy. Pansies have a charm which few are proof against, and in favourable districts can hardly be excluded from the list of spring bedding plants. To obtain strong, bushy Wall-flowers which will lift in autumn with a good ball of soil, seed should be sown from the middle of May on finely prepared though not over rich ground. The seedlings should be transplanted early on an open plot, about a foot apart. Varieties are numerous, and in addition to such standard sorts as Vulcan and Phoenix, those which are available under a wider range of colours are worth including. *Y. G.*

is another yellow Toadflax, which, with me, was brighter and dwarfer than *L. dalmatica*, of which it is said to be only a form, and both are quite superior to *L. genistifolia*, another yellow *Linaria*. Those who know *L. vulgaris* need not think that *L. dalmatica* resembles it. The latter is much superior. *S. Arnott.*

#### SPETCHLEY PRIMROSES.

HAD these flowers been mine, I would have labelled them "Spetchley Polyanthuses," for that is what they are to all appearances. However, it may be the above title is adopted to make sure that there is no confusion between them and those (dare I use the word in a non-florists' age) real Polyanthuses that delighted the hearts of a past generation—those smooth and sleek looking, gold-laced beauties which have gone the way that nearly all our old florists' flowers are going. Perhaps it is; or perhaps it is because it is more correct or scientific, and the botanic sense of Mrs. Berkeley, their raiser, would be offended were it otherwise. The point is only of academic interest, in view of the fact that in the Spetchley Primroses we have a wonderfully large and attractively coloured strain of what are commonly called Polyanthuses. A beautiful selection filled one of the corners of the R.H.S. Hall on April the 25th. It happened to be the show day of the southern

available they should be grown in a border by themselves. East Lothian Stocks are perfectly hardy, and form one of the most useful subjects for furnishing a supply of cut flowers. Lovely as they are in the garden, they are equally beautiful when used as cut blooms in vases, and, as they develop many flowering side-growths during the summer, they provide plenty of material for indoor floral decoration. The flowers are of many lovely shades of colour, and sweetly scented. These Stocks may well be used to fill blank spaces along the fronts of the herbaceous borders, whilst for planting in and around clumps of Tulips on such borders. East Lothian Stocks are invaluable, for they flower when the foliage of the Tulips is fading. *B.*

#### SMALL DECORATIVE PLANTS FOR FURNISHING.

THE gardener who is responsible for the furnishing of the dwelling house with plants should now take stock of his supply of ornamental foliage plants used in the decoration of vases, baskets, etc.

In the present stress of work this is often overlooked, with the result that autumn finds him with a very limited number of these plants, whereas, by a very little thought, he may have quite a good stock, even from plants raised from seed sown now, or in other cases by division of old plants or from cuttings.

*Cyperus natalensis* is one of the most useful subjects for this work, owing, in the first place to its easy culture, and secondly to its hardness, for it may be used in any dwelling room, even in draughty places, without any fear of its immediate death or decay. The seeds should be sown at once in a light, sandy mixture, preferably in pans, which should be at least three inches deep, and lightly covered with soil. Keep the soil moist with the usual covering of a sheet of glass, shade it from bright sunshine, and the seeds should germinate in about seven days, if the house in which they are placed is kept closed at night.

When the plants are about half an inch high, place about six or seven of them in a clump in the centre of a three-inch pot, using a light mixture of soil, which should not be too rich. The plants will grow rapidly and, if needed, may be potted into the 48 sized pots in heavier soil. Grow them always in a cool place, but do not shade them too much.

These cultural notes apply also to those two lovely grasses, *Festuca glauca* and *Isolepis gracilis*, excepting that these plants should not be potted beyond the 60 sized pots.

Old plants of *Eulalia japonica* and *E. zebrina* should be divided, and, given a generous, loamy soil, will make valuable specimens by August, and may be used either as decorative plants or as cut foliage.

Of the many Selaginellas there is none that lends itself to general work so much as *S. caesia*: old plants divided and potted in sandy soil will grow luxuriantly in a moist, warm house with shade from bright sunshine. If carefully hardened they may be used with advantage in conjunction with almost any flowers. The trailing stems of blue-green colour are in great request for decorating dinner tables.

The present is a suitable time for ordering small Ferns and Palms for growing on, and these, on receipt from the nursery, should be afforded warm and generous treatment, remembering that a sudden change from their previous warm conditions spells failure.

Insert a further supply of cuttings of *Panicum* in small pots; and the cuttings will root very quickly in a moist house. A sandy compost, but not too poor, is all they require. A few seeds of *Asparagus sprengeri* should be sown in heat to furnish a stock of young plants, and being gross feeders, a rich loam is useful in their development. It must not be forgotten that the most important point in using all these plants successfully is to harden them gradually, to allow them, so far as is possible, to become accustomed to the cooler and drier conditions of the dwelling house. *J. S. D.*

FIG. 126.—DENDROBIUM ASHWORTHIAE. (See p. 241.)

#### HARDY FLOWER BORDER.

##### LINARIA DALMATICA.

*LINARIA dalmatica* possesses considerable charm, and there are few border plants of undoubted hardiness which possess anything like the same appearance, so that it lends a distinct effect to the place in which it is cultivated. When well grown, it reaches a height of four or five feet, but in poorer soil may grow only two or three feet high. Even at its lowest stature it is pretty, but is much finer when grown in a rich soil, for it will then produce plenty of its pretty glaucous leaves and branching stems, well furnished with good, yellow flowers. It is not easy to describe the precise shade of yellow; I have just picked up at random three works containing references to *L. dalmatica*. One describes the colour as "lemon yellow," another as "sulphur yellow," and the third speaks of the blooms as being "golden." Whichever of these shades we may be disposed to accept, there is no doubt that the Snapdragon-like flowers are very pleasing and that it is a plant of much worth in the border. It is a true hardy perennial, giving no trouble, except that it is inclined to run a little at the root, and may require to be watched lest it spread too much for the comfort of its neighbours. *L. macedonica*

section of the National Auricula and Primrose Society, so it was a simple matter to compare them with those shown in competition, as well as with some staged in the usual way in the trade exhibits. In size of bloom and the general vigour of the plants, these were left far behind, and the display showed that the patient labour of years had not been in vain. Almost every shade and colour that coloured Polyanthuses are capable of developing were represented. There was a flower, as it were, for everyone. There was hardly one, Miss Willmott told me, that had not had its admirer that afternoon. Personally, I did not care for those in which the colours run into one another, but I know many of these are Mrs. Berkeley's special favourites. Women like them, I think, better than men, just as they seem to prefer varieties of Carnations and other flowers at which men look askance. A selection has been made of some of the best, and these have been named, but I feel sure that a packet of seed, which can be had from Mr. Stewart at the Hospital Gardens, Chelsea, will give equal satisfaction. There is nothing like seedlings for size and vigour. *Joseph Jacob.*

##### EAST LOTHIAN STOCKS.

THE main batch of these Stocks should now be planted out, and where plenty of plants are

## DENDROBIUM ASHWORTHIAE AND ALLIED SPECIES.

THE strong and well-flowered plant of the rare New Guinea species, *D. Ashworthiae*, shown by Dr. F. Bedford, Esleforde, Marden, Kent, at the meeting of the Royal Horticultural Society on April 25, calls to mind not only a charming species which many supposed was lost to our gardens, but also a section of beautiful species which may well be classed with it, especially for the purposes of cultivation. With few exceptions, these have never been sufficiently represented in gardens, from which, if not carefully tended, they will probably vanish. To replace them by importation in these times is very difficult; therefore, those who have specimens of the class referred to would be well advised to obtain true seeds by fertilisation with pollen of the same plant and obtain home-raised specimens.

*D. Ashworthiae* was imported by Messrs. Sanders through their collector in New Guinea, Micholitz, in 1898, all the marked plants passing into the collection of Elijah Ashworth, Esq., Harefield Hall, Wilmslow, who showed it before the R.H.S. on January 15, 1901. It was fully described and illustrated in *The Gardeners' Chronicle*, February 9, 1901. The growth of the plant, as with most of its class, is somewhat like that of a small *Dendrobium thyrsoiflorum*, the flattened pseudo-bulbs being slender at the base and bearing several firm, green leaves at the apex, from which ascending spikes, bearing usually six or eight flowers, proceed. The sepals are yellowish, or slightly tinged with green, and the petals and lip white, the latter bearing a few small purple lines at the base.

*D. Johnsoniae*, of similar habit, is probably the most beautiful of the class, its scapes bearing several pure white flowers, each four inches across, the base of the lip having some dark purple lines, and the general appearance of the blooms calling to mind a white *Laelia anceps*. It has a curious history. In *The Gardeners' Chronicle*, 1882, vol. xviii., p. 520, Reichenbach described it as *D. Macfarlanei*, a name with two objections; first that the name had been used for another species, and second that F. Mueller had described the plant as *D. Johnsoniae* shortly before. The first few plants to arrive were imported by Messrs. Jas Veitch and Sons, who obtained a First-Class Certificate for this Orchid as *D. Macfarlanei* on January 14, 1890. Soon after that Messrs. Sanders obtained a good collection of it, and showed it frequently, their best specimen being that which the exhibitors showed with ten spikes in their fine group at the Whitsuntide exhibition at Old Trafford, Manchester, May 23, 1890. Unfortunately, this Orchid is rarely seen now.

*D. Madonae*, also of Messrs. Sanders' importing, is of smaller and more slender growth than the preceding. It bears sprays of pretty white flowers with pink markings on the lip. It was first shown in flower on January 23, 1900.

*D. atroviolaceum*, Rolfe, in *Gard. Chron.*, 1890, vol. VII., p. 512, originally imported by Messrs. Veitch and Sons, and later in quantity by Messrs. Sanders, is one of the finest and most distinct of the New Guinea *Dendrobiums*, and one which thrives well in a warm, moist house. It bears strong, ascending spikes of many cream-coloured flowers, spotted with chocolate red, the labellums having bright purple markings unlike those of any other species, except *D. Hodgkinsonii*. It was at one time well represented in gardens and flourishes satisfactorily in pans or baskets suspended from the roof of a warm, moist Orchid house, a position in which most of the class do best.

*D. Hodgkinsonii*, *Bot. Mag.*, t. 7,900, was introduced by Messrs. Sanders from New Guinea in small quantities, and it has always been rare. It is nearly allied to *D. atroviolaceum*, from which it differs in having light green, unspotted, acuminate sepals and petals, the lip having radiating lines of violet colour. It flowered in the collection of Dr. Hodgkinson, The Grange, Wilmslow.

*Dendrobium macrophyllum* (Veitchianum) is one of the oldest representatives of a stately

section of this class, Messrs J. Veitch and Sons obtaining a First-Class Certificate for it on June 29, 1870. It varies in stature and in the spotting of its greenish-cream flowers, but is always a free grower and profuse flowerer, even when grown in a warm fruit or forcing house or well-heated conservatory.

*Dendrobium spectabile*, Miq., long a mystery plant on the strength of Blume's description of it as *Latourea spectabilis* in 1848, is a native of New Guinea and the Solomon Isles, and was first known in gardens through a coloured sketch

the section with long, narrow, curiously twisted, erect sepals, such as *D. undulatum*, *D. lineale*, *D. Stratiotes* and *D. strebloceras*, and others, which have at various times been well represented in gardens. It is to be hoped that some still survive. *J. O'B.*

## DENDROBIUM PHALAEOPSIS. SCHRODERIANA.

MANY plants of this delightful Orchid were lost during the war, owing to the difficulty of

FIG. 127.—DENDROBIUM ATROVIOLACEUM.

and plant received by Sir Trevor Lawrence in 1896. Five years later, Messrs. Sanders received a good importation, the plants of which flowered well in some gardens, and notably in that of Major Joicey, whose gardener, Mr. Thorne, grew all the species of the section procurable very successfully in a span-roofed stove house, where they were suspended in full light near the roof glass. A specimen shown from those gardens at the Royal Horticultural Society with many tall spikes of yellowish flowers spotted with red, the extraordinary showy elongated lip being beautifully veined, received a F.C.C. on December 19, 1899.

There is also a goodly number of species of

procuring coal and other things necessary to their maintenance. There is no more beautiful object in gardens than a well-grown batch of this species, which produces its flowers at a season when choice flowers are appreciated. This Orchid will now be starting into growth, and the present is a suitable time to repot any plants that need it. This species does best in small pans suspended close to the roof glass in the warmest house, where it will receive an abundance of light, heat, and moisture. When in full growth, liberal waterings may be given, and the syringe should be used freely. Being a sun-loving Orchid, very little shade is necessary. *B.*

## The Week's Work.

### HARDY FRUIT GARDEN.

By H. MARKHAM, Gardener to the EARL OF STAFFORD, Wrotham Park, Barnet.

**Apricots.**—These trees are usually trained in fan shape, and their training should be very carefully carried out. When disbudding the young growths in their early stages, crowding of the branches should not be permitted. Well-placed shoots should be retained to take the places of older shoots that are likely to die off, as is frequently the case with Apricot trees. If the fruits have set in clusters, their thinning is best done at an early stage, in order that those left to furnish the crop may attain a large size before the stoning period. Remove those badly placed and all the smaller ones that are not wanted. Young, foreright shoots should be stopped at the third or fourth leaf. Old trees in free bearing will be benefited by giving the roots a good watering, whenever the soil is sufficiently dry, and a sprinkling of guano.

**Apples and Pears.**—Young standard Apple and Pear trees that were planted late should be pruned rather more severely than those planted early, to cause the young shoots to develop strongly. Make good the soil about the roots, apply a mulch of suitable manure, and secure the trees to stout stakes to prevent damage by winds, etc.

**Strawberries.**—Plants which have been forced under glass and duly hardened should be planted early in well prepared land, there being nothing gained by keeping them in the pots, but the reverse. If the ground intended for these plants was well prepared some time ago, all that is now required is to hoe it over to destroy seedling weeds, and to level the surface. Set out the rows at 2 feet apart, and put the plants 18 inches asunder in the rows. See that the roots are thoroughly moistened prior to turning them out of the pots. Shake away some of the old soil, but do not reduce the balls of earth too much, and plant firmly. If the land is of a light texture, and newly prepared, give it a good treading, and bury the roots a little deeper to allow for the surrounding soil sinking. Spread a thick mulch of manure between the rows, and with due care a first-rate crop of berries should be obtained next year.

**Morello Cherries.**—As the principal crop of these fruits is usually borne on the previous year's growth timely disbudding should be practised in a similar manner to that adopted for the Peach. Guard against crowding of the shoots, but endeavour to have a supply of healthy young branches at intervals all over the trees, so that any of the older branches likely to die may be quickly replaced by young, fruitful wood. Although Morello Cherries are chiefly borne on young wood, fruits are also produced on spurs. Keep a sharp watch for black aphid, which is one of the worst insect pests of the Morello Cherry the grower has to contend with, and if not destroyed will quickly ruin young trees. X.L. nicotine insecticide is a capital remedy if applied as advised by the makers, and it may be safely used when the fruits are quite small. Quassia extract is also very effective when applied with care.

### THE ORCHID HOUSES.

By J. T. BARKER, Gardener to His Grace the DUKE OF MARRBOROUGH, K.G., Blenheim Palace, Woodstock, Oxon.

**Dendrobium.**—The evergreen members of this large genus, such as *D. chrysotoxum*, *D. densiflorum*, *D. thyrsiflorum*, *D. suavisimum*, *D. Brymerianum*, *D. clavatum*, *D. aggregatum*, *D. Farmeri*, *D. Dalhousieanum*, and others which produce their flowers at this season, make splendid subjects for exhibition or bold decorations. Soon after the flowers fade, new growths appear from the base of the plants, and any necessary repotting should be done as soon as possible.

The roots of the stronger growing evergreen kinds are usually larger and more robust than those of the deciduous species, and the compost for them may be used in a rough state. Two parts of *Osmunda* or AI fibre to one part of *Sphagnum*-moss, with plenty of broken crocks added to keep the mixture open forms a suitable rooting-medium. In preparing the compost, it is essential that the ingredients should be well pulled to pieces, removing all the earthy particles, and any pieces which show a tendency to produce fungus growth. Old and decomposed compost causes the roots to decay. For the strong growing species, pots are the best receptacles, and they should be well drained, and the plants potted firmly. With the present-day material, if thoroughly prepared, in proper condition and neither too wet nor too dry, it is almost impossible to pot too firmly. After repotting, place the plants at once well up to the light in their growing quarters. The dwarf growing species are best grown in shallow pans suspended from the roof rafters. For a time very little water at the roots will suffice—only enough, in fact, to keep the rooting material just moist; but plenty of atmosphere moisture and frequent sprayings overhead when the weather is bright and warm will assist the plants in making clean and satisfactory growth. During the growing season, as the plants become well rooted, liberal supplies of water will be needed. The majority of these Orchids thrive best when kept to a regular season of growth and rest, and when grown in an even temperature, such as a warm Cattleya house provides.

**D. Dalhousieanum**, **D. moschatum** and **D. fimbratum.**—These are stately plants, and at one time good specimens were much sought after; as the racemes of flowers they produce are not surpassed by any others in the genus. They are commencing to grow, and any necessary repotting should receive attention forthwith. The above remarks apply to these species, with the exception that these vigorous growing Orchids delight in a tropical temperature and an abundance of moisture both at their roots and in the atmosphere whilst making their growth. These old species are not cultivated so extensively as their merits deserve, but, undoubtedly, as time goes on, their beauties will once more claim recognition.

### THE FLOWER GARDEN.

By EDWIN BECKETT, Gardener to the Hon. VICARY Gians, Aldenham House, Hertfordshire.

**Pentstemons.**—The beautiful hybrids or, as they are sometimes called, "florists'" Pentstemons, that were raised from cuttings rooted last autumn, in cold frames, may now be planted out. This is most effectively done on a border in rows, allowing about 18 inches between the plants and the rows. The plants should be staked at the time of planting, using for the purpose a *Spiraea*, Willow or thin Bamboo stick, which in its turn should be tied to a string, run tautly along the row from two or more stout hazel stakes. Carefully tie the main shoot to the sticks, and, as side growths are formed, loop these in carefully by means of raffia, to support them from boisterous wind. A light watering overhead should be afforded Pentstemons during dry weather. Protection against slugs should be afforded by putting a ring of sharp cinder ashes around each plant. Seedling Pentstemons may also be planted out in a similar way, but they do not require so much growing space generally as the plants raised from cuttings.

**Hollyhocks.**—These plants are fine subjects for growing in a mass, either by themselves or as groups, at the back of the herbaceous border. Plenty of space should be allowed between the plants, say up to 3 ft. 6 in., and they require a well trenched soil enriched with well-decayed farmyard manure. Support the growths with stout stakes. To obtain extra fine spikes it is as well to remove the side growths. To obtain blooms for exhibition, the point of the spike should be nipped out when the lowest rosettes commence to expand. "Rust" is a frequent cause of trouble in plants growing in heavy, tenacious soil, but the use of Vert's Hollyhock powder has proved most effective with us.

### FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

**Permanent Fig Trees in Borders.**—Trained Fig trees in succession houses will require constant attention in thinning, stopping, and tying the shoots where there is room for the leading branches to extend. Extension training, where space admits, is the simplest of all modes of growing the Fig, but in order to carry it out properly old branches which have reached the extremities of the trellis should be well thinned at the winter pruning, and feeding should be on a liberal scale. The roots of such trees are kept within bounds by means of turf or brick walls, and surface feeding roots are encouraged by mulchings of light, rich manure and watering with weak liquid, soot and guano water alternately. Fire heat cannot yet be dispensed with, but the valves of the pipes should be closed early on bright mornings. Air should be admitted when the temperature reaches 70°, gradually rising to 80°, and the ventilators closed again about 3 p.m. or earlier should the temperature show signs of declining. The latest houses containing trees from which one good crop only is expected should be kept cool, dry and well ventilated until the point buds begin to push into growth. If fire-heat is at command there is no necessity for delay, but, lacking this, early growth should be kept as hardy and backward as possible until all danger from frost is over. These late trees need not be pinched if they have an abundance of room; each shoot may be allowed to grow and form as many fruits and leaves as possible, to give ripe fruits in succession throughout August and September. The later fruits might prolong the season, but they should be rubbed off as they appear, otherwise the trees would suffer the following year. The roots of these trees are in a very limited area, and should be fed by liberal top dressings and diluted liquid manure applied two or three times a week. Cold water should not be used, but over-watering at this period is almost impossible.

**Early Figs.**—Pot Fig trees stood on inverted pots and pedestals and surrounded to the pot rims with fermenting materials will now be sending their white, fleshy roots over the sides of the receptacles in search of fresh food and moisture, of which the decaying manure affords a never-failing supply. Encourage these roots to develop during the growing season by spreading large sods well over the sides of the pots, but do not neglect to water the matted balls of roots within the pots, using warm diluted liquid manure occasionally, and keeping the turf and plunging material constantly moist. The syringe should be used freely not only during the flowering stage, but also through the period of the last swelling of the fruits that are ripening, when the amount of ventilation and fire-heat is increased. Exposure to sun light being essential for the fruits to obtain high colour and rich flavour, all gross shoots should be kept pinched, and weak or crowded growths removed as they appear. By these means, and allowing the temperature to reach 60° to 65° at night, with a little air, and 70° to 80° on bright days, the first crop of fruits will attain their fullest size and ripen quickly, while young shoots laden with small Figs will become well advanced for the succession crop.

### THE KITCHEN GARDEN.

By JAMES E. HATHWAY, Gardener to JOHN BRENNAND, Esq., Baldersby Park, Thirsk, Yorkshire.

**Cucumbers.**—Seed should be sown now to obtain plants in readiness for planting in frames as soon as the latter are at liberty.

**Onion Fly.**—Precautions should be taken to guard against this pest whilst the plants are young. As soon as the seedlings appear the beds should be dressed liberally with a mixture of half soot and fresh lime every ten days, and after showers. Another method is to sprinkle sand or sawdust saturated with paraffin between the rows. Rows of young Carrots should be treated on similar lines. It is important

to adopt these measures early and prevent attack, for once the pest is allowed to become established it is almost impossible to check it.

**Celery.**—The early batch of Celery plants should be planted out in trenches made 15 inches wide and 1 foot deep. The bottom of the trench should be broken up and well manured; the trench should then be half filled with well-rotted farmyard manure, and on this place a good layer of soil. The soil should be made firm, and the plants put in single rows 10 inches apart. Lift the roots with as large a ball of soil as possible and make them firm. On heavy land Celery trenches are often made too deep. Trenches for the plants comprising the main crop are better if made a good time in advance of planting, and these should be 3 feet 6 inches apart and 18 inches wide to allow for planting double rows. Dress the plants overhead with soot once a week as a deterrent to the Celery fly.

**Borecole, Broccoli and Lettuce.**—Make the main sowing of Borecole now on ground which has not been recently manured; also make a late sowing of Broccoli and sow more Lettuce seed to maintain a constant supply.

**Gourds.**—Sow seeds of Gourds in small pots in gentle heat to obtain plants for setting out at the end of the present month. Gourds are both useful and ornamental, and may be planted to cover unsightly places.

#### PLANTS UNDER GLASS.

By T. PATEMAN, Gardener to Sir C. NALL-CAIN, Bart., The Node, Codicote, Welwyn, Hertfordshire.

**Violets.**—Where Violet runners have been especially grown to produce flowering plants for next season they may now be planted out in well-prepared ground. Choose, if possible, a situation that is partially shaded, but do not plant Violets near large trees. Extra care is required in watering the plants after planting them, and also during hot sunshine. Good results may be obtained by dividing the plants, but when this is done take care not to select the central crown.

**Begonia Gloire de Sceaux.**—This fine ornamental and free-flowering Begonia is, in my opinion, not grown so extensively as its merits deserve. As the plant flowers in the early spring, it is doubly valuable for grouping in warm corners of the plant house. When well grown it forms a delightful subject, for its large rose-coloured blossoms and handsome bronzy leaves are very attractive. To obtain large specimens of this Begonia cuttings should now be inserted. The best cuttings are obtained from shoots growing from the base of the plant, and they should be inserted singly or three in a small pot. Use a compost of an open texture, and add sand to further ensure a free drainage. Plunge the pots in a warm propagating frame and shade the cuttings from bright sunshine.

**Tuberous Begonias.**—The newer hybrid Begonias that were reported as advised previously will have made sufficient growth suitable for use as cuttings for propagating purposes. These hybrid Begonias always appear to be slow in making new growth until about the middle of the present month, but after that date they will be found to grow very rapidly provided a little attention is given to their requirements. Good strong growths taken from the base of the old plant will be found most suitable for use as cuttings. The receptacle should be prepared in advance; use a good open compost consisting of loam, leaf-mould, and peat, with a good dash of silver sand added. The cuttings should be placed in a propagating frame having a temperature of about 65°. They may be inserted either singly or three in a small pot. We generally place three cuttings around the edge of a small 60-sized pot, and immediately they are rooted sufficiently they are potted singly. This work is best done before the roots become matted together. Cuttings of these Begonia root very easily, and when once rooted they will be found to grow very quickly. Some of the best varieties include Optima, Eclipse, Scarlet Beauty, Exquisite, Emita, Elatior, Mrs. Heal and Ideala.

## THE BULB GARDEN.

### HIPPEASTRUM.

SOME of the finest plants of Hippeastrum (syn. Amaryllis) may be allowed to ripen seeds for the purpose of raising a stock of young plants. The bursting of the capsule will indicate when the seeds are ripe. Although the seed of the Amaryllis will germinate freely at any time, it should be sown as soon as it is ripe to allow the seedlings time to make good progress before the advent of winter. The seeds may be sown thinly in a pan, or in 6-inch pots filled with a soil composed of two parts good loam, leaf-mould and silver sand. Finely-sifted soil should be placed over the seeds to the depth of a quarter of an inch. After watering them, the pots should be stood in a warm, moist propagating frame in which the seeds will soon ger-

until they flower, which a considerable number of them will do in the following spring. That is about twenty months from the sowing of the seed. After flowering, the seedlings may be treated the same as old bulbs. W. Steward, Alfreton Park Gardens, Alfreton, Derbyshire.

### NARCISSUS PRESIDENT VIGER.

At the last meeting of the Société Nationale d'Horticulture de France (held on April 13, 1922), MM. Vilmorin, Andrieux and Co. exhibited a vase of cut flowers of the magnificent Narcissus Président Viger, so curious by reason of its frilled trumpet, forming a ruffled out-growth similar to that of *Begonia cristata*, and giving it an altogether new and original aspect. This variety, raised by M. Chédanne, is said to be a sport from Sir Watkin. It received a Certificate of Merit from the Société Nationale d'Horticulture de France in 1913. A. M.

FIG. 123.—NARCISSUS ORANGE GLOW. AWARD OF MERIT, R.H.S., APRIL 25 (see p. 220).

minate. When the seedlings appear the pots should be placed on a shelf under the shade of a thin blind and watered very carefully. The young plants will make sturdy growth, and when they have formed their third leaf they should be potted singly into thumb pots, using the same kind of compost as before. The plants should again be placed on a shelf, and so long as there is room for the plants to grow without touching the glass there is no better position for them until they require larger pots. If watering is done carefully the young plants will make good progress until they require to be placed in 6-inch pots. The soil for this potting should be richer than for the previous pottings, and a compost consisting of three parts loam, one-quarter part leaf-mould and coarse silver sand with rough charcoal, the whole mixed well together, is suitable. It is essential that the pots be well drained. Some growers rest seedling Hippeastrums during the winter, but I think it is best to keep them growing continuously

### TRILLIUM UNDULATUM.

This species of Trillium is more difficult to cultivate than *T. grandiflorum*, and in many cases fails to establish itself in gardens. Yet it can be successfully cultivated in a cool, shady place in gritty peat, where the roots are moist, yet not excessively wet.

The blooms are white, brightly painted with stripes and blotches of richest crimson towards the base of the petals. That the plant is hardy there seems no question, but it is often lost through planting it in a dry soil or a situation exposed to too much sun. Besides being found in the woods of the more southerly parts of the North American continent, it is indigenous from Nova Scotia to Ontario, and is hardy enough to stand our climatic conditions, so far as cold is concerned. It loves the shade of woods and a cool, moist environment. This Trillium is often known as *T. pictum* and *T. erythrocarpum*. S. Arnott.

**EDITORIAL NOTICE.**

**ADVERTISEMENTS** should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, W.C.2.

**Special Notice to Correspondents.**—The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.

**Letters for Publication,** as well as specimens of plants for naming, should be addressed to the EDITORS, 5, Tavistock Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

**Local News.**—Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

**Editors and Publisher.**—Our correspondents would obviate delay in obtaining answers to their communications, and save as much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the EDITORS. The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.

**MARKET FRUIT GARDEN.**

**A**PRIL was cold and wet. The wind was frequently in the North or East, and it was keen even when it blew from other quarters. At my place rain fell on nineteen days, the total amount for the month being 3.11 inches. This makes it the wettest April since 1913, a fact which was not realised till the records were examined. There were 11° of frost on the first and fourth days, 4 feet above ground level, and the thermometer fell a little below freezing point several times, even at the end of the month, whilst there were ground frosts nearly every night. In such conditions vegetation was naturally held back. Fruit blossom is a month later than last year, which makes it about a fortnight behind the normal. All varieties of Plums bloomed during April, the earliest being in full display on the 15th. Early-blooming varieties of Cherries and Pears were also open in the latter half of the month, but later kinds had not burst their buds at the close. No Apple bloom appeared, whereas last year blooming started on April 12th, and was general by the 28th. I have never heard less of the cuckoo during April.

**PLUM PROSPECTS.**

All varieties of Plum have been full of bloom, some of them too full. The order of blooming was as follows: Black Diamond, Monarch, President, Rivers' Early Prolific, Czar, Victoria, Pond's Seedling, Belle de Louvain. The weather during blooming time gave a good deal of anxiety, as it certainly did not seem to be favourable to pollination. It is true that 3° of frost was the most recorded 4 feet above the ground during this period, but the thermometer frequently approached freezing point at night, and the days were often cold and windy or else wet, and, therefore, against the work of bees and other insects. However, there were intervals when the welcome drone of the bumble bees sounded amongst the trees, and it is to be hoped that their work proved effective. If they set one bloom in a hundred there would be a fair crop. It is too early yet to judge results, but the bloom seems inclined to hang on.

I am very glad I decided to spray with nicotine and soft soap just before the opening of the bloom. Examination proved that this killed most of the stem-mothers of the dreaded leaf-curling Plum aphid. I think there would otherwise have been a severe attack, as plenty of these insects were found on a few trees in full bloom that were not sprayed before the buds burst, breeding evidently having started. I think it is a good rule to spray all Plums before blooming every year. Spraying as soon as the bloom has fallen may or may not be just in time to catch the pests before they curl the

leaves and protect themselves; but by that time the aphids have multiplied, and killing them is bound to be a more difficult matter.

**A RESULT OF THE DROUGHT.**

It is evident that last year's drought matured young wood to an unusual extent. Plums, of course, often bloom on wood of the previous season's growth, but seldom to the extent seen this spring. My Rivers' Early Prolific bloomed right to the tips of the young shoots; and some young trees of several varieties planted as maidens in the autumn of 1920 were covered with bloom from top to bottom. This, of course, is undesirable, and the bloom was promptly picked off to give the trees a better chance of growing. But this blooming on year-old shoots is more unusual with Apples. This year it occurs in many cases, some of them annoying, as where the bud to which a leader was pruned turns out to be a fruit bud. In other instances the drought did good service by throwing vigorous young trees into fruit. So far it looks as though a good proportion of this year's crop would be borne on

FIG. 129.—THE LODER RHODODENDRON CUP (see below).

young trees that have not carried much fruit before.

**THE SPRAY-GUN.**

Readers of American publications must often have seen mention of the spray-gun, and may have wondered how it differs from the spraying appliances used in this country. I find that spray-guns are now obtainable in England, and that several growers have tried them and gained a favourable impression. I have just become possessed of one, and have given it a test, though not an exhaustive one so far.

The main object of the gun is to enable the sprayer to reach the top of a tall tree without using a nozzle on the end of a long lance, which is heavy and awkward to handle amongst trees, and does not effect its purpose any too well if the trees are very tall. The gun is only 2 feet long, and therefore very handy. In appearance it is like a brass syringe. There is a big nozzle at one end, but the handle at the other, instead of being for working in and out, as in a syringe, is twisted by the hand to regulate the adjustment of the nozzle. The gun is attached to a

hose much as a lance would be, the hose screwing on to a short elbow just above the handle of the gun. The slightest turn of the handle alters the character of the spray. To wash the lower part of the tree the handle is screwed up so as to produce a very wide cone of spray. To reach the higher branches it is unscrewed less than half a turn, and the cone of spray becomes narrow and far-reaching. Provided there is plenty of pressure available (the gun is intended for use with power sprayers only) there is no difficulty in reaching the top of the highest fruit-tree. If the handle is screwed right home the spray is cut off altogether to allow moving from one tree to another. Owing to the big cone of spray produced and the ease of handling, a sprayer can get over the ground much more rapidly with a gun than with a long lance; but he needs to move about in a lively manner, or he would waste the wash.

For winter spraying and the use of contact washes in summer, when the object is to drench the trees, the gun seems to be ideal; but I am doubtful whether it would be wise to use it for applying fungicides to trees in foliage. As the cone of spray is lengthened it naturally becomes coarser, and *vice versa*. Thus the top of the tree receives a coarse spray and the bottom a fine spray. In the case of a fungicide this might cause scorching of the top branches. Apertures of different sizes are provided for the nozzle, but the spray must always become coarser as it is lengthened to reach to a distance. This is the only fault I have to find with the spray-gun.

**INCREASING CONSUMPTION OF FRUIT.**

Hitherto growers and distributors of fruit have relied upon the mere presence of the produce in the markets and shops to secure its sale. No attempt has been made to increase consumption and avoid gluts. It is hoped that this will be altered in the coming season. Growers are notoriously slow to combine, but they are organising with unusual enthusiasm to support two big advertising schemes, one to deal with glass-house produce, and the other with outdoor fruit and vegetables. In the latter effort growers and distributors are combining. During the marketing season the value and attractiveness of home-grown fruit will be brought to the notice of the public by means of advertisements in newspapers and magazines, special films in cinemas, and posters in the tube railways and elsewhere.

Special efforts will be made to stimulate the demand for any particular fruit at times when gluts are most to be feared, and in this way it is confidently expected that the demand will be caused to keep pace with the supply. Advertising experts, who are familiar with the power of propaganda, have no doubt as to the success of these schemes. It is a mere matter of creating in the public a habit of eating more fruit and vegetables. At present the British people consume less of such food than any other people in the world outside the Arctic Circle; so there is plenty of room for improvement. Although something like £112,000 will be spent on these advertising campaigns, the cost to the individual grower will be very small indeed; and, naturally, the greater the number of growers who give their support the lighter the burden will be for each. *Market Grower.*

**THE LODER RHODODENDRON CUP.**

THIS Cup was presented to the Royal Horticultural Society in 1921 by Mr. Gerald Loder, in memory of his brother, the late Sir Edmund Loder, to encourage the study and cultivation of the genus *Rhododendron* (including *Azalea*).

The award is to be made in October of each year, and in making the award the judges will take into consideration not merely floral display, but the value to horticulture of the work of the recipient, whether such work shall include the production of flowers or not.

There are five judges, three appointed by the R.H.S. and two by the Rhododendron Society; the Cup is not to be awarded to the same individual more than once in seven years.

The first award was made last October, when

Sir Isaac Bayley Balfour was selected by the judges to be the first holder. It will generally be agreed that no more fitting choice could have been made. As is well known, Sir Isaac has devoted many years to the study of Rhododendrons; he has worked out large numbers of new species discovered by Wilson, Forrest, Kingdon Ward, Farrer and others, and has raised many of them from seed.

The actual presentation of the Cup was postponed from last autumn, in the hope that after being relieved of his duties as Regius Professor at Edinburgh, Sir Isaac might be able to receive the Cup from the hands of the President of the Royal Horticultural Society. Ill-health has, unfortunately, prevented the realisation of this hope, and it has now been arranged to present it to him privately.

The Cup (Fig. 129), which is of silver-gilt, stands about 15 inches high, and though not an exact copy of an old piece, is antique in character and style. The ornamentation is Celtic, and is similar to that on the Ardagh Cup made in the 10th Century, now in the Dublin Museum.

almost entirely supplanted by a crowd of hardy immigrants from the northern hemisphere."

It is remarkable that, notwithstanding the great number of flowering plants of the southern hemisphere cultivated in European gardens no successful counter-colonisation has taken place. This rule, however, is not without exceptions. I have noted four species of shrubs that have become thoroughly naturalised in this neighbourhood, growing self-sown so freely both in garden borders and woodland, that they have to be rooted out in some places to prevent them suppressing other growths. These are *Berberis Darwinii* and *D. buxifolia* from South America, and *Veronica Traversi* and *V. parviflora* from New Zealand. The last named is so prolific as to amount to a nuisance in the garden; but the nearly related and more desirable *V. salicifolia* shows no such tendency.

It is strange, in view of the preponderance of composite plants in Australasia, and the prodigious cloud of seeds discharged every year by the many species of *Olearia* and *Senecio*, that none of them has succeeded as a colonist in this

At this time careful watch must be kept for caterpillars, and if discovered steps should at once be taken to eradicate these pests. The Rose Slug-worm does a great deal of damage, and especially to climbing Roses, eating the upper skin of the leaf, but leaving the lower, with a result that the foliage assumes an unhealthy appearance, being covered at first with white blotches which soon turn brown, and cause much of the leaf to become semi-transparent.

As the foliage appears, commence spraying and dusting with sulphur, as a preventive against the various pests and diseases to which Roses are liable. Spraying should not be done late in the evening, nor in showery weather, and, of course, should never be carried out during bright sunny spells.

Hoing around the plants should be done frequently to keep the soil in good condition, whilst the spraying and dusting of the plants with specifics should be continued assiduously, for at this period pests begin to get very troublesome, and prevention is far more satisfactory than cure. Endeavour to keep enemies at bay from the beginning. When spraying, be sure to work

FIG. 130.—RHODODENDRON ORFODOXA (see p. 239).

## NORTHERN AND SOUTHERN PLANTS.

THE overflow of the human population of the northern hemisphere into the southern hemisphere, without any counteracting migration on the part of southern races, has its parallel in the vegetation of the globe. The readiness with which many flowering plants indigenous to lands in the northern temperate zone have become naturalised in Australasia and other lands in the southern temperate zone, has long been recognised as presenting a striking contrast with the inability of nearly all species from the southern hemisphere to compete successfully with the indigenous flora of the northern hemisphere and to establish themselves as colonists. In his *Manual of the New Zealand Flora*, Mr. Cheeseman states that in several districts of New Zealand introduced species now constitute the larger portion of the flora. He enumerates 523 of these introduced species (excluding what are obviously chance, and perhaps transient, escapes from gardens), whereof 425 are natives of the northern temperate zone. "At the present time," he remarks, "there are many districts where the indigenous flora has been

country. We grow here a considerable number of species of each of these genera, yet a single seedling of *O. nummularifolia* is the only self-sown offspring I have found in the course of many years. *Herbert Maxwell, Monreith.*

## THE ROSE GARDEN.

### SEASONABLE WORK.

THE pruning of Roses, where it is not yet completed, should now be finished without further delay, as the growths are making rapid headway. Care should be taken to remove all prunings at the time the work is carried out, or later one will find to one's cost what neglect in this direction means by happening upon an unnoticed thorn or two with painful results.

After the work of pruning is finished, apply a light mulch of well-rotted manure over the root area, and prick it lightly into the soil to a depth of three or four inches. This work should be done by an experienced and careful hand, as it is very necessary to guard against disturbing the roots when forking in the manure.

the mixture well under the foliage, as this is probably even more important than wetting the upper surface, as it is on the under sides of the leaves that pests, as a rule, harbour.

Plants raised from cuttings inserted last September or early October may now safely be placed out of doors to grow on, even though they have not started to throw out roots, provided they are well calloused; a sheltered situation should be selected. Cuttings offer an ideal method of raising fresh stocks of the lovely *Wichuraiana* group. Cuttings of well-ripened wood, cut to a joint, should be inserted in 48-sized pots filled with good, sandy compost, and the cuttings rooted in a cold frame. The same method may be employed for most of the Climbing Roses, and for some of the stronger growing Hybrid Teas and Hybrid Perpetuals, though for the latter two groups it is a more tedious way than budding, as greater time has to elapse ere the desired results are obtained.

Examine the stakes of Standard Roses and replace any that are decayed at the base; some may need withdrawing and placing in an upright position. This will also afford an opportunity to release any ties that are compressing the bark. *B.*

## PASSPORTS FOR PLANTS.\*

(Concluded from page 22A.)

In the year 1920, 124,000 kg. of Beans were imported into Rotterdam harbour alone. In America Beans are severely attacked by a dangerous disease, which might be carried to Western Europe. It has never been found with scientific certainty on this side of the Atlantic yet. The disease in question is called the Bean Blight (*Bacterium phaseoli*). But America's famous bacteriologist, Erwin Smith, thinks it highly probable that it is commonly carried on the seed, and Edgerton's experiments seem to prove this. Erwin Smith states that it affects the seed coat without destroying the seedling embryo, and the organism has a great resistance to drought. It is a well-known fact that it is a dangerous disease in a moist climate. The bacterial spots are seen on the leaves as minute translucent dots, which become somewhat protuberant, and, later, are sunken and discoloured. The pods are also heavily infected, and finally the ripening and the grown-out seeds. The United States and South Africa are the places where the disease occurs very often.

Again, what about the vegetable seeds, of which in the year 1920 16,000 kg. were imported into the port of Rotterdam? The pathology of vegetable seeds is only partly known. In the case of several diseases, the way in which they are transmitted is not known, but there are indications that a number may be carried by the seeds.

In the U.S.A. there is a dangerous bacterial disease of the Tomato, caused by *Aplanobacter michiganense*, which causes a phloem disease. It shows a withering of the stems, a leaf wilt, and, finally, a rotting of all the tissues. Erwin Smith says of it: "I think that it is a seed-borne infection. I have seen its yellow slimes close under the seed in the middle of green Tomato fruits and also in the coat of an immature seed. Whether or not it actually occurs in the interior of seeds capable of germination, the frequent extensive invasion of the outer part of the Tomato fruit is certain to bring about a surface continuation on the seeds."

These examples illustrate some of the dangers that threaten European horticulture and agriculture. If Europe follows the same lines her points are as convincing as those of the Americans.

England has, in 1921, issued an Order against four American plant diseases, the Chestnut Canker (*Endothia parasitica*), Downy Mildew of Hops (*Peronosplasmopara humuli*), Pear Blight (*Bacillus amylovorus*), and Black Knot of Plum (*Plovrighitia morbosa*). From a purely scientific standpoint the two fruit diseases may be carried over by fresh fruit. The Order will be of value in the case of Blight and Black Knot, when scions and twigs are sent from the U.S.A. to Europe; so it is with the Chestnut Canker, which is a real twig parasite. The Order shows that the interests of English horticulture and agriculture are focussed on this point.

Before trying to answer the second question (whether the danger is so large as the U.S.A. makes us believe) I wish to make some remarks on Quarantine Order No. 37. This Order has been the focus point of interest for horticulturists. It has been criticised by different scientists, and by our phytopathological services, so that it nearly seems superfluous to speak of it again.

I take it that every cultivated plant which may not be imported into America is refused on account of a special disease. If the Paeony and the *Gladiolus* are excluded (the import occurs only by special permit) I can only think of two diseases. The Paeony suffers in the U.S.A. and in Western Europe from *Botrytis paeoniae*, Oud. In the U.S.A. this is very common, and has been studied at different phytopathological centres. I have the impression that it is more common in the U.S.A. than it is here, but on both sides it is well known, and there is no danger of harming each other on either side. With the *Gladiolus* it is the same thing. The only disease that has certain influence is the Hard Rot that is caused by the fungus *Septoria gladioli*. This

occurs on both sides of the Atlantic, and was first described in the U.S.A. by Massey. The growers here know it well, and in the U.S.A. it is wide-spread. To a phytopathological scientist it is absolutely incomprehensible why these plants are excluded.

The same may be said of the Dahlias, of which, so far as I know, no dangerous infectious disease exists.

Let us now look at the practical side of the question, and examine the lists of the fungal and bacterial parasites America has found in different shipments of plants from Holland. It will show to us whether or not the consignments of plants are loaded with parasites. The phytopathological service has already pointed out, by analysing these lists, how clean the plants are, and how few parasites are to be found on them.

In the course of four years (1915-1918) they found no noxious diseases; 16 that had been known for years in the U.S.A., 8 organisms without parasitic characters, and 21 insufficiently described fungi of no noxious influence.

It strikes one that *Botrytis parasitica* on Tulips, which is spread on both sides of the ocean, has only been determined three times. We find mentioned *Glomerella cingulata* (*Gloeosporium fructigenum*) and we know that the American strain of the fungus is different from the European, as I put forward at the beginning of my remarks. *Rhizoctonia solani* has been found, which is a parasite common in the soil in all parts of the world. *Bacterium tumefaciens*, the Crown Rot of Apples and Quinces, was found in shipments. It is rather general here, but not of large economic influence, though well known to growers and pathologists. In the U.S.A. it is of more influence, causing a severe trouble with Apple seedlings, and as for the Quince, a Californian grower told me that "tumours were normal on these plants." It cannot be of any importance to American cultures whether *B. tumefaciens* be imported or not. We do not know whether it is a question of difference in strains in the bacteria or of difference in the host plant. I notice in the lists *Sphaeropsis malorum*, known in the U.S.A. as the Pernicious New York Apple Canker. It is not yet known as a Canker-producing parasite here, but we must keep a look out for it. If the fungus occurs here the strain of fungus does not seem to be virulent.

As already mentioned, I cannot find any severe diseases in these lists. The modern methods of control minimise the danger of transmitting parasites. But we know that American scientists think it possible that a harmless bacterium or fungus from here may prove fatal to them, and we know that Europe runs the same risks.

There is a slight risk, but if the world accepts this thesis, we shall look in future upon an impossible kind of life.

We can imagine passengers suffering from colds; the bacilli may change in the different climate into pernicious pneumonia bacilli, and become noxious to our people. But not only coughing passengers carry the cause of disease, but apparently healthy people may. This is specially the case with those people known as typhoid carriers, who are laden with germs of a pest. These people, according to the hysterically fearful, should be killed!

But no, Man is not worth so many billions of dollars as plants are! Measures against man's diseases are not so rigorous; but the measures against all possible and impossible plant diseases become sharper and sharper. Without very rigorous quarantine man's epidemics are well kept in check. The immigration of man has never been prohibited on account of diseases which he is not suffering from, but which he might carry. With international understanding regarding inspection, disinfection and fumigation, the exchanging and transportation of horticultural and agricultural products should continue with a certain amount of supervision, but should not be crippled by too severe rules. The certificates of pathologists should be recognised in the same way as those of human doctors.

The interchange of plants should not be prohibited, but only controlled. Prohibition is always a sign of weakness. It is only on this

basis that a healthy development of horticulture and agriculture may flourish. Competition is a necessary factor for the advancement of the world, and this will not take place if the present stringent conditions are insisted upon by America.

## THE GRAPE VINE.\*

(Continued from page 233.)

The size of the berry in the Grape is to a large extent determined by the number of fully developed seeds in it, which points to the value of proper fertilisation. Suppress all laterals as they appear. We do not close the houses in the early afternoon, for, although to do so might cause the vines very little harm, it certainly does them no good. This so-called bottling up of the sun, and incidentally charging the atmosphere with moisture, causes the leaves to soften, and thus makes them an easy prey for all insect pests. The only way to obtain strong, leathery leaves is to close the ventilators gradually in the evening till about 8 p.m., when the bottom ventilator should be closed to an inch and the top ventilators to two inches; if the thermometer falls to 55° no harm will be done to the vines during the stoning period. This is the time that the bloom is laid on and when the berry is built up. The longer the berries are in colouring the better, but, once they begin to turn, they cannot be ripened too quickly, for, when ripe in sixteen days from the time they commence to colour, they have perfect bloom, deep colour, and high flavour; moreover, the bunches will keep better, the berries being firm and solid. It may be said, "How are we to guard against mildew on vines under this treatment, with cold air reaching the leaves more or less continually, when it is known that the spores of this fungus are always present in the outside atmosphere in great numbers, and that they must be continually passing over the leaves?" It is quite simple when it is realised that it is only under certain conditions that these spores can develop, and these conditions are certainly not found on hard, leathery vine leaves and with a comparatively dry, clear atmosphere. But I would qualify the statement so far as a young vine in its first three years of growth is concerned, which must be kept growing further into the season to develop wood, and, therefore, must be kept cosier.

### WATERING.

Watering should be done very carefully throughout the year. For the first watering, done ten days before the house is closed, always use tepid water, and thus warm the border a little. For subsequent applications the water should be a little warmer than the temperature of the house. Some growers withhold water from the roots during the ripening period and keep the borders comparatively dry while the fruit is hanging ripe on the vines. I have not yet found that water at the roots has any influence on the bunches; any damage that may be done through moisture is from the atmosphere; but I am convinced that the lack of moisture in the border in the autumn has an adverse influence on the next year's crop, because by withholding water from the roots, before the leaves have fallen, the plant is forced to use up the reserve food stored in the stem and branches in the autumn, instead of carrying this reserve forward for another year. The best plan is to give water any time the border is dry. It may be said that dryness helps to ripen the wood. It certainly hardens it. We go further than that, and give the borders a thorough drenching after the leaves have fallen, not that the roots require it, but to cleanse the soil of impurities given off by the small, decaying root hairs. These tiny root hairs die back annually and leave a toxin in the soil. Nature provides for this contingency in the winter rains.

(To be concluded.)

\* An address given by Prof. (Miss) Westerdyk, of Utrecht and Baarn, at the Conference of the Federation Horticole Professionnelle Internationale, at the Hague, on April 21.

\* A lecture delivered by Mr. Malcolm Macnaughton, Scone Palace Gardens, Perth, in the Technical College, Dundee, before the members of the Dundee Horticultural Association.

## HARDY FRUIT GARDEN.

### THE GRAFTING OF APPLE TREES.

On page 124 Mr. Markham advises the cutting down of old Apple trees for re-grafting. It may be of interest to many readers to direct attention to an alternative plan, which will give first-rate results. It consists in grafting the numerous extremities over the whole tree, in preference to heading down the stock nearly to the main stem which admits of only a limited number of grafts being accommodated on the resulting stumps, and the tree will take several years to form a fruitful head. A good instance of the success attending the other method I saw late last summer, when paying a visit to the nurseries of Messrs. James Harris and Sons at Blackpill, near Swansea. Observing some large trees bearing heavy crops of clean, well-developed Apples, Mr. Harris informed me that many years ago when he took over the land numerous old fruit trees of a decrepid, exhausted nature were growing on it, the varieties being mostly inferior, and the few fruits produced hardly developed beyond the scrump stage. He decided not to head them down, but to graft them on the extension or multiple plan. The result is seen to-day in trees having fine heads of fruitful growth. One often hears of the influence of stock on scion, but here it was of interest to note the contrary, the influence of the scion on the stock. In some cases the original variety had not been eliminated, but was growing together with the adopted variety. For instance, I saw Bramley's Seedling and King of the Pippins on the same tree, and the first graft, King of the Pippins, was not one wit less healthy and fruitful than the other, and both sorts were bearing heavy crops of good fruit. Another point may be mentioned: these trees, although they bore evidence of bad attacks of woolly aphid in the past, were found on a close scrutiny to be entirely free of this pest. This seemed important, seeing that the season of 1921 was one of the worst for woolly aphid—at least, such was my experience in the metropolitan district. Can it be that double grafting in the case of some varieties may render the tree immune. *Hortus.*

### PEACHES AND NECTARINES ON OUTSIDE WALLS.

At the end of April Peach and Nectarine trees were showing a very fine display of blossom, both on south, south-east, and south-west walls, and should the season prove kind there is promise of good crops of fine fruit. The wood ripened splendidly last autumn, and at the time of pruning there was scarcely an unripened tip that needed to be cut away. As this season is a very late one, there should be little need for artificial pollination, as bees and other insects should be plentiful. Leaf blister, a source of trouble and annoyance in many gardens should not be so prevalent as usual, owing to better ripened wood, as I am quite sure the bulk of this disease comes on badly ripened shoots. Although this trouble is rare in these gardens (with the exception of one variety of Peach, viz., *Crimson Galande*), we always take preventive measures by spraying late in the season (just before the bulbs burst), either with lime sulphur at the strength of 1—25, or sulphide of potassium, at the rate of one ounce to one gallon of water, with a small amount of soft soap dissolved in the same. *R. H. Crockford, Weston Park Gardens, Stevenage.*

## FRUIT REGISTER.

### APPLE LAXTON'S PEARMAIN.

If this Apple is at its best about Christmas, (see p. 201) it must, indeed, be an excellent variety. I ate one on February 10 last, took a description of it, and concerning the flesh, I wrote, "greenish yellow, soft, remarkably juicy, aromatic, and highly flavoured, still in first class condition, core small, with very small compressed cavities and few seeds." The two last charac-

ters may not always hold good, because both may have been due to imperfect fertilisation. Concerning colour my remarks were, "dull, deep crimson, except on the shaded side, which is greenish-yellow, shaded with crimson." The comparison made between the colour of this Apple and Cox's Orange Pippin on p. 201 would be helpful if the last-named Apple were always as highly coloured as exhibited at the fruit show of the R.H.S. in 1920, or, indeed, any year. There are thousands of people who have to depend on the market, or fruiterers' shops, for a supply of this excellent British Apple. As it comes from the west of Middlesex old and overcrowded orchards, the fruit is russet-brown throughout, and nearly the same as Ribston Pippin, both being undersized and poor in colour. Besides the two pairs of Apples mentioned on p. 201, another notable pair, raised from the same fruit, were Cox's Orange Pippin and Cox's Pomona. *J. F.*

## HOME CORRESPONDENCE.

[The Editors do not hold themselves responsible for the opinions expressed by correspondents.]

**A Proliferous Cone.**—I enclose a proliferous cone of the Umbrella Pine, *Sciadopitys verticillata*, which may be of interest to you. It was taken from a tree about 20 feet high, grow-

FIG. 131.—A PROLIFEROUS CONE OF *SCIADOPITYS*.

ing at Ballyarthur, Co. Wicklow, the property of Major A. Bayly. *A. C. Forbes, Dublin.*

[The *Sciadopitys* not infrequently exhibits this abnormality; a similar example to the one you send was illustrated in *Gard. Chron.*, March 1, 1884, p. 282, and the illustration is reproduced in Fig. 131.—Eds.]

**A Nicotine Substitute.**—Nicotine is now scarce and dear. Any substance that will replace it is worth trying, and I suggest that growers should try chlor-cresol. This is a chemical substance, not a proprietary or patent preparation. Used at 2 pounds per 100 gallons of water, with the necessary soap, it is, in my experience, a good contact insecticide, a very good deterrent to insects, and a good fungicide for mildews. It is definitely not a soil insecticide, though Dr. Russell, of Rothamsted, has drawn attention to its value as a soil steriliser for other organisms. I believe that fruit growers, nurserymen, and others would do well to give a trial to this chemical. Nicotine can never be available at a reasonable price, and we have to find a substitute. I think this is a possible one. *N. M. Lefroy, Westbrook House, Heston, Middlesex.*

**Orn's "Flower Garden."**—Mr. Jacob's note on p. 193 affords me an opportunity to state that *The Flower Garden*, which was by an unknown author, but obviously by a Scot, was really written or compiled by the author of the

other books of the series—McIntosh—but without his name. I find them all advertised later as by him, and a review in another periodical in the early forties gives McIntosh as the author. My copies were obviously bought in parts, and are bound in half calf, and no doubt might have had wider margins to the prints than they have, but still there is a margin, which Mr. Jacob's seems not to have. They were sold, bound in cloth, at 10s. 6d. each. Probably Mr. Jacob is a little unfair to McIntosh in condemning him for using scissors and paste. The other volumes clearly show that fruit was more the forte of the author than flowers, and if he knew little or nothing about Pinks and other florist flowers, it was at least honest of him to give directions from experts, with their names, than to presume to a knowledge of which he was ignorant. Moreover it was a common practice. *R. P. Brotherton.*

**Do Plants Know Time?**—On page 216, Mr. Mark Mills considers my explanations refer more or less to the opening and closing of the floral organs. That was the only subject at issue. He also says, I conclude that the opening and closing of certain flowers mentioned are due to incomplete growth. That is not my standpoint. Those movements are only possible while growth is incomplete, and cease as soon as growth is completed. I did not mention the cause of the opening of the flower heads of *Tragopogon*; that is another story. They open to receive their numerous insect visitors—beetles, flies, bees and butterflies—in order that their florets may get cross-fertilised, for that is the chief end of their existence. By the rolling of the arms of the stigma, the older florets get fertilised by the pollen of the younger ones. This method of fertilisation is termed *geitonogamy*, and it is more effectually carried out by the closing of the flower heads. Here also Mark Mills may notice a movement of the green bracts surrounding the head, and which are no part of the floral organs, but a stage nearer the true leaves. Two remarkable movements of other plant organs may also be observed in the *Scarlet Runner*. These are movements that are not hereditary. The opening of the flowers of forced plants cannot be called hereditary. It is quite true that I referred to the incomplete growth of individual flowers. A Sweet Pea may be made to produce a succession of flowers all the summer, and an Oak tree will continue producing them for hundreds of years. Each organ of a plant has its own periodicity of growth. I have made observations on the opening of the flowers of *Oenothera Lamarckiana*, and have seen them opening at some distance away, as it is very rapid. The failure of the flowers to close on a dull day was due to retarded growth. I cannot admit that a plant understands what time it has at its disposal for completing its growth. If a tall growing, late variety of Maize has not completed its growth before frost happens, it gets killed. *J. F.*

**Veronicas and Lilies as Greenhouse Plants.**—As an old and interested reader of your journal, I was pleased to note on p. 209 your correspondent *J. C.* recommending Veronicas for pot culture. In these days of heavy expenses, much more use should be made of these semi-hardy plants. I am not acquainted with either of the species named, but are they superior to *V. Hullekeana*, which now charms most of its beholders? This species is not quite hardy, but does well in a cold house. With regard to the articles on Lilies for greenhouse decorations, on p. 203, I have had experience with most of the species and varieties mentioned. Regarding *L. auratum*, I have found the varieties *platyphyllum* and *rubro vittatum*, more satisfactory in pots than the type plant. May I remark that those who have not tried *L. Henryi* in pots should do so. This species, grown here under not the best treatment, has done remarkably well, and increased rapidly, so much so that we are trying it in the open this season. Seed ripened last season, has germinated after being sown about 10 weeks. *L. testaceum* is another Lily which is making good growth in pots under cold treatment this season. *J. E., Felcourt Gardens, East Grinstead.*

## SOCIETIES.

### CHAMBER OF HORTICULTURE.

#### ANNUAL MEETING.

THERE was a large attendance at the third annual general meeting of the Chamber of Horticulture held at 18, Bedford Square, at 3 o'clock on Wednesday, the 3rd inst. In the unavoidable absence of the President, Sir Harry J. Veitch, Mr. George Monro presided, and was supported by Mr. G. W. Leak, one of the Vice-Presidents. The private members, the Horticultural Trades' Association, the British Florists' Federation, and the Federation of British Growers were all well represented. Lord Winterton, Sir Harry J. Veitch, Dr. Keeble, Alderman E. C. Moore, Mr. W. H. Page and Mr. W. Seabrook all sent letters expressing regret at their inability to attend the meeting.

The annual report and accounts presented proved particularly interesting, and a few of the principal items were those referring to the establishment of a strong Parliamentary Committee, which has had under consideration such matters as the taxation of motor lorries, improved transport facilities, marking of foreign produce, and the regulation of imports. The reclassification of goods conveyed by rail has occupied the attention of the Chamber to the very great advantage of horticultural traders. A matter under immediate consideration is that dealing with the conveyance of horticultural produce by passenger train. It appears also that the Insecticides Committee of the Chamber has done excellent work, while the Technical Committee has been particularly energetic in dealing with various insect pests and their treatment. The Report made reference to the value of the Imperial Fruit Show and to the International Horticultural Conference held in London last year at the offices of the Chamber. It is of interest to observe that the Chamber has representation at the National Institute of Agricultural Botany, the Advisory Committee on Willow Growing, the British Colonial Fruit Show, the Horticultural Advisory Council, and the International Commercial Horticultural Conference. The accounts show a very much better condition of affairs than previously; a large amount outstanding for legal expenses has been met during the year and this, together with the general expenses, have almost been met by subscriptions, donations and affiliation fees. There is still a deficit on the general account, and the chief creditor, and a very generous one, is Mr. George Monro. The Chamber has now seven prominent associations in affiliation with it, and nine non-trading societies. It has a private membership of nearly 150.

The Chairman referred to the several items already noted and stated that in his opinion the Chamber had come successfully through a very difficult period, during which there had been a heavy fall in the sale of prices of horticultural produce and practically no reduction in the cost of production. He also stated that the item of £378 7s. 4d. for cleaning, caretaking and repairs, included one of over £200 incurred in connection with the painting and repairing of 18, Bedford Square, but one not likely to appear again for some time. Mr. G. H. Barr moved the adoption of the report and accounts, and this was seconded by Mr. W. Nutting. Mr. R. H. Page and others considered the publication of a "Bulletin" was essential to the best interests of the Chamber, and other matters raised by members present were the taxation of motor-cars used for business purposes, the supply and strength of nicotine, prepayment of carriage, and owners' risks. The Report and Accounts were then adopted.

On the motion of Mr. Geo. Monro, seconded by Mr. J. Harrison, junr., Mr. G. W. Leak was unanimously appointed President for the ensuing year. In taking the chair and returning thanks for the honour accorded him, Mr. Leak expressed the hope that all members of the Chamber and all sections of the trade would pull together for the benefit of the horticultural industry, so that the Chamber might fulfill the purpose its founders set out to achieve. Messrs.

J. Harrison, junr., H. O. Larsen, W. Seabrook, C. E. Pearson, J. Rochford, and A. W. White were elected Vice-Presidents of the Chamber. Alderman E. C. Moore was reappointed Hon. Treasurer and heartily thanked for his services on the motion of Mr. G. Monro and Mr. H. Mount, while Messrs. Cobley, Kay and Co., were reappointed auditors on the motion of Messrs. Du Cann and C. H. Curtis. The election of eight representatives of private members to the Council followed, with the result that Messrs. R. H. Page, W. H. Page, G. Shawyer, F. Ridley, G. H. Barr, W. Wallace, W. H. Press, and Col. Fletcher were appointed.

The meeting agreed that a letter of thanks be sent to Sir Harry J. Veitch, the past president, together with an expression of hope that his health would soon permit him to come among his friends again. Mr. George Monro was also heartily thanked for his services during the year, as were Mr. C. M. Matthews, the Secretary, and the staff of the Chamber.

#### ANNUAL DINNER.

Mr. G. W. Leak, the new President, presided at the annual dinner held during the evening at the Hotel Cecil, and he was supported by Sir Arthur Griffith Boscawen, Minister of Agriculture, Mr. and Mrs. Geo. Monro, Sir Daniel Hall, Alderman and Mrs. Moore, Col. C. R. Burn, Mr. and Mrs. Geo. Shawyer, and Mr. and Mrs. J. Rochford, and there was also present a large company of ladies and gentlemen interested in commercial horticulture.

"Success to Horticulture" was proposed by Mr. G. W. Leak, who suggested that commercial horticulturists might be divided into two sections, those who cultivated plants good for food and those who grow plants desirable for their beauty. He referred briefly to the British fruit growing industry and expressed the view that although fruit cultivation had reached a very high degree of excellence in certain parts of the country, there was room for very much improvement in other directions, notably in the south-west of England, and he suggested that the Ministry of Agriculture might give special attention to educational matters in that part of the country. He also considered it desirable that growers should pay a visit to the Westlands of Holland so that they might become conversant with the splendid methods of fruit cultivation adopted there; indeed, he thought it was advisable for flower growers as well as fruit growers, to rub shoulders with those engaged in similar pursuits in other countries because there was usually something to be learnt. With regard to the flower industry, he considered our leading growers had little to learn in regard to cultivation and marketing. He expressed his very strong belief in a central co-ordinating body on behalf of all sections of the horticultural trade, and considered that the Chamber of Horticulture had filled that position to the advantage of all. There was room, in his opinion, for a very much wider interest in horticultural matters than at present obtained in this country, and he hoped that the impetus given to allotment cultivation by the war would not be allowed to lapse, and, particularly, he asked the ladies present to use their influence to extend the use of home-grown flowers, fruits and vegetables. Sir A. Griffith Boscawen responded to this toast in a very interesting and often humorous speech, and one to which we have referred on p. 237. He made special reference to the Hague Conference, to the need for organisation and statistical information in horticultural trade, and to the Plant Conference at Washington, which Mr. W. G. Lobjoit is on his way to attend with, he hoped, good results. At the conclusion of his remarks, Sir Arthur presented Mr. George Monro with his portrait in oils, painted by Mrs. Beresford. This life-like portrait was unveiled at this point, and was greatly admired by the whole of the company, and Sir Arthur expressed the feelings of all present when he said that the portrait was a modest token of the great regard in which Mr. Monro was held, and a little reward for the energy and enthusiasm which he had put into the founding and conduct of the Chamber of Horticulture. In acknowledging the presentation, Mr. Monro said he could scarcely

say that it came as a surprise, seeing that he had sat fifteen or sixteen times in Mrs. Beresford's studio, nor was he conceited enough to consider it a "handsome" present. Nevertheless, he was delighted with this evidence of the goodwill of his many friends, and the portrait would be kept as a heirloom in his family. He did not mind being hung on the wall, but he strongly objected to being placed on the shelf. The Presentation Committee had suggested that the portrait might be hung in the Council Room of the Chamber of Horticulture but his Scottish instinct would not allow him to accept the hint. However, to meet the views of his friends, he had asked Mrs. Beresford to paint an exact copy of his portrait, and when this was finished, he would be delighted to hand it over to the Chamber. Mr. Monro had a magnificent reception, and was accorded musical honours.

The toast "Our Guests" was proposed by Mr. Alderman E. C. Moore, and responded to by Sir Daniel Hall, while the toast of "The Chairman" was very capably proposed by Mr. F. R. Ridley, and duly given with musical honours.

### MANCHESTER AND NORTH OF ENGLAND ORCHID.

APRIL 20.—Committee present: The Rev. J. Crombleholme (in the chair), Messrs. R. Ashworth, D. F. Bedford, J. Birchenall, A. Burns, A. Coningsby, D. A. Cowan, J. C. Cowan, J. Ellwood, J. Evans, A. Hanmer, J. Howes, A. Keeling, D. McLeod, J. McNah, E. W. Thompson, J. Thrower, and H. Arthur.

#### AWARDS.

##### FIRST-CLASS CERTIFICATES.

*Cattleya Tityus* var. *Royalist*: A variety with mauve sepals and petals and a large, broad lip of deep intense magenta colour and bright yellow throat; *Odontoglossum crispum* West Point *Elegance*, a large flower of good shape with white ground heavily blotched with deep reddish brown. *Odontoglossum St. George* var. *Brilliant* (*Alexandrina* × *eximium*). A large, well-shaped flower also with a white ground that is heavily blotched with claret red. From S. GRATRIX, Esq.

*Odontoglossum Duke of Clarence* (*crispum* *Luciani* × *Colossus*). A fine flower heavily blotched with reddish-brown; *Brasso-Cattleya Jupiter*, *Lady May Cambridge*. A large flower with mauve sepals and petals and mauve lip with deep magenta markings. From Mrs. GRATRIX. *Dendrobium Ashworthiae* Bedford's variety. The petals and sepals are white and the lip greenish white; *Catasetum Trulla*, *Dovercourt* var.; sepals and petals almost black and lip green. From Dr. F. BEDFORD. *Cymbidium Garnet* (*Lowianum* × *Parishii* *Sanderæ*). A very fine dark variety; *Cymbidium eburneo-giganteum* (*eburneum* × *giganteum*). A form with reddish sepals and petals and dark lip. From the Rev. J. CROMBLEHOLME. *Odontoglossum Pesatorei alba* Haddon House var. A pure white flower of good form with a yellow crest. *Odontoglossum Doraq* (*Paris* × *Aquatania*). A large flower of good shape. From P. SMITH, Esq. *Lycaste Imschootiana*, *Bridge Hall* variety from Mrs. BRUCE and Miss WRIGLEY. *Odontioda Evelyn*, *Edgemoor* var. A flower of good shape and bright scarlet colour. From A. HANMER, Esq. *Odontioda Sultan* (*Charlesworthii* × *crispo-Harryanum*). The sepals and petals are nearly black; lip reddish. From Messrs. KEELING and SON.

#### AWARDS OF MERIT.

*Lycaste Skinneri Red Cap*. From Mrs. BRUCE and Miss WRIGLEY. *Sophranitis grandiflora* Bedford's variety. From Dr. F. BEDFORD. *Odontioda Hypatia*, *West Point* variety. From S. GRATRIX, Esq. *Odontoglossum Amber* from A. HANMER, Esq.

#### GROUPS.

S. GRATRIX, Esq., West Point (gr. Mr. J. Hawes) was awarded a Gold Medal for a group of *Cattleyas* and hybrids in great variety. Messrs. CHARLESWORTH and Co. were awarded a Gold Medal for a fine group.

## ROYAL HORTICULTURAL.

MAY 9 AND 10.—The Hall at Vincent Square was filled to its utmost capacity on the above dates with a great variety of subjects, the chief of which were Daffodils, Rhododendrons, flowering shrubs of many sorts, alpine and early hardy flowers, a few Orchids, Pansies, and a few Saxifrages. A larger representation of the last was anticipated, and in the ordinary course of weather there would have been plenty of Tulips. The opening day was brilliant and hot, and the hall was uncomfortably full of Fellows and visitors during the early part of the afternoon.

## Orchid Committee.

*Present*:—Sir Jeremiah Colman, Bart. (in the chair), Prince Shimadzu, Messrs. Jas. O'Brien (hon. secretary), C. J. Lucas, Gurney Wilson, R. Brooman White, Frederick J. Hanbury, Arthur Dye, Fred. K. Sander, H. G. Alexander, W. H. Hatcher, A. McBean, Richard G. Thwaites, W. J. Kaye, E. R. Ashton, Pantia Ralli and Stuart H. Low.

Only five plants were entered for awards, and most of them had previously been given awards; none received distinction on this occasion. H. T. PITT, Esq., Rosslyn, Stamford Hill (gr. Mr. Thurgood), was awarded a Silver Flora Medal. A fine feature in the group was the variety of grand Miltonias showing the forms of *M. vexillaria*, ranging from the best pure white variety to the rich rose and crimson *M. vexillaria* Lyoth, also the richly coloured *M. vexillaria* Memoria G. D. Owen, *M. Hyeana* var. F. M. Ogilvie, a large white flower with blackish base to the lip; *M. Bleuana* Hessele variety, the best of its section, *M. Venus* var. Fascinator, a beautiful flower of rosy-mauve and white colouring, and the superb *M. Bleuana* Queen Elizabeth. Among the *Cymbidiums* was *C. Low-grinnum* Rosslyn variety, which had previously obtained an award.

## OTHER EXHIBITS.

G. W. BIRD, Esq., Manor House, West Wickham (gr. Mr. H. Redden), showed a grand plant of *Odontioda Sultan* var. *Scutari* (Odm. *crispoharryanum* × *Oda. Charlesworthii*) with a spike two feet tall, of eighteen flowers, that were heavily blotched with claret red.

R. GERRISH, Esq., Milford Manor, Salisbury (gr. Mr. W. Sorrell), showed *Odontoglossum majesticum* Gerrish's variety (exmum × *percutulum*) with a spike of three large and finely formed flowers of rich violet and white colour.

R. G. THWAITES, Esq., Chessington, Streatham Hill (gr. Mr. F. Gover), exhibited *Sophracattleya Gwendoline* var. *Golden Dawn* (*C. Octave Doin* × *S.-C. Wellesleyae*), a pretty flower with sulphur yellow sepals and petals, the latter tinged with pink, and a yellowish lip with clear ruby red front.

J. J. BOLTON, Esq., Claygate Lodge, Claygate, Surrey (gr. Mr. S. Lyues), showed cut blooms of two of the finest hybrid *Orchids* of their class ever exhibited, viz., *Cattleya Corydon* (*armavillierensis* × *Trianae* Backhousiana), a perfect flower, nine inches across and with proportionately broad petals of rich rosy mauve, the broad lip being ruby-crimson in front; and *Brassia-Laelio-Cattleya Jupiter* var. *John Cowan* (*B.-L.-C. Veitchii* × *C. armavillierensis*), an immense flower, perfect in form and over ten inches across. The petals are white tinged with rose; the broad, circular-fronted lip is deep violet with a clear yellow disc.

## Narcissus and Tulip Committee.

*Present*: Messrs. E. A. Bowles (in the chair), G. W. Leak, J. de Graaff, Peter R. Barr, J. D. Pearson, C. W. Needham, H. V. Warrender, F. H. Chapman, J. W. Jones, Geo. Monro, W. Poupert, Rollo Meyer, W. B. Cranfield and Charles H. Curtis (Hon. Sec.).

## FIRST-CLASS CERTIFICATE.

*Narcissus Firetail*.—This beautiful *Barrii* variety, with its ample cream white perianth segments and bright orange-red crown, is now well known to specialists and those who visit spring shows. It is a fine Daffodil, and gained an Award of Merit about a year ago. Shown

by Mr. F. H. CHAPMAN, Rye; DONARD NURSERY Co., Newcastle, Co. Down; and the ANGLESEY BULB GROWERS' ASSOCIATION.

## AWARDS OF MERIT.

*Narcissus Silver Salver*.—A small-cupped *Leedsii* variety, with white perianth and white cup, the latter prettily plated, and with a greenish eye. Shown by Mr. F. H. CHAPMAN.

*Narcissus Pelican*.—An attractive *Barrii* variety raised by the late Mrs. R. O. Backhouse. The large perianth segments are soft yellow, while the rounded cup is vivid orange. Shown by the ANGLESEY BULB GROWERS' ASSOCIATION.

*Narcissus White Coral*.—This delightful and dainty triandrus hybrid is wholly white; the perianth segments reflex slightly and the wide-mouthed trumpet is prettily frilled.

*Narcissus Sea Shell*.—A charming giant *Leedsii* variety, with broad white perianth segments that are pointed rather than rounded at the ends; the short trumpet is pale yellow at the frilled rim, and this colour shades down to white about halfway to the base. Both shown by Mr. W. B. CRANFIELD, Enfield.

## PRELIMINARY COMMENDATION.

*Narcissus Ypres*.—A strikingly handsome variety, with broad, frilled orange-vermilion cup, and broad perianth segments of palest buff tint, with the orange of the cup staining the bases of the segments. It belongs to the *incomparabilis* class and is the first variety to gain the Preliminary Commendation from the *Narcissus* Committee. Shown by Mr. GEORGE MONRO, Red House, Finchley.

## GROUPS.

Messrs. BARR AND SON created a record by being awarded a Gold Medal at three successive meetings for the same flower. On the present occasion their admirable collection was but little inferior to the group at the previous meeting. It was the *Barrii* sorts that "took the eye" most, and these included *Nysa*, *Coeur de Lion*, *Prince Fushimi*, *Red Gauntlet* and *Angela*. The Pheasant's Eye type was also well represented (Gold Medal).

Just inside the entrance Messrs. SUTTON AND SONS splendidly illustrated the decorative value of *Narcissi*. The flowers were all of first quality and the arrangement was deserving of high praise. In tall stands we noted generous quantities of *Whitewell*, *Horizon*, *Memento*, *Red Lady*, *Red Chief*, *Tritoma* and similar sorts, while the central collection of such varieties as *Homer*, *Radiant*, *Crater*, *Buttercup*, *White Wonder* and a few *Poeticus* seedlings were equally fascinating (*Silver-Gilt Banksian* Medal).

On the other side of the entrance the DONARD NURSERY Co. had an interesting collection in which the large coronas in such sorts as *Will Scarlet*, *Donax*, *Croesus* and *Dragon* were especially showy (*Silver-Gilt Banksian* Medal).

The exhibit by Messrs. J. R. PEARSON AND SONS was stated to be composed of flowers from home-grown bulbs, and they illustrated in an admirable degree the excellence of the British product. Of the many varieties so well shown, *Croesus*, *Nannie Nunn*, *Marshallight*, *Gipsy Queen* and *Lucifer* of the *Barrii* type, and *Virgil*, *Thelma*, and *Acme* of the *Poets' Narcissus* were excellent (*Silver-Gilt Flora* Medal).

Varieties chiefly of garden value were shown by Messrs. RYDER AND SON, and these included beautiful vases of *Nannie Nunn*, *Helios*, *Horace* and *Majestic*. The *Tazetta* sorts were especially plentiful and the most prominent were *Fanny Halls*, *Sulphur Orange*, *Elvira* and *Orange Cup*.

Amongst the many varieties shown by Messrs. R. H. BATH, LTD., were *Matchless*, *Unique*, *Firetail*, *Lilian Cave* and *Marseillaise*. Besides the *Narcissi* there were vases of *Irises* and *Grape Hyacinths* (*Silver-Gilt Banksian* Medal).

Numerous promising seedlings were shown by Mr. W. B. CRANFIELD, with some new sorts. All were of great merit and attractively arranged. The most prominent varieties included *Flintstone*, *John Macfield*, *Firetail*, *Cosack*, *Crimson Braud*, *Mountaineer*, *Trace* and *Cockatrice* (*Silver-Gilt Banksian* Medal).

Besides some excellent seedlings Messrs. F. H. CHAPMAN, LTD., showed *Orgy*, a very showy *Barrii* bloom with a broad corona, shading from greenish yellow in the centre to a fiery orange at the rim. *Debutante* has a chaste bloom, which has a small red corona.

Messrs. E. H. KRELAG AND SONS showed a few sorts, mostly of the large *Trumet* section. These included *Faust*, *Pegasus* and *Dulcimea*, with seedlings. A couple of vases of *Tulip Siren*, of bluish pink shading and elegant form, were very attractive.

In the Orchid annexe the ANGLESEY BULB GROWERS' ASSOCIATION arranged a small collection of such attractive *Narcissi* as *Jingle*, *Jovial*, *Jester*, *Lantern*, *Vixen* and *Jorrocks*.

## Floral Committee.

*Present*: Messrs. H. B. May (in the chair), S. Morris, R. C. Notcutt, John Heal, Geo. Harrow, G. Reuthe, J. F. McLeod, W. J. Bean, H. J. Jones, H. V. Warrender, D. B. Crane, H. R. Darlington, Arthur Turner, C. R. Fielder, W. B. Gingell, M. C. Allwood, W. B. Cranfield, Andrew Ireland and J. Jennings.

## AWARDS OF MERIT.

*Primula fasciculata*.—A tiny and apparently very variable species, about two or three inches high, and bearing a few deeply notched flowers on short, slender stalks. The smooth green leaves are ovate, on slender petioles, and suggest the foliage of some of the small-growing *Campanulas*. The colour of the flowers varies from lilac to lavender and blue, and there is a yellow rim around the eye. We believe this is one of *Forrest's* plants. Shown by the ROYAL HORTICULTURAL SOCIETY.

*Acacia Korang Yuki*.—A bright, free-flowering and attractive variety of the *Kurume* section, making a dwarf densely twiggy bush. The flowers are small, of the *A. amoena* type, and they are of a rich reddish-salmon colour. Shown by Mr. R. C. NOTCUTT, Ipswich.

*Rhododendron sino-grande*.—At its first appearance in London this much-talked-of and much written about *Rhododendron* did not have a particularly good reception, judging from the observations of many visitors at Vincent Square. The species appears to be much like the well-known *R. grande*, but has very much larger leaves, indeed, in a cool house it might pass as a handsome foliage plant. A comparatively small leaf shown was about 16 inches long by 9 inches wide, and we have heard of leaves measuring 20 inches by 11 inches. The campanulate flowers are cream coloured, stained at the base with crimson, and the anthers are crimson; in the truss shown there were twenty-six flowers, and it was evident that two others had fallen. It is not hardy at Horsham. Shown by DAME ALICE GODMAN, Horsham, Sussex.

*Erimvea pungens*.—This interesting plant—the Hedgehog Prickum—was admirably represented at Vincent Square by a specimen, grown in a pot, covered with flowers. It is a native of Valencia and Morocco, and was discovered by *Clusius*. The plant forms a dense, dwarf, almost leafless shrub, erect and very spiny, and bears its purplish-blue flowers, each set in a silky calyx, in clusters of three to eight, just below the ends of the branchlets. A fine specimen at the Cambridge Botanic Garden was figured in *Gard. Chron.*, Vol. lxx., fig. 121. Shown by Mr. MAURICE PRICHARD, Christchurch.

*Rose White Ophelia*.—An exquisitely beautiful cream white counter-part of the very popular market *Rose, Ophelia*. The blooms are of almost perfect form and carried on long, stiff stems. Shown by Mr. ELISIA HICKS, Twyford.

*Pyrus Eleyi*.—An effective hybrid obtained by crossing *P. Niedwetzkyana* with *P. spectabilis*. The large flowers are of intense old-rose colour, almost crimson in the newly opened bloom, and shown by CHAS. ELY, Esq., East Bergholt, Suffolk.

## GROUPS.

Flowering shrubs were a pleasing feature of the meeting. On a floor space Messrs. L. R. RUSSELL, LTD., displayed excellent bushes of such large-flowered greenhouse *Rhododendrons* as *Dalhousiae*, *Countess of Haddington*, and *Nuttallii*. There were also examples of *Cerasus*

James H. Veitch, many Clematises and the old-time greenhouse climber *Rhynchospermum jasmimoides* (Bronze Flora Medal).

A corner space was well filled by Mr. R. C. NORCUTT with a good collection of double-flowered Cherries, various *Pyruses* and *Azalea Kaempferi* varieties. There was also a particularly good bush of *Enkianthus campanulatus* (Silver Flora Medal).

Near by Mr. J. C. ALLGROVE had a splendid collection of forced Lilacs. *Souv. de L. Spath*, President Grévy, Madame Lemoine and Marie Legray were very attractive. A plant of the uncommon *Paeonia obovata alba*, introduced from Hupeh in 1900, also attracted much attention (Silver Banksian Medal).

On a floor space Messrs. R. and G. CUTHBERT displayed Cherry James H. Veitch, with many plants of *Azalea mollis* and *A. Hexe*. They also had examples of the fragrant *Staphylea colchica* and some little bushes of *Deutzia gracilis* (Bronze Flora Medal).

Some very handsome sprays of *Pyrus Malus* varieties were shown by Messrs. J. CHEAL AND SONS. Besides *floribunda purpurea* and *Neidzwetzkyana*, they had large branches of *P. prunifolia coccinea*. In another place Messrs. Cheal staged several pot plants of *Hydrangea Madame Mouliere* also a few vases of *Star*, *Dahlia*s (Bronze Flora Medal).

Some good varieties of the "Kersbergen" *Azaleas* were again exhibited by Messrs. WALLACE AND CO., who included many plants of *Azalea Hexe* and *Rhododendron Hugo de Vries* (Silver Flora Medal). A large branch of *Rhododendron Nuttallii* was shown by Messrs. R. GILL AND SON, who also had beautiful trusses of *Gill's Triumph*, *Dalhousiae* and *Beauty of Tremough* (Silver Banksian Medal).

An especially interesting collection of *Rhododendrons* was contributed by DAME ALICE GODMAN, South Lodge, Horsham. These included *R. campylocarpum* and a rather paler yellow variety; *Loder's White*, *Luscombei splendens* and an *Aucklandii* hybrid bearing an unusually large and shapely truss (Bronze Banksian Medal). Messrs. R. VEITCH AND SON, Exeter, showed handsome sprays of *Dendromecon rigidum*, *Prostanthera rotundifolia* and *Sophora tetraptera*, to the latter of which a Cultural Certificate was granted.

Messrs. JOHN PEED AND SON filled a goodly length of tabling with a collection of handsome *Hippeastrums* (Silver Flora Medal). Several large plants of their new *Golden Mrs. F. Sander Marguerite* were shown by Messrs. Sanders.

*Auriculas* of superb quality were shown by Mr. JAMES DOUGLAS. Amongst the many varieties *Brillianty*, a cerise self show variety with a white centre and mealy leaves, was especially prominent (Silver-Gilt Banksian Medal). A smaller collection, contributed by Messrs. LOWE AND GIBSON, included such sorts as *Argus* and *Great Warley* (Bronze Banksian Medal).

Roses were shown in increased numbers and of great merit. Messrs. B. R. CANT AND SONS included such valuable sorts as *Cupid*, *Padre* and their new variety *Sovereign*, in a collection of beautiful blooms. Mr. E. J. HUCKS had many vases of useful blooms. The deep pink *Premier*, with *Columbia*, were admirable, while the central collection of *White Ophelia* was very chaste and charming (Silver Banksian Medal). *Augustine Hartmann*, *Ophelia, K. of K.*, and some immense blooms of *Mrs. Foley Hobbs* were included in a good collection of *Roses* by Mr. GEORGE PRINCE (Silver Banksian Medal).

On a floor space Messrs. WM. CUTBUSH AND SON had a very graceful and pleasing group of free-flowering *Roses* (Silver Flora Medal).

The customary quantities of excellent cut *Carnations* were on view. Messrs. ALLWOOD BROS. showed many interesting and decorative varieties of *Dianthus Allwoodii*, with such good perpetuals as *Edward Allwood* and *Mary Allwood* (Silver-Gilt Banksian Medal).

Such brilliant varieties as *Tarzan*, *Ethel Fisher* and *Topsy* were well shown by Mr. C. ENGLMANN, who also had admirable vases of *Mrs. C. F. Raphael* and *Lady Miller* (Silver Banksian Medal).

Messrs. STUART LOW AND CO. also showed good *Carnations*, and adjoining them staged ex-

ceedingly floriferous *Mimosas*. *Acacia armata* and *A. pendula* were especially good. They also included *Oranges* in full bloom, and a plant of the now rare *Aphelaxis macrantha purpurea* (Silver Flora Medal).

*Saxifrage*s were not extensively shown, though these were expected to be the chief feature of the meeting. The Society sent a representative collection from Wisley. The more showy varieties included *Pink Beauty*, *Wenlock Best* of *All. S. ligulata lantoscana*, *S. peltata* and *S. tellimoides* (Bronze Flora Medal).

In a pleasant exhibit Messrs. WATERER, SONS AND CRISP included such *Saxifrage*s as *Wallacei*, *Diana*, *affinis*, *sanguinea superba*, with *Iris punila violacea*, and also had a nice group of the dwarf *Rhododendron fastigiatum* (Silver Flora Medal).

A plant of the quaint *Podophyllum Emodii* major was shown by Mr. M. PRICHARD. He also displayed *Delphinium nudicaule* and *Gazania montana* of great interest (Silver Banksian Medal). Mr. G. REUTHE had his customary collection of new and rare plants (Silver Banksian Medal). *Gentiana acaulis* and the brilliant bedding *Daisy Ball of Fire*, with a fine batch of *Primula Sieboldii*, were arranged by Messrs. LADHAMS, LTD. (Bronze Flora Medal).

Various alpinines, especially *Saxifrage*s and *Androsaces* of merit, were exhibited by Messrs. MAXWELL AND BEALE (Bronze Flora Medal). Dwarf *Phloxes*, bearing quantities of blooms, *Anemone alba major* and a colony of *Houstonia serpyllifolia* were displayed by Messrs. SKELTON AND KIRBY (Bronze Flora Medal). Mr. C. ELLIOTT had *Gentiana acaulis* and *Primula*, *Dusty Miller*, with *Sisyrinchium filifolium* (Bronze Flora Medal). Mr. G. W. MILLER showed *Polyanthuses* and alpinines (Bronze Flora Medal). Interesting alpinines were displayed by Mr. F. G. WOOD (Bronze Banksian Medal).

*Daphne Cneorum*, many *Primulas* and *Armeria caespitosa* were the principal features of the exhibit by Messrs. W. H. ROGERS AND SON (Bronze Flora Medal).

Messrs. PIPER AND SON showed a good batch of *Primulas* such as *P. Bulleyana* and *P. pulverulenta* (Silver Banksian Medal). In a corner space the CHALK HILL NURSERY CO. displayed an excellent strain of *Pansy* (Bronze Flora Medal).

THE MAYTHAM GARDENS showed beautiful blooms of *Tulip Ellen Willmott* with *Lobelia Warley Blue* and *Phlox subulata lilacina*.

#### Fruit and Vegetable Committee.

*Present*: Messrs. C. G. A. Nix (in the chair), Jos. Cheal, Geo. F. Tinley, S. B. Dicks, W. F. Giles, H. Prince, P. D. Tuckett, T. Pateman, A. C. Smith, H. Markham, F. Jordan, G. Reynolds, J. C. Allgrove, J. Wilson, W. H. Divers, A. Bullock, A. H. Pearson, A. Metcalfe, Owen Thomas, P. C. M. Veitch, E. A. Bunyard and Geo. Kelf.

There were no exhibits of any importance before this Committee. The Chairman, Mr. C. G. A. Nix, referred to the death of Mr. S. T. Wright, who had been secretary of the Committee for the past twenty-five years. He said that all knew him as a faithful, hard-working member of the Royal Horticultural Society's staff, and all present had lost a dear friend. He asked the members to send their condolences to Mrs. Wright and her family, and also proposed the following resolution: "The members of the R.H.S. Fruit and Vegetable Committee desire to express their heartfelt sympathy with Mrs. S. T. Wright and the other members of his family in the terrible sorrow which Mr. Wright's sudden death at Matlock must have brought upon them." The Chairman also proposed to be put on record on the Committee's minutes the very high esteem in which they have always held Mr. Wright, and to acknowledge as amply as is now possible their deep sense of his unflinching courtesy and consideration and of the very high value of his knowledge, experience and counsel during the many years in which he had so faithfully and diligently served the Committee and the whole Society. These proposals were adopted by the Committee.

## Obituary.

**Alexander Forbes Irvine.**—Keen regret will be felt in arboricultural circles at the death of Mr. A. F. Irvine, of Drum, Aberdeenshire, which took place on Saturday, April 29, at the comparatively early age of 41. The scion of a family which descended in the male line from William de Irewyn, Secretary and Armour Bearer to King Robert the Bruce, the deceased was one of the most popular lairds in the North of Scotland. Mr. Irvine was warmly interested in forestry, and was president of the Aberdeen branch of the Royal Scottish Arboricultural Society, wherein he did much useful and valuable work. On several occasions he gained the society's medals with exhibits from his estate, of which he was justly proud. Only recently Mr. Irvine was appointed to the Forestry Committee of the North of Scotland College of Agriculture. Mr. Irvine had within his policies a finely equipped nursery, from which he replenished the woodlands on his estate. Mr. Irvine joined the Army at the outbreak of hostilities as a private, after which he was granted a commission in the Grenadier Guards. With this regiment he went through very severe fighting, and was dangerously wounded. He returned home shattered and maimed for life, and his early and untimely end must be attributed to the hardships he then underwent. He is survived by a widow and five sons.

**Professor George Simonds Boulger.**—We learn with deep regret that Professor George S. Boulger died at Kew on the 4th inst. He was for thirty years associated with the Royal Agricultural College, Cirencester, as Professor of Natural History. He had also been Lecturer on Botany and Geology at the City of London College since 1884, and at the Imperial Institute since 1917. Professor Boulger was an active member of the Selborne Society, the Essex Field Club, the South-Eastern Union of Scientific Societies, and other associations. He was the author of several works on natural history, including *The Uses of Plants*, *Familiar Trees*, *Biographical Index of British and Irish Botanists* (with J. Britten), *The Country Month by Month* (with J. A. Aven), *Elementary Geology*, and *Plant-Geography*.

## ANSWERS TO CORRESPONDENTS.

**BETLES FOUND IN A WRITING CASE: II. M.**  
The insect is *Anobium striatum*. This beetle belongs to the family of *Ptinidae*, a group of small and very destructive beetles. They are very destructive to woodwork, but are not in the least particular as to their diet, and will devour almost any kind of food. The tapping to which you refer is the call of the *Anobium* to its mate.

**BLOOD AS A MANURE: L. D.** The blood should be dried before it is used as manure. If it is allowed to stand for sometime after adding from 1.3 to 3 per cent. of lime the mass will solidify and subsequently can be air dried with ease and without undergoing decomposition. Dry blood is a valuable organic fertiliser, and contains from six to fourteen per cent. of nitrogen.

**TRAINING IN HORTICULTURE: G. W. R. S.** All the institutions you enumerate may be recommended, and we should say that a course of training at either one would be equally valuable. The practical experience you would gain at either the Royal Horticultural Society's Gardens, Wisley, or Reading University College, would also be very valuable.

**THUYOPSIS SHOOTS DYING AT THE TIPS: Erin.**  
The withering of the tips of the branches is not due to organic disease caused by a fungus. It is probably due to unsatisfactory conditions at the roots which may have been caused by the abnormal drought of last summer.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 53.1.

ACTUAL TEMPERATURE:—  
Gardeners' Chronicle Office, 5, Tavistock Street, Covent Garden, London, Wednesday, May 17, 10 a.m. Bar. 29.8; temp. 53°. Weather—Raining.

On "Hardening" Plants. Few garden practices are so universally followed by good gardeners or so little understood by anybody, as is the practice of hardening plants. Everyone who raises plants under glass knows that to transfer them directly in the early part of the year from the heat in which they are grown to the chances and changes of temperature in the open is to court failure. Gardeners also know that the hardening process is somewhat slow and that one or two days only in a cold frame does not suffice to harden young plants. Experiments carried out a few years ago by Mr. Harvey\*, show in a most interesting manner that although the hardening process begins at once when plants are transferred from greenhouse to cold frame—in one day the plants acquire some measure of increased resistance to cold—yet at least five days elapse before the plants become really hard. Thus Cabbage, after five days' exposure to cold frame temperature—three degrees above freezing—were able to resist thirty minutes' exposure to 3° C., although the temperature froze them stiff and killed outright unhardened plants. He also showed what is of great interest to gardeners in this capricious climate, that hardened plants lose under-warm conditions their hardiness in about the same time as they acquire it. If, therefore, tempted by a genial spell of weather, the gardener puts out his hardened plants, and if that genial spell lasts long enough to

make the plants soft again, they are almost as prone to damage as they would have been had they not been hardened at all. "More haste less speed," is the motto to observe in planting out. Physiologists who have investigated the effects of frost on plants have given us a good definition of hardiness. It is the ability to survive ice formation within the tissues. Of our garden plants the tender ones do not possess this power, and we know of no means of making them acquire it. Some possess it, as it were, naturally; others and they are the ones that interest us here, may acquire hardness. The Cabbage is an example of this last class, whereas the Tomato cannot be "taught" to resist a temperature below 5° Centigrade. The adept in gardening can tell by the appearance and still more by the "feel" of a plant, whether it has been well hardened. This is due to the fact that during the hardening process growth is checked and hence leaves and soft stems, instead of appearing sappy, have a stiffish appearance and are springy and elastic. They are smaller and thicker than are those of unhardened plants of equal age. Experiment has shown that hardening may be assisted in watering plants with solutions which check growth. Give them nitrates such as potassium or calcium nitrate and the plants' growth is stimulated. They become sappy and soft, but water them with a weak solution of common salt or washing soda (at the rate of about two oz. to the gallon) and their hardiness is increased for the same reason that it increases in the cold frame, namely, because growth is checked. Withholding water is, of course, another means of aiding the hardening process. It follows from what has been said, that age is a factor to be taken into account. Young tissues, for example those of leaves, are more easily injured than are older tissues; a fact which has to be borne in mind in autumn sowing and autumn planting. There are apparent exceptions to this rule; for example, July sown Beet may be left in the ground, if the soil be not a very wet one, well into the winter, by which time old roots would have perished. This, however, is to be attributed to the fact that the "root" of the mature Beet consists of tissues, the cells of which are on the down grade of life, they are, as it were, over-mature, and begin to show the reduced resistance of old age. Plants which are hardy in the sense in which the word is used here may show signs of "frost-bite," although they do not succumb to a hard frost. These signs—also exhibited by tender plants when grown in too low a temperature—take the form of spots on the leaves. These spots are at first translucent, owing to the fact that they represent areas in which the intercellular spaces, normally full of air, have become injected with water which has been excreted from the neighbouring cells as a result of the low temperature. Even hardy plants may show these frosted areas, but in their case the frost spots disappear, whereas in tender plants they become brown as the cells disintegrate. Some hardy plants, like the Cabbage, show curious after-effects in the spotted areas. As Mr. Harvey has shown, each spot gives rise in the course of a few days to an embossed area of a colour lighter than that of the rest of the leaf. These intumescences go on growing and may reach a large size, and a Cabbage leaf which has been exposed to and recovered from frost, may have its surface puckered and rolled in most fantastic shapes. This behaviour may be likened to that often produced by mechanical injury and the formation of those intumescences must be referred to the plant's reaction to the wound-stimulus of frost. Bloom on the leaf often serves, as may be shown by observing different

varieties of Cabbage, to prevent injury from frost. This, according to Mr. Harvey, is probably due to the waxy layer acting as a water-proof preventing communication between water on the outside of the leaf and that lining the cell walls and occurring in the cells. When frost comes, the water on the leaf-surface is cooled and in the absence of wax this cooling is transmitted to the water of the cell-walls and cells. As the process continues, this water is undercooled. It does not freeze, however, unless the ice crystals which form on the surface are in continuity with the water in the walls and cells. The bloom breaks the continuity and hence ice—which is the danger—forms less readily in a leaf with bloom than in one without it. There are numerous hypotheses as to the actual cause of death from freezing; the most probable is that as water escapes from the cells, the nitrogenous complex compounds (proteins) on which cell vitality depends are salted out, that is, precipitated, and that once this process has been set up, recovery is impossible, because the vital mechanism has been destroyed. Hardening on this hypothesis is due to a change in the composition of the proteins of the cell. During the process of hardening these substances give rise to other proteins of simpler construction which are less apt to be salted out, that is, thrown out of the vital mechanism.

It is common practice to spray plants which have been subjected to frost. The practice is a good one, but how it achieves the end is obscure. It was thought at one time that it caused a slower thawing and gave time to the cells which had lost water to recover it. In point of fact, spraying hastens the thawing process and it seems more probable that its good effect is due to transpiration being checked. Mr. Harvey has made a curious observation which lends some collateral support to this view. He finds that if the leaves of a frost-spotted Cabbage are submerged in water, the intumescences already described do not develop. Water appears, therefore, to arrest the pathological processes set up by frost and the recovery of a frosted leaf which has been sprayed must be included in the already long list of "water cures."

Chelsea Show.—The great annual exhibition to be held by the Royal Horticultural Society, in the grounds of Chelsea Hospital, on May 23, 24, and 25, promises to be one of the largest and most attractive yet held on this historic site. There is no lack of exhibitors, indeed, it has been found impossible to provide sufficient space for all, and we understand some would-be exhibitors have been crowded out, notwithstanding that the big, well ventilated tent has been extended. The refreshment tents have been placed in the Ranelagh Gardens, and the space they have usually occupied is being filled by formal gardens. The lecture tent is retained, and one tent is also provided for the use of exhibitors and the members of trade and other horticultural organisations. The scientific and educational features of the show will occupy a separate tent. In this section, the Royal Horticultural Society will contribute exhibits illustrating some of the experimental work in progress at the Laboratory at Wisley, and is also arranging an information bureau where Fellows and visitors may consult the Society's Garden Adviser and members of the Wisley staff on matters concerning cultivation of crops and the prevention and cure of diseases. Fine weather appears to be all that is needed to make the Chelsea show a financial success.

French Flower Growers' Visit to London.—A party of some twenty of the largest cultivators of flowers in the South of France will pay a visit to London during the ensuing week. The Paris, Lyon and Mediterranean Railway Co., over whose service the bulk of the French flowers travel to England, has arranged the trip, and

\* "Hardening Process in Plants and Developments from Frost Injury." *Journal of Agricultural Research*, XV., 2, 1918.

the following is the programme:—Sunday, May 21, visit to the Royal Gardens, Kew, conducted by Dr. A. Hill; Monday, May 22, visit to Messrs. Sutton and Sons, Reading; Tuesday, May 23, visit to Chelsea Show, and official reception by Lord Lambourne, President of the R.H.S.; Wednesday, May 24, an early visit to Covent Garden market, and invitation to breakfast by Mr. George Monro; afternoon, visit to Messrs. Ernest Stevens' nurseries at Cheshunt; Thursday, May 25, visit to the R.H.S. Gardens, Wisley, lunch at The Hut, by invitation of the Royal Horticultural Society, and tea in the gardens; Friday, May 26, early visit to Covent Garden Flower Market, and reception by the British Florists' Federation; afternoon, visit to Messrs. Low and Shawyer's establishment at Uxbridge; Saturday, May 27, motor trip to Mr. C. Engelmann's nursery at Saffron Walden, and lunch by invitation of Mr. Engelmann.

**Presentation to a Lady Gardener.**—Miss M. Williamson, whose retirement as principal of the School of Practical Gardening for Women, under the auspices of the Royal Botanic Society, was announced in our issue for April 29, has been presented by the students, past and present, of the gardening school, with a gold wristlet-watch as a token of their appreciation of her twenty-three years work among them.

**Asiatic Palms.\***—Volume 12, Part 2, of the monumental *Annals of the Royal Botanic Garden, Calcutta*, has reached us. This is part of the work on Asiatic Palms carried out by Dr. Odoardo Beccari, and it consists of 231 pages of text, including index, six plates (14 by 11 inches) of analytical figures of flowers, fruits and seeds and 118 double plates, each 16½ by 14 inches, representing various genera of the section Lepidocarpaceae. The illustrations are superb reproductions, and include representations of *Calospatha Scortechinii*, six species of *Ceratolobus*, seven species of *Eugeissona*, twenty-eight species of *Korthalsia*, ten species of *Metroxylon*, *Myrialepis Scortechinii*, *Pigafetta filaris*, thirteen species of *Plectocomia*, five species of *Plectocomiopsis*, and thirteen species of *Zalacca*. No fewer than ten varieties of *Metroxylon Rumphii* are described and illustrated, three varieties of *Metroxylon Sagus*, four varieties of *Metroxylon squarrosium*, and two varieties of *Zalacca edulis*. The wonderful thoroughness in which the work is carried out may be gathered from the statement that a minute description of the Sago Palm, *Metroxylon Sagus*, occupies a whole page, apart from the references to synonyms. Then follow notes on the habitat of the species, its distinguishing features and interesting observations on its uses. These occupy another page and are followed by descriptions of several varieties of the species. Altogether, the account of *Metroxylon Sagus* occupies nearly five pages. In the observations on this species, it is recorded that it yields the flour or farina of Sago and the well-known granulated starch, exactly as *Metroxylon Rumphii*, and, like that species, affords numerous other commodities to the natives. *M. Sagus* corresponds to *Sagus laevis* of Rumph., of which he wrote that the plant receives in Amboina the name of "Lapia molat," and that it produces an excellent kind of flour, of which the Amboinese make their much esteemed gruel named "Papeda" and a kind of bread. Biscuits of general use are also made by cooking the flour in small, heated, stone moulds. We gather also that *Metroxylon Sagus* is the "Rambia" of the Malays of Java and Sumatra. "Kirai" is its Javanese name, and it is known now in Amboina as the "Sagu perampuan" (the female Sagu) or the "Sagu papeda" (the gruel Sagu). The text is printed in eight-page sheets with ample margins, uncut, ready for binding and the double plates are loose, in a thick paper folio, and enclosed in a stiff cardboard case. The price of this part of the *Annals* is four rupees Indian (£3). It appears that the superb, double plate photogravures have been reproduced in Florence.

\* Asiatic Palms—Lepidocarpaceae, Part 3. By Dr. Odoardo Beccari. *Annals of the Royal Botanic Garden, Calcutta*. Vol. XII., Part 2. The Bengal Secretariat Book Depot, Calcutta.

**Retirement of Sir Frederick Moore.**—Mr. W. Watson writes:—The professional career of Sir F. W. Moore was detailed in *The Gardeners' Chronicle* last year (April, p. 158), and brief reference has since been made to his approaching retirement from the Keepership of the Glasnevin Botanic Garden. This actually occurred on April 30 this year, after over 45 years' service. I have known him since 1879, when he took charge of Glasnevin, and I was engaged as a foreman at Kew. Few years have since passed without our meeting either for a plant foray together or for some celebration. Moore was great at both. He took charge of me when we went plant hunting in Continental countries, for he speaks the French, German, Dutch and Flemish languages like a native, and his personality is of the kind which wins through where the average man often gets stuck. Hundreds of men have felt the magnetism of Moore and have been all the better for his company, either when there was work to be done or when pleasure was the object. The gods were good to him in giving him a big, generous soul and a strong body (he hasn't had a day's illness since he became Keeper of Glasnevin), both of which he has made great use of. If Moore has an enemy or traducer, I have never heard of him. For many years he has been the doyen

SIR FREDERICK MOORE, V.M.H.

of our calling. I have become acquainted with many of the best men in it, and he stands first, an easy first, in my opinion. Glasnevin has long been the Mecca of gardeners, amateur and professional. Rich collections of all kinds of plants were there, and good cultivation. There was also the Keeper, the life and soul of the whole. If it were worth while, I could expatiate on the great work Sir Frederick Moore has done in Ireland, on his wonderful knowledge of plants, of all kinds, on his achievements as a collector and cultivator, and on his brilliant success as the head of an important teaching, scientific establishment. But these things are known to the cognoscenti, and the others may go and see for themselves. I was there three weeks ago ("looting" on behalf of Kew), and, acquainted as I am with most of the leading botanical gardens of Europe, say deliberately that, taken all round, Glasnevin is unsurpassed by none and equalled by very few. All this has been accomplished by Moore, single-handed. Ever since I have known him he has managed everything in such a way that all his men adored him. Moore's attitude towards scientific horticulture has always been correct. There is a tendency nowadays to neglect the arts of cultivation, in other words, that knowledge of plants and their requirements that enables one to propagate them, to keep them in good health and to turn them

to the best account. This knowledge can only be obtained by long practice, close observation and study. With it the cultivator is able to steer clear of most of the troubles which beset those who do not possess it. And yet we have no real schools of horticulture where all that appertains to good cultivation is systematically taught; no research workers on purely horticultural problems. There are plenty for the ill that come of wrong cultivation—pathologists, entomologists, chemists, etc., who know little about the plants, and who are interested only in those that are sick. This, to me, is like beginning at the wrong end. The cultivator who knows the requirements of his plants and has a practical acquaintance with the approved best methods of providing them, is independent of the plant doctor's skill. What has all this to do with Sir Frederick Moore? This much. It expresses views, convictions which he and I have long held. He has a gardeners' feeling for plants, he loves them, and is unhappy when they are not happy. We have looked upon things together which have drawn from him strong words of condemnation of the wasted effort, the hopeless mess that ignorance and stupidity had resulted in. I, like many others, am sorry that the limitations of age have compelled Sir Frederick to put down his tools, for he has been a real master of the craft, a splendid example of devotion to duty, and is "a worthy knight," if ever there was one.

**Sale of a portion of Covent Garden Estate.**—A portion of the Covent Garden Estate was sold by public auction on Tuesday and Wednesday last by Messrs. Hampton and Sons. The total result of the first day's auction was £49,575. Some of the freehold ground rents realised from forty to forty-two years purchase, although the reversions of these properties are by no means near. The lots offered totalled fifty-nine and included several premises used for the sale of produce, but no portion of the market proper.

**Plant Conference at Washington.**—Mr. W. J. Lobjoit, the Controller of Horticulture, has arrived in Washington for the Plant Conference, at which quarantine regulations are to be discussed. For the time being, Mr. Lobjoit's address is Lee House Hotel, Washington.

**Fibre from Bromelias.**—Excellent fibre has been produced from the leaves of *Bromelia sylvestris* and *B. Pinuela* (?), in Colombia, South America, and the fibre from *B. sylvestris* is divisible into one ten-thousandth of an inch, and, according to the *Journal of the Royal Society of Arts*, has as much tensile strength as Flax. The Indians used it for fish nets, and mummies wrapped in it show the fibre still in a good state of preservation. It is estimated that a ton of leaves of these Bromelias, the gathering of which costs about £2, will produce five hundred pounds of fibre. It is also stated that Colombia is capable of producing 100,000 tons of Bromelia fibre annually.

**Fairchild Lecture.**—The Worshipful Company of Gardeners has arranged for the Fairchild lecture to be delivered in Shoreditch Parish Church on Tuesday, June 6, at 5 p.m. The lecture will be delivered by the Rev. Horace Rollo Meyer, M.A., rector of Watton, Hertfordshire, Rural Dean of Welwyn, and a member of the R.H.S. Daffodil Committee and the Horticultural Club. The company will assemble in the Church Room, adjoining Shoreditch Church, at 4.45 p.m., and will be met by the Vicar, the Rev. F. E. Birch, and enter the church in procession. The church is about five minutes' walk from the Old-street Tube Station, and a tram from that station passes the church doors. Motor omnibuses from most parts of London, and trams from Liverpool-street, stop by the church. It will be remembered that Fairchild was a gardener at Hoxton, and left a legacy to provide money for the preaching of a sermon in the Church of St. Leonard's, Shoreditch, in every Whitsun week in each year, on either "The Wonderful Works of God in the Creation," or on "The Certainty of the Resurrection of the Dead, proved by the certain changes of the Animal and Vegetable parts of the Creation."

**Ornamental Flowering Crabs.**—Lady Moore, writing in *Irish Gardening* for May, describes *Pyrus magdeburgensis*, a cross between *P. spectabilis* and *P. Malus*, as one of the finest of all Crabs; it bears handsome clusters of large, deep rose coloured double flowers. At Glasnevin Botanic Garden the tree was somewhat slow of growth at first, but with attention to feeding made good progress and promises to form a fine specimen in a few years. Amongst other Crabs which are especially recommended by Lady Moore, and which have been exceptionally fine in the Glasnevin Botanic Gardens, are *P. Ringo*, which is one of the first to bloom and one of the best; the flowers are rosy coloured in the bud, but paler when open, and they have a sweet perfume; *P. spectabilis*, one of the largest and the best of the *Malus* group; *P. Malus Scheideckeri*, which has branches a yard long, wreathed in flowers from end to end, and *P. Malus floribunda*, which never fails to bloom profusely each season and puts forth its blossoms in fair or foul weather.

**Appointments for the ensuing Week.**—Tuesday, May 23.—Royal Horticultural Society's Chelsea show (three days); second day, lecture by Dr. A. B. Rendle, on "Plants of Interest Exhibited." Wednesday, May 24.—Kew Guild annual meeting and dinner; Horticultural Club annual meeting and dinner; Linnean Society's anniversary meeting, at 3 p.m. Thursday, May 25.—Bristol and District Gardeners' Association's meeting; Royal Botanic Society's meeting.

"The Gardeners' Chronicle" Seventy-five Years Ago.—*The Botanic Garden at Kew.* When it was some years since proposed to restore the Botanic Garden at Kew to a state of efficiency the recommendation was objected to on three grounds. It was thought that Parliament would refuse the funds required for its support; that if Parliament proved liberal, no useful purpose would be answered by the outlay; and that even if it should prove of abstract utility nobody would care a straw about the place except a few botanical zealots. In each of these particulars the objectors prove to have been mistaken. Parliament grudges no reasonable outlay; the utility of the establishment is universally admitted; the interest taken in it by the public, it is second to no public institution; and no harm has followed their free and unrestricted admission. A Parliamentary paper now before us contains Sir William Hooker's last report on the subject, in which we find the following statement: "The public of all ranks frequent the garden during the good season in a manner that proves the advantage it brings to them as a place of relaxation, both for body and mind. They have unrestricted access to every part of the grounds and houses, and truly gratifying it is to see how highly the privilege is appreciated, and how slightly it is abused. The visitors, it must be remembered, are chiefly confined to the summer months; and the increased and increasing usefulness of the establishment cannot, perhaps, be better estimated than by giving a glance at the amount of admittances since 1841, when the gardens were thrown open to the public."

In 1841	the number of visitors was	9,174
In 1842	do do.	11,400
In 1843	do do.	13,492
In 1844	do do.	15,114
In 1845	do do.	28,139
In 1846	do do.	46,573"

From this we learn, that although the number of visitors has quintupled, and their access to every part of the grounds and houses is unrestricted, the privilege is so slightly abused as to require no observation. Thus it always is; restrain men needlessly, and they become troublesome and mischievous; let them alone, deal with them fairly, avoid setting spies upon their actions, and good conduct becomes a point of honour. *Gard. Chron.*, May 22, 1847.

**Publications Received.**—*Lawns and Their Upkeep.* By James MacDonald. Reprinted from the *Journal of the Royal Horticultural Society*. Vol. XL. Part 3.

## THE BULB GARDEN.

### A NOTE ON THE GLORIES OF THE SNOW.

Now that the *Chionodoxas*, or Glories of the Snow, are just over, a short note regarding them may interest some. The popular *Chionodoxa Luciliae*, which has been in cultivation for many years, is a general favourite and is lovely with its *Nemophila*-like flowers, that are possessed of a greater depth of blue than in the popular annual, which sets off the white centres. It is very charming. It was introduced by Mr. George Maw, but is not the original *C. Luciliae*, as found by Boissier, which is even finer, but is slightly later with me. This one, sold as *C. Luciliae*, Boissier, has the blue surrounding the white centre much more intense than in Maw's plant. It varies a

nearly all forms of *C. Luciliae*. They are lovely flowers, and the writer still remembers the excitement caused by the appearance of *C. Luciliae* in the British Isles when it was distributed. *S. Arnott.*

### HIABRANTHUS (HIPPEASTRUM) PRATENSIS.

This very choice plant of the *Amaryllis* family has been effectively exhibited at the Chelsea Show on many occasions. It is the most brilliant of scarlet-flowered bulbs, and, although a native of Chili, it is much hardier than is generally supposed. In southern and eastern counties it has proved quite hardy, and it is a feature of many Norfolk gardens, making a wonderful show of bloom at Westwick and other famous gardens around Nor-

FIG. 132.—NARCISSUS NEVIS. A REFINED WHITE TRUMPET DAFFODIL EXHIBITED AT BIRMINGHAM ON APRIL 20 BY DR. N. Y. LOWER, PRESTEIGN.

little, but all the flowers are very charming. *C. Tmolusii*, again, which comes still later, resembles the two foregoing greatly, but also differs in its blooms, being more purple or magenta-blue than blue, although this description of its colouring is apt to convey an erroneous impression. There are white forms of all these. *C. gigantea* (syn. *C. grandiflora*) is one of the earliest, and has large, lovely lavender-blue or lilac flowers, and is dwarfier than the foregoing. There is a white variety of this also. As for *C. Allenii* it differs little, but should have more and larger flowers on a stem. *C. sardensis* is well known. It has smaller flowers than *C. Luciliae*, and should be self-coloured blue, but some collected in different districts have a white eye. There is a white variety of *C. sardensis*. Of *C. nana* it may be said that it is more of botanical interest than of value for the garden. It has small, light coloured flowers of no great attraction. Such is a brief note of the leading *Chionodoxas*, which are practically

wich. *Hiabranthus pratensis* grows freely in strong loam to which leaf-mould and sand have been added, or it will thrive in pure sand, but prefers a well-drained slope or warm position under a south wall. The bulbs require a thorough roasting in the sun after flowering. The new leaves follow the flowers, and should remain green through the winter. The scarlet Lily-shaped flowers, borne on stout stems about one foot high, usually expand in early June. The flowers, of brightest scarlet, are feathered with golden yellow at the base. Roez, who described this species, states, "It is impossible to render in a drawing the brilliancy of colour of this fine plant." This very choice subject should find a place in the select bulb garden or sheltered sunny rock garden where uncommon plants are cherished. Although the plant is hardy in warm districts, it needs protection in the colder parts of the country, and this may be afforded by covering the clumps in severe weather with a layer of leaves, heather, straw or litter. *H. Cowley.*

## SUMMER BEDDING SCHEMES.

As the bedding-out season approaches many planters find some difficulty in making up their minds as to the best colour combination to use. Of course, where there are set schemes of beds, especially of a formal character, the scheme of planting should have been settled last season, so that stocks of suitable plants could be got ready for planting out now. But in many gardens cultivators have been handicapped by not knowing what they really could manage in this connection. In such cases some simpler arrangement must be substituted for more elaborate schemes; this is, perhaps, just as well, for the simpler arrangement generally proves the most satisfactory in the end. Such an article as this can only give suggestions, for, after all, the plants and their arrangement depend on the individual taste of the owner. One fact remains, however, and it is that

beds, laid out in more or less geometrical lines; in spite of the contention of the so-called natural school that it does not really matter, the fact remains that such a formal garden should be planted in a more or less formal manner. Indeed, this is essential if proportion and balance are to be maintained. Such a scheme need not, however, look stiff and formal, as a light and elegant appearance may be obtained by the use of suitable foliage plants; and here I would state that most bedding schemes would be greatly improved by a freer use of suitable foliage plants as foils to the brighter subjects.

Another bone of contention is the use of edging plants, some holding that the grass is the best setting for a mass of colour, while others contend that an edging of some suitable plant gives the better finish. It really all depends on the size of the beds and the class of plant used. Large beds are generally improved by the use of a suitable edging plant, but in the

tails much labour, to say nothing of house space and fuel, during winter. This has led to an increased use of many suitable plants that can easily be raised from seeds early in the new year. Still, the bedding *Pelargonium* is valuable for many formal arrangements, and we have no other summer bedding plant that gives that brilliant mass of colour afforded by Paul Crampel, especially when associated with grey-foliaged plants such as *Cineraria maritima*, *Centaurea candidissima*, *C. gymnocarpa*, or *Senecio leucostachys*, while one of the best white-flowered plants to use with it is *Chrysanthemum frutescens*, var. Mrs. Sander, popularly known as the double-flowered Marguerite.

The many fine varieties of *Antirrhinum* now available are very suitable for formal bedding schemes; well-selected strains come practically true from seed, and what few rogues appear are easily detected in the seedling stage, as each variety has a distinct leaf character. The intermediate varieties are best for bedding purposes, and the colours, with the exception of purple and mauve, may be happily planted together. Where a formal set of beds are in question they may be massed in separate colours. A scheme may consist of pink, rose, yellow and white varieties, or with the orange, scarlet and crimson sorts, again using yellow and white with them. The silvery pink Ivy-leaved *Pelargonium* Mme. Crousse is a cool-looking subject for the formal garden, and with it should be used the pale yellow *Calceolaria amplexicanlis*. *Chrysanthemum frutescens* Mrs. Sander could also be used and plants with silvery foliage would also be appropriate. If the scheme is large enough, *Melanthus major*, with its glaucous green foliage would be very suitable.

Verbenas, at one time great favourites, and propagated in separate colours by means of cuttings, are now seldom seen, but beds of mixed colours raised from seed are very effective and last all the season; while a bed of Mrs. Willmott interplanted and carpeted with *Leucophyta Brownii* is very effective. *Verbena venosa* is a more or less hardy perennial, but is best raised from seed every year; if sown in heat during January, good plants will be ready for putting out during May. There is no other bedding plant with its particular shade of purple, and a large bed of it proves very effective, either alone or grouped with a silvery foliage plant such as *Centaurea candidissima*. It could also be used in a large bed with a permanent edging of *Cerastium tomentosum*. This *Verbena* is also very effective for a set of formal beds grouped with grey foliage plants and *Calceolaria amplexicaulis*.

*Phlox Drummondii* is one of our best half-hardy annuals for bedding, as it lasts in flower until cut down by frost. *Nemesias* and *Dimorphotheca aurantiaca* are good half-hardy annuals that may be used for odd beds; they do not last out the season, but may be followed by border *Chrysanthemums* grown in the reserve garden for this purpose. *Zinnias* also make very effective beds, and are very fine during hot seasons. *Delphinium grandiflorum* var. Blue Butterfly is very beautiful and can be interplanted with the dwarf forms of *Koenigia maritima*, one of the most popular and useful of all plants for this purpose. *Heliotropes* are always popular for summer bedding and are best grouped with grey foliage plants, or carpeted with *Koenigia maritima*. The giant *Heliotropes* may be raised from seed during the spring, and a large bed is effective, as they quickly attain a height of three to four feet.

*Salvia splendens* var. *Glory of Zurich* is effective either alone or with an edging of *Centaurea candidissima*. This *Salvia* should be raised from cuttings, as seedlings vary somewhat, especially in height, and in time of flowering. *Begonias* of the tuberous-rooted section are invaluable for bedding either in mixture or in separate colours. A good pink variety interplanted with *Leucophyta Brownii* and carpeted with *Koenigia maritima*, proves very effective. *Begonia semperflorens*, of which there are many varieties, is very fine, and can be raised from seed early in the year, as good

FIG. 135.—SUMMER BEDDING IN ASSOCIATION WITH STATUARY.

all bedding arrangements should be as simple as possible, and colour harmonies rather than contrasts should be aimed at, for unless one has a keen sense of colour value contrasts are apt to be dangerous. Not everyone is gifted with a keen sense of colour, yet, by some study of colour values, many pitfalls may be avoided.

Here it may prove useful to give a sequence of colours in harmonising shades. Blues, dark and light, may be grouped with pale yellow and white. These may be followed by pink and then rose, leading up to crimson and scarlet, orange and bright yellow. Pale yellow and white will then lead up to lilac, lavender and purple. Silvery leaved plants are invaluable for grouping with lilac, lavender and purple colours, and also with scarlet, or, in fact, with almost any colour scheme, as it is a much safer arrangement than a too liberal use of white. From the above grouping of colours anyone should be able to plan out many suitable colour combinations, and use the available material to the best effect.

Perhaps the most difficult of all bedding schemes is one where there is a formal set of

case of small beds an edging tends to destroy the broad effect. Again, tall plants that do not carry plenty of foliage right down to the ground demand a suitable edging. Care should always be taken to group plants together that present a harmonious effect.

As an example of how not to do it, I may be allowed to mention one I noticed in a public park some years ago. A noble group of really fine Hollyhocks had an edging of small semperflorens *Begonias*, whereas what was really needed was a bold edging of some noble foliage plant, and a hardy one for preference, such as *Funkia* or *Acanthus*.

In all bedding arrangements restraint should be the keynote. Two, or at the most three, varieties or kinds of plants are enough to use in any one bed, and not "anything from a hardy annual to a stove plant," as was usual in the past.

The bedding *Pelargonium* is somewhat under a cloud at present, and this is partly due to the inevitable reaction from a too common use of this plant, and also partly due to the war years, for the maintenance of large stocks en-

## BREAKING IN FREESIAS.

FREESIAS are becoming increasingly popular, I mean, of course, coloured Freesias. I think it will be found when the nib lists arrive that more than one firm will have included a few named varieties for the first time. Unfortunately, I did not see any of the exhibits at Vincent Square this spring, nor have I been able to have any Freesia talks with fellow seedling raisers. I want to know more about breaking. My own experience tells me that, as in the case of Tulip hybrids, it will be found that only the whites and the yellows are immune. It would seem that it is only a question of time when any of the other coloured ones will break. I have had several jars in this last flowering season. Rosebud has had unmistakable breaks: so has one of my most charming pink varieties, called Pink Beauty. In both these cases the breaks are not offensive, in fact, I personally think them very pleasing; and the local shopkeeper who has my flowers wanted all I had. With Daddy-long-legs, the result of its breaking is

or unusual perhaps is a better word, vigour has been given to Tulip bulbs by the heat and sun of 1921, why should not we see the same results in Freesias? *Joseph Jacob.*

## THE ALPINE GARDEN.

### CYANANTHUS LOBATUS.

ALTHOUGH several new species of *Cyananthus* have been found within recent years, few are in cultivation. So far as I can find from catalogues, the only ones offered are the two which have been in cultivation for a good number of years. One of these, *Cyananthus incanus*, is not often met with, and has nothing to recommend it in preference to *C. lobatus*, which is considerably more plentiful both in nurseries and gardens, although not by any means a common plant. It is a very lovely subject for the rock garden, and where time can be spared to attend to it, and the conditions are favourable, it should not be omitted from the garden, as it is one of the most charming of all alpine flowers.

FIG. 134.—DAHLIA DELICE AS USED FOR BEDDING AT KEW.

a perfectly horrid flower. Merry Widow showed no sign of a break while it was with me. Mr. Dalrymple has the stock now. It would be of great interest to know if it is still immune with him. This question is a serious one and must affect the future of the coloured Freesia. Can any one put his finger on the spot and say if there is anything in the way that the plants are grown that causes it; or if there is anything that can be done to prevent it?

Another point of interest in Freesia culture is the question of "duds." I am told this lying perfectly dormant for a year is a way that several South African bulbs have. In every year up to the present I have had a few "duds," notoriously in a variety called Red Indian. This year we have hardly had one anywhere. I put it down to the extra warm summer of 1921. If every year was like last year, would there continue to be none? Would heat alone or sun alone produce the same result? or, must it be a combination of both? Are "duds" a sign of lack of vigour? If Tulips are any guide, the hot summer of last year has made many varieties extra strong, and we have fasciated stems and small flowers rising up from the bulbs alongside of the big main flower. When I paid a visit to Messrs. R. Veitch and Son's Exeter nursery in April I was much impressed with the fasciated stems of almost all the Tulips that were there. Golden Bronze I have grown for years. Until then I never saw any fasciation on it. If additional,

It is of trailing habit, but not aggressive in any way. Its branches are only about eight inches long; they have prettily formed leaves clad with white hairs, and bear at the end an exquisite flower of a most beautiful blue and a calyx decorated with white hairs. The flowers resemble those of *Vinca minor*, the Periwinkle, and are almost as large, and even more lovely in their colouring. But the white hairs on the plant are a source of danger from wet in winter, especially those on the calyx, and some recommend that the flowers should be removed as soon as their beauty is over. It is much better, however, to cover the plant with a sheet of glass or a handlight or bell-glass, slightly tilted, during winter, so as to throw off the rains, sleet, and snow.

*C. lobatus* is difficult to accommodate in the rock garden, unless great care is taken. It needs a light, gritty, well-drained soil, and plenty of water during the late spring and the summer months. After flowering, which begins in August, water may be withheld, unless the plants show signs of distress. A moraine, with water flowing underneath, has been recommended, but I have not had experience of this method with this flower. It appears likely to be suitable if the supply of water is cut off in winter and earliest spring. The plant appears to need partial shade. Propagation is best effected by rooting the branches by layering or by cuttings inserted during spring or early summer in sandy peat. *S. Arnott.*

strains come true from seed; two good varieties are Pink Profusion and Bonne. These seem indifferent to weather conditions, and flower profusely all the season; they may be used alone or grouped with foliage plants, such as *Grevillea robusta* or *Albizia lophantha*.

Large lawn beds may be filled with large foliage plants such as *Cannas*, *Nicotiana glauca*, *Polygonum lanigerum*, *Solanums* such as *S. Balbisii*, and the beautiful, silvery-leaved *S. marginatum*; *Wigandia imperialis*, *Melanthus major*; variegated and quadricoloured Maize—to mention only a few subjects that are easily raised from seed.

Dahlias are also invaluable for large lawn beds, and are most effective when one variety is used in a bed. In the decorative section, *K. A. Victoria*, white; *Souv. Gustave de Bouzon*, orange-scarlet; *Papa Charmet*, crimson; *Delice* and *Loveliness*, pink; *Brentwood Yellow*; and *President Wilson*, vivid scarlet; are all good in their respective colours. *Crawley Star* and *White Crawley Star*, are the best in their class for massing, while large masses of good mixed Collette varieties find many admirers. The dwarf, crimson, *Coltess Gem*, which only grows some eighteen inches high and flowers with wonderful profusion, may well prove a rival to the bedding *Pelargonium*. A large bed of *Dahlia Delice* at Kew is illustrated in Fig. 134.

In the foregoing notes, I have only touched the fringe of a large subject, and have made no attempt to give elaborate schemes, or to mention plants that require much house room during the winter months; rather have I tried to indicate what may be done in a simple way.

While summer bedding plants will always be more or less necessary in the well kept garden, every effort should be made to, in part, replace them—where conditions are suitable—with hardy plants, many of which are suitable for furnishing large lawn beds. Wherever possible, two or more sorts should be planted together, and thus give a prolonged flowering season.

The examples I give below are what I have had personal experience of, and have proved their value for this purpose. A very delightful combination is a large planting of *Lavender* and the old pink *Monthly Rose*, with groups of *Lilium candidum* and *Galtonia candicans* for autumn flowering. Along with these were planted *Viola Mrs. Neil* and *Crocus zonatus*. *Pegonias* may be interplanted with *Narcissi* and *Gladiolus* or *Galtonia candicans* for succeeding the *Paeonias*. A large planting of *Rose Caroline Testout* is very effective with *Nepeta Mussini*, *Achillea filipendulina* makes a fine subject for a large bed and may be underplanted with *Narcissi* or *Onithogalum nutans* for spring effect. Another combination which gives a long display is *Eryngium planum* and *Campanula Telham Beauty*. *Salvia virgata*, edged with a broad band of *Artemisia ludoviciana* var. *gnaphaloides* is very beautiful, while *Cerastium tomentosum* or *C. Biebersteini* may be used instead of the *Artemisia*. *Aster King George*, edged with the *Artemisia*, is good, while for spring effect, the bed could be carpeted with *Scillas* or *Muscari Heavenly Blue*. *Bocconia cordata*, *Acanthus mollis* and *A. latifolius* are all fine for large beds. *Kniphofias* are very effective in large beds, and may be grouped with *Yuccas* and *Pampas Grass*. Some of the best *Asters* make fine lawn beds, as does *Anchusa italica* vars. *Dropmore* and *Opal*. For a long display, a large bed planted with *Lilium regale*, *Montbretias* and *Watsonia Meriana* var. *alba* is very fine and distinctive in character. *Sedum spectabile* is effective and may be interplanted with *Narcissi*.

A sub-tropical effect may be obtained with various trees and shrubs by cutting them down to the ground every spring, when they send up a strong shoot with large handsome foliage. *Rhus typhina*, *Paulownia imperialis* and *Ailanthus glandulosa* are all very suitable for this purpose and the beds may be edged with *Funkias* or *Acanthus* and carpeted with spring-flowering bulbs. The few examples given will serve to show that, with a little forethought, there are many useful and beautiful combinations to be worked out with hardy plants. *J. Coultis, Kew.*

## The Week's Work.

### THE FLOWER GARDEN.

By EDWIN BECKETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Hertfordshire.

**The Shrubbery.**—Shrubs that have finished flowering, such as Forsythias, Ribes, Loniceras (bush sorts), Spiraeas and Neillias, should be examined with a view to removing thin, weak growths, and thus assisting the plants to throw all their energies into completing the healthy and stronger growths. On the other hand, shrubs that develop gross, rampant shoots, should have these shortened, otherwise the normal growths may suffer impoverishment for the benefit of the few. Philadelphus in particular has this habit, which requires curbing. Evergreens, and especially those that have not made on forward growth, may generally be moved this month with comparative safety, and especially when the weather is inclined to be dull and showery, consequently, where this work has been delayed, it should be completed forthwith. Trees and shrubs of this class should be trimmed where considered necessary after flowering, but the pruning should be less drastic than is permissible with members of the deciduous type. Attend to climbers frequently, with a view to checking too great activity in growth; train the shoots in orderly fashion, removing any surplus ones where necessary to attain this object, thus preventing the growths from becoming tangled, as this frequently spoils what is otherwise a beautiful plant. Roses, Clematis and Vines especially call for this attention. The growths of Clematis are so brittle that grave risk is run of their snapping off if an attempt is made to disentangle them; they should be trained from the start, otherwise serious damage may easily be done. Wichuraiana Roses oftentimes develop many young and weak growths from the base, which should be removed at a very early stage, otherwise a tangle of growths that are of very little use for flowering may result. If desired, these Roses may be trimmed to form pretty, free-flowering bushes.

**Bulbous Plants.**—Narcissi and other bulbous plants are doing well in the woodlands this season, despite several sharp frosts. Where similar bulbs were forced under glass and are now over they should be planted out in the woodlands, where in course of time they will prove extremely beautiful at this period of the year. Take them from the boxes and pots in which they have been forced, and, leaving the green growth to die away naturally, plant them out in large patches. Other bulbs, such as Hyacinths and Muscari, that have been grown in pots, may be similarly dealt with.

**Bamboos.**—On p. 178 I dealt with the best way of preparing Bamboos for forming a plantation, by starting them into growth first in pots under glass, and where this was carried out, and the plants have thrown up healthy, young shoots, harden them off and plant them in their new quarters as soon as convenient.

### THE ORCHID HOUSES.

By J. T. BARETT, Gardener to His Grace the Duke of Marlborough, K.G., Blenheim Palace, Woodstock, Oxon.

**Odontoglossum.**—Odontoglossums of the grande and Inslayi section require a slightly higher temperature than *O. crispum*, and the same is true of *O. citrosum* and its varieties. During the winter these Orchids are best grown in the cooler end of the intermediate house, and kept comparatively dry, but during the summer the warmer end of the *Odontoglossum* house is more suitable. *O. grande* and its varieties, with others of these Mexican *Odontoglossums*, will have commenced to grow, and when new roots are seen to be pushing from the new growths such plants as require it may be repotted. I do not recommend top-dressing instead of repotting, for if the compost is decomposed

at the top, that at the bottom of the receptacle will be in a worse condition, and it increases the difficulty of those entrusted with the application of water. The usual *Odontoglossum* compost is suitable for these plants. *O. citrosum* should be repotted or re-basketed, whichever mode of culture is adopted, immediately the flower scapes are removed. Care must be taken in the application of water to the newly potted plants until they become established; but when well rooted and in full growth an abundant supply of moisture should be given the roots. As soon as its growth is completed, this Orchid needs a long rest, by keeping it dry and exposing it to as much light as possible to favour the ripening and consolidating of the newly made growths.

**Odontoglossum Rossii.**—This species and its hybrids will also require attention as regards repotting, as they pass out of flower and their young growths develop freely. They will thrive in shallow pans suspended in a cool, intermediate house, in a position where they do not receive a superabundance of light whilst making their growth.

**Oncidium.**—The *Cyrtorchilum* section of this genus includes *O. macranthum*, *O. serratum*, *O. lamelligerum*, *O. corynephorum* and several others. The plants are of comparatively easy culture if afforded a cool, intermediate temperature. There are several hybrids of these species which will succeed under precisely the same conditions. They should receive all the light possible during the winter, but be protected from strong sunshine during the summer. The plants should not be allowed to produce flower spikes until they have become fairly strong specimens, and even then their long, trailing flower spikes should not be allowed to remain upon them for any considerable length of time after the last flower has opened.

### HARDY FRUIT GARDEN.

By H. MAREHAM, Gardener to the EARL OF STRAFFORD, Wrotham Park, Barnet.

**Raspberries.**—Where a reasonable crop of large berries is preferred to a superabundance of small, tasteless, undeveloped fruits, ample nourishment should be afforded the roots of Raspberries, and especially is this needed on light land. A heavy mulching of rich, decayed manure and liberal supplies of liquid manure are extremely beneficial to the plants as the season advances. The present is a suitable time to examine the beds and pull up all weak and useless suckers, leaving only sufficient to fill the places of this season's fruiting canes when they are cut out after the crop has been gathered. If new plantations are required, young rooted suckers may be lifted carefully and transplanted. If carefully watered and mulched until they have become well established they will make capital fruiting canes by the end of the present season. Although some of the older varieties are excellent croppers, I believe in a change of stock.

**Gooseberries.**—Keep a watchful eye on the tiny fruits of Gooseberries, Cherries, etc., and should sparrows prove troublesome use black cotton over the bushes or trees. In some gardens very little harm is done by birds, but in others just the reverse is the case. It is when the fruits have barely set that birds usually damage Gooseberries, and much harm is done quickly if not checked.

**The Fruit Blossom.**—There has been, and still is, a wonderful display of blossom on fruit trees, and the prospects, so far, are very promising. Even two-year and three-year-old trees are, in many cases, bearing many trusses of blossom, but these should be removed to allow all the energies of the plants to go to growth development, as even a few fruits would draw much energy from the plants and result in a reduction of branch and shoot development.

**The Fruit Quarters.**—In favourable weather the hoe should be used freely amongst fruit bushes to keep down weeds. If hoeing is done early and before the weeds have time to seed no difficulty will be experienced in keeping the ground clean

### FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

**Vines.**—With the weather far from satisfactory the daily operations in the warm vineries must be carried out with the greatest care. In the earliest houses the Grapes are beginning to colour and the bunches should be examined to see if any of the berries are crowded; if so, a few of the smallest ones should be removed carefully. Gross laterals may still be pinched, but unless the premier leaves are likely to become crowded, those of moderate growth will do good service and may be left intact. Copious feeding of the roots with diluted liquid manure warmed to a temperature of 80°, and damping the bare spaces at night with the same, will encourage good growth and check red spider, always provided the manure is not used at too great a strength, and a little air is admitted at night. If the vines are rather heavily cropped and perfect finish of the berries in doubt, maintain a rather lower night temperature of 60° when the weather is cold, and ventilate freely through the early part of the day. A maximum temperature of 80°, with sun heat, from noon to 2 p.m., when there should be a sharp reduction in the amount of ventilation to obtain a rise to 85° to 90° with sun heat, and moisture, will assist the swelling of the berries.

**Successional Vines.**—The principal work in the successional vinery will be the final thinning of the bunches, the tying and stopping of the leading laterals, and the removal of a few more berries. If large, late Grapes, such as Gros Maroo and Gros Colmar are grown, medium-sized bunches should have preference over larger ones, which take more finishing and do not keep so well when ripe. These Grapes are, as a rule, always under-thinned. When thinning is finished, a light mulch of fresh stable litter may be spread over the inside borders, which should be kept well moistened with warm diluted liquid manure and guano water used alternately until the Grapes begin to colour, when pure water only should be used. Ventilation should be liberal up to 1 o'clock; the ventilators should be closed early to obtain a temperature of 85° or 90°, if only for a short time, on bright, sunny afternoons. Late Muscats, Mrs. Pince and other shy-setting late Grapes, coming into flower require artificial pollination with foreign pollen, that obtained from Black Hamburg being the best. If fine weather prevails and air can be admitted freely and the roots are in a satisfactory condition most of the berries will set, but it is not well to trust to chance. Many growers formerly kept these vineries at a warmth of 70° through the night, but beyond hastening the progress of the vines, this high temperature is not necessary, as one frequently obtains perfect fertilisation when the temperature falls to 60° in the morning, and that by day rarely exceeds 50°. Do not allow the atmosphere to become excessively dry, but damp the floors and other bare spaces on two or three occasions on fine, bright days. The thinning of the bunches should be kept well in hand.

### THE KITCHEN GARDEN.

By JAMES F. HATHAWAY, Gardener to JOHN BRENNAND, Esq., Baldersby Park, Thirsk, Yorkshire.

**Runner Beans.**—These Beans should now be sown on ground that has been deeply trenched and well manured, or in trenches 2 feet deep, made similar to Celery trenches and filled with well decayed manure with a layer of old potting soil on the top of the dung. Sow the seeds in a double row, making the latter 10 inches apart, and put each Bean 8 inches asunder and 2 inches deep. Slugs are often troublesome, and as soon as the seed begins to germinate, the rows should be kept dusted with soot and lime; it is a good plan to sow a few Beans in small pots to make good any that fail in the rows. Best of All, Scarlet Emperor and Hackwood Park Success are some of the best varieties.

**Haricot Beans.**—These Beans should be sown and treated in the same manner as dwarf French Beans.

**Seakale.**—The plants which have not been forced should be examined, and any throwing up flowers should be relieved of them. Seakale crowns disbudded to one shoot are the best for forcing.

**Tomatos.**—The early plants indoors require plenty of air. All side shoots should be kept pinched out, and if the foliage is very dense the tips of the leaves may be removed to allow the sunlight to reach the fruits. The roots require plenty of water and should be stimulated with liquid manure and a concentrated fertiliser.

**Hoeing.**—The hoe should be kept constantly in use to prevent weeds from seeding and to break up the surface of the soil.

#### PLANTS UNDER GLASS.

By T. PATEMAN, Gardener to Sir C. NALL-CAIN, Bart., The Node, Codicote, Welwyn, Hertfordshire.

**Begonia nitida.**—*Begonia nitida* and its variety *alba* bloom practically the whole year through, and are useful either as pot plants or for planting out and training to pillars in a stove or a warm plant house. Well-cultivated specimens in pots will grow to a height of 4 ft. to 5 ft., and the flowers are freely produced. Cuttings should now be inserted and treated as advised for *Begonia Gloire de Sceaux*.

**Richardia.**—*Arum Lilies* that have been grown under cool conditions are passing out of flower, and may be stood in the open where they can receive some light protection in the event of frost. Water the plants for a few weeks, reducing the supply gradually until finally moisture at the roots is withheld entirely to allow the plants a complete rest. Some growers plant them out after they have been hardened sufficiently to allow of this being done, while others prefer to keep them in their pots, dry them off, and repot them again during August.

**Bouvardia.**—Rooted cuttings of *Bouvardia* should be potted singly immediately they have rooted sufficiently to allow of doing it. Use a rich, open compost, and grow the plants in a temperature of 60° to 65° until they are re-established in the soil. As they advance in growth the tops should be pinched out several times to cause them to form bushy specimens. They may then be grown in a house with a lower temperature. Good results may be obtained by planting *Bouvardias* out in cold frames during the summer and placing them in their flowering pots early in September.

**Caladium.**—*Caladiums* that have been started into growth in boxes or small pots should be ready for their final potting. The soil should be of a rich nature and open in texture to favour the production of large, brightly coloured foliage. As the receptacles become well filled with roots the latter should be fed twice each week with liquid manure obtained from the drainage of manure heaps. Failing a supply of this stimulant, place some sheep manure in a small bag and allow it to soak for several days in a tub of water. The liquid will be very beneficial to the plants once they have become well established in their final pots. A heavy shade and a moist stove atmosphere is essential at this stage of growth but a lighter shade will suffice in the plant's latter stages.

**Abutilon Savitzii.**—This *Abutilon* is a useful subject for decorative purposes during the late summer, being one of the best ornamental foliage plants of its kind. Cuttings may be inserted in small pots filled with compost of an open texture and rooted in a propagating frame. This *Abutilon* requires more heat than some others. In plenty of warmth it grows rapidly and makes fine specimens for grouping with other subjects.

**Repotting.**—At this season of the year the repotting of various plants calls for attention. Young plants of *Streptocarpus*, *Browallia*, *Gloxinia*, tuberous *Begonias*, as well as rooted cuttings of various plants as they become ready, need this attention. It is not wise to allow young plants to get into a starved condition before they are repotted.

## TREES AND SHRUBS.

### THE DWARF OR SCRUB OAK

INTERESTING plantations of the dwarf or scrub Oak may be seen near the entrance to Aber waterfall, in Carnarvonshire, and on the steep bank of the River Dart, near the entrance to Dartmoor. How old these trees are it would be difficult to say, though in writings of three centuries ago both woods are referred to, and in counting the annual rings in a section of one of the stems I found the age to approximate five hundred and ten years. The Dartmouth plantation, which is known as Wistman's Wood, was referred to in his writings by Tristram Risden three hundred years ago. It is a small tract of stunted Oak trees, about four acres in extent, which occupy an elevated situation amongst granite boulders on the steep left bank of the River Dart, the individual trees of

The Aber trees which occupy the left side of the valley on the way to the well-known Welsh waterfalls, are other examples of the influence of the rocky situation and scanty supply of poor soil on the growth of the Oak.

Here the trees are generally larger in size than those in Dartmoor, but of an equally contorted description, with short, Carrot-shaped trunks that twist about amongst the rocks, rarely rising to more than 20 feet in height, but with comparatively short, thick stems and bushy heads. The plantation covers a considerable area of ground, near the middle of which stands Llewellyn's Castle, a small stone building, said to have been built for that prince on one of the most beautiful and commanding sites in the Principality. Here the trees produce a small quantity of acorns, and seedlings appear amongst the rocks, where they grow slowly and ramble about in a most remarkable manner. The timber produced by these Oaks is of very excellent quality, remarkably fine of grain, hard and difficult to cut, which may be accounted for by the unusually slow rate of growth and age of the trees, and it is rare to get trunks of sufficient size to convert for any class of constructional work. Such timber, therefore, is valueless unless for fencing and firewood, but in the matter of game shelter, and as clothing rocky ground where few other species could succeed, the dwarf Oak is not to be despised. A. D. Webster.

FIG. 135.—GARRYA ELLIPTICA ON ST. LEONARD'S SCHOOL-HOUSE, FIFE.

which average about 11 feet in height, and rarely exceed 15 feet, with a trunk diameter of sometimes 18 inches near ground level. Most of the trees are gnarled and twisted, in both stem and branch, some assuming the most grotesque and weird shapes, and in places, owing to an excess of humidity, are thickly mantled with mosses, lichens and the common Polypody Fern, which impart to certain parts of the wood a strange, hoary appearance. Few of the trees are clear of branches for more than 3 feet in length.

How and when the plantation was formed is not known, but the probabilities are that it is of natural growth, and as acorns are produced, though sparingly, its origin may be accounted for in that way.

For many years there has been little or no increase in the size of the plantation and the fact that the trees, both in height and the area of ground they cover, are almost similar to-day to the description given of them three centuries ago, goes far in supporting the idea that the wood is of natural growth. The trees which compose the whole area do not differ from the ordinary pedunculate variety, except in so far as a stunted growth has been brought about by the peculiarities of site and soil. A few Mountain Ash grow around the margin of the wood.

### GARRYA ELLIPTICA.

THERE is no hardy plant which attracts so much attention in early spring as *Garrya elliptica*. Under proper treatment it can be relied upon to produce a crop of catkins yearly in any aspect, but it attains its full beauty when planted against a wall with a warm, southern aspect. I could, however, instance a plant facing east which would compare favourably with many in better situations, and perhaps the healthiest specimen I have seen was planted against the north wall of a house, all of which proves the comparative hardiness of this shrub. While the margins of the leaves may become slightly browned by the action of the sun in frosty weather on a plant having a southern exposure, no such disfigurement occurs on a plant facing north, and in the latter position there are usually enough catkins produced to make a specimen interesting.

The photograph I send (Fig. 135) is of a plant probably thirty years old, growing against the south wall of the venerable old School House of St. Leonard's. It reaches to the eaves, above the second storey, and its name is asked for more often than that of any other subject in the gardens.

*Garrya elliptica* is easily propagated from cuttings inserted under a bell glass in spring. It also roots readily if layered, and, in common with many other shrubs, the secret of its successful cultivation for the production of catkins, and of still keeping it within bounds as a wall plant, is to prune it at the proper time, which is immediately before it breaks into fresh growth.

Flowering branches cut for decoration are both handsome and welcome from early in December until well into March. As an isolated specimen, it may not flower so profusely as the plant depicted, but, left to develop with very little pruning, it will retain its catkins longer and always attract attention. Moreover, it is not fastidious as to soil, and succeeds as well on a clayey soil as on a sandy loam. W. M. Macdonald, *The Gardens, St. Leonard's School, St. Andrews, Fife.*

**EDITORIAL NOTICE.**

**ADVERTISEMENTS** should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, W.C.2.

**Special Notice to Correspondents.**—The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.

**Letters for Publication,** as well as specimens of plants for naming, should be addressed to the EDITORS, 5, Tavistock Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

**Local News.**—Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

**Editors and Publisher.**—Our correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the EDITORS. The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.

**THE ARNISTON LARCHES.**

AS to when the common Larch was introduced into England there seems to be no authentic record. It is mentioned by both Tusser and Gerard, and the name occurs in the latter's catalogue of the plants grown in his physic garden at Chelsea in 1596. But the mere occurrence of the name in this list affords no proof that the tree was then in cultivation elsewhere in the country, and it is not till 1629, when Parkinson published his *Paradisus*, that we find indubitable evidence of this. Parkinson, however, refers to it as "in our land being rare, and nursed up but with a few, and those only lovers of rarities." Evelyn, in 1664, mentions a Larch of "goodly stature," as growing at Chelmsford, but the tree appears still to have been rare at that time; in fact, it is only after the lapse of a century that it seems to have become common in England, and then only as an ornamental tree, for all that Miller has to say about it in the first edition of his *Gardeners' Dictionary* published in 1731, is that it "is now pretty common in English gardens." He also mentions that there were some large trees at Wimbledon, which produced annually a great crop of cones. At this time then, when it had just crossed the border into Scotland, where in the next half century it was destined to effect what was little short of a revolution in Scottish forestry, there seems to be no reliable evidence of the Larch having been extensively planted in England for timber purposes.

The date of introduction of the Larch into Scotland is also uncertain. According to Sir Thomas Dick Lauder, in *Gilpin's Forest Scenery* (1834), the first Larches introduced into Scotland were planted at Dawyck, in Peebles-shire, in 1725, but Loudon doubts this, and points out in his *Arboretum et Fruticetum Britannicum* (1844) that "according to Dr. Walker, whose attention to the history of exotic trees in Scotland is well known, the first Larches were planted at Dunkeld in 1727" (see Fig. 136). Dick Lauder seems to have been well aware of Dr. Walker's statement, for he states that "it is said that the first Larches introduced into Scotland were sent to the father of the late Duke of Athol, in the year 1727," and he repeats the popular story about their having been grown in a greenhouse, and how, after they were supposed to have died, they were thrown on a rubbish heap, in which they took root, and soon became vigorous. Dick Lauder goes on to say: "Such is the popular account of the introduction of the first Larches into Scotland; but from all the evidence we can collect, those introduced by Sir James Nasmyth, Baronet, at Dawick in Tweedale, in the year 1725, appear to have been the first Larches planted in Scotland; for, from the account published in the *Transactions of the Highland*

*Society*, under the authority of the Duke of Athol's trustees, we learn that it was not until the year 1738 that Mr. Menzies, of Megenry, in Glenlyon, brought a few small Larch plants from London, in his portmanteau, five of which he left at Dunkeld, and eleven at Blair, as presents to the Duke of Athol. The five were planted in the lawn at Dunkeld, in an alluvial gravelly soil, abounding with round stones, and in a sheltered situation at an elevation of 40 feet above the River Tay, and 130 feet above the level of the sea." Dick Lauder does not, however, state anything about the nature of the evidence he had collected regarding the Dawyck Larches. Loudon also gives this statement from the Highland Society's *Transactions in Arboretum et Fruticetum Britannicum*, but he makes the comment that "it is possible that he makes this account, of which one version states

the largest girthing well over 11 feet at 5 feet from the ground, with fine boles, each containing over 200 cubic feet of timber. As we are informed in the *Arniston Memoirs* (1887), which were edited from the private papers of the Dundas family, in whose possession the Arniston estate has been since 1571, by Mr. George T. Omond, advocate, they were planted by the first President Dundas, second son of the second Lord Arniston, who succeeded to the estate in 1726, and by whom many improvements were effected on the property; and as Mr. Omond has reproduced the nurseryman's account for the plants in the *Memoirs*, there is no doubt whatever about the year in which they were planted. There were fourteen plants in all, two of them being four and five feet respectively, and the others were "smaller." The date on which the plants were supplied (by Robert McLellan) was

FIG. 136.—THE DUNKELD LARCHES, AS THEY APPEARED IN 1876.

that the servant of Mr. Menzies carried the Larches before him on his saddle, is quite incorrect; for we can hardly suppose that Dr. Walker would give the date of 1727 as that of the first planting of the Larches at Dunkeld, without some positive evidence of the fact."

When we come to the Arniston Larches we are on more reliable ground than in the case of either the Atholl or the Dawyck trees, for, fortunately, their history is well authenticated. It is surprising, however, that these Larches, which I have known for over fifty years, and which, as well as being among the oldest are among the finest in Scotland, have never, so far as I am aware, been referred to in any of the numerous works on arboriculture and forestry. They grow on an elevated plateau, to the west of Arniston House, in the county of Midlothian, in a part of the policies called the Wilderness, overlooking the South Esk river, on a rough gravel subsoil, about 500 feet above sea level; and while they are not quite so large as the Dunkeld Larches, they are of very ample dimen-

February 8, 1738, and we may assume that they were very soon thereafter committed to the soil.

Such is the account of the introduction of the Arniston Larches, and although it does not throw any light on the date when the Dawyck Larches were planted, it seems to definitely settle the question as to whether the Atholl Larches were introduced in 1727 or 1738. In the *Memoirs* it is stated that at that time (1738) "plantations, as well for the supply of timber as for shelter, were being made throughout the country. The Larch, introduced about the year 1725, was becoming one of the standard forest trees. A few were planted in the Wilderness . . ." Presumably the reference to 1725 is to the Dawyck Larches, but if, as it stated in the *Memoirs*, the Larch was becoming one of the standard forest trees in 1738, it is highly improbable, as was suggested by Loudon, that the statement in the *Transactions of the Highland Society* that it was introduced to Atholl in 1738 can be correct; for it is inconceivable that people in Perthshire, presumably who knew about such matters,

## SOLANDRA GRANDIFLORA.

THE Solandras belong to a small genus of tropical shrubs closely allied to *Datura*, and consist of about seven recognised species, of which *Solandra grandiflora* is one of the best, with its magnificent trumpet-like flowers and thick, Laurel-like leaves which are obovate-oblong; acute, and glabrous. The species was introduced into this country in 1781 from Jamaica, where it is indigenous, but it is now a favourite plant in many gardens in the tropics, where it is used freely for covering verandahs, screens and for climbing up trees.

A plant at the Botanic Garden, Cambridge, growing in a corner of one of the houses where the temperature is seldom higher than 45° during the winter, has flowered with exceptional freedom this season (see Fig. 137), and for some

markings, and even purple, while according to the *Bot. Mag.*, t. 1874, they are pale flesh colour in Jamaica, and known as the Peach-blossomed Trumpet flowers.

Cuttings of the young shoots, or ripened wood, strike freely in heat, and as the cultivation of the plant is not difficult there is no more worthy greenhouse climber than *Solandra grandiflora*, and certainly not one more handsome. *F. G. Preston, Botanic Gardens, Cambridge.*

## CULTIVATION OF HYBRID CYMBIDIUMS.

In practically every genus of the showy, popular kinds of Orchids the hybridist has effected great and astounding improvements, but it is doubtful whether his efforts have ever

should be so ignorant of the character of the tree as to treat it as a tender exotic at the very time when a nurseryman in Midlothian was distributing plants up to five feet for general planting, and when, apparently, it was becoming one of the standard forest trees throughout the country. We must therefore conclude that the Dunkeld Larches were introduced in 1727, but whether before or after the Dawick trees is uncertain, unless we accept Dr. Walker's statement that they were really the first to be introduced into the country. At any rate the story of the Arniston Larches seems to narrow down the question of the introduction of the larch into Scotland to 1725 or 1727.

These conflicting statements of the older authorities regarding the date of introduction of the Larch have, as was inevitable, led to some contradiction in the works of later authors. Dr. Nisbet, in *The Forester* (1905) and all his earlier works, accepts 1725 as the year of its introduction into the Lowlands of Scotland, and 1727 for the Highlands. Hunter, in his *Woods, Forests and Estates of Perthshire* (1833), a work by a local author, which contains much valuable information regarding the earlier plantations of the Larch in that country, states that the famous "parent Larches" at Dunkeld "were treated as greenhouse plants," and "were planted in 1738"; and Adolphus Kent, the author of *Veitch's Manual of Coniferæ* (2nd. ed. 1900), the standard English work on the subject, refers to them as "the survivors of five planted by Duke James in 1738." And in the latest work on British arboriculture, *Trees and Shrubs Hardy in the British Isles* (1914), by W. J. Beau, of the Royal Gardens, Kew, the author, referring to the parent Larches, states that "two of the oldest, or perhaps the very oldest Larches in the British Isles are standing near the old cathedral at Dunkeld, planted in 1738." It seems quite clear, however, that with the exception of Dr. Nisbet all the writers referred to above have given a wrong date for the Dunkeld Larches. *A. D. Richardson, Edinburgh.*

## INDOOR PLANTS.

## VERONICA HULKEANA AS A POT PLANT.

THIS useful and fascinating plant is at this time commencing to put forth its very graceful spikes of delicate lilac-coloured flowers. When massed in the conservatory or dwelling house, and intermixed with *Adiantum Farleyense* and *Selaginellas*, or something of a bronzy tint, it cannot fail to attract attention. Another good point in its favour is the length of time it lasts fresh in flower. I find the best method of cultivation is to strike cuttings, taken from the base of the plants at the present time, placing three cuttings around the side of a small sixty-sized pot filled with a sandy compost. The receptacles should be placed in a propagating case with slight warmth; failing this, a closed cold frame will suffice. When rooted, knock the plants out of the small pots and pot them on intact in 4½-inch pots, using this time, loam, two parts, leaf mould, one part, and a good sprinkling of sand and a small quantity of burnt refuse. Grow the plants on in a cold frame, and as soon as the pots are filled with roots, repot the plants into 7-inch pots, using a similar compost as before, but with the soil in a rougher condition, and add a light sprinkling of old soot and a small quantity of bone meal. Pot fairly firmly and return the plants to the cold frame, standing them on a coal-ash base. Water the roots carefully, and syringe the plants after hot days. When the pots are filled with roots, apply weak liquid manure about once a week. Do not stake the plants, but allow them to grow in their own natural way, or much of their graceful effect will be lost. They usually attain a height of about 2 feet 6 inches. Give the plants cool treatment, and, during the winter, plunge the pots in ashes or anything that will prevent the frost from cracking them; also, when the weather is very frosty, cover the lights with mats, but otherwise, allow all the light and sunshine available to reach the plants. *R. H. Crockford, Weston Park Gardens.*

FIG. 137.—SOLANDRA GRANDIFLORA IN THE CAMBRIDGE BOTANIC GARDEN.

weeks has been covered with its large flowers, as many as sixty-seven being out at one time. This freedom is undoubtedly partly due to the heat of last summer, as well as to keeping the soil dry at the roots during the autumn and winter months, this being essential after the plant has been allowed to grow freely, with moist conditions, during the early part of the season. The plant should be exposed to all the bright sunlight possible, which induces short, sturdy growth and the production of flowers.

The tubular flowers are eight inches long and seven inches across, sweetly scented, and interesting from the time the buds begin to expand. The change in the colour of the flower is very remarkable, pale olive-green tinged with yellow in the bud stage, and turning to white when open, the throat being cream, while the whole flower finally turns to buff-colour with age, and even then is very attractive. Flowers on different plants must vary in colour, for one reads of them being yellow, yellow with purple

been better rewarded than in the case of *Cymbidium*s, and the use of the erect, tall-growing species, *C. insignis*, and the distinct and beautiful *C. Parishii Sanderae*. These have been principally concerned in the production of the splendid new race of *Cymbidium* hybrids, whose foremost position among Orchids is assured by reason of their grace and usefulness and adaptability to cultivation.

For the beginner there is no better group with which to commence Orchid culture, and the cost of cultivating these plants is not greater, in fact less, than the cost of growing the majority of plants needing glass protection, nor, unless unique varieties are desired, is the initial cost of the plants a serious matter. In their native country *Cymbidium*s are usually found growing at a considerable elevation, *C. insignis* being found up to an altitude of 5,000 feet, hence they are, for Orchids, comparatively hardy and cool-growing plants under cultivation. "Cool-growing," however, must not be

misunderstood. It does not mean a cold, damp atmosphere; far from it. It simply means that the plants may be grown without artificial heat, except in bad weather in winter. I have had experience of these hybrid Cymbidiums in houses when the temperature has dropped almost to freezing point, and no harm has come to the plants; but at times of low temperature, the plants and the atmosphere must be comparatively dry. Such a low temperature is, of course, not advisable, 45° minimum in winter is a reasonable and safer figure.

Many of the old ideas associated with Cymbidium culture, as with the cultivation of many other Orchids, were, viewed in the light of present day methods of culture, extraordinary, and the idea still exists that Cymbidiums should be heavily shaded and treated as bog plants at all seasons. This is a very erroneous idea, resulting in deceptive growth. For a time the plants may show increased development of the pseudo-bulbs and leaves, especially young plants, but the time usually comes when such growth exhausts itself, and sooner or later the plants show signs of distress. Sunlight and sun-warmth are just as important factors in maintaining the general health of Cymbidiums, and to ensure satisfactory flowering, as in the successful cultivation of the majority of flowering plants. I do not for one moment suggest that these hybrid Cymbidiums will bear full exposure to sunshine, but the aim should be to allow them as much light as possible without risk of injuring the foliage.

Cymbidiums are, for the most part, strong-growing plants, having thick, fleshy roots, and at that period of the growing season when making up their pseudo-bulbs, in the autumn, a fairly liberal supply of water at the roots is needed, but at all other times they should be treated as ordinary greenhouse plants, always allowing them to dry out before giving the roots a further supply of moisture. Immediately after the flowering season, before the plants get well into growth, is the period when the least amount of water is required at the roots. While I have termed these plants hardy, cool-growing Orchids, they are at the same time lovers of a high day temperature, by sun-heat, so long as moisture and air are abundant, but they dislike being shut up, especially at night, in a high temperature and stuffy atmosphere. During hot weather, the foliage of Cymbidiums is subject to attacks of red spider, but if the syringe be freely used in bright weather, both over and under the foliage, little difficulty will be found in combating this pest. During the exceptional hot weather last summer, it was very difficult to keep down this pest, and dipping the foliage of the plants in insecticide was the only remedy.

The repotting of Cymbidiums is not required annually, but when this operation is necessary, it is best done soon after the flowering period, before the new growths get too far advanced. It is a mistake to disturb plants that are well established in good material, and in pots of sufficient size for the development of the new season's growth, as root-bound plants always produce the best flower-spikes. Cymbidiums require a strong soil to grow in, and this should be a mixture of three-fifths good turfy, heavy loam, one-fifth turfy peat and one-fifth leaf soil or Sphagnum-moss, the latter for preference. The compost should be used in as lumpy a condition as possible, adding plenty of rough material, such as crushed crocks, charcoal and silver sand to keep the whole porous. I never use, or recommend the use of, manures of any kind for these plants, as excellent results may be obtained, and the general health of the plants better maintained, without them.

Over-potting should always be avoided, as the plants are more easily managed in the matter of watering, and they flower better when the roots are confined to a moderate amount of rooting material. Good open drainage is very essential and should always be covered with a layer of thin turf. In the process of potting the soil should be made firm about the roots, and the base of the plant kept about one inch below the rim of the pot, with the crown of the plant on a level with the surface of the soil. *H. G. Alexander, Westonbirt.*

## MR. KINGDON WARD'S SIXTH EXPEDITION IN ASIA.\*

No. 15.—MU-LI.

Mu-li, which to all intents and purposes is the monastery with its six hundred monks, is situated some 2,000 feet above the Litang river, on the left bank. Immediately above the building, which forms a compact block on the steep hill-side, the limestone cliffs rise another 2,000 feet in a series of gigantic scarps. The south facing slopes, below these cliffs, are clothed with a forest of Oak, but on the sheltered slopes there are many shrubs, such as the Rhododendron (four species), Desmodium, Berberis, Corylus, Willow, etc., and higher up, Pine woods shading all sorts of flowers—Lilies, Roscoea, Cypripediums, and other Orchids; *Primula septemloba* and so on.

For a few days I took stock of the position, while exploring the limestone cliff, where it was not quite naked. There were several directions in which I might proceed, as thus: (i) the limestone range we had already crossed, due south of Mu-li; (ii) the range immediately above Mu-li to the west; this forms the watershed between the Litang river and a considerable stream to the west, called the Shui-lu; (iii) the watershed between the Litang river and the Yalung, to the east, by a choice of two roads, one going northwards to Tatsienlu, the other due east. Finally I decided to visit all three regions, starting westwards first. Meanwhile, we explored the cliff above the monastery, found a Rhododendron like *R. racemosum* (not in flower), the violet *Nivalis Primula* (very abundant), a violet flowered *Ajuga*, rather a pretty weed, and one or two other trivivial plants.

The weather looked quite promising as yet, for though it was cloudy, the clouds were high and there was no serious threat of rain. It seemed best to get away before the rainy season set in, and having invoked the aid of the monastery, we started westwards on June 13.

As already stated, immediately behind the monastery there rises a high limestone cliff, very craggy, and not to be climbed, which stretches north and south for several miles. To proceed westwards, therefore, this cliff has to be turned, either at its northern or southern end. The main road to the Shui-lu and on into Chinese Tibet, runs north, following the valley of the Litang river for a couple of miles, and then crosses the range by a pass about 13,000 feet above sea level. It was by this route that we returned, and it is interesting because, while the immediate slopes about Mu-li, and the cliffs above being exposed, are rather bare, covered with scattered shrubs or with forest of gnarled Oak, those facing north-east are well wooded and support a rich flora. It was here, close to Mu-li itself, that I found on the limestone cliffs a *Suffruticosa Primula*, forming thick cushions, a foot or more across, and several inches deep. The flowers were practically over as early as June 28, but appeared to be purple with yellow eye, the leaves curiously sticky. Some of the plants met with, laboriously built up into compact tufts, thanks to the persistence of the old leaves, must have been many years old, for the concealed stems were hard and woody. These *Suffruticosa Primulas* are all cliff plants, and most, if not all, limestone plants. They grow on the very barest rock where nothing else will deign to grow, the crowded leaves absorbing moisture like a sponge. Unfortunately, they require several years to establish themselves, though they are well worth growing in the rock garden. This Mu-li species resembles the beautiful *P. pulvinata* (discovered in Eastern Tibet in 1913, flowered in 1917), in that the flowers nestle amongst the leaves instead of being carried above them, as, for instance, in *P. Forrestii* and *P. redolens*. I have no doubt that this Mu-li species is a new plant.

\* The previous articles by Mr. Kingdon Ward were published in our issues of May 14, June 18, July 23, August 20, September 3, October 8, October 29, 1921; January 7, January 21, March 11, March 25, April 8, April 22, and May 6, 1922.

Another striking plant of these sheltered limestone cliffs, growing in the Pine woods, was a slipper Orchid, not unlike a species found on the north-east frontier of Burma in 1914, but on a larger scale.

From between a pair of large, oval, glistening leaves, lying flat on the ground, rises the large, chocolate coloured flower, with its fat pouch and spreading outer segments; but the scape is so short that the solitary flower appears to be sessile between the twin leaves. It is a species of *Cypripedium*.

*Primula septemloba* with umbels of drooping, purplish-pink flowers also grew here in thick undergrowth, and a Clematis with drooping maroon-purple flowers, which latter, however, was not common. Several ground Orchids, species of *Roscoea*, *Thalictrum*, *Lilium*, *Pyrola*, etc., were at home on these Pine-clad slopes.

The second road westwards turns the cliff at its southern extremity, and crosses the range some distance south of Mu-li. This is the main road to Chung-tien; and it was this road we followed to begin with on June 13, only we turned off due west as soon as the end of the cliff was reached, following a path which leads to the alpine pastures, and thence over the divide by a 14,000 foot pass and so down to the Shui-lu, rumbling in its deep gorge.

In the shrub belt there was not much in flower, a *Deutzia*, *Rosa sericea*, *Hypericum patulum*, white Jasmine, *Cotoneaster*, *Desmodium*, *Lycocystis*, etc., besides two or three species of *Arisaema*, *Amphicome arguta* and a *Vitis*. As we got higher, *Iris kumaonensis* appeared, with purple *Pleione*, *Epilobium* and *Morina*. Then came masses of pink *Androsace spinulifera* alternating with patches of violet *Primula*, making a very pretty combination.

Forest now began to replace shrub growth—*Pinus Armandii*, *Pseudotsuga*, *Picea*, *Maple*, *Birch*, *Oak* and *Rhododendrons*; lastly, *Larix tibetica*, which ascends higher than any tree here, except *Abies*, sp.

Following up a valley, we climbed steeply under the towering walls of the Mu-li cliff, where *Cypripedium luteum* and *Primula septemloba* were conspicuous in the shade.

Emerging from the forest, on to open slopes, with scattered bushes of *Rosa* (two species), *Potentilla fruticosa*, *Berberis*, sp., etc., the fierce crimson of *Incarvillea grandiflora* at once caught the eye; there were also a few white flowered specimens, these being much more pleasing to look at. A tall *Nivalis Primula*, with mauve flowers, was also abundant here; the flowers were over, but we found plenty next day a little higher up. The species is common in the A-tun-tzu district, on the Mekong-Salween divide—*P. sinoplangtaginea*, I think it is.

We camped for the night by a small stream coming down from the limestone range. As usual in this region, it was lined with *Primula secundiflora* and *P. pseudo-sikkimensis*; I have never seen the one species without the other. Yet in the A-tun-tzu district, where *P. pseudo-sikkimensis* is common enough, *P. secundiflora* is not found. Possibly the A-tun-tzu plant is another microform of *P. sikkimensis*; namely, *P. microdonta*. The poverty of shrubs was quite astonishing. Beyond those already mentioned with *Lonicera*, *Salix*, scrub *Juniper*, and one or two more, there was nothing. This, however, is only a generalisation of the particular fact already noticed, that there are very few species of *Rhododendron* so far east, though I found two more on this very range, bringing the total number found in the Yung-ning Mu-li area to something over a dozen species, but less than 15! I have no doubt, however, that could one but get at the highest peaks, many more species would be found.

On June 14, we continued the ascent to the summit of the range, and presently came on a pretty *Anemone*, perhaps *A. rupicola*, under the trees. Numerous prostrate *Leguminosae* of all colours began to appear—species of *Oxytropis*, chiefly, with here and there a dwarf, blue *Iris*, probably the widely spread *I. kumaonensis*. *P. Kingdon Ward.*

**MESEMBRYANTHEMUM AND SOME NEW GENERA SEPARATED FROM IT.**

(Continued from page 231.)

14.—*C. saxetanum*, N. E. Br. Plant forming very dense hemispherical tufts of very small growths, each about 4-6 lines long and 1½-2½ lines thick, cylindrical or cylindrical-clavate, very convex at the apex (type A.), with a minute and very inconspicuous orifice, green, more or less tinted with purple where exposed to the sun, with or without a few inconspicuous darker green dots around the orifice. Often the growths are more or less included in their old skins. Flowers not seen alive, but on one dried specimen it appeared to be rosy, Dr. Marloth, however, states that it is "whitish or cream-coloured," possibly it varies.—*M. saxetanum*, N. E. Br. in *Journ. Linn. Soc. Bot.*, v. 45, p. 99. *M. fimbriatum*, Marloth in *Trans. Roy. Soc. S. Afr.*, v. 1, p. 406, not of Sonder.

Great Namaqualand. In fissures of rocks near Angara Pequena, flowering in May, Marloth, 4676, at Kew (4674 ex Marloth), Pole Evans.

Some of the native tufts of this species must be very old, as upon counting the number of sheaths upon a short measured length of one of the stems this species forms, I found that at a rough estimate that particular plant was at least one hundred years old. The growths form only one sheath each year under natural conditions.

CCC. Flower white, see also 14, *C. saxetanum*, and 18, *C. translucens*.

15. *C. viridicatum*, N. E. Br. Growths 6-10 lines long and 5-8 lines in their greater diameter, obconic, with a shallow groove-like depression across the elliptic slightly convex or flattish top (type F., but with a deeper notch), and often with a faint obtuse ridge on each side of the orifice, uniformly green, like young Apples, without markings, or (on the same plant in different

elliptic, slightly convex top (type E). Corolla 6-7 lines in diameter, opening late in the afternoon, scentless; petals 25-28, straw-yellow. Anthers all shortly exserted. Style very short; stigmas not attaining to the mouth of the corolla-tube.—*M. albertense*, N. E. Br., in *Journ. Linn. Soc. Bot.*, v. 45, p. 92. Sent to Kew by the late Prof. H. H. W. Pearson, as having been collected near Prince Albert, but as I have had what appears to be the same plant sent to me by Mr. N. S. Pillans from near Prince Albert Road, the latter locality may have been intended.

17. *C. fraternum*, N. E. Br. (Fig. 138).

FIG. 139.—*CONOPHYTUM GRATUM*, N.E.BR. NATURAL SIZE.

Growths 4.7 lines long and 3.5 lines in diameter, obconic, flattish at the top, with the centre often slightly depressed (somewhat as in type J), pale greyish-green, with scattered dark green or finally purplish dots. Calyx usually exserted, 4-lobed, whitish or pale greenish, sometimes tinted with purplish. Corolla 7-10 lines in diameter, opening in the morning and closing towards evening, scentless; tube very much longer than the calyx, dull ochreous-yellow or whitish; petals pale pink, fading into yellow at the mouth of the tube, or entirely white. Stamens with orange filaments and yellow anthers. Style as long as or longer than the stamens, filiform, with 4 minute stigmas orange-red or light yellow.—*M. fraternum*, N. E. Br., in *Kew Bull.*, 1913, p. 118.

Little Namaqualand. Hills south-west of Chulhiessis, Pearson, 6177

18. *C. translucens*, N. E. Br. Growths 3-6 lines long and 3-5 lines in their greater diameter, obconic, slightly convex at the top (type E), scarcely, or but slightly depressed at the orifice, "translucent green, with slightly darker distinct spots only showing under a lens, and a few yellowish spots, not confluent. Flowers open at night heavily scented." Calyx-tube much exserted, 2-3 lines long, 5-lobed. Corolla about half an inch in diameter; tube not exserted from the calyx; petals numerous, widely spreading, creamy-white. Anthers exserted, yellow.

Locality unknown, Bolus Herb, 15,183. This is evidently a very distinct species, but is only known to me from a coloured drawing made by Miss Page, and sent to me by Mrs. L. Bolus. The translucent green colouring is unlike anything I have seen.

19. *C. piluliforme*, N. E. Br. Growths very small, 1½-3 lines in diameter, obconic, convex on the top (type D, but very small), different plants varying from dull greyish-green to dingy purplish or purplish-green, marked with a few scattered dark purple or dark green dots, and often a line of confluent dots, transverse to the orifice, and the orifice outlined with the same colour. Calyx 4-lobed, dull dark red. Corolla insignificant, night-flowering, scentless (but stated to be slightly scented in S. Africa), about 4 lines in diameter, with 16-20 lax, irregularly arranged, very narrow petals, of a peculiar reddish-ochreous colour or dull coppery red.

Anthers yellow, all shortly exserted. Style about half as long as the tube of the corolla, with 4 filiform stigmas rising to the base of the anthers, reddish. Top of the ovary domeshaped.—*M. piluliforme*, N. E. Br., in *Journ. Linn. Soc., Bot.*, v. 45, p. 98.

Robertson Div. Near Montagu. Collector unknown.

20. *C. gratum*, N. E. Br. (Fig. 139). Growths somewhat top-shaped in side view, globose viewed from above, convex at the top, with a broad and shallow V-shaped notch across it, pale bluish-green, sprinkled with dark green dots, and the orifice outlined with dark green, very conspicuous on the young growth, but becoming fainter with age, and later a dark pink dot appears on each side of the orifice. Calyx usually exserted, 4-5-lobed, whitish. Corolla 6-7 lines in diameter, expanding in the daytime, irrespective of sunshine: tube 3-4 lines long; petals 28-32 strongly recurved, rich magenta, shining. Stamens about 35-40, in 1-2 series, shortly exserted, yellow. Style 4.5 lines long, with 4-5 stigmas about 1 line long, dull yellow, finally exceeding the stamens.—*M. gratum*, N. E. Br., in *Journ. Linn. Soc. Bot.*, v. 45, p. 93. *M. nanum*, L. Bolus in *Ann. S. Afr. Mus.*, v. 9, p. 141, not of Schlechter.

Little Namaqualand. Barren slopes north of Daunahis, Pearson, 6063.

21. *C. truncatum*, N. E. Br. Plant with age forming a dense tuft of crowded stems up to 1 inch long, densely covered with the remains of old sheaths, firm in substance and of a tan-brown colour. Each branch terminated by an obconic growth about 4 lines long and 3-4 lines in diameter, scarcely or but slightly exceeding the old sheath, apparently flattish or slightly convex on the top, and of a light brown colour in the dried state, but Thunberg describes them as being subtruncate and subretuse—truncate, green and dotted, and as having a 4-lobed calyx or perianth. But the specimen is in fruit only, and I see no trace of calyx-lobes, although as it is 5-angled it was doubtless 5-lobed. The

Photo by Dr. Rodier Heath.

FIG. 138.—*CONOPHYTUM FRATERNUM*, N.E.BR. NATURAL SIZE.

years) with some very small inconspicuous darker green dots. Calyx 5-lobed, whitish. Corolla, about 9 lines in diameter, opening after sunset, scentless, with about 30 recurved-spreading very narrow white petals. Stamens exserted; anthers yellow. Style very short; stigmas 5; about 1 line long, very pale yellowish.—*M. viridicatum*, N. E. Br., in *Journ. Linn. Soc. Bot.*, v. 45, p. 101.

South Africa. Locality and collector unknown.

BB.

Growths more or less marked with dots or lines (species 16-49). See also a few species mentioned under B.

D.

Dots all scattered and separate (species 16-22). See also species noted under B, and 27 *C. Nevillei*, and 30 *C. parvipetalum*.

16. *C. albertense*, N. E. Br. Growths 4-7 lines in diameter, at the circular or broadly

capsule is just exserted from the orifice so as to rest on the top of the growth, and is distinctly 5-valved, and about 2½ lines in diameter.—*M. truncatum*, Thunb., in *Acad. Cuesar. Leop. Carol. Nat. Curios. Ephem.*, v. 8, *Append.* p. 5 (1791), and *Fl. Cap.*, p. 412, not of other authors.

Uniondale Div. Among rocks in Kamanassie Karoo.

The above description is made from Thunberg's type specimens, which I have had the privilege of examining. This species has never been introduced into cultivation, although the name has been erroneously applied to various cultivated plants.

22. *C. truncatellum*, N. E. Br. (Fig. 140). Growths 6-10 lines high and 6-12 lines in diameter, very broadly obconic, circular in outline at the top, which is flat or more usually shallowly depressed at the centre (type J), with a slight but usually distinct blunt ridge on each side of the orifice, light glaucous-green, sprinkled

all over the top with small dark green dots, sometimes mingled with purple dots, calyx exerted or included, 5-lobed. Corolla 7-8 lines in diameter, opening at about 5 p.m., closed during the day, delicately scented; tube 2.5 lines long; petals 30-50, recurved-spreading, very narrow, pale straw-coloured or light yellow. Stamens numerous, in 2 series; anthers yellow. Style 1-1½ line long; stigmas 5-6, about 1-1½ line long, attaining to about half the length of the corolla-tube, pale greenish.—*M. truncatellum*, Haw. *Misc. Nat.*, p. 22 (1803).

Locality unknown. Introduced by Masson in 1795. *N. E. Brown.*

(To be continued.)

## TASTING DAY AT LONG ASHTON.

GRADUALLY pre-war conditions are being restored in various directions, and the revival of Tasting Day at the National Fruit and Cider Institute on the first Thursday in May marks the resumption of an annual practice now of many years' standing which was interrupted by the war. While its primary object was to demonstrate the results of the experiments on cider-making conducted during the 1921-22 season, opportunities were provided for visitors to see something of the other activities of the station.

In the cider house were displayed some fifty samples of cider, each made from a distinct variety of Apple. This method of separate treatment allows a judgment to be formed of the vintage merits of each sort tested, and its suitability for use alone or its requirements for blending as the case may be. With the number of samples available almost unlimited scope was afforded for testing the bewildering combinations to be obtained by blending different types and varying their proportions. It was interesting to note the effect of the very hot and dry summer of last year on the quality of the cider. As expected, the juices proved to be abnormally rich in sugar, but the fruit yielded very little juice. It appears likely to be demonstrated that an excess of heat and drought, such as that experienced last summer, does not lead to the production of cider of the best quality.

To anyone acquainted with the farm orchards of the cider districts it is evident that among the almost innumerable sorts of Apples to be found in them, a large percentage must be unworthy of their place from both cultural and vintage points of view. These tests of cider-making with individual varieties, which have now been carried out at Long Ashton for many years, have led to definite conclusions as to the varieties which can be recommended, and it is hoped that further planting of cider orchards will be restricted to these.

Of more immediate interest to fruit growers generally were the tests made with the commercial varieties, Bramley's Seedling and Lane's Prince Albert. In course of time, as grading becomes an established practice in the marketing of Apples, there will be an increasing amount of blemished and undersized fruit for which the grower will need to find a profitable outlet. The possibility of its use for cider-making is now being explored, and, if the results shown at Long Ashton on this occasion can be regarded as typical, there is good reason for hope in that direction. By themselves the ciders made from the varieties named would not rank high; but the demonstrations given of methods of blending with true vintage varieties of suitable character proved that good marketable ciders can be produced by their use, even when so high a proportion as 50 per. cent. of the commercial variety is used in the blend.

Another important line of work with which the station is concerned, viz., that on methods of preservation of fruit and vegetables, which it is conducting in conjunction with the Campden Experimental Station on Fruit and Vegetable Preservation, was illustrated by exhibits of a comparatively new method of preserving fruit for jam-making purposes by direct treatment in the cold with a very dilute solution of sulphur dioxide. The results thus far are extremely

promising, the quality of the jam produced being distinctly superior to that made from fruit pulp. It seems likely that the practice of pulping may be superseded by it.

Space will not permit of more than brief reference to the many points of interest which were to be seen during the course of the tour through the fruit plantations, and mention will be confined mainly to some of the newer lines of work in hand. In these considerable extension has made possible a large programme of "field experiments." This includes continued work on the control of big bud in Black Currants by the use of lime-sulphur sprays of different strengths and different dates of application, and also on that of the Loganberry beetle with arsenate of lead and paraffin emulsion.

Extensive manurial experiments are now under way to test the comparative values of organic and inorganic nitrogen, and especially to find out the most favourable time of year at which to apply fertilisers to fruit trees. The fruit-breeding programmes of former years have produced large numbers of young seedlings, of which a large proportion has been planted out to undergo field trials.

In conjunction with the Cheddar Fruit Growers' Association, a considerable trial of Strawberries has just been commenced. Work is also being done on Strawberries to discover the possible existence of definite strains in the variety Royal Sovereign.

The collection of little-known Apple varieties of promise is being continually increased, and it is intended to initiate next autumn a scheme for collecting and testing such kinds which from time to time are reported in old farm orchards.

At a later date in the summer it is likely that another field day will be arranged, when further opportunity will be afforded for reviewing in more detail the experimental work on fruit culture now in progress.

## THE GRAPE VINE.\*

(Concluded from page 246.)

### PESTS OF THE VINE.

It is impossible for me to deal adequately with all the insect pests and diseases of the vine; I can only touch on a few of the more common. Red spider is the most troublesome insect. There are two kinds of red spider, the more common and smaller of the two lives on the under-side of the leaves, where it spins its web and multiplies with great rapidity. The other is larger and brighter in colour and lives on the upper side of the leaves and is easily seen by the naked eye. Sometimes the presence of red spider is not detected till brown patches appear on the leaves caused by the insect living on the chlorophyll. For red spider or any other pest which leaves the foliage light in colour, a dressing of sulphate of iron at the rate of one-half pound to ten square yards of the border will tone up the leaves and give them a rich green colour in a few days. Every endeavour should be made to eradicate the spider before it has time to damage the leaves, and a strict watch kept on any leaves near the hot-water pipes, which should on no account, be allowed to become excessively hot after the end of March. Directly red spider is detected, sponge the affected leaves, using warm soapy water. This may be a tedious operation, but it is effective. Thrips attack the leaves in much the same way, and perhaps cause more damage, but fortunately this pest is not often met with on vines. Its presence can generally be traced to Azaleas or some other plant which may have been placed under the vines to recuperate. The most certain way to dispose of a severe attack of spider or thrips is to fumigate with "XL-ALL" fumigant three times in succession, or more if necessary, at intervals of nine days, so as to destroy the larvae as it advances into active life. I do not advise excessive moisture in the atmosphere, which is often resorted to for the destruction of this

pest. This remedy is nearly as bad as the disease, inasmuch as it invariably results in a variety of diseases no less virulent than those we are dealing with—mildew, to mention only one. Mildew is caused chiefly by a stagnant atmosphere, and, if not at once arrested, will certainly destroy the crop. It attacks the young leaves, and descends from them to the bunches, which have then the appearance of having been dusted with flour. The best preventive of mildew is to have no young leaves or tendrils of any sort on the vine, but to remove them as they appear. When the disease is first noticed on leaves that cannot be spared, such as on young canes, apply flowers of sulphur to the leaves attacked, when the mildew will disappear. Freshly slaked lime may be placed on the borders with good results, but sulphur is the standard specific for mildew. Rust can hardly be termed a disease, but some of the finer-skinned varieties are very liable to it. It cannot be cured, but can be prevented by avoiding everything likely to produce it. Rubbing the berries with the hands or the hair when working among them, or allowing the pipes to become excessively hot through careless stoking, will cause rust on the berries. Scalding is a malady which often gives trouble, one or two varieties of vines being very susceptible to it. Lady Downes and Muscat of Alexandria in particular. It generally occurs when the berries are more or less half-grown, but, fortunately, if the vines are healthy, it only lasts about three weeks. It is caused by faulty ventilation, the moisture in the atmosphere condensing on the berries before the sun reaches them in the morning. This appears to be the principal cause, but not the only one, for scalded berries are found in bunches where the sun's rays never reach them. This moisture causes the skin of the berries to become tender, with the result that the cells collapse as they expand with a rising temperature in the early morning. Admit a little air by the top and bottom ventilators, both day and night. A dry atmosphere is required, so that moisture will not condense on the berry. The amount of air should be increased early in the morning. If these details are observed, there is little to be feared from scalding.

"Shanking" is a very serious disease, and difficult to trace to its source, but it will be found, in nine cases out of ten, to be caused by having too much organic matter in the soil of which the border is composed. Organic matter has the effect of producing too many roots of a long, spongy nature in the early season. These die back at a critical time—at the stoning period, usually. These roots favour the development of large quantities of leaves and wood which fails to ripen properly, and so the trouble is carried on from year to year. This excessive root action may be obviated by limiting the top growth early in the season, retaining only a limited number of primary leaves and suppressing all others. This will reduce the pressure on the roots after the plant starts into growth, and, instead of spongy roots, thin, wiry, branching rootlets will develop. We have practised this method of combating shanking for several years, and there is seldom a shanked berry now on vines that formerly gave a lot of trouble with this complaint. If aerial roots are noticed, be prepared for shanking, because it is a sure sign that top and root growth are not properly balanced. Mealy bug is a marvellously persistent pest. Every conceivable specific has been used for its destruction, from coal tar to prussic acid gas. To rid vines of mealy bug entirely takes time and patience; on old, gnarled rods it is well-nigh impossible. There is nothing better than to scrub the rods twice during the winter, and again after growth has commenced, with a strong solution of "Gishurst compound," using a stiff brush. The white, mealy substance from which the insect derives its name is proof against water, unless very hot, but melts when touched with a drop of methylated spirit.

When the grapes are thoroughly ripe in early October, there is nothing to be gained by leaving them on the vine, for, as a matter of fact, the bunches keep equally as well in a well-constructed Grape room.

\* A lecture delivered by Mr. Malcolm Macnaghton, Scene Palace Gardens, Perth, in the Technical College, Dundee, before the members of the Dundee Horticultural Association.

## HOME CORRESPONDENCE.

[The Editors do not hold themselves responsible for the opinions expressed by correspondents.]

**Orn's "Flower Garden."**—Having the 1838 edition of this work, Mr. Joseph Jacobs' note (on p. 193) interested me, though I never came across the second edition. It is a well-bound volume, containing about half a score of excellent, coloured plates of bulbs, annuals, perennials, etc., with a number of engravings of vases, fountains, geometrical gardens, etc. It is to be supposed that this work was published in January, as the author (whoever he may be) promised a volume in March on tender or exotic plants, which was to embrace the situation and structure best adapted to greenhouses, stoves, and conservatories, a comparison of the best methods of warming, illustrated by diagrams; the management of the houses and plants, with select lists of plants arranged according to their height and colour, "as in *The Flower Garden*, and the whole will be written by Mr. McIntosh, gardener to His Majesty the King of the Belgians at Claremont." Has Mr. Jacob or Mr. Brotherton seen this volume? It has not come my way. Mr. Paxton, when at Chatsworth, is frequently quoted as an authority on many subjects; in fact, the book abounds with the opinions of others from different parts of the country, which almost tempts one to try one's hand at authorship if it were feasible to call in outside help to such an extent as given in the first edition. *James Mayne.*

**Carnation Bis Greenfield** (see pp. 158 and 184). Whilst admitting that the colour and size of the flower of this variety are good, and the plant vigorous, it lacks—most important of all—perpetuality in flowering. The true perpetual Carnation produces flowers in succession, but Bis Greenfield fails to do this here under good treatment. It is therefore entirely out of place as a perpetual variety, and is not to be compared with such sorts as Brilliant, Edward Allwood, Scarlet Carola, or even Mrs. McKinnon. I may add that after growing Bis Greenfield for 18 months the variety has produced one bloom only. *Midland Grower.*

**Giant Larches.**—Your correspondent, Mr. Mark Mills, gives in your issue of April 29, p. 213, the measurements of some fine Larch trees at Coombe House. It may interest Mr. Mills to know that we have on the lawn here, three Larches, with the following measurements:—No. 1, circumference 3 ft. from ground, 11 ft. 8 inches; height, 90 ft. No. 2, circumference 10 ft. 10 inches, height 84 ft. No. 3, 9 ft. 8 inches, height 85 ft. In the absence of the lower branches, the spread of the trees is not very great, the widest being 60 ft. Like Mr. Mills, I should like to know the age of these specimens. Another feature in the garden here is an old zig-zag fruit wall. Can anyone give me the approximate date when this kind of wall was built, and state if there are other examples still standing? *L. Dawes, Charlton Lea Gardens, Old Headington, Oxford.*

**The Setting of Muscat Grapes.** At the date of writing (May 3) our Muscat Grapes have set and are swelling, and I would like to give an account of the method practised by us. About a week before the bunches come into flower the border is watered. When the first signs of flowering appear, the night temperature is kept as 70°, with a little air admitted by both the top and bottom ventilators. Every morning about 10 o'clock the whole surface of the border is damped with tepid water through a rose can. The moisture in the house then condenses on the bunches and has the effect of loosening the caps; about noon, when the air is dry (as it is up till late evening), the vine rods are struck heavily with the fist, whereupon the flower caps are easily dislodged and fertilisation takes place. The above method I have practised for many years, and always with first-class results. *Arthur Allardice, Burwarton Gardens, Bridgenorth.*

**Musa Cavendishii** (see pp. 106, 142, 202, 234).—The various notes on the fruiting of the Banana in gardens have doubtless been read

with much interest by many old gardeners. I had not seen Bananas growing for some years until I planted a house with them at Hall Place, Tonbridge, where Mr. Pringle grows them very well indeed. Having served as a young man in two gardens where these fruits were grown, I was naturally keenly interested when I took charge of the gardens at Impney to find the centre of a house planted with Bananas. I enclose a photograph (see Fig. 141) of a bunch I grew there in 1898. The bunch had 283 fingers and weighed 114 lbs.; it was one of many I grew there over 100 lbs. in weight. The plants were grown in a bed 6 feet by 4 feet, raised 20 inches above the ground level, without bottom-heat, from which two ripe bunches were produced each year. Some fruits were sent to the late Mr. John Wright, V.M.H., who expressed the opinion that it was the largest bunch with the finest Bananas he had ever seen. He informed me that Mr. Ollerhead had been awarded a Gold Medal by the Royal Horticultural

FIG. 141.—A HOME GROWN BUNCH OF BANANAS (MUSA CAVENDISHII) CONTAINING 283 FRUITS AND WEIGHING 114 LBS.

tural Society for a bunch weighing 97 lb. The chief needs of this exotic fruit are plenty of heat and moisture and heavy feeding, both solid and liquid, especially when the plants are throwing out their bunches and when the fingers are swelling. The plants develop plenty of suckers, which may easily be fruited and the bunches ripened in 18 months or 2 years. *F. Jordan.*

—In reply to Mr. Snell's inquiry on p. 234, to the best of my recollection the Banana grown at Wimbledon House, with a bunch of fruit weighing about one hundred lb., was *Musa Cavendishii*. Possibly one might find out by referring to Wright's *Fruit Growers' Guide*, as I believe Mr. Ollerhead wrote the article on Banana growing in that book. *Thos. E. Furnell, Quakers' Hall Nursery, Sevenoaks.*

## SOCIETIES.

## NATIONAL VIOLA AND PANSY.

THE monthly meeting and first monthly show of the National Viola and Pansy Society for 1922 was held at headquarters, the Crown Hotel, Birmingham, on the 3rd inst., Mr. H. J. Milnor in the chair. There was a good attendance of the members and six new members and one vice-president were elected. The number of entries, as was to be expected after the adverse weather of late, was small and far below the average. Mr. D. Calderbank gave a very instructive and interesting lecture on "Manures (Organic and Inorganic): Their Values and Application."

## ROYAL CALEDONIAN HORTICULTURAL.

MAY 2.—The ordinary monthly meeting of this Society was held at 5, St. Andrews Square, Edinburgh, on this date, Mr. David King, President, in the chair.

A paper on "Daffodils" by the Brodie of Brodie was, in the unavoidable absence of the author, read by Mr. W. G. Pirie. The paper dealt largely with the question of raising new varieties, and the author also discussed the cultivation of the plant. Speaking of the latter, he advised growing the plants in the kitchen garden, after a vegetable crop, rather than in the flower garden, where the bulbs were apt to get dug over. As manures, he recommended finely ground bone-meal and wood ash, with no farmyard manure. In crossing for the raising of new varieties, he advised the use of really good, but not necessarily expensive, varieties, with fairly long flower-stalks.

The exhibits were:—Seedling Daffodils from the BRODIE OF BRODIE (awarded a cultural Certificate); Seedling Daffodils, from Mr. W. G. PIRIE, Dalhousie Estate (awarded a Silver Medal); *Genista fragrans*, new dwarf variety (awarded a First-Class Certificate), from Messrs. GORDON BROTHERS, Edinburgh.

It was intimated that the first examination for the certificate in horticulture, recently instituted by the Society, was held last month, and that Mr. A. E. LIVINGSTON, North Borland, Dunlop, Ayrshire, had obtained the First-Class Certificate.

## UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

At the monthly meeting of this Society, held in the R.H.S. Hall, on Monday, May 8, Mr. Chas. H. Curtis presided, and ten new members were elected. Two members withdrew interest amounting to £4 12s. 2d., and the sum of £31 5s. 1d. was passed for payment to the nominee of one deceased member.

The Committee decided to appoint agents in every part of the country to introduce new members, and such agents will receive a stated sum for every member introduced and elected. The sick pay for the month on the private side came to £58 5s. 10d., and on the State section to £60 17s., while maternity claims amounted to £8. Grants from the State section to five members towards the cost of dental treatment amounted to £20 15s.; six further applications were received for extra benefits, and were dealt with.

## Obituary.

**Gabriel Luizet.**—We regret to announce the death of Mons. Gabriel Luizet, the well-known President of the Société Pomologique de France, which occurred on the 27th April. Gabriel Luizet was a descendant of the well-known firm of nurserymen at Lyon; though he had been retired for some time his interest in all gardening matters, and particularly fruit, was as keen as ever. All who have attended the annual conference of the French Pomological Society will recall his genial conduct of business, and his great knowledge of pomological subjects. His latter years had been spent in compiling lists of synonymy of fruit, which

**The Effect of Bordeaux Mixture on Plant Processes.**

The laborious experiments which have been carried out by numerous investigators during the past few years on the effects which spraying with Bordeaux mixture produce on plant activities are of considerable interest to gardeners. Every gardener nowadays, it is to be presumed, considers carefully the question whether he shall or shall not use Bordeaux mixture for spraying fruit trees and Potatos. He generally weighs the probable advantage against the certain disadvantage in the form of labour and time spent on the operation and cost of material, and, at all events in the case of Potatos, meteorological conditions and the situation of his garden—whether in a dry or wet district—usually give the casting vote. If the season is a wet one, of overcast days and muggy nights, or if the garden is situated in a moist district, the gardener generally elects to spray this crop; but if on the other hand the season is fine and dry and the district is one with a low average rainfall, spraying is often omitted. There are, of course, many large Potato growers, for example in Lincolnshire, who have adopted spraying as part of the routine of Potato cultivation, and who spray this crop always twice or thrice during the growing season. If, however, it could be shown that spraying with preparations of copper sulphate produces beneficial results apart from its undoubted effect in preventing "blight," the practice would undoubtedly become more general, and growers in this country would spray with Bordeaux mixture as regularly as do the Potato-growers in Ireland. In the present state of knowledge, however, it cannot be said that spraying with copper sulphate preparations does produce beneficial results. That it produces well-marked and definite effects on plant growth is, of course, well known. For example, it has often been

pointed out by growers that sprayed plants keep green longer than unsprayed plants, stand longer, and ripen their tubers later. It is also probable that, because of the longer season of growth induced by spraying with Bordeaux mixture, the crop yielded by sprayed plots is larger than that yielded by unsprayed plots even when disease has been absent from both. Clearly the advantage of the heavier crop may at times be outweighed by the disadvantage of delayed ripening, for as everyone knows, the keeping power of Potatos is affected adversely by unfavourable weather conditions at the time of lifting, and as the autumn wears on, the weather is apt to grow worse. Nevertheless, and particularly for gardeners who grow successional Potato crops, an increased yield is a strong point in favour of spraying; since even if the year proved a good one and no blight occurred, the cost of the operation would, at least in part and perhaps in whole, be recovered in the value of the increased crop. Moreover, the gardener, at all events, has a ready means of discounting the retarding effect of spraying. By sprouting the sets he is able to delay planting till the risk of the haulm being affected by late spring frosts is but slender and yet get his crop in early. There is, of course, no need here to dwell upon the advantages of sprouting the sets, though it may be worth while to mention that in large scale experiments which we had an opportunity of witnessing last year, sprouting made a difference in the yield of one ton to the acre. As to physiological effects of spraying with Bordeaux mixture, experiments by Messrs. Dugger and Benns\* and by other investigators show conclusively that the rate of water loss (by transpiration) is increased as the result of spraying. They also make the further interesting observation that the increase of transpiration takes place not, as might have been expected, by day, but at night. They incline to the view that the mode of operation of the film of copper sulphate on the leaves is physical and that the increased rate of loss of water at night is due to guttated drops of water excreted from the leaves running as films on the copper sulphate particles, and thus getting evaporated more quickly. In support of this view, they point out that films of other substances, iron, aluminium and magnesium hydrate, produce an effect analogous to that brought about by copper sulphate. The explanation does not seem to us to be very satisfactory, and before accepting it we should require to know whether the increased natural transpiration rate is or is not accompanied by increased growth. It is evident that further investigation of the problem is required, and it is much to be desired that it should be so carried out as to provide a conclusive answer to the question—of some practical importance—whether spraying produces such an increase of crop as to make it a paying proposition even in seasons when blight does not make its appearance or work its havoc on a large scale.

**Royal Visit to Kew.**—In the early part of last week Her Majesty Queen Mary, accompanied by His Royal Highness the Duke of Connaught, paid an unofficial visit to the Royal Gardens, Kew, and stayed for some time in the Azalea garden, admiring the Azaleas and Magnolias, and also in the Queen's Cottage ground, where the Bluebells covered acres of woodland with their azure blooms.

**The Dahlia in America.**—In an interesting bulletin on "Dahlias and their Culture," published by the New York Agriculture Experi-

ment Station, by Mr. F. H. Hall, it is stated that several plantations of from fifty to one hundred and twenty or more acres are to be found near the Atlantic seaboard, and that others, of hundreds of varieties, extend in an almost unbroken line of states to the Mississippi, while a few lie in the eastern foothills of the Rocky Mountains and a large number again in California, Washington, and Oregon. The Pacific Slope became, during the world war, and has continued since, one of the leading Dahlia-producing sections. From coast to coast, collections, some of them very choice, are grown in thousands of amateurs' gardens, and, yearly, increasing numbers of plants are seen in dooryards, lawn borders, and plant beds near city, village, and rural homes. An indication of the great interest in Dahlias in America at present is shown by the fact that in 1920 and 1921, 284 new varieties, from about fifty growers in fifteen States, were entered for test on the trial grounds of the American Dahlia Society, at the Connecticut Agricultural College. Probably as many or more varieties were announced by growers, but not presented to the Society for registration.

**Back-Yard Gardens in U.S.A.**—The late Mr. J. H. Patterson, Chairman of the National Cash Register Company, was a pioneer of industrial welfare and hygiene in his country. He started gardens for boys, giving them tools and seeds, and later formed schools of gardening, offering prizes and forming neighbourhood improvement associations. This work, which he commenced in 1894, was the beginning of the back-yard and vacant land movement in America. In 1917 there were 3,000 of these back-yard gardens at Dayton. Mr. Patterson also started similar gardens for girls in 1912.

**New Species of Pedicularis.**—Since the beginning of the great war, numerous species of Pedicularis collected in the Far East have arrived at the Herbarium of the Royal Botanic Garden, Edinburgh. The study of these specimens was entrusted to Mr. Gustave Bonati by Prof. Isaac Bayley Balfour, and the result of that study is now published in Vol. XIII, Nos. 65 and 64 of *Notes from the Royal Botanic Garden, Edinburgh*. Mr. Bonati describes thirty-four species or varieties of Pedicularis, and groups them into the series Longiflorae, Macranthae, Longipes, Oliganthae, Polyphyllatae, Pectinatae, Debiles, Paucifoliatae, Racemosae, Tristes, Lyratae, and Melampyriflorae. In his study of this genus Mr. Bonati determined eighty-two specimens collected by Mr. G. Forrest, five collected by Father Monbeig, thirty-three collected by Father Maire, one by Mr. Ridley, forty-one by Mr. E. Kingdon Ward, eight by the late Mr. Reginald Farrer, five by Mr. C. Schneider, and two by Mrs. Clemens. The particulars of these new species, together with *Phtheospermum auratum*, occupy forty-six pages. The issue quoted also includes descriptions of numerous new species of other genera of plants and a descriptive list of new Orchids of Yunnan and Northern Burma.

**Conference of Allotment Holders.**—A conference of allotment societies affiliated to the Agricultural Organisation Society within a radius of fifteen miles of Charing Cross will be held on Wednesday, June 14, at 6.30 p.m., at 40, Broadway, Westminster, S.W.1, to discuss the provisions of the Allotments Bill recently introduced to the House of Lords.

**The Jersey Potato Trade 100 Years Ago.**—An interesting side light is thrown on the condition of the Jersey Potato trade one hundred years ago in the *Times* of the 19th inst., in a paragraph from the *Times* of May 20, 1822. The paragraph reads as follows:—"A vessel with 40 tons of Potatos arrived here a few days since, from Jersey, for which the master had given in that island 20s. per ton; immediately on her anchoring she was visited by a speculator in the article who purchased the cargo at 45s. per ton; on his way from Spithead to the Point he met a second speculator, who gave him 50s. per ton, which the third purchaser retailed in a few hours after the arrival of the vessel.

\* "The Effect of Bordeaux Mixture on the Rate of Transpiration. *Annals of the Missouri Botanical Garden*, Vol. 11, 1918.

at 80s. per ton. If they were sold retail at the then market price £7 6s. 8d. was obtained for what a few days before cost twenty shillings.

**Legacies to Gardeners.**—Mr. Dudley Stuart White, of Dockelle House, Penrith, Cumberland, who died on March 31, aged 62 years, leaving estate of the gross value of £9,263, and net personally £7,571, bequeathed all his property equally between his gardener, Mr. Thomas Robinson, and his housekeeper, Mrs. Ellen Clarke, and nominated them as executor and executrix.—Dame Sarah Elizabeth Moreshead, of Tregaddick, Blisland, Bodmin, Cornwall, and of Forest Lodge, Binfield, Berkshire, who died on April 7, aged 78, left an annuity of £100 to her gardener, Mr. G. Jacobs, and a life annuity of £80 to her second gardener, Mr. Henry Day.

**British Empire Exhibition of 1924.**—Considerable progress has already been made at Wembley Park with the arrangements for the great British Empire Exhibition to be held there in 1924. Many large beds and groups of Rhododendrons, which had been overgrown with Brambles and weeds, have been effectively cleared of intruders, and promise, in due course, to become features of beauty in the grounds. Some fine groups of *Prunus Pissardii* have also been rescued, and the undergrowth has been cleared from some of the finer trees so that their beauty may become fully developed. Building and excavating in connection with the Stadium, which is to hold 130,000 people, has already commenced, and the turf on the putting greens and fair-way of the old golf course is being carefully preserved for use during the coming autumn to provide the green sward on the five acres of playing area within the Stadium. Near the Wembley Park Station entrance a large lake offers exceptional opportunities for the display of plants and flowers which are naturally associated with water scenery, and it is hoped that the authorities will take full advantage of the facilities this fine sheet of water affords.

**Spring Flowers in Hyde Park.**—On a recent occasion in the House of Commons Viscount Curzon asked the Hon. Member for the Pollok Division of Glasgow, as representing the First Commissioner of Works, whether any steps had yet been taken to restore the flower-beds in Hyde Park in conjunction with any large horticultural firms. In replying for the First Commissioner of Works, Sir John Gilmour stated that a generous gift of British-grown bulbs had been made to Hyde Park through the Chamber of Horticulture. The question of restoring the flower-beds in that park in conjunction with large horticultural firms had been considered in the past, but there proved to be many serious objections to the proposal, including the cost to the firms. He said the First Commissioner would be willing, however, to reconsider the matter carefully should any proposal be made. Our readers will remember that a number of Gladioli presented by Dutch growers were used in the flower borders of Regent's Park last season, and that the Chamber of Horticulture offered to provide a quantity of Daffodil and Tulip bulbs for the flower beds in Hyde Park. This offer was accepted, and at the present moment the Tulips from these British-grown bulbs are providing a fine floral picture, the leading varieties being Clara Butt, Mr. Farncombe Sanders, Bartigon, Pride of Haarlem, Caledonia, Inglescombe Yellow, and William Copeland.

**Iris Exhibition and Conference at Vincent Square.**—In connection with the special Iris Exhibition and Conference to be held by the Royal Horticultural Society at Vincent Square on Wednesday and Thursday, June 7 and 8, three classes will be provided for new seedling Irises shown by the raisers and not yet in commerce, *i.e.*, not yet offered in any catalogue. These classes are (1) three spikes of one seedling (prize presented by Messrs. R. W. Wallace and Co., Tunbridge Wells); (2) one spike each of three seedlings (prize presented by Messrs. C. G. Whitelegg and Co., of Chislehurst and Orpington); (3) one single spike of a new seedling (prize presented by Mr. Amos Perry, Enfield). Entries for these classes should be sent so as to reach the Secretary of the R.H.S. not later than

Friday, June 2. All varieties shown must be named, and all exhibits must be staged not later than 10 a.m. on Wednesday, June 7. At 5 p.m. on June 7 there will be an informal conference on Irises, when Mr. W. R. Dykes will give an account of the Paris Conference, and invite discussion on any topics or plants of interest. On Thursday, June 8, there will be a meeting at 11.30 a.m., when Mr. F. J. Chittenden will explain the scheme of Iris classification recently published by the society. At this special meeting all growers of Bearded Irises are invited to send specimens of the varieties they have in flower in order that they may be arranged in the hall in accordance with the classification scheme.

**Mr. George Yeld.**—From his youth up, Mr. George Yeld, formerly of York, and now of Oundle, has been a gardener, but his scholastic duties and his work as an alpinist have somewhat obscured his horticultural activities, or rather, have not permitted him to come prominently before the horticultural world. Over a quarter of a century has passed since we first made Mr. Yeld's acquaintance at York Gala. He was then busy at work on the improvement of *Hemerocallis*. Mr. Yeld was educated at Brasenose College, Oxford, and in

MR. GEORGE YELD.

1867 went to St. Peter's School, York, as assistant master; here he taught for fifty-two years, and for about half that period was second master. In his little garden at York he grew Day Lilies and Irises extensively, made crosses and raised seedlings, and many of the latter were grown, after first flowering, in Messrs. Backhouse and Sons' nurseries. Mr. Yeld was quickly successful with *Hemerocallis*, and his variety *Apricot* is still a popular border plant. But even greater success attended his work among Irises, and, if he had done nothing else but raise *Lord of June*, *Neptune*, *Asia*, and *Prospero*, he would deserve well of all lovers of first-class plants. In 1919 and again in 1920 Mr. Yeld was awarded a gold medal at York Gala for seedling *Hemerocallis* and Irises of his own raising. Mr. Yeld is an occasional contributor to these pages, and his "*Lilies of the North*," contributed to the Lily Conference, and his "*Hybrid Hemerocallis*," contributed to the Third International Conference on Genetics, are papers of special value, but Mr. Yeld's literary work includes that of editing the *Alpine Journal* for twenty-five years. It was in 1877 he joined the Alpine Club, and for several years in succession he explored the Eastern Graian Alps, his experiences being given in an interesting little volume entitled *Scrambles in the Eastern Graian Alps, 1873-1897*. With

Mr. G. P. Baker he visited Daghestan (Eastern Caucasus) in 1890, and made the first ascent of Basardusi, 14,722 feet—the monarch of that part of the Caucasian chain. History and sport have claimed some of Mr. Yeld's attention, and in his retirement he finds recreation in golfing and gardening; we feel sure, however, that, in Iris time, sport will not make such progress as art.

**Bluebells and Lilac at Kew.**—Favoured by the summer weather of Saturday and Sunday, May 20 and 21, large numbers of people visited Kew, where they found the Bluebells in perfect condition in the Queen's Cottage grounds. The Lilacs, in various parts of the gardens, and particularly near the Temperate House, provided another beautiful and fragrant attraction, while the Azaleas furnished gay colouring, and many Rhododendrons were in bloom. The Chestnut trees at Kew, and also at the not far distant Busby Park, were already beautiful, but will not be at their best until Sunday, May 28.

**Underground Water Levels.**—In an interesting communication to the current issue of the *Meteorological Magazine*, Mr. Spencer Russell states that to judge by the present condition of the chalk walls at Detling, to the north of Maidstone, it is practically certain that there will be hardly any yield of water during the coming summer. Regular observations, covering a period of nearly forty years, of the water level in a well at the Croft, Detling, show that the saturation level is usually highest between mid-March and mid-April, and is succeeded by a gradual decline to the lowest position in November or December. On March 1, of this year, the saturation level was only three inches above the well bottom (the well is 112 feet in depth, in chalk throughout), and the well became entirely dry on March 21, a condition of affairs which is still maintained, though it has never before occurred, at this season, during the past seventy years. It is on record that the supply failed in 1858, and again in 1902; the well was dry throughout December of the latter year, a rise set in, however, during the first week of 1903, and by mid-April, the saturation level was ten feet above the well bottom. In another well, half a mile south-west of the Croft, dug in the chalk, and just reaching the gault at a depth of sixty-three feet, the yield failed on October 3, 1921, the well continuing dry to March 20, 1922. On March 27, two inches of water were recorded, eighteen inches on April 3, twenty-four inches on April 10, and twenty-five inches on April 17. On April 24, the water had fallen to fifteen inches, showing a definite decline in the saturation level of ten inches.

**Edmonton to Peace River and North-West Territories.**—A very informative guide, entitled *Peace River Guide*, sent us by the Superintendent of Emigration for Canada, deals with the Peace River basin, in which is situated the important township of Edmonton, the capital of Alberta. The district is an important one agriculturally, and the value of its produce and life stock in 1920 amounted to \$184,415,554.98. In Edmonton, is the important nursery of Messrs. Walter Ramsay, Ltd., which is claimed to have the most northern glasshouses in America. The province of Alberta alone has an area of 255,580 square miles.

**Bath and West and Southern Counties' Show.**—The exhibition of the Bath and West and Southern Counties' Society, to be held at Plymouth on June 1, 2, 3, 5 and 6, will include many exhibits of interest to horticulturists. In addition to a horticultural exhibition, there will be demonstrations of the conversion and utilisation of English timber; practical instruction in beekeeping, by the Devon Beekeepers' Association; an address by Prof. D. A. Gilchrist on "Seeds, Mixtures, and the Improvement of Grass Lands"; a small-holders' exhibition on Saturday, June 3, and demonstrations showing grafting and pruning on the Whit Monday. Besides exhibits of agricultural produce, cattle, sheep, goats, pigs, etc., there will be classes for implements, machinery, forestry, nature study, and handicrafts.

## NOTES FROM WISLEY.

A SEVERE frost in mid-May is greatly dreaded by gardeners, and justification for this fear was furnished at Wisley on the night of May 12, when 14° of frost were registered on the grass. The damaging effects were most evident among the Potatoes and the Pear blossom, while the flowers of some of the Azaleas out in the open were blackened. The more protected specimens in the wood were not touched, and the promised gorgeous display of bloom was not checked.

Though the scent of some individual varieties of Azalea is delightful, the combined odour of Azaleas which fills the wood is not altogether pleasant, and is suggestive of decaying vegetation. On the whole, Azaleas have come through the year of drought better than the Rhododendrons.

A smaller shrub, and one suitable for the rock garden, is *Cydonia Sargentii*; the flowers are bright orange red, and the fruits make a good conserve.

Although it has recently been cleaned out the pond at the foot of the rock garden is again covered with the leaves and flowers of the Cape Pondweed (*Aponogeton distachyon*). This pretty plant has curious inflorescences which look like little white boats on the water, and are very fragrant, accounting for the alternative name of "Water Hawthorn." *Aponogeton* appears to be rather curious in its likes and dislikes, and often refuses to establish itself in certain ponds. The presence of lime seems to be fatal to success with this plant. Where, however, it does succeed, the Cape Pond weed may grow so freely and spread so rapidly as to need thinning occasionally.

FIG. 142.—IRIS DOMINION EXHIBITED AT THE CHELSEA SHOW BY MESSRS. R. WALLACE AND CO.

Among the latter, *Rhododendron kewense* (a hybrid between *R. Hookeri* and *R. Griffithianum*) is flowering well; the flowers are large pale pink, and pleasantly scented. Another distinct and well-known *Rhododendron* in flower is *R. Thomsonii*, with semi-glaucous leaves and blood-red flowers. In a normal season it flowers much earlier. Other flowering shrubs are similarly late; the deliciously scented *Viburnum Carlesi* has not long been in flower, nor has the Snowdrop Tree (*Halesia tetraptera*) which, like *Excochorda grandiflora*, is planted far less than it deserves.

The *Halesia* is given its older name of *carolina* in *Trees and Shrubs, Hardy in the British Isles*, which was conferred on the plant by Linnaeus before Ellis adopted the name of *tetraptera*.

Near the higher rock pools the beautiful *Caltha polypetala* is to be seen. The flowers are very much larger than those of our native *C. palustris*.

One of the best of the *Polygalas*, *P. Vayredae*, is happy looking, the flowers being magenta, with a touch of yellow. The yellow *Linum capitatum* is also in bloom, and *Veronica pyroliformis*, a rare plant, is also flowering finely.

In the Alpine house is a collection of *Saxifrage*s, some of which were shown at the fortnightly meeting of the Royal Horticultural Society on the 9th inst. Here also is to be seen *Lewisia Howellii*, and *Ranunculus aconitifolius*—"Fair Maids of France"—seldom seen nowadays, though at one time a favourite in cottage gardens. *J. E. G. White*.

**Popular Flowers in India.**—Mrs. Bryan, wife of Rev. Alison Bryan, of the American Presbyterian Mission, and daughter of Mr. W. Outhbertson, sends a note of flowers in bloom at the end of April in Ootacamund, Southern India, which is, of course, in the hills. She writes: "Last evening we visited the Botanic Gardens. As we are accustomed to the bareness of the plains the gardens seem beautiful, and they are especially interesting to me because of the great number of old friends among the flowers. *Pelargoniums* grow everywhere in great profusion, and climb up over bushes and houses just as *Roses* do at home. Just at present there are great masses of bloom everywhere. Other old friends I was glad to recognise were: *Lupins*, *Delphiniums*, *Petunias*, *Candytuft*, *Sweet Williams*, *Pentstemons*, *Irises*, *Foxgloves* and *Nasturtiums*. I saw the finest *Sweet Peas* I have yet seen in India, but that is not saying much! I am going to buy some acclimatised seeds and try them at Kodai. The little garden round the house where we are staying is very gay in spite of the fact that rain is badly wanted—*Roses*, *Pelargoniums*, *Begonias*, *Pentstemons*, *Hollyhocks*, *Pansies* (very small), *Heliotropes*, *Hydrangeas*, *Cosmos*, *Honeysuckle*, and many others make a very gay colour scheme. Fruit here is also very fine, and we greatly enjoy it. So far we have *Mangos*, *Tree Tomatos*, *Plums*, *Peaches* (small and very bitter but refreshing), *Pears*, and the usual *Bananas* and *Papai*, as well as *Pineapples*."

**Appointments for the Ensuing Week.**—Monday, May 29.—Wakefield and Northern Tulip Society's show (two days). Wednesday, May 31.—Irish Gardeners' Association's meeting; Elgin Horticultural Society's meeting. Thursday, June 1.—Linnean Society's meeting at 5 p.m.; Bath and West and Southern Counties Society's show at Plymouth (five days). Friday, June 2.—Paisley Florists' Society's meeting; British Mycological Society's spring Foray at Norwich (five days). Saturday, June 3.—Darwen and District Agricultural Association's Hort. Show.

"**Gardeners' Chronicle,**" Seventy-Five Years Ago.—*British Queen Strawberry.*—Much diversity of opinion exists among gardeners as to the best variety of Strawberry for forcing. I have tried Keen's seedling, *Alice Maude*, *Prince Albert*, and others, but I can find none to equal the *Queen* in flavour, quantity, and size. I commenced the early part of January for my first crop, which ripened off nicely by the end of March; and for my second in February, which is nearly over. I gathered the other morning from half-a-dozen 8-inch pots twenty-two Strawberries, weighing 10½ ounces; seven from one plant weighed three ounces; several weighing more than three-quarters of an ounce, being 5 inches in girth. I have others that bid fair to weigh an ounce. The compost I use is one-third old lime rubbish, one-third burnt turf, and one-third leaf mould and rotten dung, using a good drainage. I was led to use lime from noticing the *Alpine* to grow freely on old walls. The plants were lifted, and potted in 5-inch pots, shaded for a few days, and afterwards fully exposed. They were repotted into 8-inch pots, and watered with manure water occasionally during summer. In repotting I am careful to elevate the crown of the plant. Perhaps some of your correspondents may state how *Strawberry* forcing has succeeded with them this season.—*E. Shepstone, Charlton Gardens, May 1, "Gard. Chron.," May 29, 1847.*

**Publications Received.**—*Early British Botanists and their Gardens.* By R. T. Gunther, University Press, Oxford. Price £2 2s. *County Court Practice Made Easy.* By a Solicitor. Eppingham Wilson, 16, Copthall Avenue, E.C.2. Price 4s. net. *Hardy Perennials.* By A. J. Macself. Thornton Butterworth, Ltd., 15, Bedford Street, Strand, W.C.2. Price 7s 6d. net. *Fruit Foes.* By T. W. Sanders. *Vegetable Foes.* By T. W. Sanders. W. H. and L. Collingridge, 148, Aldersgate Street, E.C.1. Price 4s. 6d. each. *Olive Growing.* By C. F. Kinman. Farmers' Bulletin 1249. Government Printing Office, Washington.

## The Week's Work.

### FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Ligfield, Surrey.

**Vines Eyes.**—Vines raised from eyes of the previous year, and intended for cutting back or planting out next spring, should receive their final shift into 7-inch pots. Having been grown in bottom heat, the compost, consisting of fibrous loam, lime-rubble, and a little bone-meal, should be warm and dry enough to bear ramming well. See that the ball of soil and roots is moist before the plants are turned out of the pots, as no amount of watering afterwards will restore them to a proper growing condition. Replunge the vines in a bed with gentle bottom-heat, syringe them lightly, and shade them from bright sun for a few days until fresh root action has commenced. The temperature by night may range between 65° to 68°, and that by day 75° to 80°, air being admitted and the ventilators closed again in time for the temperature to rise to 85°. When the pots are filled with roots, the latter will require plenty of water and weak liquid manure. It will be necessary to syringe the canes to prevent red-spider from attacking the foliage.

**Spring Planting of Vines.**—Vines may be planted as late as the first or second week in June, and with favourable weather the canes will make rapid progress, provided they are well rooted. A border 4 feet wide and 2 to 2½ feet deep, resting on ample drainage, is quite large enough for the first year. Plant shallowly, packing a little of the warmest compost firmly about the roots with the hands. Cover the surface of the ball with one inch of soil, and train the roots carefully in the desired direction. When the vines have started into fresh growth a good soaking with water at a temperature of 85° through a rose will settle the soil firmly about the roots. Keep the house close, moist, and lightly shaded for a few days until the vines recover from the disturbance.

### THE KITCHEN GARDEN.

By JAMES E. HATHAWAY, Gardener to JOHN BRENNAND, Esq., Baldersby Park, Thirsk, Yorkshire.

**Tomatos.**—Plants raised from seed sown in March should be ready for planting out-of-doors. If a border under a wall is not available some other sheltered position should be selected. If the plants have not been well hardened defer planting them for a week or so; the larger the plants are the better. An excessively rich soil is not desirable, as it is better to mulch and feed the roots after the plants have set their first clusters of fruit. Put the plants 2 ft. apart and make the soil moderately firm. Keep the plants to one stem and remove the side shoots as soon as they are big enough to be nipped out.

**Ridge Cucumbers.**—Place a heap of litter, leaves and any garden refuse in a warm spot, and set Ridge Cucumbers on it about 15 inches apart. The heap should be covered with old potting soil about 1 foot deep.

**Vegetable Marrows.**—If these plants have been hardened they should now be planted out in trenches at 3 feet apart.

**Broad Beans.**—A final sowing of Broad Beans should be made, choosing the green seeded type, such as Sutton's Green Giant. Remove the tops from Broad Beans in flower.

**Watering.**—Newly planted crops are often ruined through neglecting to water them in dry weather. The plants should be damped overhead both night and morning; the later in the evening the better. Seed beds and seedlings should also be carefully watered.

**General Remarks.**—A sharp watch should be kept for slugs, mice and birds, as they quickly ruin the crops.

### HARDY FRUIT GARDEN.

By H. MARSHAM, Gardener to the EARL OF STRAFFORD, Wrotham Park, Buret.

**Protecting Materials.**—Gradually remove protective materials from Peach and other trees where the fruits have set, the leaves now being sufficiently forward to serve as a protection against any further frost. Blinds should be rolled up carefully when perfectly dry and stored until they are wanted another season, fish netting that will be required for the protection of ripe fruits of Strawberries, Raspberries, etc., should be gathered up and numbered according to size and quality to prevent confusion when the time comes for their use. All poles, boards and other things that have been in use should be stored carefully at once.

**Peach and Nectarines.**—These trees have set a very satisfactory crop of fruits, but, owing to cold nights, the latter are not swelling so fast as could be wished, and the growth is much retarded. Disbudding should not be done too severely for the present.

**Mulching.**—The drought of last year will long be remembered by fruit growers, and especially where the land is light and resting on sand or gravel. Those who mulched the roots of their trees early were well rewarded for their labour, both the fruits and growth being greatly benefited. I would strongly advise growers to be on the safe side by mulching their trees early. If the surface soil is very hard it should be slightly pricked over with a fork before applying a mulch of half-rotted farmyard manure. Trees growing on south walls and bush trees should be the first to receive attention. Young, vigorous trees, and any that are lightly cropped, growing on deep land, will not need mulching. Remove all suckers springing from the roots of Plums and Peaches at an early stage of their development. In some cases it will be necessary to remove a little of the surface soil, especially if the suckers are numerous, and cut the latter off as close to the roots as is possible.

### THE ORCHID HOUSES.

By J. T. BARBER, Gardener to His Grace the DUKE OF MAREBOROUGH, K.G., Blenheim Palace, Woodstock, Oxon.

**Epidendrum vitellinum.**—This brightly coloured Orchid may be grown in a cool house the whole year round. There are summer and autumn-flowering varieties. Many failures to grow these plants successfully may be attributed to the use of too much fire heat; few Orchids will stand a much lower temperature provided the compost is in a dry condition. Repotting is best done when the new growth begins to send forth fresh roots. Shallow pans half-filled with drainage material form the best receptacles. Very little moisture is needed at the roots when the season of growth is completed.

**Summer Quarters.**—Those plants which succeed best in an equable temperature the whole year round may, notwithstanding it is late in the season, be removed from the intermediate house, where they have passed the winter, to the cool house, where they may remain until the autumn. They include *Laelia harpophylla*, *L. pumila*, *L. praestans*, *L. Jongheana*, *L. Dayana* and others, also *Dendrobium infundibulum*, *D. Jamiesianum*, *Odontoglossum Kramerii*, *O. naevium*, *Miltonia vexillaria* and its hybrids, as they pass out of bloom, also *M. Phalaenopsis*, *M. Endresii*, and *M. Schröderiana*, with *Ada aurantiaca*, and many others which will succeed best during the winter in a light position in the intermediate house. During the summer or the hottest months they prefer the conditions found in a cool house. The most suitable time to remove them will vary in different districts, but it may safely be done when the temperature of the cool house rises to 60° without the aid of fire heat. For some little time after removing them it is advisable to keep the plants a trifle drier at the roots than they have been in the warmer division. Some *Masdevallias* thrive remarkably in these conditions, especially those of the *M. Chimaera* section, *M. tovarensis*, and a few others. Removing them also affords an opportunity of observing the presence of insect pests.

### PLANTS UNDER GLASS.

By T. PATEMAN, Gardener to Sir C. NALL-CAIN, Bart., The Node, Codicote, Welwyn, Hertfordshire.

**Azaleas.**—Plants that were forced into flower early will have almost completed their season's growth, and any that require repotting into larger receptacles or top-dressing should be attended to forthwith. Good fibrous loam and peat in equal parts, with a liberal dash of silver sand added, will provide a suitable compost for these plants. After repotting keep them in a moist atmosphere for a short time; afterwards harden them gradually until they are finally stood out-of-doors, where they may remain during the summer, but given shade from the mid-day sun. Examine the plants for thrips, and should any of this pest be detected lay the plants on their sides and spray them with nicotine-emulsion, letting the insecticide well wet the under sides of the leaves.

**Cyclamen.**—Young plants of Cyclamen that were raised from seed sown last August, and have been grown on as advised, should be ready for their final potting. The compost should be of an open nature, and consist of good, fibrous loam and leaf mould in equal parts, with plenty of sand, broken charcoal, and a little bone-meal added. Cyclamens require moisture, but they fail to grow satisfactorily in water-logged soil. After potting, the plants may be stood in a cold frame on an ash base near to the glass. They should be sprayed lightly overhead both night and morning. Close the frames early in the afternoon until the plants have become well established in the new soil, and shade them from bright sunshine. When the evenings become warmer the lights may be removed during nights when rain is not expected.

**Euphorbia pulcherrima (Poinsettia).**—Stock plants of Poinsettia that were introduced into heat to produce cuttings are breaking into growth freely. The cuttings should receive the same treatment as advised in a previous calendar for those of *Euphorbia jacquinaeflora*.

### THE FLOWER GARDEN.

By EDWIN BECKETT, Gardener to the Hon. VICARY GIBBS, Aldeham House, Hertfordshire.

**Tree Paeonies.**—These Paeonies have developed fine growth, and are advancing to the flowering stage. During the present month care should be taken to protect the growths from frosts, as they are somewhat tender. They form beautiful specimens in the shrubberies, where undoubtedly they are seen to the greatest advantage, with their magnificent large flowers of various hues. Growths from the stock on which they are grafted should be removed.

**Antirrhinums.**—These old-fashioned favourites, of which there are many lovely named varieties, should be planted out this month. They form admirable beds by themselves. The spikes are most useful for cutting for vase decorations, and, where grown for supplying cut blooms they should be planted out in rows, with a thin stick to each for support, which in its turn should be secured to stout string running along the rows and attached to stouter stakes.

**Border Chrysanthemums.**—These plants should now be set out in their growing quarters. They make good beds, in a similar way to Antirrhinums, and are useful for supplying blooms late in the season. When planted, carefully stake and support the plants, and frequently, during their growing period, look over them with a view to supporting any shoots that need it.

**Dahlias.**—In the less favoured districts Dahlias have not yet been planted out, as the young plants are decidedly tender, but this can now be carried out provided the plants have been well hardened. We grow them at Aldenham chiefly in reserve beds for cutting purposes, and choose for their quarters a good, deeply-worked soil, that is fairly rich, as they are somewhat gross feeders. From the time they are planted they should be supported securely by means of stakes that are sufficiently strong for the class of plant, as they form heavy tops when in flower, and the growths are very brittle, being easily damaged by strong winds.

## NOTES ON TULIPS.

As I write these lines we are in the midst of the out-of-door Tulip season of 1922. The "earlies" are getting past their best. Already Pink Beauty is in full blow, and Le Rêve and Couleur Cardinal are more than showing colour. One is aware, too, that such Darwins as Fra Angelico, Allard Pierson, Jeffries, and Sieraad van Flora are getting ready, and will not be long behind. Nowadays from early April until somewhere about the third week of May there are few gardens which are entirely devoid of Tulips. What a show they make!! How they would be missed!! There is a rare Dutch book called *Dapes Inemptae*, by Petrus Hondius, published at Leiden in 1621 (that is fourteen years before the famous mania time), which in many ways is the counterpart of our Thomas Tusser's *Five Hundred Points of Good Husbandry*, treating, as it does, of the ordinary life of the country. The author is very sarcastic about the growing fondness for Tulips. This is what he says:—

"Here in Netherland  
One can find at hand,  
So many fools who in their gardens  
Solely praise this flower."

And again:

"Fools who build their gardens  
For one flower and no other."

Old Hondius must have been one of those people who never let themselves go. Accordingly he had not much sympathy with those who scrapped all other plants to make room for Tulips. Possibly it was wanton of them to neglect herb growing. Herbs were so much more useful, and there were no motor-cars, and doctors and chemists were none too plentiful. All the same, he had a few Tulip beds:—

"In my garden five, six beds  
For tulips have been raised."

Most of us to-day copy the old Dutchman. We grow other things, but we must find room for some Tulips.

My purpose in this article is to suggest a few varieties which I would like those who have not already grown them to try. They are a promiscuous selection taken haphazard from different sections as my fancy dictates; *Tulipa dasystemon* (1). This is a dwarf plant, growing about six to eight inches high, with pretty, simple-looking yellow and white flowers, which always remind me of the bee-loving annual, *Limnanthes Douglasii*. Unlike so many of the species which have come to us from Mid-Asia, it has a splendid constitution, and in my garden seeds freely. It is a good plant for the rock garden. Pink Beauty (2). There is only one thing to say about this early Tulip, and that is, that it is one of the very best in this section. Personally, I think Rose Beauty would have been a more appropriate name. It is only in its younger stage that there is any pink about it. Fully developed it has petals of the deepest rose, with a big flame of white on their exterior. It is a Tulip which emphatically has a smart, well-groomed appearance.

Monsieur S. Mottet (3). At last I am told that this variety is being again offered by the trade, so doubtless some of our retail houses will have it in their catalogues this autumn. It was in that of Messrs. James Carter and Co. a few years back, but they dropped it because customers complained that it did not branch as it was advertised to do. Branching with this Tulip depends on good cultivation in rich soil, and it may be also, seeing what has happened to mine last year, on a plentiful supply of sun. It is a fairly tall grower, with long, egg-shaped flowers, which flush with age. There are several on a stem, and as they are borne at different heights a bed of them is not the rather stiff affair that a bed of most other Tulips is.

The variety Boadicea (4) is one of the finest of all cottage Tulips. It has large, mahogany-red flowers, edged with deep orange, borne on fairly

tall stems. They are long in shape, and their petals are bluntly pointed. Everyone likes Boadicea when they come round my garden. It is exceedingly handsome as a cut bloom. Salomon (5). This is classed as a Dutch breeder, or in some catalogues, where that distinction is not made, it will be found under the Cottage section. It features in colour and shape the Darwin Euterpe. It is a beautiful clear rosy mauve, with a pure white base, just as if it were one of our own florist's Tulips. Cramoisi Royal (6). On the recommendation of Mr. Bull, of Ramsgate, I planted a bed of this variety last autumn. For an "early" it is a tall grower, like Prince of Austria. It belongs to the same colour section as the well-known Proserpine. It might be described as a pigeon's-blood-ruby red. It has

(several) have an equal fascination when used as purely decorative flowers in vases.

Illuminator (9). Everyone knows what a good cottage Tulip Golden Crown is. Illuminator is a sort of improved Golden Crown with rather brighter colouring. It comes into bloom a few days later. Marconi (10.) Which is it to be of the dark-purple Darwins? It is impossible in any ordinary garden to grow them all. There are Marconi and Courbet; Giant and Gryphus; St. Simon and Vespuccio; Viola and Viking; which is it to be? After Moralist and The Bishop we might, if we wish for a redder-toned purple, try Marconi. It has a large flower of fine form and substance; grows two feet and a half high; and lasts well. Rose Tendre (11). This is an early Tulip of the

FIG. 143.—PERPETUAL BORDER CARNATIONS EXHIBITED AT CHELSEA SHOW BY MESSRS. ALLWOOD BROTHERS. BRILLIANT—ROSALIND—HIGHLAND LASSIE.

come in for much admiration, and I agree with my visitors about the colour, but the flowers have, many of them, a curious habit of nodding, not because the stem is at all weakly, but just as if they had from some unknown cause a stiff neck. It may only be the result of the inclement spring. I will have to "winter" and "spring" it a second time before I know. Hypoute (7), the Darwin, wants bringing out of its obscurity. It is a beautiful silvery mauve; I have watched it now for some years, and familiarity has gained the old proverb, and bred nothing but admiration.

Do Little (8). This fine old Tulip is a precious relic of a past age when Tulip shows were all the rage in very many parts of England. Alas! it passed out of favour with the florists because its shape was wrong, and its pretty, rosy-red markings were too irregular. All the same, it makes a most effective cut flower, with its bright splashes and blobs of colour on a pure white ground. Neither Mabel nor Mrs. Collier nor Annie Mac (Do Little's modern coun-

Cottage Maid type. It is absolutely first-class in pots and for forcing. It is also a good bedder if placed in a suitable position. Pinks do not look their best in a garden unless they can be seen more or less against the sun. I cannot appreciate them when I see them with a bright sun more or less behind me. It seems to take away all their good looks, and they appear insipid and faded. The point of view from which pink Tulips are to be seen should be studied. Marksman (12). If is a bright orange-scarlet flower is wanted Marksman is the very thing. A bed of it by itself spells splendour. It is the same colour as the old British army. Sentiment and sight recommend it. It has not the stature of Ronald Gunn and other tall Darwins, but it is none the worse for that, though one does not always want giants in one's beds. Another point about these lower growing Tulips is that when they occupy a bed all to themselves there is no necessity for any carpet plant below them—Marksman certainly does not. Brilliance unadorned is brilliance's self. *Joseph Jacob.*

**EDITORIAL NOTICE.**

**ADVERTISEMENTS** should be sent to the **PUBLISHER, 5, Tavistock Street, Covent Garden, W.C.2.**

**Special Notice to Correspondents.**—The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.

**Letters for Publication,** as well as specimens of plants for naming, should be addressed to the **EDITORS, 5, Tavistock Street, Covent Garden, London.** Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

**Local News.**—Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

**Editors and Publisher.**—Our correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the **PUBLISHER**; and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the **EDITORS.** The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.

**Illustrations.**—The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.

## CHINESE CLIMBERS AT ALDENHAM.

HAVING dealt already with some of the most noteworthy and beautiful of the more or less erect Shrubs discovered by Mr. E. H. Wilson during his Chinese travels, I now follow with a selection of climbing plants among which are to be found some of the famous collector's most striking discoveries.

**ACTINIDIA.**—Although known to both Fortune and Mariès, we really owe the present existence in our gardens of *Actinidia chinensis* to Wilson. It has probably the largest and most ornamental foliage of the genus, and, in its native home is highly esteemed for its Gooseberry-like, edible fruits. The upper surface of the leaves is dark green, the underside very hairy, and of greyish tone, whilst the young shoots are clothed with conspicuous red hairs. *Actinidia venosa* is another good species, well adapted for any position where a rapid climber is required. The fine foliage is seen to advantage when clothing, as at Aldenham, a stout Larch pole in the shrubberies.

**CELASTRUS ANGULATUS.**—An admirable climber, of strong growth, well adapted for covering old tree roots, or for any position where the rambling shoots can be naturally disposed. The large, handsome leaves are sufficient to make this a desirable addition, but its freely produced fruits have been found at Aldenham to be highly decorative, as is the case with so many of the older members of the genus. The seed cases are yellow, and open, when ripe, to reveal the vermilion-coloured fruits.

**CLEMATIS.**—*Clematis Armandii*, a remarkable evergreen climber, which was introduced by Wilson in 1900, and first flowered at Coombe Wood, has, fortunately, proved quite hardy at Aldenham, and is certainly one of the most striking members of a large genus, noteworthy for the many good garden plants it contains. It is a vigorous grower, requiring ample room to accommodate the rampant stems. Failing a suitable wall, or pergola, it may be grown successfully in the shrubbery, trained around rustic poles. The sweetly-scented, white flowers, each about 2 inches across, are freely disposed among the glossy green leaves in April, and change to rose with age. *Clematis montana rubens* introduced at the same time as the preceding, has proved one of the most charming of hardy, climbing plants. Although capable of covering large areas, it is well adapted to those of smaller dimensions, as the excellent

illustration in Mr. W. J. Bean's *Trees and Shrubs Hardy in the British Isles* shows, and even young plants blossom freely. On well-established specimens, the rosy-red flowers are produced freely in June, and the reddish colour of the foliage and young stems make it additionally attractive. *C. m. Wilsonii* differs from the well-known *C. montana* in its later blooming (July and August), and the greater size of the flowers, which are fully 3 inches across, and pure white. In addition to being one of the most beautiful of climbing plants, its late-flowering period gives it an added value. *C. nutans* is a free-growing species which cannot lay claim to great floral beauty; nevertheless it is a most delightful plant in the late summer and autumn, when the pale primrose-coloured flowers, which are bell-shaped, are borne in large numbers and emit a most pleasant odour of Cowslips. It is particularly happy when growing over old

FIG. 144.—*HOLBOELLIA CORIACEA.*

stumps, or similar rustic work. *C. Spooneri* is a handsome species, with fleshy leaves densely covered with yellowish, silky hairs, and carrying large white flowers of much substance. In its native habitat it is said to grow naturally over rocks fully exposed to the sun, and at Aldenham it enjoys a warm position.

**COCCULUS VARIABILIS.**—As the name implies, the foliage of this free-growing climber is variable in shape, but in general appearance suggests a Catalpa. The leaves are about 6 inches long by 4 inches wide. It is well worth growing for the fine, deep green, luxuriant foliage. The flowers are inconspicuous, and the fruits are described as black, with a blue bloom, produced in slender panicles about a foot in length.

**DRAGEA SINENSIS.**—For the more favoured parts of the country, this uncommon plant will

be a pleasing addition. At Aldenham it is grown on a south wall, and protected in winter, with the happy result that it grows and blossoms abundantly. The sweetly-scented flowers are white, with lilac markings, produced in umbels very much in the same way as those of *Hoya carnosus*, and are succeeded by very interesting green fruits not unlike small Cucumbers.

**HOLBOELLIA CORIACEA.**—To the small number of evergreen climbing plants which we now possess, this *Holboellia* (Fig. 144) is a welcome addition, and apparently a perfectly hardy member of the genus. At Aldenham it succeeds well when trained to a rustic pole in the shrubbery, where the glossy green foliage shows to advantage, especially during the winter season. I do not know whether it has flowered in this country, but Mr. Wilson states that the male flowers are white, the female purple, and the purple fruits of large size.

**LONICERA.**—On account of the persistent character of its foliage, *Lonicera Henryi* is a most useful Honeysuckle, and though the purple flowers are not conspicuous, these are succeeded by blackish-purple berries, which remain in good condition through the winter months, and make a better show than the flowers. *L. tragophylla* (Fig. 145) is very effective when grown on poles. This species, which I first saw flowering at Coombe Wood in 1904, has long, bright yellow flowers freely produced in terminal heads. They are among the largest and most conspicuous of any produced in this popular genus, but lack the well-known and delightful fragrance of the common Honeysuckle.

(To be concluded.)

## FAILURE OF SOUTHERN PLANTS TO COLONISE IN THE NORTHERN HEMISPHERE.

Sir Herbert Maxwell, in his interesting note on p. 245, refers especially to Australasian composites, and mentions the genera *Olearia* and *Senecio* as not colonising in the northern hemisphere. The composites are very generally self-sterile, and I suggest that this is the reason why no fertile seeds are produced by the plants in question. This, I think, may be the explanation, because from the probable methods of propagation all the plants of the same kind would merely be parts of the same individual. In this case good seed would most likely be impossible. No one knows how far the Compositæ are self-sterile, and it would form a very useful and interesting investigation to find out. I can answer for a few, especially the Canarian *Cinerarias*—which are *Senecios*. I have combined all introduced species with the common greenhouse *Cineraria* into one plant, while I know that a single plant of any one of them, with perfect pollen and perfect ovaries, is no better than dead for the production of pure seed if one wants to preserve the type of its species or any individual peculiarity. It is a curious fact that the most diverse species of some self-sterile genera, like *Passiflora* (self-sterile certainly in some species), and *Cineraria*, will readily cross, while individual plants are absolutely barren without extraneous pollen of some kind. The physiology of self-sterility appears to be quite unknown; Darwin's dictum that "Nature abhors perpetual self-fertilisation," does suggest a good reason why it should exist—and, indeed, it is exceedingly effective—but we do not know how it comes about. I may be forgiven, perhaps, if I make a further suggestion, hardly justified perhaps, because it has little or no application to the subject of Sir Herbert Maxwell's article. It is, if the seeds were good, they might be little likely to grow under the conditions they meet with. Quantities of good seed are shed in gardens that never germinate, while if gathered and sown in pots or pans they grow perfectly well. Kinds of Elm within my experience hardly ever come up from self-sown seed, but the same seeds grow readily if promptly sown in boxes.—*R. Irwin Lynch.*

## TREES AND SHRUBS.

### PRUNUS AMYGDALUS MACROCARPA.

Of all the Prunuses that have flowered here this year, none has created greater interest than *Prunus Amygdalus macrocarpa*. The flowers are over 2 inches across, very pale in colour, almost white, with a dark reddish centre. It is at once one of the most handsome members of its genus, and possibly the largest flowered. Why this magnificent variety is not more generally cultivated it is not easy to understand. It is, of course, a variety of the Almond, in which the flowers are very much larger than the type. It makes an excellent standard or low tree, and should be planted in a sunny lay with a background of dark evergreens. When grown against a background, say, of Conifers or Hollies the masses of flower are seen to best advantage. South-Western Suburbia is noted for the luxuriance and beauty of its flowering Almonds. The very mention of the name Almond brings to mind the observations by the late R. Hooper Pearson at Wandsworth on the time of flowering, and I am pleased to see the notes continued in these pages. The Almonds are among the most beautiful of all early-flowering trees, and provide a feast of soft pink colour. Not only are the flowers of *macrocarpa* much larger than the type, but the variety is notable also for its very large fruits, which are over 3 inches in diameter. This variety finds a place in Southern gardens by virtue of its large fruits. Like other Almonds it will produce good, eatable nuts in England, but it is for the beauty of its large and numerous flowers that it is specially recommended. *Herbert Cowley, Tunbridge Wells.*

## BEDDING OUT SIXTY YEARS AGO,

THE examination recently of old note-books, which contained lists of bedding plants used about sixty years ago, methods of arrangement, with plans of beds, and other cognate material, startled me on account of the changes that have taken place in flower gardening since then. At the period indicated "bedding-out" had reached its zenith, yet among the plants included there do not appear East Lothian Stocks, Violas, Snapdragons, Begonias, and others now so popular, while some rarely seen in these days enjoyed the esteem alike of gardener and employer. The former usually was hampered for space to keep plants through the winter, for means of propagating in spring, and for bringing them forward to the time of planting. It is not unbelievable that there existed among gardeners a foolish desire to extend this kind of floral display to extreme limits at the expense of other departments, thus adding largely to their responsibilities and labour.

At the same time, these lists demonstrate how the oft-repeated assertion that flower gardens were furnished almost solely with scarlet Geraniums, blue Lobelias, and yellow Calceolarias is inconsistent with fact. The names of the plants used are as follows: *Arabis lucida variegata*, *Ageratum mexicanum*, *Calceolaria* (two yellow and two brown sorts), *Centaurea ragusina*, *Fuchsia Madame Cornelson*, a variety with white corolla, upright habit, and, as I remember it, of such distinction that I would be glad to have it now. There were also *Gazania splendens*, *Pelargonium Cerise Unique*, six scarlet flowered sorts, of which Tom Thumb was dwarf, and Warren's Scarlet so tall that it had to be staked; two were rose-coloured, one white, three with variegated white leaves and two—Golden Chain and Mrs. Pollock—with yellow foliage. *Gladioli* were brought forward in pots, and planted with other bedding plants. There were eight kinds of bedding Dahlias, of which one apparently was a pompon, named German Daisy, and sixty show and fancy varieties planted in conjunction with Double Hollyhocks and Sweet Peas. Of *Heliotrope*, two kinds were set out in beds by themselves, as such a sweet-smelling flower demanded. *Humea elegans* was used for pot plants. *Koniga variegata*, *Perillanankinensis*,

*Saponaria calabrica*, and its white form, and *Verbenas*, in five colours by name, of which the largest number were of Purple King, were others.

In addition to all these, there were Ten-week Stocks, Asters, *Phlox Drummondii*, Marigolds, and other short-lived plants, odd specimens of scented-leaved *Pelargoniums*, laeod Pinks, florist Carnations, and a large collection of Roses. Plans of the beds show that many of these were standards arranged along the side of the flower garden, and each rising from a little bed, which was carpeted with some dwarf-growing plant. The best of the Roses were Jules Margottin, Charles Lefevre, John Hopper, Général Jacqueminot, Senateur Vaisse, and Maurice Bernardin. The varieties mostly are described, and their qualities noted. *Mme. Désiré Giraud*, for in-

FIG. 145.—*LONICERA TRAGOPHYLLA* (SEE P. 270).

stance, is "white, striped with lively rose," a not unusual combination in an H.P.

Iron standards, with connections forming a continuous chain, was another feature of the garden, and these were furnished with "Ayrshires," no names of these being given. Only seven tea-scented Roses are named as grown, the inevitable Gloire de Dijon being one, with *Devoniensis*, *Maréchal Niel*, and *Souvenir d'un ami*, "deep rose," others. A rose hedge was formed of hybrid Bourbons: C. Duval, Charles Lawson, Coupe d'Hébé, Frederic the Second, Paul Péras, and Paul Ricaut. Mention is made of only one bed of Roses, and that furnished with a variety of H.Ps.

The arrangement of the bedding plants is meticulously described, spaced, and numbered. Many were set 15 to 18 inches apart, Dahlias and Hollyhocks as much as 6 feet, being planted alternately, the latter just a little behind the first named. Many of the beds contained only one kind of plant, some were edged, and the borders, not massed, but in single lines of one sort—hence called ribbon borders. One of these,

10 feet in width, was planted in this way. Commencing at the front the plants were *Geranium Golden Chain*, *Verberna Purple King*, "*Geranium*" *Bijon*, white-leaved; *Perilla nankinensis*, chocolate; *Calceolaria Kavi*, light yellow; *Geranium Prince of Wales*, scarlet; *Ageratum mexicanum*, blue; and *Dahlia albafloribunda*, white.

In addition to the plants named as occupying beds, etc., numbers of *Pelargoniums*, *Verbenas*, etc., are described, and were probably on trial. Some of these afterwards became popular. Novelties in Dahlias and Hollyhocks are not only described, but prices quoted, the latter being as much as 15s. each.

Most of the garden mould appears to have been trenched annually and liberally manured with one-half cow manure and one-half stable manure. The only fertiliser mentioned is guano, a note having reference to a foreman watering some newly-potted plants with water to which a handful of the potful of water was added!

A great deal of time was occupied in the spring months in shifting plants from one structure to another, and to frames. One recollects thousands of plants being rooted in manure-leached frames, splendid stuff, that might be considerably damaged subsequently for lack of provision to carry them forward. Vineries and Peach-houses had tiers of shelves on the back walls, and hanging shelves for the purpose. Scarcely any were forwarded in boxes or planted in frames, even *Calceolarias* and *Verbenas* being potted up.

Bedding plants are, of course, only one item in many noted. I find so many rods of Grape vines and their names, the same with Peaches, and rough sketches of pits, with dimensions, and the names of their occupants, also of the greenhouse and stove, mostly plants, scarcely any of which are now grown. Working hours were from 6 a.m. to 6 p.m., but in times of stress the writer noted how he rose at 4.30 a.m. to thin Grapes or to mow lawns. One night, as late as 10 p.m., he and another had to let down the blinds on all the walls as security against a sudden frost. One of his summer duties was syringing Peach trees on walls every day. Here and there are items of expenditure, and living cost little, if anything, less than before the war, but eggs were from 5d. to 6d. per dozen, and ham—not bacon—5d. per lb., which shows a difference. Wages were from 11s. to 14s. weekly, so that many things besides the furnishing of flower gardens have changed considerably in the intervening years.—*R. P. Brotherton.*

## ORCHID NOTES AND GLEANINGS.

### ODONTIODA HENRYI, ORCHIDHURST VARIETY.

FLOWERS of this superb, dark scarlet hybrid between *Cochlioda Noezliana* and *Odontoglossum harvengtense* (*crispum* × *triumphans*), sent by Messrs. Armstrong and Brown, Orchidhurst, Tunbridge Wells, represents one of the finest of this favourite class, and probably the largest, its flowers being equal in size and shape to those of a good *Odontoglossum crispum*, but of the clearest scarlet colour. A good strain of the cross was raised at Tunbridge Wells, and flowered in 1912, when Mr. Goodson showed it. Later, another batch, in which a finer form of *O. harvengtense* was used, was successfully raised, and proves very superior to the original.

### ODONTOGLOSSUM PURPLE QUEEN.

A FIRST flower of a very good novelty obtained by crossing *O. Delta* and *O. Corona* comes from C. J. Lucas, Esq., Warnham Court. *O. Delta* is between *O. Othello* (*Adrianae* × *Harryanum*) and *O. Rolfeae*, a combination which has proved very successful at Warnham Court. The flower is circular in outline, and broad in all the segments, which are pure dark violet in colour with a few very slight white markings. The lip is almost circular and flatly displayed, the area in front of the yellow crest being closely marked with violet colour; the front of the lip is white.

# ROYAL HORTICULTURAL SOCIETY.

## EXHIBITION AT CHELSEA.

May 23, 24 and 25.

A week-end of perfect summer weather, followed by a Monday of tropical temperature, is not the best possible prelude to a great Chelsea Show; but, no matter what the vagaries of the weather, whether spring be early or late, the Chelsea Show is always good, and a worthy demonstration of British horticultural skill. Fortunately, rain fell on the eve of the show, and this gave the out-door exhibits a much-needed refreshing shower, and laid the dust. The heat was so great on the day before the

variety and the numerous novelties were eloquent of the skill of the raiser and the collector. Orchids were numerous and beautiful, but scarcely up to the high standard set in 1921. Tulips were a special feature, as many years have elapsed since a display of these flowers was possible at the end of May. Rhododendrons and Azaleas were grandly represented by leading firms, and other flowering shrubs, either distinct or beautiful, filled considerable space. The old style of tables of hardy flowers has

Messrs. Jas. O'Brien (hon. secretary), Arthur Dye, J. E. Shill, A. McBean, W. H. Hatcher, T. Armstrong, Gurney Wilson, H. G. Alexander, Stuart H. Low, Pantia Ralli, Fred K. Sander, W. H. White, J. Cypher, H. T. Pitt, C. Cookson, E. R. Ashton, Richard G. Thwaites, J. T. Barker and C. J. Lucas.

The plan of arrangement in the Orchid section was practically the same as last year. Groups of varying extent were arranged around the sides of the large tent, and two sections of cross staging arranged. In extent, the exhibits did not appear quite to equal those of last year, the contributions by amateurs especially being wanting.

### AWARDS.

#### FIRST-CLASS CERTIFICATE.

*Odontoglossum Faustina Claygate Lodge* variety (*eximum* × *Dora*), from J. J. BOLTON, Esq., Claygate Lodge, Claygate (gr. Mr. S. Lynes). A grand flower and one of the best of its class; the broad sepals and petals have a white ground, heavily blotched with claret-red, the margins and front of the lip being white.

*Brasso-Laelio-Cattleya Jupiter His Majesty* (*B.-L.-C. Veitchii* × *C. armainvilliersensis*), from Messrs. STUART LOW AND CO., Jarvisbrook, Sussex. The noblest and one of the grandest of *Brassovola* crosses, the immense flower being pale blush rose, with showy purple colour on the front of its broadly expanded lip.

*Odontoglossum Purple Emperor* (*The Czar* × *Dusky Monarch*) (see Fig. 146), from Messrs. CHARLESWORTH, Hayward's Heath. A triumph of successful *Odontoglossum* raising; the flower, which is of large size and has great depth of colour—deep, pure purple of the darkest shades—possesses fine substance.

#### AWARDS OF MERIT.

*Brasso-Laelio-Cattleya Jupiter, Jarvisbrook* variety, from Messrs. STUART LOW AND CO. A model flower of pale rose tint with yellow disc to the lip, and purple blotch in front.

*Odontioda Radiant* (*Chantecler* × *Royal Gem*), from Messrs. J. and A. McBEAN, Cooksbridge. A grand scarlet flower tinged with orange, and with light markings on the lip.

*Odontioda Eulalia* (*Coronation* × *Vuykstekeae*) The large flower is of the shape of *Coronation*, and is heavily blotched with rose-purple on a light ground.

*Odontioda Orange King* (*Chantecler* × unknown), from Mons. C. VUYLSTEKE. A good form with light orange-scarlet flowers.

*Cymbidium Nelly* var. *Golden Glow* (*Pauwelsii* × *Albatross*), from Messrs. SANDERS, St. Albans. A welcome change in colour from the ordinary type, the prettily shaped flowers being clear light yellow.

#### CULTURAL COMMENDATION.

To Mr. Collier, gr. to Sir J. COLMAN, Bart., for a plant of *Dendrobium acuminatum* with four fine spikes.

#### GROUPS.

Sir JEREMIAH COLMAN, Bart., Gatton Park (gr. Mr. Collier), was the only amateur to show a large group and in it he well demonstrated the excellence of his Orchid collection, both in extent and in the very fine cultivation of the plants. *Dendrobiums* formed the centre, several specimens of the rare *D. Dalhousieanum luteum*, with plants of the hybrid *D. illustre*, *D. Gatton Sunray*, and other yellow *Gatton* seedlings being included. The *Gatton Odontoglossums* and *Odontiodas* were well shown; a batch of the clear yellow *Odontoglossum Wilckeanum Colmanii* was effective among a fine series of

FIG. 146.—ODONTOGLOSSUM PURPLE EMPEROR. EXHIBITED AT CHELSEA SHOW BY MESSRS. CHARLESWORTH AND CO. AWARDED A FIRST-CLASS CERTIFICATE.

show opened that, no matter how willing the workers were, they could not do themselves justice; consequently the exhibits were not so complete as usual early on the opening day. However, all was ready by judging time, 8.45 a.m. on Tuesday.

The great tent covered a larger area than usual, and as the refreshment tents were placed in the adjacent Ranelagh Gardens, there was ample room for a larger number of formal and other gardens near the great tent. These presented a greater variety of style than on any previous occasion, and proved a great attraction.

From this statement it will be gathered that Chelsea Show this year was larger than any other since the International Exhibition of 1912. It was probably more gorgeous in colouring than its predecessors; indeed, the masses of brilliant blooms needed an ampler setting of foliage, or green lawns. In point of quality there was not much evidence of progress, but the wonderful

almost disappeared, and a steady improvement in grouping on the ground is evident year after year. Greenhouse and stove plants have rarely been so well displayed, and Roses, Begonias, Calceolarias, Clarkias, Carnations, Cinerarias, Schizanthus, Hydrangeas and Hippeastrums were all of outstanding quality. The scarcity of vegetables and fruits was a matter of general regret.

The attendance was good, and early in the opening day the notable visitors included Princess Mary, the Queen of Spain and her two daughters, Viscount Lascelles and Lord Rothschild.

The Chelsea Show entails a vast amount of labour and organisation, and we congratulate the R.H.S. and the exhibitors on a notably great achievement.

#### Orchid Committee.

Present: Sir Jeremiah Colman, Bart. (in the chair), Prince Shimadzu, Sir F. W. Moore,

hybrid *Odontoglossums* and *Odontiodas*. *Lycaste*, a speciality at Gatton Park, was well represented, the forms of *L. Skinneri* varying from the fine, pure white form to the richly-coloured variety Mrs. Hamilton Smith. A set of pure white *Brasso-Cattleyas* had for the best the forms of B.-C. Gatton Lily, though rich colour in other members of the section, and superb *Laelio-Cattleyas* were not wanting. As always in the Gatton collection, species were well represented, a notable example being the several specimens of the rare Philippine *Dendrobium acuminatum*, one of which bore four strong spikes of pretty pink flowers.

A neat group of scarlet *Odontiodas* and showy *Odontoglossums*, *Cypripediums* and scarlet *Cochlidia*, from Mr. HARRY DIXON, Wandsworth Common, completed the side.

Messrs. SANDERS, St. Albans, filled a long

*Laelio-Cattleya Dominicana* arranged with *L.-C. luminosa aurea*, of yellow and purple colour. A good general selection of other *Cattleyas*, *Laelio-Cattleyas* and *Brasso-Cattleyas*, with remarkably fine hybrid *Odontoglossums* and *Odontiodas* were also well displayed, with various *Sopironitis* crosses. The best selection in the group was *Odontioda Eileen* (Odm. Dreadnought × Oda. Coronation), a broad, *Odontoglossum*-like flower of superb quality with white ground, effectively blotched with pale mauve; *Brasso-Laelio-Cattleya Triune* var. *Triumph*, a noble, blush-white flower with broad, rose-purple lip; and *Cattleya Dusse-dorfei Aquinae* a new form, of light rose colour with dark rose front to the lip and purple tints to the petals.

Messrs. CHARLESWORTH AND Co., Haywards Heath, commenced the side staging with a mag-

Alcippe) and the beautiful commemorative *Charleswortha Alpha* var. *grandis* (*Miltoniodes Ajax* × *Oncidioda Cooksoniae*), a very fine departure from the type, of great beauty and with graceful scarlet flowers.

Continuing the side staging, an important group by Messrs. MANSELL AND HATCHER, Rawdon, Leeds, was arranged with brilliant *Odontiodas*, showy *Odontoglossums* and delicately tinted *Brasso-Cattleyas* and *Laelio-Cattleyas* as the leading feature; white *Cattleyas*, including the pretty *C. Douoi*, were noted, and among many well-grown species was a superb plant of the emerald green and black *Coelegyne pandurata*.

Messrs. FLORY AND BLACK had a select group of *Odontoglossums*, *Laelio-Cattleyas*, and *Sopironitis* crosses, for which they are famed.

FIG 147.—ROSA LUCENS, THE PREMIER. EXHIBITED AT CHELSEA SHOW BY MESSRS. PAUL AND SON.

stage with superbly grown specimens admirably arranged. The centre was of fine specimens of *Cattleyas*, fronted by white and coloured forms *Laelio-Cattleya Fascinator* and other *Laelio-Cattleya Mossiae* and the charming white *C. Evelyn Sander* and *C. Magali Sander*, two of the best whites. Fine hybrid *Cymbidiums* arched over the group, mingling with the drooping *Cattleya citrina*, rich scarlet *Odontiodas* and showy *Odontoglossums*. In the centre were tall specimens of the now rare *Cyrtopodium punctatum* and *Ansellia africana* with many spikes. There were also fine specimens of *Phalaenopsis Rimstadiana* and a fine series of *Miltonias* from pure white with nearly black mask to rose colour. One of the best of the *Odontoglossums* was *O. ardentissimum conspicuum*, whilst choice *Odontiodas* were the glowing red *Oda. brilliantissima* and *Oda. Grenadier*. Their new *Angulocastes* were also shown.

Messrs. STUART LOW AND Co., Jarvisbrook, Sussex, had an equally fine group on the cross staging, the centre being of very dark forms of

nificent group extending over sixty feet by six feet, and filled in one side, the angle and return, with a magnificent series of plants, in which most of the Orchids of the season were well represented, and especially their grand strain of the pure white xanthotes section of *Odontoglossums*, various combinations of which with pure white flowers, having an occasional straw-yellow blotch, were staged in three batches. A bank of *Cymbidiums* filled the corner; batches of richly-coloured *Laelio-Cattleyas* and scarlet *Odontiodas* were well harmonised. *Miltonias* of large size and various tints attracted the eye, and above all stood many showy novelties, a selection of which includes *Odontoglossum Purple Emperor* (*The Czar* × *Dusky Monarch*) (see Fig. 146), a grand flower well worthy of its name; *Odontoglossum Llewellyn* var. *purpureum* (*amabile* × *Georgius Rex*), another rich purple variety. Odm. *Asian* var. *Goliath* (*Solon* × *Aquitania*) a superb novelty; *Brasso-Cattleya Apollo* (*B.-C. Digbyano-Mossiae* × *C. Mendelii*), *Laelio-Cattleya Circe* var. *gloriosa* (*Hyppatia* ×

*Cattleya Cowanae* and other whites were effectively displayed with coloured *Miltonias*.

Messrs. J. CYPHER AND SONS., Cheltenham, had a beautiful group arranged in their customary artistic manner, the principal foliage plants being graceful Palms, the striped yellow and green *Dracaena Victoriae*, and the rose, green, and white *Phyllanthus*. The central Orchid was a grand example of the large, bluish-white *Brasso-Cattleya Digbyano-Mossiae* with twelve flowers, the earliest and still one of the best of *Brasso-Cattleyas*. *Brasso-Laelio-Cattleya Veitchii* in various forms, one being the richest in colour yet seen, and other *Brasso-vola* hybrids and *Cattleyas* and *Laelio-Cattleyas* were in profusion, also scarlet and yellow *Epipendiums*, *Cypripediums*, and other rare species and hybrids.

Messrs. J. AND A. McBEAN, Cooksbridge, the great demonstrators of excellence in *Odontoglossums* and *Odontiodas* especially, staged a very remarkable group of good things, the kinds mentioned, with their scarlet, purple,

and white flowers mingling with the drooping sprays of hybrid Cymbidiums, and having on each side selections of Cattleyas, Laelio-Cattleyas, and Brasso-Cattleyas. Among the best noted were Odontioda Cheringes var Admiration (Oda Joan × Odm. Lawrenceanum), a large scarlet-red flower; Oda. President Harding, a large Odontoglossum-like flower closely spotted with pale mauve; Oda. Borham var. Bronze Wings (Oda. Charlesworthii × Odm. Vulcan), a large, bronzy orange variety, the plant bearing ten flowers; and Oda. Radiant (Oda. Chantecler × Oda. Royal Gem), a very fine novelty. Among the best Odontoglossums were Odm. Arabic (eximium × Midnight), a grand flower, heavily blotched with claret purple; Odm. St. George and Odm. in new varieties.

Messrs. ARMSTRONG AND BROWN, Tunbridge Wells, staged a select group of exceptionally fine hybrids, all of which were of grand quality. Among the Odontiodas, the forms of their Oda. Henry Orchardhurst variety were bright scarlet, one plant bearing twenty flowers and buds, and the variety splendens two immense scarlet-red blooms. Superb forms of other types were shown, and among the Odontoglossums with their large, pure white Odm. Promerens xanthotes Orchardhurst variety and Odm. Promerens Royal Purple

Shown by the Rev. A. T. BOSCAWEN, Ludgvan Rectory, Cornwall.

*Rhododendron orbiculare*.—An interesting species with roundish green leaves that are grey on the underside. The flowers, about 1½ inch across, are campanulate, rose-pink, with rounded lobes at the mouth. From ten to twelve flowers are borne in each cluster. Shown by the Hon. H. D. McLAREN, Talycafn.

*Rhododendron Falconeri*.—Yet another old favourite plant, a Himalayan species introduced about 1850. Unfortunately, it is hardy only in the warmer parts of the country, and in other places it needs the protection of a temperate house. The flowers, closely placed in large rounded clusters, are white, and the large leathery leaves are glossy green on the surface and rusty brown on the underside. Shown by Messrs. GILL, Falmouth.

*Hydrangea Parsifal*.—This handsome fringed, deep rose-pink Hydrangea, shown in fine condition, was described in our issue of April 29, p. 218, in connection with the Hague Show. Shown by Messrs. WM. CUTBUSH AND SON, Highgate.

*Polargonium Sir Percy Blakeney*.—A rich scarlet coloured Ivy-leaved variety of sturdy growth. As our readers will remember, Sir Percy Blakeney was "the Scarlet Pimpernel"

and become bright pink with age. There are a few brown dots in the throat. Shown by Mr. P. D. WILLIAMS.

*Rhododendron Jeffery Millais*.—In the width of its flowers this is probably the largest of the new Rhododendrons shown at Chelsea. The blooms, carried in large, erect, elongated trusses, are bluish white, with a few brown and green spots on the upper segment. Shown by Mr. P. D. WILLIAMS.

*Stellera chamaejasme*.—A neat little plant, with Pimelia-like heads of tiny white or bluish flowers. These heads are rounded and borne at the ends of slender growths clothed with short, reflexed grey green leaves. Shown by MAJOR STONE, High Down, Goring, Sussex.

*Carnation Cream Saffron*.—A pale cream-coloured variety that is probably a sport from the richer-hued Saffron. Shown by Mr. C. ENGELMANN, Saffron Walden

*Iris Orestes*.—An interesting regelio-cyclis Iris of modest growth and with flowers of bronzy red or rich brown colouring, with purple blue shading of the stigmas, and some fancy yellow markings at the base of the falls. Shown by Messrs. BARR AND SONS, Covent Garden.

*Carnation Steerforth*.—A border variety of large size and capital form. It has a white ground, and is heavily edged and flaked with brilliant crimson. Shown by Mr. JAS. DOUGLAS.

*Carnation Vicroy*.—A large and handsome yellow ground fancy border Carnation. The rich crimson colouring is shaded with purple on the inner petals. Towards the margins the yellow ground shades almost white as it enters brilliant crimson. Shown by Mr. JAS. DOUGLAS.

*Carnation Orangeman*.—A showy border variety, with colouring as indicated by its name. Shown by Mr. JAS. DOUGLAS.

*Rhododendron Coalition*.—A quaint name for a beautiful variety of richest orange pink colouring, shaded with paler pink. One of the showiest varieties seen for some time. Shown by Mr. LIONEL DE ROTHSCHILD, Exbury, Hampshire.

*Primula obovata Salmon Queen*.—A particularly fine form of a well-known and useful greenhouse plant. The flowers are of good size and form, of a bright salmon, pink shade. Shown by Messrs. SUTTON AND SONS, Reading.

#### OTHER NOVELTIES.

Messrs. W. CUTBUSH AND SON exhibited a rich crimson scarlet Rhododendron named Barnet Glory. Cytisus Donard seedling, a rose and lawn-coloured hybrid between C. Dallimorei and C. ochroleuca, from the Donard Nursery Co., appears to be as free growing as it is free flowering. Rhododendron Dawn, a lovely pink variety, was sent by Mr. LIONEL DE ROTHSCHILD, Exbury. Dendroceon rigidum, carrying many of its Buttercup-yellow flowers, was well shown by Messrs. R. VEITCH AND SON, Exeter. Cytisus proliferans, with grey young leaves and whitish flowers, came from St. Keverne, where Mr. P. D. WILLIAMS grows it finely.

Mr. H. J. ELWES' little box of succulent plants proved a source of great interest, especially as it was housed in the cage with the new plants; Pileocereus senilis, Cotyledon sp., with pendent reddish flowers; C. setosa, with yellow blooms; and Urbinia Purpusii were included in this little collection.

#### Roses.

Roses have always a great fascination for the public and the Rose exhibits are always certain of a full share of the attention of visitors at flower shows. The Roses have always formed a great feature at Chelsea, and, although the season has been most unfavourable to their development, yet some of the finest floral displays were to be found in the Rose exhibits.

Messrs. W. PAUL AND SON, Waltham Cross, arranged a half-circular group of Roses at the end of one of the tents; this was formed entirely of a magnificent collection of these favourite flowers. The general effect was splendid, there being ample fine pillar and standard sorts without any sense of crowding, and below these were magnificent pot plants of the H. T., T. and other large-flowered varieties. The centre-piece was a charming plant of the brilliant Paul's

FIG. 143.—DIANTHUS ALLWOODII EXHIBITED BY MESSRS. ALLWOOD BROS. AT THE CHELSEA SHOW.

were remarkable variations. Fine forms of their Odm. Victory strain and other seedlings were also shown, and the distinct Brasso-Cattleya Dietrichiana, Orchardhurst variety, some seedling Cymbidiums, one a distinct yellow form; while Cattleyas and a very dark Laelio-Cattleya were also noted.

Mons. CHAS. VUULSTIÈRE, Lochristy, Ghent, the only Continental exhibitor gave a welcome display of various fine and richly coloured Odontiodas of new types, two of which will be described in the list of awards.

#### Floral Committee.

*Present*.—Mr. H. B. May (in the chair), and Messrs. W. H. Morter, C. R. Fielder, W. B. Cranfield, W. G. Baker, J. W. Blakey, George Harrow, G. Reuthe, W. J. Bean, Reginald Cory, J. F. McLeod, John Heal, Jas. Whytock, W. N. Page, H. R. Darlington, H. V. Warren, F. Page Roberts, Hugh Dickson, A. G. Jackman, W. B. Gingell, D. B. Crane, and R. C. Notcutt.

#### FIRST-CLASS CERTIFICATES.

*Teloplia speciosissima*.—An old inhabitant of our gardens, but one seldom seen in flower in such fine form as on this occasion. It is the Australian Waratah, and a member of the national order Proteaceae. The big heads of flowers and bracts are brilliant crimson-scarlet, carried at the ends of stout growths clothed with oblong or obovate leaves toothed at the margins. The species was introduced in 1789, and figured in *Gard. Chron.*, vol. XVII., p. 677.

of fiction. Shown by the BLAKENEY NURSERIES, Plumtree, Nottingham.

*Rhododendron Norman Gill*.—A lovely variety evidently of Aucklandii breed. The widely expanded blooms are bluish coloured, and carried in a large shapely cluster. A charming and dainty Rhododendron. Shown by Messrs. GILL, Falmouth.

*Pink Red Indian*.—This charming Pink has large, admirably formed flowers, broad and smooth petalled, and of a rich reddish rose colour.

*Pink Bridesmaid*.—A very pretty Pink, with broad slightly fringed petals of purest white, with palest scarlet markings at the base.

*Pink Lord Lambourne*.—This handsome variety, of large size and rich carmine red coloured, marked at the base of the petals with brilliant crimson, was greatly admired for its size and rich colouring. These three Pinks were shown by Mr. C. H. HERBERT, Birmingham.

*Hydrangea Prof. Bois*.—This is a large-flowered form of rich pink colouring, and, as shown, it is capable of carrying enormous heads that suggest the variety may become popular for market use. Shown by Mr. H. J. JONES, Ryecroft Nursery, Lewisham.

*Rhododendron Robert Fortune*.—An effective variety, with upright spikes of widely opened pure white flowers. Shown by Mr. P. D. WILLIAMS, St. Keverne, Cornwall.

*Rhododendron St. Keverne*.—This gorgeous variety has elongated, campanulate flowers of light and bright scarlet hue. When the flowers are fully open, they lose some of their brilli-

Scarlet Climber, which showed to advantage immediately in front and on either side of White Dorothy Perkins. Of the general collection, Sunburst, Mme. Caristie Martel, palest lemon; Mrs. Aaron Ward, Gloria (a new, fragrant, cerise coloured H. T. variety); Florence, and Mrs. Chas. Hunter (a beautiful rosy-pink H. T.), Prince de Bulgarie and Mme. Charles Lutaud were of outstanding merit.

Mr. C. TURNER, Slough, showed Roses in association with their fine Lilacs. The centre of their group was massed with H. T. and H. P. varieties, such as Mrs. Geo. Shawyer, Lady Ashtown, Flame of Fire, a pretty shade of Apricot with golden sheen; Golden Emblem, a very charming yellow Rose of the Pernetiana type; and Richmond. They also showed their

Messrs. FRANK CANT AND CO., Colchester, had a massed bank of Roses on tabling, so cleverly arranged that the value of each variety could be readily appraised, and the inclusion of standards with blooms of exhibition quality, which overhung the general collection, was a happy thought. The new varieties, Capt. F. S. Harvey Cant—a pink H.T. variety—and Mrs. F. S. Harvey Cant, pale blush, in the style of Yvonne Vacherot were prominent in the centre, and other sorts of note were Mrs. Alfred West, a big bloom of rosy-pink colour, and Mrs. Rosabel Walker, a rich red H.T., shaded with maroon on the older outer petals—a glorious bit of colour for the garden, as it is almost sunproof.

Messrs. J. CHEAL AND SONS, Crawley, filled

The general collection included perfect specimens in pots of notable H.T. and T. varieties. One of the most charming features of this glorious bank of Roses was a group of the pale blush semi-double variety of *Rosa luscens* named the Premier (see Fig 147), which forms bold pillars as much as 12 feet high, furnished with bloom from the bottom to the top of the plants.

Messrs. J. PIPER AND SON, LTD., included many beautiful Roses in their collection of miscellaneous plants. The richly-coloured Paul's Scarlet Climber showed to advantage against trellising, which added a pleasing feature as a background on which, besides Roses, were trained Clematis, Vines, and other climbers.

A bank of beautiful Roses was exhibited by Mr. E. J. HICKS, Twyford, the group being

FIG. 149.—PORTION OF MESSRS. SUTTON AND SONS' GOLD MEDAL EXHIBIT AT THE CHELSEA SHOW.

new pillar variety Fairy Queen semi-double, of delicate lemon-yellow, with a fine boss of golden stamens, and sweetly scented.

Messrs. B. R. CANT AND SONS, Colchester, showed Roses on tabling, a screen of Climbers and Ramblers at the back giving a good effect. In front were arranged masses of fine blooms of such sorts as Padre, a glorious shade of orange-scarlet, flushed with yellow at the base; Sovereign, a Pernetiana variety of gold colour with buff shading; Covent Garden, Constance Casson, a Pernetiana with pretty blooms of gold colour, heavily suffused with rose, and with extra large foliage; and Phoebe, a lemon-yellow hybrid tea variety.

Messrs. LAXTON BROS., Bedford, showed two pyramidal groups of their new polyantha Rose Pink Delight with their exhibit of Strawberries.

Mr. GEO. PRINCE, Oxford, had a small, but select group of Roses, arranged in big epergnes. The most notable sorts were Premier, Mrs. Foley Hobbs Richmond, Melody, Mme. Butterfly—a pretty bloom of delicate shell-pink colour—and Melody.

eight panel beds with polyantha Roses in their formal garden out-of-doors (see Fig. 151), and also utilised Roses in the borders and on the pergola.

Messrs. W. CUTBUSH AND SON, Highgate, made a very effective display with Roses, at the end bay of their fine group of flowering plants. Polyantha varieties, which this firm grows and shows so well, were utilised as a groundwork, and rising above them were charming standard, weeping standards, and pillar varieties. Amongst the polyanthas was the new fine red semi-double Rudolf Kluis, but the pick of all was the larger-flowered soft pink, Baby Tausendschön. Pink Delight is a pretty single variety rather taller than most of this section.

Messrs. PAUL AND SON, Cheshunt, had some of the brightest and freshest Roses in the show, a large mass of beautiful blooms in a small space, forming a pleasing feature near the central exit. The pillar and standard plants of such sorts as Excelsa, Ethel, Hiawatha, Lady Godiva, and the American Pillar, were blooming profusely, these serving to introduce variety.

arranged in the usual style adopted by modern exhibitors, that of massing pot plants, with tall pillar and rambler varieties rising above them at intervals. Ophelia occupied the place of honour in the centre—one of the best Roses for all purposes.

Mr. R. MURRELL, Shepperton-on-Thames, showed a pretty polyantha Rose named Coral Cluster.

The Rev. J. H. PEMBERTON, Avering-Atte-Bower, exhibited a small group of Roses of varieties mostly of his raising. In a group of polyantha sorts were arranged the taller Pemberton's White Rambler and a new pink climber named Havering Rambler.

#### Carnations and Pinks.

One of the features of the show was the magnificent collections of Carnations, and that from Messrs ALLWOOD BROS., Wivelsfield Nurseries, Haywards Heath, was one of the largest groups ever staged in the history of horticulture. It occupied the whole of one end of No. 1 tent, the centre being tastefully arranged with fine blooms of the perpetual-

flowering varieties, while on either side was a well-arranged walled garden (see Fig. 148) bedded out with the twenty-four varieties of *Dianthus Allwoodii*, and relieved here and there with lead vases filled with the same subjects. Just near was also a circular group of *Allwoodii* Dianthus grown in pots, so that the habit of this free-flowering section could be readily observed. There was a magnificent pot of the variety *Rufus*; this specimen, we believe, has now been exhibited at the Chelsea Show for four consecutive years. Of the perpetual-flowering varieties, a fine epergne of the magnificent *Edward Allwood* occupied a central position, and other flowers of note were *Chintz*; *Wivelsfield White*; *Jessie Allwood*, a new yellow *Malmaison*; *Wivelsfield Pink*; and *Marian Wilson*, orange yellow with red markings. Amongst the *Allwoodii* varieties, *Marion*, rose; *Betty*, white, with red centre; *Rufus*, a large deep rose flower; and *Susan*, pale lilac, with deep red eye, were of great merit.

Another highly effective group came from Mr. C. ENGLEMAN, Saffron Walden, who dis-

shown by Mr. JAMES DOUGLAS, Great Bookham, Surrey, and amongst recent introductions were *Steerforth*, white ground, pencilled with crimson; *Highland Mary*, cream, marked with pink; *Crystal Clove*, white; *Douglas Dale*, orange salmon; *Kelso*, apricot ground, marked lavender grey; and *Maréchal Niel*, a fine yellow self. The same firm also showed a representative collection of well grown *Auriculas*. Close by Mr. H. LAKEMAN, Thornton Heath, showed a table group of border *Carnations*, the vases being arranged in three tiers, prominent varieties being *Lieut. Shackleton*, yellow ground with pink markings; *Orangeman*, orange-scarlet; *Columbine*, pink and white; *Grey Douglas*, slate grey; *Elaine*, white; *Border Yellow*, and *The King*, crimson. Mr. C. H. HERBERT, Acocks Green, Birmingham, showed a unique collection of hybrid *Pinks*, including *Victory*, a fine crimson self; *Model*, a perfectly-formed flower, with rose petals and deep crimson base; *Red Indian*, dull red self; *Queen Mary*, deep rose with crimson eye; *Sweet Will*, pink, with dark red base; and

In the effective display of greenhouse plants by Messrs. JAMES CARTER AND CO., Raynes Park, S.W., Sweet Peas were shown in ornamental wicker baskets, and included *White Perfection*; *Picture*, shell pink; *Viscountess Lascelles*, lavender; *Mrs. Stirling Stent*, salmon rose; *Royal Scot*, scarlet; and *Tangerine*.

Messrs. DOBBIE AND CO., Edinburgh, had a splendidly arranged group of Sweet Peas, the style of arrangement being original, and each variety was so displayed that it was an exhibit in itself. The principal varieties were *Geo. Shawyer*, a beautiful salmon rose flower; *Orchid*, lavender; *Majestic*, cream; *Royal Scot*, scarlet; *Renova*, deep rose, suffused with salmon; *Tangerine*, salmon; *Dignity*, pink; *Dobbie's Maroon*; and *Constance Hinton*, white.

Messrs. IRELAND AND HITCHCOCK, Marks Tey, displayed flowers of excellent quality and of exceptional colour. The chief varieties included were *Matchless*, cream; *Annie Ireland*, picotee; *Mascotts Helio*, rosy lavender; *Mascotts White*; *Le Mahdi*, bluish purple; and *Shamrock*, rosy mauve.

From Mr. J. STEVENSON, Wimborne, came a very pretty collection of Sweet Peas arranged in epergnes with *Asparagus* foliage. Of novelties the sun-proof orange-red self, named *Poppy*, was particularly meritorious; and *Wild Rose*, pale soft rose; *Diana*, a good lavender; and *Cynthia*, a pale lavender flower were also very fine.

Mr. ROBERT BOLTON AND SON, Halstead, Essex, staged a neat table group of Sweet Peas, chief among which were the new *Elsie Dene*, lavender; *Comrade*, apricot pink flushed with lilac; *Wonderful*, a good sun-proof scarlet; *Artistry*, rose-lavender; and *Picture*, pink.

#### Ferns.

Stove and greenhouse Ferns which in by-gone days were such an important feature of the spring show, were sparsely represented on the present occasion. The only contribution was by Mr. H. ELLISON, who included such genera as *Adiantum*, *Davallia*, *Lomaria* and *Platynerium* with his collection of succulent plants, and many well coloured little plants of *Saxifraga sarmentosa* tricolour.

Somewhat similarly Mr. AMOS PERRY associated hardy Ferns with a very large collection of *Irises*, *Tulips*, *Kurume Azaleas*, and general border plants. The Ferns were shown in considerable quantity and of high quality. Of the many interesting and valuable plants on view, space permits to mention only of a few. *Athyrium Felix-foemina plumosa cristatum*, *A.F.f. p. corymbiferum*, *A.F.f. curtum cristatum*, and *A.F.f. congestum polydactylum*, of the crested varieties were very graceful of cool appearance and altogether charming. The genus *Osmunda* was also well represented, and included *Osmunda regalis cristata*, *O. r. purpurascens*, and *O. Claytoniana*.

#### Begonias.

The only exhibit of tuberous-rooted *Begonias* was by Messrs. BLACKMORE AND LANGDON, and this was of the very high quality associated with these growers. The ground work was composed of an admirable collection of double-flowered sorts. Each plant seemed to be a perfect specimen, dwarf and compact, bearing ample healthy foliage and an unusual number of very large and perfectly double *Camellia*-shaped blooms. Although these flowers were of unusual size, they were of refined quality and free from any suggestion of coarseness. Of the many varieties we selected the following as being typical of the collection: *James Braid*, crimson; *Mrs. J. S. Brunton*, mid-pink; *Mrs. T. Crawford*, salmon-pink; *J. W. Pyeman* deep vivid scarlet, and *Irene Tamby*, rich orange. Above these varieties were placed on tall stands elegant plants of such "basket *Begonias*" as *Stella*, *Coralina* and *Mrs. Bilkey*.

#### Hardy Flowers.

A very tastefully arranged formal garden was erected by Messrs. R. W. WALLACE AND CO., Tunbridge Wells, in No. 1 tent. Rectangular in shape, of an area of about forty-five feet by forty-six feet, it was approached by four

FIG. 150.—TUDOR GARDEN EXHIBITED BY MR. HERBERT JONES AT THE CHELSEA SHOW.

played a choice selection of well-grown blooms in the form of a circular column rising from the ground sixteen feet in height. The apex consisted of a mass of the very fine scarlet variety, *Tarzan*; and other choice varieties were *Laddie*, pale salmon pink; *Crystal White*; *Edward Page*, deep pink and very fine in form; *Cream Saffron*, a sport from the yellow *Saffron*; *Goliath*, light pink; and *White Pearl*.

Mr. KEITH LUXFORD AND CO., Harlow, set up a nice table group of *Carnations*, which included the new yellow *Maine Sunshine*; *Aviator*, scarlet; *Mrs. C.W. Ward*, pink; *White Benora*; and *Mary Allwood*.

Messrs. STUART LOW AND CO., Enfield, effectively displayed such varieties as *Reginald Cory*, glowing cerise; *Mrs. T. Ives*, salmon pink, a very excellent variety for summer bedding; *Eileen Low*, salmon pink; and *Sir Mackay Edgar*, an improved form of *British Triumph*. Perpetual *Malmaisons* were represented by the Hon. Charlotte Knollys; *Miracle*, a beautiful large cerise flower; and *Hugh Low*, a new blush pink variety.

The Right Hon. LORD LAMBOURNE, C.V.O., Bishops Hall, Romford, sent a collection of good flowers, representing such varieties as *Edward Allwood*; *White Enchantress*; *Wivelsfield Beauty*, a fine yellow fancy; *Wivelsfield Claret*; *Saffron*; and *Mary Allwood*.

Border *Carnations* of distinctive quality were

*Bridesmaid*, pale salmon, with deeper coloured base.

A part of the group of miscellaneous flowering plants from Messrs. W. CUTBUSH AND SON, Barnet, was set aside for perpetual-flowering *Carnations*, and the blooms were displayed in grey wicker baskets and vases interspersed with trails of *Asparagus* and *Smilax* foliage. Excellent flowers of *Winsor*, pink; *King Albert*, maroon red; *White Wonder*, white; *Laddie*, salmon pink; and *Thor*, scarlet, were shown.

#### Sweet Peas.

Sweet Peas were again exceptionally good, and some thoroughly attractive exhibits were arranged by specialists in this flower. A mammoth group came from Messrs. ALEX. DICKSON AND SONS, LTD., Hawlmark, Belfast. Large epergnes were set along the back, each framed with trails of *Smilax* worked on the black background, and towards the front were tripods and large vases and bowls filled with flowers of grand form and colour. In all, about forty varieties were shown, chief of which were the two novelties, *Fairie Queen*, old rose on cream ground and *Powerscroft*, pure lavender. *Hawlmark Cream*; *King Mauve*; *Royal Scot*, scarlet; *Tangerine*, bright salmon; *Constance Hinton*, white; *Elegance*, blush pink; *Conquest*, old rose on white ground; *Hawlmark Pink* were others of special merit.

broad entrances centrally placed on each side. Raised about two feet above the ground level, and flanked by stone walls, the stone path led to a circular bed of bearded Irises. Here we found magnificent plants of Dawn, white; Hermoine, pink; Isolene, Dominion, deep blue (see Fig. 142); King, Asia, Lent A. Williamson, and Lord of June. The side beds were occupied with ornamental Acaers, Rhododendrons, and Azaleas, interplanted with Liliums, of such kinds as L. R. O. Backhouse, L. monodelphum Szovitzianum, L. regale, L. umbellatum erectum and L. n. incomparabile, L. Krameri, a beautiful white flower, and the brightly-coloured L. elegans aureum maculatum. The outer borders at a lower level were filled with some charming subjects, including the scarlet Habranthus pratensis, Veronica gentianoides pallidiflora, and masses of dwarf Irises, Rhododendrons, Azaleas and Primulas. It was a delightfully cool and pleasing exhibit, and attracted the admiration of the many visitors. Messrs. W. H. ROGERS AND SONS, Southampton, had a table group of hardy plants, among which were Primula hybrida Flambean, a cross between P. pulverulenta and P. Cockburniana; Cupressus obtusa tetragona minima, and C. o. caespitosa, Sempervivum alpinum decorum, and a spray of Tricuspidaria Hookeri.

From Messrs. SFELTON AND KIRBY, Pirbright, came Viola gracilis and V. g. lutea, Androsace Chumbyi, a good clump of Arenaria balearica, and Aethionema Warley Gem, while close by Messrs. R. TUCKER AND SONS, Oxford, arranged Edraianthus serpyllifolia, Oxalis adenophylla, Dianthus alpinus, and Trillium grandiflorum among the Yorkshire Arnside stone. Messrs. WATERER, SONS AND CRISP, LTD., arranged a grand group of herbaceous plants with Lupinus Sunshine, and long-spurred Aquilegia hybrids occupying a prominent position. Bearded Irises were represented by I. pallida, I. germanica, Alcazar, a very fine flower, and Isolene. Paeony Peregrine, a pink single, and a number of Tulips were also included in the group. Messrs. REANSBOTOM AND CO., Geashill, Ireland, staged their famous strain of St. Brigid Anemones, while Mr. H. HEMSLEY, Crawley, exhibited among other choice plants Anemone rivularis, Dianthus Freynii nana, Cistus unicolor, and Lychnis lapponica, together with his named varieties of hybrid alpine Antirrhinums. The Misses HOPKINS, Shepperton-on-Thames, showed a small rock garden exhibit planted with suitable subjects. From Mr. W. WELLS, JUN., Merstham, came a very choice collection of alpine plants in pots. Anemone sylvestris, Globularia nudicaulis, Phlox Vivid, Mazus rugosus, and Primula siberica were but a few of the many good things on view.

Messrs. GEO. JACKMAN AND SON, Woking, had a representative display of herbaceous plants, including Irises Isolene and Alcazar, Lavatera Olbia, Lupinus Sunshine, Campanula Telham Beauty, and the pale blue Delphinium Capri. Mr. G. W. MILLER, Wisbech, brought named varieties of Trollius, the pick of which were Orange Princess, Earliest of All, and Mrs. J. B. Hall, while delightful strains of Polyanthus and Pansies were also seen on this stand. Mr. G. REUTHE, Keston, staged an interesting group of rock plants, and the dainty Thalictrum anemoneoides, Anemone sylvestris grandiflora, Oxalis enneaphylla, and Dianthus murale were noteworthy subjects.

A highly decorative group of Irises and herbaceous plants were shown by Mr. AMOS PERRY, Enfield. Regelio-cyclus Irises were represented by Beatrice, Isis and Pothex, and other choice Irises were I. Hoogiana, I. Vaga, I. Susiana, and the yellow I. bosniaca major. Azaleas provided a wealth of colour at one end of the group, and these formed a fitting background to the herbaceous plants, which included Geum Dolly North, a good orange flower, Pyrethrum Queen Mary and Euphorbia polychroma. Interesting, too, were the hybrids between Cheiranthus alpinus and C. Allioni; and the pretty Aquilegia calcarata, a dwarf Tibetan species with deep purplish-blue flowers attracted attention. Messrs. STORRIE AND STORRIE, Glencarse, Perthshire, exhibited a magnificent strain of long-

spurred Aquilegias of bluish pink, orange-red, scarlet, white and yellow colours. Their invincible strains of Auriculas, Polyanthus and Ox-slips were also displayed in goodly quantity.

Messrs. BEES, LTD., Liverpool, made a very pleasing exhibit of herbaceous and rock plants, among which were noted Gentiana acaulis, Trillium grandiflorum, Lilium croceum, Achillea umbellata, Roscoea cautiloides, Androsace Watkinsii, and a very desirable strain of long-spurred Aquilegias. Messrs. WHITELEGG AND CO., Orpington, made a feature of Iris Hoogiana and I. regelia Korola. Some very prettily veined flowers of I. regelio-cyclus hybrids were also staged, and of named varieties Thalia, Vera, Freya, and Una.

The CHALK HILL NURSERIES, LTD., Reading, showed their fine Chalk Hill giant strains of Mimulus and Pansies of wide range of colours. Sprays of Pelargonium were also shown by the same firm, the chief varieties being Snowstorm, white; Maxime, Kovalesky, pale salmon; The Speaker, double orange pink; and Victory, pale salmon. Messrs. MAXWELL AND BEALE, Broadstone, showed Saxifraga cochlearis lingu-

Primulas was staged by Dr. J. Macwatt, Duns, Scotland, included amongst which were the pale yellow P. sikkimensis; P. burmanica, rose-purple; P. helodoxa, deep yellow; P. Watsonii, P. longiflora, and P. geraniifolia. Mr. R. Prichard, Wimborne, brought Cotyledon simplicifolia, Onosma sericeum, Lychnis pyrenaica rosea and a pretty, dwarf white Cistus. From Messrs. J. CHEAL AND SONS, LTD., Crawley, came Alyssum saxatile plena, Phlox Newry Seedling, Sedum ternatum, and Pentstemon Scouleri. The same firm also showed their Star Dahlias in choice varieties.

Mr. E. SCAPLEHORN, Hayward's Heath, occupied a narrow table length with a raised rock garden effectively planted with Daphne Cneorum major, Primula helodoxa, Armeria alpina nana Saxifraga longifolia, and S. lantoscana. Viola blooms were seen in variety in the collection from Mr. H. CLARK, Taunton, Moseley Perfection, yellow; Maggie Mott lavender; Mrs. Fisher, violet; and Oxhill Purple being represented by high-grade blooms.

Mr. G. R. DOWNER, Chichester, specialised in

FIG. 151.—PORTION OF MESSRS. J. CHEAL AND SONS' FORMAL ROSE GARDEN AT THE CHELSEA SHOW.

lata, Dryas octopetala, Gazania montana, Phlox Vivid, and other choice plants amongst rockwork. Messrs. M. PRICHARD AND SONS, Christchurch, arranged a large collection of plants occupying a whole table length. Here were to be found masses of Veronica Hullekeana with pale lavender racemes, Primula Aileen Aron, Erigeron Bertram Gentle, Dianthus Adoree, a very charming plant; Dianthus Prichardii, a new race of hybrid Pinks, and the new double Arenaria verna plena.

Messrs. BOWELL AND SKARRAT, Cheltenham, displayed the bright Azalea Hinemanyo, together with Iris Hoogiana, Viola pedata bicolor, Androsace arachnoides, and Cytisus Beanii. Messrs. CLARENCE ELLIOTT, LTD., Stevenage, made a pleasing rock garden on the table, and noteworthy subjects employed were Pentstemon Bridgesii, P. Six Hills Hybrid, Primula capitulata, Oxalis adeno-phylla, and O. enneaphylla, Lewisia Howelii, and the pretty double pink Silene acaulis flore plena. Messrs. CARTER, PAGE AND CO., London Wall, E.C., made use of Maianthemum biflora, the scarlet Verbenia chamedraefolia, Campanula hirsuta alba and Leontopodium alpinum in a neat rock garden arrangement. The same firm also showed a pretty group of Dahlias representative of the many classes of hardy

A very interesting collection of hardy

seedling Lupins, the only named variety being Pink Pearl, a magnificent flower, with large spikes of rosy purple bloom. A number of varieties of Phlox subulata was also shown in the group.

Mr. JOHN FORBES, Hawick, showed Violas, East Lothian Stocks, Auriculas, and Phlox Arendsi in variety, and just near Mr. F. J. WARD, Ashted, set out Viola Dot alba, Aquilegia glandulosa, and Mimulus Scarlet Queen in rock work. Messrs. B. LADHAMS, LTD., Southampton, displayed Erigeron B. Ladhams, Edwardsia grandiflora, Primula Sieboldi, and Verbascum B. Ladhams, and from Messrs. Baker's, Ltd., Wolverhampton, came a neat rock garden, backed with brightly coloured Azaleas, and planted with such good things as Saxifraga bathoniensis, Helichrysum bellidifolium, and Myosotis rupicola. Opposite, the same firm made a feature of the fine yellow Trollius Goldquelle, and a good strain of Sunbeam Poppies.

Messrs. G. & A. CLARKE, LTD., Dover, had a circular ground group of herbaceous plants, prominent position being given to Gerbera hybrids of striking colour, Eremurus himalaicus, Saxifraga rotundifolia, Astilbe Venus, and Lupins and Irises in variety. Mr. J. C. ALLGROVE, Slough, displayed baskets of Iris Kharpur, deep blue; Alyssum saxatile citrina; Aster Pardomii, and Primula Forrestii in front of his large collection

of flowering shrubs Mr. A. D. THOMPSON, Adelphi, and Mr. ERNEST DIXON, Putney, S.W., erected neat miniature gardens on the tables, as well as showing larger gardens out of doors.

#### Trees and Shrubs.

General collections of trees and shrubs were not so extensive as in some former years. The most noteworthy, from some points of view, was the excellent display of Maples by Messrs. W. FROMOW AND SONS. In a large angle formed by the tents at the Hospital entrance they arranged a great variety which has probably never been surpassed for effect. The rich yellows of many specimens of *Acer japonica aureum* and the intense crimsons of the large bushes of *A. palmatum sanguineum* provided glorious masses of colour. The rather

showed, in large quantities, many of the rarer shrubs in which he specialises. The branches of *Embothrium coccineum* were densely furnished with brilliant flowers. Many interesting *Rhododendrons*, such as *R. Dalhousiae*, *Thomsoni*, and *Loder's White* were well shown. *Mitraria coccinea*, *Crinodendron* (*Tricuspidaria*) *Hookeri*, and *Dacrydium cupressoides* were also very attractive amongst the many trees and shrubs. The uncommon Norfolk Island *Forget-Me-Not*, *Myosotidium nobile*, was largely represented.

In the large tent Mr. J. C. ALLGROVE exhibited such hardy shrubs as *Cornus florida rubra*, bearing large quantities of very showy flowers. There were also many Lilacs, Maples, Veronicas, *Rhododendrons*, Azaleas, and the

also very charming. In the centre of their large group the DONARD NURSERY Co. massed their new Donard Seedling Broom, which is stated to be a cross between *C. Dallimorei* and *C. ochroleuca*. It is a very graceful, vigorous, and free-flowering variety, with flowers much like the former, but brighter and more fawn-coloured. *Leptospermum*, *Pittosporum* in variety, the variegated Myrtle, *Lomatia pinnatifolia*, *Picea Pinsapo aurea*, *Retinospora squarrosa subhirsuta*, and a brilliant little plant of *Acer Chisio* were also very noteworthy.

A large corner space was attractively filled by Messrs. WM. CUTBUSH AND SONS with a delightful grouping of Polyantha Roses, followed by general shrubs, the chief of which were Japanese Maples of rich colouring, various *Rhododendrons*, Azaleas of all types, particularly the mollis and dainty little Kurume varieties. Hydrangeas and Brooms, with Astilbes and other herbaceous plants.

A couple of groups from Messrs. FLETCHER BROS. were well filled with various *Rhododendrons*, such as Alice, Pink Pearl and Boule de Nègre, Brooms, dwarf Conifers and Bay trees.

Clematises of great excellence were largely contributed by Messrs. G. JACKMAN AND SONS. These were particularly vigorous plants, bearing numerous large flowers of great beauty. The chief of what may be termed the standard varieties were Nelly Moser, Lasurstern, Gloire de St. Julien, Lady Caroline Nevill, Lord Neville and Fairy Queen. Several excellent new sorts included Crimson King, which may be described as a greatly improved Ville de Lyon, Lady Betty Balfour, of Jackmanni appearance, but greatly improved in size and richness of colour; and King of the Belgians, a silvery mauve patens variety. Of the double-flowered sorts, the most noteworthy were Lady Lovelace, pale purple; Duchess of Edinburgh, white; and Belle of Woking, pale lavender. Floriferous Clematises were also shown by Messrs. JOHN PEED AND SON, who included Duchess of Edinburgh, Mrs. Geo. Jackman, Marcel Moser and Duke of Norfolk in a general collection.

#### Rhododendrons and Azaleas.

Several very large groups of handsome *Rhododendrons* were arranged by Messrs. WATERER, SONS AND CRISP and these were in the pink of perfection, making a glorious display of colour. One large group was filled solely with Alice, a large pink variety nearly equal in size to Pink Pearl, which figured largely in other groups, and of deeper shade of colour. The new variety Bernard Crisp, of pale blush pink colour, which deepened at the edges, and Corona, a smaller truss, which has cardinal red buds opening to pink and passing to blush shades were also very charming. The brilliant Doncaster and very large bushes of George Hardy were other noteworthy varieties in this excellent display. In another part of the tent Messrs. WATERER, SONS AND CRISP displayed Maples, and many Ghent Azaleas bordered with *Ledum palustre*. A handsome group of such valuable *Rhododendrons* as The Gem, Mrs. E. C. Stirling and Pink Pearl was attractively arranged by Mr. LEWIS, and these hardy evergreen shrubs were also freely used by Messrs. WALLACE AND CO., and Messrs. KENT AND BRYDON in their formal gardens.

The more tender varieties were shown by Messrs. R. GILL AND SONS, who also had sprays of the brilliant *Embothrium coccineum*. Of their many *Rhododendrons* several varieties of *R. Aucklandii*, *R. Nuttalli*, *R. Dalhousiae*, *R. Falconeri* and *R. Norman Gill* were very handsome. The last-named is a cross between *R. Aucklandii* and *R. Beauty of Tremough*, and the trusses of large flowers are a delightful blush pink shade. A smaller collection was shown by LADY ABERCONWAY (gr. Mr. F. C. Peddle), Bodnant, N. Wales. Besides a number of the large-flowered sorts, apparently of *R. Aucklandii* origin, there were trusses of *R. Roylei*, *R. Sargentiana*, with small pale primrose flowers, the fragrant Lady Alice Fitzwilliam and *R. bullatum*. A glorious display of Azalea mollis and Ghent

FIG. 152.—ROCK GARDEN EXHIBITED BY MESSRS. G. G. WHITELEGG AND CO. AT THE CHELSEA SHOW.

slow-growing *A. p. roseo-marginatum* was also in excellent condition and most delicately beautiful. A tall specimen of *A. p. septemlobum* was bearing numbers of brightly coloured fruits, while a smaller example of *A. p. aureum* was in flower. Not only was there a very great variety on view, but the disposition was very praiseworthy.

Outside the Embankment end of the large tent Messrs. L. R. RUSSELL, LTD., had a graceful arrangement of miscellaneous trees and shrubs. Trained examples of ornamental Vines predominated, and of these mention may be made of *Vitis Ciotat*, a very graceful climber; *V. armata Veitchii*, and *V. Thunbergii*. There were also several useful species of *Ceanothus*, such as *C. rigidus* and *C. Veitchianus*, just coming into flower, and *Eleagnus glabra variegata*, *Rhus typhina*, and various *Pittosporums*, while in the foreground we noted batches of an erect-growing Rosemary.

In a couple of graceful groups Mr. G. REUTHE

fragrant *Staphylea colchica*. Another noteworthy feature was the sprays of *Davidia involucrata*, bearing large quantities of the conspicuous white bracts surrounding the flowers. Associated with these shrubs were many valuable border plants, including tall spikes of *Eremurus*, various *Paeonies*, *Iberis gibraltarica*, *Veronicas* in variety and the like. Near by Mr. R. C. NORCUTT had a graceful group of standard Brooms, *Pyruses*, and Lilacs, with brightly coloured Japanese Maples, Kurume and Ghent Azaleas, *Ericas*, excellent bushes of *Kalmia latifolia*, and *Daphne Cneorum*. In an adjoining group Mr. NORCUTT exhibited many varieties of Lilac, both as bushes and as cut sprays.

An elegant arrangement was made by Messrs. J. CHEAL AND SONS with many standard Pink Pearl *Rhododendrons*, Maples, Laburnums, *Staphylea colchica*, and Brooms. The little bushes of *Pyrus Malus* varieties, *Ceanothuses*, *Kalmias* and Kurume Azaleas were

varieties was made by Messrs. R. AND G. CUTHBERT. These filled a considerable area, and the plants bore enormous quantities of bloom, providing masses of glowing vivid colour. The mollis varieties predominated, and of these J. C. Van Thol, Imperial, deep orange shaded with rose; Anthony Koster, a rich yellow, and Isabella Van Houtte, were very prominent. Of the very many varieties of Ghent Azaleas it was probably those with double or semi-double flowers that best withstood the heat and attracted most attention. Of this type, Aida, soft pink, and Rosetta, blush, were very delightful. At one end of these larger sorts, there was a charming little collection of the smaller Kurume Azaleas in a great variety of colours and a plant of the vivid purple *A. rhombica*.

#### Topiary.

Clipped shrubs occupied a considerable space out-of-doors at the Embankment end of the grounds. Nearest to the entrance there was a large collection of well-trained specimens, which are euphemistically described as "Cutbush's Cut-bushes," by Messrs. WM. CUTBUSH AND SON. These were of almost every conceivable form, and they met with the unqualified approval of all who have a liking for topiary specimens. A little farther on, Mr. J. KLINKERT had an even more ambitious display. Spacious intersecting avenues of trim Box specimens of perfect form were bordered by *Nepeta Mussinii*, thus giving a bright, though cool, effect. Within the enclosures so formed, Mr. KLINKERT had arranged a great number of spirals, birds, seats, columns surmounted by balls, and other designs, all fashioned in the living Box or Yew.

Adjoining their pleasant Rose garden, Messrs. CHEAL AND SONS set out excellent topiary specimens on either side of a broad grass path. For the most part these were exceptionally large examples, and displayed excellent workmanship.

#### Stove and Greenhouse Plants.

The only general exhibit of stove plants was a very good collection by Messrs. L. R. RUSSELL, LTD. The most prominent feature was *Medinilla magnifica*, which was represented by several plants distinctly larger than has been seen at shows during recent years. These were well furnished with large, handsome leaves and long, hanging racemes of beautiful pink flowers. Many well-coloured Crotons, the golden *Dracaena Victoriae*, *Aralias* of graceful, slender habit, *Gloriosa superba*, *G. Rothschildiana*, many *Anthuriums*, and several species of *Phyllanthus* were other plants of interest. The arrangement of the collection was admirable, and all the plants illustrated the highest cultivation.

*Caladiums* were shown in quantity and of considerable excellence by Messrs. JOHN PEED AND SON. This extensive collection included a great number of the older sorts, while amongst the new varieties were *May Queen*, a large leaf, freely mottled with rose-pink over green; *Sir Ernest Shackleton* is another large foliaged variety in which the white and green leaves are spotted with carmine. *Red Ensign* may be termed an improved *Mikado*, and possesses most brilliant colour. *Dorothy Hodgson* is not quite so large, but has nearly transparent leaves freely flushed with pink, which are green at the margins. *Crested Wave* is one of the very transparent varieties that are so difficult to grow to perfection, but the specimen on view was admirable. Besides the handsome *Caladiums* there were *Streptocarpus* of an excellent strain, many *Hydrangeas*, *Petunia Mrs. John Campbell*, double blue; and a great double rose-pink variety. A plant of *Carnation Bis Greenfield*, a variety, which has been the subject of recent correspondence in our pages, showed beyond question that it may be grown to produce an abundance of large, brilliant blooms.

A magnificent collection of *Hippeastrums* was shown by Lt.-Col. Sir GEORGE HOLFORD (gr. Mr. Clark), from Westombirt. This is not the easiest of plants to arrange to great effect unless associated with miscellaneous plants, but with only the addition of *Cocos plumosus* and *Phoenix Roebelinii* Palms a most attractive exhibit was

made. The plants were all of the highest quality and included an excellent white variety and splendid examples of all the possible shades of colour.

Many plants of *Dracaena Deremensis* Bausei was shown by Mr. Bause to illustrate its value as a pot plant for general decoration. These were all sturdy and vigorous, and the broad, central white lines on the foliage stood out in sharp contrast to the dark green margins.

An extensive group, largely of excellent plants of *Schizanthus* was shown by Baron BRUNO SCHROEDER (gr. Mr. E. J. Henderson), Dell Park, Englefield Green. This was an excellent display, and besides the great number of perfectly-grown *Schizanthus*, included many good *Streptocarpus*, *Calceolarias* and *Hydrangeas*.

An uncommon style of arrangement was made by Messrs. SUTTON AND SONS to display a great quantity of flowering plants raised from their seeds. It was in a series of bays, and when, which was performed the case after the show opened, each section was viewed separately, it was an admirable method of displaying the different plants (see Fig. 149). Several large *Kentias* added to the grace and charm, and gave relief from the abundant bloom. At intervals large baskets of white *Gloxinia Her Majesty*, made pleasant breaks in the colour scheme. The many other plants used included *Clarkia elegans Salmon Scarlet*, as tall plants bearing countless numbers of flowers; a great variety of excellent *Salpiglossis*, tall plants of *Lavatera Loveliness*, many *Star Cinerarias*, the graceful *Lobelia tenuior*, *Dimorphotheca aurantiaca*, *Schizanthus* in great numbers, and *Phlox Drummondii Bright Crimson*.

The outline of the magnificent exhibit by Messrs. J. CARTER AND CO., was a large circle, with four smaller attendant rings. A great amount of thought must have been expended to bring this design to such a successful conclusion. The quality of the immense number of plants and the colour arrangement are deserving of the highest praise. The circle idea was carried to its logical conclusion, inasmuch as within the large circle was a series of smaller circles, which each contained such plants as *Stocks Empress Elizabeth*, *Scarlet Brompton*, *White Brompton*, various *Clarkias*, *Star Cinerarias*, *Delphinium Blue Butterfly*, *Coleus Cordelia*, *Streptocarpus*, long-spurred *Aquilegias* and *Schizanthus*. Midway around the large circle there were raised vases of excellent sweet Peas in distinct varieties.

*Star Cinerarias* in great variety were well shown by Messrs. WEBB AND SONS, who also exhibited equally good strains of the large-flowered type of herbaceous *Calceolarias*, *Schizanthus*, and a number of very pretty plants of *Rhodanthe maculata*.

Messrs. STORRIE AND STORRIE also exhibited large-flowered *Cinerarias*, and these unfortunately displayed signs of distress after the long journey, but the individual flowers were very large and shapely.

The finest *Stocks* in the Show were associated with sturdy floriferous little bushes of *Schizanthus roseus compactus* by Messrs. DOBBIE AND CO. The *Stocks* were all of the variety *Snow-drift*, and each plant bore a tall, perfect pyramid of pure white fragrant flowers. *Schizanthus grandiflora* strain was contributed by Messrs. J. GODFREY AND SON, who also staged such show *Pelargoniums* as *Godfrey Heard*, *Topsy*, *Fascination*, and the *Prince*.

Interesting collections of zonal *Pelargoniums* were shown by several growers. Messrs. JARMAN AND CO. had such double-flowered sorts as *Dora Pasteur*, *Ville de Poitiers*, *W. Savory*, and the small pink Cactus-like *W. S. Bevis*. The CHALK HILL NURSERY CO. showed many trusses of good singles next to their magnificent plants of *Mimulus*. The *Pelargoniums* included *Maxime Kolvalesky*, *Mrs. J. Pearson*, *Goldfinch*, *Excelsior* and *Sir R. Batty*. Mr. R. J. CASE displayed *Pelargoniums Mrs. W. A. Cull*, *Dagata*, *Lady Warwick*, *Mrs. W. J. Case* and *Somerset Lad*; while Messrs. STUART, LOW AND CO. exhibited a group of useful bedding

varieties; and the BLAKENEY NURSERIES showed Ivy-leaved *Pelargonium Sir Percy Blakeney*.

An interesting collection of Australian plants was made by Messrs. STUART LOW AND CO. At the back there were many floriferous specimens of *Mimosa*, and they also showed the Bottle-brush tree (*Metrosideros floribunda*), and *Boronia elatior* with blue *Hydrangeas* and a small collection of *Phyllocactus*. A large circular group of excellent *Hydrangeas* was arranged by Mr. H. J. JONES. The large trusses of the Apple-blossom-pink *Professor du Bois*, which received an Award of Merit, were very prominent, as also was the deeper pink of *Etinclant*, the crimped petals of the white *Madame M. Moulrière*, and the intense blue of *Mons. Ghys*. A large bush of the graceful trailing *Lobelia Arethusa* was shown by Messrs. WALSHAW AND SONS.

#### Rock Gardens.

The customary space was devoted to the ever-popular Rock Gardens; but, on the whole, these were scarcely so successful as usual. In several instances the boulders were far too sparsely used, giving an unkempt appearance, which approximate the hill-tops around some of our southern seaside resorts rather than Alpine scenery.

One of the exceptions to the above was the rock garden by Messrs. G. G. WHITELEGG, LTD., on which it was fully evident a deal of understanding thought and skill had been expended. The tumbling hillside rocky stream (see Fig. 152) was one of the most delightful features of the show, and was in perfect harmony with the surroundings. No doubt in self-defence Mr. Whitelegg had roped in this charming rock garden, so a critical examination of the plants used was impossible, but the general effect was very good, and the most prominent species were *Sedum pilosum*, *Gentians*, *Lithospermums*, with dwarf *Phloxes* of amoena type, including the delightful pink-colour *Phlox Vivid*.

A very pleasant hillside rockery was made by Messrs. PULHAM, LTD., and here again it had been necessary to keep the visitors from over-running it. But the general arrangement was good and the waterfall, stream, and pool gave a most grateful cool and restful effect. In a little bog garden attached to the rock garden there were several *Irises*, *Rodgersias* and *Primulas*.

A low rock garden of pleasing outline was made by Mr. CLARENCE ELLIOTT, and in it he planted *Gentiana verna angulosa*, *Sedum spathifolium*, *S. sarmentosa*, and other sorts, with *Aquilegia flabellata* and *Viola gracilis* in happy association. A little colony of the upright Irish *Juniper*, and a group of *Alpina Auriculas* amongst the many plants were also very effective.

A stream tumbling down the hillside between rocky boulders and on into a pool with a moraine beyond was a good feature in the rock garden exhibit of Messrs. R. TUCKER AND SONS. The Moraine contained such plants as the *Morisias*, *Phlox Douglasii*, *Edraianthus pumilionum*, and *Erodium cicutarium*. The grey-toned boulders were very restful and well adapted to display the very appropriate plants set amongst them.

Rock gardens which were noteworthy more for the boulders they contained than for their disposal or for the planting amongst them were made by Capt. SYMONS-JEUNE, Mr. J. WOOD and Messrs. HONSONS, LTD. Part of Mr. Wood's exhibit was a miniature thin Larch plantation, but the colony of *Gentians* was very attractive.

At the Ranelagh end of the Rock Gardens there was a very pleasant herbaceous border arranged by the MAYTHAM GARDENS. The design and general planting was quite good and received a deal of commendation. The Association of *Eucalyptus globulus* would not be everyone's choice, but the grey-green foliage was cool and restful and served as a good foil to the bright colours of the border flowers. Of the latter the most prominent were *Irises*, *Lupins* and dwarf *Phloxes*, and these were pleasantly interspersed with *Lavender* bushes in flower. At one end there was a blue corner composed of *Hydrangeas* and *Lobelias*.

A small collection of *Auriculas* was staged by Mr. JAMES DOUGLAS. With few exceptions, it

was composed of alpine varieties, of which Argus, Majestic, Kaffir, and Mildred Jay is a selection.

A pool in a dell, as arranged by Messrs. R. WALLACE AND Co., provided a most cool and restful retreat from the heat for those who were fortunate enough to enter. The sides of the pool were planted with sufficient suitable species to give colour, which, with the tall Rhododendron and Ghent Azaleas, served to brighten it and dispel any gloom that might have suggested itself. On the way to the pool there were masses of Rhododendrons, Azaleas, Enkianthus, Brooms, and other flowering shrubs, backed by cool green Pines and Cypresses.

The well-designed rock garden, with stream and pool, designed by Messrs. KENT AND BRYDON, was in the nature of a surprise garden, for the winding path around the ample beds of Rhododendrons, Azaleas, and other flowering shrubs gave no promise of this delightful feature, though in themselves they were a great attraction. The disposal of the boulders and the planting in the rock garden was deserving of great

AND Co., attracted an immense amount of deserved admiration. It was a very ingenious and most successful effort. In the sunken centre the clock face was planted with Violas and Daisies, while the hour figures were of white Iberis sempervirens, set in squares of green grass, over which the long clock hours told the hours. The borders above the stone wall were filled with a brilliant display of the best Darwin Tulips, while beyond these were beds and borders of Rhododendrons, Azaleas, Anemone Dropmore variety, and Geums. Altogether it was a very interesting, uncommon, and attractive garden.

Many beds and borders of floriferous Rhododendrons, Azaleas, Ledums and Pittosporums led the way to a sunken paved oval, where Messrs. WATERER, SONS, AND CRISP had the beds filled with Tulips and Nepeta Mussinii. The borders above the stone retaining wall were planted with numbers of excellent little bushes of Rhododendron Pink Pearl, which provided a feast of rich pink colour. At the back there were some excellent topiary specimens, which added to the attractions of the garden.

Lupins, Aquilegias, and Iberis was made by Mr. E. DIXON, while Messrs. R. NEAL AND SONS built a summer-house, together with a paved forecourt and pools, with water lilies, while at the sides they planted Rhododendrons and Maples, and in front made a low rock garden, in which the boulders were rather prominent.

Of the many formal gardens that by Mr. JAS. MACDONALD, to display a great variety of grasses was one of the most successful. The ornamental grasses include such genera as Elymus, Eulalia, Holcus, Stipa, Glycera, Agrostis, and Spartina, and these were set in the perfect greensward, which was of rich green colour, and entirely free from weeds.

#### Tulip Committee

*Present:* Sir Daniel Hall (in the chair), and Messrs. H. V. Warrander, J. W. Jones, George Churcher, Herbert Smith, W. A. Milner, H. Backhouse, C. W. Needham, George Monro, P. R. Barr and Charles H. Curtis (Hon. Sec.).

#### FIRST-CLASS CERTIFICATE.

*Tulip Carrara.*—The first pure white Darwin Tulip. A sturdy grower with broad, white petals and yellowish-green stigma and anthers. Gained an Award of Merit in 1921. Shown by Messrs. BARR AND SONS.

#### AWARDS OF MERIT.

*Tulip Dido.*—This handsome, strong-growing Darwin Tulip, of soft orange colouring, heavily suffused on the outside with carmine-red is of good shape and size. Shown by Messrs. BARR AND SONS, and Messrs. DOBBIE AND Co.

*Tulip Fantasy.*—A glorious Parrot Tulip of glistening rich pink colour, shaded with orange pink on the inside of its ragged segments, and stained with brownish green on the outside of the three outer segments. This handsome variety was raised by Messrs. de Graaff Brothers, and shown by Messrs. BARR AND SONS, but an error has occurred, inasmuch as Messrs. Sutton and Sons received an A.M. for the variety in 1921.

*Tulip Phemis.*—A white variety, of rounded form and good substance, with pale green stigma and anthers. Rather short in the flower, but otherwise good. Shown by Messrs. BARR AND SONS.

#### GROUPS.

Rarely have Tulips been displayed in such quantity for a number of years at this show, the season, as a rule, being a little earlier than the present one. The blooms throughout were very clean and good, but the heat of the tents played havoc with the flowers. Not only did it cause them to open to a stage almost beyond recognition but the blooms of many varieties drooped their heads. Messrs. BARR AND SONS, King Street, Covent Garden, filled a sixty-five feet table length with vases of Tulips, relieved with ornamental Acers. The very beautiful breeder Tulip, Louis XIV., was particularly fine, as were also the flowers of Mrs. Farncombe Sanders, red; Dom Pedro, bronze; Margaret, blush; Moonlight, yellow; Europe, bright red; The Bishop, purple; Bouton d'Or, yellow; Prince of Orange, orange-red; and Afterglow, a beautifully shaded flower of Apricot bronze, and pink shades.

Messrs. R. H. BATH, LTD., Wisbech, staged a representative collection of May-flowering Tulips in the form of a ground group, the flowers arranged with sprays of Solomon's Seal and Ornithogalum nutans. The principal varieties were Anthony Roozen, pink; Eclipse, dark red; Inglescombe Yellow; Zulu, black; St. Simon, claret; Golden Bronze, King Harold, crimson; Sir Francis Darwin, red; and Panorama, a lovely breeder variety.

Messrs. DOBBIE AND Co., Edinburgh, excelled with a beautifully arranged group of epergnes, vases, and bowls of Tulips, set off against a black background and interspersed with trails of Asparagus and Palms. The flowers were of excellent quality, and were represented by such varieties as Isis, scarlet; W. T. Ware, yellow; White Swan; Clara Butt, pink; Ergaste, lavender; Mrs. Moon, yellow; La Candeur, nearly white; Europe, scarlet; Inglescombe Yellow; Sir Harry Veitch, crimson; and Prof. Michael Forster, red. Among Parrot Tulips,

FIG. 153.—PORTION OF MESSRS. R. WALLACE AND CO'S. IRIS GARDEN AT THE CHELSEA SHOW (SHERWOOD CUP). (SEE PAGE 276.)

praise. In view of the type of garden, the planting was done with a wise restraint, and while the association of Gentians and dwarf Junipers may not appeal to the purist it was exceedingly effective. In the garden itself the breadths of Phlox canadensis, Lithospermums, and Saxifrages were very successful.

#### Formal Gardens.

A sunken Rose garden, intersected by a canal, widening to a square pool in the centre was the motif of a charming garden set out by Messrs. J. CHEAL AND SONS. The eight rectangular Rosebeds were filled with such graceful little polyantha varieties as Ellen Poulsen, Jessie, Mr. W. H. Cutbush, and the bright Triomphe d'Orleans (see Fig. 151). There was ample green sward, and a low retaining wall bounded a border, which contained dwarf Lavenders and Nepeta Mussinii. Beyond the flagged terrace walk there was a border of such herbaceous plants as Trollius, Lupins, Polemonium coeruleum, various Irises, and Spiraea Queen Alexandra. A well-built pergola, with a border of Roses, Rhododendrons and Azaleas, separated the garden from the topiary, which is referred to elsewhere.

The clock garden, made by Messrs. JAS. CARTER

The outdoor Iris garden planted by Messrs. G. BUNYARD AND Co. attracted a deal of admiration. The arrangement served to display a great variety, chiefly of the germanica section, to great advantage, and many visitors were charmed by the central sundial, and the plants around it. Of the very many Irises we selected the following as being typical and desirable sorts: Princess of Wales, Kharput, Dr. Bernice, Innocenza, Hector, Azure, Raffet, Lord of June, and Crusader.

Although primarily designed and made to display the value of the stone from his quarries, Mr. HERBERT JONES succeeded in having one of the most fascinating gardens in the show. It was in the style of an old orchard Tudor garden (see Fig. 150), with a small stream enclosed by an old thatched wall, and containing a charming garden house. As was proper, the planting was lightly done, and it was made a very desirable haven during the broiling weather. Stonework was the chief feature in the formal garden by Messrs. BOTANICUS, LTD., while the EN TOUT CAS Co., Messrs. GAZE AND SONS, and Mr. A. D. THOMPSON made formal gardens to contain their special forms of hard-courts for tennis.

A sunken garden planted with Violas, Saxifrages,

Sensation and Markgraaf attracted attention, and Carrara was a beautiful white flower, a cross, we believe, between White Swan and a Darwin variety. Adjacent, the same firm displayed the new white Stock, Snowdrift, a magnificent variety, represented by finely grown specimens, arranged a little too stiffly amongst a groundwork of neat plants of *Schizanthus roseus compactus*.

Messrs. RYDER AND SON (1920), LTD., St. Albans, also contributed Tulips in fine selection and quality, Bartigon, red; Rosabelle, rose pink; Louis XIV., bronze purple; Centenaire, pink; King George V., scarlet; and Baronne de la Tonnyay, pink; were some of the varieties used.

Vases of Tulips were exhibited by Mr. ALFRED DAWKINS, Kings Road, Chelsea, and very fine blooms of Madame Krelage, rose pink; Ellen Willmott, yellow; Pride of Haarlem, purplish red; and Mrs. Farncombe Sanders, red, were on view. The same firm also showed some charming Dutch Irises, including Rembrandt, deep blue; Anton Mauve, pale blue; and Hartz, pale blue with white falls. *Iris filifolia*, in dark and pale blue form, was also represented. High quality Tulips were also staged by THE ANGLESEY BULB GROWERS' ASSOCIATION, Llanfair, P.G., Anglesey, the flowers being arranged in pretty decorative baskets. Emerald Gem, rose flushed salmon; Lord Cochran, bronze; Andromaque, rose purple; Bouton d'Or, yellow; Clara Butt, pink; Zwanenberg, a new white Darwin with black stamens; Louise de la Valliere, rose; W. T. Ware, deep yellow; and Louis XIV., dark purplish bronze, were a few of the varieties represented by high-class blooms. Messrs. RICH AND Co., Bath, also showed Tulips of which Pride of Haarlem, La Merveille, Wona Wona, Rev. Ewbank, Negro, and Inglescombe Yellow were a few of the best.

#### Fruit and Vegetable Committee.

Present: Messrs. A. H. Pearson (in the chair), W. H. Divers, W. Bates, Owen Thomas, G. Reynolds, A. Bullock, J. G. Weston, E. Neal, J. Cheal, Geo. Berry, H. S. Rivers, W. Crump, J. Basham, S. B. Dicks, J. Harrison, W. F. Giles, E. A. Merryweather, A. C. Smith, P. C. M. Veitch, E. A. Bunyard, H. Prince, J. C. Allgrove, E. Beckett, T. Pateman, J. Gibson, G. F. Tinley and F. Jordan.

#### FRUIT.

Messrs. GEO. BUNYARD AND Co., LTD., Maidstone, staged fifty-six varieties of Apples, all of remarkably fine quality considering the lateness of the season, and staged in a most pleasing manner, with Palms and Ferns as foils. The outstanding varieties were Encore, Wagener, Sturmer Pippin, Beauty of Stoke, Adams's Pearmain, Striped Beefing, Hornead Pearmain, Brownlee's Russet, Royal Russet, and Alfriston.

Messrs. LAXTON BROS. showed baskets of Strawberries representing their latest and best varieties. The round-fruited Sir Douglas Haig variety was exceptionally fine, pot plants carrying heavy crops of ripe berries. This is one of the best flavoured of the early varieties, and takes on a very dark colour. Lord Beatty is a wedge-shaped, paler variety, recommended for its heavy cropping and good flavour. Others shown were The Duke and a first early—Maréchal Foch—with the "Viscountess" flavour.

Messrs. T. S. RIVERS AND SON, Sawbridge-worth, showed pot fruit trees grown in orchard houses. The plants were perfect specimens, and well fruited, but not so forward as some we have seen from this firm on previous occasions, the season having been unfavourable. For this system of cultivation Peaches, Nectarines and Figs are eminently suitable, and the varieties shown were those which answer best for the earliest cropping, such as Duke of York Peach, Cardinal Nectarine, and Brown Turkey Fig.

Messrs. S. SPOONER AND SONS, Hounslow, staged, in the open, finely trained pot trees of Gooseberries and Currants.

#### VEGETABLES.

The only exhibit of vegetables was a collection from the Hon. VICARY GIBBS' gardens at Aldenham, and Mr. BECKETT well maintained his high reputation both for skill in cultivation and effec-

tive method of displaying the various dishes, for it was as attractive as a floral group. The exhibit was self-contained, on a table with a pale green ground, which harmonised well with the vegetables and with the fancy stands of varying heights. The variety and quality of the subjects was remarkable so early in the season, and in a year when it is difficult for the exhibitor to attain such perfection, practically every available kind of vegetable was included. The dish of *Oxalis tuberosum*, which was of a rich red colour, attracted much notice.

#### AWARDS MADE BY THE COUNCIL.

##### SPECIAL SILVER CUPS.

*Sherwood Cup*, for the most meritorious exhibit in the show: to Messrs. R. WALLACE AND Co.

"Daily Graphic" Cup, for rock garden: to Messrs. PULHAM AND SONS.

*Coin Cup*, for the best exhibit by an amateur: to the Hon. VICARY GIBBS (gr. Mr. Ed. Beckett).

##### ORCHIDS.

*Gold Medal*.—To Sir JEREMIAH COLMAN, Bart. (gr. J. Collier), and Messrs. CHARLESWORTH AND Co.

*Small Silver Cup*.—To Messrs. STUART LOW AND Co.

*Silver-Gilt Flora Medal*.—To Messrs. JAMES CYPHER AND SON; to Messrs. JAMES AND A. McBEAN; and to Messrs. SANDERS.

*Silver-Gilt Banksian Medal*.—To Messrs. MANSSELL AND HATCHER, LTD.

*Silver Banksian Medal*.—To Mr. H. DIXON; and to Messrs. FLORY AND BLACK.

##### ROCK GARDENS.

*Gold Medal and Congratulations*.—To Messrs. R. TUCKER AND SONS.

*Large Silver Cup*.—To Messrs. G. G. WHITELEGG AND Co.; and to Mr. B. H. B. SYMONS-JEUNE.

*Silver-Gilt Flora Medal*.—To Messrs. HODSONS, LTD.; and to Messrs. KENT AND BRYDON.

*Silver-Gilt Banksian Medal*.—To Mr. CLARENCE ELLIOTT.

##### TULIPS.

*Gold Medal*.—To Messrs. DOBBIE AND Co., LTD.

*Large Silver Cup*.—To Messrs. BARR AND SONS.

*Small Silver Cup*.—To the ANGLESEY BULB GROWERS' ASSOCIATION.

*Silver-Gilt Banksian Medal*.—To Messrs. R. H. BATH, LTD.

*Silver Flora Medal*.—To Messrs. RYDER AND SON, LTD. (Tulips).

*Silver Banksian Medal*.—To Messrs. RYDER AND SON, LTD.

##### FORMAL GARDENS.

*Gold Medal*.—To Messrs. G. BUNYARD AND Co., LTD.

*Small Silver Cup*.—To Mr. H. JONES; and to Messrs. R. WALLACE AND Co.

*Silver-Gilt Flora Medal*.—To Messrs. J. CHEAL AND SONS; to Messrs. W. H. GAZE AND SONS, LTD.; and to Messrs. JOHN WATERER, SONS AND CRISP, LTD.

*Silver-Gilt Banksian Medal*.—To Mr. E. DIXON; to EN-FOUT-CAS; to Messrs. GILLIAM AND Co.; to Messrs. R. NEAL AND SON; and to Messrs. JAMES CARTER AND Co.

##### CARNATIONS.

*Gold Medal*.—To Messrs. ALLWOOD BROS.

*Allwood Bowl*.—To Rt. Hon. LORD LAMBORNE, C.V.O.

*Large Silver Cup*.—To Mr. C. ENGELMANN.

*Silver-Gilt Flora Medal*.—To Messrs. WM. CUTBUSH AND SON; to Messrs. STUART LOW AND Co.; to Mr. JAMES DOUGLAS; to Mr. H. LAKE-MAN; and to Mr. C. H. HERBERT.

*Silver-Gilt Banksian Medal*.—To Messrs. K. LUXFORD AND Co.

##### SWEET PEAS.

*Gold Medal*.—To Messrs. DOBBIE AND Co.

*Large Silver Cup*.—To Messrs. ALEX. DICKSON AND SONS, LTD.

*Silver-Gilt Banksian Medal*.—To Messrs. R. BOFTON AND SON; and to Messrs. IRELAND AND HITCHCOCK.

*Silver Flora Medal*.—To Mr. J. STEVENSON.

##### TREES AND SHRUBS.

*Gold Medal*.—To Messrs. R. AND G. CUTBERT; to Messrs. R. WALLACE AND Co.; and to Messrs. JOHN WATERER, SONS AND CRISP.

*Small Silver Cup*.—To Messrs. R. GILL AND SONS.

*Silver-Gilt Flora Medal*.—To DONARD NURSERY Co.; to Messrs. WM. CUTBUSH AND SON; to Hon. H. D. McLAREN; to Mr. R. C. NOTCUTT; to Mr. G. REUTHE; to YOKOHAMA NURSERY Co.; and to Messrs. J. CHEAL AND SONS, LTD.

*Silver-Gilt Banksian Medal*.—To Mr. J. C. ALLGROVE; to Messrs. FLETCHER BROS.; to Messrs. HILLIER AND SONS, LTD.; to Mr. T. LEWIS; and to Messrs. STUART LOW AND Co. (Hardy plants).

*Silver Flora Medal*.—To Messrs. JOHN WATERER, SONS AND CRISP, LTD.

##### ROSES.

*Large Silver Cup*.—To Messrs. WM. PAUL AND SON, LTD.

*Small Silver Cup*.—To Mr. ELISHA J. HICKS.

*Silver-Gilt Flora Medal*.—To Messrs. B. R. CANT AND SONS.

*Silver-Gilt Banksian Medal*.—To Messrs. WM. CUTBUSH AND SON; and to Messrs. G. PAUL AND SONS.

*Silver Flora Medal*.—To Messrs. F. CANT AND Co.; and to Mr. G. PRINCE.

*Silver Banksian Medal*.—To Rev. J. H. PEMBERTON; and to Mr. CHARLES TURNER.

##### HARDY PLANTS.

*Gold Medal*.—To Messrs. M. PRITCHARD AND SONS (Alpines).

*Large Silver Cup*.—To Messrs. G. JACKMAN AND SONS (Clematis and Herbaceous plants); to Messrs. BEES, LTD. (Herbaceous plants).

*Small Silver Cup*.—To Messrs. STORRIE AND STORRIE.

*Silver-Gilt Flora Medal*.—To Mr. J. C. ALLGROVE (shrubs and flowers); to Messrs. BAKERS, LTD. (Herbaceous plants, Alpines and Shrubs); to Messrs. BOWELL AND SKARRAIT (Herbaceous plants, Alpines and Shrubs); to Mr. CLARENCE ELLIOTT (Alpines); to Messrs. MAXWELL AND BEALE (Alpines); to Mr. G. REUTHE (Alpines); and to Messrs. R. TUCKER AND SONS (Herbaceous plants and Alpines); to Mr. AMOS PERRY (Ferns and Herbaceous plants); to Messrs. H. J. JONES, LTD. (Hydrangeas); and to Messrs. JOHN WATERER, SONS AND CRISP (Irises, Herbaceous and Alpine plants).

*Silver-Gilt Banksian Medal*.—To Messrs. G. AND A. CLARK, LTD.; and to Messrs. J. PIPER AND SONS (Flowering plants); to Messrs. CARTER PAGE AND Co. (Alpines); to Messrs. J. CHEAL AND SONS, LTD. (Alpines); to Mr. R. PRITCHARD (Alpines); and to Messrs. JOHN WATERER, SONS AND CRISP (Alpines and Herbaceous plants).

*Silver Flora Medal*.—To Messrs. B. LADHAMS, LTD.; to Messrs. W. H. ROGERS AND SONS; to Mr. W. WELLS, Junr.; to Messrs. SKELTON AND KIRBY; to Mr. E. SCAPLEHORN; to Messrs. RICH AND Co.; to Mr. H. HEMSLEY (Alpines); and to the Misses HOPKINS (Alpines).

*Silver Banksian Medal*.—To Mr. G. R. DOWNER; to Mr. G. W. MILLER; to Messrs. G. G. WHITELEGG AND Co. (Irises); to Messrs. JOHN PEED AND SONS (Clematis).

## VEGETABLES.

*Gold Medal and Congratulations.*—To the Hon. VICARY GIBBS (gr. Mr. E. Beckett).

## FRUIT.

*Gold Medal.*—To MESSRS. G. BUNYARD AND CO. (Apples).

*Silver-Gilt Hogg Medal.*—To MESSRS. RIVERS AND SON, LTD. (fruit trees in pots).

*Bronze Hogg Medal.*—To MESSRS. LAXTON BROS. (Strawberries).

## MISCELLANEOUS.

*Gold Medal.*—To MESSRS. BLACKMORE AND LANGDON (Begonias); to SIR GEORGE HOLFORD, K.C.V.O. (gr. Mr. Clark) (Amaryllis); to MR. L. R. RUSSELL (Stove plants); to MR. JAMES MACDONALD (Grasses); to MESSRS. JAMES CARTER AND CO. (Flowering plants); and to MESSRS. SUTTON AND SONS (Flowering plants).

*Silver-Gilt Lindley Medal.*—To MR. E. BECKETT, for cultivation; to MR. JOHN MACWATT (Primulas); and to MR. H. CUNNINGHAM, for cultivation.

*Small Silver Cup.*—To MESSRS. DOBBIE AND CO. (Schizanthus and Stocks).

*Silver-Gilt Flora Medal.*—To MESSRS. JOHN PEED AND SONS (Stove and Greenhouse Plants); to MESSRS. FROMOW AND SONS (Clipped trees); and to MR. L. R. RUSSELL (Mixed group); to BARON B. SCHRÖDER (gr. Mr. E. J. Henderson) (Flowering plants).

*Silver Flora Medal.*—To MR. R. ELLISON (Cacti, Ferns and Palms); to MR. J. KLINKERT (Clipped trees); to MATTHAY GARDENS (Herbaceous border); to MESSRS. W.M. CUTBUSH AND SON (Clipped trees); and to MR. A. F. WOOTTEN, K.C. (Show Pelargoniums).

*Silver Banksian Medal.*—To MESSRS. WEBB AND SON (Flowering plants); to MESSRS. STORRIE AND STORRIE (Cinerarias); to CHALK HILL NURSERIES (Mimulus, Pansies, Pelargoniums).

*Bronze Flora Medal.*—To MESSRS. JARMAN AND CO. (Geraniums, Violas, etc.); and to MESSRS. GODFREY AND SON (Pelargoniums, Schizanthus, etc.).

## Obituary.

**J. Garton.**—It is with deep regret we learn of the death of Mr. J. Garton, of Messrs. Garton's, Seedsmen, Warrington. He died at his residence, Hafryn, Upper Colwyn Bay, on Tuesday, the 16th inst., following an illness of several weeks. He was born at Newton-le-Willows, in 1863, and very early in life was interested in the reproduction of farm plants, gaining knowledge which he put to great service in the raising of cereals and other farm crops. His success in plant breeding is known to the whole English-speaking agricultural world through results obtained by crossing numerous species and varieties of Oats, including wild Oats, by means of which he introduced vigour of constitution and great yielding capacity to the new breeds, materially improving the food-producing capacity of the best arable soils. He also raised new Wheats, Barley and roots, including Potatoes. In 1892, he introduced a new breed of white Oat, named Abundance, the result of a cross between White Agusut and White Swedish, and this variety is one of the most extensively grown in the country. Mr. Garton was awarded the Gold Medal of the Highland Society of Scotland, and he won Gold Medals at the Chicago Exhibition, the Paris Exposition, and the Brussels Exhibition. The Senate of Edinburgh University proposed to confer the honorary degree of LL.D. on Mr. Garton, in recognition of his life's work, and this degree, had he lived, would have been conferred on him in Edinburgh in July next. On more than one occasion the Department of Agriculture in the United States invited Mr. Garton to lecture in that country, but pressure of his own research work prevented his acceptance of the invitation. The funeral took place at the Wargrave Cemetery, Newton-le-Willows, on Friday, May 19.

## TRADE NOTES.

WITH a view to demonstrating still further the value of their Atco motor in connection with the mowing of lawns, cricket pitches, and football grounds, Messrs. Charles H. Pugh, Ltd., Whitworth Works, Birmingham, have made arrangements whereby clients may have an Atco motor attached to a push mower, thus converting it at once into a motor mower, which may be used by one man or a lad. Clients who find that the motor saves much time and labour may, if they so wish, subsequently have it built into an Atco body at a very reasonable figure. The possibility of having a push mower converted into a motor mower will doubtless attract many who have the care of extensive lawns, and especially at this season when grass grows with such rapidity.

THE Standard Terms and Conditions of Carriage, submitted by the railway companies, pursuant to Section 42 of the Railways Act, 1921, have been investigated by the Transport Sub-Committee of the Chamber of Horticulture. The railways' proposals were in many instances found to be distinctly disadvantageous to horticultural traders, and, consequently, objections have been lodged with the Tribunal, in addition to which the Chamber has associated itself with the objections in this respect lodged by the National Federation of Fruit and Potato Trades' Association. The existing terms and conditions may be found on the back of consignment notes, and any special modifications which readers may desire to press should be notified to the Secretary, together with full details.

Following the public meeting for the discussion of "General Principles," which was held on Tuesday last (May 23), notice is given that detailed objections to the proposed classification of goods (other than perishables) by passenger train must be lodged on or before June 7.

## NEW INVENTIONS.

MR. H. E. AYCKBOURN, of the Atlantic Engineering Works, Northfleet, Kent, has designed a new type, self-propelled, double-purpose spraying machine, for the use of hop and fruit growers, capable of carrying about 100 gallons of liquid and 2 cwt. powder. The mechanism is so arranged that all or individual operations can be undertaken at will. It is possible to spray both powder and liquid simultaneously, and at the same time the machine can be made to travel; or, both spraying operations may be maintained whilst the machine is at rest.

It is intended to manufacture the machine in several types, self-propelled in all cases, but fitted in such a way that powder or liquid can be carried and sprayed in large quantities.

## INQUIRY.

CAN any reader favour me with particulars of names and addresses of makers of the specially prepared terra-cotta or clay material used for surfacing the best constructed hard tennis courts. IF. J. C.

## ANSWERS TO CORRESPONDENTS.

**CATTLEYA CIRRINA:** *F. F.* This Mexican Orchid is one which many have some difficulty in growing successfully. It produces its yellow flowers from May to August; they are large for the size of the plant, and very fragrant. It may be grown on blocks or in shallow pans, but in any case it must not be overburdened with material about the roots. A clean, fibrous compost as used for other Cattleyas is suitable for this species. It thrives with other Mexican Orchids; that is, the plants enjoy a fair amount of heat whilst making their growth, with a long, dry rest, and exposed to all the light possible the whole year round. Shading should only be used

to prevent scorching during the hottest and brightest part of the day, and then only in very hot weather. Close observation will show the best possible time to undertake any necessary re-potting or re-blocking. The plants should be made absolutely firm in either case, upon blocks by hindring them firmly with fine copper wire, and in pans by placing the material firmly around them. The plants grow in a downward direction, and the flowers last a considerable time in perfection upon the plants.

**GRAPES DISEASED:** *J. O. M.* The berries are affected with spot disease, caused by the fungus *Gloeosporium ampelophagum*. Spray the vines and bunches with liver of sulphur, at the strength of  $\frac{1}{2}$  oz. in two gallons of water, or dust flowers of sulphur on the leaves and bunches, and again at intervals of ten days. It has been found of service to thoroughly wet the rods with a solution of iron sulphate when the vines are dormant. Do not use an excessive amount of rich animal manures on the borders.

**NAMES OF PLANTS:** *F. L. 1.* Cedrus Deodara; *2.* Cedrus Libani; *3.* Juniperus communis var. fastigiata; *4.* Picea orientalis; *5.* Stewartia pentagona; *6.* Thuja plicata; *7.* Cupressus Lawsoniana var. ochroleuca; *8.* Abies Pinsapo; *9.* Pinus muricata; *10.* Picea excelsa.—*W. H. C.* An unnamed seedling variety.—*C. H. L.* Veronica Hulkeana.—*L. R. A.* The specimen was very much shrivelled, but, judging by the colour, it would seem to be Rhododendron Cunningham's Sulphur.—*D. W. C.* Rubus spectabilis.—*H. K. A.* Helleborus foetidus.

**RED SPIDER:** *J. D. C.* The red spider enclosed is credited with being the parent of the objectionable harvest mite, which later in the year causes severe annoyance to human beings. The mite is at present in its adult state and is a common feature of gardens during the month of April. It belongs to the group called velvet mites, from the velvety surface of their bodies. Their food appears to be any dead animal matter, such as dead flies or other insects, but they do not attack living aphids. After pairing, their eggs are laid in the ground. The larvae are six legged, minute, red mites, which creep over vegetation, being apparently especially fond of climbing to the tops of cereals, grasses, weeds, etc. From this position human beings and warm-blooded animals detach them. The mites penetrate the skin, especially in any position where the clothes touch. Their burrowings cause excessive itching, but the victim has comfort in the thought that the mite always dies in this position. It probably only passes through to the adult state when chance puts it into contact with cold-blooded animals. During the winter the mites hibernate and reappear as soon as the weather becomes favourable in the spring.

**TOMATO SEEDLINGS DYING:** *Correspondent.* The trouble is due to the disease commonly known as "damping off," which is caused by a fungus, a species of Phytophthora, and infection may have arisen from the soil, seed, boxes, pots, or water supply. A solution of copper sulphate and ammonium carbonate should be used as a spray, in the proportion of two oz. of copper sulphate to eleven oz. of ammonium carbonate. Both the chemicals should be reduced to a fine state by crushing. Use the specific at the rate of one oz. to two gallons of water, putting one oz. of the dry mixture in a little hot water and adding the two gallons of water. Do not use vessels of iron, tin or zinc, as it would corrode them. The fungicide will not save any of the plants that are already attacked. Take care to thoroughly sterilise the soil, boxes or pots used for Tomato seedlings, and well water the soil with the solution after sowing and covering the seeds. The frame you mention would be suitable for growing either Melons or Cucumbers, provided the cultural details are satisfactory.

Plant Sensitiveness.

Since Charles Darwin wrote the series of delightful books dealing with various aspects of plant sensitiveness, as illustrated by climbing and insectivorous plants, and by the movements of plants, little has been done to bring advancing knowledge of this branch of plant physiology to the notice of the general public. It is true that Sir Francis Darwin, whose researches have contributed so much to our knowledge of plant sensitiveness, has written in his own inimitable style on the movement of plants, but his presentation of the subject was deliberately in the interests of the student rather than in those of the general public. If we may judge from the interest taken by those who attended the lectures on plant sensitiveness given recently by Professor Keeble at the Royal Institution, the time is opportune for the publication of a new work on that subject which would summarise in readable style the many new and remarkable facts concerning the ways in which plants adjust themselves to, and maintain their adjustments with their environment. Few people, even among those interested in natural history, realise the extraordinary sensitiveness of plants to those external changes which are called stimuli, or know that this sensitiveness is reflected in incessant movements of adjustment carried out by plants. Everyone is aware of the remarkable and rapid movements of the leaves of the Sensitive Plant, *Mimosa pudica* and allied species, and of the no less sensitive *Neptunia oleracea*; but few realise that these plants only give extreme expression to the powers of movement which

exist in all plants. One reason for the common and erroneous view that plants are relatively passive—in comparison with animals—is doubtless that the machinery of plant-movement is more clumsy, more primitive and less capable of rapid action than is the machinery of muscle-nerve of the animal kingdom. This is true even of the rapidly-executed movements of *Mimosa* and of tendrils. Although the motor mechanism of plants, which is a hydraulic mechanism, lacks the power of effecting extremely rapid movements, and although the transmission of excitation from one point to another in a plant never shows the swiftness which characterises transmission by the nerves of animals, this is not to be ascribed to a lack of quick and delicate "perception" on the part of plants, but rather to a "deliberate" adaptation on the part of plants. Fixed in position by their roots, they cannot run away, but can only turn away from inimical surroundings. Since their adjustments are directed in the main to securing the most favourable position for root, stem and leaf, it would never do for the plants to take cognisance of every insignificant and transitory change in their environment. Otherwise each breath of wind, every passing shadow of a cloud, every rain-drop falling, say, on a tendril, would distract the plant from its proper purpose of "growing into" its environment, and would lead to movements which would have at every moment to be reversed and corrected by others in an opposite sense. That this view is probably correct may be judged from the fact that in delicacy of perception, as opposed to rapidity of response, the plant may exhibit a sensitiveness as acute as, or even acuter than that of an animal. Thus a leaf will respond by curvature of its petiole to a difference of illumination on its two halves as slight, or almost as slight, as that which can be appreciated by the human eye. The latter organ is capable of perceiving a difference of one-hundredth in the intensities of two beams of light. With advancing age this sensitiveness becomes less and differences of only one-thirtieth are perceived; a leaf may perceive differences of one seventy-fifth. The sensitiveness to contact of a tendril is more delicate than is the human skin. The most sensitive of tendrils respond by greater curvature to the contact stimulus produced by the movement of a thread 0.0005 milligrams in weight, whereas the slightest pressure which the human skin can "feel" is about ten times as great. Modern physiology holds to the view that there are in the animal two distinct means whereby regulated movement and orderly growth are carried on. One is physical, by way of the nervous system, the other chemical, by way of the vascular system. There is ground for believing that in plants two corresponding systems also exist. One is chemical, and probably in all respects similar to that of animals. Specific substances manufactured by the tissues are distributed throughout the plant body, but produce specific effects only when they reach certain tissues. The other apparatus for plant reaction to stimuli is physical, and although nothing comparable with nerves exist in plants, there is a physical transmission of the results of stimulation which results in a distant tissue reacting to a local stimulus. Thus the base of the seedling or a grass may be seen to curve after the tip only of the seedling has been illuminated on one side. Cutting the "stem" of the seedling half-way through does not prevent transmission, but if a mica plate be inserted in the cut, no "impulse" passes. Evidently the plant uses a system of water transmission, but of the precise nature of the mode of transmission of the effects of stimulation to the motor region

little is known. There are grounds for believing that plants, like animals, possess special sense organs—localised apparatuses for receiving and recording stimuli. Thus in tendrils of the Cucurbitaceae tactile pits occur, and it is believed that these thin places of the outer cell wall serve to allow slight pressure to affect the living protoplasm beneath. In the response of plants to gravity cells (statocytes) containing movable starch grains are frequently found in those regions in which perception can be proved to occur, and many physiologists hold that "perception" of the stimulus of gravity consists in a disturbance of the protoplasm of these statocytes due to the falling of the starch grains which takes place when the organ containing the statocytes is displaced from its previous position in space. It is perhaps not too fanciful to believe also that the papillose outgrowths of the epidermal cells of the leaves of plants serve as organs of light perception—functioning by focusing the light on the floor of the cell. If the leaf is moved, the spot of light moves, and this disturbance being reflected in a disturbance of the protoplasm leads to excitation of this highly sensitive living material and hence, and speedily, by unknown ways to a movement of adjustment of the leaf stalk, so that the blade is once again brought back to its former position in which the spot of light is "centred." Whether these views are accepted or no, it is abundantly clear that "sensitiveness" is fundamentally the same phenomenon in plants and animals, consisting of a series of operations which include perceptive excitation of the cells of the perceptive zone, transmission of the results of that excitation to, it may be, a distant tissue which, undergoing in its turn excitation, undergoes movement or responds in some other way to that message from the outer world which is called a stimulus.

**Our Coloured Plate.**—With the present issue we publish a coloured plate of *Codiaeum B. Comte*, one of the most handsome of the broad-leaved plants so popular a few years ago for table decoration and known in gardens as *Crotons*. *Codiaeum B. Comte* is described in an article on *Codiaeums*, by Mr. J. Heal, on page 291.

**The Next R.H.S. Meeting.**—The attention of our readers is drawn particularly to the date upon which the next meeting of the Royal Horticultural Society will be held at Vincent Square, Westminster. It is usual for the Committees to meet on a Tuesday, but next week they will meet at the usual hour, but on Wednesday, June 7, as a consequence of the Whit-sun-tide holiday.

**Severe Damage by Hailstorms.**—During the afternoon of May 25 many parts of the country were visited by storms of varying severity, often accompanied by hail. Mr. Mark Mills informs us that during his forty years' experience at Coombe House Gardens, Croydon, he has never seen such a storm as that which occurred about 3.15 p.m. on the above date. He writes that although little wind accompanied the hailstorm over 200 panes of twenty-one ounce glass were broken, while young Figs on walls, Gooseberries, Currants, and Pea pods were stripped, and the spikes of Horse Chestnut, Laburnum, and Lilac were cut off with, in most cases, the first leaf attached. May-flowering Tulips and *Aquilegias* were cropped down closely to the ground. Apples, Pears and Plums suffered considerably, and the young cones from the Cedars of Lebanon were broken off and spread on the ground in hundreds. The hailstones were the largest ever seen in the district, perfectly round, and many of them measured 1½ inch in diameter. Mr. R. G. Pringle writes that the scene in the gardens at Hall Place, Tonbridge, after the passage of the storm,

legged description. Vegetable crops were completely ruined, fruit trees and bushes which were carrying splendid crops were stripped of their fruit and most of their foliage, while over 400 panes of glass were broken in the houses and frames. Some of the hailstones were as large as full-sized Walnuts. In some instances the hailstorms appear to have been very local, thus Piccadilly was white with hail for nearly a quarter of an hour, and the pavement next the Green Park was strewn with pieces of light green foliage cut from the trees by the hailstones, which were about the size of ordinary marbles, but at Chelsea there was very little hail, although a considerable amount of rain fell in a short time. At Bedale, in Yorkshire, a severe hailstorm occurred during the earlier part of the week, and damage was done in the nurseries of Messrs. Harkness and Sons and Messrs. Gibson and Son of that town.

**British Horticulture and Quarantine Order No. 37.**—Mr. W. G. Lobjoit, Controller of Horticulture, who represented British horticultural interests at the Plant Conference held at Washington on May 15, has sent a letter to the Ministry of Agriculture from which we learn that an effort was made to prevent British, Dutch, Belgian, and other delegates from expressing their views with regard to Quarantine No. 37 and a possible extension of this order. As, however, the conference was a public one, it was not possible to exclude foreigners, consequently their points of view were placed before the meeting. Eventually, an arrangement was made whereby the authorities representing the U.S.A. Board of Agriculture should meet the Federal Horticultural Board and the foreign delegates to consider the matter further. In view of the fact that the conference did not prohibit further discussion, there is ground for hope that an extension of the present Quarantine arrangements will not be imposed, but for the present it may be too much to expect any serious modification of the Order already in operation. However, the door is still open, and something useful may result from the pourparier which followed the conference. We learn from another source that the speech made by Mr. W. G. Lobjoit when presenting the claims of British horticulture for consideration, created an excellent impression and even appeared to convince Dr. Marlet that Britain was at least taking as many risks in importing horticultural produce from the United States as was the latter in admitting exports from Great Britain. These risks on either side could, Mr. Lobjoit asserted, be reduced to a minimum by the granting of a certificate of health on lines to be mutually agreed on by the Pathological Services of the two countries.

**Earliest Out-door Strawberries.**—On Tuesday, the 23rd ult., the first consignment of out-door Strawberries from the Southampton district reached Covent Garden, and was sold at 7s. per lb.

**Re-opening of Cirencester Agricultural College.**—Mr. M. J. R. Dunstan, who for twenty years was head of the Agricultural College at Wye, has been appointed to re-organise and develop the Royal Agricultural College at Cirencester, which will be re-opened during the autumn. The council has adopted a programme especially adapted for the training of landowners, farmers and others aiming at a career on the land, and the scheme of education will be more commercial and economic in its nature and application, rather than specialising in science, as it is recognised that other existing colleges provide ample facilities for that branch of education.

**Cambridge Botanic Garden.**—The Botanic Garden Syndicate of Cambridge states that the garden has reached a state of acute financial difficulty, and that an advance of £1,000 on the previous income is needed to carry on the garden, even at its present level of efficiency. The trouble is caused by the greatly increased costs in every direction. Mr. Reginald Cory, of Duffryn, has made a generous gift of £1,000, besides other generous benefactions, and Mr. Lionel de Rothschild and Sir R. Waley Cohen have also afforded financial help, but in spite of this assistance the income is inadequate.

**Mr. H. G. Alexander.**—Among Orchid growers who have charge of private collections, Mr. H. Alexander, of Westonbirt Gardens, occupies a foremost position; indeed, as a cultivator and raiser combined, he has no superior. He commenced his horticultural career in a small nursery on the outskirts of his native city of Bath and subsequently was employed by the late Rev. H. Handley. Leaving Bath in 1894, he entered the service of the late Mr. Broom at Sunny Hill, Llandudno, where Mr. Shill, now of Egham, then had charge of the Orchid collection. It was not long, however, before Mr. Alexander became foreman in the late Capt. G. W. Law Schofield's gardens at Rawtenstall, a position he occupied for three years. After leaving Rawtenstall he was appointed Orchid foreman at Blenheim Palace, where he remained for a short period, and in April, 1899, went to Westonbirt to take charge of Sir George Holford's collection of Orchids. His success has been phenomenal, but he would be the first to acknowledge that, with regard to the construction of the houses, the atmosphere at Westonbirt, and, above all, the intense interest Sir George Holford takes in the collection and the encouragement received from him, he has a combination of favourable circumstances not given to every grower. In

MR. H. G. ALEXANDER.

the year 1900 Mr. Alexander commenced to raise seedling Orchids, and evidence of the success that has attended these efforts may be gathered from the statement that twenty-one Cattleyas, twenty-six Laelias, Laelio-Cattleyas, or Brasso-Cattleyas, eighteen Cypripediums, six Odontoglossums, four Cymbidiums and fourteen other Orchids from the Westonbirt collection have obtained the First-Class Certificate of the Royal Horticultural Society, and, out of this total of ninety-two Orchids, fifty were raised at Westonbirt. No fewer than 149 Awards of Merit have been obtained, including thirty-two for Cattleyas, forty-three for Laelias, Laelio-Cattleyas, or Brasso-Cattleyas, twenty-eight for Cypripediums, seven for Sophronitis hybrids, sixteen for Odontoglossums, seven for Cymbidiums, and sixteen for miscellaneous kinds, and ninety-seven of these were given to plants raised at Westonbirt. From the cultural point of view Mr. Alexander's success has been no less remarkable, as he has received fifty-six Cultural Commendations from the R.H.S., and a silver-gilt Lindley Medal, which is an award granted for high cultivation. Mr. Alexander's first attempt to stage an Orchid group of any importance was made in 1902, when a Gold Medal was awarded. He staged large groups of Orchids at the Ghent Quinquennial Exhibi-

tion, 1908, the York Jubilee Show, and at the Royal Agricultural Society's exhibitions at Gloucester and at Bristol, but his greatest effort was at the International Exhibition of 1912, where the Westonbirt Orchids occupied a space of over 1,100 square feet and were awarded the King's Cup. At the same exhibition the William Bull Cup and the Hye de Crom Cup were also won by Sir George Holford's Orchids. Other special awards for groups include a silver cup at the Temple Show in 1904, the Veitch Cup at the Temple Show, 1907, a silver cup at the R.H.S. Autumn Show in 1912, and a silver-gilt cup at Holland House Show in 1914. Altogether, up to date, Mr. Alexander's ability as a grower, raiser, and exhibitor have won for Sir George Holford's collection of Orchids thirty gold medals, one silver-gilt Lindley medal, twelve Lindley medals, thirty silver medals, and the seven cups already referred to. The Westonbirt Orchids occupy twenty-seven houses, but when Mr. Alexander went to Westonbirt in 1899 the collection was contained in four houses. During the war the greatest difficulty was experienced in maintaining the collection, as the whole of Mr. Alexander's staff, with the exception of one unfit man, served with the colours, but with the aid of this one man, two boys, and two girls the collection was kept in being, and that it suffered no irreparable damage has been made evident by the magnificent displays, especially of Cymbidiums, made during the current year. Mr. Alexander's methods of cultivation are not always orthodox, but they are effective, and the superb condition of his plants is a cause for wonder to those who have had the privilege of a visit to Westonbirt.

**American Iris Society's Medal.**—At the Royal Horticultural Society's Iris meeting on June 7 and 8 there will be offered for competition the silver medal of the American Iris Society. This will be awarded to the best collection of twelve varieties already in commerce.

**Chestnut Sunday.**—The flowering of the magnificent Chestnut trees in the long avenues at Bushey Park results in a great pilgrimage to Hampton Court, yearly by Londoners when the trees are at their best, and as most of London's workers make their visit on a Sunday, there has been for many years past a Chestnut Sunday, although, of course, the date varies each year. This spring the Chestnut trees are nearly a month late; two years ago they were at their finest during the early days of May, and there was another early celebration last year. The many thousands of people who journeyed to Hampton Court last Sunday were rewarded by a magnificent display of blossom and brilliant weather. From early morning the highways leading to Hampton Court were thronged with traffic, but many visitors chose the river route, travelling by steamer. Beside the beautiful Chestnuts in Bushey Park, the gardens of Hampton Court Palace were gay with Hawthorns, Laburnums, Rhododendrons, and other beautiful plants, while hardy border plants have made remarkable progress during the past week or so, and the earliest of these were also in bloom.

**Decorations at Holyrood Palace.**—In connection with the visit of the Lord High Commissioner of Scotland, His Grace the Duke of Sutherland, to Holyrood, the precincts of the palace were decorated by Messrs. T. Methven and Sons. On either side of the main entrance to the courtyard the grey walls and the pillars of the piazza were decorated with flowering plants, such as Wistarias, Lilacs, Hydrangeas, scarlet Geums and Rhododendrons, with a setting of Bamboos and Japanese Acers. The quadrangle was brightened with groups of Laburnum, Privet and evergreens, interspersed with Rhododendrons. The scheme of decoration also included some of the more important rooms and the fine staircase.

**Conveyance of Pot Plants by Passenger Train.**—In view of the very severe disabilities under which the pot-plant industry labours, owing to the high railway rates charged for the conveyance of pot plants by passenger

NOTES FROM IRELAND.

train, a strongly worded protest has been sent to the Railway Clearing House by the Chamber of Horticulture, together with a list of actual instances showing the rates charged to be from fifty per cent. to one hundred per cent. of the value of the goods forwarded. In view of the pending re-classification of this class of traffic the Chamber has asked the railway companies to receive a deputation of growers for the purpose of discussing the rates in the hope that these may be amended in a manner satisfactory to both parties without the necessity of an appeal to the Railway Rates Tribunal.

**Theft of Horticultural Medals.**—A burglary of a rather unusual nature occurred recently at The Node, Sir Charles Nall-Cain's residence, about two miles from Welwyn. The thieves apparently entered the house after midnight through an unshuttered billiard-room window, and passed to the adjoining dining hall where Sir Charles Nall-Cain had displayed his collection of trophies, including numerous medals won by his gardener, Mr. T. Pateman, at flower shows. It is remarkable that although the room contained many art treasures only the horticultural medals, including four gold and twenty silver-gilt medals, and a gold medal representing a golf prize were taken. In *Gard. Chron.*, December 17, 1921, p. 312, in an account of the Node Gardens, Welwyn, it was stated that Mr. Pateman had won nearly 800 prizes at flower shows, and very many of these were in the form of medals. Those who realise the great amount of skill and work which the winning of such prizes at flower shows entails will understand the great disappointment of Sir Charles and Mr. Pateman at their loss.

**Appointments for the Ensuing Week.**—Tuesday, June 6: Royal Caledonian Horticultural Society's meeting; Bournemouth Gardeners' Association meeting. Wednesday, June 7: Royal Agricultural Society's Council meeting; Royal Horticultural Society's Committee meeting (two days); National Viola and Pansy Society's meeting and exhibition; Essex Agricultural Society's Horticultural show at Hylands Park, Chelmsford (two days). Thursday, June 8: Bristol and District Gardeners' Association's meeting, Saturday, June 10: Ringwood Society's meeting.

**"Gardeners' Chronicle" Seventy-Five Years Ago.**—*The Dean of Manchester (William Herbert).*—The Dean of Manchester is the greatest loss which horticulture has sustained since the death of Mr. Andrew Knight, not merely on account of his skill as an experienced cultivator, but because of his scientific attainments and profound knowledge of the laws of hybridising, which had been so fully elucidated by himself in the experience of a long life, which he had applied with admirable judgment, and to which we must continue to look for years to come as the surest aid to the improvement of the races of plants. Fortunately for the world, his latest views on the subject have been preserved in two valuable papers, "Upon Hybridisation Among Vegetables," which have been published in the *Journal of the Horticultural Society*, and which constitute a rich mine of valuable facts and not less valuable reasoning. William Herbert was beyond all other persons instrumental in establishing and rendering popular the botanical theory of hybridisation among plants; as he was also among the earliest, and one of the most eminently successful of those who applied it to horticultural practice. Upon the phenomena of hybrid inter-mixture he mainly founded those conclusions at which he arrived concerning natural classification, and the doctrine of genus and species. They will be found embodied in an essay on Hybridisation among Vegetables, in the *Journal of the Horticultural Society*. On the last day of his life (Friday, May 23, 1847), and just five hours before its close, he addressed to the writer of these lines a description of an undescribed flower, from the Morea, sufficiently accurate even for publication, and in a clear handwriting. *A. H., Gard. Chron., June 5, 1847.*

MAY neared its end in the most amiable of moods, crowned with a wealth of blossom, in which the Apple was most conspicuous.

Rarely, indeed, has the Apple risen to such supreme heights of floral profusion; commencing with the warm-toned Irish Peach, a favoured variety around Dublin, the climax seemed to come in Bramley's Seedling, studded with clusters of huge, cooler-hued flowers, and all smiling with exuberant vitality.

Examinations for the Certificate in Horticulture (Ireland) will be repeated on the lines of those held last year, under the auspices of the Department of Agriculture, during July. Applications of intending candidates must be sent to the Secretary, Department of Agriculture, Upper Merrion Street, Dublin, by June 17. These examinations, initiated last year, were well attended, with satisfactory results.

At the May meeting of the Royal Horticultural Society's Council, held at the offices, 5, Molesworth Street, Dublin, Mr. F. Streeter,

rock, the branch of an old firm with a new name under new conditions, with Mr. Andrew Dickson as proprietor and manager.

This is the time of Tulips, and the bedding in the People's Gardens is this year confined to these bulbs, including, of course, the delightful Darwins. Dublin dwellers have such a feast of colour as has not been possible since pre-war days, and it was a happy thought of Mr. Anderson's to concentrate on a time when the public are lured by the call of long, genial spring days to make their visits.

Now, these gardens at the entrance to the noble Phoenix Park, with its panoramic peeps of mountain scenery in the background, are lovely, and the rich colouring of such Tulips as Bartigon, Caledonia, Clara Butt, and Pride of Haarlem, on a groundwork of Aubrietia, double white Arabis, fragrant Wallflowers, hybrid Primroses, and Forget-Me-Not make a picture of indescribable richness and beauty.

Even at the park entrance one is met with a long vista of *Berberis stenophylla*, although away on the rising ground over the lake in the gardens a great mass of the same "Golden Rain" bush comes as the apotheosis of this variety.

FIG. 154.—ROCK AND WATER GARDEN EXHIBITED BY MESSRS. W. H. GAZE AND SONS AT THE CHELSEA SHOW (see p. 295).

gardener to B. H. Barton, Esq., D.L., Straffan House, Co. Kildare, was awarded a First-Class Certificate for the fine new Rhubarb, Straffan Crimson, and Awards of Merit for three dishes of Royal Sovereign Strawberry, and for Mushrooms. Mr. Streeter also set up a score of vases of flowers, in which Orchids predominated.

The very successful spring show of the Royal Dublin Society, on May 16, 17, 18, was remarkable for the extensive and splendidly organised display, monopolising the whole of a large hall and its annexe, set up by the Irish Department of Agriculture, which included both gardening and forestry, and in both of the latter the pathological part was prominent, and by the aid of experts' discourses interesting and instructive.

At this show, in the spacious Ballsbridge premises, Tulips were well represented by two groups in the main hall staged by the Holland in Ireland Bulb Farm Co., Rush, Co. Dublin, the only other floral feature being an attractive display of hardy and greenhouse flowers exhibited by the Dublin Nursery Co., Black-

There are good things to come, for a fine colony of *Rhododendron Pink Pearl* in one of the skilfully planned shrubberies is crowded with huge clustering buds. At Whitefields, Mr. Anderson's residence, to reach which some three miles of the park have to be negotiated, a great foaming mound of *Cytisus kewensis* is very wonderful in its own way.

At the annual general meeting of the Irish Forestry Society, May 17, in the Royal College of Science, Dublin, Sir Thomas Grattan Esmonde, presiding, it was intimated that the Minister of Agriculture, Rialtas Sealdach Na hEireann, would receive a deputation of the Society to consider some urgent matters the committee is anxious to place before him for consideration, the most urgent, probably, being protection for existing woods now being pilfered in all parts of the country. Further, the committee consider it absolutely necessary to make adequate provision at once for the training of working foresters, and have suggested that the Forestry School, Avondale, Co. Wicklow, be re-opened without delay. *K., Dublin.*

## EFFECTS OF THE DROUGHT OF 1921.

A MARKED feature last year, during the drought, was the blueness of the green leafage. This was not limited to certain sorts of plants, but seemed fairly widely spread—Brassicæ, Apple-trees, Potatoes. In calling attention of others to this point, I ventured to liken it to the colour which is to be seen in a corn field where a couch bonfire has been burnt, or amongst Potatoes planted on the site of a burnt rubbish heap. These phenomena one rather associates with a high potash manuring, though possibly other elements of the soil are also in absorbable abundance, and I wondered whether they might not be caused in the drought-affected plants by a high concentration of potash in the cell sap.

The reduction of sap flow from deficient water, where this deficiency has not been too excessive, and its consequent concentration appear to have had a marked effect on turning

*Tulipa saxatilis* seems to have enjoyed the baking of last summer; I have a small patch which has not been disturbed for twelve years, in the sunniest part of the rockery, and usually there are some three or four to a dozen blossoms, yet this year there have been two dozen flower heads with mostly two, three, and some even with four, blooms; the advice sometimes given to take up the bulbs every year and dry them well thus seems to have support. *Gladiolus* which might have rejoiced in the torrid sun did very badly, perhaps through being unwatered, and there was a very slight production of cornets. The drought interfered with seed production. Regarding Pears and Apples, it was curious to note how frequently there were no fully formed plump pips in otherwise well-formed fruits, more often there was only a single pip, the others being withered and shrunken. Herbaceous plants, too, did not seed well; a special strain of Radish is noteworthy for not only were the pods few and small, but they were very slow in ripening. Some other things

a year old. I sowed them at once, and they have come up splendidly, but I have to watch them during the winter, which fortunately is nothing like yours. If the seed had been sent on at once I would most likely have saved a season, and could have planted in late September, 1921.

Perhaps you may be good enough to publish this invitation. The British Trade Commissioner here has been pleased to send a number of trade periodicals regularly. The *Gardeners' Chronicle* is filed and bound.

I am personally keenly interested in horticulture, and have accompanied Dr. Cockayne on some of his botanical trips.—*Herbert Baillic, Librarian, Public Library, Wellington, New Zealand.*

## MUTISIA DECURRENS.

THE subject of this note was introduced in 1861 by Messrs. R. Veitch and Son, of Exeter, from the Chilean Andes, through their collector, Richard Pearce. The genus *Mutisia* includes some sixty species, all natives of South America, but very few of them have ever been in cultivation. They are shrubby, or subshrubby, climbing Composites, of which there are two sections, one with pinnate leaves terminated with tendrils, the other—to which *M. decurrens* belongs—with entire leaves, which, in the case of *M. decurrens*, are terminated with forked tendrils; it is also remarkable for the leaf blade running down the stem in the form of a wing.

The flowers, which are produced at the ends of the shoots, are a beautiful orange-yellow, and four or five inches wide. *M. decurrens* has never been common in cultivation, as it has proved a very capricious subject. This failure is probably due to local climatic conditions; that it is quite hardy is proved by the fact that for many years it has flourished in the rock garden in the Botanic Garden, Edinburgh (see Fig. 155), where it is planted among and scrambles over low-growing shrubs. But the best plant I have seen was planted by the writer, when in charge of the late Sir T. D. Acland's beautiful garden at Killerton Park, near Exeter. There the plant attained a height of some ten feet, and on one occasion there were no fewer than 300 flowers open on it at once. It was planted against a wall facing West, and the soil consisted of good loam with the addition of a little peat and coarse sand, while all over the bed stones were half buried. The underground stolons ran along the side of the wall and round the stones, sending up numerous shoots over the edges of the stones. These shoots afforded a ready means of propagation, as the smaller shoots could be taken off with roots attached. This particular plant also ripened plenty of good seeds every year.

It seems almost certain that a cool and partially shaded root run is essential to success with this climber. Next to this, I have no doubt, the determining factor in the successful cultivation of this plant is cool and moist atmospheric conditions.

*Mutisia decurrens* is figured in the *Bot. Mag.* t. 5, 273. There is also a very beautiful coloured plate of it in the *Florist and Pomologist*, 1872, where the glaucous-green leaves and the large glaucous-coloured and purple-tipped scales of the involucre are very faithfully portrayed. There are only two other species of *Mutisia* that have been cultivated to any extent, viz., *M. ilicifolia* (*Bot. Mag.* t. 6, 009), with entire, Holly-like leaves terminated with the usual tendril. This is a variable plant, the flowers varying in colour from white through several shades of pink; and generally it has not proved over-tree flowering. The other, *M. Clematis* (*Bot. Mag.* t. 8, 391), belongs to the pinnate-leaved section, and is a strong growing climber, in a cool house, or outdoors in the warmer parts of the country. It produces its red flowers quite freely. They are smaller than those of *M. decurrens*, and altogether the plant lacks the unique and distinctive appearance that so characterises *M. decurrens*. *J. Coultis, Kew.*

FIG. 155.—MUTISIA DECURRENS FLOWERING ON A ROCKERY.

the "dard" into a fully developed fruit bud. Thus I note that notwithstanding heavy Apple crops on trees last season, there is generally a very good amount of bloom now. Two trees only are entirely without blossom, and both are in the sunniest spot in the garden. The bloom on the Pears is phenomenal, but somewhat scanty, though sufficient, on some wall trees which bore heavily last year. One tree, a cordon in grass, has not consented to flower for ten years, and its identity is uncertain; had scab having been cured, it was "loretted" and made to produce apparently good fruit buds, which however did not get beyond the "dard" stage; this year matters have improved and there is a fair amount of blossom.

A fan trained Plum (Jefferson) on a wall seems to show the influence of direct sunshine in producing blossom buds (owing to buildings and the aspect, slightly west of north, about one-third of the tree never gets a ray of sunshine); this season there were not more than half a dozen blossoms on the shaded part, though the rest of the tree did well—the appearance was quite striking when the flowers were out.

collapsed altogether without seeding, and thus it would appear that adequate moisture must be present at some critical period after pollenation. *H. E. Durham.*

## OVERSEAS CORRESPONDENCE.

## APPEAL FOR CATALOGUES.

IN the interests of British trade I shall be glad to place in our Reference Room retail catalogues from British seedsmen. I think that New Zealanders are inclined to follow the example of the British, and become enthusiastic amateur gardeners. If early copies of catalogues are sent here they may result in early orders. As you know, our seasons are exactly the opposite to yours, consequently our gardeners get busy about October. Recently I received seeds of Carnations from England in February—these must have been harvested in July or August, 1921—and the instructions were, "plant in March," which meant that I should hold until next September, and the seed would then be more than

## NOTICES OF BOOKS.

## Practical Gardening.

A YOUNG man or woman who is learning the art and practice of gardening at various private, public, or commercial establishments—according to the aim in view—does not usually find it convenient to carry from place to place a library of horticultural books. Nevertheless, students who are ambitious will need books to which reference may be made when the various problems concerning the life of plants and their cultural requirements confront them. To meet such needs, Mr. W. P. Wright has produced a practical gardening work\* of six volumes well filled with the wisdom and experience of those who have excelled in various departments of horticultural activity. In by-gone years MacIntosh's *Book of the Garden* and Thompson's *Gardeners' Assistant*, to mention only two books, were prized for their concise teaching on most gardening subjects, and many good gardeners of to-day regard their copies as old and well-tried friends. What these works did for former generations of gardeners, we believe *Practical Gardening* will accomplish for present and future generations. It is, in fact, a gardener's library in itself; a splendid and useful gift for an aspiring horticulturist; while as an investment it cannot fail to give a good return in information to the intelligent amateur or experienced professional gardener. The practical aim of the work appeals to us, as also does the clear, pleasant, interesting, and convincing way in which the principles underlying practice are set forth. For instance, Dr. Russell's chapters dealing with soils are fascinating and in reading them the student, no matter how young or old, cannot fail to find instruction. So, too, with plant classification, a subject at which the young gardener frequently looks askance as being dry and useless, but Mr. F. J. Chittenden opens it up in a way that does not frighten the gardener, but rather encourages him to proceed until he understands the fundamentals of systematic botany. Popular names of plants, an interesting study to many, occupy a long chapter near the end of the first volume, and the botanical equivalents are set out in correct form, but in the chapter where the botanical names precede the popular ones every specific name commences with a capital letter, which is neither according to the *Kew Hand List* nor the *Index Kewensis*. This is a weakness in a volume which opens with a comparison between gardening of fifty years ago and that of to-day, written by that doyen of horticulturists, Sir Harry J. Veitch, in whose nursery at Chelsea, by the way, Mr. W. P. Wright commenced his horticultural career.

Volume II. is devoted entirely to vegetables and their cultivation, and consists of sixteen chapters, one of which on "Growing Vegetables for Exhibition" is from the pen of that eminently successful competitor and grower, Mr. E. Beckett, while another chapter dealing with the preserving of vegetables is by Mrs. E. Beckett, who is no less successful in her sphere than is her husband in his. "Practical Fruit-Growing" is the sub-title of Volume III., in which the problems of the commercial cultivator, the private grower, the housewife, and the exhibitor are considered. From soil preparation, onward through propagation, planting, pruning, protecting, spraying, thinning, packing, storing, and otherwise preserving the resulting crop, the whole range of fruit-growing is discussed. The cultivation of choice fruits under glass also receives full consideration, and even the treatment of the Banana and of the Orange is detailed. Mr. J. Weathers is responsible for the section dealing with the important matter of commercial fruit-growing. On the principle that "he who loves a garden" must "love a greenhouse too," one volume, and that the fourth, is devoted to greenhouses and pot plants, and a very serviceable and freely illustrated volume it is. The late Mr.

R. A. Rolfe contributed the chapter on Orchids, which extends to over fifty pages and includes forty-one illustrations and a full-page plate in colour of Messrs. Charlesworth and Co.'s *Laelio-Cattleya Sylvia*. Chapters on Cacti and foliage plants follow, and then comes a calendar of indoor work while a long chapter provides select lists of indoor plants, beginning with *Abelia* and finishing with *Zygopetalum*. This concludes a volume which opens with the uses and attractions of greenhouses, and gives freely illustrated information regarding the construction of greenhouses for various purposes.

A sign of the times is found in the two concluding volumes, which, together, form a compendium of all matters relating to outdoor gardening in so far as they come under the

## ORCHID NOTES AND GLEANINGS.

## Laelio-Cattleya Melita.

A TWO-FLOWERED inflorescence of this pretty, new hybrid, raised between *Cattleya Mossiae* Reineckiana and *Laelio-Cattleya Cupid*, yellow variety (*C. Mossiae* × *L. Latona*) is sent by Pantia Ralli, Esq., Ashted Park (Orchid grower Mr. Farnes). In the shape and general character of its flowers, *C. Mossiae* Reineckiana is closely followed, the sepals and petals being white, the lip yellow at the base and white in front, the centre bearing some branched, purple lines, after the manner of the *C. Mossiae* parent. The only trace of *L. cinnabarina* and *L. purpurata*, through *L. Latona*, in the parentage, is the

FIG. 156.—ODONTOGLOSSUM FAUSTINA, CLAYGATE LODGE VAR., R.H.S. FIRST CLASS CERTIFICATE, MAY 23. (see p. 272).

general heading of flower gardens. The construction and planting of rock gardens, summer bedding, the management of lawns, selections of suitable trees and shrubs for parks and gardens, hardy Ferns, water gardening, bulbs, annuals, Roses, Carnations, Antirrhinums, Sweet Peas, Irises, and Daffodils are a few of the subjects to which chapters are devoted exclusively. Mr. J. Hudson deals interestingly with Japanese gardens, and the consideration of landscape gardening is capably set forth by Mr. J. Cheal. Volume VI. is a dictionary of plants suitable for the flower garden, commencing with *Abies* and concluding on its three hundred and sixtieth page with *Zinnia*. A capital index concludes what is probably the most ambitious work Mr. W. Wright has produced, and which forms a fitting keystone to the wide arch of his literary activity in connection with horticulture.

yellow tint of the reverse side of the sepals of the flowers of *L.-C. Melita*, and a very slight sulphur shade in the white of both sepals and petals, near the margins.

## ORCHIDS IN HOT WEATHER.

THE plants in all departments have already responded to the increased light and sun heat of the past few weeks, and now the outside conditions are more favourable to maintaining healthy growing conditions, every inducement should be given the plants to enable them to build up healthy pseudo-bulbs by the end of the season. The temperature in all the warmer divisions should be brought up to the maximum, with an increased amount of atmospheric moisture in every department. Air should be given on all favourable occasions, both during the day and at night, as even tropical plants cannot thrive in a badly ventilated house. J. T. B.

# The Week's Work.

## THE ORCHID HOUSES.

By J. T. BARKER, Gardener to His Grace the DUKE OF MARLBOROUGH, K.G., Blenheim Palace, Woodstock, Oxon.

**Cypripedium.**—*C. niveum*, *C. bellatulum*, *C. concolor*, *C. Godefroyae*, and any of their hybrids, which are in flower or passing out of flower, and are in need of new rooting material, through the compost becoming loose or sour, should be attended to as soon as possible after their flowering period is over. Speaking generally, these are difficult Orchids to keep in vigorous health. I believe most failures are attributable to keeping them much too dry, and potting them in shallow pans, as when in good health they are rather deep-rooting subjects, and when well established and well rooted require an abundant supply of water at the roots whilst making their growth. Yet at times one meets with them thriving under quite contrary conditions. A compost I recommend consists of equal parts of good loam fibre and good fibrous peat, mixed with coarse sand, broken crocks, and Sphagnum-moss. Ordinary pots are suitable receptacles, and are preferable to pans. The pots should be well drained with soft, broken, porous bricks, which retain moisture and give it off as the compost becomes dry. The water will have a free passage through this compost, and it is an important point that it should never be allowed to remain dry for any length of time whilst the plants are making their growth. Whilst these Orchids are at rest water the roots just sufficiently to prevent the leaves shrivelling. The warmer end of the warm-intermediate house is suitable for them, and plenty of moisture should be maintained in the atmosphere and around the plants during hot weather. Overhead syringing is detrimental, but a slight spraying is beneficial during very hot weather, in preventing attacks of thrip and other insect pests.

**Seedling Cypripediums.**—The development of seedling Cypripediums of all sections should be encouraged, and new rooting material may be afforded at almost any season. Care should be taken that the plants are not overpotted. A clean, fibrous compost, cut up finely, is suitable for these small plants.

## PLANTS UNDER GLASS.

By T. PATSMAN, Gardener to Sir C. NALL-CAIN, Bart., The Node, Codicote, Welwyn, Hertfordshire.

**Chrysanthemums.**—Plants intended for producing large flowers should now be ready for their final potting, but much will depend upon the amount of growth they have made. Those that have been given cool treatment in frame are undoubtedly much later than usual, owing chiefly to the cool weather experienced during April, and unless they have filled their receptacles with roots it will be advisable to defer the final potting of these plants for a week or ten days. They should not, however, be allowed to become pot-bound before this work is carried out, otherwise they will soon lose their bottom foliage. Before potting see that each plant is well supplied with water, for it is very unwise to repot any plant when in a dry condition. The Chrysanthemum delights in a somewhat retentive rooting medium, therefore, loam should form the greater bulk of the potting material. To the loam add leaf-mould, manure from a spent mushroom bed, a little soot, old mortar rubble and sand, adding a 6-inch pot full of bone meal to each barrowload of the compost. The soil should be made fairly firm in the pot, therefore the potting material should be in a suitable condition of moisture and not too wet to allow a small rammer to be used. After potting the plants they should be staked, stood in an open situation on boards, and made secure from strong winds by putting up a wire trellis erected for the purpose. Spray the plants

several times daily, and water them carefully until they have become established in the new soil.

**Gardenia.**—Gardenias may be grown very successfully in pots, but where a low-roofed house can be set apart for planting them out in a prepared border they will be found to produce far more flowers and of a finer quality than those that are cultivated in pots. This plant delights in plenty of heat and moisture during its growing season, but care is needed in watering until the roots are plentiful, when they may be fed liberally with stimulating manure.

**Cineraria.**—Cinerarias of the *sinensis* and *stellata* types may be sown now, and another sowing made in about six weeks' time to provide plants for successional blooming. It is not necessary to use fire-heat to raise the plants, the seed will germinate very quickly in a cool greenhouse, and produce sturdier plants than if treated otherwise. The seed may be sown in 6-inch pots or pans containing a good, open mixture of loam, leaf-mould, and sand. Cover the receptacles with a sheet of paper until the seeds have germinated, when they may be removed to a cold frame and the plants kept shaded from bright sunshine. Slugs are very partial to Cinerarias, therefore it is advisable to dust the surface of the frame with soot to keep these pests in check.

**Primula.**—A further sowing of *Primula sinensis* and of the *stellata* type, also another batch of *Primula obconica*, may be made now to ensure plenty of plants for a long succession of bloom. Seedlings raised from seeds sown some weeks ago will be ready for pricking out, either in boxes or in small pots. After this operation, they should be kept in a trifle closer atmosphere for a few days and then gradually hardened off in a house or frame having a cooler temperature, growing them as near to the roof glass as possible and keeping them shaded from bright sunshine.

## HARDY FRUIT GARDEN.

By H. MARKEAM, Gardener to the EARL OF STRAFFORD, Wrotham Park, Barnet.

**Insect Pests.**—Aphis on Peach and other trees should be thoroughly eradicated before the young shoots become damaged, as free, early growth is most important in connection with fruit culture. As these shoots have a long period to develop in, they should be well matured by the end of the season. There was a severe attack of American Blight last year, and measures to destroy any blight seen this season should be taken early. Dress thoroughly the infested parts with nicotine insecticide, or paraffin emulsion, brushing the specific well into the crevices with a well-worn painter's brush.

**Peaches and Nectarines.**—Most of our Peach and Nectarine trees have set very satisfactory crops of fruits and the latter are swelling rapidly, so that the thinning of any that are ill-placed or in clusters will at once be carried out, leaving the final thinning to be done after the stoning stage. I do not allow these trees to carry heavy crops, but regulate the number of the individual fruits according to the size and strength of the trees. A very heavy crop on older trees tends to the production of inferior fruits, both in size and flavour, and also cripples the energies of the trees so much that the young growths are not able to produce strong flowers the following season.

**Plums.**—The Plum crop is very promising; an abundance of fruits has set on most trees and they are swelling nicely. Coe's Golden Drop is one of our most reliable dessert Plums, and usually produces fruits when other sorts are practically failures. The trees should be kept free from insects and the young growths neatly secured to the walls or trellises early, especially the leaders which have not reached their allotted space. Some amount of disbudding and stopping should be done, but in carrying out this work see that a reasonable supply of young wood is retained at intervals all over the trees, as these shoots usually produce the best fruits.

## THE FLOWER GARDEN.

By EDWIN BECKETT, Gardener to the Hon. VICARY GIBBS, Aldecham House, Hertfordshire.

**The Herbaceous Borders.**—The borders will need close attention, for much growth will have been made, and staking will be necessary for many subjects. Too much stress cannot be laid on the importance of getting all this work done in good time to afford the necessary support to plants as soon as it is required. Too frequently staking is neglected until such time as heavy rains or boisterous winds have damaged the plants badly, laying the growth flat, and possibly breaking many of them off. For the tall subjects, such as Aconitums, Delphiniums, Heleniums, Solidago and Hollyhocks, stout hazel sticks should be used, and they should be thrust well into the ground. The growths should be looped to the stakes where this is possible. For those plants which form stout clumps of many growths, a number of stakes of suitable lengths should be thrust in around the plant and two or three lengths of tar-twine tied round the specimens as growth is made, taking the twine from stake to stake, and at the same time training some of the growths up the front of the stakes to hide the latter as much as possible. Carefully done, this results in a well supported plant without the means of support being visible. In any case plants should not have a number of growths tied in to a single stake only, otherwise they will present ugly-shaped specimens. Short growing herbaceous plants that require supports, such as Statice, Veronicas, Pyrethrums, Potentillas, and Nepetas, should have twigs short sticks worked among them in such a way that they will support the growth, if required, without the twigs being too apparent to the eye, and a similar method should be employed for annuals requiring support. After staking, gaps in the border will become more apparent, and steps should be taken to fill these with such plants as Stocks, Pentstemons, and any suitable subjects that may be growing in pots ready for the purpose. When all is finished, give the borders a thorough hoeing, and leave them neat and tidy. As growth progresses the shoots should be tied in where such treatment is seen to be required, and, throughout the season—especially during the early part—the Dutch hoe should be used on frequent occasions to destroy weeds and keep the surface soil loose.

## FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Maceor, Lingfield, Surrey.

**Pot Vines.**—If the Grapes on pot vines have done well, they will now be ripe or approaching that stage. Being largely dependent for their daily supply of food on the small amount of soil in the pots, the roots must not feel the want of water, even when the Grapes are quite ripe. In order to prevent the soil from drying too much, each pot may be well watered and covered with half-rotted leaves or some other non-fermenting material. The floor and paths should be damped regularly on fine days and gentle heat provided equal to the maintenance of a free circulation of warm air in the house throughout the colouring process. If heavily cropped, and colour is doubtful, extra air, more time, and a gradual lowering of the night temperature, with the use of soot water and clear liquid manure, warmed to 80° to 85°, will most likely help the berries to finish better. As finer weather comes, and the Grapes become fit for use, a lower temperature by night and day will be necessary, and pure water only should be used instead of liquid manure. White Grapes should receive plenty of sunlight, not by the removal of leaves or laterals, but by tying or turning them aside, whilst black Grapes will colour best under dense, healthy foliage. Pot vines intended for next year's fruiting are growing very fast, and when the roots have penetrated through the balls of compost they should be liberally fed with warm liquid manure. Use the syringe freely for damping the walls and surface of the beds when the morning temperature begins to rise, and for thoroughly wetting the foliage immediately after closing

**THE BULB GARDEN.**

**HABRANTHUS (HIPPEASTRUM) PRATENSIS.**

Mr. H Cowley states (p. 253) that *Habranthus pratensis* is much hardier than is generally supposed, and that it has proved quite hardy in southern and eastern counties. It has also proved quite hardy in Scotland, with myself in East Lothian, and also with many other growers in different parts of the country. My experience is that *Habranthus pratensis* is as hardy as a Daffodil and is quite as easily grown. Mr. Cowley observes that the new leaves follow the flowers and should remain green through the winter. This might be expected in the case of one of the *Hippeastrum* family, but I do not find it to be so with *Habranthus pratensis*. With me it behaves exactly like a Daffodil and the foliage dies down in similar manner. I owe my introduction to this brilliantly-coloured flower to the late Mr. Osgood Mackenzie, of Poolewe, Ross-shire. In the *Journal of the Royal Horticultural Society* (Vol. XLIII, part 1), for May, 1918, he contributed an article entitled "A Year in a Garden on the North-

lands. I cannot grow it, however, but it is quite evident that *Habranthus pratensis* is at home, and is going to increase in quantity. I introduced the Chilean Fire Bush (*Embothrium coccineum*) at the same time as *Habranthus pratensis*. I can make nothing of it. I am pleased, however, with my success so far as *Habranthus pratensis* is concerned, and it has encouraged me to try two other forms of the Field Amaryllis. *George M. Taylor, Edinburgh.*

**THE ALPINE GARDEN.**

**POTENTILLA NITIDA.**

PICTURE a little carpet of silver and grey trifoliate leaves, spreading closely from a woody stem and hardly rising more than an inch or so above the ground. The leaves of *Potentilla nitida* are so beautiful in form, and so exquisitely adorned with silver and grey, that words fail one to praise them sufficiently without appearing to exaggerate. When this *Potentilla* is happy, it will almost cover its carpet of silvery hue with wonderfully large flowers of rose, rose pink, or white, which continue for a

FIG. 157.—FLOWER BORDER EXHIBIT FROM THE MAYTHAM GARDENS, AT CHELSEA SHOW (see p. 279).

West Coast of Ross-shire," and he dealt fully with many of the rare flowers and shrubs which he grew so successfully there.

I give the extract from that paper regarding *Habranthus pratensis*. He wrote: "I often wonder how little is known by the general public about that hardy, June-flowering bulb, *Habranthus pratensis*, and how seldom it is grown. I have a small clump of it with three fine flowering stalks, the blooms just expanding (June, 1916), and I mean to go in for it on a larger scale. It is just a kind of Amaryllis, and as lavish with its glittering scarlet as the Fire Bush. I know a place in Norfolk where they grow it on quite a large scale, but the public are somewhat slow in taking up a new thing, though, in truth, this is far from new. It is warranted hardy." I procured six bulbs of *Habranthus pratensis* in the autumn of 1918, and planted them in a pocket in the rock-garden. It increased so rapidly that I had to remove it, and last autumn I planted out over eighty young bulbs. The most of these bulbs are showing flower stems now. The soil is a light loam over brown whinstone.

This subject is a companion in exile with *Tropaeolum speciosum*. When the latter was introduced it was grown in the stove; now it is almost a weed in the coldest parts of the High-

long time in summer and even into autumn in some places. They have been likened to Dog Roses, but are smaller. The colouring varies, as may be gathered from the remark above. Some flowers are pale pink, others much deeper, and some almost pure rose-pink, while pretty white varieties are also to be found. Sometimes the pink ones are offered for sale under name; and that which passes as *P. nitida* var. *atrorubens* is excellent. Personally, I care less for the white than the pink varieties, but there are many who admire and prize the white forms. The whole plant is not more than three inches high, and often less.

But some readers who have grown *P. nitida* may ask "Why whet one's desire to possess a plant which is so shy of flowering? There is no reason why it should not flower well if it receives proper treatment. In the first place it objects to rich soil. It will produce plenty of leaves there, but it will give hardly any, if any, flowers. It craves for poor soil, and, above all, it longs for lime. In nature it is rarely ever found on anything but limestone, and when away from the latter it is unhappy and unhealthy as a rule. In cultivation plenty of stones should be jammed about its roots and a poor, gritty soil, with plenty of lime, should be afforded it. *S. Arnott.*

**THE KITCHEN GARDEN.**

By JAMES F. HATHAWAY, Gardener to JOHN BRENNAND, Esq., Baldersby Park, Thirsk, Yorkshire.

**Thinning Plants.**—Carrots should be thinned lightly, leaving twice as many roots as are required for the final crop. These, when large enough, may be drawn as required for use, leaving those for the final crop nine inches apart. As soon as Parsnips get into the rough leaf the seedlings should be thinned to one foot apart. Beetroot requires a space of nine inches to one foot. It is not advisable to retain the strongest plants in all cases; any inclined to coarseness should be rejected, and it is the safest plan to thin all vegetable crops on two occasions. Onions, unless they are growing very thickly, do not need much thinning; usually sufficient will be taken out for use as salad. If the weather is dry the hoe should be worked through the rows, and the plants afterwards watered, as it helps to settle them in the soil after disturbing them by thinning.

**Leeks.**—These plants do best grown in trenches, made similar to Celery trenches, and 3 ft. apart. Good results may also be had with Leeks for spring use by drawing a deep trench on ground that has been heavily manured, and as soon as the plants are large enough keeping them earthed up similar to Potatoes. Holes should be made with the dibber, 1 ft. apart, in the bottom of the trench, for a single row, placing the plants in the holes and leaving the tops just out of the ground. Fill the hole with water, and keep the plants supplied with water liberally. When in full growth feed the roots with liquid manure to ensure a quick growth, which is essential to good results. Leeks are one of the best and most reliable of winter crops.

**Lettuce.**—To ensure regular supplies of Lettuce fresh sowings should be made every fortnight. The seed is best sown thinly in the drills in the summer to obviate transplanting, for the plants will be less liable to run to seed in hot weather if they are not transplanted. Thin them out to 1 ft. apart. The ridges of Celery trenches should be used for growing Lettuce.

**Celery.**—The main crop of Celery should now be planted in trenches, as previously recommended, planting in double rows, and allowing 18 in. between each plant. Give copious waterings as soon as the plants get a good start.

**Maize.**—Plants raised in pots should be hardened off and planted in a sunny position. Work the ground to a fine tilth and plant the Maize in rows made 3 ft. apart allowing a space of 18 in. between each plant. Plenty of water should be given this crop in hot, dry weather.

**EDITORIAL NOTICE.**

**ADVERTISEMENTS** should be sent to the **PUBLISHER, 5, Tavistock Street, Covent Garden, W.C.2.**

**Special Notice to Correspondents.**—The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.

**Letters for Publication, as well as specimens of plants for naming, should be addressed to the EDITORS, 5, Tavistock Street, Covent Garden, London.** Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

**Local News.**—Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

**Editors and Publisher.**—Our correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the EDITORS. The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.

**Illustrations.**—The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.

## MR. KINGDON WARD'S SIXTH EXPEDITION IN ASIA.\*

No. 16.—GLACIER LAKE CAMP.

WE now turned south, ascending a ridge above the pass, and presently crossing from limestone to slate rocks. A tiny, white-flowered *Lloydia* was abundant here; it nestled against the cold ground instead of lolling easily from the cliffs, like most of the species.

Crossing a meadow valley, the sides of which were plastered with flowers, though of few species, we reached the crest of a spur overlooking a wide alpine valley; and descending on a long slant through a forest of Larch, Abies and Rhododendron, reached the bottom, which was paved with emerald-green meadow. However, we found this rather deceptive, for it was mostly a bog.

Ascending the valley for a mile or two, sometimes climbing over high gravel mounds covered with trees (they were, as a matter of fact, ancient moraines, and yielded up glacier scratched stones), sometimes splashing through marshes, we reached a comparatively dry grassy pitch, where some yak herders lived in a log hut, and camped at an altitude of about 13,000 feet; the valley forked here, and it was evident we were not far from its head.

It had been raining most of the afternoon, and a bitter wind was blowing, so that, take it all round, the prospect was not very inviting. However, we found a sheltered spot (parenthetically I may remark, it was so ill selected that a few days later we were flooded out), and when the tents were up and the fires blazing, I felt better. There were some fine looking peaks rising 2,500 feet right above us, and I selected one to climb on the morrow.

The vegetation of these mountains divides itself into a number of well-defined belts as follows:—(i.) High alpine belt, 15,000 feet and upwards. No shrubs. Many "cushion" plants, *Primulas*, *Meconopsis*, *Cochlearia*, etc. (ii.) Alpine belt of dwarf Rhododendron (three species); *Primula bella*, (ii.) Larch and Abies forest, with bush Rhododendron (three species, *Irroratum* type); a little lower *Picea* appears. (iv.) Marsh, at the bottom of the valley; small shrubs, especially *Salix*, *Spiraea laevigata*, etc.,

many *Primulas*, such as *P. pseudosikkimensis*, *P. secundiflora*.

These belts vary a good deal, according to whether the slope is protected or not. Thus the dwarf Rhododendron is apt to be largely replaced by Juniper scrub on very open, southern slopes and the Larch forest by grass slopes dotted with *Incarvillea*, *Meconopsis*, *Primula nivalis*, *Pedicularis*, etc. Substantially, however, we can always recognise these formations, or plant associations. Crossing a stream lined with Willows, beneath which a small violet muscarioid *Primula* clustered, and plants of *Rheum Alexandrae* were coming up, we ascended a steep, grassy slope, more or less thickly clothed with shrubs—*Daphne*, *Lonicera*, *Berberis* Willow and *Potentilla fruticosa*, with thickets of Rhododendron. There were few flowers under foot as yet.

At last we left the shrubs behind and entered upon Heath Rhododendrons. And here, weaving bright violet patterns over the soil was *Primula bella*. What a little gem it is at its best! But it is small, and must be seen in cultivation

FIG. 158.—RHODODENDRON SINOGRANDE.

to be thoroughly appreciated. The colour varies; violet is the more common, but purple is not rare.

Reaching the steeper rocky slopes which led up to the summit ridge, alpine now began to appear in some variety. A charming little *Nivalis* *Primula*, deep lilac, with large white eye, after the manner of *P. miror*, clung bravely to the most dreary-looking slopes, or cuddled against the roughest cliffs. It was in full bloom, and a joy to behold. Another *Nivalis*, with deep Tyrian purple flowers and silver-coated riband leaves was not less enchanting. Already we had added four more *Primulas* to our list this journey! The *Nivalis* type appears to be particularly well developed in these mountains. We had found some half-dozen species of that phylum to date.

Here, too, were many "cushion" plants, stuck on the rocks as sponges are at the sea bottom. It always surprises me that the numerous stems should grow exactly the same length, radiating out from the common root-stock, so that a half sphere is formed. A Saxifrage, with white flowers, a pink-flowered *Androsace*, *Arenaria polytrichoides*, and, to a lesser extent, the charming little *Diapensia himalaica*, had all adopted these cuddling tactics to keep themselves warm. And then our attention was riveted by the most wonderful alpine plant in Asia. I was gazing at a hemisphere of heavenly blue gems in a setting of

green and glistening silver. A score of unwinking porcelain eyes, like bluest turquoise, stared back at me, innocently, from a hemisphere of cloisonné, made up of little silver-lined leaves clasped in each others embrace. It was *Myosotis Hookeri*, long known from the Himalaya, yet never seen in England. "Ah! if I could only take this plant home!" I thought. "I had not travelled to Chinese Tibet for nothing."

The rock here was slate, not limestone, for a wonder, and much safer to climb. By ascending from the opposite direction to the dip we had no difficulty on the cliffs, which were conveniently ledged, and easily reached the summit, from which we had a fine view. Far away in the south was a tremendous range of snowy peaks, and to the north-east were other isolated snow mountains. To the east were the towering limestone crags we had crossed from Yung-ning, white in the sunshine. Westwards, at no great distance, but across a deep chasm, several fine snow pyramids rose into view, and in every direction we looked over a tumbled sea of blue mountains whose summits nosed the frothing clouds.

But perhaps the most interesting sight of all was at our very feet, where, in the high valley, lay a chain of jade green lakes, separated by cliffs, over which tinkled streams of silver water. The whole region had been glaciated, as I proved conclusively by finding near camp a moraine with ice-scored stones. This fact was not merely interesting in itself; it might help to throw light on the origin and relationships of the flora.

As for Rhododendrons, three species, and no more, formed the dwarf "heath" beyond the tree belt; not a single one of the *Campylogynum* series turned up. On the other hand, descending the more sheltered slopes which were covered with a mixture of Rhododendron, *Abies* and *Larix*, two more species were found. One was almost a tree, some twenty or thirty feet high, and grew socially to the exclusion of everything else practically. Its time of flowering was long past, but one or two lingering blooms were white. It was a large-leaved species, possibly of the *Irroratum* series. The second was a bushy shrub, forming dense thickets with a species previously met with, and very like it in appearance, though ascending to higher altitudes. It was easily distinguished by the leaves, however, which were crowded in rosettes at the ends of the twigs; further, by their very thick coating of rusty red indumentum—silver on the young leaves.

By the glacier lake were many *Primulas* such as we had seen before—a white-flowered *Cochlearia*, *Grass-of-Parnassus*, and, growing in the streams, a beautiful *Corydalis* with massive spikes of maroon flowers.

The weather at this time was very restless, thunder storms heralding the approach of the wet season. One afternoon, with scarcely any warning, a terrific hail storm swooped down, and in an hour the whole valley was white, giving it a most wintry aspect; and, indeed, on clear nights there was always a ground frost at dawn. By day the temperature would rise as high as 66° F. in fine weather.

We spent five days at this camp, climbing adjacent peaks and passes. One of the last plants we found was a fine, tall Muscarioid *Primula* with pale lilac flowers, growing in shady marshes; like all of its kind, it was sweetly fragrant. This was possibly *P. conica*.

The mountains held out promise of more flowers later, but for the moment we seemed to have exhausted them, and on June 21 we broke camp and crossed a high pass, descending to a little meadow under a ledge of limestone on the west flank of the range.

One of the first plants we found here was another *Primula* on the limestone. It had mauve flowers and beautifully silvered leaves, and grew very much scattered on the sheltered cliff. A striking *Pedicularis*, with milk-white lower lip, on which the purple upper lip lay twisted, was also seen. Whatever differences there may be between the flora of Mu-li and that of A-tun-tzw, both have in common

\* The previous articles by Mr. Kingdon Ward were published in our issues of May 14, June 18, July 23, August 20, September 3, October 8, October 29, 1921; January 7, January 21, March 11, March 25, April 8, April 22, May 6, and May 20, 1922.

PLANTS NEW OR NOTEWORTHY.

RHODODENDRON SINOGRANDE.

ONE of the most remarkable of the new Rhododendrons introduced from Western China is Rhododendron sinogrande, which is flowering in this country for the first time this year. We have a plant, presented to Mr. T. Robins Bolitho by Mr. J. C. Williams, of Caerhays Castle, and, judging from its growth, it was raised from seeds sown seven or eight years ago. This young plant is flowering well, and no doubt its success is due to the hot and dry summer experienced last year. The flowers are of wax-like texture, and are of Primrose-yellow when first open, with a splash of crimson on the upper part. The blooms rest on the dark green, glossy foliage, and the plant has a stately appearance. The specimen, of which I enclose a photograph (see Fig. 158), is 3 feet 9 inches high, and its largest leaf is 22 inches long and 9½ inches wide. It had five flower buds, and produced a total of 98 fully developed flowers. Close by this Rhododendron we have two plants of R. Falconeri at least 30 years old and 15 feet in height,

perature of about 70° to 75°. If kept in a close frame the seedlings are liable to damp off. When sufficiently strong they should be potted in small thumb pots, placing three or four seedlings by the side of each pot. When sufficiently established they should be transferred to small pots singly and grown on in the same temperature. As they become stronger and well rooted they should be shifted into still larger pots to be grown amongst the ordinary collection of plants. Newly potted plants require careful attention, and should not be watered too freely until the roots have reached the sides of the pots. They form handsome subjects for exhibition, and are indispensable for table and other decorations. Members of the narrow-leaved section are well adapted for the table on account of their elegant and graceful habit, and when grown in small pots may be utilised for decorating small vases. A few of the best varieties are Golden Ring, the golden yellow leaves of which are twisted; Lucy, leaves with foliage of olive-green ground, blotched with crimson; Aigburth Gem, leaves interrupted and coloured crimson; Chelsonii, leaves bright red in colour; Golden Gem, bright golden yellow

this wealth of Pedicularis, and most of the species are identical in the two areas. Many of the A-tun-tzw Primulas occur here, too, but mostly such as are widely spread—for instance, P. bella and P. pseudosikkimensis; for the most part, the Primula relationship is on the north and south line, being connected with that of Tatsienlu in the north (through P. Cockburniana, of which more anon), and Likiang in the south, through P. Littoniana, P. vincaeflora, and others. Of species more or less widely spread in N.W. Yunnan we find P. septemloba, P. lichiangensis, P. brevifolia, and P. Poissonii.

Of the Rhododendron relationship I will not venture to speak, as I am not up in that intricate genus. A few of those met with were certainly similar in appearance to others found in the A-tun-tzw district eight years previously. (What a long time ago! I had almost forgotten it, and have had to start learning my Yunnan flora over again!) Others are widely spread over the province—R. racemoseum, for instance, and a white, purple-washed Azalea; we had found them long before we had reached Ta-li-fu. But quite half of them I do not remember ever to have seen

FIG. 159.—RHODODENDRON ORBICULARE. R.H.S. AWARD OF MERIT, MAY 23. (see p. 274)

before. However, as I have already remarked, this is not a Rhododendron country, and probably the total of species found does not exceed twenty. Another plant abundant on the limestone round our new camp was a Mecynopsis of the Aculeatae section—a stiff, perky thing, covered all over with hard prickles. The flowers, of a fine shimmering violet, were just beginning to open. It is no doubt a close relation of M. Pratii, if not identical with it; but, in spite of their numerous, large, and often brilliant flowers, the Aculeatae are too stuck up to be pretty, and are rarely worth a place in the garden. (I make an exception in favour of M. speciosa though!) Besides, in spite of the large number of flowers they unfurl during the season, comparatively few of these are in bloom at the same time; they are short-lived—wind and rain soon batter them to pieces or dismember them, at least in their native haunts. Personally I consider them absurdly overrated plants. But the Primulinae series—that is another story.

The clouds were now accumulating, and a veil was finally drawn across the snowy peaks. On June 23 we broke camp once more, and, crossing three high passes in quick succession, found ourselves back in our original valley, but much lower down; and that afternoon we began the descent to the Shiu-lu gorge. F. Kingdon Ward.

which are also flowering here for the first time. A. J. Creek, Trenqwainton Gardens, Heamoor, Cornwall.

CODIAEUMS.

CODIAEUMS, which are perhaps better known to most gardeners as Crotons, are amongst the most valuable of decorative indoor plants. The foliage has a marvellous range of colour, and the plants have great diversity in habit of growth. When well cultivated Codiaeums are the finest of all ornamental foliage plants, and may be turned to good account in various ways. They were introduced in the 'sixties and 'seventies of the last century from Australia and the South Sea Islands, with Dracaenas and other fine foliage plants. Many that were first introduced are still cultivated. The species and hybrids of the present day are very numerous, and the great majority of them are worth growing. No new varieties are procured by cross fertilisation. The seeds should be sown as soon as they are ripe, in well drained pots filled with light, sandy soil! They should be lightly covered and kept moist, but not too wet, nor should they be allowed to get dry. They may be germinated on the plant stage of a warm house having a tem-

perature of about 70° to 75°. If kept in a close frame the seedlings are liable to damp off. When sufficiently strong they should be potted in small thumb pots, placing three or four seedlings by the side of each pot. When sufficiently established they should be transferred to small pots singly and grown on in the same temperature. As they become stronger and well rooted they should be shifted into still larger pots to be grown amongst the ordinary collection of plants. Newly potted plants require careful attention, and should not be watered too freely until the roots have reached the sides of the pots. They form handsome subjects for exhibition, and are indispensable for table and other decorations. Members of the narrow-leaved section are well adapted for the table on account of their elegant and graceful habit, and when grown in small pots may be utilised for decorating small vases. A few of the best varieties are Golden Ring, the golden yellow leaves of which are twisted; Lucy, leaves with foliage of olive-green ground, blotched with crimson; Aigburth Gem, leaves interrupted and coloured crimson; Chelsonii, leaves bright red in colour; Golden Gem, bright golden yellow

and of very graceful appearance; and Aigburthensis, leaves ivory white. Others with long, twisted leaves are, when well grown, magnificent plants for furnishing large vases, and are a great attraction when used for grouping purposes at exhibitions, or for conservatory decoration.

Amongst the finest varieties of this type are Warrenii, with long and twisted leaves that are spotted with yellow and red; candatus tortilus, leaves twisted and golden yellow; Princess of Wales, leaves creamy white; Prince of Wales, leaves twisted and bright orange; Sinitzinianus, variegated green and yellow; and elegantissima, bright yellow.

Others have broad, massive foliage, such as B. Comte, which forms the subject of the Supplementary Coloured Plate. The leaves are bright orange, and it is one of the best Crotons for exhibition or decorative purposes on account of its hardy constitution. Emperor Alexander III, bright red; Reidii, creamy pink and dark red; Baroness James de Rothschild, dark crimson; Invieta, lemon colour, very distinct; and Andreanus, a variety with large, bright orange red leaves, are other beautiful varieties in this section.

The section with tri-lobed foliage is very distinct, and the plants are of good habit. Disraeli (see Fig. 160), one of the first intro-

duced and best of this section, has leaves coloured orange red. Others are Earl of Derby, centre of the foliage bright yellow; Thomsonii, centre yellow, bordered with green; Evansianus, brilliant red; Montefontainensis, yellow and crimson; and F. Sander, centre bright yellow, bordered green.

The type of medium width and compact habit is represented by such kinds as Queen Victoria, orange yellow; Weismannii, variegated green and yellow, a very compact growing variety; undulatus, leaves olive green spotted and mottled with crimson; Hawkerii, leaves with a pale yellow centre and green border; and Nestor, spotted red and yellow.

There are many other fine species and hybrids, but those described are amongst the

the plant from flagging when it is parted from the parent. The stem should be cut below the pot, and the rooted top placed in a close, moist house for a few days to become well established. Then the old stem may be placed in a warm corner of the house, or shaken out of the pot, laid in a warm, moist frame, and covered lightly with cocoanut fibre, Sphagnum-moss, or other light material to encourage it to make growths suitable for use as cuttings. Newly-potted plants should not be watered too copiously. The majority of the plants may be grown in small pots provided the roots are not allowed to get dry, for at no time should they suffer from want of water, especially when they are well rooted.

Codiaeums require a moist atmosphere, a

## AN AMERICAN'S IMPRESSIONS OF THE CHELSEA SHOW.

For an American gardener a visit to the Chelsea Show is a rare and happy privilege, an inspiring lesson in the possibilities of making a flower show not only instructive, but beautiful, and also, alas! a source of despair in seeing so many exquisite plants which will not survive our cold winters and hot summers.

In recent years we have had in the Eastern United States many fine flower shows of which we are very proud, but even the large size of our biggest national shows had left me unprepared for any show on such a

FIG. 160.—CODIAEUM DISRAELI, ONE OF THE EARLIEST OF THE TRI-LOBED VARIETIES.

best. Cuttings made from well ripened wood root freely under a hand-light or frame in a moist atmosphere of 70° to 75°. The cuttings should be shaded from the sun and kept in a moist state. When rooted the plants should be transferred to larger receptacles and re-potted as required. When large plants have shed their leaves and become unsightly, the top may be rooted by ringing. This is done by making one or two incisions in the stem about 1½ to 2 inches long, and placing the halves of a 3 inch or 4 inch pot, cut for the purpose, on opposite sides of the stem. The pot is filled with a mixture of fibrous peat, turfy loam and silver sand, or with fresh Sphagnum-moss. The compost should be kept moist, and the plant placed in the warmest part of a house having a temperature about 70° to 75°. If the top is large and heavy, it should be supported with a couple of sticks. As soon as the pot is filled with roots, a larger pot should be put around the stem; this is necessary to encourage more roots and prevent

temperature of 65° to 70°, and plenty of light, with slight shading from the hot midday sun. There are many varieties that may be grown without any shading whatever, but slight shading is advisable for all when the sun is very powerful.

During hot summer weather syringe the plants freely, but in the winter syringing must be governed by the condition of the weather and the heat of the pipes. On cold days keeping the house moist without syringing will be sufficient. Frequent syringings with plenty of moisture will prevent red spider and mite attacking the plants, pests that cause the young leaves at the point of the shoot to drop until the stem is completely denuded of foliage. A little fresh air is beneficial to the plants when the weather permits of ventilating and the temperature of the house is high, but do not cause a draught. The soil should consist of two-thirds rich, yellow, turfy loam, and one-third good peat or leaf-mould, with silver sand added. *John Heal, V.M.H.*

gigantic scale as the 1922 Chelsea Exhibition. We hope that the rapidly growing interest in horticulture may make such shows possible with us in the not far distant future.

The show impressed me on account of its great size, its artistic arrangement, the high quality of the exhibits, and the tremendous variety of the plant material used. I liked it all so much that it is difficult for me to try to pick out the best things to comment on, for, with the possible exception of the big Carter clock and the garden surrounded by bright pink dwarf Rhododendrons, I liked everything.

As my greatest interest is in the Iris, I naturally spent much time in Messrs. R. Wallace and Co.'s garden, which received such high honours. This garden was a gem of design and colour arrangement, and contained two of the newest Irises of English origin, Asia and Nicopero, side by side with the French Ambassador and Souv. de Mme. Gaudichau and the American Lent A. Williamson. Lady Foster, Crusader,

and Neptune also appeared to good advantage here, but Dominion had suffered from too hard forcing, and the flower was not characteristic. The Lilies, Azaleas and Regelio-Cyclus Iris blended well with the Iris, and made a perfect whole.

The Bunyard Iris garden was also a source of delight to me, and here *Ambassadeur*, *Lord or June*, *Magnifica* and *Isolene* stood out as giants among some of the older sorts. In the Perry and Whitelegg exhibits, *Regelio-Cyclus* Iris were the feature.

Perhaps even more fascinating than the Iris gardens were the rock gardens, something we hardly know in America. I liked Mr. Wood's conception best, because it was so very simple that it reminded me of some exquisite bits of wild landscape in some of our New Hampshire or Vermont hills.

Messrs. R. Tucker and Sons' garden contained a greater variety of plant material, and was also very beautiful; in fact, nearly all the rock gardens struck me as being wonderfully artistic, as well as showing many exquisite little plants, and I spent more time with them than I did in some of the formal gardens.

The *Rhododendrons* were finer than any I had ever seen, the big bushes in one of the big tents and in Messrs. R. Wallace and Co.'s natural garden being the most striking. To *Rhododendron* experts the cut flowers were probably equally interesting.

Another group of plants that I admired particularly were the *Clematis* hybrids exhibited by Messrs. G. Jackman and Co. and one or two others. European gardeners are used to these, but to an American all but one or two varieties are totally new. I do not know how they would grow under our conditions.

We are used to fine displays of *Roses* in our American shows, and perhaps for this reason the *Roses* did not impress me so much as some of the other flowers. They were of splendid quality on the first day, and I was glad to see some of the triumphs of two of America's greatest *Rose* breeders, Dr. Van Fleet and Mr. H. Walsh, both of whom have died within the past few months. The varieties noted were *American Pillar*, *Hiawatha*, *Paradise*, *Excelsa* and *Minnehaha*. We are very glad that these are appreciated in England, where so many fine *Roses* have originated. The *American Rose Los Angeles*, which won a gold medal at Bagatelle in 1918, was also noted in good condition, as were several other American varieties. The number of varieties exhibited was much greater than in most American shows.

*Paul's Scarlet Climber* was seen in wonderful form, but I did not think the flowers of the beautiful new *Souv. de Claudius Pernet* were quite as fine as those staged in our New York show last March.

There were so many new *Roses* to attract attention that I can comment on only a few. I liked *Padre* the best, but admired also *Rev. F. Page Roberts*, the singles *Mrs. Oakley Fisher* and *Pink Delight*, and the *Polyanthas Queen Wilhelmina* and *La Reine Elizabeth*.

The *Tulips* were gorgeous. I have never seen a display as fine as Messrs. Dobbie and Co.'s, although I have seen as fine flowers in small quantities in our shows at home. As usual, I liked *La Tulip Noire* the best of all, and *Dom Pedro*, *Faust* and *Louis XIV* were noted in fine condition in many exhibits.

*Carnations* surprised me, because I had always supposed the *American Carnation* was far superior to those grown in Europe. True, there was a liberal sprinkling of *American* varieties like *Enchantress Supreme*, *Beacon*, *Benora* and *White Wonder*, all of excellent quality, and also a few of *Laddie*, which were not nearly so big as with us, but the *British* varieties seemed equally good. I made no notes on varieties, but *Thor* impressed me the most. We have no commercially important *Carnation* of the colour of *Marion Wilson*, which I liked very much. I was also impressed with the fact that at least one breeder was emphasising the fragrance of his new varieties—a point forgotten by many *American* breeders in the race after size and productiveness.

The *Sweet Peas* were as fine as those shown by *Burpee* in New York, and were shown in greater quantity. The display of *Orchids* was larger than usually seen with us, with the exception of the recent special *Orchid* exhibitions put on by Mr. Burrage, president of the *Massachusetts Horticultural Society*.

These notes have already grown longer than I intended, because I do not know where to stop. I cannot close without mentioning how hungry I got every time I passed *Laxton's* wonderful *Strawberries*, the like of which I have never seen. We are used to seeing fine vegetable and fruit displays at home, but for this season of the year the *Hon. Vicary Gibbs'* collection of vegetables was remarkable, and so was Messrs. *Bungard and Co.'s* collection of *Apple* varieties, which interested me as showing me many *Apples* I had read about in your columns in previous years. No *American* varieties were shown, and they are probably as unsuited to your climate as your varieties are to ours.

I am sorry that you had to treat us to some real *American* summer weather during the show week, for it was not only hard on people but on the flowers, many of which were not in good condition on the last day, but my surprise was to see how remarkably they stood up under such adverse conditions. All praise is due to the skilful growers and to the able exhibitors and managers of the show who put on these wonderful shows year after year. I hope I may be able to attend many more of them. *John C. Wister.*

## AQUATIC AND WATERSIDE PLANTS.

AQUATIC and moisture-loving plants are extremely fascinating. May and June is undoubtedly the best time for planting or transplanting *Nymphaeas*. I have seen it stated that it is necessary to have three to four feet of water for the *Marliac* varieties of *Water Lilies*, but this is misleading; granted they will do in that depth of water, but I know from experience they succeed splendidly in water only one and a half foot to two feet deep. Young plants obtained this time of the year (May or June) may be very easily established. If for tanks with cement or concrete bottoms, planting in shallow baskets will be found the best method of establishing them in the water, placing a few pieces of sandstone around them when in position to form a basin and filling in round the basket with rich turfy loam. This will keep the plants in good condition for many years after the baskets have disappeared. If the plants are required for ponds with ordinary muddy base, an easy and successful method of planting is to secure some thick turves of loam and tie one round the roots of each plant. Wire will be found better than string for keeping the loam in position until the plants establish themselves. Sufficient loam should be used to ensure keeping the *Water Lilies* upright when sinking them in their respective positions. The following are good, hardy varieties of *Nymphaeas*: *N. Marliacea albidia*, pure white; *N. Marliacea chromatella*, pale primrose; *N. Marliacea carnea*, pale flesh-pink; *N. Marliacea rosea*, deep rose; *N. Laydeckerii lilacea*; *N. Laydeckerii purpurata*; *N. Laydeckerii rosea*; *N. Aurora*, deep crimson. *N. Gloriosa*, bright rose.

For waterside planting the following are all very beautiful aquatics and if submerged at various times during the year they will come to no harm. The *Siberian Iris* are charming both in flower and foliage for the leaves are quite graceful, giving a glorious effect at the waterside. The following varieties are very good:—*Iris siberica* (type), pale blue; *Iris s. alba*; *Iris s. acuta*, blue-purple, fine; *Iris s. lilacina*; *Iris s. orientalis*, deep blue; *Iris s. Purple King*, fine; *Iris s. Snow Queen*, lovely pure white. *Iris Monnierii*, rich deep yellow, and *Iris ochroleuca*, white, with yellow blotch, are other beautiful aquatic species.

*Iris Kaempferii*, the *Japanese Flag Iris*, is splendidly effective in pockets by the water's edge.

*Astilbes* may also be used for the margins of lakes and ponds with grand effect. *A. Philadelphia*, deep rose; *A. Pink Pearl*, *A. Snowy*

*Plume*, *A. Ceres*, *A. Mont Blanc* and *A. Salmon Queen* are all extremely fine sorts.

*Funkias* in variety are noble subjects, with their massive foliage; *Hemerocallis* (*Day Lilies*) may also be used for the same purpose, with beautiful effect; both their orange and yellow spikes of blooms and graceful foliage are attractive in association with water. *R. H. Holton.*

## FAILURE OF SOUTHERN PLANTS TO COLONISE IN THE NORTHERN HEMISPHERE.

THE explanation given by Mr. Irwin Lynch on page 270 for the failure of Australasian Composites to establish themselves by seed in the northern hemisphere seems to meet the case of any solitary species to do so. But, as Mr. Lynch has proved, the most diverse species of self-sterile genera will cross freely with each other. How comes it, then, that in places where many such species are cultivated, crossing does not take place, with the result of a crop of hybrid seedlings? We have here many plants of *Senecio Greyii*, *S. laxiflorus*, *S. Huntii*, *S. Hectorii*, *S. Monroii*, and *S. Buchananiai*, and *Olearia nitida*, *O. macrodonta*, *O. ilicifolia*, *O. nummularifolia*, *O. avicenniaefolia*, *O. Traversii* and *O. Itaastii*, all of which discharge clouds of seed every season; but, as mentioned in my former note on this subject, in the course of many years I have recovered only a single seedling (*O. nummularifolia*), which is now a fair-sized bush. It is true that, as Mr. Lynch observes, quantities of seed, even if fertile, shed in woodland or garden ground never get a chance of growing, owing to rank herbage or cultivation. But that does not interfere with the southern *Veronica Traversii* and *V. parvifolia* coming up in garden borders and paths in troublesome swarms.

Again, *British Composites* have established themselves profusely in Australasia, no doubt from seed unintentionally imported with farm and garden plants and seeds. What influence has prevailed to prevent a similar result in Europe from the counter-importation of Australasian Composite seeds? For instance, thousands of tons of *Dicksonia* and other *Ferns* have been brought to this country (not to mention vast quantities of wool and wheat) and plenty of seed must have come with these consignments from a region peculiarly rich in Composite plants. *Herbert Maxwell, Monreith.*

## HOME CORRESPONDENCE.

[The Editors do not hold themselves responsible for the opinions expressed by correspondents.]

**A New Planting Tool.**—Some years ago I advocated, in these pages, a "dibber" of oval section instead of the ordinary round one. Under the name of "*Koolpootijzer*" I have lately obtained (from Messrs. Tubergen, jun.) a still more efficient tool. It consists of a lance-shaped steel blade about 9½ inches long and 2 inches wide, with a shank fitted into a slightly obliquely placed cross handle, giving an overall length of about a foot. The angle at which the handle is put on is a distinct point, as the handle lies comfortably in the grasp when thrusting the "dibber" in the soil. In this respect it recalls the *Malayan kris*, whilst perhaps the blade might be likened to that of a *Zulu assegai*. On trial it is found to accelerate planting, since it is so easily pushed into the soil; a slight side movement gives room for the roots to be inserted, when it is withdrawn and pushed down near by, as with the ordinary dibber, to finish the work. One great advantage seems to be that the soil is not compressed. A smaller model would no doubt be a good tool for the pricking out of seedlings in pans. *H. E. Durham.*

**Davidia involucrata.**—*Davidia involucrata* is flowering very profusely at the present time in *Tortworth Gardens*, *Falfield*, *R.S.O.*, *Glos.* The particular plant referred to (we have

three) was planted by the late Lord Ducie in 1903. It is 23 feet high, 18 inches in girth of stem at 4 feet high, and 20 inches in girth of stem at 3 feet high. It has  $9\frac{1}{2}$  feet of clean stem, and a 24 ft. spread of branches. It is planted in a somewhat sheltered spot in the kitchen garden. The flowers are pendulous, the white creamy bracts attached to the flowers being very conspicuous, and are seen to the best advantage from under the tree and looking upwards. This Western China tree has flowered before, but never so profusely as this year. *John Banting, Tortworth Gardens, Falfield.*

**Aquilegia Stuartii.**—I am much indebted to Mr. G. M. Taylor (see p. 234) for kindly drawing my attention to the true parentage of *A. Stuartii* as given in the report of the Conference of the Royal Horticultural Society. When writing the note on this Columbine, the reference to it given in the Conference report had quite escaped my memory, and I mentioned the reputed parentage as given by a writer whose views on this and other matters connected with plants deserve every respect. However, it is satisfactory to know that we have a really authoritative statement regarding the parentage of *A. Stuartii*, and it may be helpful to those who are working on the hybridisation of *Aquilegias*, and may lead to the creation of a hybrid possessing all the beauty of *A. Stuartii* without its difficulties in cultivation. *S. Arnott.*

**White Fly.**—With the advent of warmer weather, gardeners will, without a doubt, receive visits from the pest known variously as White Fly, White Thrip and Holy Ghost Fly. There is no question about the anxiety this enemy creates, and it is up to every grower who knows a preventive or remedial measure to make it widely known. Fumigating is effective, and it is very necessary, but fumigating will not kill the young flies, which often seem embedded in the epidermis of the leaf. Something is required to meet these young arrivals at the birth, and this is to be found in a free use of *Tipulite*. The plan is to sprinkle *Tipulite* about the path, staging, bed, border, and all bare surfaces, and renew the application weekly; the fumes given off overtake the young insects and cause their death. If this method of treatment is adopted, fumigating is not needed so frequently, and it is much less expensive and much less dangerous than cyaniding.—*Majester Palae.*

**Effect of "Drip" on Seedlings.**—At Redfields, Hampshire, where we are raising plants for this year's Tobacco crop under frames, we notice that the seedlings immediately under the bars of the lights grow much better and are more forward and healthier than the rest of the seedlings. The plants are strongest where the moisture, which condenses on the glass, drips on to them. The seedlings are always watered with tepid water, and they are kept shaded during the early stages. It is before the shading is dispensed with that the difference in growth is noticeable. Has condensed water any effect in causing greater plant growth?—*J. Ware, Redfields Gardens, Church Crookham.*

**Giant Larches.**—I have recently measured three Larches on this estate. They are in a plantation opposite the one that gained the gold medal at Cardiff, 1919, for the best plantation. Of course, they have not the spread of branches given by Mr. Mills, as the trees average 7 feet apart throughout the plantation. No. 1 is 120 feet high, with a girth 3 feet from the ground of 6 feet 3 inches; No. 2 is 116 feet high, with a girth of 5 feet  $7\frac{1}{2}$  inches; No. 3 is 109 feet high, with a girth of 5 feet 2 inches. There are plenty of other trees between 90 feet and 100 feet high. I also measured one lying trimmed on the ground. The butt was 2 feet 1 inch in diameter; the top, 4 inches in diameter; and the length of the stem was 90 feet. This particular tree was blown down by a gale last Christmas. This plantation was planted by Colonel Johns, who was a keen agriculturist and arboriculturist, about 140 years ago. *D. H. Dunn, Hafod, Devil's Bridge, Aberystwyth.*

## SOCIETIES.

### HORTICULTURAL CLUB.

#### ANNUAL MEETING AND LECTURE.

THE annual meeting of the Horticultural Club was held on the 24th ult., in the Trocadero Restaurant, Piccadilly. The President Lord Lambourne, C.V.O., was unable to be present, and the chair was occupied by Mr. Peter R. Barr. A letter was read from the Hon. Treasurer and Chairman, Sir Harry J. Veitch, regretting his inability to be present, owing to his doctor having forbidden him to attend any meetings.

The Hon. Secretary read the report of the Committee for 1921, of which the following are extracts:—

#### EXTRACTS FROM THE REPORT.

The number of members on December 31, 1921, was 162, compared with 209 on December 31, 1914, a period when probably the Club was at its highest state of prosperity.

By the kindness of the Chamber of Horticulture the Club has, for the past year, been installed at 18, Bedford Square, but the district is not easily accessible to the majority of the members, and few have attended there. The Committee has now made arrangements to have the exclusive use of a convenient room for the Club at the Hotel Belgravia, Buckingham Palace Road, Westminster, on Mondays and Tuesdays in the weeks when the R.H.S. meetings are held, and on other occasions when important horticultural functions are held in the Metropolis. In addition to the club-room the members would have the free use of all the public rooms in the hotel and the service and attention of a large staff. The club-room would be available for use at any hour on the Monday and Tuesday, and letters, messages, etc., would always receive the most careful attention. The Hotel Belgravia is close to Victoria Station and within a short distance of Vincent Square. Members will be able to obtain sleeping accommodation and other hotel accommodation at special terms.

The members will learn with the deepest regret that the Hon. Treasurer and Chairman of Committee, Sir Harry J. Veitch, is relinquishing, under his doctors' orders, all public engagements, including those connected with the Club. The splendid assistance which Sir Harry has rendered in both those capacities, and his interest in everything pertaining to the welfare of the Club over a large number of years, have been reflected in much of the prosperity which the Club attained, and his resignation is deeply deplored. It is a pleasure to know that as a vice-president he will continue to be associated with us, and we trust that his honoured name will long be found on the list of members. The Committee recommends the election of Mr. Peter R. Barr to the office of Hon. Treasurer in place of Sir Harry Veitch.

The death of Mr. George Paul, V.M.H., who had served as a member of the General Committee for many years, involves a great loss to the Club, and the Committee also regrets the deaths of three other members, Mr. R. A. Rolfe, Mr. F. K. Sanders, and Mr. James Coey.

Regret was general that Sir Harry J. Veitch was compelled to resign the important offices he held, and the Hon. Secretary was instructed to send a letter expressing the great regret and deepest sympathy of the members, together with the paragraph from the report referring to him.

Lord Lambourne was re-elected President, and the three Vice-Presidents were also re-elected. Mr. J. F. McLeod was appointed Chairman, and Mr. P. R. Barr, Hon. Treasurer, in succession to Sir Harry J. Veitch. Mr. G. F. Tinley was re-appointed Hon. Secretary and thanked for his past services. The following gentlemen were appointed members of the Committee:—Messrs. P. Rudolph Barr, W. A. Bilney, E. A. Bunyard, P. F. Bunyard, W. B. Cranfield, W. Cuthbertson, H. R. Darlington, W. J. Jefferies, H. B. May, J. McLeod, G. Monro, C. E. Pearson, R. Pinches, H. S. Rivers, and E. White. The trustees and auditors were also re-appointed.

Following the annual meeting, the members dined together, and amongst the guests were Mr. H. V. Taylor, Deputy Controller of Horticulture; Mr. J. C. Wister, President of the American Iris Society; and Mr. Leo Bonnewitz, a former President of the American Peony Society. After the toast of the King had been given by the Chairman, Mr. W. Wallace proposed "The Health of Visitors from Abroad," to which both Mr. Wister and Mr. Bonnewitz responded. Mr. Wister said it was a happy experience to come to London and see the Chelsea Show, a desire which he had had as

long as he could remember. Before he had seen the show, he always considered that those who wrote the account of the exhibition in *The Gardeners' Chronicle* always looked through a long glass, but now he realised that the reports were not exaggerated. Indeed, it was the most wonderful show which he had ever seen, and they had nothing in the way of floral exhibitions in the U.S.A. to compare with it. Referring to Quarantine No. 37, he said that the American Controller had a strong case, for many serious pests had been introduced to America from Europe, yet he advised those on this side to keep on fighting until a more reasonable quarantine was adopted. Mr. Bonnewitz said that he had spent four of the happiest days of his life since he had reached London, and amongst the things that had impressed him most were the beds of Tulips in Hyde Park, the beauties of Kew Gardens, which he had visited on two days, and the great show at Chelsea, but he was most delighted with the show, and he was afraid that when he returned home and told of its beauties he would be regarded as an international liar.

#### LECTURE ON ALGERIA

Mr. E. A. Bunyard's lecture on Algeria, which was freely illustrated by lantern slides, was greatly enjoyed. His knowledge of the country, flora and the peoples was as though he had lived in Algeria all his life, for nothing seemed to have escaped his eye. He stated that Algeria is composed of three distinct parts—one, the coast district, which has a climate and flora like that of the Riviera, where up-to-date cultivation is practised, and such crops as Potatoes and Asparagus raised in perfection. This district is succeeded by high, rolling plateaux, where the land is cultivated by the plough and Wheat largely grown, the plough being exactly similar to the one used in Egypt in the days of the Pharaohs. Beyond this is the desert of Sahara, and there the land is cultivated in the most primitive manner by the hoe, and no spade tillage is adopted at all in that part, the hoe being used somewhat like a mattock for chopping the soil, rather than hoeing. The lecturer pointed out how small is the native flora, Cedrus atlantica being the outstanding large tree, Palms, Eucalyptus, Pepper, and other exotics, which now form the largest and most conspicuous trees, all having been introduced. Amongst fruits met with are Apricots, Oranges, and Olives; these also have all been introduced. Palms are a great feature of the country, and one of the slides showed a fine avenue of *Lantana borbonica* in the Botanic Garden at Algiers. In the valley district the cultivation of vegetables is almost wholly in the hands of Spaniards, who take meticulous care with every detail. For instance, each little plant of dwarf Bean has a Palm leaf placed by its side to protect it from too much sun. It is from this district that we obtain our earliest imported Asparagus. The forests of *Eucalyptus globulus* are a marvellous sight, and the trees emit a delightful scent. The Algerian Iris (*unguicularis*) covers miles of land, and is as common as Gorse in some parts of this country. Around Algiers it all appears to be the common lilacina form, and he saw none of the white-flowered type. *Chamaeris humilis* grows on the uplands in abundance and goats graze on it, so that the trees are very dwarf and not more than two feet tall. Accompanying it are *Cistus* and many Orchids. He was also interested in a dwarf Marigold, about six inches high, of which he was unable to determine the species. Blidah, about fifteen miles from Algiers, is the centre of the Orange industry, and there are vineyards thereabouts of large size, those of 400 to 500 acres being common. Several pictures showed the Date culture at Biskra and the systems of irrigation. Some of the most interesting pictures referred to the old Roman town of Timgad, which has been excavated by the French. Mr. Bunyard stated it was an Eldorado for the architectural gardener, as it contained stone in abundance, and such things as capitals, vases and tanks in plenty. One of the most interesting pictures was the garden of a Roman house, in which the plants were grown principally in stone basins

or stone troughs. The Date trees are very long lived and bear good crops for eighty or one hundred years. A single bunch of Dates will often weigh as much as 1 cwt., and there are some hundreds of varieties. The Date Palms are only cultivated in districts where there is a water supply and the water is the property of the community in general, one cultivator being afforded a certain time for irrigating his trees, when another's turn arrives; and the measuring of the time is done in a most primitive way by water dripping through a hole in the bottom of a receptacle, just so long as it takes for the vessel to empty being the time apportioned for each owner's trees. Practically no cultivation is adopted by the owners of the Palm trees, and a so-called orchard of Date Palms has no method of arrangement, the trees being planted in groups in a most haphazard manner.

## ROYAL HORTICULTURAL CHELSEA SHOW.

(Continued from page 282.)

The informal rock garden and water garden attached to the tennis hard court of Messrs. GAZE AND Co., LTD. (see Fig. 154), were particularly pleasing and valuable, in that they both could well be adapted for a garden of quite modest dimensions—most of the rock gardens at Chelsea were distinctly ambitious in their conception. Much thought and knowledge had evidently been expended on the arrangement of the boulders, and the planting was equally successful. The sunken blue garden was a pleasant and restful place, which would also appeal to the owner of a comparatively small garden.

A considerable selection of the dwarfed Japanese trees, of which they hold an extensive assortment, was shown by the YOKOHAMA NURSERY COMPANY in the large tent. There were Larches, Pines and Cupressus obtusa, apparently of great age, and several fascinating pans of Japanese Maples bearing delicately beautiful coloured leaves. Several old, yet floriferous, examples of Azalea Kaempferi were also included in their interesting collection.

Mr. ERNEST DIXON, Putney, had a neat sunken garden in the open, in which he utilised many old garden ornaments in lead and stone.

### Scientific Exhibits.

A special tent was devoted to exhibits of scientific interest from the Royal Horticultural Society's Gardens. Experiments are in progress at Wisley in green manuring and the relative value of the various crops which can be thus employed were shown. Specimens of seeds and growing plants of green-manure crops were exhibited; leguminous plants being represented by Red Clover, Medick, Vetch, and Crimson Clover, and non-leguminous plants by White Mustard, Turnip, Oats, Rape, and Rye.

A very interesting exhibit came from the pathological department at Wisley, where many important diseases are being investigated by Mr. Dawson. Specimens were shown of Roses seriously effected with "die back" disease due to a species of Gnomonia, together with specimens of the fungus in culture. The advice given is to remove all infected shoots well below the region of the disease, and to spray with a solution of liver of sulphur just before the buds open. Research work has also been conducted on the "wilt" of Michaelmas Daisies, and a very satisfactory advance has been made in controlling this disease, which is becoming more and more troublesome to growers of these popular plants. The disease is caused by a soil fungus (Fusarium species), which attacks the root stocks, and shoots thus affected rarely reach the flowering stage. Rooted suckers from diseased plants must not be employed for propagating purposes as diseased plants generally result, but as the upper half of the young shoots usually escape, this part should be used as cuttings. Specimens of diseases conveyed by seeds were also exhibited, and included Bean Pod Canker (Colletotrichum lindemuthiana); Pseudomonas seminum, which causes a bacterial disease in

Peas; and Septeria Apii, affecting Celery, diseased seeds when sown giving rise to leaf-spotted plants.

From the entomological department at Wisley came some very finely prepared specimens of insect visitors to Apple, Pear, and Plum trees, and samples of spray fluids and chemicals were also on view. The use of Saponin as a spray spreader was also well illustrated by means of "leaves" made from waxed paper. Soap is added to sprays to increase their adhesive properties, but it has the disadvantage of sometimes adversely affecting the quality of the sprays, and, with some sprays, it cannot be mixed at all. Saponin may be mixed with all sprays without altering the effectiveness of their component parts. Charts were exhibited giving information on cross-pollination of fruits and the injurious effect of grass on Apple trees.

The various types of Perpetual-flowering Carnations were shown by means of photographs, as were also types of Strawberries; specimen plants of the latter, growing in pots, were also included.

Around the scientific tent were displayed models of the principal fungous and insect pests affecting fruits and vegetables.

### SUNDRIES.

The many and varied adjuncts to successful gardening occupied their accustomed place along the Lime Avenue and in part of the Main Avenue at Chelsea Show. Although there has not been, so far, the usual great need for insecticides in the outdoor garden, green fly and other pests are certain to call for rigid suppression before long, and wise gardeners were anticipating their inevitable requirements. Messrs. AROL, LTD., had a very attractively-arranged stand, where they displayed a great variety of non-poisonous insecticides and fungicides, together with their well-known Abol syringe, which gives such a finely divided spray. They also showed valuable fertilisers. Lime preparations were shown by the BUXTON LIME FIRMS Co., LTD.; while Messrs. EDWARD COOK AND Co. made a great show of "Gyp," their non-poisonous insecticides and fungicides and various fertilisers.

Their well-known and valuable V. 1 and V. 2 washes were presented in the tent of Messrs. WM. COOPER AND NEPHEWS, LTD., who also presented various types of sprayers and weed killers. Fowler's lawn sand and Lethorion cones for fumigating were exceedingly prominent exhibits amongst the various sundries staged by Messrs. CORRY AND Co. Under such popular names as Sox and Dwooved, Messrs. HAWKER AND BOTWOOD, LTD., displayed effective insecticides and weed-killer.

Many generations of gardeners have proved the efficacy of Gishurst Compound, which, with Gishurstine, was prominently exhibited by Messrs. PRICE'S PATENT CANDLE COMPANY. They also stock a useful soap and quassia mixture, and "Manulav" soap, which is an admirable cleanser for the hands, no matter how stained they may be. In addition to their famous disinfectant, Messrs. JEYES, LTD., had, in Lignosol, a wood preservative which also stains the wood a pleasing brown colour; Messrs. JEYES also exhibited amongst other compounds samples of their summer wash, which was found a cure for mildew on Roses at the R.H.S. trials in 1919. Messrs. MURPHY AND SON, LTD., showed their "Alvesco" insecticides and fumigants. The scientific application of arsenate of lead, especially in control of sucking insects, was a great speciality of Messrs. W. VOSS AND Co., who were distributing concise and interesting literature on the subject. Another important feature in this tent was the extensive collection of moths, flies, and their destructive progeny, together with the, unfortunately, fewer "friendly" insects. Messrs. VOSS AND Co. now distribute Blighty, in addition to their Bordeaux—two valuable Potato blight specifics.

Spraying machines were present in great variety, and foremost amongst them was the "Vermorel," shown by Messrs. COOPER, PEGLER AND Co. The FOUR OAKS SPRAYING

MACHINE COMPANY displayed a wide range of sprayers, all of good quality, as well as well-made pumps and syringes. The well-known Haws's patent watering-can, ranging from tiny "baby" cans to receptacles of four gallons capacity, and a useful-looking syringe were staged by Mr. J. HAWS; while the AUTOMATIC UTILITIES COMPANY demonstrated the ease in working their Mist garden waterer. Mr. J. SINGLETON was busy with his Neuspray, and Messrs. WEBSTER AND SON had their cascade nozzle, which may be fixed to any ordinary watering-can.

A wide range of sprayers, syringes and other appliances, with their Multiple preparations and lawn sand, were contributed by Messrs. ROBINSON BROS., LTD. In the extensive exhibit of the STONEHOUSE WORKS COMPANY many excellent sprayers and syringes, with a large assortment of fertilisers and insecticides, were to be seen. The Ubel knapsack sprayer, of good design, was exhibited with syringes, etc., by the UNITED BRASSFOUNDERS AND ENGINEERS, LTD.

Fertilisers enjoyed a wide popularity, and most of the exhibits devoted to them were rendered very attractive by the addition of plants, fruits and vegetables grown by their aid. Messrs. ALLWOOD BROS. had a house filled with Carnation sundries, including manure and calyx rings. Thick, fibrous turves of excellent yellow loam were shown by Mr. A. B. JOHNSTONE. Messrs. MASKELL, HARRIS AND Co. set out attractive samples of their proprietary manures, and Mr. Leo. Harris was present to give advice on all matters appertaining to their use. Beautiful Hydrangeas, bearing large heads of pink and of blue flowers, on the stand of the MOLASSINE COMPANY, testified to the great value of Rito, and added to the gaiety of the avenue. Ideal Tomato fruits, Cucumbers, white Marguerites and other flowering plants rendered the stand of Messrs. PRENTICE BROS. very bright and gay, and also drew the attention of the visitors to the old and tried Ichemic guano, as well as the newer Tomorite.

Greenhouses, complete with boilers and hot-water pipes, and garden frames, were quite important features of the sundries section. In the main avenue Messrs. J. L. WEEKS AND Co. built full-sized models of their well-known types of plant houses. Messrs. D. SWAIN AND Co. also had several useful glass houses and frames, and a summer-house of comfortable appearance.

In the Lime Avenue, Messrs. MESSENGER AND Co. had quite an extensive collection of excellent glass houses and frames. Messrs. BOULTON AND PAUL erected a full-sized greenhouse and various useful frames, all of excellent design and workmanship. An attractive lean-to glass house and several equally well made garden frames were shown by Messrs. J. GRAY, LTD.; while in another place Messrs. W. DUNCAN TUCKER AND SONS had an extensive range of their well-known glass houses and frames. These were all of well seasoned timber and elegant design. Their Wire Tension greenhouses and novel glide-house—the latter for placing temporarily over crops—were displayed by Messrs. SKINNER, BOARD AND Co. Patent greenhouse repairing apparatus and garden implements were shown by Messrs. A. SMELLIE AND Co.

Anti-corrosion and other paints were exhibited by Messrs. W. CARSON AND SONS, and, near by, were the CHASE CONTINUOUS CLOCHE and the Cloche Clips. On the opposite side of the avenue Messrs. C. M. DAVIES AND Co. attracted a great deal of interest with their Windowlite, a glass substitute which is said to be an improvement on Spondite.

Greenhouse boilers of great power, and lengths of hot-water pipes were set out by Messrs. C. P. KINNELL AND Co. Besides their well-known Beeston, Rochford and Robin Hood boilers, they had a full-sized New Twin-Fire boiler, which attracted favourable notice.

Lawn mowers of various designs were shown by Messrs. RANSOMES, SIMS AND JEFFRIES, who, in addition to their well-known hand machines, had several patterns with motor attachment. The old-established makers, Messrs. A. SHANKS AND SONS also demonstrated the ease with which

their hand, horse and motor lawn mowers are worked. Other manufacturers who displayed mowers were the WALTHAM ENGINEERING COMPANY; Messrs. C. H. PUGH, LTD., who specialise in the Atco lawn mower; the NENE ENGINEERING COMPANY, and the J. P. SUPER LAWN MOWER, LTD. Various implements were set out by the ACME PATENT LADDER COMPANY, the ELLIOTT PRUNER COMPANY, the WILKINSON SWORD COMPANY, whose scateavers, etc., are made of sword steel; the HOUSE AND GARDEN SUNDRIES COMPANY, Mr. C. A. JARDINE, and Messrs. MOTES, LTD., who had a handy Horti Plow. Mr. H. PATTISSON had his horse-boots, which are valuable for use on lawns and playing grounds. Mr. J. PINCHES, in a tent next to that where *The Gardeners' Chronicle* was "at home" to callers, showed his excellent metal labels, bloom protectors, exhibition boxes and similar necessities.

A great many garden seats and similar articles of garden furniture were set out by such firms as Messrs HARRODS LTD., the CASTLES' SHIP-BREAKING COMPANY, Messrs. A. W. GAMAGE AND CO., Messrs. PIGGOTT BROS. AND CO., the ENHAM VILLAGE CENTRE, Messrs. KELLY AND CO., and Messrs. B. MAGGS AND CO., while the GARDEN SUPPLIES, LTD., showed what appeared to be a very handy concrete roller at a low price.

Many beehives and accessories, with fruit-storing appliances, shown by Messrs. E. H. TAYLOR, LTD., were the objects of much interest, though the greatest attention of the visitors was directed to the demonstration beehive where, through the glass sides, could be seen the colony of bees busily working.

#### NATIONAL TULIP. (SOUTHERN SECTION.)

MAY 24 AND 25.—The annual show of this old-established florists' society was held in a committee tent at Chelsea during the R.H.S. Great Spring Show. Unfortunately the show did not receive anything approaching the amount of attention the merits of the exhibits deserved, and very few persons of the many thousands who went to Chelsea saw the florists' Tulips. The reason is not far to seek. It may be summed up in a word—ignorance. The National Tulip Society does not advertise; there was not even a modest placard bearing the name of the society, much less the object of the exhibition, consequently the general public knew nothing about it. This is a great pity, as, although it was only a small show and exhibitors were few, there were sufficient really good blooms to give an indication of the charm and beauty of the Old English Tulip. There are signs that a revival of interest in the Tulip by garden lovers in the south would be a comparatively easy matter. Quite a number of visitors were attracted to the florists' varieties in the magnificent exhibits of Tulips by Messrs. BARR AND SONS, Messrs. R. H. BATH, LTD., and others in the large tents. But the National Tulip Society seems to be allowing the golden opportunity to slip by.

At the National Tulip Society's show most of the first prizes were won by Mr. J. W. BENTLEY, Middleton. His twelve rectified Tulips included an almost perfect flower of S. Barlow, the premier flamed bloom. Other good flamed blooms were Sir J. Paxton (bizarre) and Annie McGregor (rose), while the chief featured blooms were Stockport (bybloemen) and Mabel (rose). In the class for six blooms he had good examples of S. Barlow (fl. biz.) and Stockport (fr. byb.). His three feathered blooms included a very fine Stockport, while in the classes for three flamed varieties he had fine specimens of S. Barlow and Adonis. Mr. Bentley's six breeder Tulips were very good indeed. The best were Gleam, a beautiful rose, which was the premier breeder bloom, Rose Hill and Adonis. His three breeders, though good, were not quite equal to the six, but Adonis was again one of his best. He won the Samuel Barlow prize with S. Barlow (fl. byb.) and Mrs. Collier (fr. rose).

Mr. W. PETERS, Cambridge, was second with twelve and six dissimilar blooms, and in the latter class he ran the winner very close indeed,

his blooms of Mrs. Jackson (fr. byb.), Sir J. Paxton (fl. biz.) were admirable. He was also second with six breeder varieties.

Competition in the classes for small growers was not great. Mr. A. E. CHATER, North Finchley, was first with six and second with two dissimilar rectified blooms, and was also second in the class for three flamed Tulips.

The only trade exhibit of twenty vases of dissimilar garden Tulips was by Messrs. BARR AND SONS, who were awarded a gold medal for a handsome collection of such sorts as Eclipse, Velvet King and Kepler (Darwin's), Kroeschel, Columbus, and L'Union.

Messrs. BARR AND SONS also exhibited an exceedingly interesting collection of breeder and rectified blooms on a board. Of the former there were splendid blooms of Annie McGregor, Talisman and Lady Constance Grosvenor, while of the rectified blooms Sir Joseph Paxton, Dr. Hardy and Bessie were also noteworthy for high quality.

### Obituary.

**William Henderson.**—The many friends of this veteran gardener will learn with keen regret of his death, which took place on the 23rd ult. at Balbirnie Gardens, Marckinch, Fifeshire. In early life he was employed under the late David Thomson at Archerfield, with whom he

THE LATE WM. HENDERSON.

moved to Drumlanrig, where he became one of his principal foremen. He was appointed to the charge of the late John Balfour's gardens at Balbirnie over fifty years ago, succeeding Mungo Temple. Mr. Henderson had no bobby save that of cultivating the stage Auricula, but was a born enthusiast in everything pertaining to gardening, and under his judgment and care the Balbirnie gardens soon established a name for high-class production, which it has borne throughout Scotland for many years. Of a modest disposition, he never entered the competitive lists, though often pressed to do so, and the writer is confident that had he done so his exhibits would have met with the success they deserved, for he was a grower of no mean order. It was also due in a large measure to his untiring energy that the Village Flower Show of Marckinch (which has been held in the Balbirnie grounds for many years) has gained such success, this being one of the most flourishing village shows in Scotland. Mr. Henderson leaves a widow and two daughters to mourn his loss. *J. F. McL.*

**Alexander Davidson Christie.**—It is with deep regret we learn of the death, in his 74th year, of Alexander Davidson Christie, following an operation, in the Selly Oak Hospital, Birmingham. Mr. Christie was born at Woodside, in Aberdeen, and served his apprenticeship at Stoneywood House in the vicinity. Later he proceeded to Dalkeith, and served under those two great masters in their craft, Thompson and Malcolm Dunn, and thus laid the foundation of his own special knowledge

which made him famous as a good, all-round practical gardener. From Dalkeith he went as foreman to the Earl of Wilton's gardener at Heaton Park, Manchester, and afterwards spent some time in Messrs. J. Veitch and Sons' Chelsea Nursery, whence he was sent in 1876 to take charge of a garden in Moscow, where he remained for some time. But he was never happy in his isolation, and in 1878 he became gardener at Warneford Park, Hampshire. His next move was to Warwick Castle, where some of his best work was done during the time these famous gardens were at the zenith of their fame. From Warwick Castle he went to Ragley Hall in the same county, also famous for its fine flower garden and hardy fruits, and he was at this period a constant contributor to our pages on these subjects. Until two years ago Mr. Christie was in the employ of E. A. Wilson, Esq., of Edghaston, whose garden was famous for its varied collection of Alpine plants, and such was the kindly interest between Mr. Christie and his employer, that Mr. Wilson travelled from Bristol to Lodge Hill Cemetery, Selly Oak, to pay his last respects to his old friend. The Birmingham Chrysanthemum Society and the Birmingham Gardeners' Association, in which Mr. Christie had long taken an active part, also sent representatives to the funeral. Many of the younger generation will always look back with gratitude to the ever-ready help they received at Mr. Christie's hands, and strive to emulate his cheery manners and follow his wise counsels.

**Mrs. Neve.**—The many friends of the late Mr. Thomas Neve, who for 43 years was gardener at Sindlesham House, Wokingham, and for many years the valued Honorary Local Secretary for Reading and District of the Royal Gardeners' Orphan Fund, will regret to learn of the death, on Sunday last, of his widow, Mrs. Margaret Neve, who passed peacefully away in her 78th year, at the residence of her son, "Hursley," Woodstock Road, Wolvercote, Oxford.

### ANSWERS TO CORRESPONDENTS.

**BLACK CURRANT LEAF BLISTER:** *H. M.* Currant leaf blister is not a serious disease, although it renders the bushes unsightly. It may be kept in check by spraying with dilute Bordeaux mixture at an early stage of the attack.

**COLEUS:** *Chagford.* Mr. L. Russell, the Nurseries, Richmond; Messrs. W. Cutbush and Son, Hightate; or Mr. P. Ladds, Swanley Junction, Kent, may be able to supply you with the plants you need.

**CRICKETS IN GREENHOUSE:** *R. W. T.* The quickest means of destroying crickets in greenhouses is found in the use of poisons. Phosphor paste, borax powder, also arsenic mixed with some such food as Potatoes, will kill them in numbers. Steiner's Vermin Paste has also been found a satisfactory remedy. Baits of this last remedy, about the size of a nut, should be placed about the house on pieces of paper, just before dark, removing in the morning what remains of the paste, and setting the baits again each night, so long as the pests continue to be troublesome.

**NAMES OF PLANTS:** *Q.* Narrow foliage, Scilla italica; broad foliage, S. Libo-hyacinthus. *D. R. D.* Viburnum Carlesii; blue flower, Chionodoxa gigantea.

**PEACH TREE DISEASED:** *D. C.* The trouble is due to silver leaf, as you suspect. Cut out the diseased bunches well below the seat of attack and burn them.

**TREES AND SHRUBS:** *W. H. L.* You will find all the information you require in *Trees and Shrubs Hardy in the British Isles*, by Mr. W. J. Bean, which can be obtained from our Publishing Department, price three guineas, two volumes.

**Communications Received.**—*J. P.—P. M.—W. L. B.—P. J. S.—J. J. S.—E. F. G.—B. C.—J. U.—F. O.—A. F.—E. R. S. T.*

### The Journal of Pomology and Horticultural Science.

We congratulate the Ministry of agriculture upon what we believe to be the successful conclusion of its efforts to assist horticulture generally and the horticultural research stations in establishing a journal in which the results of research in horticulture may be recorded in permanent form. The need for such a journal has long been felt, and by none more than the investigators at the horticultural research stations. It is true that existing journals have from time to time published the results achieved at their stations and that they are willing to give the hospitality of their columns to such publications. But even so, and at the best, this mode of publication leads to the unfortunate result that cognate researches are only to be found by consulting a number of different journals. By the present arrangement this defect is remedied, and with the establishment of the new journal, horticulturists will be able to find within its covers all, or at least the chief, publications which are of interest to them. The thanks of horticulturists are due to Mr. E. A. Bunyard, who has consented to this enlargement of scope of the journal which he founded, and who has also in the most public-spirited way, undertaken the duties of editorship. Mr. Bunyard will be assisted by a Publications Committee consisting of Professors Barber and Bifen, Mr. Hatton, and Messrs. Dale and Taylor, of the Ministry of Agriculture. The journal will be published quarterly and will be issued post free for an annual subscription of 15s. It is proposed to publish the first number in November of this year. We hope that every-

one interested in the advancement of horticulture will become a subscriber. If they do, the financial responsibility which has been assumed by the Research Stations at Long Ashton and Cambridge should be easily borne and a long career of usefulness will be assured to the journal.

### Carriage of Pot Plants by Passenger Train.

Previous to the war, railway companies not only conveyed pot plants by passenger train at reasonable rates, but where two or more routes were open to the trade, the companies competed for the business. War conditions brought about higher charges and, after consultation with the railway officials, the growers of pot plants agreed to pack in a manner which, while relieving the railways, added considerably to the cost of production. The growers carried out these obligations in a manner that has won the approbation of railway authorities, but now that railways are free from Government control, the growers feel some of the difficulties they have experienced should be removed. Everyone familiar with the pot plant trade is aware that high cost of production, coupled with particularly heavy freightage charges, has crippled the industry, and at least one firm, formerly among the most extensive cultivators, is giving up this part of their business. The public is ready to purchase pot plants, but the costs of distribution by rail—and passenger train affords the only safe and speedy means of transport to many centres—added to those of production, render the price prohibitive. When carriage adds 10s. to the price of a plant which is 1s. at the nursery and in Covent Garden, business declines to a minimum; this is not an exceptional figure, as a recent deputation to the Railway Clearing House was able to prove many instances where the charge for carriage was from 50 per cent. to 100 per cent. of the cost of the plants conveyed. Expectations are by no means always fulfilled, but the deputation referred to, consisting of representatives of the Chamber of Horticulture, the British Florists' Federation, and the Horticultural Trades' Association presented such an excellent case for the growers and the arguments put forward on their behalf by Mr. Frank Ladds were so convincing that the railway authorities were greatly impressed. It is not too much to expect that considerable concessions will be allowed with regard to the classification of goods and the charges. If the extra 25 per cent. charged on this traffic is removed, and if specially reduced rates are allowed to consignments of from one cwt. to ten cwt., the pot plant growers will find considerable relief and business will improve again; moreover, in due course pot plants will benefit from any general reduction in owners' risk rates. We believe the members of the trade acted very wisely in going direct to the railway authorities instead of waiting to discuss their difficulties before a tribunal to which they still have recourse in the unlikely event of the meeting at the Railway Clearing House proving a failure.

### Harmful Effect of Coal Gas on Plants.

Professor J. H. Priestley gave the result of experiments on the effect of coal gas on growing plants at a meeting of the Association of Economic Biologists at Leeds, on May 19. His experiments show that if one or two c.c.m. of coal gas are bubbled into a vessel containing the young plant, marked degenerations occur within forty-eight hours. The root and stem structures become swollen and bent, the young leaves curl over, and the flower petals wither. He proved that ethylene, one of the constituents of illuminating gas, produces a toxic effect on plants at a concentration of

one in a million in air. Such a small amount of gas as could not be detected by the smell may prove toxic to plants, and the Professor attributes this poisonous action of these small quantities of gas to the unsaturated hydrocarbons, which attack the endodermis of the plant. An interesting point noticed in Prof. Priestley's experiments was that coal gas affects some varieties of the same plant more than others.

**Naturalisation of Plants in New Zealand.**—The Cambridge University Press announces the publication of *The Naturalisation of Animals and Plants in New Zealand*, by the Hon. Geo. M. Thomson; and a second edition of *A Naturalist's Calendar*, an interesting record kept at Swaffham Bulbeck, Cambridgeshire, by Leonard Blomefield circa. 1820-1831, and edited by Sir Francis Darwin.

**Kew Guild Annual Meeting and Dinner.**—The attendance at the annual meeting of the Kew Guild held at the Imperial Hotel, Russell Square, on May 24, was particularly good and an excellent report of the year's work and finances was presented. Some discussion took place concerning the allocation of the balance of about £30 remaining in the War Memorial account; some members were in favour of placing the sum to the account of the Benevolent Fund, while others urged that it should form the foundation of a fund for providing scholarships for promising Kew students. Several of the older members, including Mr. Hales, Mr. E. H. Wilson, and Mr. J. Coutts, favoured the latter proposal, and expressed the hope that if a suitable scheme could be drawn up ample funds would be forthcoming from old Kewites who were best able to appreciate the value financial assistance would prove in the education of promising young men just finishing their course at Kew. Opinions were pretty generally in favour of such a scheme, but many members considered the sum too small for a beginning; finally, the scholarship scheme was adopted, but only by the casting vote of the chairman, Mr. C. H. Curtis. At the annual dinner which followed the meeting, Mr. E. H. Wilson, the new President, presided over a record attendance of about 150 persons representing various parts of the Empire. Sir David Prain, Dr. A. Hill, Mr. Dawe, and Mr. Wilson were the chief speakers in connection with the several toasts concerning Kew and Kewites. Ample time was afforded for the renewal of old acquaintances and the making of new ones; Miss Watson and Mr. Briscoe sang; the tables were splendidly decorated with Mollis and Ghent Azaleas and the whole arrangements were carried out admirably by Mr. Osborn, the Hon. Secretary of the Guild.

**Postponement of Windsor Rose Show.**—We are informed that Windsor and Eton Rose and Horticultural Society's Exhibition, arranged to take place on June 24th, has been postponed to Saturday, July 1. Entries close on June 24.

**National Chrysanthemum Society.**—Although the exhibition of the National Chrysanthemum Society has not yet returned to its pre-war importance there are signs that growers are as keenly interested in this beautiful flower as ever, and the Society's exhibition last year proved a great success, both from the point of view of exhibits and visitors. The annual show for the current year has been fixed for November 16 and 17 in the Royal Horticultural Hall, Vincent Square, Westminster. We are glad to notice that the schedule has been enlarged to admit the smaller amateurs and especially those who employ no paid assistant in the cultivation of their Chrysanthemums, to compete. The Society is fortunate in possessing numerous trophies and challenge cups, and Messrs. Clay and Son again offer a gold medal for the best exhibit in the show. In the open classes, from which traders are excluded, the Holmes Memorial Challenge Cup is offered in a class for thirty-six Japanese blooms distinct. The President, Lt.-Col. Sir Albert Rollit, offers a silver cup or bowl valued at £5 5s. for twenty-four Japanese blooms distinct, and another Holmes Memorial cup is offered for twenty-

four incurved blooms distinct. The handsome Geo. Monro Challenge Cup is offered in the class open to all, for twelve vases of large singles, distinct. A challenge trophy is also offered for competition amongst the affiliated societies. A sum of £10 is offered as first prize in the Wm. Wells Memorial class for thirty-six Japanese blooms in twelve varieties, three blooms of each, with second and third prizes of £6 and £4 respectively. In the interesting class open to amateurs for a single plant of Chrysanthemum shown in a pot the prizes are offered by the proprietors of *Amateur Gardening*. The Society has offered a silver cup valued at £20 for the best exhibit of Chrysanthemums at the Royal Horticultural Society's exhibition at Holland Park Rink, Kensington, on October 5, 6 and 7.

**American Sweet Pea Society.**—The *Bulletin* of this Society for 1922 has reached us rather later in the year than usual. The contents are of interest to others than members, and includes the schedule for the 14th annual show to be held in the Horticultural Hall, Boston, on the 24th and 25th inst. The scale of points for judging is as follows:—Length of stem, 25; colour, 20; size, 25; substance, 15; number of flowers on a stem, 15; total, 100. The prize list contains 25 classes, in which silver cups, money, and medals are offered by the Society, and in addition there are classes in which the prizes are offered by the Massachusetts Horticultural Society, in whose hall the show will take place. Literary articles comprise "Sweet Peas under Glass," by Wm. Sim; "Classification of Early or Winter Flowering Sweet Peas"; "Growing Sweet Peas in Tubs," by A. E. Thatcher; "Classification of Sweet Peas"; "Everybody's Flower," by Edwin Jenkins; Financial Report, etc. The secretary is Wm. Gray, Bellevue Avenue, Newport, Rhode Island.

**New Lilacs.**—In a summary of the Lilacs cultivated in the Arnold Arboretum,\* U.S.A., it is stated that the most promising as garden plants introduced during the past twenty years are *Syringa Sweginzowii*, *S. Julianae*, *S. reflexa*, and *S. Wolfii*. *S. Sweginzowii* has slightly fragrant flowers, borne in long, narrow clusters on slender, erect branches. The flowers are flesh-coloured in the bud, but become nearly white after they are open. The plant blooms freely every year at Harvard. It has a close relationship to *S. pubescens*, but is a smaller shrub and slightly earlier flowering. *S. Julianae*, which is also related to *S. pubescens*, has flowers of violet-purple colour on the outer surface and white in the interior. The racemes are shorter and much less fragrant than those of *S. pubescens*. *S. reflexa* resembles *S. villosa* in size, habit and foliage, and differs from other Lilacs in its narrow, pendant flower clusters. *S. Wolfii* is a rare plant in cultivation, a native of Mongolia or Northern Korea. It was sent to Harvard from St. Petersburg by the Russian traveller and botanist, Komarov. The flowers are violet-purple in colour, and are produced in much larger clusters than those of *S. villosa*. It is stated that when *S. Wolfii* is better known it will probably be considered one of the handsomest of this group of late-flowering Lilacs.

**Dyeing Arsenical Weed Killers.**—As a consequence of recent unfortunate events several of the leading manufacturers of powder weed-killers have enlisted the aid of the British Dye-stuffs Corporation Ltd. in order to discover the best means of colouring arsenic. It is confidently expected to be able to dye arsenic such a colour as red without interfering with its chemical properties.

**Potato Chips.**—In a Bulletin published by the United States Department of Agriculture on the method of making Potato Chips, by Miss Margaret Connor Vosbury, of ten different methods adopted the following gained the best results: cut the Potatoes in thin, even slices with an accurate vegetable slicer, soak them thoroughly in water and fry them in a clean high-grade fat

at a high temperature. Care should be taken in clean cold water after a bath of cold running not to cook too many chips at once and the fat should be deep enough to cover the slices completely and allow them to lie flat. The trade in chip Potatoes is very extensive, and they are now sold by provision merchants already prepared for use.

**Honours for Horticulturists.**—The King's birthday list of honours contained the names of two gentlemen whose work has rendered them famous in the realm of scientific horticulture. Professor F. W. Keeble, F.R.S., Sherardian Professor of Botany, Oxford University, has been awarded a knighthood, and among many congratulations he received none were heartier than those from the staff of *The Gardeners' Chronicle*, with whom he has been associated for many years as one of the Directors, formerly Co-Editor, and now as Scientific Adviser. Our readers will remember that Professor Keeble was for several years Professor of Botany at University College, Reading, and left that position to become Director of the Royal Horticultural Society's Gardens at Wisley, where he established the laboratory and laid plans for research work of scientific and practical value. During the war he was head of the Food Production De-

PROF. SIR FREDERICK W. KEEBLE, F.R.S.

partment, and although the nation profited by his efforts in this position, only a few people have any idea of the vast amount of forethought and labour his duties entailed. Sir Frederick is the author of *Plant Animals and Plant Physiology*, and in his literary work, as in his lectures, he has the enviable ability to deal with his subjects in a highly entertaining as well as instructive manner. The knighthood awarded to Dr. Russell, of Rothamsted, is an honour won by long years of close study of soil problems, soil science, and the admirable organising and administrative ability he has brought to bear upon the conduct of the famous research and experimental station at Harpenden. An appreciation and portrait of Sir E. J. Russell appeared on page 74 of our issue of February 18, 1922.

**The Value of Green Manuring.**—The United States Department of Agriculture has published some useful information on green manuring.\* The value of green manuring on the texture of the soil is shown in the effect that freezing has on land containing organic matter. When soil from which organic matter has been extracted is allowed to freeze and thaw it remains compact and does not crumble, yet when the organic matter previously dissolved out of this

soil is returned to it the soil crumbles after freezing. Thus, added to the good effects of green manuring, must be included facilitation in obtaining a good tilth. The value of organic material to soil bacteria is well known to gardeners, but not all are aware that there are injurious bacterias as well as good ones, and that the former can and the latter cannot exist without a plentiful supply of air. Thus green manuring is especially valuable in the case of stiff clays, and even in the case of sandy soils where there is air enough, the addition of humus helps in retaining moisture and thus benefits the useful bacteria which need moisture as well as air. To sum up, the physical condition of the soil depends largely on the amount of organic matter present in it. The chief crops used in America for green manuring are Red, Crimson and Sweet Clover (*Melilotus alba*), Yellow Annual Melilot, *Medicago fabacea*, *M. hispida denticulata*, *M. sativa* (Alfalfa), Vetches, Cow-pea, Soy Beans, and Buck Wheat.

**Flowering of *Rhododendron sino-grande*.**—The flowering of *Rhododendron sino-grande* in Dame Alice Godman's garden at Horsham (p. 249) and in Mr. T. Bolitho's garden at Tregwanton, Cornwall (p. 281), has created considerable interest among lovers of *Rhododendron* species and a desire has arisen to know when and where *R. sino-grande* first flowered in the British Isles. So far as our information goes the species first flowered in the Edinburgh Botanic garden in April, 1920.

**Whit-Monday at Kew.**—The improved facilities for travel—the Thames steamboats are now running frequently and with regularity, and an additional bus service, with a terminus at Kew, has been inaugurated—resulted in over 56,000 persons paying for admission to the Royal Botanic Gardens, Kew, on Whit-Monday. In spite of the great heat, the glass-houses were a great centre of attraction. The Cattleyas in the tropical Orchid house, which for some time past have been exceptionally fine, were still in great beauty and the "Conservatory," as the public insists on designating No. 4 house, was filled with a great variety of flowering plants. In the great Temperate House the visitors found an agreeable climate, and there the tall tree of *Davidia involucreata*, well furnished with the characteristic button-like clusters of flowers, which are accompanied by a pair of white bracts fully 6 inches long, excited admiration and wonderment. The rare *Rosa Brunoniiana* is also flowering freely in this house. This is a vigorous climber from Burma, and the long, spinous shoots are terminated by large trusses of five-petalled, pure white, musk-scented flowers. Out of doors the visitors found the *Rhododendron* Dell at its best, and many of the Great and hybrid *Azaleas* near by were in great beauty. The *Pyrauses*, *Prunuses* and *Horse Chestnuts*, which have been so beautiful this year, were just over, but amongst flowering trees now in bloom the *Manna Ash* and *Robinia Pseudacacia*, and *R. Decaisneana* were in full bloom. The most showy of the dwarfier species are *Robinia hispida macrophylla* and *R. Kelsevi*. A great variety of Brooms were in full bloom.

**Certificate in Horticulture.**—At the examination in horticulture held by the Royal Caledonian Horticultural Society in April a first-class certificate was gained by Mr. A. E. Livingstone, North Berland, Dunlop. The syllabus of the examination includes practical gardening, physics, chemistry, meteorology, botany, entomology, mensuration and land surveying, and bookkeeping.

**Peach Leaf-Curl.**—This disease is always more in evidence when there is a sudden fall in temperature, and especially when cold winds prevail, but it is checked by an increase of temperature. The affected leaves should be removed and burnt. Spraying the trees with Burgundy mixture just before the leaf buds burst is a preventive measure that has proved eminently satisfactory; the mixture is rendered more effective if  $\frac{3}{4}$  pint of milk is added to every three gallons, as this addition increases its adhesiveness.

\* *Green Manuring*.—By C. V. Piper and A. J. Pieters. Farmers' Bulletin, 1250. U.S. Department of Agriculture, Washington, D.C.

**French Chrysanthemum Society.**—The 23rd conference of this Society will be held in Paris on October 27 next. The Organising Committee has been appointed, and consists of M. Momméja, the president; M. Blot, vice-president; M. Ph. Rivoire, secretary; and MM. Clement and Bernard representing the National Horticultural Society of France. The agenda has not been finally decided upon, but will include such subjects as Late Varieties, Market Plants, The Improvement of Novelties, Sports, Insects and Diseases. The current number of *Le Chrysanthème* is most encouraging for the members. The Society now numbers 734 persons, inclusive of 57 affiliated societies. There is a report of the Annual Meeting held on April 26 last, followed by the Report for the past year. The financial statement shows a credit balance in hand of Frs. 6,419. The President M. Momméja, contributes a brief biographical notice of Capt. Bernet, the first man to raise Chrysanthemums in Europe, and an excellent coloured engraving of Grand Napoleon, one of the earliest of Bernet's seedlings, is given. Practical notes on culture, stopping and taking the bud for single bloom culture with an instalment of the catalogue of new Chrysanthemums sent out in 1921 are among the principal literary items in this issue.

**Appointments for the Ensuing Week.**—Monday, June 12.—United Horticultural Benefit and Provident Society's meeting; Purley Horticultural Society's meeting. Wednesday, June 14.—Grand Yorkshire Flower Show in Bootham Park, York (3 days); East Anglian Horticultural Society's meeting; Sheffield Chrysanthemum Society's meeting. Thursday, June 15.—Linnean Society's meeting at 5 p.m. Friday, June 16.—Paisley Florists' Society's meeting; Eastbourne Horticultural Society's meeting. Saturday, June 17.—British Mycological Society's Spring Foray for London students.

**"Gardeners' Chronicle" Seventy-Five Years Ago.**—*Propagation of the Potato from Cuttings.*—As it may not be generally known to farmers and cottagers that the Potato plant may be propagated at this season to an enormous extent by its leaves, I beg leave to state that I put in leaves of the Potato as cuttings on the 21st of May, and in fourteen days they had formed roots and pushed a stem two inches high. The weather at this season of the year is generally warm, if not hot, and therefore the plain earth, finely pulverised and kept moist, is a first-rate hot-bed, as every gardener can testify who has struck cuttings in the open air in summer; and it is really astonishing to see how many of the fine indoor plants may be struck without artificial heat in summer. *Phaenocoma prolifera* (better known as *Elichrysum proliferum*) is generally considered very difficult to strike, and this I have seen take root freely behind a north wall in the heat of summer. Whoever attempts to strike cuttings in this way, will do well to attend to the pulverising of the soil in a very particular manner; and if the soil could be got as fine as flour, and the cuttings inserted in it whilst it is as wet as dough, there would be no occasion for shading or watering, unless the weather was very hot indeed, and the locality very dry or exposed. The stems of the Potatos may be cut leaf by leaf, and every leaf will make a plant in a fortnight, and that very much stronger than plants obtained from seeds of the Potato Apple. This piece of practical information is well known to gardeners, and it would be well if they would make some experiments to show the cottagers how to strike cuttings, not only of Potatos but of the common fruits and flowers, which are so readily and economically increased in this manner in the open air during the summer. *Alex. Forsyth, Alton Towers. "Gard. Chron.," June 12, 1847.*

**Publication Received.**—*Simple Weather Forecasting for Everyone.* By Messrs D. W. Forner and W. M. Robertson. The Courier Printing and Publishing Co., Ltd., 19, Grove Hill Road, Tunbridge Wells. Price 1s. 1½d. post free.

**PLANTS NEW OR NOTEWORTHY.**

**RHODODENDRON ORBICULARE, DECAISNE (R. ROTUNDIFOLIUM, DAVID).**

AMONGST the Rhododendrons introduced during the present century from Western China this is one of the most distinct and easily recognised. Its leaves are almost orbicular, but rather longer than wide, glaucous beneath, and measure from 2 to 4 inches in length; they are deeply notched at the base, and, except for a short mucro at the end, are not pointed. The general outline resembles that of a small Nuphar leaf. The flowers appear in April or May in a terminal truss of eight to ten blossoms; each flower is 2 to 2½ inches wide, and borne on a slender stalk 2 to 3 inches long. The corolla is seven-lobed, bell-shaped, and rosy red. The stamens number

Geoffrey Millais, and not Jeffery Millais (see p. 274). To this correction we add another—*i.e.*, the variety was exhibited by Mr. Lionel de Rothschild, and therefore should have been credited to him instead of to Mr. P. D. Williams.

**STELLERA CHAMAEJASME.**

**STELLERA** is a small genus belonging to the Natural Order Thymelaeaceae, of which *Daphne* is a better known member. There are about six species, all natives of the northern and temperate parts of Asia, low growing, shrubby, half shrubby or perennial in habit. *S. chamaejasme*, which is here illustrated (Fig. 161) from the photograph of a plant shown at the recent Chelsea show by Major Stern, has a wide distribution, being recorded from Dahuria as well as Western China and Tibet. The plant was raised from seeds sent

FIG. 161.—STELLERA CHAMAEJASME. R.H.S. AWARD OF MERIT, MAY 23.

fourteen, and their stalks, like the style and ovary, are quite smooth. Although the species is hardy near London, one has to go to Cornish gardens, or places with a similar climate, to see it at its best. There it forms a rounded bush of dense hemispherical shape 5 to 7 feet through. Originally discovered by the Abbé David about forty years ago, it was introduced by E. H. Wilson in 1904, when collecting for Messrs. J. Veitch and Sons. According to him, it occurs in woodland, and under cultivation thrives best in partial shade. He found it up to 12 feet high.

The flowers on the branch exhibited by the Hon. H. D. McLaren at the recent Chelsea Show (see Fig. 159, June 3), and given an Award of Merit, were rather small, and scarcely showed the plant at its best. The species is one of great interest and distinction, but belongs, perhaps, rather to the connoisseur than to the ordinary cultivators of Rhododendron, for it is certainly not one of the easiest to grow. *W. J. B.*

**RHODODENDRON GEOFFREY MILLAIS.**

Mr. Lionel de Rothschild points out that the correct name of this fine Rhododendron is

home by Mr. R. Farrer, who found it in the Stone Mountains. Farrer, in his book, writes: "Stellera stood up from the cropped grass in myriads of round-headed, tiny bushes bearing pink flowers." It grows from six inches to one foot high, many annual stems springing from a woody rootstock. These are clothed with narrow, lanceolate leaves and bear umbels of rosy-pink buds which open into pale pink flowers. It promises to be quite hardy, but so far has been afforded the shelter of a cold frame.

This species has been discovered by several collectors, but had not found its way into cultivation till Farrer sent home the seeds. Hosie found it in Kansu in 1910; Wilson also found it at an elevation of 10-12,000 feet; while Przewalski found it in Kansu in 1873. Forrest found it, or a closely allied species, which he describes as having bright orange-yellow flowers. It was growing on dry, stony, hilly pasture-land in the Lang Kong Valley, N.W. Yunnan.

*Stellera Albertii*, a yellow flowered species from Central Asia, was introduced some years ago, but is probably a scarce plant in gardens, even if it is at present in cultivation. *W. J.*

## FORESTRY.

### STRIPPING AND HARVESTING OAK BARK.

COLD, easterly winds are responsible for the present barking season being quite a month later than usual, for, whereas this work usually starts about the middle of April, it was only in full operation in most parts of the country during the latter part of May.

During ordinary seasons, and throughout England generally, bark-stripping commences during the third week in April, and continues for about a month, or until such time as the trees are in full leafage, whereas in some parts of Scotland, especially the north, the operation is frequently nearly a month later. No mistake can, however, arise as to the right time to start barking in any locality, as the period when the bud is first bursting into leaf will be found the proper time for felling, in order to ensure easy stripping and the best quality of bark.

The period of bark-stripping, but especially harvesting, is one of the most anxious seasons of the year with the forester, as the quality of the bark is so largely dependent on the weather during the time that intervenes between stripping and stacking, as well as carrying out the work at the proper time to secure easy and expeditious peeling. In most cases, also, the time when the bud is just expanding into leaf is that which gives the greatest weight of bark of the best quality and with the smallest amount of labour. By deferring the work even for a few days, there is often a loss of weight amounting to as much as 10 per cent., and a great deterioration in quality as well. Even in the most favourable situations it is seldom that the season for stripping extends beyond twenty-eight days. It is also rarely that all the trees in the same wood can be barked at once, the great difficulty being in getting the bark to "run" freely, so that what are known as "black" trees have to be left for sometimes a week or ten days after the others have been felled and stripped. As spotted, blackened, or otherwise, damaged bark is of comparatively little value, every endeavour should be made to retain the original cream colour of the fleshy side by as little exposure to alternate rain and sunshine as possible.

Some twenty years or so ago an extensive trade was done with both English and Irish tanneries, and buyers of Oak bark scoured the country in order to obtain what they wanted. To-day, however, matters are totally different in this respect, and, in order to dispose of even a small parcel of splendidly harvested bark, the owner has to advertise for and solicit buyers, and as often as not the season's produce is "flayed" or "hatched" and stored in anticipation of a more remunerative market twelve months hence, the delay in selling being often worth while.

Of late years, Oak bark has been nearly ousted by various chemical substitutes, including iron, chromic acid, etc., as well as Cutch, Gambier, Myrobalanas, and Quebracho wood. A century ago, Oak bark was sold in London at £14 15s. per ton, the average at present being £4 10s. per ton. Several contracts that have been entered into for this season's bark are at the rate of £4 5s. for the bark in rough and delivered to the tanneries. Where conditions of sale include chopping, "flaying" or "hatching," as this operation is called in several parts of the country, the price is about another 50s. per ton, or round about £7 10s. These prices are extremely low, and leave but a small margin of profit to the owner, after 40s. per ton is paid for stripping, without taking into account the risky business of harvesting, cost of cartage, supervision, and other incidental expenses in connection with the industry.

Well-seasoned bark should have the fleshy side of a creamy colour, whereas such as has been exposed to sun and rain is of a dull brown or chocolate colour, wanting in tanning matter and consequently inferior in value. When the bark will snap crisply across, rather than bend

or yield to pressure, it is ready for stacking or delivering direct to the tanneries.

When the weather is favourable for harvesting, the bark should be ready for stacking in about a fortnight from the time it was removed from the trees, but, should close, damp weather intervene, it may be found necessary to turn the bark occasionally, thus adding to the time required for harvesting, as also the risk of deterioration in value. It should be remembered that the less turning the bark receives after being placed on the drying stage the better will the quality be. As it is useful to arrive at an approximate estimate of the quantity of bark to be removed, the following data will be found fairly reliable.—(1) If branches down to an inch in diameter are peeled, a tree with an average spread of head should yield about 6 cwt. of bark for every ton of measurable timber. (2) Field and hedgerow trees generally yield a ton of bark to every three tons of timber. (3) When growing in close woodland, the yield is usually a ton of bark to every four and a half tons of timber. (4) Oak poles will average five tons of timber to a ton of bark.

Short stems with spreading heads give the largest yield in proportion to the quantity of timber, and tall, clean stems, as when the poles are grown thickly on the ground, the smallest amount of bark serviceable for tanning. *A. D. Webster.*

## TREES AND SHRUBS.

### RHODODENDRON CAMPANULATUM.

FOR weeks past a very large specimen of *Rhododendron campanulatum* has been an object of much interest here. The tree was planted over sixty years ago. It has no main trunk, but in its place seven rigid branches each rise to a height of over 15 feet. The tree takes the form of a large rounded head, with a spread of branches 17 feet across. The bark on the main stems has a peculiar way of peeling. Doubtless there are specimens in this country of even greater dimensions, but, as this is one of the largest examples of this species, it is worthy of record.

Mr. W. J. Bean, in his work on *Trees and Shrubs Hardy in the British Isles*, refers to *Rhododendron campanulatum* as the hardiest and most satisfactory of the Himalayan *Rhododendrons* near London, where it flowers regularly and profusely, but he gives the height of the species as being from six to twelve feet—much less than the height of the specimen under notice.

*Rhododendron campanulatum* has not flowered so freely as usual this year, but some very fine trusses were borne near the tips of the highest branches. The flowers are broadly bell-shaped, in colour varying even on the same tree from lilac to almost pure white. There are crimson chocolate spots on the upper petals. The variation in the number of anthers in *Rhododendrons* is curious, but *Rhododendron campanulatum*, like a well-behaved species, has consistently ten prominent brown anthers.

This species is a native of the interior of Sikkim and Nepal, where it grows at an altitude of 14,000 feet. It was first introduced in 1825, and it is said that trees grow to a height of 16 feet in semi-shade in their native habitat, from which it may be assumed that the tree here is now fully grown. The leaves are elliptic, dark shining green above, with dense red-brown felt beneath; the under side of the leaves presents a rusty appearance. In very cold weather the leaves roll up for protection, only to unroll on the arrival of milder weather.

*Rhododendron campanulatum* is particularly hardy, and its popularity is due to its hardiness as well as to the very fine flower trusses of the best forms. There is great variation in the species in cultivation, owing, no doubt, to the fact that the plant is very widely distributed in the Himalaya, and seed of many forms has been sent home by various collectors. *Herbert Cowley, Tunbridge Wells, Kent.*

## FLORAL PICTURES AT THE ROYAL ACADEMY.

THE Royal Academy this year has a much greater interest for flower and fruit lovers than the exhibition in the summer of 1921. Taking the pictures in their numerical order, the first to study is No. 5. This a severe work of Fuchsias, Irises, Delphiniums, Pelargoniums, and Michaelmas Daisies, very striking and very bright. A very pale study comes next, Roses by an open window, with a dark Japanese curtain as a contrast, and then a tumbled mass of Anemones in No. 59. A strong painting by H. Davis Richter is a glowing group of Pomegranates, Apples, Lemons, and a Melon on a table, with a highly polished vessel at the back. There is next a very nice study of blue and white Cinerarias in a tall grey pottery vase on a Sheraton table, and lying in the front a vivid red "Geranium."

The next important flower picture shows bright Anemones in a black vase, with colour introduced into the groundwork. No. 119 is a large colour piece—market produce and dish of bright red Apples, banked up at the back by Daffodils and Wallflowers. Mr. Richter shows another of his fine works in No. 123—tea chests, and polished brass and pottery ware, with an Azalea at the summit and floating Anemones and Cinerarias as foreground. Michaelmas Daisies in a turquoise vase, with the addition of a tea service, is pleasing, and in contrast the next picture is that of a Continental garden, very bright and sharp. S. Melton-Fisher, R.A., shows a lovely warm group of Azaleas in a glass vessel, against a dark ground. Next comes a vase of loose Anemones, Scabious, Iris, and Lupins, and No. 294 is a strong painting of Zinnias of varied colours in a polished brass vase.

A novel effect in pink and blue is gained in a picture of wild Roses in a shallow dish, with blue pottery at the side and blue flowers and Roses at the back. There is a fine study of Paeonies—white—in a polished brass pot, and, farther on, a small study of Anemones in a green pottery jug. A group of fruit follows next, with a small glass dish of mixed fruit, Bananas, Grapes and Apples. No. 560 is a small study of pink Roses in a shallow pottery dish, and 427, a study of pink and yellow Tulips, with five jars, on a windowsill. Anemones in a ginger jar, a lustre jug with Dielytra, Tulips, Anemones, and Jonquils, etc., on a windowsill, with view of river behind, is an attractive study, and in No. 471 we see a lovely little study of yellow Chrysanthemums in a pewter pot. A brilliant group of Capsicums, Apples and Rose-haws makes a fine bit of colour, and in contrast we have next an impressionist study of Roses and Paeonies. A delicious corner in a garden, by J. Farquharson, R.A., shows borders of Delphiniums and herbaceous plants, and the same artist gives us another delight in a picture of massed white and orange Chrysanthemums in a garden bed.

A sunny effect is gained in a picture called "Summer," the subject being a child gazing through a window, with Poppies on a table, and a dish of Cherries and Lemons. Solomon J. Solomon, R.A., makes a new departure from his usual portraits by presenting a fine work of Orchids—*Brasso-Cattleya Olympus*. The next picture is by another R.A., of a Dorset garden, with two hedges of Yew and flower beds beneath. There are also several floral pictures in the water-colour room.

One of the pictures gives a rather weird effect of three Roses in a tumbler of water. Another group of Roses is by Ethel Hatch, portrayed with wet effect. A rough study of a peacock butterfly on a Thistle, with Poppies against an ultramarine sky, is by the same artist as the painting of Sweet Williams and Delphinium Blue Butterfly. A pleasing work of white Azaleas in a blue pitcher and another of a small rockery with Rose garden as background are two more water-colours. *Artist.*

ORCHID NOTES AND GLEANINGS.

DENDROBIUMS OF THE D. PHALAENOPSIS GROUP.

THE members of the Phalaenopsis section of Dendrobium are all natives of the New Guinea region, the coast of Queensland, and the Islands of the Torres Straits. *D. Phalaenopsis* (Fitzgerald, in *Gard. Chron.*, 1880, II., p. 38) is one of the most beautiful and popular members of the genus (Fig. 162), and the first plant shown by Messrs. Jas. Veitch and Sons at the Royal Horticultural Society's meeting of October 14, 1884, gained a First-Class Certificate. Later, Messrs. Sanders

ianum, resembles *D. superbiens* in habit and colour, but differs much in the openly displayed form of the lip. It was awarded a First-Class Certificate when shown by Messrs. Sanders, on November 10, 1891. Several forms have appeared, and it was thought by Mr. R. A. Rolfe to be a hybrid between *D. Phalaenopsis* and *D. superbiens*, but the evidence supporting such a theory is very slight.

*D. Williamsianum* (Fig. 164) originally described by Reichenbach in 1878, from dried specimens sent by Mr. Goldie from New Guinea to Mr. B. S. Williams, of Holloway, is of the *D. Phalaenopsis* section in the growth and shape of its flowers, which are over two inches across.

section for hybridising, but if the species could be made available, some fine results would accrue. Probably they have been tried without success, but there is no reason to suppose that they would not cross, especially with allied species. Under cultivation all require a uniformly warm house, and not such a vigorous drying off at the resting season as the deciduous species receive, although drier and more airy quarters when growth is completed are beneficial. *J. O'Brien*.

CATTELEYA INTERMEDIA AQUINII AND C. DUSSELDORFEI AQUINII.

In the *Gard. Chron.*, February 10, 1900, p. 83, an illustration of the remarkable *C. inter-*

FIG. 162.—DENDROBIUM PHALAENOPSIS.

FIG. 163.—DENDROBIUM LEEANUM.

obtained a large importation from a new locality with flowers of large size, and which varied in colour from the pure white form, for which they gained a First-Class Certificate in December, 1909, through all shades of rose and pale mauve, with variously coloured lips, indeed, variation in colour is most conspicuous in this form which has become commonly known as *Dendrobium Phalaenopsis Schröderianum*. About fifteen distinct forms of it have received awards from the Royal Horticultural Society.

*D. Statterianum*, which appeared in Messrs. Sanders' Nurseries at St. Albans, in 1889, and was figured in *Reichenbachia*, ser. 2, Vol. I., p. 15, as *D. Phalaenopsis Statterianum*, is of smaller and more slender growth than *D. Phalaenopsis*, and is darker in colour, the flowers being uniformly rosy-mauve with claret markings on the lip. As it appeared in an importation of *D. Phalaenopsis*, it was suggested that it might be a natural hybrid between *D. Phalaenopsis* and *D. bigibbum*, but a later importation of it in quantity, and which showed scarcely any variation, proved that it was of specific rank. The species is very floriferous, and like all others of the group, a good subject for cultivation for cut flowers or decorative purposes, although it never secured the popularity of *D. Phalaenopsis*.

*D. bigibbum*, originally described by Lindley in 1852, was the earliest of the section to appear in gardens. It is a charming species of compact habit, and bears erect spikes of pretty, rose-coloured flowers, with darker labellum. It was first shown by Messrs. Jas. Veitch and Sons on September 1, 1880, when a First-Class Certificate was awarded, a like award being given to the variety *superbum* in 1876. A white form, appeared in Sir Jeremiah Colman's collection, and also some other very fine varieties, one of which is *D. bigibbum* var. *Lady Colman*.

*D. Leeanum* (O'Brien, in *Gard. Chron.*, 1891, II., pp. 640, 641) (Fig. 163), imported by Messrs. Sanders with *D. Phalaenopsis Schröder-*

of light mauve colour, the lip being mauve-purple. Plants also sent by Mr. Goldie were unfortunate until Mr. Williams succeeded in getting a few alive, for one of which he obtained a First-Class Certificate, July 13, 1896. But it has always been a rare plant, and a fair importation of it would be a satisfactory horticultural event.

*D. superbiens* (Rehb. f., *Gard. Chron.*, 1876, II., p. 516) is a showy species, of tall habit and bearing erect spikes of many bright, rosy-mauve flowers, the segments of which are narrower than in the other species named.

*D. Goldiei* (Rehb. f., *Gard. Chron.*, 1878, I., p. 652) was thought to be a natural hybrid, but its close proximity to *D. superbiens* seems to indicate that it is a fine local form of that

*media Aquinii* was given; this is a showy peloriate variety, in which the petals partake of the labellum in form, and also in the bright rosy-mauve colouring at the tips. A long and interesting account of the discovery of the only known plant at Porto Alegre, S. Brazil, was also given. A part of the plant arrived in this country and was shown by Mr. Kromer at the Royal Horticultural Society on May 28, 1902, when it obtained an Award of Merit. At Chelsea this year Messrs. Stuart, Low and Co., showed *C. Dusseldorfei Aquinii*, a cross between *C. intermedia Aquinii* and *C. Mossiae alba*, and in which the broadening of the petals and their colouring in intensified degree was the great feature. It is interesting to note that even abnormal characters are effective in the hands of the hybridist.

COELOGYNE PANDURATA AND ITS HYBRIDS.

FEW plants among the rare species shown at the recent Chelsea Show attracted more attention than the fine specimen of the handsome Bornean *CoeLOGYNE pandurata*, with its long racemes of emerald-green flowers, that have black markings on the lip, each flower being over 4 inches across. It was displayed in the group of Messrs. Mansell and Hatcher. It is a strong growing, ornamental, warm-house plant, even when not in bloom, and when in flower its quaint Apple-scented blooms are without comparison in its class. In Messrs. Charlesworth's group was the similarly coloured *C. burfordiense* (*asperata* × *pandurata*), a very desirable hybrid, though still very rare. Messrs. Sanders flowered *C. albanense* (*pandurata* × *Sanderiana*) in 1913; in the same year Messrs. Cypher and Sons, of Cheltenham, first bloomed *C. intermedia* (*cristata* × *Massangeana*), a floriferous, decorative plant. Three other distinct hybrid *CoeLOGYNE*s have been raised by Sir Jeremiah Colman, Bart., Gatton Park. All are very desirable plants; but, unfortunately, still rare.

FIG. 164.—DENDROBIUM WILLIAMSIANUM.

species, so far as the material in gardens has shown

*D. Fitzgeraldii* (F. Mueller, 1884) is allied to *D. superbiens*, and is little known in gardens. It also is a suggested natural hybrid.

*D. lencolophotum*, (Rehb. f., *Gard. Chron.*, 1882, II., p. 552), from the Malay Archipelago, also comes into this group, for garden purposes. It bears slender sprays of white flowers.

It appears that no use has been made of this

## The Week's Work.

### THE ORCHID HOUSES.

By J. T. BARKER, Gardener to His Grace the DUKE OF MABLAGOROUGH, K.G., Blenheim Palace, Woodstock, Oxon.

**Epidendrum prismatocarpum.**—This is a most useful Orchid flowering at this season, and one which, in some cases, gives some little trouble to grow and flower satisfactorily. When properly grown it is robust, free flowering, and remarkable for the lasting qualities of its flowers; a well-bloomed specimen makes a fine exhibition plant. Frequent disturbance at the roots is resented by this plant, but when re-potting is necessary it should be done immediately the plant has finished flowering. Remove decayed roots, pseudo-bulbs and rhizomes, also sour compost, and place the plants in larger or smaller pots, according to their condition. The roots should not be too much restricted, but to prevent sourness in the compost it is advisable to add plenty of hard, porous material, such as broken bricks, or crocks, and the pots should be thoroughly drained. The usual mixture of Osmunda or A1 fibre and Sphagnum-moss in a rough condition suits this species well. Make the material firm about the roots, and keep the bases of the pseudo-bulbs on a level with the rim of the pot, or pan. Deep pans, or wide pots, form suitable receptacles in which to grow large specimens of this interesting Orchid. Being an evergreen species, the roots need to be watered regularly so long as growth is active, and even when at rest sufficient moisture should be given to prevent the plant shrivelling. A position in the Cattleya house or similar structure, where plenty of light and air are available, with shade from bright sunshine, is suitable for this Orchid. Insects seldom trouble plants grown under these conditions, but should scale or red spider be detected, they should at once be destroyed, or the fine, healthy appearance of the foliage will soon be disfigured. This Orchid, from my observations, apparently succeeds better in the south than in the north, obviously owing to the greater amount of light in southern gardens.

**Epidendrum radicans.**—This Orchid and its hybrids are beautiful plants flowering at this season, and the individual spikes continue in perfection for a long time. Thus they are most useful plants, either for exhibition, or furnishing a display of flowers for the conservatory, or as cut blooms. As these reed-like Epidendrums produce aerial roots freely, their propagation is easily affected by removing a portion of the growth with roots attached. Given a cool, intermediate temperature, a position where they will receive plenty of light and air at all times, and frequent syringing or spraying during bright weather throughout the summer, the cultivation of these plants is relatively easy. Large specimens may be had by planting a number of stems together in well-drained pots or pans, and training the stems around neat stakes. All through the summer, when they are well rooted and in full growth, afford these plants plenty of moisture at the roots and in the atmosphere.

### HARDY FRUIT GARDEN.

By H. MARRHAM, Gardener to the EARL OF STRAFFORD, Wrotham Park, Barnet.

**Strawberries.**—The warm weather has hastened the development of the berries, and should the hot weather continue they will ripen quickly. If large fruits are desired give the roots a good soaking with liquid manure on two occasions before netting the beds, also pull up any weeds that may be present and place sufficient straw around the plants to keep the fruits clean. A simple and very effective method of protecting ripe strawberries from birds is to insert stout stakes at intervals along the sides of the beds 4 feet out of the ground, and others in the beds 8 feet or 10 feet apart to carry strong wire

stretched as tightly as possible on which to rest old fish netting; along the outside of the beds place netting of 1-inch mesh, 2½ feet to 3 feet high. The fish netting should hang about 1 foot below the top of the wire netting, and may be tied to it with thin string. I have used wire netting around the outside of Strawberry beds and other fruit quarters for many years with good results; not only is the wire a capital protection, but it saves much damage to the fish netting. Keep a watchful eye on the berries, and should mice or rats prove troublesome, put down baited traps and attend to these daily till the pests are destroyed.

**Sweet Cherries.**—Trees of Kivers' Early, Napoleon Bigarreau, and other varieties growing on west walls and trained fan-shape have set an abundance of fruits and the foliage is healthy and free from aphid. These trees will be given a good soaking of water at an early date to assist the swelling of the fruits, our soil being somewhat light in texture and resting on gravel. In colder parts, and where the soil is of a good depth and naturally moist, watering at the present time will not be so essential.

**Vines.**—Attend to the disbudding and the removal of useless shoots early, taking care not to damage the leaders and other shoots that are needed. As the side laterals develop, pinch out the points about two or three joints above the bunches. To obtain the best results with outdoor Vines they need timely attention and care throughout the season. See that the roots are kept sufficiently moist, and especially when the Vines are growing in a restricted well-prepared border.

### PLANTS UNDER GLASS.

By T. PATEMAN, Gardener to Sir C. NAUL-CAIRN, Bart., The Noda, Codiote, Welwyn, Hertfordshire.

**Annuals.**—The conservatory and greenhouse may be kept bright during the summer by growing various kinds of annuals in pots, such as Lobelia tenuior, Petunias, Salpiglossis, Phlox Drummondii, and Statice. They should be potted in a moderately rich, open compost, for in such soil they will have a longer season of flowering.

**Lachenalia.**—Lachenalia plants have practically finished their growth, and water should be withheld from the roots gradually to allow them to rest until August. Stand the pots on a shelf in a cool greenhouse fully exposed to the sun; by this treatment they will be found to bloom more freely than when stored in a shady position.

**Begonia Gloire de Lorraine.**—These plants should be allowed to grow freely at this season of the year. The earliest struck cuttings are ready for shifting into receptacles 4½ inches in diameter; use a rich, open compost with plenty of silver sand added. Where these Begonias are grown in baskets suspended from the roof rafters, the present is a suitable time to transfer them to the baskets. Keep the young plants growing in a temperature of 65°, which may be exceeded with sun heat. The plants need a moist atmosphere during the whole of their growing season. Fumigate the house occasionally to keep mite and other pests in check.

**Winter Flowering Carnations.**—The latest rooted plants are ready for their final potting, and attention should be given to this work at the earliest opportunity. It is a great mistake to allow these plants to become pot-bound before placing them in their final receptacles. The soil in small pots dries out quickly at this season, and where this is allowed to continue for any length of time it will cause a loss of roots, resulting in hardened growth. After potting them, the plants may be placed on a bed of ashes in a cold frame, but first place a small stake to each plant to keep the growth upright. Use water sparingly until the roots are active in the new soil. Admit an abundance of fresh air, and when the plants are well established remove the lights entirely, but protect the plants from heavy rains.

### THE FLOWER GARDEN.

By EDWIN BECKETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Hertfordshire.

**Summer Bedding.**—Plants that have been suitably prepared should be put out in the open, and well hardened off ready for placing in the beds and borders during the next week or two. Too often the proper preparation of the beds and borders for summer bedding is neglected, because of pressure of other work at this season, or, may be, the spring bedding plants have occupied the beds too late to permit of this being done. There is no question, however, but that it pays to prepare the soil carefully, and to this end it should be worked as deeply as possible, and at the time of doing this a good quantity of well decayed manure should be incorporated with it. This will provide the necessary food for the plants, and even of nearly as great importance than this, will assist in the conservation of soil moisture, a matter that requires careful consideration with the prospect of several dry months ahead for the plants, when artificial watering, though necessary, can never be equal in value to the natural supplies of moisture afforded by good rains. One point that also calls for mention where beds and borders are formed in grass borders, lawns, etc., is the desirability of building up the surface of such beds so that they are somewhat above the level of the surrounding ground. Where this is carefully and efficiently done, the effect when the plants are put in is decidedly to enhance the beauty of the scheme. Such spring bedding plants as are required for propagating stock for next season should be lifted as carefully as possible, without too much root disturbance, and replanted in fresh and suitable quarters with as little loss of time as possible, for a few days delay in this matter, or careless handling and treatment, may have a very harmful effect on the results.

**Arrangement.**—The design of the bed is a subject that is always worthy of the most careful consideration and study. Consider the best positions for particular subjects so that plants that are benefited by partial, or complete, shade, are allotted suitable quarters, whilst those that prefer the full sunshine gain their desired positions. Colours, too, should be considered so as to obtain the best colour effects, and the heights of the various plants should be taken into consideration with a view to obtaining a harmonious effect from this point of view.

**Standards in Summer Bedding.**—Much beauty is added to flower beds by the judicious employment of standard plants of such subjects as Fuchsias, Heliotropes and Pelargoniums, as these, carefully placed, with suitable plants as a base, will greatly assist in relieving what may otherwise prove a flat effect, especially if the scheme follows the rather old-fashioned carpet-bedding system.

### FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Lieut.-Col. SPENNER CLAY, M.P., Ford Manor, Lingfield, Surrey.

**Figs.**—Unlike many other fruit trees the Fig becomes more fertile with age, as the shoots become hard and short jointed. The Fig is also a gross feeder, and requires rich and liberal feeding to bring out its best qualities in pots and in confined borders. The secret of success in growing good pot Figs is to pinch the roots instead of the shoots, and to feed them well throughout the plants' season of growth. As the first crop in the early house will now be ripe, the syringe should be used sparingly, especially on dark, dull days, when a free circulation of fresh air cannot be maintained. Syringing cannot, however, be entirely discontinued, as the earliest fruits ripen up in batches, and any fruits forming the second crop are well advanced and must be kept swelling by the aid of atmospheric moisture. Fire-heat being unnecessary now, a sharp eye should be kept on external conditions, and afternoon syringing be done cautiously, but the walls and paths may be

THE ALPINE GARDEN.

THE BULB GARDEN.

GENTIANELLA (GENTIANA ACAULIS).

The splendour of this matchless Alpine just now brings to mind frequent complaints about its refusal to flower freely in some gardens. Perhaps this is the result of misunderstanding its requirements, which are of the simplest. No doubt there may be conditions in certain places unfavourable to its vigour, but these have not come under my notice. In this district it demands attention only in one respect, namely, that when the plants have grown into a dense mat and flower less abundantly, they must be broken up and replanted in small shreds. This division we have found necessary every four years on an average. If this is done imme-

BABIANA STRICTA RUBRO-CYANEA.

Among the Babianas that I know, *B. stricta rubro-cyanea* is undoubtedly the best. It came to me from one of the most famous homes of good plants—Colesbourne. Fortunately we seem to have hit upon the right way to treat it, with the gratifying result that we have better potfuls each year. I mentioned the plant in *The Gardeners' Chronicle* last year and now I am able to send a photograph (Fig. 165) to show the shape of the flower, and gives an idea of the inflorescence. A five-inch or six-inch pot, with about six or seven bulbs, presents a glorious sight on a bright, sunny April day, when the plants—grown in a cool

FIG. 165.—BABIANA STRICTA RUBRO-CYANEA.

diately after flowering, say early in June, each shred will have grown into a nice rosette before the winter, ready to blossom in the following spring. The drought of 1921 was a severe test upon a recently planted edging of this Gentian along a gravel path, and I anticipated failure; but the edging is now—May 18—well set with crowded flowers. We generally put in some ground limestone or old mortar when replanting, but that is not necessary, for the clumps seem quite as happy without it.

Very different is my experience with *Gentiana verna*. Times without number during the past fifty years have we got fresh plants from Ireland and elsewhere. Every care has been bestowed upon them; they flower well the first season, less well the second, after which they dwindle steadily, and finally disappear. I frankly admit defeat. *Herbert Maxwell, Monreith.*

greenhouse all through the winter—are flowering. It is surprising to find how well the carmine centre tones with the blue which surrounds it, without a suspicion of harshness. I cannot remember having ever seen this *Babiana* advertised in a dealer's list. Surely someone should obtain stock and press its sale! Many gardeners, I am sure, would be only too glad to give the plant a trial if attention were drawn to its easy culture. Light soil, early autumn potting, plenty of air, and the coolest treatment possible, provided frost is excluded, are the cultural conditions for its successful cultivation. *Joseph Jacob.*

[Under the name of *Ixia rubro-cyanea*, this showy Irid was figured in *Bot. Mag.*, t. 410, and in the accompanying text we learn that the plant "flowered with Mr. Colvill, Nurseryman, King's-road, May 24, 1797."—Eps.]

damped regularly, with the occasional use of weak liquid manure to circumvent the attacks of red spider. An opportunity to syringe the trees is immediately after the ripe fruits have been gathered. These remarks apply especially to trees growing in light, well-ventilated houses where the atmosphere is likely to become very dry and favour the spread of red spider. Houses that are dark and with a less buoyant atmosphere in which the trees make strong growth may require to be kept much drier. The supply of water at the roots should be regular and plentiful, with a fairly high temperature that should be regulated by day and night ventilation. As soon as the first crop is cleared, shoots which have been turned or tied aside to allow the light to reach the fruits should be rearranged, and possibly some of the shoots stopped to concentrate the energies of the trees on the second crop of fruits, which may require thinning. It is not a good plan, unless the shoots are very strong, to pinch them, much in advance of the second crop, as the first crop next season greatly depends on the points of the shoots becoming thoroughly ripened.

**Successional Figs.**—Trees in the successional houses that were started after the turn of the year will now be shortening the space which existed between the two crops. The trees will respond to any amount of heat, provided plenty of air is admitted and there is ample atmospheric moisture. It is not, however, wise to force too hard through the night, especially when the Figs are in flower, but once this stage is over a minimum of 70° will do no harm. If trained on the long shoot system, each growth should have plenty of room for the full development of its foliage. This house should be syringed regularly twice on fine days, but only once when the weather is dull, for much as the Figs enjoy moisture, the leaves should always become dry before nightfall.

**Late Figs.**—Trees from which one crop is secured do not need hard forcing. The maximum temperature of 80° to 85° can always be secured by closing the house early, with sun-heat. If more than one tree is grown in this house, varieties which succeed each other should be planted. Brown Turkey will form the chief sort, with other prolific varieties, such as Negro, Largo, White Marseilles, and Osborn's Prolific, a delicious Fig, which requires an abundance of dry, warm, summer air to ripen its fruits.

THE KITCHEN GARDEN.

By JAMES F. HATHAWAY, Gardener to JOHN BRENNAN, Esq., Baldershy Park, Thirsk, Yorkshire.

**Broccoli.**—Make a planting of Broccoli as soon as possible on ground which is firm. An old Strawberry bed from which the Strawberry plants have been chopped off with a spade and the ground cleaned is very suitable for this crop. Make the holes with a crowbar in rows 2 ft. 6 in. apart and 2 ft. asunder in the rows.

**Carrots.**—To ensure a constant supply of young Carrots further sowings of the Scarlet Horn type should be made on ground which has been cropped with early Potatos. Level the ground and make the drills 1 ft. apart. It is best at this season of the year to water the drills before putting in the seed.

**Turnips.**—Small sowings of Turnip should be made frequently, as the very hot weather soon causes the plants to run to seed. Sprinkle the rows with light dustings of soot and apply a dressing of manure from a spent mushroom bed to help to keep the roots moist, and thus favour a quick growth.

**Potatos.**—The hoe should be kept going amongst the late batches of Potatos and the plants earthed up, if possible after a shower. If necessary, give a dressing of artificial manure in the rows before earthing up the plants. Bentley's Potato manure is a reliable fertiliser.

**General Remarks.**—The work of chief importance in the kitchen garden is stirring the soil with the push hoe and giving constant attention to watering Peas and Runner Beans should be staked before they grow tall and fall over.

**EDITORIAL NOTICE.**

**ADVERTISEMENTS** should be sent to the **PUBLISHER, 5, Tavistock Street, Covent Garden, W.C.2.**

**Special Notice to Correspondents.**—The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.

**Letters for Publication,** as well as specimens of plants for naming, should be addressed to the **EDITORS, 5, Tavistock Street, Covent Garden, London.** Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

**Local News.**—Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

**Editors and Publisher.**—Our correspondents should obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notices printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the EDITORS. The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.

**Illustrations.**—The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.

**WHITE WORMS.**

IT is perfectly natural that white worms should be regarded with suspicion when they are found in pots and soil at the roots of unhealthy and decaying plants. Not only is Celery frequently found to be infested with them, but Enchytraeid worms have, for three quarters of a century at least, been associated with disease. So early as 1849, Hardy gave the name "putrid" worm to the common white worm which occurs in manure heaps and elsewhere, because he found it connected with plants in a state of putrescence. This species of worm, which is now known as *Enchytraeus albidus*, Heule, has been more frequently described than any other, and under a greater variety of names. It is, moreover, larger than most of its congeners, more easily observed, and by reason of its flourishing vigorously in rich soil and old muck, more frequently found under suspicious circumstances than any other. Johnston, in 1863, described it as *E. vermicularis*, and stated that it was found in soil under the bark of rotted trees, in decaying leaves, and at the roots of decayed vegetables. He does not assert that the worm causes decay, but there is a feeling that it is suspect.

Vejdovsky seems to be the first writer to draw definite attention to them as possible agents in the destruction of living plants. In 1877 he discovered a new white worm, which, on account of its being destitute of setae, he named *Achaeta*, thus founding a new genus. He speaks of these worms as tiny, maggot-like annelids, which flourish everywhere in moist earth, in marshy places, and even in water, in decaying wood and in the soil, and especially in flower-pots. In 1879 he makes the definite statement that his new worm, *Achaeta*, "lives in great numbers in somewhat dry soil." I have observed specimens the whole year through in the Prague Museum Gardens, living at the roots of *Viola*, *Erythronium* and *Corydalis*. "What were they doing there? The answer came from Vejdovsky himself, in 1891, in a communication bearing the title, "Can Enchytraeids Cause Root-sickness?" He refers to the foregoing statement made two years earlier, and says that Eisen informs him that he also had found certain species concealed among the roots of plants. Further, in 1880, he had received information respecting the injury done to sugar Beet by these tiny worms.

In May, 1890, a correspondent had sent Vejdovsky some Enchytraeid worms found in Potatoes and other plants, and in September of

the same year, a second consignment followed. This led him to the conclusion that white worms were capable of causing root-sickness. The question now arose, which, out of the many different species, was the guilty party, or were all species alike to be suspected? No clear or conclusive answer, however, was supplied.

A further question was involved. Have these minute worms the organs that are necessary to enable them to pierce the roots of plants and suck their juices? To this inquiry the author gives a definite reply. When engaged on the examination of some white worms found at the roots of decaying plants (he says) he found a specimen of one of these worms whose stylet was so deeply imbedded in the tissues that the muscles could not retract it. Although eel-worms or nematodes were frequently found with the plants which were diseased, Vejdovsky's conclusion was that they were less capable of inflicting damage on plants than the Enchytraeids were. Such a judgment, from so expert an authority, was calculated to weigh heavily; but the writer himself shows that only by special research can these and similar questions be settled, and this he was not in a position to undertake.

FIG. 166.—CHINESE VINES AT ALDENHAM. (See p. 305.)

In the meantime, the matter was arousing considerable interest in our own country. In 1885 Miss Ormerod, the well-known entomologist and naturalist, had received specimens of small white worms, found in soil among the roots of plants, and had submitted them to another investigator for examination. They were suspected of damaging the plants among which they were found, but Mr. Harker's opinion was that "it did not seem very probable that they could seriously injure the plants." The worms, an inch and a half in length, were evidently fully developed specimens of *Enchytraeus albidus*, Heule, since no other worm commonly found under these conditions attains such dimensions. Now I have given this worm and its allied forms much attention for many years, but have never succeeded in finding a stylet or chitinous tongue such as Vejdovsky speaks of in relation to *Achaeta*. The organ which does exist in the mouth is very soft and cellular.

In 1888 the Rev. W. Lockett, of Littledean, sent soil containing a large number of Enchytraeids, to Mr. Harker, complaining that many of his plants were attacked by them. The following year Mr. Harker wrote to *Nature*, stating that he suspected certain small worms of damaging, if not destroying, cultivated plants. He therefore instituted a series of experiments with Enchytraeid worms, but the

results seem to me to be quite inconclusive, though his opinion was that Clover-sickness was caused thereby, and that Mr. Lockett's plants, including *Spiraeas*, *Marrows*, *Fuchsias*, and *Gloxinias*, died from the same cause. These worms, he remarks, "have not hitherto, so far as I can learn, been accused of causing serious injury to plants. In what manner they directly injure the plant remains to be observed—probably by sucking the fine root-hairs. If, as seems not improbable, further corroboration could be forthcoming, we may find that we have to add to the list of enemies of the Clover plant from which it so mysteriously suffers, these unsuspected Oligochaets." Then came the paper by Vejdovsky, referred to above, and another from Dr. Collin, bearing the same title. In 1893 I received from Valencia Island, Kerry, a number of white worms with a note saying: "They are making fearful havoc in my seeds and plants, eating the seeds especially. They hide in the crevices of the little wooden boxes in which I have seeds, and come out at night. They crawl along very fast, and when frightened seem to sink into the wood till almost invisible." I reviewed the position in 1897, in a paper on White Worms as Plant Pests, and

gave what I then thought to be indubitable proof that Enchytraeids were destructive parasites. Near Birmingham the China Asters were badly affected, and a tiny worm was found at their roots, which I named *Enchytraeus parvulus*. For many years thereafter I continued to regard these creatures with suspicion, especially the Aster worms. These suspicions were deepened when in 1898 my Celery began to suffer.

In 1899, some Fritillary bulbs, from Kew, were submitted to me, infested with the Aster worm, and during the year many inquiries reached me on the subject of disease and white worms. "A Pasture Problem," was the title of an article printed in this *Journal* (*Gard. Chron.*, June 17th, 1899, p. 391), in which I gave details respecting the supposed injurious action of one of these worms (*Fridericia agricola*, Moore), at Maidstone. The conclusion was that "the worms are not hastily to be condemned; though they were found in the stems of grasses, they may have been there as scavengers, because the grass was already injured."

In 1900, Bretecher, dealing with Swiss Enchytraeids says that though Vejdovsky and Friend have shown that these worms are sometimes injurious to plants, it must not be supposed that this is the rule. Myriads of white worms exist, they are constantly at their

appointed task, yet it is only in exceptional years that they are found in any number under circumstances which arouse suspicion. The year 1902 was one which brought me many letters of inquiry, especially from Ireland. One reported trouble among Lilies, another in Celery, a third in Tomatoes, and a fourth in Swede Turnips.

Professor Theobald also reported about this time that garden plants at Nottingham were suffering from attacks. During following years, down to the outbreak of war, Asters, Cucumbers, Strawberries, Wheat and many other plants were said by one and another to show signs of decay, owing to white worms. It was with surprise that I learned that trees also were supposed to suffer from these creatures, which had passed from Asters and Celery to Chrysanthemums and Hops, and finally to the Cherry and the Larch!

'There is a natural tendency, under such circumstances as these, to become suspicious. It is a case of "Give a dog a bad name," and everyone will prove him guilty. When once we are prejudiced we are in danger of following a false scent, and this tends to warp judgment, delay research and prejudge the guiltless. I therefore urged that the matter should be taken up, either by the Board of Agriculture, or some other competent body, and had just succeeded in securing attention when the war broke out. *Hilderic Friend.*

## CHINESE CLIMBERS AT ALDENHAM.

(Concluded from p. 270.)

**RUBUS bambusarum** (Fig. 167), of evergreen character, was first discovered by Dr. Henry (after whom a very similar species is named), and introduced by Wilson in 1900. It grows rapidly, and the long slender shoots, if trained to a pole, have a singularly graceful effect. The foliage, divided into three or more leaflets, is dark green above, and thickly covered with a whitish down on the under surface, whilst the edible black fruits, in long panicles, are quite striking. *R. flagelliformis* probably has the most ornamental foliage of any Chinese Bramble, and though the annual growth is not so long as that of the last-named species, it should be trained in the same way to a pole or other support. The numerous slender stems are then enabled to droop gracefully around on all sides. It has clusters of white flowers, and edible black fruits of good size.

*Rubus irenaeus* has proved a very valuable addition to the number of evergreen shrubs which may be used satisfactorily for clothing shady banks, bare places under trees, and similar positions where comparatively few shrubs thrive. The beauty of the large, round leaves is enhanced by the metallic lustre on the upper surface, and they are pale brown below. The fruit is said to be large and red, but it is very shy of producing them, at any rate, at Aldenham.

**SARGENTODXA CUNEATA**.—This representative of a new genus, named in compliment to the distinguished Director of the Arnold Arboretum, resembles *Holboellia*, but differs primarily from it in its very distinct fruits. It thrives at Aldenham on a wall facing east, and will be watched with much interest, as Mr. Wilson states "For warmer districts than the Arnold Arboretum it will be a handsome climber with pendulous racemes of yellow, fragrant flowers in spring."

**SCHIZANDRA GRANDIFLORA**.—The older members of this genus are said to be very decorative when fruiting, and this new species may be expected to prove an addition to the number of climbers of moderate proportions. The foliage is quite ornamental, and Mr. Wilson describes the flowers as flesh-pink, and the fruits red.

**SINOFRANCHETTA CHINENSIS**.—This represents another new genus, allied to *Holboellia*, which has proved quite hardy and of free growth. Its deciduous foliage is very distinct, being composed of three leaflets, each about 6 inches long and very glaucous on the underside. The strong stems should be supported on a pole of good

height. The flowers are dull white, but the large, purple, Grape-like fruits deserve mention.

**VITIS**.—China has proved remarkably rich in ornamental species and varieties of the Vine, and a great diversity of form and colouring will be found among the undermentioned. The majority need ample space for proper development, and at Aldenham splendid specimens may be seen growing on the walls of the mansion, on arches (Fig. 166), pergolas, trellises, and other old trees, etc.

*Vitis armata*, also known as *Spinovitis Davidii*, has been grown in England since 1885, but was sent to Messrs. J. Veitch and Sons by Wilson in 1900. It is a very luxuriant grower, and its stems are armed with strong hooked spines. These short, closely packed spines present an appearance strongly resembling clusters of green fly, and Mr. Gibbs tells me that he found one of his friends puffing away at the plant with his pipe, being under the impression that he was helping to rid him of that common pest! The

attractive. The young leaves and stems are reddish-purple; these gradually assume a greenish tone, the leaves finally changing to a rich port-wine red, before falling. Of the beautiful *V. Vicarii* little is known, as it is a chance plant discovered at Aldenham among many of Mr. Wilson's seedlings. It is especially noteworthy on account of its brilliant rose and primrose autumn colouring. It is a self-clinging species, of rapid growth, suggestive in its general appearance of the well-known Virginian creeper, but with more refined and more corrugated foliage. The name has no scientific authority, and has been attached to it provisionally at Aldenham until someone can assign another. So far, though seen by many experts, it is still unrecognised.

The hardy ornamental-leaved vines are a much neglected race of plants generally, seeing how valuable they are for summer and autumn decoration of the garden, and there are few plants that give such rich autumn tinting. *A. E. Thatcher.*

FIG. 167.—RUBUS BAMBUSARUM AT ALDENHAM

fine large foliage generally assumes a brilliant red colour in the autumn. *V. a. cyanocarpa*, also known as *V. a. Veitchii*, is more vigorous than the type, and its autumn dress is even richer. *V. flexuosa Wilsonii* is a very charming variety of moderate growth, with small leaves, which are bronzy green above, with a metallic sheen, and purple beneath. *V. Henryana* is a strong-growing Vine well adapted for clothing the north side of a building, to which the tendrils enable it to cling. The handsome foliage, dark green, with white and pink variegation, changes to red before falling. *V. heterophylla Delavayana* is a self-clinging climber of great beauty in the autumn, when the leaves put on the most brilliant red hues. *V. megalophylla* is an extraordinary Vine, which has fortunately proved quite hardy. The fine bi-pinnate foliage, frequently more than 2 feet in length and width, is attractive and interesting, though it puts on no rich autumn colour. This Vine is well suited for training on a pole of good height, where the great leaves are seen at their best.

*Vitis Piasezkii* is a very pretty climber of moderate growth, with small leaves, which turn a very brilliant red in the autumn. *V. Thompsonii* is one of the most pleasing of the small growing Vines, and the foliage is particularly

## BLUE FLOWERING CLIMBERS FOR THE GREENHOUSE.

Of the many tender flowering climbers suitable for the embellishment of the greenhouse and conservatory during the summer few surpass *Sollya Drummondii* (syn. *S. parviflora*), a pretty, neat, evergreen twiner from Australia. With its exquisite blue colouring it is worthy of a place in every cool greenhouse or conservatory, but for some reason or other it is comparatively very little known. Those who have not previously grown it would be much gratified by its floral display. Few plants excel it in neatness of growth and free flowering habit. It has small, dark foliage and deep blue flowers, which are produced in abundance during July and August. It may be grown in many ways, for instance, in 5-inch to 6-inch pots, and allowed to twine itself on a stick 2 feet to 4 feet long, and it will continue to twine until it becomes a thick mass of growth full of flowers. In this form it makes a very effective decorative plant, and is very attractive dotted amongst a group of miscellaneous plants. *Sollya Drummondii*, when planted out, is admirably adapted for covering pillars, trellises, or walls, and makes an ideal plant for covering dead Tree Ferns, or

rough poles, climbing amongst them and requiring very little attention. It may be increased from seed sown in slight heat in March, or by cuttings inserted in that month. Young shoots that are a little firm at the base should be inserted in sandy soil in slight heat under a bell-glass, hand-light, or frame. The plant requires a winter temperature of 40° to 45°. It should be grown in a mixture of light, turfy loam, and fibrous peat, or leaf mould with silver sand added.

*Sollya heterophylla* (the Australian Blue-bell Creeper) is a free growing and free flowering evergreen species, with light green foliage and pale blue flowers that are borne in gracefully drooping clusters from July to September. It is most suitable for growing in any ordinary greenhouse or conservatory either as a pot specimen, or planted out for covering pillars or for training to the rafters, and is well adapted for growing in any small house on account of its neat and compact habit of growth. It requires similar treatment to *S. Drummondii*.

FIG. 168.—CARNATION PLANTS AS PACKED FOR EXPORT, AFTER NEARLY TWO MONTHS SOJOURN IN COLD STORAGE.

*Tibouchina semidecandra* (syns. *Pleroma* and *Lasiandra macrantha*) is a very beautiful autumn and winter flowering plant, especially useful for covering a back wall or pillars in an intermediate house or conservatory where the temperature is not so warm as in a stove or so low as in an ordinary cool greenhouse. It flowers freely when quite small, in pots, and its rich violet-blue flowers are exceedingly welcome during the winter. Cuttings of half-ripened side shoots root readily in sandy soil, in a frame or hand-light over a little bottom heat. When well-rooted the plants should be potted in a compost consisting of equal parts light turfy loam, fibrous peat, or leaf mould, with silver sand added. Syringe the plants freely during the summer, and give them a moderate amount of air, but do not expose them to cold draughts. A slight ripening of the wood is beneficial during the autumn. After flowering, the growth may be moderately shortened. The plant should be grown in a winter temperature 50° to 55°.

*Plumbago capensis* is one of the most useful,

free flowering, easily grown plants we possess. It develops large heads of pale blue flowers, and lasts in bloom for several months during the summer and autumn. It is very suitable for furnishing pillars and rafters in the greenhouse or conservatory, and is invaluable for summer bedding arranged with other plants in mixed beds or borders. This *Plumbago* is also very effectively trained as a standard or half standard. Cuttings of well-ripened wood root freely in sandy soil under a hand-light or frame over slight bottom heat. The soil should consist of two-thirds turfy loam, one-third fibrous peat or leaf-mould, with silver sand added.

*Ipomoea rubro-coerulea* (Heavenly Blue or Morning Glory) is a lovely climber of rapid growth, and neat habit, most admirably adapted for covering trellis work, pillars, and rafters in an ordinary greenhouse or conservatory. It produces an abundance of beautiful, sky-blue flowers four to five months after the seed is sown. It requires a moderately sunny position;

## PACKING CARNATIONS FOR EXPORT.

AN exceedingly successful illustration of his method of packing young Carnation plants for exportation overseas was given by Mr. C. Engelmann at the recent Chelsea Show. The plants, which had been grown in "small 60's," were turned out of their pots and packed into a box on March 28 last. The box was then placed in cold storage, under similar conditions to those which obtain on board ship, until May 23, when it was brought to the Chelsea Show and opened in the presence of Lord Lambourne. It was readily seen that the plants, after having been shut up for just eight weeks, were in splendid condition. This demonstration box containing 75 plants, was one-half the standard size, and its capacity about half a cubic foot—an important matter when it is remembered that the steamship companies base their charges for goods carried in cold storage by their cubic area and not by weight. The accompanying illustration (see Fig. 168) shows the method of packing adopted, and it will be seen that the soil and roots of each plant are wrapped in grease-proof paper to check evaporation. The box in question was sealed down, when packed, by Lord Lambourne, and by an error it was sent from cold storage to Saffron Walden instead of direct to Chelsea; this necessitated a return journey, and a whole day on rail did not tend to improve the plants. The plants were prepared for export before being packed, and they stood the test remarkably well—indeed, they appeared as though packed only two or three days previously.

## FRUIT REGISTER.

### PEARMAIN APPLES.

THE name Pearmain has always been understood by fruit growers and pomologists generally to indicate a conical or pointed variety, and most sorts of the section are of first rate quality, especially those that are in use late in the season.

Christmas Pearmain is a good cropper and grower. The fruits are of medium size coloured red, with russet markings. The flesh is crisp and of excellent flavour. This variety produces heavy crops on bushes and espaliers.

Baxter's Pearmain bears fruits of medium size, which have a crisp and agreeable flavour. They are of greenish colour tinted with red. This variety makes plenty of wood growth and is very hardy. Its season is December to March.

Scarlet Pearmain or Oxford Peach is another excellent variety for cropping, the fruits being beautifully coloured deep crimson and red. They are of middle size, oval in shape, with a small, deeply-sunken eye and a stalk, which is also deeply inserted, half an inch long. This variety is suitable for growing on light loamy soils and the fruits are in season at Christmas.

Claygate Pearmain is an old variety of much merit, and added to its excellent quality are prolific cropping and long keeping. On rich soils the fruits grow to a large size, but this Apple has always a rich, sweet flavour. The skin is coloured dull yellow with several broad stripes of red; the flesh is yellow.

Blue Pearmain is a remarkable Apple owing to the intense bloom which develops on the skin, giving it a blue appearance. It is perhaps a little too large for dessert purposes, but it lacks nothing in flavour. The plant makes a strong bush and also does well as a standard. It is in season from December to February.

Mannington Pearmain is another excellent Apple and keeps as late as April, yet it retains its rich flavour. The fruit is of medium size, with a rich golden yellow skin that has a brownish hue on the side next to the sun.

Adams's Pearmain is a fine late Apple that crops abundantly. The fruits are of medium size, coloured red and yellow with a splash of russet. The flesh is firm, crisp and highly aromatic. *Pomona*.

if grown in a shady part of the house it does not flower well, and the growth becomes weak and spindly. The seeds should be sown in spring in shallow pans or well drained pots, filled with sandy loam, peat, or leaf-mould in equal parts. Cover the seeds lightly and germinate them in gentle heat. *Solanum Wendlandii* is a most decorative plant producing long terminal cymes of from fifteen to twenty flowers each, the individual blooms being from 1½ inch to 2½ inches across. They are light purplish blue with a club-like cluster of yellow stamens. Trained to pillars or the roof rafters of a warm greenhouse or conservatory it produces a most striking display during the months of July, August, and September. It also makes a good plant for flowering in pots. This *Solanum* may be propagated from well ripened shoots, making the cuttings 2 to 3 inches long, with one or two eyes. They should be inserted perpendicularly in pots, with the bud just level with the surface of the soil, and placed in bottom heat in January or February. *John Heal, V.M.H.*

**MESEMBRYANTHEMUM AND SOME NEW GENERA SEPARATED FROM IT.**

(Continued from page 262.)

DD.

Some or all of the dots confluent or connected into lines, or the growths marked with lines not formed of dots, often forming a sort of pattern. (Species 23-49). See also 19 *C. piluliforme*.

E.

Top of the growths flattish, or with a shallow, trough-like transverse depression nearly as broad as the top, or slightly excavated and shallowly cup-shaped. (Species 23-31). See also 33 *C. leviculum*, and 37 *C. signatum*.

23. *C. minimum*, N. E. Br. Growths very small, about six lines high, obconic, truncate, with each side rising a little higher than the middle, causing them to appear as if transversely channelled, with a scarcely perceptible central puberulous orifice, smooth, somewhat glaucous-green, marked with several single and confluent spots, forming somewhat branched lines. Flower small, calyx 5-lobed, cylindric, membranous, at length campanulate, prettily spotted with red. Ovary exserted above the top of the plant. Petals whitish-yellow or whitish.—*M. minimum*, Haw., *Obs. Mesemb.*, p. 126 and 131, under *M. nuciforme*, and 450 (1795), and *Misc. Nat.*, p. 21.

Locality unknown. Introduced by Masson before 1776.

petals recurved-spreading, pale cream-coloured. Stamens scarcely exserted, whitish. Style about  $\frac{1}{2}$  line long; stigmas 4, nearly 1 line long.

Locality unknown. Bolus, 15933.

This species is unknown to me, I have described it from an excellent coloured drawing made by Miss M. Page from a living plant, which I understand is now dead.

26. *C. obmetale*, N. E. Br. Growths 5-10 lines long and  $4\frac{1}{2}$ -7 lines in diameter, obconic, nearly circular in outline at the nearly-flat top (type F), greyish-green or dull green, marked with very distinct dull purplish-brown or dark green branching lines formed of confluent dots, with a few separate dots scattered among them. Calyx 4-lobed. Corolla 5-5 $\frac{1}{2}$  lines in diameter, opening about sunset, closed during the day, scentless; tube about as long as the calyx; petals 16-30, recurved-spreading, milk-white, very shining. Stamens 12-25, in two series, the upper anthers just exserted, yellow. Style about one line long; stigmas 4, plumose-filiform,  $1\frac{1}{2}$  lines long, whitish or yellowish-green.—*M. obmetale*, N. E. Br. in *Journ. Linn. Soc. Bot.*, Vol. 45, p. 95 (1920).

South Africa. Locality and collector unknown.

27. *C. Nevillei*, N. E. Br. (Fig. 169). Growths of newly-introduced plants 4-6 lines long and 4-6 lines in diameter, sometimes becoming under cultivation up to one inch long, and as much in their greater diameter, broadly obconic, usually flat the circular or broadly elliptic top, but different plants varying (types F and K), sometimes being slightly obcordate, or with the centre depressed in a slight cup-like manner, more or less purple on the sides, but the top varying much in different individuals, being light green, dull green, grey-green, or rather bright rosy-carmine marked with dark green or dark purple dots, which are more or less connected or confluent into simple or branching lines, or occasionally all, or nearly all, separate, and are often faintly raised, varying on different plants in arrangement and size. Calyx-tube more or less exserted, 5-lobed, ovary included or exserted. Corolla finally 4-7 lines in diameter, opening after sunset, slightly scented; tube about as long as the calyx; petals 30-40, in 2-3 series, recurved-spreading, white or creamy-white. Stamens with slightly exserted pale yellow anthers. Style very short or nearly obsolete; stigmas 4, less than 1 line long, filiform, white.—*M. Nevillei*, N. E. Br. in *Journ. Linn. Soc. Bot.*, Vol. 45, p. 95. *M. obcordellum*, Sims, *Bot. Mag.*, t. 1647, not of Haw.

Van Rhyndorp Div., near Van Rhyndorp, Pillans.

This is a very variable species in shape, colour and size, and I find that the plant figured in the *Botanical Magazine* as *M. obcordellum* is undoubtedly this species, for I have had some growths of my plants as large as or larger than that figure, and in every way like it. I have one plant of this species which in summer becomes entirely of a rosy-carmine tint, and is then a very pretty and distinct-looking plant.

28. *C. obcordellum*, N. E. Br. Growths usually about 4-5 lines long, 4-6 lines broad and  $3\frac{1}{2}$ -5 lines thick, but sometimes much larger, obcordately obconic, from a transverse notch across the top (type L), green or more or less glaucous-green, usually tinted with purple when exposed to full sunshine, marked on the top with raised or tubercle-like dots, mostly confluent into irregular lines, of a dark purplish or dark green colour, according to sunshine. Calyx 4-5-lobed. Corolla 5-10 lines in diameter, sometimes both sizes on the same plant at the same time, expanding between 4 and 5 p.m., closed during the day, faintly or scarcely scented; tube 2-2 $\frac{1}{2}$  lines long; petals 25-40, recurved-spreading, lax, milk-white to very pale straw-colour, sometimes tinged with pink at the tips. Stamens slightly exserted, anthers pale yellow. Style  $\frac{1}{2}$  line long, whitish or greenish. *M. obcordellum*, Haw. *Misc. Nat.*, p. 21 (1803); Salm Dyck, *Mesemb.* § 1, f. 2. *M. obconellum*, Haw. *Misc. Nat.*, p. 21 (1803); Salm Dyck, *Mesemb.* § 1, f. 3.

Worcester Div., near Worcester, Cooper. Clanwilliam Div., near Clanwilliam, Pillans.

There is no character whatever to distinguish the two plants known in gardens and figured by Salm Dyck as *M. obcordellum* and *M. obconellum*, the distinction given by Salm Dyck and by Berger being purely fictitious. As Haworth's original descriptions are inaccessible to the majority, I here give a translation of them. "*M. obcordellum*. Twice as large as the preceding (i.e., *M. minutum*) and more obcordate, glaucous, with the spots more elevated or sub-tubercular, and more confluent and branched or map-like. Ovary included, not raised above the surface of the plant." And in another place he describes the corolla as "whitish"

"*M. obconellum*. Greenish, with confluent tubercle-like dots. Ovary included. Calyx 4-lobed. Petals white. Very like the preceding (i.e., *M. obcordellum*) and of the same size or a little larger, and apparently distinct. It differs by being less obcordate and less glaucous, and with the spots less branched, but more elevated or tubercle-like."

From these descriptions it is clear that there is no real specific distinction between them, the only distinctions mentioned being that one is more glaucous than the other and the markings differently branched and differently elevated. These characters of colour and markings, however, I find, vary on different individuals of this (and also of other) species, when a sufficient number of different individuals are examined. By different individuals, I mean separate plants originating from separate seeds.

29. *C. mundum*, N. E. Br. (Fig. 170). Growths about 5-6 lines long 4-9 lines broad and 4-7 lines thick, broadly obconic, with a shallow v-shaped depression across the full breadth of the elliptic or circular top (type K), or sometimes the top is concave with a raised rim all around it,

FIG. 170.—*CONOPHYTUM MUNDUM*, N. E. BR. NATURAL SIZE.

or occasionally almost flat, dull greyish-green or glaucous-green, tinted with purple, marked with conspicuous blackish-green or blackish-purple, raised or tubercle-like dots that are mostly confluent into irregular lines or groups. Calyx 4-5-lobed; in well nourished plants, the tube and ovary is entirely exserted from the orifice, but sometimes is partly or wholly included in the plant. Corolla, 3-6 lines in diameter, expanding between 4 and 5 p.m., closed during the day, faintly scented; tube equalling or longer than the calyx; petals 30-40, spirally arranged, recurved, white, pale straw-coloured, or pale pink. Style 1-1 $\frac{1}{2}$  line long; stigmas 4-5, about  $1\frac{1}{2}$  line long, pale greenish.

South Africa. Locality and collector unknown.

This is one of the most distinct species of this genus, being easily recognised by the depressed top and rather large, raised, blackish dots, confluent into lines. *N. E. Brown*.

(To be continued.)

**High Prices for Old Garden Books.**—At a sale by Messrs. Hodgson of books from the Cassiobury Park library, the property of the Earl and Dowager Countess of Essex, a copy of P. J. Redouté's *Les Liliacées*, with 468 coloured plates, Paris, chez l'Auteur, 1802-16, realised £100, and a copy of E. P. Venat's *Jardin de la Malmaison*, 1803, with plates in colours, sold for £51.

FIG. 169.—*CONOPHYTUM NEVILLEI*, N. E. BR. NATURAL SIZE.

This has long been lost to cultivation, and I have not seen any species that will agree with Haworth's description as above given.

24. *C. perpusillum*, N. E. Br. "Differs only from *M. minimum* by its included ovary, and a little in its numerous offsets and darker colour. Smooth, green, with stout confluent branched spots. Ovary included."—*M. perpusillum*, Haw., *Rev. Pl. Succ.*, p. 82 (1821).

Locality unknown.

This species is also quite unknown to me. But there are at least three species in cultivation under the name *M. perpusillum*, neither of which in any way agree with Haworth's description of it. Possibly *C. perpusillum* is not specifically distinct from *C. minimum*, but this cannot be decided until the plants are rediscovered.

25. *C. praeinatum*, N. E. Br. Growths 4-5 lines long, 3-4 lines broad and 2-3 lines thick at the flattish top, which is elliptic-oblong in outline and not depressed at the orifice; the sides are purple, and the top greyish-green, often tinged with purple, marked with a dark purple (or probably sometimes dark green) ring formed of confluent dots parallel with and inside the margin, and a very few scattered dots of the same colour. Calyx-tube exserted, 5-lobed; ovary included. Corolla 5-6 lines in diameter, expanding in the evening, scented; tube 2 $\frac{1}{2}$ -3 lines long, about as long as the calyx;

## HOME CORRESPONDENCE.

[The Editors do not hold themselves responsible for the opinions expressed by correspondents.]

**Roofing of Garden Fruit Cages.**—Our fruit garden is 80 yards by 60 yards, and surrounded by a board fence 8 feet high. Just previous to my coming here, 9 years ago, it was covered with wire, on wooden posts 10 feet high. The stock of fruit trees consists of fifty pyramid Pears, 9 ft. high, Cherries, three hundred Gooseberry and Currant cordons, Black Currants, Raspberries, and eighty Gooseberry bushes. Trained against the fence are one hundred cordon Pears, also Plums and Cherries. All these fruits succeed well, as do all kinds of vegetables; but Royal Sovereign Strawberry absolutely refuses, either from forced plants or runners from outside, to make one single leaf. As this is the case with plants set out in April, it is not likely to be caused by drip from the wire. The plants grow splendidly until they are put out, and do so now just outside, round the border; inside the cage, Laxton's Latest and Givon's Late Prolific do fairly well and I hope to find other sorts to grow. On the whole, the cage is very useful. Mr. Preece, on page 216, has an excellent suggestion, i.e. to remove the sides to admit both air and birds. Our large expanse of wire requires the snow to be shaken through by tapping underneath with rakes, and as the snow falls on those who dislodge it, sometimes at 10 p.m., the remarks are varied and not always complimentary to permanent wire coverings. *J. W. Harris, Beverdean Gardens, Oxshott, Surrey.*

—Both my employer, Mrs. Insole, and myself have read with interest the correspondence on the roofing of garden fruit cages. In these gardens we have a fruit cage completely wired in and with an iron door at each end. It is planted with Red and Black Currants, Raspberries, standard and bush Gooseberries, and a bed of Strawberries. On March 31 snow fell heavily all day in this locality, and the next morning I had the mortification of finding the cage level with the ground. Several of the fruit bushes were badly damaged, two of the standard Gooseberries being snapped off at the base. The iron supports were bent in all shapes, which necessitated the dismantling of the whole structure and the sending of the supports to the blacksmith. I have not seen any ill effects on the plants from zinc salts. The one pest we are troubled with is caterpillar on the Gooseberry bushes. We find the pest is best destroyed by syringing with an insecticide. After the above experience, I think a roofing of ordinary garden netting, which could be put on or removed as the occasion demands, would be the most serviceable. *Albert Vickery, The Court Gardens, Llandaff, South Wales.*

**Magnolia Soulangeana.**—I have pleasure in sending you a photograph of a fine specimen of this magnificent early flowering Magnolia. The tree is growing in the garden of Sherwood House, Windlesham, Surrey, which is occupied by Mr. W. R. Oldham, who is manager of the extensive nurseries of Messrs. W. Frowen and Sons. The photograph does not really do justice to this handsome specimen. [We regret it is unsuitable for reproduction.—Eds.] At the time it was taken rough measurements were made and it was found that the tree stands 27 feet high, with a spread of 30 feet. Planted some 40 years ago, it has done well, and flowers regularly and profusely every year. In the fine clear air of this part of Surrey the flowers open perfectly, and are superb as regards colour and form. The tree was worth travelling far to see when in bloom. *A. H. Hoare.*

**Begonia Dregel.**—Besides the hybrids mentioned by "W." in his note on this plant on p. 209, another hybrid of Dregel is *B. carminata*, raised some years ago by Messrs. J. Veitch and Sons. The other parent was the tall-growing *B. coccinea*. *Begonia carminata* forms a bushy specimen, from two feet to three feet in height. The flowers, which are borne in pendulous clusters towards the end of the summer and in early autumn, are of a bright carmine-pink

colour. It is of great value in the greenhouse at a time when some of the summer-flowering occupants of that structure are past their best. *T.*

**Primula obconica.**—Readers who have specially fine varieties of *Primula obconica* should not throw them away. It carefully divided as soon as the best of the flowers are past, not into large pieces, but small ones, potted into a light rooting compost, and kept close and shaded for a time in a cold frame, subsequently shifting them on into larger pots, they will succeed admirably, and flower more abundantly than one-year-old seedlings.—*R. P. B.*

**Fruiting of Ficus stipulata.**—*Ficus stipulata*, better known in gardens as *F. repens*, is fruiting in these gardens in an old disused house, where it has been growing for upwards of forty years. Formerly the plant was kept closely trimmed, and it entirely covered the wall, but for several years past it has been allowed to grow at will and now has fruited. I am not sure whether this species of *Ficus* has ever fruited previously in this county, but, in any case, fruiting must be a somewhat rare occurrence. *G. G., Temple House Gardens, Marlow.*

[The fruiting of *Ficus stipulata* is fairly common in greenhouses in this country; see *Gard. Chron.*, March 12, 1904, where a fruit is illustrated in Fig. 72.—Eds.]

**Carnation Bis Greenfield.**—I fail to understand *Midland Grower's* treatment of Bis Greenfield Carnation (see p. 263). I most emphatically state that I have found it quite as good as Carol, and not so shy in producing blooms as he states. The plants, from my point of view, are always vigorous, healthy and resistant to rust. *Midland Grower's* treatment puzzles me, as any Carnation grown under good treatment, no matter how shy in producing blooms, will produce more than one flower in eighteen months. From my experience, Carnation Bis Greenfield is second to none among the perpetual-flowering type as a scarlet variety. *C. H. Cooper, Polesden Lacey Gardens, Dorking, Surrey.*

**Musa Cavendishii.**—Mr. Jordan's note on 263 and his reference to my late father bring most vividly to my mind the receipt of those wonderful Impney Bananas at the office of the *Journal of Horticulture*. They were of extraordinary size, of speckless cleanliness, of splendidly rich colour, and of superb flavour—indeed, that was the first occasion on which I tasted a Banana. I have had many since from my gardener friends up and down the country, and the flavour has been always as incomparably superior to the imported fruits as are Rivers' Oranges to the foreigners. Reverting to my father, his pleasure in those Bananas, as in point of fact it was in every example of particularly conspicuous cultural merit which came under his notice, was immense, and, if I remember aright, his immediate decision, after he had momentarily exhausted his expressions of delight, was that he must write to Mr. Jordan one of his characteristic letters, on this occasion, of whole-hearted, sincere congratulation, though some of us know that all of his epistles did not proceed on the suavest lines. Meanwhile the printers were waiting for "copy," and the foreman was well-nigh beside himself with rage at the delay. When the printer found an opportunity to come into personal touch with my father, he started to speak, but my father simply looked at the Bananas lovingly once more and told him to go and wait. MSS. and proofs were swept ruthlessly aside and the letter was written—the grand fruits occupied my father's mind to the exclusion of aught else. I do not like to speak too firmly after a lapse of roughly 30 years, but I have good reason, since all the copy passed through my hands, to believe that Mr. Furnell (page 263) is in error in attributing the Banana article in the *Fruit Grower's Guide* to Mr. Ollerhead, who, however, most probably read and approved it in proof form, as he and my father were great friends, with an intense mutual respect. *Horace J. Wright, Lidlington, Beds.*

## SOCIETIES.

## MANCHESTER AND NORTH OF ENGLAND ORCHID

THURSDAY, MAY 11.—Committee present: The Rev. J. Crombleholme (in the chair), Messrs. R. Ashworth, B. J. Beckett, J. Birchenall, A. Burns, A. Coningsby, D. A. Cowan, C. Cowan, J. Cypher, A. G. Ellwood, J. Evans, W. Giles, A. Hammer, J. Howes, A. Keeling, D. McLeod, J. Thrower, E. W. Thompson, and H. Arthur (secretary).

## AWARDS.

## FIRST-CLASS CERTIFICATES.

*Odontoglossum crispum Earl Balfour.* A fine variety of the Dora type; *O. crispum Queen of the May*, a beautiful variety of the Dora type with rose-coloured flowers; *Brasso-Laetia-Cattleya Lady Rachel var. Ivorine.* A pure white flower with a rose blotch on the lip. All from Mrs. GRATRUX.

*Odontoglossum Doreen var. Queen of the Belgians.* A large flower of grand shape, heavily blotched reddish brown; *O. Colossus (eximium x Armstrongiae).* Flower heavily spotted and barred with reddish brown; *Brasso-Laetia-Cattleya Joan var. Golden Aureole.* A beautiful variety with deep, clear yellow flowers. All from S. GRATRUX, Esq.; *Brasso-Laetia-Cattleya Jupiter var. Jove.* A mauve-coloured flower with a blotch of magenta on the lip. From Mrs. BRUCE and Miss WHIGLEY. *Odm. eximium rotundum (C. Leonard Perfect x ardentissimum).* A white flower with very broad sepals and petals, blotched and spotted with reddish brown. From P. SMITH, Esq.

## AWARDS OF MERIT.

*Odontoglossum crispum Mary Regina; O. Pescatorei Gratirixiae; Brasso-Cattleya Andre Maron (B.-C. Leemanae x G. Schröderae); Laetia-Cattleya Vesuvius var. Flammea.* All from S. GRATRUX, Esq. *Brasso-Cattleya Pink Pearl (B.-C. Empress of Russia and C. Schröderae); B.-C. Hon. Mrs. Fitzroy (B.-C. Thorntonii x C. Mossiae Wagnerii); Cattleya Irene var. Grandis.* From Mrs. GRATRUX. *Odm. Conqueror var. Illustris.* From P. SMITH, Esq.

## GROUPS.

S. GRATRUX, Esq., West Point (gr. Mr. J. Howes), staged a group in variety for which a Gold Medal was awarded. A. HANMER, Esq., Buxton (gr. Mr. Giles) was awarded a Silver-Gilt Medal for a group of *Odontoglossums* and *Odontiodias* in variety.

MESSRS. CYPHER AND SONS, Cheltenham, were awarded a large Silver Medal for a miscellaneous group.

## ANNUAL MEETING.

The annual meeting was held at 2.30 p.m. The President, Mr. A. Hammer; the Hon. Treasurer, Mr. R. Ashworth; the Chairman, the Rev. J. Crombleholme; and the Hon. Secretary, Mr. H. Arthur, were all re-appointed. The Committee was also appointed. The prizes were presented to the successful competitors as follow:—Mr. J. J. Bolton's Gold Medal for *Cypripediums* to S. GRATRUX, Esq. (gardener's prize, Mr. J. Howe), and the Silver-Gilt Medal offered by that gentleman for *Cypripediums* to Mrs. BRUCE and Miss WHIGLEY (gardener's prize, Mr. A. Burns), who also won the Botanic Society of Manchester's Silver-Gilt Medal; that Society's Silver Medal was won by S. GRATRUX, Esq. Dr. Hartley's prizes for excellence of culture in conjunction with the above medals were awarded as follow: Mr. A. BURNS, first; Mr. J. HOWES, second; and Mr. G. GILES, third. Messrs. Charlesworth and Co.'s prize for new awards was won by S. GRATRUX, Esq. (gardener's prize, Mr. J. Howes), and he also won Messrs. J. Cypher and Co.'s prize for arrangement of groups and Mr. Evans' prize for *Odontoglossoms*. Mr. Hammer's prize for the most points was awarded to S. GRATRUX, Esq. (gardener's prize, Mr. J. Howes), who also won Messrs. Hassall and

Co.'s prize for Cattlevas and hybrids; Mr. Gratrix's prize for Odontodas went to A. HANMER, Esq. (gardener's prize, Mr. G. Giles); and Messrs. Stuart Low and Co.'s gold medal for home-raised seedlings was won by the Rev. J. CROMBLEHOLME, and that firm also presented a silver-gilt medal for home-raised seedlings to Mrs. BRUCE and Miss WRIGLEY. Capt. Horridge's prizes in conjunction with the above medals were awarded to Mr. E. MARSHALL, first; and Mr. A. BURNS, second. Messrs. J. and A. McBean's prize for Cymbidiums was won by the Rev. J. CROMBLEHOLME (gardener's prize, Mr. E. Marshall), Mr. P. Smith's prizes for groups were awarded to Mr. J. HOWES, first; Mr. A. BURNS, second; and Messrs. G. GILES and E. MARSHALL, third. The majority of the above prizes have been offered for competition during the ensuing season.

### IRIS CONFERENCE IN PARIS.

The Paris Iris Conference was held on May 27. There was a fair attendance, over sixty persons being present, including Mr. W. R. Dykes and Mr. R. W. Wallace from England; Mr. Wister, president of the American Iris Society, and Mr. Bonnewitz, delegate from America; M. Correvois, from Geneva; and many French nurserymen and amateurs.

The hall was well filled with collections of cut spikes of garden Irises. Messrs. VILMORIN-ANDRIEUX and Co. staged about 300 varieties, including about 50 novelties of their own raising, mostly of their large flowering strain. Messrs. CAYEUX and LECLERC had a very fine and extensive display of choice varieties and some very good new sorts of their own. Mons. MILLET had also a large and goodly collection, containing some of the fine varieties raised by M. Denis and some by himself. Smaller collections came, also, from amateurs, and one of old varieties from the Paris Museum.

Mme. PH. L. DE VILMORIN contributed an exhibit of a unique collection of over 200 very accurately hand-painted plates of Iris, mostly of the Pogoniris section.

Mons. D. Bois presided, and after an address of welcome invited Messrs. Dykes and J. Wister, Presidents of Honour of the Conference, to sit with him.

The debate was then opened on the thirteen questions set out, fifteen papers having been sent in reply to these questions. It would occupy too much space to detail these, but among the most important were those from Mr. Krelage, on "The History of the Raising of Garden Pogoniris"; from Mr. Hoog, on "Oncoecylus and Regelia Irises and their Hybrids"; three papers on "The Hybridisation of Iris" from Messrs. Dykes, Bliss, and Yeld respectively; two on "The Classification of Pogoniris" by Mr. Sturtevant and another member. Other papers were on the use of Irises in garden decoration, two on the use of these plants in drugs and perfumery, one on the insects and diseases that attack Irises, and a very interesting one by M. Guillaumin on "Abnormalities in Iris." It was stated that Iris stems have produced opposite branches, and in one case decussate foliage. The specimens were preserved in Mons. de Vilmorin's herbarium, with many other abnormalities.

Then followed a discussion, opened by the American representatives, on "The Nomenclature, Description, and Registration of New Varieties." Mr. Wister, who has done a great work in collecting about 2,500 names of Iris in a large list, complained of many synonyms and lengthy names, and tried to have some of these last shortened according to the desires of the American joint committee on nomenclature. This suggestion was replied to by Messrs. Bois and Guillaumin, of the Paris Museum, that the countries, and among them France, who had representatives having accepted the rules of botanical and horticultural nomenclature of the Congresses of Vienna, 1905, and Brussels, 1910, had no power to change any of the accepted names. To

avoid duplicate names it was decided that a member of the Iris Conference would be detailed to receive the names proposed by raisers and to send them to the American society for standardisation. As for descriptions, novelties, rights, etc., these would be placed in the hands of the "Office internationale de la protection des nouveautés."

Mr. Bonnewitz desired that something be done to render assistance in relation to the work of improvement and other matters on Irises. It was decided to ask three French members to consider these questions and correspond with societies abroad. The Conference then closed, after the chairman had thanked all those who had assisted, and he reminded those present of the meeting to be held on June 1.

Messrs. Vilmorin-Andrieux and Co. kindly invited the members of the Conference to pay a visit to their grounds at Verrieres, on May 29, 9 a.m., to see their Iris collections and new varieties as they grow. Most of the French members of the Conference and many of the foreign visitors named above attended and inspected the large field of commercial varieties; another plot where new varieties are grown, some of them not yet in commerce; the collection of about 400 varieties classed both botanically and by colours; and then the trial beds of about one hundred new, home-raised varieties. Most of these new, large flowering Irises were much admired by the visitors on account of their habit, the size or the colour of their flowers. At lunch, much praise and sincere thanks were tendered to Messrs. Vilmorin by M. Bois and by M. Correvois. In the afternoon, visitors interested in trees and shrubs inspected the collection in M. de Vilmorin's park, while others dispersed in the grounds to see other economic or flowering plants. S. M.

### SOCIETE NATIONALE D'HORTICULTURE DE FRANCE.

MAY 26—JUNE 5.—The Spring Show of the French National Horticultural Society took place in Paris, in the greenhouses of the Jardin d'Acclimatation in the Bois de Boulogne. The President of the Republic, M. Millerand, honoured the exhibition by his presence on Saturday, May 27; it had been opened on the previous day by the Minister of Agriculture, M. Chéron.

The large specimen Rhododendrons from Messrs. MOSER, Versailles, and Messrs. CROUX, Chateaufort, which always form one of the attractions of the spring show, were in full beauty, and occupied two sides of the big Palmarium forming two magnificent groups.

As last year, the Orchid Committee had collected all the exhibits of the members into one large group, the name of each exhibitor appearing only on the ticket attached to the plants shown. Several fine specimens were noted, among others *Dendrobium Dahnsonianum*, with flowers of a yellowish tint bearing two purple marks deep in the interior; *Laelio-Cattleya Fudora*, with purple fringed labellum; *L.-C. Hyeana*, with purple labellum; the fine *Cypripedium Rothschildianum*, *Laelio-Cattleya Vilmoreniana* (bright pink), and many others.

The garden section of the Sea-bathing Society at Morocco sent a lovely group of the best specimen plants from their houses, including the gigantic *Asplenium Nidus-avis*, *Platycerium grande*, the beautiful *P. Willinkii* with fine foliage, markedly divided; a splendid specimen of *Nephrolepis Davallioides furcans*, a *Heliconia* with ornamental red foliage, a group of *Anthuriums* and ornamental-leaved *Bromeliads*, *Canistrum Sallieri*, *Cryptanthus zonatus*, a group of *Pandanus* consisting of fine specimens of *P. Sanderiana*, *P. Baptistii*, and others.

M. GABERT, of Paris, and MM. CHATELAIN and GALLIER, of Neuilly, also brought fine collections of ornamental-leaved plants. M. CHANTIER, of Mortefontaine, showed his usual fine collection of *Caladiums*, *Begonia Rex*, and *Codiaeums* (*Crotons*). Among the *Caladiums* were noted *Hortulanum*, with lovely pink centre and

large foliage and Mandabu, the leaves of which are tri-coloured.

Single and double tuberous *Begonias*, with enormous flowers, were shown by M. BILLARD, of the Vésinet, and MM. VALLERAND, of Taverny, who had also a collection of fine *Gloxinias*. *Hydrangeas* were extensively shown, notably a large collection of exceptional merit by Mme. FARGETON, of Angers, containing the finest and newest varieties, such as *Yvonne-Cayeux* and *Maréchal Foch*. Another exhibit, that of M. MOULLIERE, of Vendôme, contained a new variety, *Coquelicot*, a lovely pink. *Hydrangeas* were also shown by M. A. TRUFFAUT, of Versailles, and by Messrs. CROUX, of Chateaufort.

The massed group of zonal *Pelargoniums* of Messrs. POIRIER, Versailles, so marvellous in its colour and regularity of outline, having been absent for several years from these exhibitions, was seen again with the more pleasure. It contained, among other varieties, *M. Poirier*, a pretty mauve pink; *Mlle. Poirier*, pure white; and *Jean Gâtine*, cherry red.

Messrs. VILMORIN, ANDRIEUX and Co.'s exhibit occupied the centre of the show, near the entrance. The general effect was very good, and the arrangement was made with the utmost skill. Besides a very fine exhibit of *Calceolarias*, a beautiful group of *Wallflowers*, as well as *Schizanthus*, *Dimorphothecas* in variety, *Petunias*, *Poppies*, etc., were staged, the whole arranged in separate lots with a border of yellow *Tagetes*. On the bank of the stream, a little group of alpine plants were placed, including *Pinguicula*, *Saxifrages*, *Lewisia*, and *Lotus peliorhynchus*. Crowning the whole were several large vases of cut flowers, such as *Roses*, *Eremurus Eivesii*, and *E. himalaicus*.

In one of the small side houses Messrs. VILMORIN arranged a group of *Sweet Peas*, with *Pyrethrums* and *Poppies*.

MM. CAYEUX and LE CLERC, of Paris, staged a group of annual, biennial and perennial plants, *Schizanthus* and *Clarkias* predominating. M. FERARD, of Paris, had a massed group of the same kind, varied at the four corners by groups of cut Irises and *Sweet Peas*. The same firm also showed, at the entrance of the exhibition, a large rustic scene, furnished with rock plants and various hardy plants, and presenting a very pretty effect. M. LOCHARD, of Paris, showed hardy plants, his group appealing especially to connoisseurs.

*Carnations* were represented by a pretty group staged by MM. VACHEROT and LECOULE, of Boissy-St.-Léger. Their specimens, which bore large flowers, included such varieties as *Agathe Nabonnand* and *Banquise*. M. DEBEAUX, of Lyons, showed English and American varieties, including *Triumph*, red; *Mrs. C. W. Ward*, pink; and *White Enchantress*, pure white.

On the occasion of the Iris Conference, held on Saturday, May 27, at the Society's headquarters in the Rue de Grenelle, the exhibits of Irises were more numerous than usual; one important collection was staged at the Society's office on the day of the Conference.

At the exhibition, MM. CAYEUX and LE CLERC showed a large collection of cut varieties, including *Ma Mie*, white with pale lilac flush; and *Mme. Blanche Pion*, violet with yellow centre. M. MARON, of Brunoy, brought a small collection of hybrids of *Iris Ricardii* raised by M. DENIS, the well known grower, of Balaruc.

Near the water, MM. VILMORIN had arranged some fine spikes of cut flowers of the larger varieties raised by the firm, which are at the present time exceedingly popular, such as *Ambassadeur*, *Magnifica*, *Ballerine* and *Medrano*.

The following varieties were awarded Certificates of Merit by the Iris Committee:—

*Mlle. Schwartz* (F. DENIS). This was included in M. MARON's group, and has large lilac flowers.

*Queen Mary*, with absolutely pure white flowers; shown by MM. CAYEUX and LE CLERC. *Souvenir de Mme. Gaudichaud*, raised by M. MILLET, of Bourg la Reine.

Other varieties were also certificated by the Society during the conference.

Mr. G. WEISS, of St. Cloud, decorated very prettily one of the small side houses with rock

plants judiciously arranged to represent little alpine views. *Nepeta Mussinii*, dwarf Pinks, *Sempervivum*, *Sedum*, etc., were used, the whole flanked by dwarf Japanese trees, including *Larix leptolepis*, *Thuja obtusa*, *Pinus pentapaylla*, and *Zelkova Keaki*.

Roses were represented by several groups of importance. M. M. MOSER, of Versailles, brought a lovely collection of dwarf Roses, some climbing varieties, and standards; Miss Edith Cavell, a red dwarf, and Verdun, blood-red, were included. M. DEFRESNE, of Vitry, showed a fine collection of climbing Roses, including *Hiawatha* and *Dorothy Perkins*.

M. LEVEQUE, of Ivry, showed a collection of 300 standard Roses, grouped together and bordered by dwarf varieties, such as *Jean Forestier*, bright red. M. A. TRUFFAUT, of Versailles, showed a collection of pot plants, chiefly climbing *Wichuriana* Roses, in a group in the centre of the Palmarium; also a fine example of *Metrosideros florida*, with its curious and interesting red flowers. M. NONIN, of Châtillon sous Bagneux, showed a small group of Roses on a base of turf, including *Souvenir de Claudius Pernet*, bright yellow; *Châtillon-Rose*; and *Paul's Scarlet Climber*.

The landscape gardening department of M. MOSER'S firm showed a very beautiful modern garden scene with a fountain, pergola, grass walks, Rose-entwined pillars, and flowering *Rhododendrons*. Conifers were represented by fine specimens in the exhibits of Messrs. LECOLIER and THUILLANT, of La Celle St. Cloud; and Messrs. CROUX had also a creditable group of chipped Yews.

Fruit trees were represented by the usual, and always faultless, exhibit of Messrs. NOXBLOT, of Bourg la Reine. M. PARENT, of Rueil, showed a large display-window filled with appetising forced fruits, as well as trees in pots in full fruit, including Cherries, Plums and Apples.

The exhibit of vegetables of Messrs. VILMORIN was as varied and as well displayed as usual, and bordered two sides of the firm's floral display. THE GARDENERS' MUTUAL AID SOCIETY of the Seine also showed a well-assorted collection. Messrs. VILMORIN showed their collection of artificial vegetables, so cleverly reproduced that even the weights exactly corresponded to the originals.

THE SYNDICAL CHAMBER OF FLORISTS showed a collective group, entitled "A Century of Floral Art," in which the stiff and formal bouquets of 1830 were contrasted with the much prettier graceful bouquets of the present day.

Landscape gardening was worthily represented by numerous garden designs, showing work both finished and still in execution by the most prominent French garden architects. Sundry industries more or less connected with horticulture were grouped together, and consisted of a number of exhibits of great interest, among which were the small horticultural ploughs of Dr. ARTAUD and MM. HENNEQUIN and FOUCARD.

New plants were comparatively numerous; in addition to the Irises already referred to. Certificates of Merit were awarded to:—

*Croton (Codiacum)* M. André Thiébaud; *Caladium l'Etendard*, and *Caladium Dr. Marcas*, all shown by M. CHANTIER, of Morte-fontaine.

M. G. MORIN, of La Rochelle, brought three interesting Oleanders: *Botaniste Faydeau*, with pinkish white flowers, shaped like a *Camellia*; *Rochelais*, a single pink variety of pretty form; and *Aunissieu*, double pink, very floriferous. The two varieties last named received awards previously.

The chief Grand Prix d'Honneur was awarded to Messrs. VILMORIN-ANDRIEU ET C<sup>IE</sup>, for their exhibits, and the second Grand Prix to M. M. MOSER, of Versailles, for their *Rhododendrons*, *Roses*, and modern garden design.

#### BATH AND WEST SOUTHERN COUNTIES.

How closely agriculture is allied to horticulture was demonstrated at Plymouth at the show held from June 1 to 6. For many years one of the chief attractions of one of the finest agricul-

tural shows in the country has been the horticultural tent.

In choosing a superintendent for the section the executive was fortunate in the selection, for in the Rev. A. T. BOSCAWEN they secured not only one of the most celebrated gardeners of the West Country, but also an organiser whose arrangements ran absolutely smoothly and with a total absence of red tape.

Just as west country gardening is more varied than elsewhere, so, too, are the flower shows held there more varied than in other parts of the country, despite the fact that the majority of exhibitors came from "up country."

No awards are made in this exhibition, which may, perhaps, explain the lack of private exhibits.

In the group from Messrs. R. VEITCH AND SON, plants and trees which thrive in the open predominated. One of the most interesting of these was *Davidia involucreta*, with leaves resembling the common Lime tree, but carrying its inflorescence contained in a white spathe 6 or 7 inches long. *Ixia viridiflora* provided its interesting green flower, while the gorgeous *Embothrium coccineum* represented one of the popular flowering shrubs of the south-west. *Callistemon* (known here, as elsewhere, under the popular but incorrect name of *Metrosideros*) was represented by the scarce alba form, while *Eremuri* and the now rare *Witsenia corymbosa*, with intensely blue flowers, indicate the very varied nature of this group.

Messrs. CHALICE AND SON, of Plympton, also exhibited an interesting group, such as would have delighted old plantsmen; the plants included the graceful *Aotus gracillima*, *Callistemons*, *Ericas* and *Crinodendron Hookeri*, which thrive so well and make large shrubs in Devon and Cornwall.

From the Dartmoor Nurseries of Messrs. BRAY, Okehampton, came some unusually well-flowered *Rhododendrons* which, arranged in a bank, were of exceptional merit. It may be assumed that the exposed situation of these nurseries accounts for the fine substance and size of the flowers, which had not suffered from the recent heat. Rock gardens of modest dimensions which, however, did not detract from the keen interest displayed in them, were set up by Messrs. MAXWELL AND BEALE, also by Messrs. BOWLES AND SKARRATT, of Cheltenham.

Delphiniums from Messrs. BLACKMORE AND LANGDON, of Bath, like their *Begonias*, were exquisite. Millicent Blackmore has huge spikes of sky blue flowers, paler than *Eva*, another of the best. *Queen of Bath* is one of the largest of all single Delphiniums, while General Sir Douglas Haig is also fine. Their *Begonias* are well known for superb finish, but Mrs. Brunton is a salmon variety hard to beat, and *Rose Queen* a lovely shade of rose pink.

The only Sweet Peas in the show came from Mr. J. STEVENSON, of Wimborne; *Poppy*, orange, stands the sun well; *Wild Rose*, salmon old rose, and *Cynthia*, pale lavender, were good and the latter retained the much desired perfume sometimes lacking in otherwise beautiful varieties.

Pelargoniums of Show and Regal types were exhibited by Mr. W. J. GOFFRY, Exmouth, who is among the few now left with good collections of these plants.

THE DEVON ROSERY, Torquay, sent Carnations in pots, well-flowered *Roses*. *Rhododendrons*, pink, white and blue *Hydrangeas*, etc. Messrs. BAKERS, of Wolverhampton, sent their *Sunbeam Poppies*, arranged with a group of *Trollis Goldquelle*. As a useful subject to come between the last of the Tulips and the blaze of later June flowers, nothing excels the *Pvretberums* and *Lupines*, and a very tastily arranged exhibit of these was put up by Mr. W. F. GULLICK, of Salisbury. Messrs. JARMAN, of Chard, sent choice varieties of *Zonal Pelargoniums*, and a few *Roses* conspicuous among the latter being the new yellow *Souv. de C. Pernet Ducher*. Their annual *Centaureas* never fail to attract attention.

Herbaceous plants from Messrs. R. WALLACE AND Co., Tunbridge Wells, were rich in Iris: among deep mauves, Mrs. G. F. Tinley and

*Alcazar* were the best, while *Drake* is a fine shade of lavender; *Lilium regale* is worthy of more attention, and can be flowered in two years from seed. Some fine spikes of *Eremuri* were included among other good things. Messrs. RICH AND Co., Bath, also showed herbaceous plants, represented by *Ppethrums*, *Lupins* and *Heucheras*.

Roses arranged in the beautiful style so well known to visitors to shows, came from Messrs. Wm. CUTBUSH AND SON, who also included some intensely blue *Hydrangeas* that contrasted with the pink, white and red polyantha *Roses*. If only exhibitors learnt the lesson so well demonstrated here of carrying parts of their groups higher than others, with a low groundwork of flowers or foliage, instead of the eternal banks and pyramids of flowers, all shows would be more interesting.

Vegetables, associated with Spanish Irises and *Roses* were arranged by Messrs. TOOGOOD, Southampton; while Messrs. J. CARTER AND Co., Raynes Park, also displayed a choice group in their inimitable way.

A bank of cool-looking Ferns in choice varieties was staged by Messrs. ELLISON, West Bromwich.

Carnations from Messrs. ALLWOOD BROS. had stood the long journey well. They specialised in their *Dianthus Alwoodii*, which can be very prettily arranged in baskets and bowls, as on this occasion. That Carnations can be packed to withstand the heat was also demonstrated in the group from Messrs. STUART LOW AND Co., Enfield, their *White Pearl* and *Eileen Low* having travelled hundreds of miles without blemish.

Although the border of the county of Cornwall was but a couple of miles away, the Duchy was represented by only one exhibit, and this consisted of a number of *Cinerarias* from Mr. H. HODGE, St. Austell.

Messrs. REAMSBOTTOM'S *Anemones* were represented in the right spot, for these showy plants revel in the soil and climate of Devon.

The end of the large tent was filled with *Rhododendrons* from Messrs. WATERER, SONS, AND CRISP; their group contained a quantity of plants brought from far away Bagshot; *Corona*, *Bagshot Beauty* and *Lady Walsh* were among the best, and the whole group was set off by clumps of *Kalmia latifolia*.

Devon, while one of the finest counties of England for gardening, is not so well developed as some other parts, so that its possibilities make it an interesting portion of the country.

#### ROYAL HORTICULTURAL.

JUNE 7 AND 8.—Although following so closely upon Chelsea show, and coming so quickly after Whit Monday, the meeting held at Vincent Square on Wednesday was a great success, the hall being filled with exhibits. There was also a good attendance and a considerable display of novelties. Irises were especially well shown, but owing to the recent hot weather many of the flowers were past their best and many fine varieties were over and could not be represented. *Lupins* were also splendidly shown, and Mr. ELLIOTT'S sweetly scented strain attracted well-merited attention.

#### Orchid Committee.

*Present*: Sir Jeremiah Colman, Bart. (in the chair), Prince Shimadzu, Messrs. Jas. O'Brien (hon. secretary), Pantia Ralli, Gurney Wilson, H. T. Pitt, Chas. H. Curtis, and Frederick J. Hanbury.

#### FIRST-CLASS CERTIFICATE.

*Odontonia Mrape var. vivicans (Miltonia Bleuana) × Od. illustrissimum*, from Messrs. CHARLESWORTH AND Co., Haywards Heath. A charming addition to the famous section of *Odontonia* raised by this firm. The seedling plant, flowering for the first time, bore one large bloom which in form resembles most the *Miltonia* parent. The broad sepals and petals are coloured mauve, with a red shade in the centre; the circular, flatly arranged lip is rosy-mauve with a small red mask in front of the yellow crest.

## GROUPS.

Messrs. CHARLESWORTH AND Co. were awarded a Silver Flora Medal for a showy group, in which their grand strain of *Laelio-Cattleya Canhamiana* was represented by five superb specimens, the largest bearing sixteen blooms; *L.-C. Benita* alba had large white flowers, and another variety of it pink veining on the lip. *Brasso-Cattleya Digbyano-Mossiae*, with seven fine flowers, well represented one of the best forms. A fine selection of *Odontoglossums*, *Miltonias* and the Yellow *Brasso-Laelio-Cattleya Joan* were also shown.

H. T. PITT, Esq., Rosslyn, Stamford Hill (gr. Mr. Thurgood), was awarded a Silver Banksian Medal for a good group, which included many fine forms of *Odontoglossum crispum*, such as *Pittianum*, *Ivanhoe*, and *Oakfield Sunrise*. Among hybrid *Odontoglossums*, *Odm. Pomerens* var. *Princess Mary*, is a noble flower, heavily blotched with claret-red. A good selection of rare species was also included in this exhibit.

Messrs. FLOREY AND BLACK, Slough, were awarded a Bronze Banksian Medal for a small selection of exceptionally interesting hybrids. The hybrids of *Cattleya Tityus*, including *C. D. M. Lacroze* (*Octavo Poin* × *Tityus*); *C. Heatherwood* (*Mossiae* × *Tityus*) and *C. G. P. Walker* (*Mendellii* × *Tityus*) all promising crosses with their first flowers, proved the wisdom of the parentage. A large blush-white *Laelio-Cattleya*, *Fascinator-Mossiae* delicata, and good white *Cattleyas*, were also shown by this firm.

Messrs. HASSALL AND Co., Southgate, showed their new *Cattleya Everest* (*Mossiae Wagneri* × *Magali Sander*), a very fine white variety of true *Cattleya* form and with good substance.

## Floral Committee.

Present: Mr. H. B. May (in the chair), Mr. G. Reuthe, Mr. J. W. Barr, Mr. John Heal, Mr. C. R. Fielder, Mr. W. Howe, Mr. W. B. Gingell, Mr. Thos. Stevenson, Mr. W. P. Thomson, Mr. Chas. E. Shea, Mr. Chas. E. Pearson, Mr. A. G. Jackman, Mr. Arthur Turner, Mr. Donald Allan, Mr. J. Jennings and Mr. Amos Perry.

## AWARDS OF MERIT.

*Mimulus luteus flore pleno*.—This showy golden yellow, tree-flowering variety has hose-in-hose flowers, and this duplication of the corolla—or rather a golden calyx at the base of the flower—adds greatly to the effectiveness of the plant as seen in the mass. The corolla has a few deep red spots. Shown by Messrs B. LATHAMS, Southampton.

*Gloxinia Bacchus*.—A distinct and novel variety, with large, finely-formed flowers of the deepest crimson colour, shaded with deep purple towards the margins of the overlapping corolla lobes. Shown by Messrs. BLACKMORE AND LANGDON.

*Papaver orientale Thora Perry*.—A pigmy form, with neat silvery-white flowers and a central boss of blackish crimson stamens. Shown by Mr. AMOS PERRY, Enfield.

*Potentilla fruticosa var. Farreri*. A beautiful little plant of dense, shrubby habit and carrying a profusion of clear golden yellow flowers. Shown by Mr. AMOS PERRY.

*Iris ochracea caerulea*.—In this charming variety the standards are bright copper colour and the semi-horizontal falls are yellow based, with brown reticulations, while the blade is dull blue, shading to copper. Raised by M. Denis, of Balaruc/les-Bains. Shown by W. R. DYKES, Esq.

*Begonia Lady Bell*.—A magnificent double *Begonia*, with broad, substantial segments, prettily frilled at the margins and making up a finely formed flower. The colour is deep cream, but the margins are soft orange, and there is pale orange shading on the outer segments. Shown by Messrs. BLACKMORE AND LANGDON.

*Dianthus Mascott*.—This sturdy hybrid is very much like a large-flowered Sweet William, and it has a somewhat stiff habit, but the inflorescence is looser and more elegant. The lightly scented fringed flowers are a lovely deep pink colour, with paler eye, and measure about 1½ in.

across. This new *Dianthus* is the result of crossing Sweet William Scarlet Beauty with a single Carnation, and if it proves amenable to cultivation it cannot fail to become a popular garden plant. Shown by Messrs. IRELAND AND HITCHCOCK, Marks Tey.

*Iris Citronella*.—The broad light yellow standards and crimson falls, marked with yellow make this golden-bearded *Iris* very attractive. Shown by Messrs. R. WALLACE AND Co., Tunbridge Wells.

*Pyrethrum Eileen May Robinson*.—This delightful single variety, has two or three rows of florets of a charming shade of pale pink, tinted with silvery mauve. Shown by H. ROBINSON, Esq., Burbage, Hinckley, Leicestershire.

*Lupinus polyphyllus, Six Hills Strain*.—Pleasant fragrant is always appreciated in flowers, consequently this new strain of Lupins, sweetly scented and of good form and varied colours, was greatly admired. There is no doubt the Six Hills strain will enjoy great popularity. Shown by Mr. CLARENCE ELLIOTT, Six Hills Nursery, Stevenage.

## OTHER NOVELTIES.

The Hon. VICARY GIBBS (gr., Mr. E. Beckett) showed the interesting yellowish-green *Enonymus Wilsonii*, which, we understand, makes an effective bush; with the same exhibitor came *Catalpa Fargesii*, with pink flowers mottled yellow in the throat. This latter species was discovered by Pere Farges, and introduced in 1907 by Mr. E. H. WILSON.

Mr. MILLER, Wisbech, exhibited spikes of the graceful, small-flowered, pink, fragrant *Syringa Wilsonae*; and SIR WM. LAWRENCE, Burford Lodge, Dorking, sent several vases of the lovely blue *Lathyrus pubescens*, a free-flowering perennial species.

## GROUPS.

Messrs. BARR AND SONS made excellent use of low staging to display a great variety of *Irises* at a convenient level. The arrangement was deserving of high praise. A wide range of varieties, illustrating most of the sections, was shown. The fascinating *Iris squallens* type included *La Reve*, *Mary Garden*, *Eldorado*, *Quaker Lady*, and *Arnolds*. Of the pallida type, *Albert Victor*, *Crepuscle*, and *dalmatica* *Princess Beatrice* were unusually good. *Iris Lovely*, *Fro* and *Mithras* of the variegated type, *Madame Chereau* (plicated), and *Willie Barr* and *Monsignor* (neglecta) were also very beautiful. At the end of the collection there were vases of *Iris xiphium* in good varieties, and *Ixias*, such as *I. Humbert* and *Scarlet and Gold* (Gold Medal).

A large collection of *Irises* was displayed by Messrs. WALLACE AND Co. These were mostly of the pallida and squallens types and included many very beautiful varieties. *Ambigua*, reddish-claret and maroon; *M. Boyer*, slatey-purple standard, rosy-purple falls; *Isoline*, lavender blush, and rosy-lavender falls; *Souvenir de Madame Gaudichau*, deep velvety blue shades; *Cardinal* and *Ballore*, white with few lilac lines, are the names of only a few of the many excellent varieties to be seen (Gold Medal and congratulations).

A great variety of beautiful *Irises*, rising from excellent specimens of hardy Ferns, was arranged by Mr. AMOS PERRY. There were many beautiful seedlings, particularly of the pallida and squallens sections, and also such minor sorts as *Prosper Langier*, *Robert Wallace*, *Standard Bearer*, *King of Iris* and *variegata alba*. Altogether a striking collection of admirable *Irises* and cool, green hardy Ferns of equally high merit (Gold Medal).

A handsome bank of *Irises* was arranged by Messrs. J. G. WHITELEGG AND Co. Of the very many excellent sorts we selected the following as being typical of the collection: *Mrs. Neubronner*, yellow; *Iris King*, yellow and carmine bronze; *Tamar*, shades of lavender; *Queen Mary*, white; and *Prince of Orange* (Silver-gilt Flora Medal). On a floor space, Messrs. WATERER, SONS, AND CRISP had a well arranged group of *Irises*, *Lupinus* and *Delphiniums*. Amongst the *Irises* were *Fro*, golden yellow and bronze; *Isoline*, pale shades of purple; *Edward*

*Michel royal purple*; and *Princess dainty lilac blush*. A mass of *Lupinus Sansone* *Delphiniums*, *Anchusas* and *Eremurus* all added to the attractions of the exhibit (Silver-gilt Banksian Medal).

Such *Irises* as *Prosper Langier*, *Dora Langden*, *Eldorado* and *Camelot*, the latter a Bliss seedling of milk-white colour, lightly feathered with pale lavender, were shown by Messrs. LOWE AND GIBSON (Silver Flora Medal). A small collection of *Irises*, raised from *tingitana* crossed with Spanish varieties, was staged by Messrs. F. H. CHAPMAN, LTD. These *Rotherside Irises* have much the appearance of the smaller Dutch varieties, but are rather larger, and a goodly proportion bear twin-flowers (Silver Flora Medal).

An attractive collection of Dutch *Irises* was arranged by Messrs. RYDER AND SON, LTD. Of the blue shades, *E. B. Garnier* and *Imperator* were very beautiful, while amongst the white sorts which have a yellow blotch we noted *D. Haring*, *A. L. Koster*, and *White Excelsior*. *Golden Glory* and *Yellow Queen* were also very effective (Silver Banksian Medal). A collection of *Irises* arranged by Messrs. G. BUNYARD AND Co. was very strong in the squallens section, and these included beautiful spikes of *Darius*, *Madame Patti*, *Hector*, *Honourable*, and *Robert Burns*. Other desirable varieties were *Cordelia*, *Prosper Langier*, *Incogene*, and *Rhein Nixe* (Silver Flora Medal).

A small collection of excellent tuberous-rooted *Begenias* arranged by Messrs. R. BASTIN AND SON included *Lady Bell* (creamy white heavily edged with buff orange), *Mrs. W. Wilson*, *Enchantress*, and *Pride of Bexley*. Rising above these were floriferous plants of such basket sorts as *Glady's*, *Mrs. Bilkey*, and *Fleur de Chrysantheme* (Silver Banksian Medal). Collections of fresh and good *Carnations* were arranged by Mr. C. ENGELMANN and Messrs. ALLWOOD BROS. The latter included many vases of their *Dianthus Allwoodii* (Silver Banksian Medals).

A splendid collection of Sweet Peas was arranged by Messrs. R. BOLTON AND SON. The flowers were individually large, and usually the graceful stems bore five or six blooms. *Comrade*, a new sort of Picture type, but flush rose colour; *Elsie Dean*, silvery lavender self; *Wonderful*, glowing scarlet and said to be quite sun-proof; *Artistry*, a greatly improved *Princess Mary* and *Orange Flame*, a vivid fiery orange, are the names of some of the new sorts so well shown, but there were a great many standard varieties of equal merit (Silver-gilt Flora Medal).

Just inside the entrance Messrs. DOBBIE AND Co. set up a magnificent collection of *Antirrhinums*. These were all in large vases of named sorts, and made a memorable display, illustrating excellent strains and skilful cultivation. A vase of the striped *Antirrhinum* which are grown so largely for exhibition in the North, attracted a deal of attention, but most of the visitors preferred such as *Maize Queen Fascination* (pink), *Nobile* (a delicately beautiful white flower with a rosy crimson blotch), *Carmine Queen*, *Yellow King*, *White Beauty*, *Cocinea*, *Mauve Queen*, and *Prima Donna* (Silver-gilt Flora Medal).

An excellent strain of large-flowered *Streptocarpus* was shown by Messrs. JOHN PEED AND SON. Not only were the flowers very large, but they were freely produced, making a splendid display. Of the many colours, the deep rose, lavender, pale rosy mauve and white lined with purple were, perhaps, the most effective. Adjoining the *Streptocarpus* were some equally well-grown plants of double pink, double blue and white *Petunias*. (Silver Banksian Medal.)

Richly-coloured yellow *Roses* were exhibited by the Rev. J. H. PEMBERTON (Silver Banksian Medal), and Mr. GEORGE PRINCE (Silver Banksian Medal). Both showed graceful sprays of *Persian Yellow* and *Star of Persia*, while the former included a fine vase of *Rosa grandiflora*, and in Mr. Prince's stand were branches of *R. Mowet*, *Pax* and *Irish Elegance*. *Rhododendron Watsonii*, *R. parviflora* and *Michelia fuscata* were prominent in the exhibit of uncommon trees and

shrubs shown by Mr. G. REUTHE. He also had many Rhododendrons and Azaleas and also Irises and *Habranthus pratensis* tugens. (Bronze Flora Medal.)

A long row of spikes of fragrant *Lupinus polyphyllus* seedlings of great merit was shown by Mr. CLARENCE ELLIOTT, who also had an interesting collection of alpine amongst which such Pinks as *arvensis alba*, *neglectus* and a South Lodge cross were very prominent. (Silver gilt Banksian Medal.) A fairly extensive collection of *Lupinus*, also *polyphyllus* seedlings, was shown by Mr. J. R. DOWNER. These were all very robust and well flowered. The central mass of Delight, of terra cotta shades, was strikingly effective, while the vases of Pink Delight were quite charming. (Silver Flora Medal.)

A corner space was splendidly filled with excellent spikes of *Delphinium* by Messrs. BLAEMORE AND LANGDON. The dark blue sorts included Lamartine, Walter T. Ware, and the white-centred Rev. E. Lascelles, while amongst those of pale blue shades were Queen Mary, Queen of Bath, and Lizzie van Veen. (Silver-gilt Banksian Medal.)

Under the clock Mr. W. F. GULLICK displayed many vases of desirable *Pyrethrum*. The single-flowered varieties included Langport Scarlet, James Kelway, Hamlet, and General French, while amongst the doubles were Queen Mary, White Queen, J. N. Tiverdy, and Old Rose. (Bronze Flora Medal.)

Mr. M. PRICHARD contributed a goodly collection of Irises, *Lupinus*, *Heucheras*, *Pyrethrum*, and garden Pinks. *Ajuga Brockbankii*, bearing many compact spikes of deep blue flowers, was also very effective. (Silver Flora Medal.)

Various Alpines, with dwarf border flowers, were shown by Mr. F. C. WOOD, who had good *Geums*, *Lupinus* and *Erigerons*. (Bronze Flora Medal.) Messrs. MAXWELL AND BEALE showed *Lavendula strechas*, *Chenopodium speciosa rosea*, and a few interesting *Mesembryanthemums*. (Bronze Flora Medal.) Messrs. W. H. ROGERS AND SONS, LTD., had floriferous sprays of *Embothrium coccineum*, *Lithospermums* in variety, with *Primulas*, garden Pinks, and *Verbena chamaedriodes*. (Silver Banksian Medal.)

Collections of border flowers were contributed by Messrs. W. WELLS, junr., who had good Irises, *Pyrethrum*, Oriental Poppies and *Dictamnus fraxinella* (Silver Banksian Medal). Messrs. RICH AND CO. showed *Gaillardias*, *Chrysanthemum maximum* varieties, Irises, with dwarf *Phloxes* (Bronze Banksian Medal); and the Misses HOPKINS had a neat little rock garden. A collection of Messrs. KELWAY'S *Paeonies* attracted a deal of attention. The single-flowered sorts included Princess, blush-pink; Sea Shell, shell-pink; Mrs. Richmond, deep pink; and Duchess of Sutherland, white (Silver Banksian Medal).

Garden Pinks of great fascination and delicate fragrance were shown by Messrs. B. LADHAMS, LTD., along the front of a considerable collection of such border flowers as *Polygonum bistorta superba*, *Lihertia formosa nivea*, *Veronica Shirley Blue*, various coloured *Pyrethrum* and *Mimulus* (Silver Banksian Medal). A particularly interesting and attractive collection of *Aquilegia* seedlings was exhibited by V. C. VICANS, Esq. (gr. Mr. W. Watkins), Newsells Park, Royston. We learnt that these 60 varieties were the result of eight years' work in hybridising and selecting, and that some 9,000 plants are grown. The flowers illustrated an excellent strain of large-flowered, long-spurred *Columbines*. Of the many beautiful shades of colour, the most striking were the soft pink, rich yellow, rose and yellow, and the various shades of lavender and white (Bronze Flora Medal).

An interesting selection of *Heucheras* was included by Mr. J. W. MILLER in a collection of border flowers. Trevor Red, Trevor Pink, Walkeri, deep scarlet and the graceful pale rose *Tiarellodes* were all very beautiful. *Pyrethrum*, *Paeonies* and Oriental Poppies of merit were also exhibited. (Bronze Flora Medal.)

An attractive collection of such hardy shrubs as *Kalmia latifolia*, *Rhododendrons*, *Azaleas*, *Robinia Kelsey* and *R. hispida macrophylla* was

arranged by Messrs. J. CHEAL AND SONS, who also showed an interesting little collection of Star and Colletterte Dahlias. (Silver Banksian Medal.)

Amongst the many interesting shrubs shown by Mr. CHARLES TURNER was a fruiting spray of *Ochna multiflora*, bearing quantities of purple berries set on the scarlet star shaped calyces. *Deutzia hybrid* Lemoinei is an excellent little variety for similar purposes to those which *D. gracilis* is put but of superior merit. *D. Lemoinei* Bob Rose, *Syringa Sweginzowii superba* S. Emodi, *Magnolia hypoleuca*, bearing fragrant flowers, and several varieties of *Philedelphus* were also of interest. (Silver Banksian Medal.)

In the centre of a small collection of interesting shrubs Messrs. HILLER AND SONS had a good batch of *Cistus purpureus*. Other shrubs included *Cistus immaculatus*, *Robinia Kelsey*, and *Solanum crispum*.

#### COMPETITIVE IRIS CLASSES.

These exhibits were arranged at one end of the Orchid annex. Owing to the difficulties of the season, there were not so many competitors as had been hoped. The first prizes for one spike each of three seedlings and one single spike were won by Mr. A. J. BLISS. Only two of his three spikes were on view, and these were Wazi and Citronella. The latter is a most beautiful flower of squelens type, the falls are heavily lined and flushed with carmine. The single spike was of Bruno, a tall inflorescence of rich purple flowers.

The best three spikes of one seedling were of Chasseur, shown by Messrs. VILMORIN-ANDRIEUX AND Co. This is almost a soft yellow flower, paler on the falls and with rosy carmine at the base.

The prize offered by the American Iris Society for the best collection of 12 varieties in commerce resulted in a good competition, and was won by Messrs. WALLACE AND Co. with good snakes of such sorts as Prospero, Edward Michell, Ma Mie, Medrano, and Isoline.

In view of the Iris Conference, a great many spikes of bloom were brought from Wisley to illustrate the scheme of classification which is now being evolved.

#### Fruit and Vegetable Committee.

Present: Messrs. C. G. A. Nix (chairman), J. Cheal, G. Berry, Geo. F. Tinley, S. B. Dicks, E. Beckett, W. Poupert, J. C. Allgrove, H. Markham, P. D. Tuckett, W. Wilks, E. A. Bunyard and Owen Thomas.

There was no exhibit before this committee, but the awards to spring Cabbages recommended by the sub-committee, after trial at Wisley, were confirmed. The varieties, Ellam's Dwarf Early Spring, Early Feltham and First Early Market were recommended to receive Awards of Merit.

### Obituary.

Dr. William Carruthers.—By the death of Dr. William Carruthers, Ph.D., F.R.S., botany loses one of its most distinguished members, and one whose knowledge of the literary of botany was probably unsurpassed. He died at Norwood on the 2nd inst., in his ninety-third year. He was a native of Moffat, Dumfriesshire, and was educated for the Presbyterian ministry, but his interest in science led him to devote his life's work to geology and botany. When Robert Brown died in 1859, Carruthers was appointed an assistant in the department of botany in the British Museum, and in 1871 he became head of his department. He was for many years consulting botanist of the Royal Agricultural Society of England, and amongst his other activities he was president of the Glotologists Association, the Linnean Society, during its centenary, the Royal Microscopical Society, and of the Biological Section of the British Association. But he will be remembered chiefly for the work he did in connection with the acquiring of the famous botanical library which exists at the British Museum. To Carruthers

we probably owe the testing of seeds in this country to determine their germination capacity, for when he began seed testing in 1871 it was a new thing in England. His work on the observations on the vitality of farm seeds, and especially on the purity and germination of grass seeds, was of very great importance, and will always be regarded as pioneer work in this direction.

Hugh Dickson.—We very deeply regret to learn of the untimely death of Mr. Hugh Dickson, of Messrs. Hugh Dickson, Ltd., Rose growers, Royal Nurseries, Belfast, which took place at Leeds on the 30th ult., following a severe operation. Mr. Hugh Dickson was well known in the horticultural world, and particularly among rosarians, and not only was he a clever cultivator and exhibitor of Roses, but also one of the foremost of raisers, as shown by the fact that his firm received numerous awards from the National Rose Society. A few of the varieties which have emanated from the Royal Nurseries, Belfast, include Blushing Bride, Ethel Dickson, Nellie Parker, Prince Charming, Golden Spray, H. D. M. Barton, H. K. Pinkerton, Lilian Moore, Lady Craig, W. E. Wallace, Leslie Pidgeon, Earl Haig, E. Godfrey Brown, and the famous crimson-scarlet, Hugh Dickson.

### ANSWERS TO CORRESPONDENTS.

CLUB-ROOT IN BRASSICAS: J. T. W. The swollen roots in your Brassicas may be caused either by Finger-and-toe disease or the grub of the Cabbage-gall weevil. You could easily determine if the latter is responsible by cutting open the gall and seeing if the grub of the insect is present. Lime and sulphur are the best remedies for Finger-and-toe disease.

EELWORM IN CARNATIONS: J. T. W. The Carnations are affected with eelworm. No cure can be adopted for this pest, and plants that are affected should be destroyed by burning. The soil in which your Carnations are grown should be sterilised in future, either by the hot-water treatment or by baking.

FASCIATED TULIP: G. W. C. The variety of Tulip is *La Tulipe Noire*, and we have heard of other cases of fasciation in this Tulip this year, resulting in more than one flower on the stem. It is probably due to the abnormal weather of last summer.

NAME OF PLANTS: D. H. D. 1, Probably *Spiraea Thunbergii* (poor specimen); 2, *Epidendrum elongatum*; 3, *Spiraea arguta*; 4, *Magnolia stellata Ficus*. 1, *Berberis Darwinii*; 2, *B. stenophylla*; 3, *Ficus semper-virens*; 4, *Geranium* sp.; 5, *Spiraea prunifolia* var. *flore pleno*; 6, *Cupressus pisifera* var. *squarrosa*.—A. S. 1, *Acer circinatum*; 2, *Pyrus Sorbus*; 3, *Pyrus Aria*.—A. B. H. *Berberis Hookeri*.—W. D. *Paulonia imperialis*.—H. W. R. *Cornus florida*.

PEACH LEAVES DISEASED: J. T. A "shot-hole" fungus is present. A weak lime sulphur solution (1 part of the concentrate to 99 parts of water) would probably be the best specific to use.

PEACH MILDEW: N. H. N. The Peach leaves should be dusted with flowers of sulphur whilst they are damp. In cases of very bad attacks the water-pipes should be made very hot and then painted with sulphur. This is best done just before it is dusk, in order that the house may be closed for an hour or two whilst the sulphur fumes are being given off. See that the roots of the trees are not growing in a dry medium, for drought is one of the principal predisposing causes of mildew.

TULIPS EATEN: J. T. The Tulips have been bitten by rats or mice, which are very fond of both the bulb and the plant. Moles are also supposed to do similar damage. Traps should be set or poison be laid down to destroy the animals.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 58.6.

**ACTUAL TEMPERATURE:—**

Gardeners' Chronicle Office, 5, Tavistock Street, Covent Garden, London, Wednesday, June 14, 10 a.m. Bar. 30.1; temp. 54°. Weather—Cloudy.

It is a well-known fact that certain micro-organisms **Parasites**, which give rise to disease in plants may live either as saprophytes or as parasites, that is, may increase and multiply whilst living either on dead organic matter or on living plants. It is probable that many wound parasites are of this nature. They get a hold of a plant by gaining access to the dead tissues of a wound and then spread into the living tissues. Such fungous or bacterial pests are known as facultative parasites in contradistinction with obligate parasites, that is, those which live on living tissues only. There is an intermediate class of parasitic fungi which may live on dead and may destroy living plants; but which exhibit the peculiar property of first destroying the living tissue, apparently by the excretion of a toxic substance and then invading it. The wide spread fungus, *Botrytis cinerea*, is generally regarded as an example of this class of pest, and numerous researches have been made with the object of discovering the nature of its poisonous excretion. Some of these researches indicate that oxalic acid is the poison which the fungus uses to destroy the tissues on which it subsequently feeds. Recent observations made by Mr. W. Gleisberg\* and summarised in the *Review of Applied Mycology* (Vol. 1, Part 1), issued by the Imperial Bureau of Mycology, confirm, in an interesting manner, the view that *Botrytis cinerea* passes readily from the saprophytic to the parasitic state. Certain

*Primulas*—*P. cashmeriana*, *P. Veitchii*, and *P. veris*, were observed to have sharply defined brown spots on their leaves. Examination of the spots showed that they were covered with the decaying blossoms of a *Robinia Pseud-acacia* growing near by. By means of the microscope the spore producing hyphae (conidiophores) of *Botrytis cinerea* were seen emerging in bundles from the under sides of the spots of the *Primula* leaves. Similar spots were observed on Elm and Dandelion leaves on which Elm seeds had fallen. Hence it is to be concluded that *Botrytis* finds a quick means of propagating itself in the debris of vegetation from which it may spread and as a parasite attack living tissues. Evidently no means can generally be taken to prevent this means of dissemination of parasitic fungi; but at all events one important lesson may be drawn from the facts and applied in every garden and, that is, to ensure the rapid and orderly decay of dead vegetable and animal matter by consigning it to the compost heap and so ensuring that the majority of parasitic fungi are destroyed. Needless to say, where the debris consists of remains of diseased plants the bonfire and not the compost heap is its proper destination.

**Royal Horticultural Society's Next Meeting.**—

We draw the attention of our readers to the interval of nearly three weeks which occurs between the Whitsuntide meeting of the Royal Horticultural Society and the next exhibition. It will be remembered that the Whit-week meeting was held on Wednesday and Thursday, June 7 and 8, instead of opening as usual on a Tuesday. The next meeting and exhibition will be held on June 27 and 28, when there will be a competition for the Clay Challenge Cup, which is offered by Messrs. Clay and Son for the best new Rose of good form and colour possessing the true old Rose scent. The cup has been awarded previously to Messrs. Wm. Paul and Sons for Queen of Fragrance, in 1914, to Messrs. F. Cant and Sons, for Colcestrina, in 1915, and to Messrs. W. Easlea and Sons for Prince of Wales in 1921. During the afternoon of the opening day Mr. E. A. Bowles will lecture on "Plants of interest from his garden."

**National Chrysanthemum Society's Outing.**—

After a lapse of several years the National Chrysanthemum Society is reviving its annual outing. By kind permission of Sir William Cain the gardens at Wargrave Manor will be visited during the latter part of the week ending July 1, and the trip thereto will be by train from Paddington to Bourne End, and by steam launch from Bourne End to Wargrave. Lunch will be taken on arrival at Wargrave and tea just previous to the return journey. Members of the society are requested to notify the secretary, Mr. C. H. Curtis, 5, Tavistock Street, Covent Garden, as early as possible of their intention to take part in the outing.

**New Public Recreation Grounds.**—A new public recreation ground at Lowestoft was formally opened by the Mayor, Alderman Humphery, on the 8th inst. The site of the park was formerly derelict land on the south cliffs, and the work of converting the land into a recreation ground was done mainly to relieve unemployment in the district. The area is about five acres, and includes hard and grass tennis courts. Lord Penrhyn has presented the town of Bethesda with two plots of land, one for the purpose of a recreation ground and the other as a site for a local war memorial.

**French Import Tax on English Flowers.**—It is probably only known to those immediately interested, that the French Government has recently placed a tax on all flowers imported into France. This tax appears to English growers to be grossly unfair. It is found that the importation of French flowers into England exceeds by about fifty times the amount of flowers exported to France, while English flowers in no way compete with the French

produce, as the flowers sent from England consist only of certain varieties of Roses and Carnations and a few others of a choice nature such as are not produced by the French growers. The duty charged is 2 francs per kilo, which works out at approximately 5d. per pound, and is charged on the gross weight of the package containing the flowers. The result is an additional charge of approximately 6d. to 9d. per dozen blooms, and French buyers have become unwilling to purchase until English growers reduce their prices. At the International Conference held at the Hague in April last, strong protests were made by the British delegates against this duty, which was to come into force on May 1, and they were vigorously supported by all representatives with the exception of those from France. On behalf of the Chamber of Horticulture an additional protest has been made to the Minister of Agriculture, who has been asked to at once take the matter up with the French authorities, and to point out the unfairness of this imposition. It is generally agreed that the tax has been imposed as a means of protection against the large quantities of Italian flowers that are sent into France, and the French Government take up the position that they are unable to impose a tax against any particular country, therefore all must suffer. Quite recently parties of French horticulturists visited this country with a view to improving trade and gaining experience in English horticulture, and they unanimously agreed that the duty placed on English flowers was unnecessary, and in their opinion the measure should be modified in our favour. It is well known and admitted that during the war years, most of the articles that could possibly be considered as luxuries were greatly reduced, and in many cases production or importation was stopped altogether, even our own colonies being amongst the greatest sufferers, but notwithstanding this, French flowers were allowed to enter this country the whole time without interruption. It appears to English growers that this is a case for reciprocity. The Minister of Agriculture is giving the matter every attention; he has also promised to acquaint the Chamber of the result as soon as possible, but unfortunately negotiations with foreign powers take much time.

**Fire Blight.**—The disease of Apple and Pear trees known as Fire Blight is due to the activities of a bacterium, *Bacillus amylovorus*. This disease is the subject of serious concern in New Zealand, where it made its appearance in 1919 and spread with remarkable rapidity. One cause of the prevalence of the disease in New Zealand is stated\* to be due to the fact that it attacks the Hawthorn, which is largely used as a hedgerow plant. On this, as well as on its other host plant, the bacillus passes the winter, especially in the edges of wounds which its previous growth had caused. In spring the bacillus increases enormously, and the viscid drops in which the legions of bacilli are distributed by insects to new hosts. Honey bees, as well as sucking insects, may thus carry the pest, and it has been observed that once flowers are infected honey bees may spread the disease to every flower in an orchard in a few days. Shoot infection follows flower infection, and the former may result in the killing of whole branches of fruit trees. Spraying appears to offer no prospect of relief from this pest, and those engaged in its investigation hold that nothing short of a wholesale destruction of the Hawthorn in all fruit-growing districts of New Zealand will save the orchards from this pest.

**The Bechtel Crab.**—According to the *Bulletin of Popular Information*, issued by the Arnold Arboretum, the Bechtel Crab is, when in flower, one of the most popular trees in the arboretum. It is a form of *Malus ioensis*, the common Crab Apple of the northern middle western States. The type has flowers about two inches in diameter, with white or rose-coloured petals, but the Bechtel Crab is a double-flowered form, the name commemorating the man who discovered the plant growing wild in the woods in one of the western States. The pale rose-

\* *New Zealand Journal of Agriculture*, XXIII., 1, 1921.

\* *Gartendora*, LXX., 1-2 and 3-4, 1921.

coloured flowers are said to resemble small Roses. This fine double-flowered Crab needs to be grafted on one of the Crab Apples, the common form of *Malus ioensis*, being most suitable. Nursery trees are often worked on the ordinary Apple stock, but such trees are usually very short-lived. There is also another beautiful double Crab grown in America known as the Charlotte Crab, a form of *Malus coronaria*. The flowers are described as larger and whiter than those of the Bechtel Crab, and a specimen tree is said to be a splendid garden feature.

**Irises in America.**—In conjunction with the American Iris Society, no fewer than 1,000 varieties have been planted by the New York Botanical Society, in their gardens at Bronx Park, New York. On the occasion of the annual meeting of the American Iris Society, on May 27, the test garden was inspected and, according to the *American Florist*, the following varieties were amongst the most prominent: Tamar, Samapo, Queen Victoria, Mithras, Lohengrin, Sir Walter Scott, Versicolor, Candelabra, Mars, Her Majesty, Mandarin, Mrs. W. R. Fryer, A. M. Brand, Lady Frances, Fryer's Glory, Mrs. Sandford, Regale, Mrs. McKinney No. 3 and La Nieve.

**The Many Uses of a Single Palm.**—The Nipa Palm, *Nipa fruticans*, which grows in abundance in the mud on the banks of all the rivers of Sarawak, near the coast, is, according to the *Journal of the Royal Society of Arts*, utilised by the natives for a variety of purposes. From the stem, salt is produced. It is also used as floats of timber rafts, and when found floating decayed in the stream, it is collected, dried, made into a fine powder, and used for the treatment of wounds, for which it is said to be very efficacious. The skin inside the base of the leaf stems is used extensively for making boat balers. The leaf stem itself is sometimes used for flooring. The heart is eaten as a vegetable. The mature leaf is made into atap for roofing houses, and generally as wrappers (tampin), especially for Lime and Sago. The leaf ribs are used for making brooms, stands for cooking pots, in the manufacture of atap, baskets, etc. The split ribs are also frequently used in the place of string or rattan. The flower is made into a preserve. The fruit, when young, is also made into a preserve, and when old, is used instead of betel nut. The husks of the fruit are used for brushes. Sugar and vinegar are obtained from the sap from the stem of the flower or fruit.

**Control of the Cabbage Root Maggot.**—Experiments conducted in British Columbia\* for the control of Cabbage root maggot (*Chortophila brassicae*) on both Cabbages and Cauliflowers proved the superiority of treating the plants with mercury bichloride over other remedial measures, including the tar-paper protector. Twenty-five thousand Cabbage plants transplanted about April 25, received three applications of mercury bichloride, at the strength of one oz. to ten gallons of water, on May 11, 25, and June 4; and about 12,000 plants received a fourth application at the same strength on June 18. The results showed no maggot injury and no larval infestation was observed on any plants examined, either on those which received three applications or those which received four. The method of application was as follows:—A concentrated stock solution was prepared the day previous to treatment by dissolving the mercury salt in boiling water. This was done by suspending the salt in a sack in a fifty-gallon barrel, and pouring the boiling water over the sack. This stock solution was drawn on a waggon to the centre of the field, a large watering cart with a capacity of two hundred imperial gallons and a number of empty barrels being drawn also to the same point. This stock solution was reduced to make a solution of one oz. to ten gallons of water, there being two oz. of mercury salts in each gallon of stock solution. Two ordinary four-gallon oil tins were suspended on a yoke placed across

the labourer's shoulders and the diluted solution was applied to the roots of each plant, at the rate of two fluid ounces, by means of a cheap dipper. The total cost of the three applications was approximately one cent for four plants, while for four applications the cost would be one cent for three plants.

**The Cult of the Iris.**—During the past two weeks the Iris has been prominent in the world of horticulture, for conferences on these flowers have been held in Paris and London respectively, while a special Iris exhibition in connection with the London Conference was held under the auspices of the Royal Horticultural Society at Vincent Square, Westminster, on the 7th inst. As a conclusion of these activities, Messrs. R. Wallace and Co. invited prominent Iris specialists, including well-known American and French raisers, to inspect the large collection of Irises in their nurseries at Tunbridge Wells. Among those who accepted the invitation to attend were Mr. J. C. Wister and Mr. Leo Bonnewitz, from the American Iris Society, and Mons. S. Mottet, of Messrs. Vilmorin, Andrieux and Co. (whose portraits we have pleasure in reproducing below from a photograph taken during the visit to Tunbridge Wells): Messrs. E. A. Bowles, W. Cuthbertson,

IRIS SPECIALISTS FROM ABROAD VISITING MESSRS. R. WALLACE AND CO.'S NURSERY.

Left to right:—Mr. Leo Bonnewitz, U.S.A.; Mons. S. Mottet, France; Mr. J. C. Wister, President, American Iris Society.

Gerald Loder, W. A. Bilney and C. T. Musgrave, members of the Council of the Royal Horticultural Society; Mr. W. R. Dykes, Secretary of the R.H.S.; Mr. F. J. Chittenden, Director of the Wisley Gardens; such noted raisers as Sir Arthur Hort, Mr. A. J. Bliss, and Mr. G. Yeld, together with Messrs. Pilkington, Baker, Bruce, E. A. Bunyard, N. G. Bunyard, and others interested in this beautiful family of plants. Messrs. Wallace and Co.'s extensive collection of Irises embraces most of the finest varieties in cultivation, including some remarkable novelties not yet in commerce. Among these last, the variety Duke of Bedford, with violet purple falls and rich, satiny blue standards, relieved with a most brilliant orange-coloured beard, was regarded by those present as one of the best in the whole collection, which included such outstanding varieties as Citronella, Swazi, Ambassadeur, Lent A. Williamson, Jeanne, Cardinal, Balaruc, Dominion, Crusader and Madrano. Where, however, so many were of outstanding merit, it was a difficult matter to select the best, for in Irises, as in other flowers, individual taste largely governs the choice, as some particular shade of colour, type of habit, stature, or other feature may appeal

most to the individual. The firm entertained the visitors to luncheon and Mr. R. Wallace expressed the pleasure not only of himself, but of horticulturists generally in this country to have such distinguished visitors with them from both America and France. He was proud that in this country we have a few flowers which these visitors have been pleased to class as very good indeed. He asked them to drink to the health of Mons. Mottet and Messrs. Wister and Bonnewitz. Mons. Mottet, in responding, stated that he was proud to know that his firm had raised some fine varieties, but from what he had seen at Vincent Square and Tunbridge Wells, English raisers were quite ahead of them as regards Irises. In his opinion, the five best varieties were Duke of Bedford, Swazi, Cardinal, Bruno, and Dominion, and of these, his first choice was Swazi, not only because of its beautiful flowers, but because of its tall stature. Mr. Wister expressed his gratitude for the hospitality that had been afforded him and his friend, Mr. Bonnewitz, not only here, but in France. He said "Mr. Wallace spoke of the ties that bind you to France and to us, but I feel more strongly since I have been here that the English, French and American people must keep together. Mr. Mottet has told you what he considers the five finest Irises, but I feel he is much too generous to England. You have so many good Irises that it is hard to name any five or any dozen. The first three should be Ambassadeur, Prospero and Swazi. I leave out Dominion because I am not able to cultivate it in my country, where the climate has extremes of heat and cold. In America, when we pick out the five finest sorts we always include Ambassadeur; Prospero would also find a place, and then two American varieties. With regard to the American sorts, my selection is Quaker Lady, Lent A. Williamson, Afterglow, B. Y. Morrison, Queen Catherine and Shekina." Mr. Bonnewitz also responded to the toast and expressed the pleasure that it gave him to inspect the Irises, not only in this country, but also in Messrs. Vilmorin, Andrieux and Co.'s nurseries. Most of our readers are aware that Messrs. Wallace's new nursery is a portion of the old establishment of Messrs. Thomas Cripps and Sons, which was famous for the collection of trees and shrubs it contained, and many beautiful specimens remain. Large Rhododendrons form one of the glories of the place; many of them, in the form of tall standards with immense heads, border the main roadway through the nursery, the great majority being finely in flower, at the time of the visit.

**Legacy to a Gardener.**—The late Mr. Frederick W. Carver, J.P., of Oakhurst, Bexton, Knutsford, Cheshire, who died on April 13 last, left the income from £1,500 to his gardener, Mr. J. Keen, and his housemaid, Miss M. E. Mewis.

**The Effect of Acid Phosphate on the Flowering of Roses and Carnations.**—Professor P. A. Lehenbauer, University of Illinois, in an address on the fertilisation of greenhouse soils before the members of the Ohio District of the National Flower Growers' Association, at Columbus, stated that experiments carried out at the Illinois Station showed the great value of acid phosphate as a manure for Roses. Commercial acid phosphate is a mixture of pure acid phosphate and gypsum in approximately equal quantities and comprises a form of phosphate which is soluble and readily available to plants. No fewer than 1,152 Rose plants were dealt with in the trial, and those treated with acid phosphate gave an increased production of slightly over three blooms per plant. This increase of 4,800 flowers was produced at a cost of \$5.60 for the fertilisers. It was claimed, also, that the average stem length of each variety was slightly increased, which is of especial value in the case of Roses grown for market. Experiments with two varieties of Carnations showed similar results, although the increase was not quite so large, the additional flowering being just over one bloom per plant. Acid phosphate can be applied in the soil before planting in quantities sufficient for the entire growing season, for it is not readily washed out of the ground.

INDOOR PLANTS.

RHODODENDRON PRINCESS ALICE.

ON March 19, 1862, several new greenhouse Rhododendrons were exhibited at the meeting of the Royal Horticultural Society, and proved a great attraction. In the *Gardeners' Chronicle* for March 22, 1862, we find several interesting references to these, thus: "Most of the miscellaneous novelties shown came within the province of the Floral Committee, and there were some very fine things among them. One of the most promising was Rhododendron Princess Alice, a cross between *R. Edgworthii* and *ciliatum* dwarf-habited, with clean-looking foliage and good-sized white, blush tinted flowers, as sweet as those of the former parent."

a beautiful specimen 4 ft. high and 19 ft. in circumference, which flowered recently in Lady Katherine Vane's garden at Houghton Hall, near Darlington.

URCEOLINA PENDULA.

THIS *Urceolina*, which is a very pretty bulbous plant, flowers as a rule during the autumn and early winter. It is a native of the Andean region of South America, and was first introduced by Richard Pearce, of tuberous *Begonia* fame, from the province of Mima, in Peru, when travelling there on behalf of Messrs. J. Veitch and Sons. Sent home in 1863, it flowered at the Chelsea Nursery a year later. Previous to that, however, it was discovered and described by the travellers Ruiz and Pavon, but its introduction we owe to Pearce. It was first sent out by Messrs. J. Veitch and Sons as *Urceolina*

**Loss of Crop Due to Plant Diseases.**—It is stated by Mr. W. L. Stevens\* that the losses of crops due to disease amounted in the United States in 1919 to:—Cereals 482,655,000 bushels, Potatoes 86,997,000 bushels, Tomatoes 307,168,000 bushels. That losses from pests are heavy is well known and universally admitted, but we confess to a certain measure of scepticism as to the actual figures which are cited. It may well be, of course, that our scepticism is unfounded, but we doubt whether it is easy in arriving at such estimates to separate the factor "bad cultivation" from that of pest destruction. It would be of great interest to cultivation in this country if the Ministry of Agriculture would institute a careful inquiry in the actual magnitude of loss due to disease in England and Wales. If such an estimate were made judiciously it would be the best propaganda possible for the general popularising of preventive measures against plant diseases.

**Prize for Exterminating Forest Pests.**—The Forestry Commission announces that a prize of 5,000 dollars has been offered by Mr. Frank J. D. Barnjum, of Montreal, for the discovery of a practical method of combating the Spruce Bud Worm, Spruce Bark Beetle, and Spruce Borer, pests which are the cause of great damage to the forests of Eastern Canada and the United States. Intending competitors are required to submit their suggestions addressed to the donor of the prize, New Birks Building, Montreal, Canada, before August 1.

**Appointments for the Ensuing Week.**—Wednesday, June 21.—Ilford Horticultural Society's meeting; Southampton Royal Horticultural Society's Rose Show; Croydon Horticultural Society's show. Thursday, June 22.—Royal Botanic Society's meeting. Saturday, June 24.—Glasgow and West of Scotland Horticultural Society's outing to Loch Lomond Park; Streatham and District Rose and Sweet Pea Society's show.

"Gardeners' Chronicle" Seventy-five Years Ago. — *Dendrobium nobile*. Amongst the numerous species of the hardier exotic Orchids which are cultivated here for the purpose of conservatory decoration, few are perhaps more beautiful or better adapted for the purpose than the charming *Dendrobium nobile*, a tolerable specimen of which remained in flower in the conservatory during the months of April and May, without sustaining the slightest injury, although the thermometer frequently indicated 40° of night temperature during that period; and since its removal to the stove it has grown more vigorously. In the cultivation of this description of plant I find but little difficulty, after I can get them established in a pot, and I find no method better than that of attaching them to a small block of charred Oak, and then potting them firmly in small well-drained pots, in rough sandy peat and charcoal, taking especial care that the stem is not buried in the process. In most cases I think it should only just reach the soil. The plants are then placed on a brisk hot-bed of well prepared stable dung and leaves, over which are a few inches of sawdust, to keep down any rank steam that may arise. In such a situation I have found this description of plant to grow most rapidly. So soon as I think they are sufficiently established to require shifting, I break the pots as gently as possible, so as not to injure the roots that may have adhered to them, and then give the plants a large shift into my rough sandy peat, charcoal, and broken pots, taking care that the drainage is well secured; and this I effect by using inverted pots, and plenty of crocks in rather large pieces. The plants are then removed to the stove, where they are grown on the dry and cool system. *James Duncan, Basing Park, June 15, Gard. Chron., June 19, 1847.*

**Publication Received.**—*Plant Surgery; or, the Correct Methods of Pruning.* By C. A. Jardine, 86, Lavender Hill, S.W.11. Price 5s.

FIG. 171.—RHODODENDRON PRINCESS ALICE FLOWERING AT HAUGHTON HALL, DARLINGTON.

The R.H.S. granted a First Class Certificate to this new hybrid, and notified the fact in the advertisement columns. Moreover, nurserymen of those times were quick to profit by such an award, and by the description of the certificated plant given in the report of the meeting, and so, in the succeeding issue, Messrs. Veitch and Son, Royal Exotic Nurseries, Exeter and Chelsea, advertised the several new plants to which awards had been made, and the first in their list, on March 29, was Rhododendron Princess Alice, described as follows: "This exquisite variety is a hybrid raised by ourselves between Rhododendrons Edgworthii and ciliatum. The flowers are large, of a delicate rosy blush, shading off to white and possessing the delicious perfume of *R. Edgworthii*, with the neat foliage, dwarf-habit, and freedom of blooming of *R. ciliatum*. At the late exhibition of the Royal Horticultural Society, on the 19th inst., it received a First Class Certificate, and was the admiration of all who saw it." The price advertised was 42s. for a first-sized plant, and 21s. for a second-sized one.

Rhododendron Princess Alice is still a popular greenhouse plant, and in certain gardens there are fine old specimens, though, perhaps, not many exceed in size and beauty the one illustrated herewith (Fig. 171), which represents

*aurea*, a name under which it is sometimes met with at the present time. The leaves die off towards the end of the summer, and soon after this happens the flower scape is pushed up. The spike attains a height of a foot or more, and is terminated by an umbel of very striking urn-shaped blossoms, each hanging suspended by a slender stalk. The colour is bright yellow, tipped with green and margined with white, the length of the entire flower being about two inches. The cultural requirements of this *Urceolina* are not particularly exacting. After the flowers are over the plant remains dormant for some time, during which period the soil should be kept slightly moist. Then, about February, the bulbs may be repotted, keeping them in a warm greenhouse or intermediate temperature.

The compost should consist mainly of fibrous loam, lightened by a little leaf mould or peat and sand, but little water will be required till the young leaves push up, when the supply should be increased. As soon as the pots get well filled with roots, an occasional stimulant will be beneficial. As the leaves turn yellow less water will be needed.

Apart from its own intrinsic merit this *Urceolina* is interesting as being one of the parents of that singular bi-generic hybrid—*Urceocharis Clibranii*. T.

## FAILURE OF SOUTHERN PLANTS TO COLONISE IN THE NORTHERN HEMISPHERE.

I JOIN with Sir Herbert Maxwell (see p. 293) in some degree of wonder that with his various species of *Senecio* and *Olearia* growing together no hybrid has appeared among them. Spontaneous hybrids, of course, are not very common in gardens, and surprise, therefore must be qualified. In answer to Sir Herbert's query, How it is that crossing does not take place? I can only suggest certain possibilities. One is that although the plants may be well able to cross with each other they do not do so because they have no agent for the transfer of pollen.

In the case of many species of *Iris* growing together in a big bed I never knew of a hybrid coming from them, though certain species always seemed to produce true seed, which must have been the result of insect agency. It might be that the insect suited to one species is unsuited to the other in flower at the same time. I do not think that Sir Michael Foster ever drew attention to a hybrid that was not the result of his own manipulation. The *Compositae*, like the *Irises*, are made for insects and, as a rule, cannot do without them. They are incomplete entities by themselves, so to speak, and it may be that British insects do not take the place of those that "belong" to the plants in New Zealand. It may not be because of structure, as it can be in the genus *Iris*, but it is possible that our insects are not attracted by the plants.

Another possibility is that these plants are incapable of hybridising, though, indeed, I think it unlikely in all cases. Strange things do occur; we get surprises in what will cross, but equally, perhaps, in what will not cross, and the *Antipodes* have a very special natural history.

With regard to the free germination of *Veronica Traversii* and *V. parviflora*, I think it likely that they are of simpler construction and requirement than the more highly evolved *Compositae*, which have been considered to stand at the top of the scale of plant evolution. British insects, attracted by similar properties, might even be at the service of plants that belong to a British genus, for we know that certain properties are apt to run through a whole genus. I have noticed that other *Veronicas* come up self sown, where the seeds find the protection of cracks and crevices, here in Torquay. Spontaneous hybrids of New Zealand *Veronicas* have, I believe, appeared in Britain.

As touching the great question why, since Northern plants successfully colonise in the Southern Hemisphere, there is no reciprocal colonisation of Southern plants in the North, it is easier, I think, to surmise than to find knowledge. We may extend the application of the dictum that plants live, not where they could best live, but where they can live. If we accept this we may easily believe that the climate of New Zealand, for instance, is not only congenial for New Zealand plants, but the most congenial for a good many European plants. It is so according to tales that are told of subjects as diverse as men and Watercress.

It may be, too, that plants of the North find insects in the South that serve their requirements, or that they are less dependent upon them. If New Zealand is the better kind of country both for Northern and Southern vegetation, it is not perhaps surprising, taking into account that as climatic changes take place there must be a strain upon the flora. Plants certainly do keep their necessities of existence, and acclimatisation does not, I think, go very far.

In the question of Northern and Southern plants Sir Herbert Maxwell has drawn attention to phenomena of great interest, and in the absence of actual knowledge I may be forgiven, perhaps, if I have taken some licence in speculation. Darwin greatly approved what he called "a fool's experiment." R. Irwin Lynch, Torquay.

## THE BULB GARDEN.

### THE BEHAVIOUR OF TULIPS IN 1922.

MUCH has been published in the *Gardeners' Chronicle* about the effects of the dry, tropical weather of 1921 in gardens, to which I add a few remarks on the behaviour of a considerable number of May-flowering Tulips. In a large collection a few branched or fasciated plants are always in evidence. *La Tulipe Noire* is generally a pretty safe draw. This flowering season, however, many varieties have taken on this curious habit *en bloc*. It does not seem to have made any difference whether they were grown last year in Holland or England, the same variety became fasciated in 1922. I have grown Golden Bronze in my garden for years. I had it first when it used to be called *Toison d'Or*. I cannot assert that no fasciated plant ever appeared in my stock, but I cannot remember any. This flowering season at least every other one was fasciated. I happened to get an odd dozen bulbs from Holland to grow in pots. They were just the same: so was a patch of Dutch grown bulbs that I saw in Messrs. R. Veitch and Son's Exeter nursery. I grow two varieties that are supposed to be "branching," viz., *Constellation*, a red variety introduced by Messrs. Sutton and Sons, and *Mons. S. Mottet* raised by Mons. G. Bony. Both are rather shy branchers, and unless they are "done" very well, refuse to take on this habit as they ought to do. They have out-Heroded Herod in their branching this year. I could instance a good many examples, but perhaps the most surprising is the look of a hitherto rather puny-looking florist's cast-off which from its shape has had the garden name of "White Darwin." When in flower each plant resembles a little nosegay. Was it the heat or the sun, or perhaps the effect of both, that has caused these unwanted appearances? Heat artificially applied has the result of retarding the time of blooming, and more than one grower makes use of it to extend the flowering period in his nursery. For some time now I have wondered if a short dose of mild heat (artificial, of course) does not strengthen a bulb. Can any one say if this is so?

Again, I have never seen Tulip-plants throw up so many secondary blooms as they have done this year. Nearly every *Rose Tendre*, an early variety, and nearly every *Prince Charming*, a late variety, had an independent second bloom coming from the same root.

In this connection I have yet another fact to lay before readers. Some of my Dutch friends have frightened me very much about Tulip-thieves. They describe them as bulbs which suddenly give up bothering to bloom, but go in for dividing themselves up, and in doing so handing on the non-flowering habit to their descendants. I feared whether my beautiful orange, "The President" (see Wallace's 1921 list), and my Walter T. Ware had not both become a pack of thieves! That my fears were groundless 1922 has abundantly proved. The President gave a mass of bloom, and almost all the little miserable degenerate-looking bulbs of Walter T. Ware have thrown up a flower. Is 1921 accountable for this? The question of breaking is one of perennial interest. One cannot frame a new theory about it every year and scrap the last one. Often as I have come across a broken flower when taking visitors over my Tulip garden, I have said by way of a joke, "It is possible that if you dug up twelve of these self-coloured plants and put them in your garden next autumn, the following year they would be all striped like this" (pointing to a broken flower). I never thought it would be so, but only the other day I had a letter from Mr. Wakefield, of the Parsonage, Broughton-in-Furness, in which he said "I planted twenty-four bulbs of *Pride of Haarlem* last October, and every one has broken." My gardener and I had only said the very day before the letter came that we thought we never had had fewer breaks in our large collection. There was, it is true, one necessary exception to prove the rule. *Couleur Cardinal* has broken rather badly, a

thing it has never done before. Hitherto it has been practically immune. Mr. Wakefield's letter has quite upset my latest theory that the exceptional warmth of 1921 had a restraining influence on selfs and prevented them from breaking. Not only has he twenty-four recalcitrant *Pride of Haarlems*, but he added, "Never have I had so many breaks in the thirteen years I have grown Tulips." I now feel disposed to say that the hot summer of last year had no effect one way or the other on breaking. It would be interesting to know the experience of other growers on this point.

I expect most people's Tulips were like ours here. They had on the whole much shorter stems and smaller flowers than usual. Oddly enough the early section did not show this as much as the May-flowerers. I never wish to see better *Pink Beauty*, but *Valentin* and *Goudvenk* are but shadows of their former selves. Is it to be wondered at, when all the checks and vicissitudes that they have gone through in March and April are taken into account?

### BRODIAEA BRIDGESII.

THE genus *Brodiaea* is one of the omnibus genera of the botanical world. It now includes many different looking plants that once were known under other names. How few, for example, would ever recognise the well-tried and widely-grown *Milla uniflora* as *Brodiaea uniflora* or *Callipora lutea* as *Brodiaea ixoides*? On the other hand, some have been displaced from the genus. That quaint plant, *Brodiaea coccinea*, has been classed with the *Brevortias*, and the learned ones speak of *Brevortia Ida-Maia*. Thank goodness it has a well-established English name, and gardeners can still talk of it as the Californian Fire Cracker—an alien plant with a good English name more often than not denotes popularity. There are some which ought to have one but have not. I think *Brodiaea Bridgesii* is one of these. I only know it as a pot plant and that it is comparatively easy to grow on from year to year without deterioration. The flat-topped, tubular, pale purple flowers are borne in graceful, light-looking umbels, which have a main stem about a foot to eighteen inches high. They last well growing or as cut blooms. Any one who can manage the better known *Ixias* in pots can also grow this *Brodiaea*. With the selfsame soil and treatment they are a decided success here. Joseph Jacob.

## CULTURAL MEMORANDA.

### SEED SOWING.

SOMETIME during this month a pinch of seed of *Humea elegans* should be sown, and, in case of failure, which is not uncommon, other sowings may be made up to August. If good, the seed will germinate readily in a cool greenhouse temperature.

*Humea elegans* is at most times a fickle plant, requiring careful watering in all its stages, and special care should be observed when the plant is in flower, as over watering is fatal at that stage.

Seed of the brilliant flowered *Gilia coronopifolia* should be sown this month in a cool greenhouse. When large enough to handle the seedlings should be potted off singly into thumb pots, and subsequently potted again as they require it into sixty-sized pots, in which they should be wintered. The compost should be light and open, as this plant is very apt to damp off during the winter, especially in the neighbourhood of London, where special care is required to bring them safely through the winter. During that season of the year the plants should be grown in a light, airy position, close to the roof glass of a cool pit or frame, where a little heat can be applied if necessary to dry up superfluous moisture. During winter no more water should be given the roots than is necessary to prevent the plants from shrivelling, and on no account should the foliage be wetted.

The present is also a suitable time to sow seeds of *Rebmannia angulata*. Well-grown

**PALMS OF THE RIVIERA.\***

I now deal with a most interesting genus, and one which is not sufficiently planted on the Riviera, since probably all the species would succeed in the most sheltered localities in these parts, and several are hardy anywhere here. I refer to the genus *Livistona*, which is well known to gardeners everywhere, because one of the species, *Livistona chinensis*, R. Br (*Latania borbonica*) is one of the most common dwelling-room plants, and, indeed, was, at least until a few years ago, the most commonly cultivated Palm for this purpose, but now is less frequently grown for the market than *Howea* (*Kentia*) *Forsteriana*. The *Livistonas* are fan-leaved Palms, and more graceful than the other fan-leaved Palms which I have mentioned hitherto, their trunks being comparatively slender, though not so slender

building land, it being situated on a most valuable site right in the town of Nice. This is the oldest garden of Nice planted with exotic plants, it having been formed in 1862. Unfortunately, during the war, this garden, which years ago passed into the possession of a German, was placed under sequestration and quite neglected up to a few weeks ago, so that many of the most precious species have been lost. The new owners have decided to bring it back to its former splendour, and I am occupied with the determination of the plants and the general direction of the garden. I make these remarks which might seem irrelevant because I shall have to mention now and again in these notes the Palms and other plants found in this once famous garden, as they are the oldest specimens found on the Riviera. The numerous plants of *Livistona chinensis* in the park of Villa Venetienne are of very remarkable size, having heights ranging up to eight or ten metres.

plants are very useful for conservatory decoration during the summer. Seed may be sown again during July if necessary. The successful cultivation of this plant presents no difficulty, as during all its stages it grows well in a cool house, or ordinary garden frame. The plants should be repotted as often as they require a shift until they are in seven or eight inch pots.

Stocks intended for conservatory decoration should be raised from seed sown now, and sowing may be continued until August. The Beauty of Nice type, Sutton's Christmas Pink and the Lothian Stocks are most suitable for pot culture. The plants should grow strong and sturdy, without any attempt at coddling. The soil for potting should consist of rich loam mixed with old mortar rubble, or, failing this, lime should be added to the soil. Little or no leaf soil should be used, as short, firm growth is essential for success. In the country the earlier sowing should prove successful, but in the immediate neighbourhood of London, it is useless to try and flower the plants in mid-winter, therefore later sowings that will bloom during the spring should be relied on. *J. Coult.*

**TREES AND SHRUBS.**

**ACER MACROPHYLLUM.**

THE Oregon Maple is not so frequently met with as might be expected, considering the large size and handsome appearance of the leaves. Trees here and there occur in gardens, but are seen less seldom in streets, yet I have seen it so used, in company with the Sycamore and the Norway Maple. It bears hard pruning well, breaks freely, and makes good headway in replacing a head even the first year, and blooms freely the next. The panicles of flowers are as pendant as those of *A. Pseudoplatanus*, notwithstanding London's description that they are erect. The petals are much larger than those of the last-named, yellow, and the flowers are fragrant. The leaves contain a milky juice, like those of the Norway Maple. Besides their size, the leaves are notable for the depth of their divisions in some of the seedlings, more especially on adult trees. The branches grow more or less upright on young or lopped trees, but later assume a spreading habit.

**AESCULUS OCTANDRA.**

THE trees that may be placed as a group under the above name are flowering well this year, or have done so, for some of them have shed their flowers and set fruits, while others bloomed later in June. The type has soft yellow flowers, with smooth leaves, and flowers very freely, while only 6 to 10 feet high, though older trees grow much taller. The two small petals have a red blotch on the base of the lamina. I have examined a large number of the male flowers, and they contain only seven stamens, notwithstanding the specific name. This tree was named *Æ. flava* by Aiton, which is very appropriate for the colour of the flowers. Many of the trees that come under observation contain a greater or less amount of rose or red, and these are now placed under the varietal name of *purpurascens*, which is wild in the Alleghany Mountains, though there is some supposition that it may be a hybrid between *Æ. octandra* and *Æ. Pavia*. Several forms have since been named, and one of the more common is *Æ. versicolor*, which is yellowish shaded with pale red outside and deep red within. *J. F.*

**MYRTUS LUNA.**

Few shrubs grow more luxuriantly with us than *Myrtus Luna* (syn. *Eugenia apiculata*), even in shrubberies where the undergrowth of Bracken and Brambles is heavy.

As lawn specimens the plants make fine symmetrical bushes and are at all times attractive with their neat glossy, evergreen foliage and the conspicuous brown bark on the larger branches.

One of our bushes is well over thirty feet high. When in full flower, bearing thousands of small, white blossoms from base to summit, it is a beautiful object. *E. Beckett, Fota Gardens, Queenstown, Co. Cork.*

FIG. 172.—TEIOPIA SPECIOSISSIMA. R.H.S. FIRST-CLASS CERTIFICATE, CHELSEA SHOW (SEE P. 274).

as in some other fan-leaved kinds, and their leaves of a much more beautiful shape. *Livistona chinensis* has wonderfully handsome leaves, forming an almost regular convex surface, like a very low dome, from the edge of which the divisions hang down as fringes. Here this beautiful Palm is quite hardy, and was introduced as one of the very first of Palms; so far as I can find out only one other Palm, namely, *Phoenix reclinata*, Jacq, was introduced as early (always excepting the common date-Palm, *Phoenix dactylifera*). Visitors to the Riviera will know the old famous park of Villa Vigier, to which its first name, Villa Venetienne, has been restored by its new proprietors, the Count and Countess de Mileant, both keen lovers of nature, and who fortunately have saved this park from being cut up as

which may appear to be little for Palms so old, but it must be remembered that *Livistona chinensis* is a slow growing Palm, and, seen side by side with *Washingtonia filifera*, which is numerous also in this park, but planted much later, they appear small, so much quicker is the growth of the other Palm. But of the two *Livistona chinensis* is by far the most graceful, and the crown of beautiful, glossy-green leaves with their long fringe is a sight not to be forgotten. When bearing its large yellowish-white inflorescences, but especially when loaded with its bunches of fruits, the size of small Plums, and of a most splendid bluish-green with metallic gloss, this Palm, with its comparatively slender trunk, has few rivals in beauty.

The slow growth of this Palm is not a sufficient reason for it being so rarely planted, since it succeeds both in full sun and in shade; it will grow even in a northern position. *Dr. A. Robertson Proschowsky, Jardin d'Acclimatation, Les Tropiques, Nice, France.*

\* The previous articles by Dr. Proschowsky were published in our issues for May 1, June 12, July 10, September 4, November 29, December 18, 1920; May 12, April 30, June 11, October 8, November 19, 1921; January 21, February 11, and April 1, 1922.

## The Week's Work.

### THE ORCHID HOUSES.

By J. T. BARKEB, Gardener to His Grace the DUKE OF MABLBOROUGH, K.G., Blenheim Palace, Woodstock, Oxon.

**Cattleya.**—*C. Mendelii*, *C. Mossiae* and their innumerable hybrids are in flower, or have just passed that stage. *C. Trianae* and *C. Schröderae*, with their hybrids, are commencing to make new roots, and, should the compost show signs of exhaustion, fresh rooting material should be given them. These species are as easily grown as any others, provided a few simple details are observed. Their first need is a sweet and suitable rooting-medium; the second to repot them when they are producing new roots, and the third to water them very sparingly after repotting. If treated in this manner they soon become established in the new material, and receive the least check possible. The chief reason why these *Cattleyas* do not thrive in many places is want of air, and another reason is giving the roots too much water during the winter, whilst the plants should be resting, and not sufficient when they are making their growths.

**Watering and Ventilating.**—It is surprising the amount of water these plants need when they are well rooted in small pots or pans, in which they should always be grown. Most beginners make the mistake of placing these plants in too large receptacles, and growing them in a hot, dry atmosphere, in which they gradually dwindle and die. The atmosphere should be kept buoyant at all times, as a stuffy close house is detrimental to the plants. They delight in an abundance of sunlight, but are not capable of withstanding strong sunshine in glass houses.

**Cattleya Warscewiczii.**—Plants of *C. Warscewiczii* (*gigas*) that are making strong growths, and showing their flower sheaths, should have an abundance of light and heat, and be supplied with water whenever they become dry. This plant, owing to its short season of growth, should receive generous treatment after growth commences, or it will not develop strong pseudo-bulbs, and good flowers cannot be expected from weak ones. Plants of this species in bloom, and those that have not made flower sheaths, will be greatly benefited by being placed under conditions advised for flowering Orchids; that is, in a house where the conditions are dry and airy. This will assist them in consolidating their growth, and possibly be the means of producing flowers on their next growth. When the flowers are faded the plants should receive sufficient water to keep the pseudo-bulbs plump and healthy. The drastic drying process, often called resting, is most debilitating to the plants and not conducive to flowering, but rather to the general deterioration of the plants.

### FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Lieut.-Col. SPANDEA CLAY, M.P., Ford Manor, Lingfield, Surrey.

**The Orchard House.**—Where a good collection of early varieties of Peaches and Nectarines is grown, many fruits will have been gathered, and, generally, later sorts will be sufficiently forward to necessitate more fresh air, lighter syringing, and a discontinuance of fire-heat. Flavour in very early Peaches is often sacrificed by hard forcing, but by opening the ventilators freely the quality of the fruits will be improved, and their season prolonged. As these early trees are cleared of the crop they should be well syringed to keep them clear of pests. As they have made their growth, and yet have the summer before them, they may be plunged in the open where they will receive an abundance of sun-light, fresh air and water. Care in water-

ing and syringing is most important; water should be given the roots copiously. The best times to water are just before the trees are syringed, and again first thing the following morning; the roots then have the full benefit of moisture through the night. Mulching or top-dressing is as necessary as ever, and the mulching material should be supplied little and often. Bone-meal, mixed with rich, stiff loam, is an excellent fertiliser for Peaches and Nectarines, as is also liquid manure, which should be diluted.

**Late Houses.**—Thin the fruits on each tree for the final time, as there is but little danger of fruits dropping in June. Pinching and disbudding of the shoots may also be done on the free side. Water the roots as well as the foliage liberally. As the main object of this house is to obtain a good crop of fruits during the autumn, no particular object will be served by hard forcing, even with solar heat. Allow plenty of time for the fruits to complete their stoness, also when the fruits are swelling freely, then, if thought desirable, the house may be closed for two or three hours on fine evenings. All fruit-bearing trees should be well top-dressed and fed liberally. The strongest of the young shoots may be pinched at the fifth or sixth leaf, according to their size and the space at command, but the weak shoots, and especially those near the base of the tree, may not require pinching, as sometimes these shoots have but two wood buds, the removal of which would ruin them for another year.

### HARDY FRUIT GARDEN.

By H. MARKEHAM, Gardener to the EARL OF STRAFFORD, Wrotham Park, Barret.

**Late Planted Fruit Trees.**—Give every attention to the roots of late planted trees and those which were root pruned. Mulch the roots and supply fresh mulching material at intervals so long as hot, parching weather continues. Large trees that were rather severely dealt with will be greatly benefited by being shaded from the strong sun a few hours daily, and syringed to moisten the branches.

**Cuttings.**—Keep the beds of bush-fruit cuttings clean and free from weeds, and water the cuttings freely to assist in the formation of roots. It will be very helpful if a good mulching of leaf mould is applied between the rows previous to soaking the soil with water.

**Sweet Cherries.**—Examine the young growths of Cherries at intervals, and should the tips be found to be infested with black aphids, dip them in a mixture of Abol or nicotine wash and syringe them freely with either of these insecticides, so that both leaf and shoots may be thoroughly cleansed before the stoning process is over, when clear water only should be used on a few occasions to clear away all traces of the insecticides on the fruits. Do not use insecticides after the stoning is completed, otherwise the fruits may have a disagreeable taste. Train neatly all the young shoots required for extension and for filling the wall space before they receive any damage by winds, etc., also see that the roots are supplied with moisture if it is needed. A copious watering with lime-water and soot-water, or liquid manure, will greatly assist trees bearing heavy crops.

**Gooseberries.**—If large berries are required for dessert, thin the fruits early, using the smaller ones for tarts and bottling. Feed the roots at intervals with liquid manure, and mulch them with farmyard dung. Keep the foliage free from red spiders, and should caterpillars appear check them at once, otherwise they will spread rapidly and defoliate the plants.

**Loganberries.**—Examine these plants and thin out the superfluous growths. Retain those best situated to take the place of the older ones. On light land liberal supplies of water and liquid manure will assist the plants in making large, fleshy berries of the best quality. Protect the fruits from birds early, and use the berries before they get too ripe and seedy.

### THE FLOWER GARDEN.

By EOWIN BECKETT, Gardener to the Hon. VICARY GIBBS, Aldeham House, Hertfordshire.

**Planting Tender Bedding Subjects.**—Before commencing to plant, the soil of the beds, previously prepared, should be lightly forked over, and made level by raking. Set the plants in the ground firmly, staking where necessary, and leaving the whole as neat and tidy as possible. The main planting of the beds should be carried out first, and edging plants, where such are employed, put in last, otherwise the edging may be disturbed, and possibly damaged, by reaching over it to plant other items in the beds. When all is completed give the plants a good soaking with water, and thereafter spray the plants freely each day, preferably in the late afternoon or early evening, until they are well established. All carpeting subjects that require pegging down should have this done at the time of planting, and as growth is made this attention should be again afforded them.

**Berberis.**—The various Berberis have flowered very finely this season, starting with such as *B. japonica*, *B. nepalensis*, and the lovely *B. Bealei*, with its long, sweetly-fragrant racemes of yellow flowers, and followed by the striking *B. aldenhamensis*, which is probably a hybrid between *B. japonica* and *B. aquifolium*, this in turn being closely followed by *B. stenophylla*, a species that makes a fine bush and has exceedingly graceful, long growths, clad with small, dark, evergreen foliage; *B. Darwini*, which is one of the prettiest of evergreen Berberis; *B. dulcis* and *B. dulcis nana*, with their large, lemon-yellow flowers very freely borne. Many other Berberis are doing well; our native *B. vulgaris* is carrying very many flower racemes this year.

**Other Fine Shrubs.**—Amelanchiers are particularly noteworthy and free-flowering this season; *Crataegus* (Thorns) and especially the glorious American Thorns have never been finer in flower here; Horse Chestnuts, the white flowers of which appear to be particularly pure in colour in this somewhat late flowering period, and white-flowered Spiraeas, such as *S. Thunbergii*, *S. gemmosa* and *S. arguta*, are all remarkably pure in tone, and flowering with exceptional freedom. *Viburnums*, starting with *V. fragrans*, have been and still are giving excellent results. Following *V. fragrans* comes *V. Carlesii*, probably the most lovely of all in flower, for its charming umbels of waxy-white flowers are very highly perfumed. Very close to this species, but without doubt inferior, is *V. bitchuenensis*, although it is well worthy of inclusion in gardens, being free in flower and also fragrant. Many other *Viburnums* are flowering well, and the members of this family should be largely grown for their various features, such as flower, habit, foliage, and fruit.

### PLANTS UNDER GLASS.

By T. PATEMAN, Gardener to Sir G. NALL-CAIN, Bart., The Node, Codicote, Welwyn, Hertfordshire.

**Nerines.**—Plants that have completed their growth should be stood on a shelf in a cool greenhouse, where they may receive the maximum amount of sunshine to thoroughly ripen up their bulbs. Water should be withheld entirely at the roots. Plants treated in this manner will be found to flower much better than if placed under stages where they will be shaded from the sun's rays.

**Ferns.**—Plants that were not repotted in the spring but only top-dressed will be benefited now by some manurial aid. Soot water or weak liquid manure may be given the roots once a week, and these stimulants will deepen the colour of the foliage and give the plants a healthy appearance.

**Calceolarias.**—Seeds of herbaceous Calceolarias may be sown in pots or pans filled with a light, open compost. The seeds are very small, and need to be sown on a fine, even surface. It is also wise to moisten the soil with a very fine rose can several hours before sowing the seeds, which only need covering with the merest sprinkling of soil. The receptacles should be

covered with a sheet of glass and stood in a cool greenhouse, keeping their surroundings moist and shaded from bright sunshine. *Calceolaria* seed germinates very quickly, therefore it is necessary to watch carefully and remove the glass when germination has taken place. At this stage the seedlings should not be allowed to become dry, for if allowed to suffer from lack of moisture they will scorch and die off very quickly. *Calceolarias* should be pricked off into boxes, immediately they can be handled, in a light, open compost and stood in a cold frame, one for preference facing north-east. Continue to shade the seedlings from bright sunshine and keep the young plants growing actively, never allowing them to become starved for want of repotting. Green fly is a troublesome pest to these plants, and must be rigorously suppressed by spraying on frequent occasions with *Quassia* extract.

**Zonal Pelargoniums.**—Pelargoniums intended for winter flowering are ready for their final potting. The soil should consist chiefly of good, open loam, with a little manure from a spent mushroom bed and lightened with silver sand. After potting them, stand the plants in an open position where they will be fully exposed to sun and air. Pinch out the tops of the plants to cause side shoots to develop, and remove all the flower buds during the growing season. When it is found that the receptacles are well filled with roots, a light, stimulating manure may be given once every week, but not sufficient to cause sappy growth.

**Salvia.**—*Salvia splendens* and *S. leucantha* intended to produce large specimens should be placed in the pots in which they are intended to flower. The soil may consist of good loam with spent mushroom-bed manure and grit added to render it porous. Arrange the plants in a cold frame until they have rooted in the new soil; afterwards they may be stood on a bed of ashes in the open, for preference where they will be shaded from the mid-day sun. Spray the plants with clear water in the evenings to keep red spider in check.

**THE KITCHEN GARDEN.**

By JAMES E. HATHAWAY, Gardener to JOHN BRENNAND, Esq., Baldersby Park, Thirsk, Yorkshire.

**Asparagus.**—The cutting of *Asparagus* should be discontinued after this date. Keep the beds free from weeds, but do not use the hoe except in the alleys, and then apply a dressing of *Asparagus* manure or guano, which should be washed into the soil by a copious watering. Very strong growths should be supported by stakes.

**French Beans.**—Owing to the hot, dry weather it will be necessary to make further sowings of French Beans to ensure a succession of pods. Soak the drills thoroughly before putting in the seeds; this is more effective than watering after sowing.

**Tomatos.**—Another batch of Tomato plants should be raised to maintain a late supply. Sow the seeds in pots in a shady house, and pot the seedlings singly as soon as they are large enough for the purpose. Grow the plants in the open in large pots, which can be placed indoors at the end of the season. The hot weather has suited Tomatos out-of-doors, but the ground being so very dry, the roots should be supplied with moisture by means of the water can. During their early stages the plants will be benefited by a little quick acting fertiliser, such as guano water or liquid manure, but when growth is active, feeding should be discontinued, for this might cause the plants to make gross growth, which is never so fruitful as when it is of moderate strength. Take out the side shoots as soon as it is possible to do this, and see that the leading shoot is safe against damage by tying it securely to the stake.

**Parsley.**—Another batch of Parsley should be raised now to furnish a late supply of leaves. This crop needs copious waterings, especially on light land, and frequent dressings of soot.

**HARDY FLOWER BORDER.**

**SANGUINARIA CANADENSIS.**

EVERY now and again one hears a comment on *Sanguinaria canadensis*, the Canadian Blood Root, of a nature which is rather displeasing to those fond of the flower. This appears to be mainly due to an author growing or seeing inferior forms of what is, after all, a charming spring plant. That there are inferior types is known to many who have seen the plant in nature and in numerous gardens. Recently I read a note on it in a book of deservedly high reputation, written by a man of great ability and generally excellent taste. The flower was not belittled, yet the manner in which it was discussed came near to that "faint praise" which admirers of the Blood Root would indignantly meet with scorn.

That there are individual plants of *Sanguinaria canadensis* with poor flowers one cannot deny, but a good form such as that supplied from nurseries, as *S. canadensis grandiflora*, is one of the most beautiful of spring flowers.

FIG. 173.—SANGUINARIA CANADENSIS.

whether grown in the border or the rock garden. It is a pleasure to see in its earliest stages the charming leaf of blue grey coming up and shielding the developing flower, then to observe the leaf unfold, to display its charming contour and its colouring in a bolder way; next to watch the large, snow-white flower, with its golden centre, which looks so well associated with the exquisitely lobed and scalloped leaf. A plant a foot or more across, with many of these charming leaves and flowers, is beyond measure delightful in the garden. (See Fig. 173.) It is, of course, no new plant, but one which has been in our gardens for many years, and is frequently overlooked in the desire for novelty; yet it is not deserving of such treatment. Nor does it present any difficulty in cultivation. Although a native of the woods of North America, it grows well in the open border or rock garden, where it flowers excellently and remains open for a longer period each day than when under trees. It has been naturalised by a few, and looks very pretty in the wild garden, but, on the whole, I prefer it elsewhere, where it has a better chance of showing its beauties.

The plant is widely known as the Blood Root, from the red fluid which comes from the roots when they are injured. For the same reason it has also had applied to it the title of Red Indian Paint, and in some parts of Great Britain has been long known as Naked Ladies. The plant is not fas-

tidious in the matter of soil; I have seen it growing in all kinds of compost, and few seemed to cause it any discomfort, except a very poor sandy one, where it was grown well, however, by soaking the roots thoroughly every now and again during the spring and summer. If this was neglected, flagging ensued. Small plants from a nursery, as a rule, generally do well if planted in autumn. *S. Arnott.*

**GYPSOPHILA PANICULATA FL. PL.**

THE double-flowered variety of the popular *Gypsophila paniculata* is valuable as a border plant or for supplying cut bloom. Its value in the garden was never more realised by the writer than on seeing two magnificent plants in the gardens of Shambellie and S. Mary's, Newahbey. They were truly magnificent specimens of large dimensions, and each a cloudlike mass of flowers of exquisite beauty. Of the two that at Shambellie was a little larger than that at S. Mary's, but both were exceedingly fine. I always have a special interest in this double *Gynsophila*, as before it was distributed

Mr. A. J. MacSelf, so well known in horticultural circles, was in charge of the hardy flowers at Messrs. Thomson's nursery, Wimbledon, where it originated, and he sent me flowers asking if I had ever seen a double variety of *G. paniculata*. This I had never done, and it was with special pleasure that I saw the favour it soon acquired when it was distributed. *S. Arnott.*

**LITHOSPERMUM PETRAEUM.**

THE beautiful blue tints of the trailing *Gromwell* (*Lithospermum prostratum*) are very effective on the rock border, especially that of the sky-blue variety, sometimes called "Heavenly Blue." But the rich tones of the taller *Lithospermum petraeum* are not often seen, yet this valuable plant should be in all our herbaceous borders, for it blossoms from the end of May till the end of summer and produces its flowers in great profusion. They are packed in dense tufts on the points of the shoots, and the tubular blossoms are first violet (as buds), opening to clear blue, with red anthers. This small shrub is somewhat like a little Lavender bush in shape, and grows eighteen inches to two feet in height. The plant may be propagated either from seeds or cuttings, which root readily in summer if kept moist. A native of Southern Europe and Dalmatia, this species is not absolutely hardy, but in a well-sheltered position, with a well-drained gravel soil, it does well in gardens in the South of England. *I. L. R.*

## EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, W.C.2.

Special Notices to Correspondents.—The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.

Letters for Publication, as well as specimens of plants for naming, should be addressed to the EDITORS, 5, Tavistock Street, Covent Garden, London. Communications should be WRITTEN ON ONE SIDE ONLY OF THE PAPER, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Local News.—Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Editors and Publisher.—Our correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notices printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the EDITORS. The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.

Illustrations.—The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.

## THE MANSE GARDEN.

THOSE familiar with Sir Walter Scott will remember *Old Mortality*, a book that keeps in remembrance an old man who, leaving home and wife and family, for the long space of forty years led a lonely existence traversing those districts of Scotland where persecution raged during Covenanting times, and employed himself in the hewing and erection of monuments to the memory of those who suffered death, or in repairing grave-stones where these already existed.

Nathaniel Paterson, the author of *The Manse Garden*, was either the grandson or the great-grandson of *Old Mortality*, whose real name was Robert Paterson. He was, when the book was written, minister of Galashiels, at that time little more than a country village, and, later, of one of the Free Church congregations of Glasgow. Some twenty miles lower down the Tweed he had a ministerial friend imbued with a love of similar pursuits, in the person of the Rev. R. O. Bromfield, of Sprouston, articles from whose pen are to be found in *The Gardeners' Chronicle* and other journals of sixty or seventy years ago. He, however, did not venture on book production, while Dr. Paterson wrote, in addition to the one on gardening, several books on religious subjects. *The Manse Garden*, published anonymously, was immensely popular, and the first edition was exhausted in a very short time. Other editions, with the name of the author, followed until at least 15,000 copies had been sold. Like the Rev. John Lawrence a century previously, our author had doubts as to the expediency of a clergyman writing on gardening, but he concluded he could not be wrong in advising persons of sedentary habits, whose tendencies to physical and mental deterioration were great, how to escape these by means of a recreation at once profitable and pleasant and devoid of evil. So he wrote.

Ostensibly, while written to induce fellow-ministers, farmers, and others with small gardens to take to gardening, the popularity of the book did not rest on its qualities as a horticultural propagandist organ, but largely on the philosophy it applied to ordinary things. And though the author was accused of plagiarism by Mr. Patrick Neill—a well-known amateur horticulturist, and the provider of the Neill Prize in Horticulture—inasmuch as he had made use of an article the former contributed to the *Edinburgh Encyclopaedia* in its preparation, though nothing in Mr. Neill's writings gives the impression that Dr. Paterson

needed to go to them for material, theoretical or practical. Of course, it is hardly possible to write on gardening without trespassing on territory already explored or occupied, and not improbably such was the case in this instance.

Dr. Paterson's English is delightfully fresh and vivid, here and there sparkling with happy Scotticisms, illuminated with a dry humour, sometimes a little sarcastic, but never dull. Here are one or two of his sayings out of many: "If I want to know what sort of Peas I should purchase for seed, I meet with a list so long that I am perplexed, like a shopping damsel amidst an ocean of calicoes; and how should I get out of a labyrinth, if indeed I should venture in, to choose an Apple out of three hundred varieties?" Concerning the meticulous scrupulosity of florists there is this: "Florists have given recipes for composts with the trifling exactness of invalids who pore upon dietetics and weigh their food." But I think that florists are now not so pedantic as formerly. The rather lengthy episode of the blackbirds which ate all the Cherries and Plums in advance of the minister, and how

roots into the soil, and he notes how the exceptionally hot and dry summer of 1826 produced fruit of larger proportions and of finer quality than seasons of average heat, conditions and results that were apparent last year. He had not been aware that sloping walls had been recommended in the end of the seventeenth century and proved failures, else he would not have brought forward a plan of forming a sloping bank of earth to promote the ripening of high-class Apples like the Ribston Pippin. Still, there is something in the idea, for our finest Ribstons are produced here from a grass slope, and at one time very fine examples were obtained from trees trained on the roofs of the workmen's cottages here, an illustration of one of which appeared a few years ago in *Country Life*. It is worth recording that Dr. Paterson was far in advance of gardeners in the cultivation of Strawberries, planting, as he did, in August and securing a crop the next summer, while the general practice was to plant in March and to expect a crop sixteen months or so afterwards. Another practice he recommends with these was to mow off the old leaves towards the end

FIG. 174.—POPULUS GENEROSA: MALE AND FEMALE CATKINS. (see p. 321).

shooting, according to the minister's man, "never did them meikle guid," is a charming example of his humour. And the treatment recommended for the management of the "boy" is characterised by much sagacity and sympathy, and well worth attention at the present time, when boys and girls present a perplexing problem.

Evidently the author loved trees greatly, and his advice to incumbents and others, whose fields were without shelter, to pollard trees of ten to fifteen years, when they could be moved at little expense, was worth consideration at a time when much of the south of Scotland was treeless. The reason why so few trees were "moved" he attributed to the "difficulty a man has of moving himself." Pomology, as was the case with his friend at Sprouston, attracted him more than either floriculture or the vegetable garden. Clearly he was an adept at pruning, propagating by budding and grafting—all necessary accomplishments—for he asked for shoots of any Apple or Pear he found in the gardens of his contemporaries and which hitherto had been unknown to him, keeping them by him till the proper season came round for propagation. He preferred planting Apples on the surface and spreading soil over their roots rather than lowering the

of autumn in order to allow the buds for the next year's crop to ripen. This practice became obsolete some fifty years ago. At least, I have not since seen it recommended.

Concerning vegetables, our author had no love for overgrown specimens. What he would have said about the monster tubers of Potatoes we turn up in these days, or the equally obese Onions, one can only imagine, but we are sure from the remarks he made that it would have been condemnatory. Deep trenching was, in his opinion, indispensable. Previously untrenched ground he advised to be turned up to a depth of 18 inches and deepened at every subsequent operation. He was aware of the reciprocal sympathy between surface soil and deep soil in cases of drought and wetness, and regarded the thorough upturning of soil to a depth of at least 2 feet to be equal to an ordinary application of manure. Not more than eight to ten years should elapse between an operation of this kind, when the inert soil in the lower strata being brought to the surface would prove as good as soil hitherto uncropped. In this he erred somewhat, because all experience proves that ground may be trenched annually with profitable results. The Onion he estimated the most precious crop of the garden, and was assured that one sort differed from another more in accordance with

the degree of skill expended in its cultivation than in the variety. James's Keeping was even then a foremost variety.

Little need be said regarding the section devoted to flowers. The lists of varieties were ample for the time, but the remarks are less interesting than those in the other sections.

The fact that even now the gardens of Scottish manse are, as a rule, not those to which one would go for examples of good gardening raises the question how the incumbent of this, at that time, out-of-the-way village had obtained an experience to enable him to write this living book. Not improbably gardening was "in his bones." The wife of Old Mortality was the daughter of a gardener, and just as the poet Thomson's two brothers took to gardening, thus following in their grandfather's steps, so one might expect this to have been the case with Dr. Paterson. He must have had a love of plants and flowers at an early age, otherwise the original observations broadcast through his book could never have been made. R. P. Robertson, *Tynninghame Gardens, Prestonkirk.*

**PLANTS NEW OR NOTEWORTHY.**

**POPULUS × GENEROSA.**

THIS interesting hybrid Poplar was raised in 1912 by fertilising *Populus angulata* with pollen of *P. trichocarpa*. It was first described by Professor Henry in the *Gardener's Chronicle*, October 17, 1914, page 253. The cross was repeated at Kew in March, 1914, and among the seedlings raised, three in particular, proved to be very fast growing trees. To distinguish these trees from the original (1912) seedlings they have been named by Professor Henry *P. × generosa (secunda)*.

So far as I am aware previous hybrid Poplars—*P. Eugenei*, *P. robusta*, *P. regenerata*, etc., are only represented in gardens by one sex. The original tree of *P. × generosa* at Glasnevin is pistillate. It is interesting now to be able to illustrate the pistillate and staminate forms of *P. × generosa (secunda)*, both of which recently flowered at Kew (Fig. 174). Attempts were made to fertilise one with the other, but at that time (April) we had 8° to 10° of frost on several occasions which destroyed the pistillate flowers. Both have large catkins, about three inches in length, including the stalk. Those of the male tree are the more showy, being dark red-brown in colour. Though Kew, both in the climatic conditions, and its dry sandy soil is far from ideal for the growth of trees, the hybrid Poplars under notice have made splendid progress since the sowing of the seeds eight years ago. All three trees now exceed 40 feet in height with leaves 12-13 inches long, and 10-11 inches wide. A. O.

**DIPELTA FLORIBUNDA.**

AMONG the many new shrubs introduced from China during recent years none is more promising than *Dipelta floribunda*. It is now 15 years (May, 1907) since the first bush produced flowers in this country in the Coombe Wood Nursery of Messrs. James Veitch and Sons, but during half that period our energies were focussed elsewhere. Now that we are able once again to give attention to the propagation and distribution of rare plants it is pleasant to remember that the subject of this note is one of the newer shrubs which has come through the lean years with an enhanced reputation.

The species was first discovered by Dr. Piatetski, a Russian army surgeon, in 1874-75, but for its introduction to our gardens we are indebted to Mr. E. H. Wilson, who sent home living plants in 1902 from Central China, and seeds two years later from Western China.

A flowering spray, with details of the flower, was illustrated in *Gard. Chron.*, July 6, 1907, Fig. 1, from a sketch by Mr. Herman Spooner.

Among hardy shrubs the *Dipeltas* are nearly allied to the *Diervillas*. The most distinct difference is in the bracts at the base of the ovary of the *Dipelta* which develop, forming wings to the fruit, suggesting the female flower of a *Begonia*. *Dipelta floribunda* (Fig. 175) and

*D. ventricosa* (also introduced by Mr. Wilson) are both found in a wild state as large spreading bushes up to 15 feet high, and their present free growth suggests they will ultimately attain this height in this country. Found at some 3,000-5,000 feet altitude the *Dipeltas* appear to be as hardy as *Diervillas*. *D. floribunda* has ovate to oval-lanceolate leaves up to 3½ inches long and 1½ inch wide. The fragrant flowers are funnel-shaped 1 to 1½ inch long, pale pink with a yellow throat. They are borne in the axils of the leaves.

The *Dipeltas* are readily propagated by cuttings of the current season's half-mature growth about mid-summer or soon after. These root readily if inserted in pots of sandy soil, and placed in a close frame with slight bottom heat. The bushes thrive in most garden soils, but to get the best results the land should be trenched and manured. By this means one is able to obtain the abundance of flowers suggested by the name "*floribunda*," and indicated by the spray illustrated. A. O.

a wonder we got so far as we did. The men wanted to quit earlier, saying their beasts could not go on. Next day we entered a forest of magnificent *Picea* and *Pine* trees, and, descending very abruptly, reached cultivation in an hour.

We now found ourselves in one of those gorges which are such a feature of this dry, limestone country, growing steeper and narrower as it approached the main river. At first the path kept close to the torrent. There were *Lime* trees here, and several species of *Arisaema* amongst the rocks, well shaded, besides twining plants, such as *Vitis*. In fact, the ravine was fairly well wooded.

Presently we had to leave the torrent, which plunged down by an ever steeper, narrower groove to join the *Shin-lu*. Our path zig-zagged up the *Pine*-clad slope to the spur far above, from where we looked down on to the river 2,000 feet below—an inspiring sight. Across this chasm we had a fine view of the next lofty

FIG. 175.—DIPELTA FLORIBUNDA.

**MR. KINGDON WARD'S SIXTH EXPEDITION IN ASIA.\***

**No. 17.—THE SHIN-LU.**

FROM the glaciated valleys heads we plunged down through forest where graceful *Larches* glimmered against dusky *Fir* trees. Then came *Oaks*, and open hillsides clothed with scrub *Rhododendron*, and still more open patches of meadow joyous with flowers. And so down, and down again, till at dusk we halted, pitching camp by a small stream. There were only shrubs here—*Rhododendron*, *Lonicera* in flower, *Poplar*, and so on. An *Iris*, with flowers of violet velvet, was coming into bloom.

About sunset we had a brief view of the fine snow pyramid across the gorge, but presently it was swallowed up by the clouds, and weeks passed before we saw it again.

We did not really get very far this day, though we travelled long hours. We had yak transport, slowest of all animals, and it was

range to the west, only it was quite spoilt by clouds.

It was a marvel that anyone had been able to hew a path along the face of this cliff. The precipices were frightful. Hour after hour we scrambled along, up and down. I was much too intent on keeping to the narrow path to notice many flowers. However, a dirty yellowish-brown *Lily* was common hereabouts, and one or two *Orchids*.

Finally came a tremendous descent of about 1,500 feet to a village at the mouth of a valley not quite so narrow as most. The stream had thrown out a little platform of detritus, which hung some hundreds of feet above the river, and the industrious people had terraced it. I was astonished to find *Rice* cultivation here.

As for the village, it comprised half a dozen tiny houses of undressed stone and timber. The spaciousness of the Tibetan houses in the *A-tun-tzu* and *Chung-tien* districts is entirely lacking in these *Ilisan* houses.

Next day we descended to the bottom of the gorge and crossed the *Shin-lu* river—a rushing torrent some thirty yards across—by a wooden cantilever bridge of doubtful appearance. Chance took me into the bed of the river to examine the strata and there, on the slate rocks down which the water slid in a film, causing a luxuriant growth of *Maiden*

\* The previous articles by Mr. Kingdon Ward were published in our issues of May 14, June 18, July 23, August 20, September 3, October 8, October 29, 1921; January 7, January 21, March 11, March 25, April 8, April 22, May 6, May 20 and June 3, 1922.

hair Fern, were the silvery cups and sea-green leaves of a Malacoides Primula! Imagine my astonishment at meeting it again here! I had traced the plant, in one form or another, from Lashie to the Shin-lu, or from latitude 23°, longitude 98°, to latitude 28°, longitude 100° 30', a distance of 500 miles as the crow flies. But, of course, that conveys absolutely no idea of the real degree of separation attained by the most northern and southern plants. To my joy there were seeds in some of the capsules, which I collected with great care.

After crossing the river we climbed to a village perched high up, and then continued through the gorge, ascending gradually towards a mighty cliff which plunged steeply to the river swirling round its base. Except in the widely scattered villages, where Walnut trees were conspicuous, there were no trees down below, only scrubby bushes and any amount of bare rock. A small scarlet-flowered Sedum and a curious Arisaema with very aberrated yellow spathe were the only flowers noticed here. After crossing the high cliff, we found Oak and Pine woods clothing its northern flank for a bit. Purple Pleione grew here, with yellow-speckled Lilies. Down below we reached a well-shaded bog, where a crimson Candelabra Primula, something like *P. Poissonii*, was just coming into flower. This species, whatever it is, grows quite low down—so low as 7,000 feet, probably lower. At these altitudes it has a monopoly of the marshes, so far as Primulas are concerned. But it also ascends to quite 11,000 feet, and here it has to share the ground with *P. pseudo-sikkimensis* and a *Nivalis* Primula. Even so, it does its best to keep to itself, and selfishly appropriates all the ground it can, crowding the other fellows out. It is a greedy plant, and shows none of the toleration *P. pseudo-sikkimensis* and *P. secundiflora* have for each other.

We halted for lunch at a fairly big village where Rice, Buckwheat, Maize, and Wheat were in cultivation. My tame lama came in for much attention at the hands of the superstitious villagers, and was royally fed, petted, and fawned upon. As for me, I was ignored.

In the afternoon we descended gradually to the river again, finally recrossing by another cantilever bridge. There was a fair variety of shrubs down here, and a number of twining plants, such as *Vitis* and *Clematis*, besides rosette plants like *Didissandra lanuginosa* and *Selaginella* sp. on the rocks. One of the men found a white Lily.

Transport difficulties next day prevented us from getting far, and we were compelled to halt at a small village some 2,000 feet above the river, on the edge of the Pine forest. Here, in a bog, I found two small Orchids, and close by the pretty little *Vaccinium modestum*, which I discovered in 1913. It grows in the forest where there are Conifers, and I expect to get seed of it this year, for it occurs at Mu-li too.

Next day we began the long climb to the top of the divide, passing in turn through Pine forest, mixed forest, and finally Abies and Rhododendron forest. We hoped by an effort to reach Mu-li, and made a very early start with that object.

One of the first flowers met with was a pretty cream-coloured *Pyrola* lining the path. Higher up we found a new bush Rhododendron. It was over, but the foliage and habit suggested something in the way of *R. habrotrichum*. Two species of *Clematis*, one with chocolate, the other with yellow, flowers, dangled their bells over the trees in deep shade here, and there was plenty of *Primula sonchifolia*—that aggravating plant which refuses to show itself in England—in seed. The large rosy purple *Nivalis* Primula was now a fine sight. I wonder if this is *P. sino-purpurea*. It is not unlike it, at any rate. All the forest was draped with long streams of pale green lichen, and dripping wet. On the dry ridges Oak forest prevailed, and dwarf purple Rhododendron formed much of the undergrowth.

Approaching the summit, we found a wonderful display of violet Iris, *Primula pseudo-sikkimensis*, and *P. secundiflora*—those inseparable friends—in the streams and bogs. Here and there the lilac-flowered Muscarioid

*Primula*, now grown very tall, was seen under the trees.

At last we reached the pass and open moorland, where dwarf lemon yellow Rhododendron revelled. There was no view at all, everything being smothered in mist, and we began the descent with an uneasy feeling that we were "for it." No sooner had we entered the forest than it came, a perfect deluge, with loud thunder. Rivers streamed down the steep path, and the animals moved with extreme caution. It was now certain that we could not reach Mu-li that night, and after crossing a deep ravine (where *Primula septemloba* flourished in a dim, moist atmosphere) and climbing a high spur, we were glad to camp in the Pine woods, wet and tired after ten hours' travel, still three hours' journey short of Mu-li. A bush Rhododendron with scented white flowers, sometimes flushed with pink, was breaking into blossom. This species is widely distributed in Yunnan. I had met with it first in May, some days' journey south-west of Ta-li, and it was in flower then. Either it is a very variable plant, or else there are two species, or at least well-marked varieties; for besides the two colour varieties there are two distinct types of leaf. But I cannot yet be sure that one shape of leaf is always associated only with one flower colour.

On June 28 we awoke in a dense mist, packed up, and marched back to Mu-li, climbing up and down over the spurs at the base of the long line of cliffs. Here we found our first *Suffruticosa* *Primula* (already referred to), the big-leaved, pointing *Cypripedium*, and a crimson flowered *Clematis*. Quantities of Rhododendron *racemosum* grew amongst the shrubs, and there were bushes of *Cotoneaster*, *Berberis*, *Indigofera*, *Desmodium*, *Jasminum*, etc., forming a thick growth below the forest. Yellow Lilies, purple *Geranium*, *Pyrola*, Orchids, *Roscoea*, and other species grew in the shade. *F. Kingdon Ward*.

## SIR FREDERICK MOORE, V.M.H.

### AN APPRECIATION.

FOLLOWING closely upon the retirement of Sir David Prain from Kew and of Sir Isaac Bayley-Balfour from Edinburgh, it is regrettable that Sir Frederick Moore has also relinquished the Keepership of the Royal Botanic Gardens, Glasnevin. In this way the three great Royal Gardens of the British Isles have lost their able and distinguished directors in the course of the present year. Born in 1857, Sir Frederick Moore has been intimately associated with Glasnevin from his earliest infancy. His father, the late Dr. David Moore, well known as an eminent botanist and horticulturist, was appointed Curator of Glasnevin in November, 1838, and held the post until his death in June, 1879. He was then immediately succeeded by his son, Sir Frederick, on the 28th of that month. Thus Glasnevin has been under the management of father and son for the extraordinary long and continuous period of nearly 84 years. Under their very able régime, Irish horticulture progressed and prospered; indeed, it may be said they started it, and by their perseverance and enthusiasm kept it going; and thanks to them many an Irish home has been greatly embellished. They have now shown that Ireland is capable of growing exotic plants of great beauty with a success which rivals that achieved even in Cornwall. But their influence has had a much wider range; and Sir Frederick is quite as well-known and his work is quite as much appreciated in England and Scotland as in Ireland. There are, indeed, few gardens in the British Isles which are not indebted to him for much assistance and sympathetic encouragement; and he was always ready to help liberally all lovers of nature who approached him. His main desire was that the beautiful and marvellous products of the vegetable kingdom should, when introduced from other lands, be as widely distributed as possible throughout the country, wherever they might be expected to grow and flourish. It is little wonder, then, that his retirement is widely deplored by all who are devoted to the cultivation of plants.

The care and the development of Glasnevin have naturally been the principal objects of Sir Frederick's busy and useful life; and the very high position which it now holds is due to his great organising ability, his scientific knowledge, and to his unremitting labours. The plant collections there are fully representative of all classes of plants, some of them more richly so than elsewhere. It would not be possible in an appreciation of this sort to give even a meagre description of the many treasures which Glasnevin now contains. Many of the readers of *The Gardeners' Chronicle* have been there and know the place. It may be sufficient to state that the collection of Orchids is unique, and that *Ferns*, *Xerophytes*, and *Cycads* abound; *Monocotyledons*, *Alpine plants*, trees and shrubs are very numerous and nearly all the introductions which have poured into this country from the Far East during the past quarter of a century. Everything is in the best of order and condition; the plants well grown, well classified, tastefully arranged, and well displayed. The garden is a dream of beauty; and, moreover, it affords to those who wish to study from a scientific point of view, the means of doing so in the best surroundings. It is thus an educational establishment of no small practical value. And all this has been done at a very small cost to the public exchequer; for Glasnevin has never been so amply endowed with funds, nor provided with as large a staff of expert assistants, as in the case of the other Royal Gardens; indeed, Glasnevin has been somewhat neglected in these very important matters. If, then, the results achieved have been so strikingly satisfactory, it shows how much Sir Frederick, and his father before him, have done for their country, and how much is due to them for their devotion to the public service.

Sir Frederick's efforts to encourage the commercial cultivation of fruit trees and of economic plants deserve a passing notice. Perceiving that the soil and climate of Ireland were favourable to this useful form of industry, he devoted himself with his wonted energy to this important matter. His extensive practical and scientific knowledge was freely placed at the disposal of all who consulted him, and he was indefatigable in his endeavours to impart it to others. He gave frequent lectures on the subject, taught his pupils how to manage their plants to the best advantage, and made many excursions into the country personally to look after the orchards that were being established. It is satisfactory to note that these labours have not been undertaken in vain, and that he succeeded in founding in Ireland an industry of considerable commercial value. A person of his capacity, for hard work, sympathy for others, and enthusiasm, could never restrict himself solely to his duties at Glasnevin; and during his leisure, Sir Frederick devoted himself to other activities. He is a fellow of the Linnean Society, and a Member of the Royal Irish Academy, on the Council of which he has often served. His father started the Royal Horticultural Society of Ireland (now the Royal Horticultural and Aborigines Society of Ireland), and he has for many years been its moving spirit and Hon. Secretary. He is also Hon. Secretary of the Dublin Microscopic Club. He is, moreover, an active Fellow of the Royal Zoological Society of Ireland, and was its most efficient President during the war when it was difficult to keep it going; his exertions at that time are now gratefully remembered by the Society. During the war he organised an Irish association for providing the Fleet with fresh vegetables, with much success. His eminent services to horticulture were recognised by the award of the Victoria Medal of Honour in Horticulture when it was first established in 1887; he also received the silver and gold Veitchian medal. The Royal University of Ireland conferred upon him the degree of M.A. *honoris causa*; and he had the honour of knighthood bestowed upon him by His Majesty personally in 1911.

Sir Frederick leaves Glasnevin a great and thriving Irish institution which has a high international reputation. He has the immense satisfaction of knowing that this is the creation

of his father and of himself, constructed by them during their joint long term of office; with an insignificant endowment and with an inadequate staff, they have gathered there the best all-round collection of plants in the world. He leaves deeply regretted by his numerous friends and by all those who worked under him, who were always devoted to him and who learn with satisfaction that he has fixed his future home in Ireland. *Amat. Hort.*

**FLORISTS' FLOWERS.**

**DAHLIAS.**

DAHLIAS are very suitable for planting in bold groups for producing masses of colour in the late summer and throughout the autumn. The first or second week in June is undoubtedly the best time for the planting of Dahlias out-of-doors. Beds of distinct colours or lines of separate kinds are very attractive.

The following varieties are very suitable for exposed or windy positions, and the plants do not need staking. They should be planted about 18 inches apart:—Bembow, rosy crimson; Dazzler, orange scarlet; Elna, crimson scarlet; Janet, rich orange; Julius, rosy scarlet; Kathleen, rich apricot; Lonise, primrose; Mincio, scarlet; Olive, deep orange; Pembroke, deep yellow; Regent, brilliant crimson; Roma, maroon crimson; and Royal, deep velvety crimson. These are all of good bushy dwarf habit, with single flowers, none growing over 18 inches in height.

For beds of taller varieties the following sorts are splendid, and if set 2½ feet to 3 feet apart, one stake to each, standing 3 feet out of the ground, will suffice. These are decorative Dahlias, with double flowers and good, erect stems; they are excellent for garden effect or supplying blooms:—Apricot, rich apricot; Hon. Mrs. Clive Pearson, scarlet; Knyswood Beauty, primrose; Pearl, pale rose; Champion, rich coppery yellow; Cambria, pink; Delice, pink; Orange King, rich orange; Paul Crampel, scarlet; Porthos, violet; Prince of Orange, orange; Queenie, amber; and Yellow King. These grow to about 3½ feet to 4 feet.

The following are good dwarf kinds, 2½ feet high:—Barlow's Bedder, scarlet; Reginald Cory, crimson, tipped white; Crimson Flag, crimson scarlet; Cheal's White, pure white; and Brentwood Yellow. *R. H. Holton.*

**ORCHID NOTES AND GLEANINGS.**

**BRASSO-LAELIO-CATTLEYA JUPITER.**

THE many forms of this grand hybrid, first shown by Messrs. Hassall and Co. in 1920, and since by several exhibitors at the Chelsea

Show last year, indicate that in this and many other of the outstanding hybrids the parentage discloses primary ancestors of proved good repute. Brasso-Laelio-Cattleya Jupiter was obtained by crossing B.-L.-C. Veitchii (B.-C. Digbyano-Mossiae × L. purpurata) and C. armainvilliereensis (C. Mendelii × C. Warsce-

FIG. 176.—ODONTONIA MEROPE VAR. VIVICANS. R.H.S. FIRST-CLASS CERTIFICATE, JUNE 7 (see p. 310).

Odontoda Radiant	Chantecler × Royal Gem	J. & A. McBean.
Odontoda Majestic	Odontonia Laireseae × Odm. crispum Harry-anum	Sanders.

wiczii), and the result is perfection in all respects, including large size, perfect shape and colour, which varies in different forms from bluish white with clear rose front to the lip to rosy-manve with deep ruby crimson lip, all having the usual yellow tint in the centro. B.-C. Digbyano-Mossiae, the Veitchian triumph of 1889, and for which a First-Class Certificate was obtained, was well illustrated in *The Gardeners' Chronicle*, May 25, 1889, p. 657, as Laelia-Digbyana × Mossiae, authorities of that day suggesting that the generic title assigned to the now more correctly named Brassavola Digbyana should be followed. It is a noted parent, and compares favourably with most of the more modern productions

**TREVORIA CHLORIS.**

In *The Gardeners' Chronicle* of May 29, 1897, p. 345, a full description of *Trevoria Chloris* (*n. gen. et spec.*) from the pen of its discoverer in the Western Andes of Colombia, the late F. C. Lehmann, together with interesting notes on the new genus and its discovery, was given, and in the same issue a supplementary illustration of the plant was given, showing its pendulous racemes of fleshy, whitish-green flowers. In the issue of November 3, p. 319, the record of its having flowered in the Burford collection appeared. At the meeting of the Royal Horticultural Society, September 25, Elijah Ashworth, Esq., Harefield Hall, Wilmslow, Cheshire, showed a small plant of it, and later it flowered well at Glasnevin, Dublin. It would be interesting to know whether the plant is still represented in gardens. Those who have specimens of any remarkable species of which only small quantities have been imported should attempt to raise small batches from seed.

## MARKET FRUIT GARDEN.

MAY was a very dry month in my district, which missed the storms that brought rain to some places in the near neighbourhood. The rainfall was only a little over half an inch (0.56 in.), which is much less than we had in May last year, and very much below the average. Although rain will soon be urgently needed, fruit trees have so far shown no signs of suffering from drought, and the weather has favoured the work of soil cultivation and weed killing. Spraying also has been done without interruption from rain, and insect pests kept under control. The general appearance of the plantations at the close of the month was very pleasing, and I feel justified in looking forward to one of those seasons of fair average crops which are generally more profitable to the grower than years of great abundance of fruit.

### FRUIT PROSPECTS.

Plums have not quite fulfilled the promise of their great display of bloom. Monarch is almost a failure for the second year in succession, and President, which suffered from blossom wilt (brown rot), will yield very lightly. But Czar has set a tremendous amount of fruit, really too much, and there promises to be a full crop of Rivers' Early Prolific, the most consistent bearer with me. Victoria and Pond's Seedling look like giving a moderate yield only, but Belle de Louvain, often a strong bearer, has set very well indeed.

Pears and Cherries, which made a fine show of bloom, are not going to crop heavily after all; but as I do not grow these crops for market the matter is of small importance. The failure of Pears is rather surprising, as they had a rest last year. Presumably the nights were too cold at blooming time, though there was only one occasion on which the temperature fell to 2 deg. below freezing 4 ft. above ground level.

### THE APPLE CROP.

Apples began to bloom on May 8, but blooming was not general until nearly a fortnight later. Most varieties made quite a good show, and the weather was most favourable for pollination. It is rather early to speak of results, but, so far as can be judged, the crop will be much better than one dared to hope for after last year's great yield and semi-starvation through drought. Worcester Permain and Blenheim Pippin are particularly promising, whilst Allington Pippin and Beauty of Bath are quite satisfactory except in one orchard where the trees are on grass. But the surprise to me is that Cox's Orange Pippin appears to have set a good crop for the second year in succession.

I like to think that the special manuring done last August with the idea of feeding the fruit buds, and overcoming biennial bearing, was not without results. There is some evidence that this is the case. In the grass orchard just referred to the only varieties that have set a good crop are those that missed last year. The rest are going to crop very lightly. The manuring failed here, as was expected, because it could not reach the trees in time through the turf with the ground so dry as it was last autumn. But in the cultivated plantations, varieties like Cox's Orange Pippin, Bramley's Seedling, Allington Pippin, and Beauty of Bath, which cropped very heavily last year, seem to have set a lot of fruit again. Here the manures stood a much better chance of getting into action, as they were worked in by cultivation. The evidence in favour of early autumn manuring may be slender, but it is good enough to encourage me to repeat the practice.

### THE SEASON'S PESTS.

Insect pests have not so far given a great deal of trouble, though caterpillars, particularly of the winter moth, are more numerous than they have been for two or three years, especially on Plums and Currants. Aphides and suckers on Apples were easily controlled, but Apple blossom weevil, which is little affected by spraying, was very much in evi-

dence, particularly on varieties that bloomed earliest in cool weather, and were therefore rather long in the bud stage. Leaf-curling Plum aphid would probably have been very serious had not most of the stem-mothers been killed by spraying before blooming. As it was some varieties had to be sprayed again after the fall of the petals. Red Currants are badly attacked by the leaf-blister aphid, which is also found to a smaller extent on Black Currants.

### A NICOTINE SUBSTITUTE.

Chlor-cresol has been suggested as a substitute for the expensive nicotine for spraying against sucking insects. I have made such tests as were possible with a small sample, and am not at all favourably impressed. Currants were thoroughly sprayed for leaf-blister aphid, with only very partial success. Even when a leaf was dipped in the solution some aphides survived, and those that eventually died lingered for some time. Spraying with nicotine and soap, on the other hand, was almost completely successful; and when a leaf was dipped not a single aphid survived for more than a few minutes. Moreover, the chlor-cresol failed to kill half-grown caterpillars, whilst the nicotine wash made very short work of them.

I do not suggest that this small trial is in any way conclusive. I should like to have the chlor-cresol itself, and use it with soap just as I do nicotine, trying different strengths. In this case the chlor-cresol was supplied as a strong solution with soap, to be diluted with 100 parts of water, this giving 3 lb. of the actual chlor-cresol per 100 gallons of wash. This wash did not seem to have very good wetting or spreading powers, so I tried adding more soap to some of it, but without better success so far as the kill was concerned.

In any case chlor-cresol must be made much cheaper if it is to rival nicotine. This wash, when diluted for use, costs 11s. 3d. per 100 gallons when bought in bulk. My home-mixed nicotine wash, which contains 8 oz. of 95 per cent. nicotine and 8 lb. of soft soap per 100 gallons, costs only 2s. 9d. per 100 gallons more, and is probably much stronger in soap than the bought wash. As a matter of fact, 5 lb. of soap is enough with a fairly soft water, but I like to be well on the safe side, and make sure of maximum spreading powers.

We very badly need a cheap substitute for nicotine, but it must be really effective. At present nicotine is far and away the best insecticide we have for aphid and all sucking insects. It is remarkably penetrating and very quick in action, and it has the great advantage that it kills young caterpillars at the same time.

### TIPPING LEADERS.

Some of my readers may remember that I decided to tip all the leading shoots of Apples of bearing age during last winter's pruning. Hitherto the leaders have been left full length after the first few years of hard pruning for tree formation. I am pleased with the result so far. The new growth carries much stronger, larger leaves, making the trees look very healthy. Moreover, there seems to be less powdery mildew on the young shoots. This disease is becoming more serious every year. There is a good deal of it about this season, but it is mostly confined to spurs. I attribute the escape of the young shoots to the tipping. I thoroughly believe in leaving leaders full length during the period when trees are being brought into bearing; but once they have begun to crop well, and have steadied down in growth, I think it is wise to return to light tipping.

### A FINE RED CURRANT.

Growers who want to try a new variety of Red Currant should plant Laxton's Perfection. It is a strong grower, extremely prolific, and bears big bunches of very fine fruit. The season is rather late, and the fruit will hang for a long while after it is ripe if desired. This variety ought to be tried for market purposes. *Market Grower.*

## FRUIT REGISTER.

### APPLE STOKE EDITH PIPPIN.

This is an excellent dessert Apple, in use from December to early March. It was raised at Stockbridge, a small farmstead on the Stoke Edith estate, a Mr. Merrick, who lived there at one time, about a century ago, being regarded as the raiser.

It was then known as Merrick's Kernel, until a workman named Sanders grafted a number of trees on the estate with this variety, when it obtained the name of Stoke Edith Pippin. The fruit is small, tapering, of pearmain shape, and regular in outline. The skin is yellow, with deeper yellow on the side next to the sun, and marked over the surface with traces of grey russet. The eye is large, closed, and set in a plaited basin; the stalk is short. The flesh is yellow, firm, crisp, juicy, and sweet, with a perfumed flavour. The tree makes healthy growth, and is a free bearer, especially where Apples are planted in variety, for with plenty of pollen foreign to the variety, the fruits set with more certainty than with its own pollen.

Many trees of this excellent dessert Apple are found around the Ledbury side of Herefordshire, but it is not much sought after as a commercial sort, owing to the fruit being small in size and not of attractive appearance. Nevertheless, it is a first-rate Apple. *Pomona.*

## VEGETABLES.

### RUNNER BEANS.

No crop repays better for good cultivation than the Runner Bean. The most important cultural detail is deep working of the soil. A trench, two feet wide and two feet deep should be excavated in the spring, and into the bottom of this about 18 inches of well-decayed rich farmyard manure should be placed, and left in this condition until the time for planting arrives. Last year we had good results from plants raised in boxes, under glass, the seed being put in on April 26. The plants were hardened gradually, and planted in a double row a foot apart at the beginning of June. The soil previously excavated was used for covering the manure, and planting the Beans in it. By these methods, earlier and more prolific crops result. The plants were carefully and securely staked, an important point, and for this long, stout Pea-sticks are the most useful. Mulching is of great value to the plants in dry weather, and the roots should be given plentiful supplies of water; spraying the plants with clear water at the end of a warm day will prove very beneficial, and assist the flowers to set. Best of All, Prizewinner and Scarlet Emperor are three excellent varieties.

### NEW ZEALAND SPINACH.

For a hot season it would be difficult to find a more useful vegetable than New Zealand Spinach, which seems to revel in the heat, and consequently its value this year should be considerable. For early crops it should be sown in heat in boxes, and the young plants pricked off into other boxes, about four inches apart. Get them established, and then harden them off with a view to planting out in a hot, sunny position, allowing about 30 inches each way for growing space. Plants raised from seed sown in the open, in shallow drills three feet apart, at the end of April, should be thinned to 30 inches apart in the rows. Give the plants plenty of water, and beyond frequent hoeings, little attention will be necessary. The best results are obtained on light, porous soil; where the ground is on the heavy side, it should have plenty of road grit or other light friable material added, and the site should be well trenched during the winter. This vegetable is a very palatable one, and much appreciated even by those who do not care for ordinary Spinach, for it lacks the slightly bitter flavour of the latter. *E. Beckett.*

## IRIS CONFERENCE.

THE Iris Exhibition and Conference, held at Vincent Square, on June 7 and 8, brought together the best collection of garden varieties of Bearded Irises that has probably ever been seen in the Hall, and also the largest gathering of Iris growers and enthusiasts. It was a pleasure to be able to welcome Monsieur S. Mottet, who brought over a number of flowers from M.M. Vilmorin's collection at Verrières, and the President and other members of the American Iris Society, who are fast making up for their late start in the cult of the Iris, by their tireless energy and abundant enthusiasm. Another welcome visitor was Mr. G. Yeld, whom the younger generation knows as a contemporary of Sir Michael Foster, and who has given us a number of good varieties, such as Lord of June, Sunshine and Dawn.

Irises are difficult flowers to exhibit in good form. It is almost useless to go out into the garden and cut a number of flowering spikes, for it is impossible to carry them to the exhibition without crushing and mangling the flowers beyond recognition. Yet this is possibly the only method of dealing with large numbers of varieties and stems. Another drawback of the method is that the flowers which develop later from buds are always undersized when they open after the stems have been cut some forty-eight hours or even longer. There is another and somewhat laborious method, which is to choose only stems on which fully developed buds are about to open and to tie these buds with wool before cutting the stems. These can then be packed much more closely and the buds should open into perfect flowers as soon as the wool is cut, when the stems are placed in water on their arrival. It is best to cut the stems in the late afternoon, and to put them in water for some hours before they are packed for the journey.

In one way the whole meeting was disappointing. It seemed to be taken for granted that Irises mean only tall Bearded Irises of the Pogoniris section. Irises of other sections of the genus are little known and little grown, but, if an Iris show becomes an annual event, it might be well worth while to include a class for species either of the Pogoniris or of other sections.

On this occasion the prizes were nearly all won either by Messrs. Wallace and Co., of Tunbridge Wells, or by Mr. Bliss, whose flowers came from their gardens. The late date fixed for the show and the fact that their Irises are grown on a north slope, no doubt eliminated several possible competitors, and for the group of twelve varieties, staged for the silver medal of the American Iris Society, Messrs. Wallace were very nearly defeated by Mr. Baker, whose spikes of Lord of June and Asia were better than anything showed from Tunbridge Wells.

Mr. Bliss' winning varieties were Brno, a large flower of considerable substance. Indoors the colour is a dull, murky combination of brown and purple, but sunshine lights it up, and it then becomes a much-improved Prosper Laugier; Duke of Bedford and Swazi, both of a dark blue purple shade with five large flowers of much substance, better distributed on a taller stem than the much-lauded Dominion; and Citronella, a large flower with pale yellow standards and dark reddish-purple falls edged with yellow. Seen in the distance, this last is a fine addition to the numerous variegatas, which we already possess, but, when closely examined, it is seen to possess a central line of yellow, running down the red-purple of the fall, which, as one spectator expressed it, was as disfiguring as a hare lip in an individual.

All Iris raisers are striving to produce a tall variety with clear yellow flowers. A distinct advance in this direction was shown by Chasseur, one of the varieties brought over by Monsieur Mottet. In this the yellow colour is brighter at the edges of the flower than in the centre, but the variety has hardly the tall stature, which is desirable if a yellow is to appear side by side with such fine things as the dark blue Duke of Bedford and Swazi, or the purple Ambassadeur and Cardinal.

Those who judge Irises at a show or in a large collection in nursery beds are rather apt to lose sight of the fact that not all Irises must be tall or dwarf at the same point of the Iris season. In garden borders we need a gradation in height from the front to the back of the border, and this lends additional value to the tall variety of early-flowering habit and also creates a need for varieties of dwarf or moderate stature, which flower late in the season.

It was to help amateurs arrange Irises in their gardens that the R.H.S. attempted to classify the garden varieties according to colour and

at the edges or nearly all over by veinings and dottings of blue or red-purple, to those varieties where the standards are white, or nearly so, and the falls purple. The authors of the scheme of classification had attempted in the former case to separate those varieties in which the feathering appears only at the edge from those in which the colour is suffused over the whole flower, and in the latter to draw a distinction between those varieties in which the veins on the falls remain distinct, and those in which they run together so that the colour is suffused over the whole surface. When the varieties

FIG. 177.—IRIS OCHRACEA COERULEA. R.H.S. AWARD OF MERIT, JUNE 7 (SEE P. 311).

published a preliminary draft of the proposed classification in the latest number of the *Journal*. This classification rightly ignores the botanical affinities of the various varieties, for much hybridization has now obscured the original species and mixed the characteristic features. The authors of the classification have also wisely decided not to become involved in disputes as to whether a colour is lilac, lavender, pale violet or mauve, and have confined themselves to blue-purple and red-purple, qualified when necessary by the addition of light or dark.

On the occasion of the Conference, all obtainable varieties of Bearded Irises were arranged round two sides of the Hall in accordance with this classification. The series began with the whites, of which the well-known albicans may be taken as the type, and went on through such flowers as Madame Chéreau and Parisiana, where the white ground is covered either merely

were placed side by side, it was found impossible to draw these distinctions with any certainty and they were therefore abandoned.

Next in the scheme to those varieties with white standards come the purple bicolors with standards paler than the falls, and then the purple selfs, among which are to be found the great majority of the forms of *I. pallida*.

Then come those varieties in which the yellow of *I. variegata* begins to make itself felt, though it may be as little apparent as it is in *Isoline* or as obvious as in *Iris King*. The various varieties of *I. variegata* come next, and these pass naturally into the yellow of Mrs. Neubronner, and the cream of *flavescens* and Dawn, which complete the circle and bring us back again to the whites with which we began.

When the list is eventually published, all the best known varieties will be fitted into this

scheme, and details will also be given as to the height of the stem and the time of flowering. If this proves successful and useful, it should be possible, at the end of each season, to publish a supplementary list allotting to each new variety its appropriate place in the classification.

At the present the best varieties are mainly of English origin, though a few years ago those sent out by Messrs. Vilmorin-Andrieux and Co. attracted most attention. Unless the number of raisers in this country increases, it seems as though America must soon take the lead, for there the growers are already raising seedlings by the thousand, and when they do this, with our best varieties as seed—and as pollen-parents—they are bound to obtain some good results. The raising of seedlings is a fascinating pursuit, and really it is not tedious. Seeds ripened one year should, in the majority of cases, germinate the next, and, if the young plants are properly treated, a fair proportion of them may be expected to flower in the following year. Then comes the really difficult task, for to some, all geese are swans, and yet in reality the swans are few and must tend to be ever fewer in years to come.

Most raisers have a bias, conscious or unconscious, in some one direction. Some aim at uniform colour, others at the shot or smoky shades, which seem to be so popular in France. Let us hope that this divergence of tastes will save the Iris from the awful fate of becoming a florist's flower, when it would have to conform to some set of arbitrary and rigid rules. Irises are garden plants. They must have sun if they are to be healthy and to display the colours of their flowers. These colours are seldom seen to advantage in a room, and never in the gloomy yellow light that filters through the canvas of tents. *W. R. Dykes.*

## HOME CORRESPONDENCE.

**Daisies (*Chrysanthemum maximum*).**—After the Pyrethrums there is often a shortage of flowers for cutting before the Lothian Bell and King Edward type of large Daisies are ready. At a recent visit to the gardens of Framingham Manor, Norwich, I found the genial gardener, Mr. Samuel High, striving hard to obtain a variety to fill in this gap. He has thousands of seedlings now bursting into flower, many of them of extra good form and with fine stems. As a market flower there is great demand for these wiry-stemmed Daisies. *H. P.*

**Tulip Carrara.**—The beautiful snow-white Tulip Carrara, to which an Award was given by the Tulip Committee at the Chelsea Show (see p. 230), was raised by Mr. E. H. Krelage. By the way, this is not the first white Darwin Tulip, as Mr. Van Tubergen introduced a few years ago his white variety, Zwanenburg. I believe the Tulip placed before the committee as *Phemis* should be *Themis*. The wonderful pink Parrot Tulip Fantasy shown at Chelsea was a break from the Darwin Tulip Clara Butt. *Peter R. Barr.*

## SOCIETIES.

### GRAND YORKSHIRE GALA.

JUNE 14, 15, AND 16.—On these dates the Grand Yorkshire Flower Show and Gala celebrated its diamond jubilee, and its president, James Melrose, Esq., is the only man living who was present at the inaugural meeting when just over sixty years ago a few enthusiasts decided the time had arrived when the City of York should have a flower show of its own. He has seen wonderful developments in horticulture, and lived to see the York Show become one of the finest exhibitions in the country. Mr. Melrose was present on this occasion, and presided at the luncheon given to the judges and exhibitors, and, in spite of his more than ninety years, he is hale and hearty.

The exhibition, in Bootham Park, just outside the old city walls, was, in our opinion, the finest yet held at York, and we write with nearly thirty years' experience. The whole display was under one roof, as was the International

Show of 1912, and as the recent Chelsea shows have been. The arrangement was excellent, as, with few exceptions, all the taller exhibits and those needing background, were disposed at the sides, leaving the great central area for lower and lighter arrangements, for cut flowers, and for rock gardens.

The rock gardens attracted a large amount of attention, and for many of the visitors they formed the chief feature of the show. In our opinion, the hardy flowers in competitive classes provided the feature of outstanding interest, and but for the recent devastating effect of hailstorms in the Bedale district we believe this section of the show would have been superior to the high standard it reached, even under difficulties. Scarcely less interesting and effective were the Orchids, provided the non-competitive displays are included, while for extent and beauty we doubt whether York or Shrewsbury have ever previously included such a superb display of bouquets and other floral designs.

The specimen plants of other years are no more to be seen at York, but there are groups of plants, and, this year, a large contribution of Roses and Sweet Peas.

Non-competitive exhibits were large, numerous, and of excellent quality. The managing body of the show encourages traders to send exhibits, and does everything in its power to ease their expenditure and lighten their labours. The result is a very fine show, and the traders feel their presence and their exhibits are desired—they are neither patronised nor merely tolerated.

We hope fine weather and a good attendance combined to make York Show as great a financial success as it deserved to be, judged alone by the liberal prizes offered in the admirable schedule of seventy-five classes.

### Luncheon.

The officers and committee of the York Show entertained a very large party of exhibitors, judges, and visitors to luncheon on the opening morning. The veteran president, Mr. J. Melrose, proposed the loyal toasts, and the Archbishop of York proposed "The President," a toast which was received with enthusiasm, and to which Mr. Melrose responded in reminiscent vein. The Dean of York proposed "The Royal Horticultural Society," to which Mr. W. R. Dykes, R.H.S. secretary, responded. "Exhibitors and Judges," proposed by Mr. Hodgson, chairman of committee, was replied to by Mr. James Hudson, V.M.H. Mr. Hunt, vice-chairman of the Gala Committee, gave "Kindred Societies and other Visiting Friends," and to this the Lord Mayor of York and the vice-chairman of the Shrewsbury Show replied. The final toast was "Prosperity to the Grand Yorkshire Flower Show and Gala," proposed by Mr. Charles H. Curtis (*Gardeners' Chronicle*).

### Groups.

Unfortunately there was but one exhibitor in the premier class for a large group of flowering and foliage plants arranged for effect upon a space not exceeding 300 square feet. This exhibit—to which the first prize of £20 was awarded—was set up by Mr. W. A. HOLMES, West End Nurseries, Chesterfield, whose elegant arrangement only needed the addition of a few choice flowering subjects to make it a very fine display. The central arch, with Palms, Codiaeums, and pendant Fuchsias, was a feature, while tall Codiaeums, Bamboos, and Jacaranda *mimosifolia* were the principal subjects in the base of the group. *Ixoras*, *Hydrangeas*, *Lantanas*, *Clarkias*, and *Fuchsias* were the chief flowering plants, while ferns of many kinds, *Nandina domestica*, *Pandanus*, *Dracaenas*, *Coleus*, and variegated *Abutilons* served to fill in the ground work.

In the class for a smaller group there were four competitors, and together they made an effective display. Messrs. JAS. CYPHER AND SONS, Cheltenham, won the first prize with a brilliant group, in which the leading items were *Cattleyas*, *Brasso-Cattleyas*, *Odontoglossums*, yellow *Arunas*, and *Ixoras*, with Palms, Bamboos, *Codiaeums*, *Selaginellas*, *Rex Begonias*, *Caladiums*, and *Jacarandas* as the principal

foliage plants. Needless to state, the arrangement was in that good taste which always characterises the Cheltenham exhibits. Second prize fell to Mr. W. A. HOLMES, who associated *Heaths*, *Orchids*, and *Ixoras* with bright-hued and graceful foliage plants in considerable variety; third, Mr. T. M. PETER, Bradford.

Amateurs' groups were scarcely so fine as at some previous York shows, but Mr. JOSEPH ROWNTREE made a successful display, and won first prize with an arrangement of *Schizanthuses*, salmon-hued *Clarkias*, four fine specimens of *Haemanthus Katherinae*, *Kalanchoe flammica* *Spiraeas*, and *Rhodantha Manglesii*; second, Mr. E. SPINK, Harrowgate; third, Mr. J. W. CLARK, York.

### Plants.

Mr. J. ROWNTREE was an easy first prize-winner for a group of *Begonias*, as he had not only erect and pendulous tuberous-rooted sorts, but numerous *Rex* varieties, *B. Haageana*, *B. sanguinea*, and other interesting kinds.

MESSRS. BLACKMORE and LANGDON set up a group of very fine *Begonias*, surmounted by three baskets of pendulous varieties, and every plant represented high-class cultivation. Needless to state, this display secured a first prize.

Mr. J. ROWNTREE just managed to beat Mrs. AKENHEAD for eight *Gloxinias*, but a week later the lady's plants would have been the better. Dr. MACDONALD led for eight *Calceolarias* with large free-flowered loosely trained specimens; 2nd, Mrs. AKENHEAD, with smaller but admirably grown examples.

Dr. MACDONALD, York, was particularly successful in the classes for *Calceolarias*, and won first prize for a large group of these showy greenhouse plants, in which herbaceous varieties and *C. Clibrani* were pleasingly associated.

### Orchids.

Orchids are usually shown in good condition, as they were on this occasion, but we remember York shows when they were more numerous and the competition was more exciting than this year.

MESSRS. JAS. CYPHER AND SONS, Cheltenham, led in all the classes they entered. The first prize of £12 for a table of Orchids fell to their share, and their exhibit was a handsome one, in which *Vanda teres* and light Bamboos formed a pleasing background for fine *Laelio-Cattleyas*, white and coloured *Odontoglossums*, *Oncidium Papilio*, *Dendrobiums* and *Cypripedium bellatulum*, all arranged admirably.

The Cheltenham firm led for a dozen *Orchids* in bloom, and some of their best plants were examples of *Laelio-Cattleya Tyntesfieldensis*, *L.-C. Canhamiana*, *L.-C. Bedouin magnifica*; *Vanda teres*, *Brasso-Cattleya Digbvana-Mossiae*, *Brasso-Laelio-Cattleya Veitchii*, and *Dendrobium chrysotoxum*. Messrs. A. J. KEELING AND SONS were awarded a third prize. For six Orchids in bloom Messrs. J. CYPHER AND SONS led with *Cypripedium grande*, *Laelia purpurata*, *Laelio-Cattleya Aphrodite*, and *L.-C. Canhamiana alba* with five handsome flowers; 2nd, Messrs. A. J. KEELING AND SONS.

The best three Orchids came from Cheltenham, and they were *Laelio-Cattleya Wiganiana*, *L.-C. Bedouin* and *Brasso-Laelio-Cattleya Veitchii*, the latter a very fine example; 2nd, Messrs. A. J. KEELING AND SONS. Messrs. J. CYPHER AND SONS won easily in the class for a specimen Orchid, in flower, showing a handsome plant of *Laelio-Cattleya Canhamiana Rosslyn* variety, with five beautiful flowers; 2nd, Messrs. A. J. KEELING AND SONS.

In the amateurs' classes Mr. JOSEPH ROWNTREE (gr. Mr. F. Dean), Clifton Lodge, York, won first prizes for three Orchids and one Orchid.

MESSRS. FELTON AND SON, Hanover Square, W., presented a silver cup to be awarded for the best Orchid in the show, whether in competitive classes or not; the judges decided in favour of a fine plant of *Coelogyne pandurata*, with two spikes of its green and black flowers, exhibited by Messrs. MANSELL AND HATCHER, in their non-competitive group.

### Rock Gardens.

The premier award for a rock garden arranged on a space of 30 ft. by 12 ft., was won by Mr. JOHN WINN, Moorgate, York, who had a pleasing, low design wherein every plant could be

seen without effort. The laminated rock was also admirable for the purpose. The planting was carried out carefully and no effort was made to create a brilliant effect. In two of the low portions moisture-loving Mimulus and Primulas were associated, while on and among the rocks the low growing kinds of Campanula, Dianthus, Sedum, Viola, Linum, and Oxalis were disposed. Messrs. J. BACKHOUSE AND SON were awarded second prize for a restrained effort, in which were colonies of Oxalis enneaphylla, Ramondia pyreniaca, Campanulas and Dianthus in great variety, Edelweiss, Sedums, Alpine Asters, and Violas, with tiny Pines occupying the higher positions. Mr. R. V. ROGER, Pickering, was placed third for a scantily planted design, wherein the plants appeared to have been set in sand.

The ornamental rockwork class proved a great attraction, and here Mr. P. GARDNER, Ilkley, had the best arrangement in a space 30 ft. by 12 ft. The rock was disposed quite naturally and the planting was restrained. A few especially attractive plants were Viola Golden Wave, Saxifraga aizoon rosea, Helianthemum, and the white Viola Clarence Elliott. The second prize was awarded to Mr. S. PICKERING, Clifton, York, for a bold and effective arrangement, wherein the planting was a trifle too dense. A feature of this design was the admirable collection of Sempervivums.

#### Floral Designs.

The splendid array of floral designs attracted much attention and many of the items received unstinted admiration. Messrs. FELTON AND SON, Hanover Square, won the lion's share of the awards, and this firm's name occurred with monotonous frequency on the first prize cards.

In the class for a hand-basket of flowers Messrs. FELTON scored a great success with a very pretty combination of Odontiodas, Odontoglossums, Laelio-Cattleya Canhamiana, and a trail of Cymbidium over the handle; 2nd, Mr. M. STATHER, Cottingham; 3rd, Mr. F. WARD, York. In the succeeding class for a hand-basket of flowers, Orchids excluded, Messrs. FELTON AND SON led with a charming design in pale yellow Carnations and small, rose-coloured Richardias; 2nd, Mr. STATHER; 3rd, Mr. WARD. The bowls of Roses were not particularly good; Messrs. FELTON AND SON were placed first for a low arrangement of Golden Ophelia; 2nd, Mr. ELISHA J. HICKS, Twyford; 3rd, Mr. M. STATHER, who had an excess of luxuriant foliage. For a bowl of flowers the Messrs. FELTON won premier position with a bold and rich arrangement of Orchids, including Laelio-Cattleyas, dark Odontoglossums and Cymbidium Lowianum; Mr. STATHER followed with red Malmaison Carnations, and Mr. WARD took third prize with blush and crimson Carnations. The Hanover Square florists were the only exhibitors of a bowl of Nymphaeas, but their exhibit showed how successfully these Water Lilies may be used in a suitable bowl.

Messrs. FELTON AND SON won all the first prizes in the bouquet classes, and in most instances they were easy winners. Their bride's bouquet was a delightful design in white Cattleyas and Odontoglossum crispum xanthotes—a dainty, light and lovely bouquet; 2nd, Mr. STATHER, with a goodly design in white Orchids, which included Phalaenopsis Rimestadiana; 3rd, Mr. WARD, with white Carnations. Messrs. Felton's bridesmaid's bouquet was the design of a genius in floral art; it was a light combination of Odontiodas, yellow Odontoglossums and Anthuriums; Mr. STATHER came second with mauve and white Orchids, and Mr. WARD third with pink Carnations. Using chiefly large mauve and purple Laelio-Cattleyas, the Messrs. FELTON won first place for a pair of ball bouquets, their second bouquet consisting of small yellow Richardias and crimson spathes of Anthurium Andréanum and A. Scherzerianum—a glorious bit of colour work. Messrs. STATHER and BACKHOUSE AND SONS were second and third respectively. In the classes for a pair of hand bouquets and for a single bouquet the order of merit was Messrs. FELTON AND SONS, Mr. F. W. WARD and Mr. M. STATHER. Altogether, there were forty-three separate exhibits in this section.

#### Hardy Flowers.

Three very fine exhibits were forthcoming in the class for a collection of hardy perennials, including Liliums, but excluding Roses, arranged on a space not exceeding 300 square feet. In themselves these three displays made quite a respectable show, and each represented a vast amount of forethought and skill. Judgment was by points as follows:—Quality of bloom, 60; harmonious blending of colour, 20; artistic arrangement and general effect, 20; total, 100.

The prizes offered were £15, £12, £8, and £5, respectively, and Messrs. W. ARTINDALE AND SON won the first prize, and deservedly so, as their effective group was admirably arranged, and some pains had been taken to give it a good finish. The points awarded were 50, 15, and 18 respectively; total, 83, out of a possible 100. The Sheffield firm had three fine groups of Eremurus Elwesianus, comprising about nine dozen fine spikes; they also had a fine selection of Pyrethrums, Spanish and Bearded Irises, Paeonies, Erigeron Asa Gray, Poppies, Delphinium, Capri, Liliun umbellatum, L. Martagon, Dictamnus Fraxinella alba, Anchusas, and Heuchera sanguinea grandiflora. Messrs. HARKNESS AND SON won second prize with a display in which oriental Poppies and Lupins were conspicuously good; their points were 55, 12, and 13 respectively, or a total of 80 out of a possible 100, so the competition was fairly close. Messrs. G. GIBSON AND CO. won third position with 40, 10, and 12 points respectively, or 62 out of 100.

Messrs. HARKNESS AND SON were a good first in the class for a collection of hardy flowers, arranged in the form of a low bank. Papaver Kathleen, Lupins, Pyrethrums, Geums, Iris, and Liliums were all well shown; second Messrs. G. LONGSTER AND SONS; third, Messrs. G. GIBSON AND CO.; fourth, Messrs. W. ARTINDALE AND SON. All the exhibits were of good quality.

For two dozen bunches of hardy flowers the judges awarded the leading position to Messrs. G. LONGSTER AND SONS, Malton, who had very fine bunches of the white form of Lupinus polyphyllus, Pyrethrum James Kelway, P. Queen Mary, Achillea serrata, Spiraea Queen Alexandra, Verbascum Caledonia, Inula glandulosa, Centaurea aurea, Hesperis matronalis, Erigeron B. Ladham's, and other good things; second, Messrs. HARKNESS AND SON, Bedale.

Mr. W. HUTCHINSON won first prize for a dozen bunches of hardy flowers, and his best bunches were of Inula glandulosa, Heuchera sanguinea grandiflora, and Papaver Mrs. Perry; second, Mr. R. KETTLEWELL, who was strong with Pyrethrums and Erigeron B. Ladham's; third, Mr. J. KETTLEWELL.

Messrs. W. ARTINDALE AND SON led for a display of Irises, followed by Messrs. HARKNESS AND SON and Mr. H. SWANN. Messrs. HARKNESS AND SON and Messrs. E. GIBSON AND CO. won first and second prizes respectively for a group of Lupins, and the first-named firm was awarded first prize for a display of Oriental Poppies.

Messrs. E. W. KING AND CO. contributed a very fine display of Sweet Peas, arranged on a space of 100 square feet. The flowers were disposed in tall stands and in baskets, and the whole effort was very greatly admired. Advance, The Sultan, and Mrs. Tom Jones were conspicuously good varieties. This exhibit was awarded the first prize in this class.

#### Roses.

Considering the early date and the period of hot dry weather experienced, the Roses were fairly good, and, on the whole, competition was good also.

For seventy-two blooms in not less than three dozen varieties Mr. H. DREW, Ledbury, secured the first prize, and we noticed good blooms of Lyon Rose, Mdme. Edouard Herriot, and Mrs. C. E. Shea in his boxes; second, Messrs. JARMAN AND CO.; third, Mr. E. J. HICKS. Mr. DREW also had the best set of four dozen blooms, and in this class the prizes were well contested, Mr. E. J. HICKS, Messrs. JARMAN AND CO., and Mr. J. PRINCE following Mr. DREW in the order of mention.

Mr. G. PRINCE and Mr. G. BURCH were first and second respectively for a dozen blooms, dis-

tinct, and these exhibitors held similar positions in the class for twenty-four blooms. In the class for thirty-six blooms the contest was a keen one, and finally the awards were made in order to Mr. G. PRINCE, Mr. DREW, and Mr. BURCH.

The best table of decorative Roses was the one set up by Mr. GEORGE PRINCE, Oxford, who had a pleasing arrangement, wherein the vases and stands of Hoosier Beauty, Golden Emblem, Mrs. H. Moore, C. V. Haworth, Golden Ophelia, and K. of K. were the most conspicuous.

#### Fruits.

York Show is held rather too early in the season for fruits, but before the war there was invariably a good competition in the several classes provided. This year there was evidence of reviving interest, but the number of competitors was rather limited.

J. BRENNAND, Esq. (gardener, Mr. J. Hathaway), Baldersby Park, Thirsk, won first prize for a collection of six kinds of fruits, with good examples of Black Hamburg and Foster's Seedling Grapes, Cardinal Peach, Figs, Cherries, and a Melon; and for a collection of four kinds, with Black Hamburg Grapes, White Heart Cherries, Early Rivers Nectarine, and Hero of Lockinge Melon. Mr. BRENNAND was premier prize-winner in the classes for White Grapes (Foster's Seedling), for Cherries, and for a white-fleshed Melon. IIRAM CRAVEN, Esq. (gardener, Mr. N. Hague), Sunderland, led for a scarlet-fleshed Melon, a green-fleshed Melon, and six Figs. Major J. W. DENT exhibited the best Nectarines (Early Rivers), and the MARQUIS OF RIPON (gardener, Mr. E. Thomas), Studley Royal, Ripon, led for Peaches.

Mr. F. H. WARD was the only exhibitor of a decorated table of ripe fruit, and was awarded first prize. His exhibit contained Pineapples, Oranges, Apples, Apricots, Melons, Grapes, Cherries, Peaches, and Nectarines, and his floral decorations were of blush Carnations, Clarkias, and Gypsophila.

#### Medal Awards.

The following awards were made to non-competitive exhibits:—

*Large Gold Medal.*—To Messrs. MANSELL AND HATCHER, Rawdon, for Orchids; to Messrs. J. CARTER AND CO., Raynes Park, for "Queen Alexandra's Garden"; to Messrs. SUTTON AND SONS, Reading, for flowers and vegetables; to Messrs. ALLWOOD BROTHERS, Haywards Heath, for Carnations and Pinks; to Messrs. KENT AND BRYDON, for Iris, formal and water gardens; to Messrs. PULHAM AND SON, New Oxford Street, W., for rock garden and waterfall; to Messrs. R. BOLTON AND SONS, Baythorned, Halstead, for Sweet Peas; and to Messrs. S. BROADHEAD AND SON, Huddersfield, for Alpine Garden.

*Gold Medal.*—To Messrs. SANDERS, St. Albans, for Orchids; to Messrs. WHITELEGG AND CO., Chislehurst, for "Queen of Spain's Garden"; to Messrs. J. PEED AND SON, West Norwood, for stove and greenhouse plants; and to Messrs. WM. CUTBUSH AND SON, Highgate, for Roses and Hydrangeas.

*Large Silver Medal.*—To Messrs. STORRIE AND STORRIE, Glencarse, for Aquilegias; to Messrs. RYDERS, St. Albans, for flowers and vegetables; to Mr. MAURICE PRICHARD, Christchurch, for hardy flowers; to Messrs. R. H. BATH, Wisbech, for Paeonies; to Mr. C. ENGELMANN, Saffron Walden, for Carnations; to Mr. W. WELLS, Merstham, for hardy flowers; to Messrs. S. BIDE AND SONS, Farnham, for Sweet Peas; to Messrs. TOOGOODS, Southampton, for flowers and vegetables; to Mr. R. V. ROGER, Pickering, for alpine and shrubs; to Mr. G. MILLER, Wisbech, for hardy flowers; and to Messrs. MAXWELL AND BEALE, Broadstone, for hardy plants.

*Silver Medal.*—To Mr. H. N. ELLISON, West Bromwich, for Ferns and Cacti; to Mr. G. BURCH, Peterborough, for Roses; to Messrs. BAKERS, Wolverhampton, for Poppies; to Mr. P. GARDNER, Ilkley, for alpine and shrubs; to Mr. H. BROWNHILL, Sale, for seedling varieties of Campanula persicifolia; to Messrs. W. H. SIMPSON AND SONS, Birmingham, for flowers and fruits; and to Messrs. JARMAN AND CO., Chard, for Centaureas and Pelargoniums.

## NATIONAL VIOLA AND PANSY.

The monthly meeting and show of the above Society was held on June 7, at the Crown Hotel, Birmingham. Mr. H. J. Milner occupied the chair, and there were 35 members present, including the Hon. Secretaries.

Mr. CHAS. COCKBURN, of Bee Cottage, Pencaitland, East Lothian, was awarded a Silver Medal for an honorary exhibit of show Pansies, most of which were seedlings of his own raising. Mr. Cockburn is to be congratulated on his endeavours to revive the show Pansy, and the Floral Committee was of the opinion that Mr. Cockburn's blue self seedlings were exceptionally fine.

Mr. C. BECKETT, last year's most successful amateur exhibitor at the Society's shows, gave a Paper on "Violas from a Beginner's Point of View," which was both instructive and humorous. Mr. Beckett emphasised the fact that he made the mistake made by most beginners in growing too many varieties and not sufficient of each variety, and advised intending growers to stick to the best dozen or eighteen exhibition sorts and grow at least a dozen of each.

Mr. W. H. C. TOOLY DESMOND, winner of the Viola Challenge Cup in 1920 and 1921, gave the members several valuable hints as to feeding and manuring of Violas for exhibition, and Mr. J. Bastock, founder of the Society and raiser of Moseley Perfection, and several other well-known varieties, congratulated Mr. Beckett on his past successes, and moved a vote of thanks for his excellent paper.

The following awards were made in the Members' Monthly Medal Competition:—Open (Viola Vases), 1st, Mr. W. H. C. TOOLY DESMOND, Moseley; Open (Viola Boards), 1st, Mr. W. H. C. TOOLY DESMOND; Amateurs (Viola Vases), 1st, Mr. W. M. HARWARD, Sparkbrook; Amateurs (Viola Boards), 1st, Mr. A. HOLBROOK, Harborne; Amateurs (Pansy Boards), 1st, Mr. T. H. JUSTICE, Wolverhampton.

## Obituary.

F. Clarke.—We record with deep regret the death of Mr. F. Clarke, for over forty years gardener to the Earl of Lonsdale, Lowther Castle, Penrith, Cumberland. Mr. Clarke, who died at a nursing home at Carlisle, on the 31st ult., retired about seven and a half years ago, and resided at Penrith. The death of his wife about six months ago, after fifty years of happy married life, proved a great blow to him, and some three months later he had a breakdown in health. He underwent two operations, from which he so far recovered as to be able to return to his home at Penrith, but complications ensued, and he returned to the nursing home for special treatment, but, unfortunately, pneumonia supervened, and he died, as stated, in his eighty-first year. He leaves a family of one son and two daughters; the son is Lord Lonsdale's private secretary.

## THE WEATHER.

## THE WEATHER FOR MAY.

MAY was a particularly pleasant month, the easterly winds often frequent in that month being replaced by south-westerly and westerly ones, and these mainly of a light, fine, anti-cyclonic type. The month was therefore clear, sunny, warm and quiet with sea breezes practically every afternoon, and only sufficient rainfall to keep vegetable growth healthy. There was a slight excess of evaporation, and a large amount of ozone. Air pressure was above normal, and very steady. The mean temperature was 52.5°, or 2.1° above the average. The only cold spells occurred during the first few days, and from the 11th to the 14th; these included three nights with moderate frost in the open, but there was none in the screen. In marked contrast to the great heat experienced over much of England, the maximum thermometer at Southport only twice rose above even 70°, and never reached 75°. There was a shortage of nearly half an inch of rainfall, the total fall amounting to only 1.66 inch but it was spread over the usual number of days, viz. 14. Of bright sunshine, 250 hours were recorded, or nineteen more than the normal number. A shower of hail fell on the 4th, and some thunder was heard

on the 21st and 22nd, but no storms occurred, nor was any lightning seen. Gales were entirely absent. A fine lunar halo was observed on the 5th. Joseph Bazendell, The Fernley Observatory, Southport.

## THE WEATHER IN SCOTLAND.

THE cold weather which was such a marked feature of the spring of the present year extended well into May, but towards the end of the month there was a sudden rise of temperature, culminating in a day of midsummer warmth on the 31st. The rainfall was abnormally low, viz., 0.78 inch for 12 days, against an average of 0.09 inch for 14 days; the wettest days were the 20th and 21st, with 0.14 inch each. Bright sunshine was almost normal, with an aggregate of 168.3 hours, giving an average of 6.1 hours per day and a percentage of 37; there was only one sunless day while the brightest day, the 31st, registered 15.1 hours. While the mean temperature was almost normal, the mean maximum was above and the mean minimum below the normal; the figures for the month are:—Mean temperature 49.5°, mean maximum 60° and mean minimum 41°. The highest maximum of 78° was recorded on the 31st, and the lowest minimum of 30° on the 12th; there were only two nights of frost. On the grass the mean minimum was 36°, with a lowest of 23° on the 12th; there were 7 nights of ground frost. At 1 ft. deep the soil temperature, with a mean of 50°, rose with fluctuations from 45° to 56°. Hail fell on the 12th; thunder was heard on the 17th. The prevailing winds were from the south-west, with gales on the 14th and 26th. John Davidson, Director of Studies, St. Andrews Training College Gardens, Kirkton-of-Mains, near Dundee.

178,255.—Rhoads, H. F.—Insect attracting and exterminating devices.

## ABSTRACT PUBLISHED THIS MONTH.

*Pollinating Plants.* Patent No. 177,441.—An apparatus for artificially fertilising plants has been designed by Mr. M. Belgirate, of Piedmont, Italy. It consists of a water vessel heated by a burner, and containing a pump with delivery pipes and suction pipes, connected to flexible pipes having bell-mouthed ends. The flowers to be treated are placed between the ends, and the pump being operated, the pollen is sucked from the flowers and drawn through the pipes. Finely divided substances, such as talc or ash, impregnated with iron sulphate or lead arsenate, are placed in a chamber and, passing into the pump through a valve, mix with the warm air and pollen, which is carried through the pipes and thence projected upon the pistils of the flowers. The apparatus may be fitted with shoulder-straps, or may be placed on a truck, etc.

Messrs. Rayner and Co. will obtain printed copies of the published specifications, and forward on post free for the official price of 1s. each.

This list is specially compiled for *The Gardeners' Chronicle*, by Messrs. Rayner and Co., Registered Patent Agents, of 5, Chancery Lane, London, from whom all information relating to patents, trade marks, and designs, can be obtained gratuitously.

## ANSWERS TO CORRESPONDENTS.

**BLACK ROT IN TOMATOS:** E. F. G. Your Tomatos are suffering, as you suspect, from *Macrosporium tomatum* (Black rot). The diseased parts should be burnt and the plants sprayed at frequent intervals with a solution of potassium sulphide. An excess of moisture at the roots, or in the atmosphere, will cause the fruits to crack, and thus render them peculiarly susceptible to this disease.

**FOOT ROT IN TOMATOS:** J. W. B. The trouble is caused by the "damping-off" or foot-rot disease, which is a very frequent cause of collapse in seedling Tomatos. The disease is frequently fatal after water has been applied. Experiments carried out at the Experimental and Research Station, Cheshunt, by Mr. W. F. Bewley, show that infection of the seedlings comes primarily from the soil and water, and that seed boxes and pots may carry on the infection from one season to another. High temperature, careless watering, and thick sowing may all assist the spread of the disease. Sterilisation by heat or the application of formaldehyde will free the soil from disease, therefore all seeds should be sown and seedlings potted in sterilised soil. When the disease has made its appearance an application of a fine mixture of ten parts of dry slaked lime and one part of copper sulphate, at the rate of 3oz. to the square foot of soil surface, is useful in reducing the disease.

**HYDRANGEAS:** J. H. M. It is difficult to account for your failure to flower Hydrangeas. You do not state what varieties you are cultivating. Some of the older sorts of *H. hortensis* are rather uncertain in flowering. The newer varieties such as Mme. E. Mouillère, Générale Comtesse de Vibraye, and Radiant flower more regularly, as also does the black-stemmed var. *cyocnada*. Cuttings made of strong shoots, rooted now and potted on into five-inch pots, should flower next year. The plants should be grown in cold frames, and exposed freely to the weather at all times except during frost, which is apt to destroy the buds; during autumn and winter the roots should be kept on the dry side. Do not introduce the plants into strong heat directly, but start them gradually in an ordinary greenhouse temperature, for, in common with many other plants used for forcing, they need to develop gradually, and at no time should they be grown in a temperature above 60°.

**NAMES OF PLANTS:** II. N. 1, *Scilla italica*; 2, *Asphodelus ramosus*.—R. I. L. We do not recognise the variety of *Fuchsia*. Send it to some nurseryman who makes a speciality of these plants, such as Mr. H. J. Jones, Rye-croft Nurseries, Hither Green, Lewisham.

**POTATOS WITH WEAK GROWTH:** T. H. W. The trouble is doubtless due to the seed being over-ripened. We have had one or two similar cases sent us this season, and no doubt the trouble is due in part to the very hot summer of last year.

**TULIP BULBS:** A. M. L. The Tulip certainly forms a new bulb every year. If you examine a plant, you will find the new bulb and offsets already formed or in course of formation. The bulb you planted has almost disappeared, the food in the fleshy scale leaves having been absorbed by the growing plant. The stem and leaves are attached at the base to the new bulb, and on no account should the growth be severed from the bulb. After the plants are removed from the bed, heel them in, so that food which is manufactured in the leaves may pass to the new bulb. After the foliage has died down, lift the bulbs and store them in a dry place. October is the best month for planting, but you will not obtain very good flowers from bulbs which have been prematurely lifted. Such bulbs are best planted in the reserve garden and utilised for bedding the next year.

**Green Manuring,**

The question of the economic value of green manuring in garden and market garden practice is one to which no confident answer can as yet be given. Experiments were begun at Wisley some years ago, and we believe are still in progress. The results of these experiments were very interesting; but so far as we can remember, no final conclusions have as yet been published. A very thorough and readable account of Green Manuring has recently been published in America\*, but although it contains the best account which we have seen of the rationale of the process, it has reference primarily to farm, and not to ordinary garden practice. It is doubtful whether any gardener would find it necessary to consider the adoption of green manuring as part of his routine practice were it not for the fact that organic manure is becoming increasingly expensive and difficult to obtain. Where this is the case, a gardener would probably find it more economical to undertake the keeping of pigs, with the object of securing from them the organic matter needed by the garden, rather than to resort to the practice of green manuring. Pigs bought in for summer keeping, fed in part on waste garden produce and sold in the late autumn when the chats of the Potato crop are exhausted, are a not uneconomical means of providing the humus without which the fertility of garden land cannot be maintained at its highest pitch. From the poultry yard, also, with economical management, valuable manures, rich not only in nitrogen

but also in phosphorus, may be obtained, and if incorporated with the general garden debris in a well made compost heap, these supplies will prove of great benefit to garden crops. But there are many gardens in which pig-keeping cannot be practised, and it is in these places where green manuring might be tried with possible economic advantage. Anyone who decides to adopt this practice would do well to make up his mind at the outset whether he means to practise green manuring as part of a garden rotation, or by means of catch crops. Which of these two methods is adopted must depend primarily on the amount of land available. Where garden space is restricted, only the catch crop method can be tried, but where plenty of land is available, the rotation method might, perhaps, be adopted with advantage. By the catch crop method is, of course, meant the sowing of a crop for digging in between main crops of one year and the next. For example, it is possible, if the land is not required for other purposes, to sow White Mustard or other catch crops after early and second-early Potatoes have been lifted or after the main crop Peas have finished. Experience shows, however, that to leave the sowing later than about the second week of August is to risk a poor germination. The land is generally dry and always warm at that season, and it not infrequently happens that the germination even of Mustard is poor. Winter Rye sown late and dug in when the ear begins to shoot in spring, gives a good bulk of green manure, and although it does not enrich the soil in nitrogen as do the Legumes—Red or Crimson Clover, Lucerne or Vetches—Winter Rye has often given good results as revealed by the yields of crops succeeding it. It is probable that a mixture of Winter Rye and a Leguminous crop would give even better results. There is, however, to be considered in these cases the fact that the ground has to be left unworked throughout the winter—a serious drawback in the case of land on the heavy side. Mustard, of course, has an advantage in this respect, for it needs to be dug in before the autumn frosts. It is said, also, to have a good effect on land infested with wire-worm, though in our experience its value in this respect is doubtful. Where plenty of land is available, green manuring might be tried on a more systematic scale by introducing a crop to be dug in with the ordinary garden rotation. In such cases there would be no risk of partial failure of the green manuring crop, and Legumes which stand for more than one season might be used. Among such plants, Russian or Hairy Vetch (*Vicia villosa*) is often used in the United States and has the advantage of being thoroughly hardy. In our climate, however, it is not unlikely that the common Vetch (*Vicia sativa*), would prove a better plant for this purpose. In orchards in America, Alfafa (*Medicago sativa*) is much used as a cover crop and might prove valuable here for green manuring. Another plant which has been tried on a large scale in America is Crimson Clover (*Trifolium incarnatum*)—a winter annual with a high nitrogen content. Whatever crop be used it is important that it should be turned in not less than a fortnight before the ground is sown with another crop, for otherwise germination is apt to be poor, probably due to toxic substances produced during the early stages of decay. In the present state of knowledge it is not possible to state that green manuring in the garden is in all cases a profitable operation, but there is enough evidence in its favour to make it worthy of a systematic trial by all gardeners who find difficulties in securing adequate supplies of farmyard manure at reasonable cost.

**Royal Horticultural Society of Aberdeen.**—For a number of years, the directors of this Scottish society have experienced considerable anxiety over the financial results of their annual exhibition. The venue of the show for many years has been the Duthie Public Park, Aberdeen, an ideal and charming setting for such a display, but it is rather remote, being situated on the outskirts of the city. This difficulty of access has led the directors to the conclusion that if the people will not come to the show, the show must be brought to them. To this end, application was made to the Town Council, asking leave to allow the show to be held in Union Terrace Gardens, on August 24, 25 and 26, instead of in the Duthie Park. The Terrace Gardens are situated in the heart of the city, and the twenty arches which carry the roadway which gives name to them, could easily be adapted to house a large exhibition. The span measure of each arch is over 20 feet, and would enable much greater scope for a display than that afforded by the marquees and tents used in Duthie Park. The matter came before the Links and Parks Committee of the Town Council on 14th inst., and it was unanimously resolved that the application of the Society be granted.

**Gardeners' Company and London Children's Outing.**—For the seventeenth year, the Gardeners' Company is defraying the cost of a day's outing in the country for 200 poor London children, under the auspices of the Fresh Air Fund. Commencing from Tuesday, the 13th inst., the Fund will provide outings to Epping Forest for from 600 to 1,000 children daily throughout the summer.

**Economic Biologists' Visit to Wisley.**—By kind invitation of the Director of the Royal Horticultural Society's Gardens, Wisley, Ripley, Surrey, the Annual Field Meeting of the Association of Economic Biologists will be held in the R.H.S. Gardens on Friday, June 30. The party will travel by motor charabanc, leaving London about 11.15—11.30 a.m. Lunch will be partaken of at the Hut Hotel, Wisley, after which the gardens of the Society, the laboratories, orchards and field trials will be visited. The Association will be entertained to tea by Mr. F. J. Chittenden, and leave about 5.30 p.m., reaching town about 6.45 p.m. Members proposing to take part in the outing are requested to notify Mr. Wm. B. Brierley on or before Saturday June 24. The provisional programme of the day's proceedings is as follows:—(1) Variety trials and yield tests; (a) Vegetables—Peas, Beans, Potatoes, etc.; (b) Flowers—Sweet Peas, Stocks, Violas, etc.; (c) Fruits—Currants, Strawberries, and Raspberries. (2) Fruit collections—Apples, Pears, Grapes, Figs, etc. (3) Ornamental plants and new Chinese and Tibetan plants, rock garden, herbaceous borders, wild garden, and trees. (4) Fruit experiments—bud variations, pruning, planting, pollination. (5) Investigations upon plant diseases. (6) Investigations upon insect pests. (7) Green manuring experiments. (8) The laboratories.

**The late Mr. S. T. Wright.**—We are informed that a subscription list has been opened for those who wish to mark their appreciation of Mr. S. T. Wright's services to the Fellows of the Royal Horticultural Society at Wisley and elsewhere. Contributions should be sent either to Mr. F. J. Chittenden, at Wisley, or to Mr. Frank Reader, at Vincent-square, and cheques and postal orders should be made payable to one or other of these gentlemen.

**Forest Rambler's Club at Gravetye Manor.**—On Thursday last, at the invitation of Mr. William Robinson, members of the Forest Rambler's Club, some twenty in number, spent a pleasant and profitable afternoon in the beautiful gardens and grounds at Gravetye Manor, in Sussex. It would be difficult to say when Gravetye is at its best, for it is attractive at all seasons of the year, but mid-June, when Iris, Clematis, Water Lilies, and a large percentage of the rarer trees and shrubs are at their best, is perhaps the most interesting

\* Green Manuring, *Farmers' Bulletin*, 1250, United States Department of Agriculture.

period to the lover of hardy plants and trees. The Clematises in the cultivation of which Mr. Robinson specialises, and of which he has a large selection, were superb, and allowed to grow on their own roots, not grafted, as is usually the case, and they wander at will amongst the branches of trees and shrubs, presenting a sight not soon to be forgotten, whether for range of colour or size of the individual flowers. Some uncommon and interesting shrubs such as *Cornus Kousa*, *Enkianthus*, *Osmanthus*, and many kinds of *Magnolia*, were flowering with unusual freedom. Mr. Robinson, whose interest in plants has never flagged, and who is constantly adding to his collection—not in ones and twos, but by the hundred—accompanied the party around the grounds, and proved a most interesting guide.

**A Yucca Wood Table.**—The late Sir Walter Henry Harris, C.M.G., of Rothley House, Macaulay Road, Clapham, has bequeathed a table made by his father from *Yucca wood* in 1844, and his indentures of apprenticeship, to the South Kensington Museum, or, if not accepted by the museum, then to the museum at Kew Gardens.

**British-grown Tomatos.**—The enterprising effort of the Lea Valley Growers to extend the consumption of British-grown Tomatos and Cucumbers by means of advertisements induced growers of other districts to combine with them. The effort is proving so successful that a film has been produced for display at seaside cinemas; this film shows the work done at the Experiment Station at Cheshunt, and how the Tomatos are cultivated in the Lea Valley and finally packed in non-returnable containers which are boldly labelled to indicate that the contents are British grown. The pictures of the enormous ranges of glasshouses in the Lea Valley will come as a great surprise to those who see the film, and will give the British public a new idea of a great industry. A simple little love story is woven into this filmed presentation of Tomato cultivation, wherein the Love Apple (Tomato) is the means of defeating the Apple of Discord and of rekindling the love of a young and handsome husband for his young and beautiful wife.

**Bequest to a Gardener.**—Miss Alice de Rothschild, of Waddesdon Manor, Aylesbury, who died in Paris on May 3, has left to Mr. G. Sims, her bailiff, at Waddesdon, a legacy of £2,000 and an annuity of £150, and to Mr. Johnson, her gardener, £3,000 and an annuity of £52.

**Sale of a Famous Herbarium.**—The United States National Museum has purchased the herbarium of Dr. Otto Buchtien, formerly director of the Museo Nacional, La Paz, Bolivia. The herbarium is said to consist of approximately 45,000 specimens, acquired principally through many years of botanical exploration in South America, and through exchanges with institutions in many parts of the world. It is notable for its large proportion of tropical American species, particularly of the floras of Bolivia, Chile, Argentine and Paraguay.

**Distributing Insecticide by Aeroplane.**—One of our daily contemporaries devotes considerable space to the report of an experiment in spraying said to have been carried out on a farm near Sevenoaks. It appears that the crop on fifty acres of fruit trees was in danger of destruction owing to the ravages of caterpillars, when the owner hit upon the idea of having the trees sprayed with a dry powder insecticide by means of an aeroplane. Arrangements were made in due course and the aeroplane, flying from ten to twelve yards above the fruit trees, distributed about half a ton of insecticide, and "the operation was so successful that, after the whole fifty acres had been treated, hardly a caterpillar was left live." We should like to hear more about this experiment, as doubtless would the manufacturers of spraying machinery; moreover, we find it difficult to believe all the leaves could be sprayed by aeroplane, or that the majority of the caterpillars were feeding on the upper surface of the leaves at spraying time.

**Award of the Neill Prize to Mr. W. G. Pirie.**—The Neill Prize has been awarded by the Council of the Royal Caledonian Horticultural Society to Mr. William G. Pirie, Factor to the Earl of Dalhousie at Dalhousie Castle. This prize is in the gift of the Society through a bequest by the late Dr. Neill, and by the terms of the bequest falls to be awarded every second year to a distinguished Scottish botanist or cultivator. Mr. Pirie was born in 1859 at Broomfield, Midlothian, where his father was gardener to the late Mrs. Wilson. After leaving school he was indentured as a clerk in a shipping office, but as he found the business did not appeal to him he quitted it after three years. He then became an apprentice gardener at the Marquis of Tweeddale's seat at Yester, East Lothian. The gardener there at that time, Mr. Shearer, was energetic and very thorough, and Mr. Pirie obtained a good grounding in his profession. Shortly after he went to Yester Mr. Shearer asked him to draw to scale a plan of the flower garden, and this Mr. Pirie did, much to the gardener's surprise. After serving three and a half years at Yester, he was in various situations as an under gardener and ultimately took charge of the planting of vines, etc., at Gallowhill, Paisley. From there he passed on to Sunderland Hall, Selkirk, and it was when at Sunderland Hall that his connection

MR. W. G. PIRIE,

AWARDED THE NEILL PRIZE, 1922.

with the Royal Caledonian Horticultural Society and the Scottish Horticultural Association began, as he was an exhibitor at all the shows held by these societies at that time. He then began crossing *Narcissi*, and has continued this work more or less ever since, with excellent results. He has been awarded gold and silver medals for his seedlings. Mr. Pirie remained for ten years at Sunderland Hall, and then migrated to the south, where he was stationed near Newmarket. He appears, however, to have been anxious to get back to Scotland, and after two years' sojourn in England, went to Vallevfield, Penicuik, as gardener to the late Mr. Charles W. Cowan. Mr. Cowan took a lease of Dalhousie Castle, and Mr. Pirie went there with him to find only a wild garden, but with patience and perseverance he very soon transformed this into one of the finest gardens in the country. In 1916 the Earl of Dalhousie offered Mr. Pirie the management of the Dalhousie Castle Estate, which he accepted and still carries on, even in these strenuous times for landowners. He is a member of the Parish and County Councils for the Cockpen District of Midlothian. Mr. Pirie's connection with the Royal Caledonian and Scottish Horticultural Associations extends over a period of

thirty years, and he has served various terms on the Councils of both. He acted as President of the Scottish Horticultural Association for a term, and is at present a Vice-President of the combined societies.

**Flowering of *Rhododendron sino-grande*.**—Mr. Lionel de Rothschild writes:—"I noticed in your issue of June 10 (p. 298) a note about the flowering of *Rhododendron sino-grande* in this country. I think there is no doubt that the first time this occurred in England was at Heligan, where I saw it in flower in the first week of May, 1919. The plant was in the sun and the previous year's growth rather stunted, and this undoubtedly produced the early flowering, as it is essentially a shade-loving *Rhododendron*."

**Yorkshire Gala.**—The receipts on both the first and second day of the Yorkshire Gala constituted records for this show, the sums being £1,244 17s. 10d. and £1,558 respectively. The attendance on the second day was over 24,128, which is well up to the average, but not a record, for in 1908 33,505 persons were present on the second day.

**Appointments for the Ensuing Week.**—Tuesday, June 27: Royal Horticultural Society's Committee meetings (two days); lecture by Dr. E. A. Bowles on "Plants of interest from his garden"; Bonnemouth Horticultural Society's meeting (two days). Wednesday, June 28: Irish Gardeners' Association's meeting. Thursday, June 29: Bristol and District Gardeners' Association's meeting; National Rose Society's show in regent's Park; Deal and Walmer Horticultural Society's show; Norfolk and Norwich Horticultural Society's show. Friday, June 30: Association of Economic Biologists' meeting; Raistey Florists' Society's meeting. Saturday, July 1: Windsor and Eton Rose Society's show.

"Gardeners' Chronicle" Seventy-five Years Ago.—*Green Park.*—It is highly meritorious for Government to form new Parks for the benefit of the working classes. But why, in this zeal for creation, is there not even the wish for improvement on one especial spot—one so placed that in its present condition it is a positive eyesore. Why is the eastern portion of the Green Park left in its present unsightly condition? Why, in glancing from Devonshire House to Buckingham Palace, is the eye allowed to rest on nothing but a dingy surface of grass? It cannot be that the public would abuse the enjoyment of tastefully arranged public grounds. The idea is now negatived unquestionably. It cannot be that the means are wanting. The whole sum required would not be large, and even if large the nation is not insolvent. It cannot be that Lord Morpeth wants the will to improve any works which fall within his department. He has again and again proved that he has an earnest will in the right direction. It cannot be that he wants the taste; that he is known to possess in a very exalted degree. We will indulge in a hope, then, that this site, so abundant in capabilities, will ere long yield a triumph to his Lordship's taste. We trust that in the immediate neighbourhood of the residences of the Sovereign and her nobles—a spot witnessed day by day by those whose rank and station peculiarly qualify them to enjoy graceful objects—a scene will be created worthy of the metropolis; and that the nation will no longer be burdened by a reproach which hitherto it has too largely deserved. While a Paxton exists there is little doubt who would create the scenery well.—*Gard. Chron.*, June 26, 1847.

**Publications Received.**—*Insect Pests of the Horticulturist: their nature and control.* By Messrs. K. M. Smith and J. C. M. Gardner. Benn Bros., Ltd., 8, Bouverie Street, E.C.4. Price, 8s. 3d., post free. *A Critical Revision of the Genus *Eucalyptus*.* By J. H. Maiden. Vol. VI. Part LII. William Applegate Gullick, Government printer, Sydney. Price, 3s. 6d. *Phoma Rot of Tomatos.* By George K. K. Link and F. C. Meier, United States Department of Agriculture Circular, 219. Government Printing Office, Washington.

## NOTES FROM WISLEY.

THE peculiar weather of this year, following the remarkable season of 1921, has caused much irregularity in the flowering of plants. While some are very late, others are at least a month earlier than usual. Consequently there is at the present time a great wealth and variety of flowers at the gardens of the Royal Horticultural Society. Unfortunately, however, in many cases the duration of bloom has been considerably shortened owing to the succession of cloudless days.

The old ponticum *Rhododendrons* on the edge of the wild garden are unusually full of bloom and form a beautiful background to the picture of the pond at the foot of the rock garden, crossed by a bridge, from each side of which hang the long racemes of *Wistaria multijuga*. The banks of the pond are resplendent with the many coloured forms of the Japanese *Iris Kaempferi* and with the bright blue *Iris sibirica* × *orientalis*, the foliage of the *Irises* contrasting with the large leaves of *Saxifraga peltata* coming up now that the flowers are over.

A pleasing combination of colour was presented recently in the ditches, where the yellow and orange *Meconopsis cambrica* is grouped among *Bluebells* and blue *Aquilegias*, with occasional patches of pale-hued *Primula japonica*.

In the wild garden a fine example of *Azalea amoena* in flower is noteworthy in that this particular plant bears on different branches flowers of two distinct shades of crimson.

The large specimens of *Rhododendron Pink Pearl* and *R. Gauntlettii* have both flowered with their accustomed elegance, and *Kalmias* are beginning to take up the succession of bloom. Among the latter *K. latifolia* is the finest, but *K. myrtifolia*, *K. angustifolia* and *K. glauca* are also very beautiful and at home throughout the wild garden.

In shady nooks the delicate pink flowers of *Lilium rubellum* may be seen (see Fig. 178). Other Lilies will soon be in flower, such as *L. pardalinum*, the stems of which have already attained a height of about five feet. There will also be a goodly number of spikes of *L. giganteum*. Flowering beneath the latter are some plants of *Orchis maculata*. The leaves of one or two are spotted to such a degree as to be almost completely purple, and are most conspicuous on that account. The green-veined *Orchis Morio*, another of our native plants, has flowered very well this year in the grass behind the herbaceous border. Many pale pink and pure white forms were observed.

In the rock garden *Helianthemums* and *Cistus* are revelling in the dry conditions and provide a change in colour from *Genista hispanica* and *Lithospermum prostratum*. The last-named plant has a special attraction for bumble bees, and is also visited by the broad-bordered bee hawk moth.

The dwarf-growing blue and white-flowered *Aquilegia Helenae* has been much admired. It is remarkable that, though a hybrid (*A. flabellata nana* × *A. coerulea*), it has come quite true from seed collected and grown at Wisley. A very beautiful hybrid rock Pink is in flower—*Dianthus Lindsayii*. The flowers are bright pink, about  $\frac{3}{4}$  of an inch across and borne on stems 3 to 4 inches long. *Dianthus alpinus* is flowering in the moraine, as also are *D. deltoides*, *D. sylvestris* and *D. neglectus*.

Other fine plants are the purple-flowered *Calamintha alpina* and the sky blue *Linum narbonneuse*. A peculiar plant, *Ephedra helvetica*, bears its male and female flowers on separate stems.

In the new field garden several noteworthy shrubs are in flower, including a seedling from *Ceanothus azureus*, and Farrer's dwarf variety of *Potentilla fruticosa*, which gained an Award of Merit at the R.H.S. meeting on June 7. *Buddleia alternifolia*, for which we are also indebted to Farrer, has been planted here by the waterside. This plant has a very graceful habit and honey-scented, mauve flowers, which completely cover the arching stems for 2 feet or more, and when better known cannot fail to be popular in the garden. *J. E. G. White*.

## THE BULB GARDEN.

## TRITELEIA UNIFLORA.

MR. R. H. CROCKFORD, on p. 195, states that he considers the very pale purple form of *Triteleia uniflora* preferable to the pure white one. He should have seen the white masses I saw at Exmouth at the time his note appeared, and I think he would have altered his opinion, unless he is one of those who have a prejudice against white flowers in a garden. I am by no means enamoured of them myself, but the white form of *Triteleia uniflora* will henceforth be one of my exceptions. Wherever the coloured form appeared it invariably gave one the impression of something having gone wrong, or that the flowers were past their best. The picture of a long, broad edging, planted haphazard with Heavenly Blue Grape Hyacinths and pure white *Triteleia uniflora*, will long remain in my memory. I went more than once to look at the border through the garden railings.

FIG. 178.—LILIAM RUBELLUM

## ORNITHOGALUM NUTANS.

I WAS very glad to read Sir Herbert Maxwell's note, on p. 225, about this good old garden plant, which seems to have got itself a bad name; at least I know when I first planted it I told a well-known head gardener whose garden knowledge and practice I never call in question, that I had done so. He was not encouraging, but remarked, "You will rue the day you planted it. It will over-run everything and you will never get rid of it." This is not the case at Whitewell. It keeps pretty well in bounds and gives us no trouble. My original purpose in getting it was to provide a cut-flower to go with Tulips. On the occasion of a visit to the Floral Farms at Wisbech, Mr. Leak informed me that a lady told him that she always grew this flower to associate with her Tulips, and that the two made an excellent combination in a vase. The lady was quite right, *O. nutans* goes splendidly with cut Tulips, especially if a little greenery of an appropriate nature be added. The rough leaves of *Kedlock* are excellent. Why not make use of our weeds? Hedgerows might be turned into useful garden annexes more often than they are. *Joseph Jacob*.

## ORCHID NOTES AND GLEANINGS.

## FEATHER-LIPPED BULBOPHYLLUMS.

SEVERAL examples of the pretty dwarf *Bulbophyllums*, with motile, feathery labellums, which never fail to attract attention, were shown in the group staged by H. T. Pitt, Esq., Rosslyn, Stamford Hill (gr., Mr. T. Thurgood) at the recent meeting of the Royal Horticultural Society. The tropical African *B. barbigerum* is a general favourite and easy to cultivate, but the taller *B. saltatorium* and *B. Calamarium* from West Africa are rare. So also is the little Indian *B. tremulum*, a compact tuft of which, with several slender sprays of flowers with blackish feathery labellums, was also shown. Other species of this class which have flowered in collections are the strong-growing *B. Sandermanum*, originally imported with *Cattleya labiata* from Brazil, and the singular *B. Penicillium*, a native of Burma, which appear occasionally with importations from that

region. Other species have been described, but probably not received in gardens. *J. O'B.*

## REPOTTING ORCHIDS.

ORCHIDS in general are best repotted after the plants have finished flowering, for at such times new roots develop. After repotting, the chief aim of the cultivators should be to get the plants re-established as quickly as possible, and this is best accomplished by keeping the compost on the dry side. If the cultivator will look after the roots of his plants, the tops will look after themselves, provided they are kept clean and placed in suitable quarters.

The basis of a good Orchid compost should consist chiefly of Fern rhizomes; or, rather, the fibrous portions of them, from which all the finer particles of soil have been removed.

Different Orchids require different material, but most will grow quite satisfactorily in a clean, open mixture of any of the different fibres now used for the purpose, with live Sphagnum moss on the surface.

Half-decayed leaves, dried cow manure, and loam are used for some species, and a sufficient supply of all these materials should be kept ready for use. *J. T. B.*

# The Week's Work.

## THE ORCHID HOUSES.

By J. T. BARBER, Gardener to His Grace the Duke of Marlborough, K.G., Blenheim Palace, Woodstock, Oxon.

**Cattleya Dowiana.**—The beautiful *C. Dowiana*, and its variety *aurea*, having started into growth, may be placed in the warmest position in the Cattleya house, and be given generous treatment as regards heat, light and air. These plants should be very carefully watered at a times, as their roots are not capable of withstanding excesses of drought and moisture. When the flowering period is over, the plants should be gradually inured to more air and light to consolidate the growth, so that it may withstand the vicissitudes of the winter.

**Cattleya Lueddemanniana and C. Warneri.**—*C. Lueddemanniana* (*speciosissima*) is another species that delights in the temperature of the warm Cattleya house, and one that many have some difficulty in flowering. It may be treated in the same manner as regards repotting as advised for *C. gigas*. It may be taken as a general rule to repot Cattleyas, *Laelias*, *Laelio-Cattleyas*, or *Brasso-Cattleyas* a few weeks after their flowering period, provided they are making, or are about to make new roots. The many hybrids raised from the different species succeed under precisely the same conditions as their parents; and, being plants acclimatised from infancy, are considered easier to grow under artificial conditions. *C. Warneri* and its hybrids grow under similar conditions to the preceding, and the earliest plants are now producing flowers. When their flowers are over these plants also should be exposed to more air and light, but never allowed to shrivel for want of water at the roots, even whilst they are at rest.

## HARDY FRUIT GARDEN.

By H. MARHAM, Gardener to the EARL OF STRAFFORD, Wrotham Park, Berket.

**Peaches.**—These trees have good crops of fruits, and the young growths are strong and healthy. Stopping, disbudding, and training are details that need unremitting attention, and should be very carefully carried out. All new growths not wanted for next season's crop should be removed and others trained in position against the walls with light ties and small lengths of suitable twigs or canes split into small, flexible pieces, so as not to injure the soft bark. Thin the fruits to the number required to ripen, leaving those best situated and at regular distances apart. Do not overcrop the trees, but strong growing trees may be allowed to carry more fruit than older ones that are not making growth sufficiently strong to bear heavy crops annually. Syringe the trees thoroughly on all available occasions, taking care to wash the underpart of the leaves as much as possible. Syringing should be done thoroughly in order to keep the foliage clean and free from insects, especially red spider, which frequently attacks Peaches trained on brick walls. If red spider is detected, syringe the foliage with "X.L.-All" insecticide late in the afternoon, and again with clear water the following morning. See that the roots are thoroughly soaked with water at intervals, and use liquid manure occasionally, or clear water after a good mulching of manure, so that the manurial properties are thoroughly washed down to the roots. Alexander is our first Peach to ripen out-of-doors, and following this Hale's Early, River's Early York, and then the mid-season's varieties. Early York is one of the very best of Peaches to follow quickly on Hale's Early. The colour is good and the flavour excellent, while the tree is an excellent cropper. The newer Peregrine variety is an excellent Peach and as valuable for cultivation out-of-doors as under glass.

## THE KITCHEN GARDEN.

By JAMES E. HATHAWAY, Gardener to JOHN BRENNAND, Esq., Baldersby Park, Thirsk, Yorkshire.

**Runner Beans.**—Make further sowings of Runner Beans to maintain late supplies. The supports for these plants should be very strong, as they offer a great surface to the wind in autumn, and night dews at such times cause them to be heavy with moisture.

**Onions.**—Plants which were raised in pots will have grown rapidly during the recent hot weather. A dressing of manure from a spent mushroom bed or well rotted manure should be spread over the beds and watered in. A slight dressing of sulphate of ammonia will greatly assist them in their growth, as will also Icthemie guano applied once every fortnight.

**Winter Greens.**—All kinds of winter greens should now be planted. The distance between each kind must be ruled by the variety. The larger growing Brassicas require a space of not less than 2 ft. each way. The recent rain has been helpful and made the ground in a suitable condition for planting.

**Peas.**—To ensure late crops, of Peas, trenches should be made with a thick layer of manure at the bottom. Choose an open site for this sowing, as the plants will be less susceptible to attacks of mildew if they are fully exposed to the sunlight and air. *Ne Plus Ultra*, *Gladstone*, and *Sutton's Latest of All* are good varieties for this late crop.

**Leeks.**—Every encouragement should be given these plants to develop by affording them regular waterings. Plants intended for exhibiting should have brown paper collars put around them, as these can be drawn up as the stems lengthen, keeping the plants earthed up with fine mould.

## PLANTS UNDER GLASS.

By T. PATEMAN, Gardener to Sir O. NALL-CAIN, Bart., The Nods, Coddicote, Welwyn, Hertfordshire.

**Francoa ramosa.**—Where old plants of the Bridal Wreath have been given cool treatment, they will now be throwing up their flower spikes, which will undoubtedly be greatly improved if the plants are given manurial aid in the form of manure water. *Francoas* are by no means tender, and may be safely stood out of doors early in May. To have this plant in flower over a long season—a few plants may be stood in a warm greenhouse at intervals, and the main batch of plants stood under a north wall to retard their growth. *Francoa ramosa* may be raised from seed sown now, and germinated in a cool greenhouse, but I much prefer propagating by means of side growths.

**Chrysanthemums.**—Where cuttings of *Chrysanthemums* were inserted about the end of April, to produce plants for growing in small pots, they should now be ready for placing in 4½-inch receptacles. In about three weeks' time they may be shifted again into 6-inch pots, in which they may be allowed to flower. After potting, the plants should be sprayed frequently during hot weather. Where bushy specimens are required the growths may be pinched twice, finally selecting the first bud that appears from the last stopping.

**Stephanotis floribunda.**—This beautiful stove or intermediate house climber having passed out of its first blooming stage, is making a considerable amount of fresh growth, and attention should now be given to the thinning and regulating of the young shoots. *Stephanotis* is generally trained on wires near the roof rafters in a stove house. This climbing plant undoubtedly enjoys warmth and plenty of atmospheric moisture, although I have seen two excellent crops of flowers obtained from plants grown in an intermediate house. It does, perhaps, best when planted in a restricted root space, and some stimulants given the roots during the growing season. Good, fibrous loam and peat, in equal parts, with charcoal and plenty of silver sand added, form a suitable compost for *Stephanotis*.

## FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAR, M.P., Ford Manor, Lingfield, Surrey.

**Cucumbers.**—As the plants in frames are in full bearing, and the older ones in heated pits are more or less infested with spider, the latter should be cleared out and the pit replanted. Young plants make rapid progress, and replanting, wherever practicable, is more profitable than retaining old plants. When planted out in soil resting on heated chambers in a house having a close, moist atmosphere, the plants will make rapid growth, and may soon be brought into full bearing. New rough turf should be mixed with charcoal, crushed bones, old rubble, and similar materials as a compost for adding as often as is required, and warm, diluted liquid manure may be given the roots liberally. Another advantage, after this season of the year, is in lowering the trellis to an extent that will allow every leaf to be clear of the glass, when, other conditions being suitable, shading in the brightest weather will hardly be necessary.

**The Frame Ground.**—When manure is plentiful and good frames or pits are well managed, a large summer supply of Cucumbers from this time forward should be forthcoming. A single hot-water pipe is, no doubt, a great help, but, independently of this, an abundance of clean, straight fruits may be obtained by regular attention to the renewal of the fermenting materials, by linings, and external coverings. Frames in which Potatoes and other forced vegetables have been grown should be cleansed and planted as they become vacant. A steady bottom-heat being essential, manure and leaves, supplemented later by external linings, will give new life to the bed for the remainder of the season. If the summer proves extra fine and warm the plants will require water at least twice a week, not cold and in dribbles, but in overhead showers through a fine-rosed can at a temperature of 80° to 90°. Train and pinch the growths as recommended in the calendar of April 29. ventilate the frame early on fine mornings, and close it again early with sun-heat and moisture in time to cause the temperature to rise to 90°.

## THE FLOWER GARDEN.

By EDWIN BECKETT, Gardener to the Hon. VICAR GIBBS, Aldenham House, Hertfordshire.

**Ornamental Crabs.**—The various trees and shrubs have flowered finely this season, and the present is a suitable time to take stock of the best sorts to make a selection for future planting. One of the first groups that call for special attention are the flowering Crabs that for several weeks past have been such beautiful objects in these gardens, where we have a very large collection. *Pyrus Malus spectabilis* Kaido (Dippel) is one of the most glorious of them all, producing double flowers, that are larger and deeper in colour than the type, with great freedom. Closely following this is the beautiful *P. M. Scheideckeri*, which gives a wealth of semi-double, pale rose-coloured flowers in clusters of about ten blossoms. *P. M. floribunda* is too well known to need description; it is one of the most lovely flowering Crabs in British gardens today, as well as one of the first to blossom, coming into flower about a fortnight prior to *P. M. Scheideckeri*. There is a beautiful deep coloured variety known as *P. M. floribunda atrosanguinea*, which makes a fine contrast to the type, and has the further merit of possessing very pretty, shiny foliage. Another charming Crab is *P. M. purpurea*, a variety with deep purplish-rose flowers, and somewhat similar to this is *P. M. Niedzwetzkyana*, and both are worthy of inclusion in gardens. Even more lovely than either, and flowering later by a fortnight to three weeks, is *P. M. aidenhamensis*, which, besides its fine reddish-purple flowers, has purplish foliage, and in the autumn carries a wealth of deep similarly coloured fruits that hang like enormous Cherries on the trees. *P. M. arnoldiana* is another striking flowering Crab, of healthy and vigorous habit which was raised in the U.S.A., and is a charming plant in every respect.

**THE ROSE GARDEN.**

**SOME EARLY FLOWERING RAMBLERS.**

CLIMBING Roses seem to be extra vigorous this season, in contrast to the dwarf kinds, which, apparently, found the hot, dry summer of last year too exhaustive of their energies, and old plants especially seem much weakened in consequence. The foliage and growth of climbers are strong and healthy, whilst the flower trusses also are extra vigorous. Amongst the first to bloom was Carmine Pillar (syn. Paul's Carmine Pillar), a splendid early Rose for furnishing pillars, arches and pergolas, and one of the earliest of all Roses if grown against a warm wall. The habit is strong and free, and a well grown specimen gives a profusion of the big, single carmine-scarlet blossoms.

René André is another early bloomer of vigorous habit, suitable for training on arches, pergolas, pillars or walls. The flowers are Camellia-shaped and open flattish. The colour is saffron yellow shaded red, but in full sun the blooms assume a pink tone.

Albéric Barbier is a general favourite and suitable for a variety of purposes. In a well grown plant the creamy white blossoms almost smother the plant, which has fine glossy foliage. In the bud the flowers are of perfect shape and very pale cinnamon at the base. This excellent Rose makes a charming weeping standard.

Jersey Beauty ranks amongst the strongest growers, and is very fine for training over tall trellises, for the shoots grow to a great length. The flowers are small but of very dainty appearance, like little cups of ivory white.

François Guillot belongs to the Wichuraiana section, and is worthy of including in collections for its attractive glossy foliage and white flowers, which have a creamy white centre. In a collection it will hold its own as a pillar Rose, the tall, columnar plant being covered from top to bottom with the large, full petalled blooms.

François Foucard is similar to the last, but in the particular collection it was certainly inferior, although it has the additional merit of flowering again in the autumn. The blooms also, which are lemon yellow, are not so pleasing in shape. Aglaia is very free on old established plants. The small, creamy yellow blooms develop in big clusters, which have long stalks.

Tausendschön is one of my favourite Roses, and I consider it second to American Pillar, although it would be difficult to name the third, but perhaps Mrs. F. W. Flight is worthy of this honour, with Blush Rambler (see Fig. 179) running it closely. Tausendschön does not make such long growth as some others, but it is fine for a fence and splendid as a weeping standard. The rosy-pink blooms come in big clusters, which may be cut with long stalks. This fine Rose flowers from now to October. Blush Rambler has all the attributes of a good climbing Rose, and the large clusters of soft pink flowers are produced in profusion, but their season is not so early as some. Mme. d'Arblay is a pretty, hybrid-musk, white cluster Rose with a very faint pink tinge in the bud. The trusses are large and the flowers are sweetly fragrant. Being a strong grower, this Rose may be used for furnishing tall pillars and pergolas.

Goldfinch is another excellent early Rose for arches, as its growth is exceedingly vigorous. There is just a touch of gold at the base of the petals and a boss of golden stamens, which reflect their colour on the interior of the white, semi-double flowers. The buds are deep cream coloured. Shower of Gold is deeper in the centre than Goldfinch, but the plant is not such a good grower. The foliage is very pretty, being glossy and shining like that of a Tea Rose. Tea Rambler is a climbing polyantha Rose of much merit, and must be classed with the best of the ramblers. The flowers open light pink and make a flattish, double bloom. They are developed in big trusses at the ends of long, stout side growths.

Paul's Scarlet Climber is very early flowering. I have not yet seen a very vigorous specimen, and am inclined to believe that it will never grow more than some eight feet or so high. Still, as a dwarf pillar variety it is worthy of inclusion in the best company of Roses of its type. *Lomca.*

**CAPE PELARGONIUMS FOR SUMMER BEDDING.**

CAPE Pelargoniums comprise one of the most interesting groups of plants for incorporation with the summer bedding subjects. Generally known as Scented Geraniums, these plants are old favourites, of which our forebears thought a great deal, and it is now something like nearly three hundred years since the first species arrived in England from South Africa, presumably during the reign of the Stuart Kings, for it is believed to be in the year 1632, i.e., during the time of King Charles I., that Pelargonium triste came to hand. Thereafter, at intervals, came other species and varieties, until at the

will prove a very striking and effective feature, for not only does such a bed form a beautiful object, but the difference that exists between the various species always arrests the attention of visitors.

The preparation of the plants for the purpose in order to ensure good, shapely specimens is not a difficult nor arduous task. They require a certain amount of shaping as growth progresses, in the case of some of the larger-growing sorts, in order to prevent them growing in too ragged a shape, and this should be commenced from the early days of the young plants, removing growths that are too rampant, and stopping others where it is considered advisable, to ensure good shaped specimens. This work should be done carefully and with a cer-

FIG. 179.—ROSE BLUSH RAMBLER AND LAVENDER HEDGE.

present time we have something like 300 species and varieties. At Aldenham we generally employ them freely in the summer bedding, and beds and borders formed of them always afford great interest to visitors, an interest which is growing year by year as the love for these charming subjects increases.

Plants of all sizes and shapes are used, from tiny cutting plants in 60-sized pots, to large standards 6 feet high. All the plants are plunged in their pots in the soil of the beds and borders, the standards being placed in effective positions first of all. Next, the large bush and pyramid specimens, together with smaller standards, are worked into place, and the whole is finished off with the smaller plants. This method of planting can be adopted as well for small beds as for large ones, and the whole

tain knowledge of the plants, or deformed habit may result instead of merely shaping and training. Pyramid plants may be shaped by promoting the progress of the main growth and carefully stopping the side shoots. Standards are a little more difficult and are obtained by selecting a number of healthy young plants and restricting them to one growth only, and as height is attained side shoots should be cut cleanly away. When of sufficient height the main growth should be stopped and the side growths at the top of the standard encouraged to make good progress, again shaping the head as required. We use Pelargonium crispum variegatum largely for bedding, in all shapes and sizes. The variety has the same habit as the type, with fine variegated foliage, which lends itself remarkably well to the scheme. *E. Beckett.*

### EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, W.C.2.

Special Notice to Correspondents.—The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.

Letters for Publication, as well as specimens of plants for naming, should be addressed to the EDITORS, 5, Tavistock Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Local News.—Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Editors and Publisher.—Our correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notices printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the EDITORS. The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.

Illustrations.—The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.

### BUD VARIATION IN POTATOS.

FROM time to time the question of bud variation in Potatoes comes up, and gives rise to much discussion as to its possibility. Cases are brought forward where a white variety throws a coloured tuber, or vice-versa, and as these are seldom or never found attached to the plant, but are dug with the others, opponents of mutation say that it is a rogue or self-set. There is no doubt that many of the cases brought forward by non-scientific growers are of this character, but such changes of colour in the tuber are accepted by Mr. A. W. Sutton, who, in a paper read at Ormskirk, in 1918, refuses to accept the idea that bud variation can give rise to new varieties. Another probability is that a hybrid may have got into the stock, the hybrid having most of the characteristics of the parent stock, with one or more characters modified. Such is not very probable, but it would occur occasionally, although seldom seen by a grower who would notice the difference. Such a hybrid is seen well marked in the variety Marvel or Variation, where two differently coloured tubers occur on the same plant. Such cases, however, cannot be termed mutations, as they are the result of distinct crosses.

Interesting evidence, however, has come from Germany to support those who consider mutation probable. In *Deutsche Landwirtschaftliche Presse*, 45, 1918, p. 2, Von Ryx gives what is presumed to be an instance of mutation in Early Rose. Attracted by their resistance to Blight (*Phytophthora infestans*), he has found plants several times in fields, which to all intents and purposes are of the variety in question, and which have been found amongst typical plants. When grown on, these tubers, however, give rise to plants which, although Early Rose in other respects, are stronger in growth, more resistant to *Phytophthora*, and whose terminal leaves differ in a definite way from the leaves of the original stock and from leaves of many other varieties. The author finds that if the broadest part of the leaflets is taken and a line drawn across at right angles to the mid-rib, the length of the mid-rib below this line is always longer in the "sport" than the portion above it, while in the original stock and in other varieties he has examined, the reverse is the case.

Killer, in *Deuts. Landw. Presse* for December 4, 1920, p. 660, gives a more interesting instance of possible mutation. He remarks that he has had white blooms from practically undeniable Up-to-Date stocks submitted to him

from time to time. He has, however, remained unconvinced and denied the possibility of such variation. The finding of an Up-to-Date plant with an inflorescence showing both white and lilac flowers, an illustration of which is given, has led him to the statement that isolated instances may occur.

At the International Potato Conference, held in London last year (*Rept. Inter. Potato Conf., Roy. Hort. Soc. London, 1921*), the well-known Potato breeder, Mr. Donald Mackelvie, gives an instance of bud variation which he has noticed in his variety Arran Victory. Normally, this has a round, purple-skinned tuber, with white flesh and purple sprouts, but the author gives the further history of specimens with tubers having skins differently coloured from normal. Two of these gave tubers which were either normal or only varied in skin colouration, as did their parents, but the third, a white one with purple sprouts, gave a haulm identical with normal haulms of the variety, but with nine entirely white tubers and five white tubers with purple eyes and purple spot on the root end. These latter developed normal sprouts,

FIG. 180.—SARRACENIA FLAVA GIGANTEA.

but the former had sprouts which were pink at the base with green points, and were quite distinct. The tubers with purple sprouts developed into plants with normal Arran Victory characters, but the nine which had abnormal sprouts developed into plants which Mr. Mackelvie describes and which he truly says would constitute a new and distinct variety if the change proves permanent.

Such examples as are here quoted certainly suggest mutation, and in view of these and other observations, the supporters of the idea that new varieties arise through mutation, will receive a fresh stimulus. *G. C. Gough, A.R.C.Sc.*

### INDOOR PLANTS.

#### SARRACENIAS.

AMONG warm greenhouse subjects there are few in which visitors are so much interested as the various insectivorous plants. Indeed, there are not many plants more attractive than these, although there are many more gaily coloured. A goodly bank of insectivorous plants is grown each year

at the end of the Orchid house in Mrs. J. J. Neale's Garden at Oxton, Kenton, near Exeter, where *Sarracenia* and *Drosera* are grouped together. Of *Drosera dichotoma* we manage to grow large specimens, and *Sarracenia* also reach a considerable size. I enclose a photograph, taken by Miss Muriel Neale, of a plant of *Sarracenia flava gigantea*, which may serve to remind readers of the peculiar grace and striking appearance of these easily grown plants. The specimen illustrated (see Fig. 180) is two feet six inches high from the rim of the pot, and the pitchers are of a bright yellowish-green colour. Some of the specimens carry as many as twenty-six perfect pitchers, and the largest pitcher has a spread of six and a half inches across "the lid."—*E. Swinden, The Gardens, Oxton, Kenton, nr. Exeter.*

#### ZONAL PELARGONIUMS.

WHEN well-grown, there are few subjects so brilliant for furnishing the conservatory during the autumn and early winter months as Zonal Pelargoniums; but at those seasons the clear, pure air of the country is essential to their well-being. In the London neighbourhood, where fogs are prevalent, they are very uncertain subjects, as one night's fog is sufficient to spoil all the season's work.

Plants intended for winter-flowering should now be ready for transference to their flowering pots, those of six- and seven-inch diameter being a suitable size. The potting compost should consist largely of good loam of a medium texture, without too much lightening material in the way of leaf-mould, for when the soil consists mainly of loam growth is short and firm, which is so desirable in this class of plant intended for winter flowering. A 48-sized potful of bone meal may be added to every bushel of soil, and sufficient sand to render the whole porous, as a water-logged condition of the roots is fatal to the well-being of these plants. After repotting they should be placed in a cold frame for a few weeks, until they are well re-established, when they should be stood out of doors on a layer of coal-ash in full exposure to sun, light and air, to ripen and mature their growth before they are housed in the autumn. During the summer the flowers should be kept picked off, and any unduly long growth pinched, to secure shapely specimens.

#### ROUPALA POHLII (SYN. CORCOVADENSIS).

THIS handsome plant, which was at one time a general favourite in gardens, is now very seldom seen in cultivation; which is rather surprising, considering how beautiful its large pinnate leaves are, and there are few foliage plants that withstand the wear and tear of conservatory decoration better. Planted out this *Roupala* makes a fine specimen, while grown in pots and allowed to develop a single stem, it is very graceful for grouping with other plants. In the dwelling-house it gives just that bold, massive effect that is often so desirable in large rooms and saloons. The growth is very hard and woody, and cuttings generally take several months to root. Plenty of bottom heat, in a close propagating, is necessary for success in rooting them, and the smaller and less gross shoots are best suited for propagation.

The inflorescence forms a cluster of orange-red flowers, but it has no especial attraction from a decorative point of view.

#### SCUTELLARIA COSTARICANA (SYN. MOCINIANA).

THIS old garden plant is now seldom seen in collections, having shared the fate of many other beautiful subjects; because they are not suitable for supplying cut blooms. It is a very striking subject with its scarlet and yellow flowers, and its cultivation presents no difficulty, as it roots readily and is easily grown in a house having an intermediate temperature. Plants propagated some time ago should be potted on as they require it, while strong shoots rooted now should still make useful, small plants by the end of summer. *J. Coultts.*

**GARDEN NOTES FROM S.W. SCOTLAND.**

THOSE who esteem blue flowers, should make a note of the Himalayan *Cynoglossum nervosum*. Its blossoms, freely borne on bending stems two feet high, or thereby, are intensely blue. The plant has none of the coarseness which unfits some of the genus for the front of a herbaceous border, nor does it conform to rule, under which so many of the Borage order open pink before turning blue. The flowers are pure blue from start to finish and very showy. The habit of the plant is compact and its foliage bright green. It flourishes best in full sunshine.

All flowering trees and shrubs, except some of the Asiatic *Rhododendrons*, have responded lavishly to the stimulating heat of the summer of 1921. Such a result was to be expected; but in none is the effect so remarkable here as in *Xanthoceras sorbifolia*, from Northern China. This small tree, rather nearly related to the Horse Chestnut, is very shy of flowering in Scotland; so shy, indeed, that I wearied of waiting for a display, and, having two specimens here about 40 years old, allowed one of them to be nearly smothered by a Rambler Rose. Last year, neither of them bore a single flower; just now (June 9), every branch is crowded with erect panicles of bloom—white, with a carmine stain at the base of each petal. There is apt to be trouble if much fruit sets; for the capsules are as large as those of a Horse Chestnut, shaped like a pegtop, and the branches, being very brittle, are apt to snap off under the weight. The pinnate foliage, now nearly all hidden by the flowers, is very beautiful.

In a season like the present, it cannot but occur to one how much trouble is taken to grow many foreign flowering things which are far inferior in beauty to our common native Hawthorn. In May, 1913, the late Mr. Joseph Choate, so well and affectionately remembered as the American Ambassador at St. James's, took me in his car from New York, across Long Island, to lunch with the late Theodore Roosevelt, at Sagamore Hill. The woods were richly undergrown with *Cornus florida*, then in full flush of flower. "How I wish," said I, "that we could grow that lovely shrub in England." "Well," replied Choate, "it's a pretty thing, but I don't reckon it a patch beside your English May." And, truly, I think he was right.

The most startling flower in the borders at present is the Dragon's Mouth, which used to be known as *Arum crinitum*, but which we are now told answers to the less handy name of *Helicodiceros*. The massive spadix, hairy and brownish purple—nearly black—lolls along the horizontal spadix, which is of a vivid hue, suggestive of carrion, the suggestion being strengthened by the powerful stench exhaled from it. Blowflies and bluebottles, deceived by the double semblance, crowd into the chasm and deposit their eggs at the base of the spadix. I measured a flower this morning, and found that the spathe was 17 inches long and 8 inches wide. The plant is a native of Corsica, but thrives vigorously here in a sunny border. Truly, it is one of Nature's fearsome freaks. *Herbert Maxwell, Monreith.*

**THE GRAPE VINE.**

It is so seldom that the Grape Vine forms the subject of discussion that it is refreshing to read such a fresh series of articles as those recently published in your pages. The exigencies of the war period showed that the heating and steaming previously indulged in were of no use to the vine, but rather indicative of how much it can stand under domestication, and when we consider how it is cut about, and restrained in its attempts to grow as nature intended, it must be conceded that no other cultivated fruit is equally amenable to such treatment, and able, under fair conditions, to go on year after year for an almost unlimited period producing its quota of fruit.

It is surprising, at this time of day, to find vineries being constructed of far too small cubic

contents, for, however well vines may succeed in short-raftered structures, there can be no doubt that the vines in large vineries are far easier to manage, and, as a rule, produce better Grapes than is possible in those of small dimensions. And I take it that the somewhat unqualified proposal to ventilate freely, without distinguishing as to season, shows that the great benefit of fresh air as a means of keeping the vine in robust health and in a condition to fruit well is gaining ground, just as the need for steaming is losing ground.

Another cultural item worth emphasising is that of the suppression of all lateral growth which is of no benefit to the vines, probably the opposite, and results in a very great reduction in the summer work on the vines. I have known a gardener occupied for nearly two days at a time cutting away lateral growths, which, had the practice of rubbing everything from the main shoots been in operation, would never have been needed.

There are one or two points which, I think, might be improved on in practice. One is the

responding similarly to a like treatment. At the same time, there seems to be a feeling among gardeners that the cutting of vine roots is, like the suppression of lateral growth, a hazardous experiment. *B.*

**VEGETABLES.**

**RUNNER BEANS.**

I HAVE started Runner Beans in heat for several years past. In Scotland it is almost essential to do so in order to secure a supply over a sufficiently long period to pay for the trouble of growing them at all. Instead of sowing seeds in boxes, we place one bean in a five-inch pot in a compost of two parts soil to one part old manure. Directly the growth is long enough to get hold of it is pinched, and two shoots result. Runners are much harder than French Beans, and ours are stood out of doors about the middle of May and planted during the last week of that

FIG. 181.—IRIS GARDEN ARRANGED AT THE CHELSEA SHOW BY MESSRS. GEORGE BUNYARD AND CO., MALDSTONE (SEE P. 230).

supporting of the shoulders of bunches. Not only does it ease the vine to support heavy shoulders, but the whole bunch should be supported by passing a broad strand of raffia under one or two of the uppermost shoulders at their junction with the main stem of the bunch, tying it to the wires or to a piece of wood resting on the wires. Anyone who experiments with bunches from 1½ lbs. upwards will be convinced of the benefit of a support of this kind. Pushing the berries up from time to time should not be omitted.

I think that it is possible to leave too many berries in the inside of the bunch. These inner berries never colour so well as those exposed, nor are they so well flavoured, and for these reasons the inside of the bunch ought to be well thinned.

With regard to shanking, some old Black Hamburgh vines here shanked badly in some years, so the roots running outside were cut close to the wall in autumn, which proved effectual to an appreciable extent. Since then, the roots have never been allowed to extend more than about four feet from the wall; every two years a trench is dug out and fresh soil introduced. This treatment benefited the vines in another way, for before the roots were cut many of the berries were stoneless, and did not swell, but since then that objectionable fault has been little apparent.

Experience with other shrubs and trees proves that the cutting of roots is invariably followed by increased flower production and fruit, and there is nothing wonderful in the Grape vine

month. The training material used is wire sheep netting to a height of nine feet or ten feet, and to this the growths attach themselves automatically. A few years ago a white sport originated here with white flowers and white seeds, otherwise there is no difference between it and the scarlet form. The first flowers of both are open at the time of writing—June 16. *R. P. Brotherston.*

**DEEP CULTIVATION.**

The advantages accruing to the different crops of vegetables in deeply cultivated land with an abundance of rich, well-decayed manure thoroughly incorporated with the soil, is always apparent, and the extra labour bestowed in carrying out the work is amply repaid, more especially in dry seasons.

Where the soil is light and shallow, most gardeners are only too well aware that plants on deeply worked land will grow and flourish in the fullest vigour and produce heavy crops of sweet, crisp vegetables, whilst on similar soil but shallowly worked and sparingly manured, just the reverse is the case. This is not surprising seeing that the roots are able to draw food and moisture from a greater area than on shallow land, and they are enabled to grow deeply enough to reach the moist soil in the region of the subsoil, whilst the manure will absorb and retain moisture that will be available for the plants in dry weather. Mulchings of suitable materials applied early on light land and in dry seasons are of the utmost benefit and should always be applied where there is sufficient labour and ample manure, especially when the water supply is short. *H. Markham.*

## NURSERY NOTES.

## NEW IRISES AT ENFIELD.

ALTHOUGH Mr. W. R. Dykes prophesies, on p. 326, that American specialists may soon take the lead in Iris raising because of their numbers, we are glad to know that raisers in this country are still actively engaged in Iris breeding, and that such specialists as Sir Arthur Hort, Messrs. Bliss, Yeld, Wallace, Bunyard and Perry, to name only a few, are following up their former successes with novelties that should retain our supremacy, at least, for some time to come.

Mr. Amos Perry's nursery, at Enfield, which we had pleasure in visiting during the Iris season, contains a large number of Iris seedlings, and there are fine novelties in many sections, beside the tall bearded type. For instance, he has raised crosses between *I. tenax* and *I. longipetala*, and, although the progeny were poor, miserable plants in the first generation, the second generation of seedlings includes very many of merit. Again, he has crossed *I. Pseudacoris* with *I. Kaempferi* and also *I. Pseudacoris* with *I. spuria*; *I. sibirica* with erioglyphes, also longipetala and tenax; ochroleuca with euprea, and so on. *Iris tenax* crossed with *I. longipetala* has given a totally distinct form from tenax, of a beautiful violet mauve colour. The largest collection of seedlings is of the tall, bearded section, and of these there are many of great promise, although the majority were under numbers at present. The most remarkable are as follows:—A seedling from Alcazar with bronze purple standards, and another seedling of this type with clear blue standards, and purple violet falls that are pleasingly reticulated with bronze, whilst still another seedling of this type has claret coloured falls and standards.

In his endeavour to obtain tall stature in this noble race of Irises, Mr. Perry has used as one parent a form of *I. pallida*, some four to five and a half feet high, and with soft, lavender-blue flowers. This has been crossed with various others, giving some excellent results. One of the best, named Marjorie Tinley, has falls two and three-quarter inches wide, of a delicate shade of soft lavender-blue and broad falls of pale lavender, against which a rich orange beard shows conspicuously. It is a very large flower and measures five and a half inches in depth. Another seedling is a gigantic Archeveque some three feet high and with flowers three times as large as in the older sort, but of exactly the same colour, save that the standards are a little richer in tone. Another fine novelty of rich, rosy plum colour is in the style of Her Majesty, but of a better and deeper colour. A seedling of the squalens breed, of a clear, cloudy blue, is very promising. No. 190, P., is a glorious Iris, with a tall, bold spike, of lavender-blue colour, whilst 57, P., is a clear pink flower, of excellent shape, and developed on a strong spike. No. 68 has a gigantic flower of the Alcazar type, but almost double the size. A pretty Cengialtii pallida Iris, with brilliant, rosy crimson flowers, that are produced with great freedom, gives much promise as a fine garden plant. No. 179, of the Germanica type, has beautiful chocolate-brown falls and golden standards; a variety of much worth. No. 81 is a pallida seedling with broad falls of blue colour with a purple suffusion and clear blue standards. The form of this fine seedling Iris is all that could be desired. Another novelty that attracted our notice was a Belladonna pallida seedling of a delightful blue colour. No. 430 is a charming Iris of the squalens section with buff apricot standards and madder crimson falls, which are beautifully reticulated.

Altogether there are 16,000 seedling Irises in this nursery that have not yet flowered, and as the parents have been selected with the knowledge that this noted Iris-raiser possesses, they will doubtless include many that will be heard of in the future. Amongst the newer named sorts Lady Sackville has standards of the palest azure blue colour and rich blue falls that are reticulated with chocolate at the base, and set off by a fringe of orange; Mrs. Fred

Stern has standards of bright rose colour and falls of a richer rose; Mrs. Jennie Pearson is a glorious Iris of the palest blue colour; Eden Philpotts is a very distinct sort, with flowers of the largest size, often measuring more than six inches long, and coloured bright steely blue with a conspicuous yellow crest; and Miss Broughton, a tall variety bearing large, brilliantly coloured flowers with pale purple standards and bright crimson falls with a white ground at the base, on which rises a bright yellow crest.

Others that attracted our special notice were *I. Cengialtii*, The Czar, a beautiful shade of silvery blue with purplish-violet falls, that stand at right angles, and Cengialtii Perry's Favourite, a variety of the largest size and of rich violet colour in all the segments.

All the Irises in this nursery seem to grow with extra vigour, and Mr. Perry attributes their success in part to the use of burnt garden refuse and burnt soil. The large bed of tall, seedling, bearded Irises was on ground that had been top dressed with five inches of this burnt ballast, and from their appearance this material is eminently suited to Irises. Beside the Irises the nursery includes much else that is of interest, and Mr. Perry has many frames and beds filled with seedling Lilies; the extent to which Lilies are raised

back in records to the twelfth century. The "Permain" Pear is also of great antiquity, and is mentioned in 1285. Later it appears in Le Lectier's list, though it seems to have disappeared by Leroy's time, since he does not refer to it. Anyhow, both Apple and Pear must be considered together.

That the name has nothing to do with shape, as is now sometimes pretended, is clear from Gerard (1633), who uses the terms *Platomela* and *Platurchapia* (*platymela* and *platarchapia*); these evidently refer to a flattened fruit. Later we have the carefully executed figures given by T. A. Knight (*Pom. Hereford*, 1811), in which the specimens are evenly elliptical in shape in the case of the Old Pearmain; the other Pearmain he figures is The Loan, but its shape cannot be seen in the plate, although it is interesting to observe that he suggests it really to be the Marigold Apple, which, according to Worlidge (1676), was "sometimes called Johns Pearmain, from its likeness to a Pearmain." Here colouring seems to have been the Permain feature, as also with Philips (1709). Size also has evidently no connection with the name.

John Rogers (*The Fruit Cultivator*, London, 1837) wrote of the Pearmains: "Why they are called by this specific name is not very evident; but it appears that it is a cognomen

FIG. 182.—A WELL-TRAINED VETERAN TREE OF APPLE KESWICK CODLIN.  
(SEE PAGE 337.)

in this nursery may be judged from the fact that there is one batch of seven to eight thousand hybrids of *Lilium candidum*. Crosses of *L. Parryi* and *L. pardalinum* have given some glorious hybrids, of which the most striking had rich, orange-coloured flowers. *Pardal-parryi*, which gained the Royal Horticultural Society's Award of Merit on July 5, 1921, is a very beautiful Lily with yellow flowers freely spotted with dark brown. A cross between *L. superbum* and *L. pardalinum* has resulted in another very fine hybrid.

In the glasshouses plants of Mr. Farrer's *Nomocharis pardanthinum* were finely in bloom, and Farrer's description of this beautiful flower is in no wise exaggerated, for the flowers are like miniature Lilies of shell-pink colour with crimson spots at the base.

## FRUIT REGISTER.

## PEARMAIN APPLES.

"POMONA" (*Gard. Chron.*, June 10, 1922, p. 306) writes: "The name Pearmain has always been understood by fruit growers and pomologists to indicate a conical or pointed variety." This may be true to some extent of writers since somewhat before the middle of last century, but hardly accords with earlier records. The "Permene" or "Permaine" Apple goes

of some kind of pre-eminence." Summer P., "small size and oval", Scarlet P., "oval and about the middle size"; Royal P., "large," no shape given; Chester P., "small, quite the pearmain shape (that is, larger at one end than the other)"; Lamb Abbey P., "the fruit is less tapering than other pearmains, but there is a family likeness in the eye and stalk"; Herefordshire P., "middle size, oval, tapering towards the stalk, the eye and stalk like the other pearmains"; Winter P., "middle size, oval, somewhat tapering to the stalk, at which it is a little flattened." In respect to modern introductions, the use of the name Pearmain remains mysterious, for there are many which, so far as shape is concerned, present much more conical appearance, and yet have escaped being classed as Pearmains.

The trouble and confusion with a piriform, or rather ob-piriform, shape, probably arose from the two old prefixes "par" and "per" having become written with both the vowels by some seventeenth century writers.

Elsewhere (*Gard. Chron.*, October 12, 1918, and *Journal of Pomology*, Vol. 2, p. 115) I have pointed out that probably originally the term was applied to long-keeping varieties, and that the Latin "*permanere*" and old French "*parmaindre*" and "*permaindre*" showed the source of the word, which would be better spelt as Permain or Parmain. H. E. Durham.

HOME CORRESPONDENCE.

**Leaf-Curling Plum Aphid.**—I am fully convinced that *Market Grower's* method of spraying with nicotine and soft soap for leaf-curling Aphid before the opening of the blossom is the best and correct way to combat this pest. I have for several seasons past made a point of spraying Plum trees before the opening of the bloom, but last season, owing to being ill in bed with a severe chill, this work was overlooked, with the result that the trees were badly attacked with this leaf-curling pest. Although the trees were sprayed immediately the bloom was set it appeared to be too late, and undoubtedly the Aphides had protected themselves in the young leaves. To make doubly sure the trees were sprayed twice this season before the opening of the bloom, with excellent results, for they are making clean, healthy growth, with no signs of leaf-curling Aphid. *T. Pateman, The Node Gardens, Welwyn.*

**A Veteran Apple Tree.**—I send you a photograph (see Fig. 182) of an old tree of Keswick Codlin Apple, which has been planted over fifty years, and bears well in most seasons. This proves that trees properly cared for can be kept in good condition over a long period. The tree has been under my charge for over twenty-two years.—*Jno. W. Barks, Castle Estate Office, Betchingrey, Surrey.*

**"Breaking" in Freesias.**—In answer to Mr. Jacob's note on Freesias (p. 255), I am glad to say I have found no "breaking" in the variety Merry Widow, and very little in other varieties, though once a flower breaks it is broken for ever, as in Tulips, and in the majority of cases breaking spoils a Freesia. As to "duds" I have had none this year, due, I feel sure, to the hot dry summer of 1921, which ripened the cornus thoroughly. I have been of the same opinion ever since the question arose as to "duds." I think Mr. Jacob will remember my writing him that I felt sure "duds" were the result of insufficient ripening. I may be wrong, of course, but my experience is that a thorough baking in full sun is necessary to avoid "duds" appearing in the following season. *T. H. Dalrymple, The Nurseries, Bartley.*

**Branched Tulips.**—Mr. Jacob, in his notes on Tulips, on page 269, draws attention to Monsieur S. Mottet and its branching habit. I do not know this particular variety, but among the varieties I have grown this year Whistler developed this habit to a marked degree. Of fifty bulbs planted eight only carried a single bloom. Of the others four had four flowers on a stem, nineteen had three, and the remainder two. *C. G.*

**White Fly.**—The remarks of "*Majester Palae*" on p. 294 lead me to give my experience of the pest here. Last summer we had a very bad attack of White Fly, and neither fumigating with nicotine nor spraying with various specifics were of any avail to keep it in even reasonable check, with the result that at the end of the summer our Tomatos were practically ruined. This spring White Fly again attacked our plants and gradually got worse, until I tried "*Alvesco White Fly Fumigant*," made by Messrs. Murphy and Son, Mortlake. I am glad to state that this specific proved a complete cure, and all our houses are now clear of the pest. I confidently recommend this specific to anyone bothered with the pest, and claim that if the directions are followed out, no matter how bad the attack, it will destroy the fly. *Alvesco* is quite harmless to Tomatos and easy to use, having to be simply poured on the floors of the houses to become evaporated. *J. Chilcott, Dogleap Gardens, Limavady, Co. Derry, Ireland.*

**Hardening Plants** (see p. 251).—The leader on hardening plants was timely and most interesting, but may I venture to differ from the dictum that spraying frozen plants hastens the thawing. If so, why not spray with warm water and finish the job (and the plants) quicker? The best practice is to shade the plants, spray them with ice-cold water, and open the ventilators

sufficiently to cause a gentle current of air. In hot climates the natives mix a snattie (porous pot) with tepid water and hang it in the air, and the evaporation from the outside causes the water inside to become ice-cold. Again, if a human being is frost-bitten, the remedy is snow rubbed gently on the part affected. In both examples thawing is checked, not hastened. So with plants, cells that are frozen have the air driven out and are distended to bursting point, and a quick thaw means the sudden inrush of air and the fracture of weakened cell-walls, thus causing the death of the parts affected. That is my opinion, but I am open to correction, because I am—*Only a Gardener.*

**Flowering of Rhododendron sino grande.**—The statement that *Rhododendron sino grande* is flowering this year for the first time (see p. 291) in this country is not strictly accurate. I saw a plant in full flower in Mr. Tremayne's garden at Heligan, Cornwall, in June, 1919. This spring it was to be seen flowering in many Cornish Gardens. *C. W. James, Welbeck Street, London, W.*

**Fasciated Alder Growth.**—I am sending you a curiously fasciated shoot of Alder, which I hope may interest you and your readers. The

FIG. 183.—FASCIATION IN ALDER.

specimen was found in a small copse here, and at first sight appeared to be a small horse shoe caught up in the bush. I also enclose a photograph, which you may like to reproduce (see Fig. 183). *K. E. P. Trench, Belle Orchard, Hawkhurst, Kent.*

**Dunkeld Larches** (see p. 258).—The following extract from a MS. of my great great grandfather is of interest, as it gives the date of planting, also the girth of one of the Dunkeld Larches measured at 5 feet in 1817: "One of the famous Larch trees at Dunkeld, which the present Duke of Athol's father brought over as greenhouse plants in 1758, measured, August 17, 1817, girth at 5 ft., 13 ft." *H. Clinton Baker, Bayfordbury, Hertford.*

**Tulip Carrara.**—I have noticed that Tulip Carrara, which was given a First Class Certificate at the Chelsea Show, is described as a Darwin variety. I have grown this Tulip, and always regarded it as a Cottage variety, and Messrs. Barr and Sons so describe it in their list. I believe it was raised by Mr. Krelage. Who is right? *W. A. Watts, Anglesey.*

**Poor Fruit Prospects.**—Although fruit trees of all kinds, and Apples, Pears and Plums in particular, flowered in profusion in my garden, my fruit crops are almost nil. Is this general? *Essex.*

SOCIETIES.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

The monthly meeting of this society was held in the R.H.S. Hall on Monday, June 12th, Mr. Chas H. Curtis presiding. Five new members were elected. One member withdrew interest amounting to £5 0s. 4d. Five members over the age of seventy years were allowed to withdraw sums from their deposit accounts amounting in all to £228 11s. 7d. The sick pay for the month on the ordinary side was £34 15s. 8d. and on the State side £49 12s. 4d., and maternity benefits came to £4. The trustees were instructed to invest a further £500. Arrangements are being made with a view to holding the annual dinner during the R.H.S. Holland Park Rink Show in the autumn.

ROYAL SCOTTISH ARBORICULTURAL.

**ABERDEEN BRANCH.**—The members of this branch held an excursion on Saturday, 17th inst., the venue being the beautiful estate of Castle Forbes, on the banks of the Don, the seat of the premier Baron of Scotland, Lord Forbes. There was a large and representative attendance; the weather was excellent, and the sylvan beauty of this part of Aberdeenshire was seen under the most favourable conditions.

The party was warmly received by Lord Forbes, who, throughout the whole day's proceedings, proved in very truth a guide, philosopher and friend. Cattlehill Wood was first visited, where some capital specimens of Spruce and Scots Pine, of about 50 years of age, were seen. Lying low, it was quite evident the soil conditions were more suitable for the Spruce than the Scots Pine. The former were of magnificent growth and excellent in quality.

At this stage, Mr. Tait, of the Liverurie Paper Mills, exhibited samples of paper which had been made from Spruce obtained from Castle Forbes. The paper was of the very finest quality, and was very favourably commented on by the party. The episode aroused an interesting discussion as to whether it would not be possible to grow big enough Spruce woods to supply a large part of the requirements of the paper mills situated on the banks of the Don, and the conclusion come to was that it would be quite feasible.

The fine old woods on the Black Knap were next visited. The hill contains rare specimens of Scots Pine, Spruce, Oak, and other trees, planted about 1770, a period when tree planting in the north of Scotland was very active. A goodly part of the hill has been cleared, but a large part still stands, and this is to be treated as amenity woods. Some hill climbing was then enjoyed on a spur of Bennachie, where many years ago one of the best crops of Larch ever produced in this country was cut by Mr. Millar, a well-known timber merchant. The Bennachie area is to be afforested by Lord Forbes after planting on the Black Knap is completed. Some experimental plots of the following Larches, which have recently been planted, were next visited. They are *Larix kurlensis*, *L. dahurica*, and *L. Rupprechtii*, all recently introduced.

The nurseries on the estate were then inspected, and proved one of the most interesting and instructive items in the day's programme. Started in 1920, the nurseries are well stocked with different species of Conifers. In this area of Aberdeenshire it is extremely difficult to raise trees in nurseries because of frost, but this obstacle has been obviated at Castle Forbes to some extent by the adoption of a special method of protection. In the nurseries the visitors found Larch, Scots Pine, Sitka Spruce, *Abies grandis*, and the Western American Larch, which is very difficult to raise in most parts of this country, but here was thriving particularly well. The Sitka Spruce is susceptible to frost, but the others looked quite healthy. The beautiful trees in front of the Castle and stretching down to the Don were greatly admired. Handsome specimens of Spanish Chestnuts, Copper Beeches, Limes, and Elms formed an umbrageous display which it was

felt could hardly be equalled, certainly not bettered, in any part of this country.

After hours of rambling among the woods, the party were kindly entertained by Lord and Lady Forbes. Mr. John Michie, M.V.O., as senior vice-president of the branch, expressed the pleasure the members had experienced on their visit to Castle Forbes. They had seen the beautiful valley of the Don, the woods in various stages, the nurseries which were going to produce the sylvan beauty of the country which had been more or less depleted of forests, and enjoyed the hospitality of Lord and Lady Forbes. From the keen interest his lordship took in the subject of forestry, he hoped for great results. They returned to him their warm thanks for his kind invitation, and particularly to Lady Forbes for kindly honouring them with her presence that day. Lord Forbes returned thanks, and then showed the party interesting relics in the Castle, many of them associated with the history of the family and Scotland. A tour was then made of the spacious and well-stocked gardens, and thus concluded an excursion which will ever remain memorable in the annals of the Society.

A business meeting of the branch was then held, Sir John Gladstone, Bart., of Fasque, presiding. Resolutions recording the deep regret felt at the death of Mr. Alexander Forbes Irving, of Drum, a greatly esteemed member of the Society, were passed, and the next excursion was fixed to be held to Durris Estate, on September 16.

### Obituary.

**Abner Hassall.**—We regret to have to record the death of Mr. A. Hassall, which took place at his residence on June 15, after a very brief illness and while apparently he was but little beyond the prime of life. Mr. Hassall was greatly interested in Orchids for many years, especially in the Southgate Orchid Nurseries, formerly of Messrs. Lewis and Co. and afterwards Stanley, Mobbs and Aston, which was taken over as Hassall and Co., with Mr. John C. Cowan as manager, in January, 1911. The change was a great success, Mr. Cowan enlarging the scope of the firm, which was chiefly famed for Brazilian Orchids, by making the hybrid department under his direct supervision the leading feature, their new Cattleyas, Laelio-Cattleyas, and Brasso-Laelio-Cattleyas being among the best yet produced. Mr. Hassall had other business interests, which he successfully pursued, and was much esteemed by all who knew him.

**William Parkin.**—While engaged at his ordinary duties, on June 13, Mr. William Parkin, curator of Ruchill Park, Glasgow, was seized with illness and expired in a few minutes. He was overcome with faintness, and went to a well for drinking water, and while there expired. Mr. Parkin, who was only fifty-three years of age, had been in the service of the Parks Department of the City of Glasgow for about sixteen years, and was for a long time in charge of Ronken Glen Park, but was transferred to Ruchill Park about a year ago. Mr. Parkin, who belonged to Lanark, leaves a widow and two children.

### ANSWERS TO CORRESPONDENTS.

**NAMES OF PLANTS:** R. W. N. 1, *Pyrus Aria*; 2, *P. intermedia*; 3, *Spiraea van Houttei*; 4, *Amelanchier canadensis*; 5, *Phillyrea decora*; 6, too small to identify; 7, *Acer platanoides* var.; 8, *A. pseudo-platanus* var. *aucubae-folium*; 9, *Acer opulifolium*; 10, *Pyrus americana*.—*Torbay*. *Petteria ramentacea*.—*M. B.* The white flower is *Staphylea colchica* and the other *Euonymus europaeus*.—*M. P. H.* *Primula malacoides*.

**PEACH FRUITS DROPPING:** W. H. B. Your Peaches are evidently growing in too rich a compost, and will not fruit satisfactorily while in their present extra vigorous condition. Root-prune the trees next October, give

the roots no manure, except a little bone-meal, and incorporate more open material, such as lime rubble, with the soil. To grow Peaches well the trees should be planted in a moderately rich compost and fed only when carrying heavy crops of fruit. The roots should be examined at least every other year to encourage the development of hard, short-jointed wood of moderate growth.

**PEACH LEAF CURL:** J. C. This disease is always more in evidence when there is a sudden fall in temperature, and especially when cold winds prevail, but it is checked by an increase of temperature. The affected leaves should be removed and burnt. Spraying the trees with Burgundy mixture just before the leaf buds burst is a preventive measure that has proved eminently satisfactory; the mixture is rendered more effective if  $\frac{3}{4}$  pint of milk is added to every three gallons, as this addition increases its adhesiveness.

**RICHARDIAS (ARUMS) UNHEALTHY:** A. B. Your plants are affected with the bacterial disease of Arum Lilies recently investigated by Dr. Bewley, Director of the Lea Valley Research Station, Cheshunt, from whom, doubtless, information as to its control can be obtained.

**TOMATO DISEASED:** C. H. The plants are affected with foot rot disease, caused by the fungus *Phytophthora cryptogaea*. The remedy is the use of the Cheshunt compound described by Dr. Bewley in a recent number of the *Journal of the Ministry of Agriculture*.

**VEGETABLE MARROWS:** H. M. By stopping the main shoots of Marrows, the plants will develop side shoots freely, and, if these, also, are stopped after they have grown a reasonable length, short, fruitful growths will develop and prove more profitable than when the plant is allowed to run unrestricted.

**WILLOW BARK RIDDLED WITH HOLES:** R. H. L. The injury has been caused by the Willow Gall Gnat, *Cecidomyia saliciperda*, one of the two-winged or dipterous insects. The female insect deposits her eggs in chains or rows on the bark. The eggs are extremely minute, roundish at the ends and orange-yellow in colour. The pupa, which is yellow, develops just under the bark, and when the flies escape the bark is seen to be riddled with small holes. Infested shoots—which may be distinguished by their irregular, streak-like growths—should be cut off and burned before the flies have issued. Cart grease or some similar material applied to the places attacked makes it difficult for the flies to escape, for most of them become entangled in the sticky material.

**WHITE FLY:** C. E. S. In place of potassium cyanide you may use the following formula: Water 3 fluid oz., sulphuric acid  $\frac{1}{2}$  oz., sodium cyanide 1 oz. Put the water first into a glazed earthenware jar and add the acid slowly. The amount of cyanide to use is from one-fifth to one-quarter oz. per 1,000 cubic feet, according as to whether the house can be more or less completely sealed. According to the size and construction of the house the charge is distributed in a number of jars placed along the centre of the house. Prepare the water and acid in the jars in the afternoon, weigh out the proper quantities of cyanide and wrap each charge in paper. Cut off the fire-heat if this can be done with safety. Close the ventilators at dusk and place a cyanide charge by the side of, but not in, each jar. Then, the exit door being open, walk down the house from the far end, pour the cyanide from the paper into each jar in turn without undue hurry, but without pausing. Pass out and lock the door, which should be kept locked until dawn. It should then be opened and the ventilators also, which should have been arranged so as to be opened from the outside. After one hour of ventilation the house may be entered.

## MARKETS.

COVENT GARDEN, Tuesday, June 20th, 1922.

### VEGETABLES AND FRUITS.

Practically all fruits have felt the competition of the Strawberry, and prices have dropped all round. Ample supplies of Australasian Apples are on offer, and their condition is reported as better. English Cherries are now coming to hand, arrivals from France having nearly finished. Black and Red Currants are also arriving from the same country, and are in fair demand. Oranges and Lemons are quoted easier. Plums and Apricots from Spain are on offer, although supplies of the latter show a slight falling off. Choice fruits such as Grapes, Melons, Peaches, Nectarines, and Figs are meeting only a moderate demand. Gooseberries are plentiful and lower in price. New Potato values, after improving slightly, have receded. English Tomatoes are also easier, the quantities being much heavier than of late. The Cucumber trade is, however, poor, the very large quantities of Dutch Cucumbers materially altering values of home grown produce. Asparagus has been a better trade, supplies being much lighter. Mushrooms are quoted comparatively low, owing to larger arrivals. Green vegetables are fairly plentiful. Peas are cheaper, and old Potatoes are a quiet trade.

### Cut Flowers, etc.: Average Wholesale Prices.

**REMARKS.**—Large consignments of outdoor flowers are now available. Numerous varieties of Delphiniums are on sale, in excellent condition, and these flowers comprise one of the most prominent subjects in the market, although the commoner varieties exceed the present demand. All outdoor subjects show a further increase in numbers, with a general reduction in prices. *Statice sinuata* is becoming more plentiful in white, yellow, and mauve colours. Other attractive lines are the various *Glaudiolus*, including *Brenchleyense*, *Halley*, *Prince of Wales*, and *The Bride*. *Peach Blossom*, *Blushing Bride*, and *Ne Plus Ultra*. The *Bride* is arriving in good condition, but the last three are only medium in quality. *Pyrethrum* and *Paeonies* show signs of finishing. *Roses* exhibit no improvement on last week. The supply of good outdoor blooms remains limited, the most prominent sorts being *Mrs. J. Laing*, *Molly Sharma*, *Crawford*, *Fran Karl Druschki*, and *General McArthur*. Carnations are fewer in quantity and very medium in quality; no better blooms are expected until the newly grown plants are in flower. *Lilium longiflorum* is again rising in price owing to a more limited supply, and the same is true of *Lily-of-the-Valley*. Larger supplies of *Lapageria* and *Stephanotis* are on sale. There is an abundant supply of *Mrs. Sinkin* Pinks, and double white *Stokes*, also *Cornflowers* and *Gypsophila*. Spanish Irises are finishing.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 61.5°.

ACTUAL TEMPERATURE:—  
Gardeners' Chronicle Office, 5, Tavistock Street, Covent Garden, London, Wednesday, June 28, 10 a.m. Bar. 29.8; temp. 62°. Weather—Dull.

**The Chelsea Shows.**  
The last Chelsea show will doubtless remain in the memories of those who had the good fortune to witness it as a splendid illustration of the skill and good taste of British horticulturists. Rarely, if ever, have so many groups of magnificently staged plants been seen at any exhibition. From the point of view of the general public, which looks for and enjoys wealth of floral beauty, the last Chelsea show may be described as the most successful since the war. Nevertheless, we are inclined to think that horticulturists concerned with the maintenance of the great reputation which this country enjoys as a producer and introducer of new plants of horticultural value or promise, must have come away from the exhibition with somewhat mingled feelings; gratitude for and full of admiration of the many exhibits of undoubted excellence; disappointment at the relative scarcity of new plants and of recently raised or introduced varieties. If this is an accurate presentment of the feelings of horticulturists, it would seem that the moment has come for the Royal Horticultural Society to examine carefully into the question whether it is possible to do more at the Chelsea show to encourage the staging of new plants and those of conspicuous promise. Although we are aware of and applaud the many activities which the Royal Horticultural Society displays for the benefit of horticulture,

yet we would commend to its notice the desirability of making renewed and special efforts to promote yet more vigorously what may be called the creative side of our horticulture. It is possible that this could be done by an extension on a well-considered and liberal scale of their awards and rewards for exhibits. Whilst maintaining the existing system of awards it should be practicable to introduce a series of new rewards for especially noteworthy, new and promising plants, which mark a distinct advance on those already in our gardens. As matters are at present, an exhibitor is apt and wise to include his novelties in his large exhibit. But there they may fail to attract the attention they deserve. There are, of course, the special awards A.M. and F.C.C., but our point is whether a judicious and liberal allocation of rewards for horticultural enterprise might not be added thereto! There is, of course, a certain air of importance created by caging specimens of novel or new plants behind a wire screen, but we think that a more imposing method of exposition might be tried. Where possible these new plants and new varieties should be so exhibited that their full value may be judged, not as isolated specimens—though in some cases they must be so represented—but as groups. Raisers and introducers of new plants have many troubles and few rewards, and to encourage and recompense them must always be among the first concerns of the Royal Horticultural Society. The object of such an exhibition as the Chelsea show is to display to the world not only the present performance of British horticulture, but also its promise. Of the performance at Chelsea no praise can be too high, but with the increasing popularity of gardening there is a danger—signs of which were not wanting at Chelsea—lest the spectacular side of horticulture should, like the lean kine, devour the fat kine—the creative side of horticulture, which finds expression in the improvement and discovery of new plants and the encouragement of the cultivation of rare and difficult kinds of real garden value.

**Retirement of Mr. William Watson, A.L.S., V.M.H.**—The retirement of Mr. W. Watson from the Curatorship of the Royal Botanic Gardens, Kew, at the end of the present week, serves as a reminder of the inevitableness of the passing of time. To many thousands of horticulturists "W. W." and Kew seem inseparable, and to the majority of gardeners and botanists, Kew will not be quite the same place in the absence of the strong personality of Mr. Watson, who has been Curator since July, 1900, when he succeeded Mr. George Nicholson. Mr. Watson has always maintained that the first qualification of a gardener is practical experience coupled with cultural ability, and during his many years of service at Kew, he has set this ideal before several generations of young gardeners. To Mr. Watson's qualifications, qualities and services, we hope to make further reference in another issue. For the moment we add our good wishes for his continued health and a long period of happy retirement from public duties to those he will receive from hosts of appreciative horticulturists throughout the world.

**New Curator at Kew.**—Mr. W. J. Bean, V.M.H., for many years Assistant Curator, and formerly Arboretum Foreman, succeeds Mr. W. Watson as Curator of the Royal Botanic Gardens, Kew. Mr. Bean has a world-wide reputation for his unique knowledge of trees and shrubs, but his acquaintance with Orchids, tropical plants and hardy plants is scarcely less intimate. He is a Yorkshireman by birth and education, and obtained his early experience in gardening at Belvoir Castle, whence, after four years, he went to Kew, in 1883. At Kew he became sub-

foreman of the Palm House, and later of the Orchid Department, and afterwards was foreman in the Temperate House and in the Arboretum, becoming Assistant Curator in 1900. Mr. Bean has travelled somewhat widely on the Continent and in the United States, always adding to his knowledge, increasing the collections at Kew, and helping others in his quiet, modest way. He had written several books on horticulture and has been a contributor to these pages for very many years, but his chief literary work is *Trees and Shrubs Hardy in the British Isles*. Old Kewites will remember that for a period of five years Mr. Bean edited the *Journal of the Kew Guild*; they will also remember his abilities as a cricketer, and, later, as a tennis player. Mr. Bean does not love the limelight, therefore we make no attempt to refer in detail to the services he has rendered Kew in particular, and to horticulture in general. We would, however, add that in recognition of these services he was awarded the Victoria Medal of Honour in Horticulture in 1917.

**Award of the "White" Medal.**—The Massachusetts Horticultural Society has awarded the George R. White Medal, the highest horticultural award in America, to Mr. A. C. Burrage, President of the Massachusetts Horticultural Society and of the American Orchid Society. Mr. Burrage has, during the past few years, organised exhibitions of a special nature, including one of tropical Ferns and wild Orchids, and of wild flowers and wild Ferns. The latter show, held on May 3 of this year, is described in the *Florists' Exchange* as the greatest horticultural exhibition ever held in the United States and in point of attendance it eclipsed every exhibition in the history of the Massachusetts Horticultural Society. The public was admitted to the show free of charge.

**The Royal Society Conversazione.**—The Conversazione of the Royal Society, held in the Society's rooms at Burlington House on June 20, was notable by reason of the numerous and interesting botanical exhibits. Professor Seward and Mr. R. E. Holttum showed specimens of fossil and recent plants which they had collected during their recent expedition to Greenland. The specimens exhibited in striking manner the contrast between the present vegetation of Greenland and that of the Cretaceous epoch when Ferns closely resembling tropical and subtropical *Gleichenias* were abundant. From Kew were sent specimens of the double Coconut, *Lodoicea seychellarum*, which is confined to the Seychelles. One of the specimens had germinated and pushed out its long, thick cotyledonary tube, which, like that of an Onion, carries the plumule and radicle out of the seed. Another Kew exhibit was that of *Ecaanda* rubber from Angola. The source of this rubber is the tuber—which may weigh so much as fifteen pounds—of *Raphionacme utilis*. Dr. Rendle showed an interesting series of specimens and photographs illustrating replacement of the terminal bud in Horse Chestnut seedlings. An exhibit which attracted much attention was that provided by Dr. Alexander Fleming, which illustrated the recently discovered fact that tissues of the animal and plant body have the power of secreting a substance, lysozyme, which exercises a remarkable lethal action on certain bacteria. So powerful is this destructive action that it may be demonstrated in "tears" diluted to one in five million of water.

**Sale of Diseased Plants.**—The Sale of Diseased Plants Order of 1921, which came into operation on October 1, 1921, has proved very efficacious in preventing the sale of diseased plants and trees. Close watch was kept on sales throughout the country by the inspectors of the Ministry of Agriculture during the past season, and it was found that the standard of health of the plants exposed for sale was on the whole satisfactory. In some cases, it was necessary to call the attention of persons concerned to the presence of disease, but legal proceedings were instituted in one case only. There was, however, a strong feeling throughout the industry that further powers should be taken in order to enable the Ministry's inspectors to require

the treatment or destruction of badly infected plants or trees exposed for sale, and a recommendation to that effect was passed at the last meeting of the Minister's Horticultural Advisory Council. Following on this recommendation, the Minister has issued a new Order, which comes into force on July 1, giving powers to the inspectors of the Ministry to require the destruction or disinfection of any plant exposed or offered for sale which is substantially affected by any of the scheduled pests, in addition to the existing power to prevent the sale or movement of such plants.

**Hereford Rose Show.**—The schedule of the Rose show, to be held in the Shirehall, Hereford, on the 19th inst., provides liberal prizes in twenty classes for Roses, seven classes for hardy perennial flowers, Sweet Peas and Carnations, and four decorative classes. During the past two years the committee of the Hereford and West of England Rose Society has not received that enthusiastic support its work deserves, and in a letter sent out with the schedule the chairman, Sir Geoffrey Cornewall, wrote: "The committee feel that, considering the show is in a measure a county institution, it has a very meagre backing. This does not refer so much to the subscription list, though this, of course, is a prime essential, as to the lack of personal interest. There seems to be a strong feeling amongst a large proportion of the gardening community against showing, a feeling which is, of course, fatal to the efforts of the Show Committee. They not only lose thereby an equivalent proportion of exhibits, but also that personal interest and patronage which would follow entries. I appeal to those who love beautiful flowers to remember what a great part exhibitions have played in the improvement of varieties and methods of cultivation, and to help the committee by all the means in their power to make this season's show on July 19th an exhibition worthy of the horticulture of the county." We hope Sir Geoffrey Cornewall's appeal will prove successful.

**Flowers in Season.**—Mr. Amos Perry has forwarded flowers of his beautiful form of *Coreopsis grandiflora*, known as Perry's variety. The flowers are semi-double and of deep, clear yellow colour. This fine hardy perennial commences to flower early in June and continues in bloom throughout the whole of the summer.

**R.H.S. Gardens Club.**—The annual meeting and outing of the R.H.S. Gardens Club will take place on Saturday, July 8, 1922, by the kind invitation of Messrs. James Carter and Co. at their establishment at Raynes Park, S.W. (close to the L. and S.W. Railway Station). The tour of the warehouses and trial grounds will commence at 2.30 p.m. The annual meeting will be held at the conclusion of the inspection. Messrs. J. Carter and Co. are very kindly inviting the Club to tea, and in order that arrangements may be made, old Chiswick and Wisley students who hope to be present are requested to notify the Hon. Sec., Mr. W. D. Cartwright, R.H.S. Gardens, Wisley, not later than Monday, July 3.

#### Conveyance of Pot Plants by Passenger Train.

—Just as we go to press we learn that the railway companies have agreed to afford most of the facilities and rate reductions which growers asked for on the occasion of the visit of the deputation from the Chamber of Horticulture, British Florists' Federation and Horticultural Trades' Association, to the Railway Clearing House, just before Whitsuntide. We referred to this subject at some length in our issue of June 10, p. 297.

#### Gardeners' Royal Benevolent Institution.

—The annual festival dinner of the Gardeners' Royal Benevolent Institution, held on Tuesday last, in the beautiful Grocers' Hall, was the 77th of the series and one of the most successful. The Right Hon. Lord Lambourne presided, and he was supported by many distinguished horticulturists and prominent supporters of the Institution, the total number present being 215. The chairman and other speakers expressed their deep regret at the absence of the treasurer, Sir

Harry J. Veitch. Lord Lambourne made a stirring appeal on behalf of the Fund, which he stated required £5,500 annually to carry on its work. Later in the evening, the secretary, Mr. G. Ingram, announced that the total amount collected on behalf of the Fund, at and in consequence of the dinner, amounted to £3,000. A musical programme was rendered, and the whole proceedings were marked with conspicuous success.

**Mr. Walter Easlea.**—The name of Easlea has for many years been associated with Roses, for Mr. Walter Easlea, head of the firm of Messrs. Walter Easlea and Sons, of Danecroft Rosery, Eastwood, Essex, is the son of a noted Rose-grower who was connected with some of the most famous Rose nurseries in the country, including those of Mr. Thomas Laxton, Mr. G. Prince, and Messrs. Wm. Paul and Son. It is a coincidence that Mr. Walter Easlea, junior, was born in one of the most celebrated Rose-growing districts in England, for his father was then a gardener in a private establishment at Colchester. Mr. W. Easlea commenced his professional career with Mr. Laxton whilst his father was employed by that firm, and he followed him to Mr. G. Prince, of Oxford, and

MR. WALTER EASLEA.

also to Messrs. Wm. Paul and Sons at Waltham Cross, where he remained for many years. In 1909 he acquired land at Eastwood, not far from the flourishing town of Southend-on-Sea, where the soil is of a heavy, clay loam, and most suitable for Roses. The Danecroft Rosery has an area of some sixteen acres, and the whole of it is devoted to Roses, Mr. Easlea, in association with his sons, having built up an extensive business in these flowers. Mr. Easlea is not only a clever grower of Roses, but his writings on Rose matters are always read with interest, and his essay on the Hybridisation of Roses won the special prize and medal offered by the National Rose Society for a paper on that subject. He is a frequent contributor to this journal, and also to other horticultural papers. He has won many cups and medals for Roses at exhibitions, and gained several awards for novelties of his own raising. It will be remembered that the hundred-guinea Clay Challenge Cup offered for the best seedling Rose not in commerce, of good form and colour, and possessing the true old Rose scent, was won by Mr. Easlea last year with his variety, Prince of Wales. Amongst other notable Roses sent out by his firm are Climbing Mme. Abel Chatenay, Little Meg, Cherry Page, Lamia, Mrs. H. D. Greene, Countess of Warwick, Glow Worm, Lulu, Romeo, Mrs. Ramon de Escofet and Peggy Astbury. Mr.

Easlea, who is a member of the Council of the National Rose Society and a member of the American Rose Society, is a well-known personality at Rose exhibitions, where he is usually either officiating as a judge or exhibiting. During recent years the firm has erected greenhouses, one of which is especially devoted to the raising of seedling Roses. Just now the seedling Rose-house is filled with plants well set with seed pods and with many seedlings which have not yet flowered. Of a quiet, unassuming manner, Mr. Easlea has endeared himself to a wide circle of friends, and he is greatly esteemed in the Southend and Westcliff district, which the old parish of Eastwood adjoins.

**Lettuce and Crocus Trials at Wisley.**—The Royal Horticultural Society will carry out a trial of autumn-sown Lettuces in their gardens at Wisley this season. A packet of seed of each variety to be tried should be sent to reach the Director, R.H.S. Gardens, Wisley, Ripley, Surrey (from whom the necessary entry forms may be obtained) on or before July 31, 1922. Only varieties suited for autumn sowing should be sent. The society is desirous also of planting all available species and varieties of Crocus for purposes of comparison, and the Director will be glad to receive examples for this purpose so far as possible by July 31, 1922.

**Flowering Lilies.**—Mr. A. Grove, 2, Albion Street, W.C.2, writes: "I shall be obliged if you will spare me a corner of your space to ask any reader who may have a flowering specimen of one or more of the following species of *Lilium*, kindly to communicate with me: *L. Bakerianum*, *L. Delavayi*, *L. formosum*, *L. myriophyllum* (not regale), *L. Stewartianum* and *L. tabense*."

**Horticultural Club Outing.**—On Friday, July 14, members of the Horticultural Club will visit the R.H.S. Gardens, at Wisley, and Pyrford Court, Woking, the residence of Viscount and Viscountess Elveden, on the occasion of the annual outing of the Club.

**Horticultural College, Swanley.**—The annual report of the Governors for 1921 states that the College has been full throughout the year and that forty-five new students were received in January. Miss F. K. Wilkinson has resumed temporarily the post of Principal rendered vacant by the resignation of Miss F. Micklethwait. Prof. V. H. Blackman, Sir Herbert B. Cohen and Miss Eva Smithers have been elected to the Governing Body. Considerable repairs to buildings have been carried out during the year; a new dairy has been erected; existing buildings have been converted into a well-equipped chemical laboratory and the large greenhouses have been restored to their pre-war condition. A small herd of hardy goats of English breed has been added to the live stock and the poultry department has been reorganised. Old students' day has been fixed for Saturday, July 15. During the afternoon there will be a tennis match between the old and present students and a dance in the evening.

**Spring Foray of the British Mycological Society.**—The spring foray was held at Norwich during Whitsun week-end. The members assembled at the Castle (Norwich Museum) on Friday evening, June 2, and were received by the Museum authorities and a few prominent members of the Norfolk and Norwich Naturalists' Society. On Saturday morning, train was taken to Wroxham, where the party embarked on Mr. E. O. Adcock's house-boat. A landing was made near the Devil's Hole, and the marshes were worked so far as Horning, interesting to mycologists as the birthplace of the late Dr. M. C. Cooke. Several interesting rusts were gathered, the accidental stage of *Puccinia Phragmites* being particularly abundant on *Rumex* spp., as was also the accidental stage of *Puccinia Pringsheimiana* (?) on *Ribes nigrum*. From Horning the journey was made up the Bure to South Walsham Broad by fishing boat and motor launch. Very little was found here, but a colony of large specimens of *Lycoperdon giganteum*, forming a series of rings, was a

source of delight. Two of the largest puff-balls were measured, and found to be 42 inches in girth, with a diameter of 14 inches, thus falling very far short of the American record for this fungus, which gives 64 inches as the longest diameter, by 54 inches in its shorter, though the height of the specimen was only 9½ inches. After the day's collecting was over, Mr. Adeock entertained the members to dinner at Horning. On Sunday morning the party was conducted round the Museum by Mr. Donald Payler, the Assistant Curator. An excursion was made by tram to Trowse in the afternoon, and the Woods of Crown Point estate explored. Owing to the drought, few Agarics were encountered, and search was mainly directed to microfungi. Mrs. Colman kindly entertained the party to tea, and afterwards conducted the members round the garden, where the rare *Uromyces Lilii* was found on *Lilium candidum*. The only previous records of this fungus for the country are Kew Gardens and Birmingham. Mr. Adeock's Tomato and Cucumber houses were visited in the evening, and afterwards the President, Mr. F. T. Brooks, gave a talk on rusts—a particularly appropriate subject in Norfolk. On Monday, train was taken to Whittingham, and the woods on the borders of Thorpe St. Andrew and Sprowston were visited. Though fungi could not be said to be common, a fair number was found. A meeting was held at headquarters in the evening, and Mr. H. J. Howard (who was principally concerned in making the local arrangements) gave a short account of Mycetozoa, with particular reference to the rare Norfolk forms which he has succeeded in discovering. Votes of thanks were accorded to all who had assisted in making the foray such a splendid success. On Friday, June 16, a lecture was given at University College, Gower Street, W.C., by Professor A. H. R. Buller, of Winnipeg, on "The Organisation of the Hymenium for the Production and Liberation of Spores in Mushrooms and Toadstools." The following day a fungus foray was held in the neighbourhood of Weybridge for the students of London colleges. Mrs. A. A. Pearson kindly entertained the party to tea.

**Appointments for the Ensuing Week.**—Tuesday, July 4.—Royal Caledonian Horticultural Society's meeting; Royal Agricultural Society's horticultural exhibition (4 days); Bournemouth Gardeners' Association's meeting. Wednesday, July 5.—Colchester Rose and Horticultural Society's show; Cambridgeshire Horticultural Society's show (2 days); National Viola and Pansy Society's meeting and exhibition. Saturday, July 8.—Ringwood Society's meeting.

"The Gardeners' Chronicle" **Seventy-five Years Ago.**—*Profits of Grape-Growing.* In a vinery at Newton there are now (June 28) 226 bunches of Grapes, some ripe, and in an adjoining greenhouse is a later crop, consisting of 170 bunches; and in all there have been 426 bunches. There are also Peaches and Nectarines, both on trellises and in pots under the vines. The prices of hothouse Grapes during last month in Covent Garden Market were from 5s. to 10s. per pound. Now, suppose these 426 bunches to weigh, on an average, 1½ lb. each—although some of the bunches measure sixteen inches in length—the result would be 639 lb., and if these 639 lb. were all sold in July and August at, on an average, 4s. per lb., they would realise 2,556s., or £127 16s. profit, for I allow the Peaches and Nectarines to pay for the coals, and the greenhouse plants to pay for the labour. The vinery measures 36 feet by 16 feet, and the greenhouse 30 feet by 15 feet. This result will show the value of glasshouses when well managed. *R. H., gardener, Newton, near Chester. Gard. Chron., July 3, 1847.*

**Publications Received.**—*Seaside and Countryside in East Anglia* Issued by the Great Eastern Railway Company, and edited by Percy Lindley 30, Fleet Street, E.C. Price 6d. *Report of the Fifteenth Meeting of the Australasian Association for the Advancement of Science.* Hobart meeting, held in Melbourne, January, 1921. Published by the Association at Elizabeth Street, Sydney, N.S.W.

**TREES AND SHRUBS.**

**FLOWERING SHRUBS AT DRYNHAM.**

FLOWERING shrubs, and especially rare and choice varieties, have flowered uncommonly well this season, no doubt as a result of the hot weather of last summer, which caused the wood to become unusually well ripened. In these gardens the shrubs were a gorgeous spectacle in the early season. The Snowdrop tree, *Halesia tetraptera*, was extraordinarily beautiful, as also were the early *Ceanothuses*, notably *C. Veitchii* and *C. dentatus*. Lilacs of all varieties were very floriferous this spring. *Viburnums* gave a wealth of blossom, especially *V. Carlesii* and *V. tomentosum*.

All the members of the *Pyrus* family and the various *Prunuses* presented gorgeous spectacles when in flower. *Azaleas* and *Rhododendrons* were never better. Of the latter, both the Himalayan and the garden varieties were a lovely sight, and I have never seen a finer display of the variety *Pink Pearl* than our numerous plants presented, but, owing

berries have been splendid, as also have *Spiraeas* of the shrubby section, while those which are coming into flower include *cautionensis* and the like. I have never seen our shrubs flowering so beautifully as they have been this year. *H. A. Cook, Drynham Gardens, Waltham-on-Thames.*

**PLANTS NEW OR NOTEWORTHY.**

**CRATAEGO-MESPILUS ASNIERESII.**

Of the three hybrid *Crataego-Mespilus* cultivated in our gardens *Asnières's Thorn*, the subject of the illustration in Fig. 1, is the most ornamental as a specimen lawn tree.

It originated as a graft hybrid in the garden of M. Dardar, at Bronvaux, near Metz (see *Gard. Chron.*, p. 185, September 9, 1911), being first noticed in 1894. This gentleman had a Medlar (*Mespilus germanica*) grafted on the Hawthorn (*Crataegus monogyna*). Just below the point of union between the stock and scion two shoots had developed, showing intermediate

FIG. 1.—CRATAEGO-MESPILUS ASNIERESII.

to the hot sun and drying winds, their beauty was soon over.

Amongst the subjects in flower now are *Carpenteria californica*, which is blooming with great freedom; *Styrax Obassia* and *S. japonica*, both of which are carrying thousands of their pure white flowers; and *Abutilon vitifolia*, which has produced its beautiful mauve flowers with great freedom, our largest specimens, about 20 feet high, being laden with them. *Magnolia parviflora* is carrying hundreds of its pretty blossoms and presents a beautiful picture. All the *Magnolias* were good earlier in the season. *Rhus Cotinus coccineus* is most effective planted amongst *Rhododendrons* and the general collection of shrubs. The many varieties of *Philadelphus* are outstanding features in the shrubberies here, especially *P. gracillimum*, whilst *Olearias* have been very beautiful, and *Cornus Nuttallii* has given a wealth of its attractive inflorescences. Our specimens of *Chionanthus virginica*, the Fringe Tree, is some 9 feet high, and is bearing an abundance of its large panicles of pure white flowers, which individually may be likened to strips of tissue paper. This charming shrub was introduced so long ago as 1736 from North-West America, but it is rarely seen in gardens. It does best in sandy soil. The various Bar-

characters between the Hawthorn and Medlar. There was also a marked difference in the individual characters of the leaves on the two shoots. Propagated by grafting, the one having only entire leaves was named *C. M. Dardari*, and the second, with both entire and lobed leaves on the same shoot, forms the subject of this note.

A deciduous tree of bushy habit, with age probably 20-25 feet high, *C.-M. Asnièresii* produces quantities of white blossoms, ¾ inch across, in corymbs of 6 to 10 or 12 flowers. With age they change to a rose tint. In some nursery catalogues the tree is listed as *Crataegus M. Jules d'Asnières*.

*C.-M. Dardari* is of exceptional interest to the botanical student, as it produces on the same tree three and sometimes four distinct types of flowers and fruits. The large solitary flower of the Medlar (*Mespilus germanica*), typical *C.-M. Dardari* with white flowers 1½ inches across, in corymbs of 6 to 8 or 10 flowers; sprays of *C.-M. Asnièresii*, and the Common Hawthorn (*Crataegus monogyna*).

The third hybrid, *Crataego-Mespilus grandiflora* (syns. *Mespilus Smithii*, *De Candolle* and *Pyrus lobata*, *Nicholson*) is presumed to be a natural hybrid between the Hawthorn and Medlar. It is found wild in France. *A. O.*

## The Week's Work.

### THE ORCHID HOUSES.

By J. T. BARBER, Gardener to His Grace the Duke of Marlborough, K.G., Blenheim Palace, Woodstock, Oxon.

**Vanda teres** and **V. Hookeriana**.—These two terete leaved Orchids are charming subjects when seen in good condition. In some cases they do not produce flowers so freely as could be wished, although, when grown under natural conditions, they produce flowers abundantly. *V. teres* is in bloom at the present time, and during the growing season, which follows immediately the flowering period is over, the plants revel in an abundance of sun-heat, light, and moisture. All terete-leaved Orchids are capable of withstanding a great amount of sun-heat, and should only be shaded during the brightest part of the day, and then only sufficiently to prevent scorching. The work of repotting, resurfacing, or re-basketing, whichever system is adopted, should receive attention soon after the flowers are over. It is a good practice to grow the plants on long teak rods, plunging the rods into the crocks of the pots or baskets in which the plants are grown. Two or three inches of clean, chopped, live Sphagnum-moss forms a suitable compost, and the rod-like stems will soon make new roots, which will quickly adhere to the teak rods, and readily re-establish themselves, as they make aerial roots freely. The plants should be syringed freely, and the temperature forced up by sun-heat on all favourable occasions, by shutting the house early, and exposing the plants to all the light possible. When the growing season is over, the temperature should be reduced to that of the Cattleya house, and the plants kept quite dry at the roots. *Vanda Hookeriana* succeeds grown on the same lines, although it does not flower at the same season. These plants should be induced to make their growths as quickly as possible during the hottest and brightest part of the year, and then resting them carefully during the long, dark days of winter.

### THE KITCHEN GARDEN.

By JAMES E. HATHAWAY, Gardener to JOHN BRENNAN, Esq., Baldersby Park, Thirsk, Yorkshire.

**Mulching**.—Onions, Carrots and Beets should be mulched with spent Mushroom bed manure, and Artichokes, Peas, Cauliflowers and Beans with good rotten manure, which should be well soaked with water after it is applied.

**Potato Disease**.—Late blight is often very destructive to the Potato crop, and, as a preventive, the haulm should be sprayed with Bordeaux mixture when it is nearly fully grown. One spraying will as a rule suffice in dry seasons, but in warm, moist weather it is necessary to spray on two occasions (at about a fortnight's interval). To make Bordeaux mixture, dissolve 3 lb. of copper sulphate by placing it in a woven bag and suspending the bag in a wooden tub in 10 gallons of water. The copper salt should remain in the tub for a day. Put 2 lb. of quicklime in another tub, add water gradually until the lime crumbles to powder, then add more water until it forms like milk. Strain the milky liquid through a rough cloth when cold and pour into the copper solution, well stirring it at the same time. To ascertain the correct amount of lime water to be added, put some of the mixture in a white saucer and add a few drops of potassium ferrocyanide: when no red shows there is enough. Add 20 gallons of water. Bordeaux mixture should be a blue colour if properly made. It should be made fresh as required. The quantity given above will spray 25 rods of Potatoes.

**Potatoes**.—Varieties which are required for seed should be carefully looked over, and any rogues removed before the tops die down. Earthing up should now be completed.

### THE FLOWER GARDEN.

By EDWIN BECKETT, Gardener to the Hon. VICARY GREEN, Aldeham House, Hertfordshire.

**The Shrubberies**.—Such plants as Rhododendrons, Lilacs and Brooms should, after the faded blossoms stage is finished, have all the faded blossoms removed, thus preventing the formation of seed pods, for if this is not done, and each is allowed to throw its whole energy into the perfecting and maturing of its seed, then the prospects of a good flower yield during next season will be considerably diminished. Another value that results from this work, is tidiness, as a mass of faded blossom is not a picturesque item in a shrubbery. Care must of course, be taken to preserve the seed of rare plants, if needed for purposes of propagation, and the fruits of others that form objects of great beauty in autumn, such as Crabs, Thorns, Snowberries, and Viburnums. Grafted plants frequently develop growths from the stock, and these, if not checked early, will rob the grafted part of nourishment, and will also have the tendency to grow up and choke, or at any rate, damage it. The grower should continue to prune the various shrubs judiciously after they have finished flowering, to promote a good shape, and to allow the air and sunlight to enter freely and ripen the wood. Newly-planted trees should be watered in dry weather; mulching will also greatly assist in this matter, whilst the careful pruning of old wood to new growths will greatly assist in the promotion of root action. Overhead syringings are also of great benefit to trees and shrubs in hot, dry weather. Staking and tying should be attended to from time to time.

### PLANTS UNDER GLASS.

By T. PATEMAN, Gardener to Sir C. NALL-CAIN, Bart., The Node, Codicote, Welwyn, Hertfordshire.

**Mignonette**.—This delightful, sweet-scented annual makes an excellent pot plant, and is always welcomed in the conservatory or dwelling-house. If seed is sown now the plants will be valuable in the autumn. The seed may be sown in pots in which the plants are intended to flower, provided careful attention is paid to watering the seedlings in their early stages of growth. Perhaps the most suitable compost for growing this annual is loam of medium quality mixed with plenty of lime rubble. The soil should be made fairly firm in the receptacle by the use of a small rammer. Five-inch or six-inch pots are useful sizes in which to grow Mignonette. After sowing the seeds, the seed-pans may be stood in a cold frame and shaded from bright sunshine. When the seedlings have grown sufficiently to permit of thinning them, reduce the number to five or six plants. After they have filled the receptacle with roots, give the latter liberal supplies of manure water.

**Cyclamen**.—One-year-old corms of Cyclamen make fine plants when grown on the second season. Those that flowered last spring and have been kept on the dry side for a few weeks should be reotted in fresh soil. Remove the old soil carefully from the roots and place the plants in receptacles of the same size as those in which they have been previously grown, using a rich, open compost as recommended in a previous calendar for seedling plants. Spray the plants overhead lightly during hot, bright weather, but guard against heavy sprayings, as this tends to sour the surface soil and will check the growth of the plant. Shade the plants from bright sunshine, and when they are seen to be growing freely remove the lights in the evening when rain is not expected; the plants benefit by the night dew.

**Saintpaulia ionantha**.—Leaf cuttings of this beautiful intermediate-house plant that were inserted as previously advised should be ready for transferring to 4½-inch receptacles, in which they will flower. They may also be grown in shallow pans, placing five plants in each pan. When grown in this way they make a fine display. Turfy loam and peat in equal parts, with plenty of sand and broken charcoal added, form a good compost for these plants.

### FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Liogfield, Surrey.

**Mildew in Vineries**.—This pest causes much mischief in vineries, and is often a source of great annoyance to those in charge, and especially amateur growers. In many cases attacks of Vine mildew may be traced to faulty methods of ventilation. Admitting air by the front ventilators during the early stages of growth is more or less dangerous, especially when this is resorted to as a means of lowering the temperature. It is much better to retain a high temperature for a few hours than to admit a volume of air at the front of the house. In some vineries, because of their position, air may be admitted freely through both the top and front ventilators without harm occurring to the vines; but in other positions fresh air, even in the smallest amount, cannot be admitted until July without running the risk of an attack of mildew following. I believe this is the experience of those in charge at Wisley Gardens after many years' trial. Mildew may be killed, but its effects are always left behind, and the berries may as well be cut at once if they are much disfigured. Mildew is generally more prevalent in late vineries; this is often due to the absence of fire-heat during a few days of dull or damp weather. As a means of prevention as well as cure, sulphur in some form or other is effective, and where the disease has occurred previously, sulphur should be used freely as a winter dressing for the vines. Dusting or painting the pipes should be done thoroughly to be effectual, and some traces of the operation are sure to remain. Cambell's Sulphur Vaporiser is safe and effective for destroying and checking mildew indoors; the directions given should be strictly adhered to avoid setting fire to the boiling sulphur.

### HARDY FRUIT GARDEN.

By H. MAREHAM, Gardener to the EARL OF STRAFFORD, Wrotham Park, Barret.

**Pears**.—On the whole Pear trees have set heavy crops of fruit, which will need thinning. Reduce the number according to the size of the variety, and the age and strength of the trees. Keep all the leading shoots neatly secured to the wires or trellises, and thin out ill-placed, young growths and others too thickly placed that are not wanted to form spurs. Trees bearing good crops must not be allowed to suffer from dryness at the roots, and especially cordon trees growing on warm borders. Watch for the slug-worm and other insect pests of the Pear, and spray the trees with nicotine insecticide as soon as their presence is detected.

**Strawberries**.—The time is close at hand when the layering and raising of a young stock of plants from runners must be undertaken. Owing to last year's drought and the hot, dry weather we have experienced recently, I fear the runners will not be of the strongest character nor too plentifully produced, but the best available should be rooted in pots to obtain a sufficient number of plants to meet the requirements of the establishment. Plants that were put out last autumn expressly for the production of runners and from which the flower trusses have been removed, will usually produce the earliest and strongest runners, and these should be layered when large enough in small pots filled with a rather rich soil pressed firmly in the receptacle. Do not fill the pots too full with soil, but allow ample room for watering. The first and strongest of the plants should be selected and layered, stopping the leading points of the runners and removing all the latter not needed for layering. With care and attention in watering an abundance of roots will form quickly, and the plants should be ready for planting in the beds early. In the meantime, prepare the land to be occupied by the plants. If of a light texture, incorporate a goodly amount of well-decayed manure thoroughly with it; for heavier soils use less manure. Strawberries require a firm and somewhat rich rooting medium.

**TRIAL OF NEW ROSES AT BAGATELLE.**

THE judges in the Rose competition held at Bagatelle (Bois de Boulogne, Paris) met on the 15th ult. Rose experts from Holland, England, America, Spain, Paris, Lyons and Orleans—these three towns being the chief ones in France so far as Rose-growing is concerned—asssembled at 9 a.m. in front of the beds where the Roses were growing.

Madame Milleraud, who honoured the occasion by her presence, was received by the Prefect of the Seine and Mme. Autrand. She made a long examination of the Roses exhibited by the French and foreign growers, and particularly congratulated the Dutch grower, M. Looymans, on his Rose *Elvira Aramayo*, which was awarded a Gold Medal on account of its rich "Indian red" colour of an extremely brilliant shade.

Two white Roses of great promise, *Regina de Alvear* and *Mme. Autrand*, were completely denuded of their flowers by the bad weather immediately preceding the judging day, and were disqualified, although they had flowered brilliantly previously.

A very fine Rose, yellow, tinted with pink, named *Toison d'Or*, was noted, and also *Madeleine Pacaud*, a lovely flower with extra large petals. *Jules Tabard*, abundantly flowered with flesh-pink blooms, also attracted the attention of the judges. Other notable new varieties were *Geisha*, a very fine perpetual flowering Rose from Holland, with brilliant pinkish-apricot flowers; *Independence Day*, a beautiful Rose of English origin, with large and innumerable shrimp pink flowers; *Venus*, a large Rose with palest pink interior and deeper pink, lightly tinged with yellow, outside; and *Lady Elphinstone*, freely flowered, straw-yellow in colour lightly tinged with pink.

The Roses have never before suffered so severely as at the present season from the weather, which has consisted of a succession of changes from cold to burning heat, with storms of heavy rain.

The judges will meet again in September to make the awards.

The following are descriptions forwarded to us of the Roses sent for exhibition to the Rosery at Bagatelle, Paris (Bois de Boulogne).

*Portia* (Bees Ltd.).—Small foliage, well shaped buds, rather long, with incurved petals; colour salmon pink; fragrance resembling that of the Pink. The stem is not always very strong.

*Venus* (Bees).—Long stem, but weak at the extremity. Large semi-double flower with very incurved petals, the interior very pale pink, exterior deeper flesh pink; the bud is almost red. Fragrant.

*Dorothy Howard* (Bees).—A Polyantha Rose of medium size, pale pink, vigorous in growth and with healthy foliage.

*Puck* (Bees).—Of vigorous growth, bright China pink; petals incurved. Recalls *Mme Jules Grolez*.

*Lady Elphinstone* (Dobbie and Co.).—*Pernetiana* variety, very vigorous and floriferous. The abundant flowers are carried on strong stems. Colour, yellow.

*Toison d'Or* (Pernet-Ducher).—A very beautiful variety, yellow, tinged with pink; stems long and firm, foliage of medium size.

Reverend *Williamson* (Pernet-Ducher).—A large *Pernetiana* variety, semi-double, bright pink, with yellow tipped petals; the flowers are *Camellia* shaped.

*Madeleine Pacaud* (Chambard).—A pink, *Peony*-flowered variety with large petals; stems firm. Flowers abundantly.

*Souvenir de F. Roe* (Chambard).—A vigorous Rose, the flowers of pinkish-yellow hue resembling those of *Mme. Edouard Herriot*, but more yellow in colour. Stems very firm.

*Diana* (Bees).—Large white flowers, the reverses of the petals lightly tinged with yellowish pink. Flowers abundantly.

*Jules Tabard* (Barbier).—A vigorous and abundantly flowering variety, flesh pink. Very fine, long buds, incurved petals; excellent shape. The foliage is medium, stems very firm; the flowers are faintly fragrant.

*Regina de Alvear* (Sauvageot).—Vigorous in growth, with large, dark green leaves. Flowers white, and of large size and round form. The stems are generally firm; the variety recalls *Clarisse Goodacre*.

*Independence Day* (Bees).—Free-flowering and vigorous in growth; foliage medium, dark green. A semi-double flower with large, shrimp pink petals.

*Evelyn Thornton* (Bees).—A polyantha variety, flowers of medium size. Bud straw-yellow, passing to white with age. It is the "G. de Foligonde" of the Polyantha group.

*Ariel* (Bees).—Reddish-yellow, semi-double. The stems fairly strong, flowers abundant, and growth vigorous.

liant Rose with large flowers of bright pink hue, incurved, and with yellow at the tips of the petals. The buds are very large.

*General Smuts* (Van Rossen).—A vivid pink variety, the buds excellently formed, and carried on firm stems.

No. 2,980 (Leenders).—This is apparently a fine Rose and extremely floriferous. The stem is firm, the petals pinkish-white, the pink being accentuated towards the centre.

G. H. J. (Laxton).—A dainty variety, carmine red in colour, with fine dark green foliage. The petals are ruffled in a pretty way.

*Lady Maureen Stewart* (Dickson).—A semi-double Rose with large petals of a brilliant red.

FIG. 2.—CARNATION MAINE SUNSHINE; COLOUR SOFT PRIMROSE YELLOW.

*Adonis* (Bees).—A double Rose, white in colour, with a centre of pale yellow. Fine green foliage, and strong stems.

*Madame Autrand* (Leenders).—A fine white Rose, would probably force well. The buds are of very good elongated shape, resembling an urn.

*Elvira Aramayo* (Looymans).—A dwarf variety with a free-flowering habit. The flowers are cinnamon-red, through which yellow slightly shows. The colour is quite new, and striking in its singularity and brilliance. It is described by some as "Indian Red." (Gold Medal.)

*Geisha* (Van Rossen).—Very freely flowered and of vigorous growth; chiefly interesting by reason of its brilliant apricot blooms.

*President Poincaré* (Cassegrain).—A fine variety, double, of a clear pink hue. Agreeably scented.

*Macbeth* (Bees).—A H.T. variety with very fine red flowers. The stems are rather weak.

*Mme. Edouard Herriot Panaché* (Cassegrain).—This is the well-known *Mme. Edouard Herriot* with the petals marked by very irregular yellow streaks. The yellow of the markings passes to white as the flowers age.

Among the latest arrivals for the competition of 1923 are:—

*President Chérioux* (Pernet-Ducher).—A bril-

*Hawmark Crimson* (Dickson).—This dainty Rose bears flowers with large petals of a lovely dark, velvety red.

**CARNATION MAINE SUNSHINE.**

THE beautiful yellow Carnation illustrated in Fig. 2, named *Maine Sunshine*, has been shown on several occasions during the past twelve months at the Royal Horticultural Society's meetings and always attracted considerable attention as being one of the finest of the yellow-flowered, perpetual Carnations yet raised. We believe the variety originated in America, but have not the record of the raiser before us. At the trial of perpetual-flowering Carnations held in the Wisley Gardens in the past winter, this variety attracted such favourable notice from the judges as to be considered worthy of the R.H.S. Award of Merit. The colour is soft Primrose-yellow slightly deeper in the centre and the flower is of large size and perfect form. High praise is given this variety by Messrs. Allwood Bros., who state in their catalogue, "To such an extent do we realise the merits of this variety that this is the only pure yellow we are growing at our wholesale cut flower nursery at Clayton." The plant is very floriferous and the growth very healthy.

### EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, W.C.2.

**Special Notice to Correspondents.**—The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.

**Letters for Publication, or well as specimens of plants for naming, should be addressed to the EDITORS, 5, Tavistock Street, Covent Garden, London.** Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

**Local News.**—Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

**Editors and Publisher.**—Our correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the EDITORS. The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.

**Illustrations.**—The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.

## MR. KINGDON WARD'S SIXTH EXPEDITION IN ASIA.\*

No. 18.—THE LIMESTONE CLIFFS OF MU-LI.

THE limestone cliffs above the monastery were, during our brief periods spent at Mu-li, subjected to intensive exploration. They had the advantage of being on the spot, but I doubt whether the results were proportionate to the effort expended. However, they yielded several first-rate plants which we found nowhere else, so I must not malign them.

Throughout the season I kept before me the desirability of collecting, say, a thousand species from the Mu-li district, being convinced that more light will be thrown on the problems of distribution by making representative collections in selected spots rather than by collecting as many species, a plant here and a plant there, during the course of a long journey. At the same time I was eclectic, by no means prepared to gather everything I saw. Primulas, Rhododendrons, Meconopsis and all Alpines were taken without question; but in the wide field below about 12,000 feet I exercised a discretion which became more rigid as the season advanced. Indeed, I had to, when we worked at high pressure, with time and labour so valuable. Cosmopolitan weeds and too familiar plants were taboo. Such plants as grow everywhere, even those which spread over one continent, though a credit to their powers of distribution and adaptation (or possibly a slur on their capacities for variation) do not illuminate the relationships of the different parts of that continent, save in the most general terms. Even so, I had no reason to doubt that the Mu-li area was capable of yielding far more than a thousand species of plants, and that I could collect at least that number in the course of a season lasting six months.

A great limestone bastion, divided from the cliffs to north and south by deep ravines, rose behind the monastery. The ground sloped steeply up to the base of this precipice, broken here and there by smaller scarps, and was well wooded. By means of the two gullies it was possible to climb some way up the cliffs, which rose, tier on tier, to a considerable altitude. Our explorations, however, stopped at about 10,000 feet, no great height, but

sufficient to keep us busy from below, and lofty enough to harbour at least a dozen first-class plants. Perhaps the best was the Suffruticosa Primula, already referred to; but as we did not see it in flower, we were rather in the dark as regards its merits. The bright, violet-red flowered Nivalis Primula was fairly abundant; it grew indifferently in the open, or in deep shade, and was still in flower towards the end of July.

A small Soldanelloid Primula with purple flowers grew in the wet moss which clung to the cliffs within splash of a cascade. There are many varieties of this species, and after a while I got so involved with them that I had to give up trying to separate them in the field. Two very distinct forms—species, perhaps—were, however, always recognisable; for one had the under surface of the leaves brilliantly silvered with meal, the other had no meal. The former favoured open situations on the mountain top; the latter wet, shady cliffs at lower altitudes.

The curious Malvacea group of Primulas, with their big, leafy calyces, was represented

FIG. 3.—TABLE MADE FROM THE WOOD OF THE ARAUCARIA IMBRICATA AT KEW, WHICH WAS ONE OF THE TREES BROUGHT HOME BY DR. ARCHIBALD MENZIES (SEE P. 7).

on these cliffs by two species found nowhere else by us. One was a splendid plant with large, purplish-pink flowers borne in a long spike, which tended to be one-sided. As many as three dozen flowers are carried on a scape eighteen inches high, which arches over in a graceful curve. This species grew along the wayside in masses, on shady banks; but the biggest plants were found in deep thickets and woods on the precipices.

A second much smaller species, with delicate, almost orbicular leaves and pinkish mauve flowers, grew in the woods. Neither species was fragrant; in this respect Nature has been niggardly to the otherwise charming Malvacea Primulas. To these two I may add a third, perhaps the best of the three, which, though found right away down in the bed of the Jitang river, 2,000 feet below the monastery, belongs essentially to the limestone cliffs and slopes. This plant has small flowers, enveloped in the usual large, leafy calyces of a deep rose pink, darkening almost to crimson in the centre. Here again the tendency is to form an arching one-sided spike, or rather raceme; and the effect in well grown plants bearing two dozen flowers is delightful. This plant disdained shade and grew on the dry, rocky slopes, fully exposed to the sun; but these specimens were stunted, while amongst a tangle of shrubs and herbaceous growth, buried in alien vegetation, splendid specimens might be found blooming unseen.

The Campanulaceae was represented on the cliffs by several species of Campanula, Adenophora and Codonopsis. A twining plant of the last-named genus, with deep violet flowers as large as those of *C. convolvulacea* (and without the vile odour of that otherwise excellent plant) was one of our treasures. A large, violet-flowered Campanula, like a big Harebell, generally grew out of reach; but a small species with pale violet flowers and silvery foliage—the whole plant being enveloped in glistening silken hairs—was abundant on the driest, barest rock. It seemed to select situations where no water dripped and where no rain could possibly reach it; and there it formed its silvery cobwebs, tremulous with tiny pale bells.

The finest dwarf rock plant found, however, was a wee Larkspur, with comparatively large flowers of the most intense blue, such a blue as you may perceive by gazing deep down into the hot south seas with a tropical sun overhead. It was a magic blue. We found but two plants of it, unfortunately, but as it was only just coming into flower, more will doubtless be discovered later.

Another pretty plant with translucent, brick-red bell flowers dangling in a widespread raceme belongs to the Boraginaceae. Growing from a cliff edge leaning over freely, with the light showing through its glassy flowers, which contrast strangely with the grizzled stems and foliage, it is a joy. A small bushy Rhododendron, growing right on the limestone cliffs and sending its roots deeply into them, was seen nowhere else. Unfortunately, we did not find it in flower. The leafy calyx and leaves, the under surfaces of which were covered with rust-brown scales, served to identify it; but though fairly abundant, it set very little seed.

Fairly high up in a shady ravine facing north, amongst mixed forest, where Birches, Maples, Limes, Picea and Pseudotsuga all attained a considerable size, we found our first tree Rhododendron. I had reason to suspect its existence somewhere, having twice before noticed saplings in thick forest, with large leaves, but neither flowers nor fruit; and here it was at last in the flesh, or, rather, in the adult condition. The leaves are large, 18 inches long by 6 inches wide, their under surface covered with a soft, spongy, chocolate coloured felt. The capsules, too, are fairly large, long, slender and curved, and the flower trusses must be big, so many as two dozen to three dozen blooms in a truss. No doubt it is a fine sight in the early spring. Specimens seen suggest that it flowers when eight or ten years old under favourable conditions. Other plants on the Mu-li cliffs we had met with elsewhere—*Vaccinium modestum*, *Rhododendron racemosum*, *Androsace spinulifera*, species of *Clematis*, *Iris*, etc. But there was a Martagon Lily endemic there, remarkable more for its delicious fragrance than for its colouring, though it was showy enough, too.

A small Labiate with bright violet flowers, probably a species of *Ajuga*, flourished in deep shade of humus-clad slopes; quite a bright little plant.

Then there were the Gesnerads, four, perhaps five species of them, though they were by no means confined to these particular cliffs, but intruded themselves wherever there was shade and limestone, between 9,000 and 11,000 feet. Three of them were *Didissandras*, two of them species of *Oreocharis*. Of the former, *D. lanuginosa*, with its pale violet edged flowers—more white than violet inside the throat—grew everywhere on the rocks, shade or no shade. Another plant with deep violet flowers in more compact heads may have been another species or simply a variety of *D. lanuginosa*, which is a widely spread plant. The two grew associated together. The third had flowers quite like those of *D. lanuginosa*, though in larger heads; but the leaves were utterly different, being larger, dark green and glabrous, instead of covered with woolly white hairs. It was altogether a bigger plant; moreover, it demanded shade, though not such deep shade as *Oreocharis*.

\* The previous articles by Mr. Kingdon Ward were published in our issues of May 14, June 18, July 23, August 20, September 3, October 8, October 29, 1921; January 7, January 21, March 11, March 25, April 8, April 22, May 6, May 20, June 3, and June 17, 1922.

Of these last named, one with bright gamboge flowers was probably *O. Forrestii*. It had almost a monopoly of the high cliffs on their sheltered sides, covering the vertical walls with its compact rosettes of rugose hairy leaves, and drooping its bright yellow flowers. The second species was a much larger plant, though the cream-coloured flowers were about the same size as the last named. It could not bear the light, and crept into the darkest nooks of limestone rocks buried in the forest. With the exception of a single *Chirita* with creamy white flowers, which, oddly enough, grew right down in the gorge of the Litaug river, these were the only representatives of the Gesneriaceae met with—a contrast to the N.E. Frontier of Burma, with its many species of *Aeschynanthus*, *Chirita*, *Lysienetus*, etc. *P. Kingdon Ward.*

## DR. ARCHIBALD MENZIES.

THE great interest now being taken in many of the trees, shrubs and other plants first brought to Britain by Dr. Archibald Menzies, of the Royal Navy, has created a desire to know more about this great British botanist and collector. Some idea of the environment that produced such a man has been given already in these pages (Dec. 24, 1921). I am now able, through the kindness of his grand-nephew, Mr. M. C. H. Menzies Geedes, C.E., Edinburgh, to procure photographs of the Doctor's old-fashioned gold watch and the show table (Fig. 3), the latter made from the beautiful wood of one of the trees of *Araucaria imbricata* (Monkey Puzzle) brought by him from Chili in 1795, and planted in the Royal Botanic Gardens at Kew, where it flourished till 1832, when it was cut down. The wood is a lovely cream colour, and something like satinwood; it takes on a splendid polish, and such wood would make very artistic, high-class drawing-room furniture.

It is remarkable that the Botanical Badges of Clan Menzies resemble in a striking way several of the new plants then discovered by Dr. Menzies in the Sandwich Islands, in California, in North-West America, Vancouver, and other places. Some of the places explored by him were at a great altitude, but the training of his boyhood in climbing Weem Rock at the back of Weem Village and Castle Menzies—where he was educated at the Weem Parish School and got his first botanical knowledge at the gardens of Castle Menzies, lying between the Rock and the Castle—inured him to the strain of climbing rocky hills. One of the greatest feats of his life was performed on the island of Hawaii, where he was the first man to climb to the top of Mauna Kea, 13,825 feet high; during the ascent and descent of this mountain he discovered many new plants and other objects of natural history. *David Menzies, Bt., Pleas Menzies Castle, by Larbert.*

## THE WATER GARDEN IN SUMMER.

THE finest effects in ornamental gardening are obtained when the natural features of the landscape are worked into the scheme. Dense woodland on the outskirts gives a sense of seclusion to the garden; banks and depressions admit of variety in planting, whilst ponds and streams lend a special charm to their surroundings. Our illustration in Fig. 4, reproduced from a photograph taken in the gardens of Gen. Sir Arthur Paget, at Warren House, Kingston, Surrey, shows the quiet beauty of the water garden in summer, when Water Lilies of various hues unfold their blossoms on the surface and moisture-loving plants on the banks grow over and reflect their form in the water. But the greatest charms are those which no picture can portray—the peaceful atmosphere, the songs of the birds, and the hum of the insects, the pleasing perfumes of the plants and flowers and the cool, refreshing air. Such may be counted amongst the greatest delights which the garden can afford in summer.

## HARDY FLOWER BORDER.

### ALONSOA.

Of the few *Alonsoas* in cultivation certain numbers of annual species are excellent for beds or borders, where, if treated in the same way as other half-hardy annual plants, they will give a good effect with their bright flowers that are borne in axillary racemes. All those named may be treated as perennials if cultivated in a warm greenhouse, and a few have grown them under glass in winter and spring, and have planted them out in the same way as other bedding plants. Still, they are so easily raised from seeds that they are not worth troubling with as perennials except by those who wish to grow them from year to year.

*Alonsoa acutifolia*, also known as *myrtifolia*, is a pretty species, with narrow leaves and racemes of bright scarlet flowers on stems two feet or so in height. This plant is very effective in beds or when grouped in borders.

scarlet, difficult to describe precisely. The plant grows about fifteen inches high.

*A. Warszewiczii* is one of the best-known and most brilliant of the *Mask Flowers*. It grows about a foot-and-a-half high, and has toothed or incised leaves and fine vermilion-scarlet blooms with golden stamens. *S. A.*

### HARDY FLOWERS FOR EXPOSED GARDENS BY THE SEA.

GARDENERS near the coast often have a difficulty in establishing certain herbaceous plants, but there are many hardy border flowers that do excellently well in seaside gardens. *Tritomas* are very suited for gardens in such situations; they grow into large clumps very quickly and flower profusely almost continuously throughout the season. The various *Eryngiums*, or Sea Hollies, are naturally at home on the coast, and they may be planted in seaside gardens with every confidence of success. *E. agavifolium* makes a truly hand-

FIG. 4.—THE WATER GARDEN IN SUMMER: LILY POOL IN THE JAPANESE GARDEN AT WARREN HOUSE, KINGSTON.

*A. linearis* is a neat plant, with narrow leaves, growing to about two feet high, and giving a profusion of light scarlet flowers.

*A. linifolia* is another narrow-leaved species, liable to be confused in name with the preceding. There are one or two forms of this plant, one of the prettiest being *A. linifolia gracilis*, which grows about a foot-and-a-half high. It is almost Heath-like in its foliage, and has small, showy, bright orange flowers, decorated with golden-stamens. It is one of the prettiest species in cultivation.

I have some doubts as to the nomenclature of the plant sold as *A. miniata*, but the annual, or what should be treated as an annual, sold as *A. miniata* Scarlet Gem, is a very bright and pretty plant, growing fifteen or eighteen inches high and having flowers of a very effective and brilliant scarlet, with golden stamens. The plant, when well grown, is of a fine pyramidal shape.

*A. Mutisii* is only a synonym of *A. caulialata*, but the name of *A. Mutisii* seems to be the favourite one with seedsmen, who will, in all likelihood, be unable to supply it if asked for under the correct name. A pretty form, called Chamois Rose, has flowers of a kind of rosy

some subject and *E. Oliverianum* and *E. giganteum* are equally good for the purpose.

Other beautiful plants suitable for such gardens are *Romneya Coulteri*, *Clematis Davidiana*, *Gladiolus*, and *Campanulas* in variety. *Lilium candidum*, together with several other species of Lily, will grow to perfection near the coast. *Sparaxis pulcherrima* flowers freely here in the borders. Border Carnations are also very fine, and make healthy growth. Hardy Fuchsias are in the first rank as subjects for seaside planting. Geums are also excellent and flowers are produced from established plants here throughout the winter. *Montbretias* make large clumps, and those which are not divided for years, as well as those which are divided and planted in spring, all flower profusely, the flowers on the undivided clumps being equal to those on plants that are not disturbed, especially in the case of *M. crocosmaeflora* and *M. Pottii*. Other species are better for frequent division. All plants of the Leguminosae are very noticeable as growing in great luxuriance, both cultivated plants, and also the various indigenous subjects on the hills. *C. Ruse, Lambay Island, Rush, Co. Dublin.*

## COVERWOOD.

COVERWOOD, the country residence of M. E. Stevens, Esq., is beautifully situated on a spur of the North Downs, about seven miles south-east of Guildford. The present mansion was built in 1909 on the side of the hill among Pines and other forest trees, with Heather and Furze growing naturally all around. To have made a formal garden in a place of this description would have been an unpardonable sin, so beyond levelling sufficient space for the house, very little alteration has been made in the natural features of the place. Winding walks, with rustic steps, have been arranged on the hillside, which rises very sharply some 300 feet above the narrow valley, and faces north-west. A favourable place is thus secured for tender Japanese and Chinese shrubs; tall Oaks, Beeches and other forest trees give the necessary shelter in winter, and the soil is sandy peat.

Large beds of Ghent Azaleas in all their beautiful shades of colour were in flower at the time of my visit—May 30; these are judiciously grouped among other shrubs, and are visible from many points of the domain when in bloom. A large bed of Camellias had just finished flowering, and had evidently been a fine sight a short time before. Hardy Heaths in many kinds and varieties are encouraged as undergrowth among the taller shrubs, thus preventing the growth of weeds to some extent: *E. codonodes* and *E. Veitchii* were represented by many fine plants and full of flower. I also noticed a quantity of the Irish Heath—*Daboecia*, in variety.

Tall specimens of *Styrax virgata*, *Halesia tetraptera*, *Stuartia pentagyna* and *Azara microphylla* are to be found here, with Magnolias in many varieties. *Parrotia persica* and other interesting and beautiful trees and shrubs, the majority being large plants of ten feet and upwards in height, interspersed with choice Conifers, keep up a succession of interest throughout the greater portion of the year. Close to the mansion a large plot of *Genista hispanica*, some thirty feet or more in diameter, gave a beautiful patch of golden colour. The retaining walls here carried a wonderful display of *Wistaria* flowers, both the mauve and the white varieties; these plants have their branches trained horizontally about one foot apart and are kept close in to the wall: they have flowered very freely this season, and the wall was literally covered with their fragrant blossoms when I saw it.

A steep bank has been planted with *Cotoneaster microphylla* instead of Grass, thus saving much labour and ensuring a good effect in dry weather; some of the walls were draped with *Aubrietias* and other suitable plants, and even *Gentiana acanalis* was flourishing in this way in a shady place. Many kinds of *Berberis* are to be found here, including some of the best of those recently introduced. Many plants of *B. japonica* and *B. nepalensis* were in the best of health, while double Lilacs in great numbers, on their own roots, were flowering freely.

But the finest sight of all was found in the bog garden. A space of several acres has been partially cleared of timber, enough trees being left to provide the necessary shade. Small streams meander about in all directions, their banks being shaped to the best advantage and planted with seedling *Primulas*, chiefly *P. japonica* and *P. Bulleyana*, the former in all shades of colour, from white to dark crimson, with spikes in many instances two feet in length. These have grown and established themselves until the whole effect appears to be quite natural and a floral picture is formed such as one very seldom sees. Although the weather was very hot and dry in May, these *Primulas* were quite fresh and healthy. Many thousands have been raised from seed by Mr. T. W. Birkinshaw, who has charge of the gardens and farm, and takes a keen interest in the whole estate. A flourishing colony of *Primula rosea* had finished flowering, but *Astilbes* will make a fine display after the earlier flowers are over. Many fine plants of choice *Rhododendrons*, such as *Pink Pearl*, *Alice*, *Loder's White*, and many of the new Chinese kinds, were doing particularly well in

the drier portions of this garden. There are also large plots of *Delphiniums* and other herbaceous plants to keep up a display after the *Primula* picture has vanished. A few plants of *Lilium Henryi* and *L. canadense* were doing so well that it seems advisable to try various other kinds of this interesting family at Coverwood.

Improvements in the water arrangements are still in progress, and further developments may be looked for in the floral displays of this beautiful garden. *W. H. Divers, V.M.H., Westdean, Hook, near Sarbiton.*

## MESEMBRYANTHEMUM AND SOME NEW GENERA SEPARATED FROM IT.

(Continued from page 307.)

30. *C. parvipetalum*, N. E. Br. Growths 4½-6½ lines long, 4½-10 lines broad and 3½-7 lines thick, obconic, with a shallow v-shaped depression across the full breadth of the top (type K), rich dark purple on the sides, dull green on the top, tinted with rose around the orifice and marked with numerous separate dark green dots, all scattered or some of them arranged in a line transverse to the orifice. Calyx 5-lobed, with the tube very much compressed and up to 2-2½ lines broad. Corolla small and insignificant. 3-3½ lines in diameter, opening at about sunset,

FIG. 5.—*CONOPHYTUM LEVICULUM*, N. E. BR. NATURAL SIZE; PHOTOGRAPHED AT 9.30 P.M.

closed during the day; tube 2-2½ lines long, much compressed; petals numerous, about 1-1½ line long, creamy-white or very pale yellowish, faintly tinged with pink at the tips. Stamens with the yellow anthers shortly exerted. Style very short; stigmas 5, about 1½ line long, rather stout, pale greenish. *M. parvipetalum*, N. E. Br., in *Journ. Linn. Soc. Bot.*, v. 45, p. 97 (1920).

South Africa. Locality and collector unknown. This is closely allied to *C. mundum*, but is easily recognised by the dots not being raised in the same manner into tubercles, and by its flattened corolla-tube and short petals.

31. *C. aggregatum*, N. E. Br. Growths 5-6 lines long and 2-5 lines in diameter, obconic, flattish at the top (type F), which in large growths is more or less distinctly obtusely 6-angled, and in smaller growths circular, with the centre often slightly depressed and usually with a faint ridge or keel transverse to the orifice, of a dull and somewhat bluish-green, rather inconspicuously marked on the top with minute dots, which are mostly confluent into irregular branched lines of a darker green or purplish colour. Flower unknown. *M. aggregatum*, Haw. *Obs. Mesemb.*, p. 131 and 419; N. E. Br., in *Journ. Linn. Soc. Bot.*, v. 45, p. 91, excluding description of the flower.

South Africa. Locality and collector unknown. By some error, which I cannot now at all account for, unless I was interrupted in my work, the description and note of the flowers of a plant I now find to be identical with *M. piluliforme* were entered under *M. aggregatum* and published in my former account of this species. I have not yet seen expanded flowers of *M. aggregatum*, but late in November, when

too cold for them to develop, buds have appeared, which were dark red.

EE.

Top of the growths more or less convex (flattish in 33 *C. leviculum* and 37 *C. signatum*), or convex on each side of the central notch, which does not spread open over the whole breadth of the top as in some of those under E. (Species 32-44.)

32. *C. catervum*, N. E. Br. Growths 10-15 mm. long and 3½-6 lines in diameter under cultivation, but under natural conditions about 3-4 lines in diameter, obconic, convex on the top (type E), which is nearly circular or broadly elliptic in outline, pale greyish-green or glaucous-green, with three radiating lines of confluent dark green dots on each side of the orifice, the two lateral lines usually forked, and with a line and some dots or scattered dots only at each end of the orifice. Flowers not seen.—*M. catervum*, N. E. Br., in *Journ. Linn. Soc. Bot.*, v. 45, p. 93.

Laingsburg Div. Near Grootfontein, Pole Evans, 4975.

33. *C. leviculum*, N. E. Br. (Fig. 5). Growths 5-7 lines long, and 3½-7 lines in their greater diameter, obconic, elliptic or nearly circular at the flattish top (type F), often purplish on the sides, greyish-green on the top with many irregular lines and small dots of dark chocolate-purple or dark green, and a thick line bordered with chocolate dots and lines around the orifice. Calyx 4-lobed. Corolla 5-8 lines in diameter, expanding about 4 or 5 p.m., closed during the day; tube not exceeding the calyx; petals 20-25, lax, whitish (very pale straw-coloured by day), sometimes tinged with pink at the tips, with a slight satiny sheen. Stamens 12-20, the upper anthers exerted, light yellow. Style, about 1 line long; stigmas 4, about 1-1½ line long, plumose-filiform, pale greenish.—*M. leviculum*, N. E. Br., in *Journ. Linn. Soc. Bot.*, v. 45, p. 94 (1920).

South Africa. Locality and collector unknown.

34. *C. pictum*, N. E. Br. Growths 4-7½ lines long, 3-5 lines in their greater diameter, obconic, usually with a shallow notch across the centre of the oblong or elliptic top, so as to appear slightly obovate in side view (type E), often purplish on the sides, dull green, marked with some dots and numerous simple and branching lines (which are not formed of confluent dots) of a chocolate or purple-brown colour on the top. Calyx 4-lobed. Corolla 3-7 lines in diameter, expanding about 4 or 5 p.m.; tube exceeding the calyx-lobes: petals 18-24, lax, whitish. Stamens 12-20, with the upper anthers exerted, yellow. Style, less than 1 line long; stigmas 3-4, about 1-1½ line long, plumose-filiform, yellowish. *M. pictum*, N. E. Br., in *Journ. Linn. Soc. Bot.*, v. 45, p. 97.

South Africa. Locality unknown, sent to Kew and to myself by Prof. P. MacOwan, in 1878.

This species differs from *C. leviculum* by being less flattened at the top, and the orifice is outlined rather indistinctly with dull green, instead of by a very conspicuous thick line as in *C. leviculum*.

35. *C. labyrinthicum*, N. E. Br. Growths 5-7 lines long, usually 3-4 lines broad, and 2-3 lines thick, obconic convex or elliptic or elliptic-oblong in outline, at the top (type E), greyish-green, marked in a labyrinth-like manner with rather crowded branching and disconnected lines (not formed of dots) of a rich dark brownish-crimson, or in sunless seasons dark green or brownish-green. Calyx 4-lobed. Corolla 4½-5 lines in diameter, night flowering, scentless; tube not longer than the calyx; petals 18, in a single series, lax, very pale straw-coloured or whitish. Stamens several, the longer shortly exerted; anthers light yellow.—*M. labyrinthicum*, N. E. Br., in *Journ. Linn. Soc. Bot.*, v. 45, p. 94 (1920).

Locality and collector unknown. N. E. Brown.

(To be continued.)

**THE BULB GARDEN.**

**IXIAS.**

OUR *Ixias* have had a glorious time. They have revelled in the sun and heat. All day long they have been a splendid show, and visitors to the Tulips were duly taken to see the little group before they went home. I found a good many did not know what they were. I can understand the *Brodiaeas*, with which they were mixed, being something fresh, but I did think most people knew *Ixias*. All the same, I do not remember having seen them growing in the open anywhere but in Jersey and Guernsey. This, no doubt, accounts for their being a novelty to so many. Here, midway between Chester and Shrewsbury, I have never had them to bloom out-of-doors; but I get every bit as good results from our home-grown bulbs in pots as I do from those newly bought. The only one that does not do well is the beautiful cherrv red *crateroides*. It lives, but it does not flourish, like the others. However, the lovely soft rose of *Englishton* more than compensates us for this disappointment. We had a large collection last year, out of which we selected the following, as being the most distinct and pleasing: *viridiflora* (pale green, with a dark centre, late flowering); *Englishton* (soft rose); *Emperor of China* (rich yellow); *Invincible* (deep crimson); *Bridesmaid* (white with crimson eye); *Hogarth* (pale straw). Our treatment of the bulbs is very simple. They are potted in rich, light soil in five or six inch pots in October, and they are then placed in a cold, frost-proof frame, where they remain till March, when they are transferred to a cool greenhouse. After the flowers are over the plants are fed with weak liquid fertiliser and gradually dried off. The bulbs remain in a perfectly dry state in the pots all the summer under glass and get a good baking. *Joseph Jacob.*

**CAMASSIA LEICHTLINII.**

Few amateurs appear to be well acquainted with the *Camassias*, or *Quamashes*, although one occasionally comes across them in gardens where bulbs are a special feature. One of those least known is *Camassia Leichtlinii*, a good species, which is a native of British Columbia and Canada. The typical *C. Leichtlinii* has creamy-white flowers, but there is a variety called *C. L. atroviolacea*, with deep purple blooms. What are understood to be hybrids of *C. esculenta* and *C. Leichtlinii* are also in commerce, and some of these are very pretty. They range from white, through light and dark blue to purple. *C. Leichtlinii* is quite hardy with me, and I have cultivated it now for a long series of years. It is rather taller than *C. esculenta*, and when in good soil may be as much as 3 feet or more high, but in a poor compost may be as little as 2 feet. It has a handsome spike, with numerous creamy-white flowers. *S. Arnott.*

**ORCHID NOTES AND GLEANINGS.**

**DENDROBIUM SUPERBUM AND ITS ALLIES.**

*Dendrobium superbum* was one of the earliest species of this group to be introduced, and one of the most beautiful and distinct of *Dendrobiums*. In collections of Orchids shown fifty or sixty years ago it frequently appeared as large specimens heavily laden with flowers three or four inches in diameter and coloured rosy-mauve, with deep purple base to the lip; but it is now becoming rare. All the varieties have the same general form of flower, and a not unpleasant odour resembling medicinal Rhubarb. The slender variety *anosmum* (*Dayanum*), while having a slight trace of the odour of the type, is delicately fragrant.

*D. superbum* is based on Reichenbach's description (*W'ap. Ann.*, VI., p. 282, 1861), and it came as a shock to Orchidists of those times that their cherished plant with its time-honoured name of *D. macrophyllum* (*Lindl. Bot. Reg.*, 1839, and various other descriptions and figures of it) would have to go, as *D. macrophyllum*, A. Rich.—the plant usually known in gardens as *D. Veitchianum*—had priority. Lindley's

name, however, so long familiar to Orchidists—an illustration of a plant of it growing on a block having appeared in the *Gardeners' Chronicle*, 1845, illustrating an article by T. Appleby—is still commonly in use. The species is also figured in *Bot. Mag.*, t. 3970, as *D. macranthum*.

*D. superbum* was discovered by Cuming in the Philippine Islands in 1836, and flowered in Messrs. Loddiges' nursery at Hackney in 1839, the plant being the typical rosy-mauve form. *D. superbum* is widely distributed, its range embracing India, the Malay Archipelago and Borneo, each locality giving characteristic forms.

*Dendrobium Parishii*, imported by Messrs. H. Low and Co. from Moulmein, in 1863, although dwarf and stout in habit, has rosy-mauve flowers resembling *D. superbum*, but smaller in size. It has also the same kind of odour.

The large-growing typical forms of this group are distinctly warm-house subjects, requiring to be grown in suspended baskets to allow of the full development of their long, leafy stems, which have a tendency to elongate in proportion to the space available; those grown in pots or on the stages rarely attain the proportions of those suspended while growing. The leaves fade and fall at the resting season.

FIG. 6.—DENDROBIUM SUPERBUM HUTTONII.

As with many other rose and mauve Orchids, it is prolific in white forms, the beauty of which equals that of any white *Dendrobium* in cultivation.

*D. superbum Huttonii* (see Fig. 6), a large pure white flower with purple base to the lip, was imported by Messrs. J. Veitch and Sons in 1869. A very fine form of it was recently sent by W. Waters Butler, Esq., of Edgbaston, proving that it still flourishes.

*D. superbum Burkillii*, with white flowers having the lip veined with rose, was imported by Messrs. J. Veitch and Sons in 1883.

*D. superbum Dearei* (R.H.S., April 11, 1882), probably the best albino, was brought to England by Col. Deare, who first flowered it.

All these received the First-Class Certificate of the Royal Horticultural Society, but there is no record of any honour given to the coloured type, shown probably before the present list was prepared.

**HYBRIDS OF THE D. SUPERBUM SECTION.**

*D. porphyrogastrum*, raised by Messrs. J. Veitch and Sons, between *D. Dalhousieanum* and *D. superbum Huttonii*, has racemes of rosy flowers with dark markings on the lip. It is a very distinct hybrid and quite intermediate in character.

*D. Gemma* (*superbum* × *aureum*) flowered with the late Mr. Chas. Winn in 1895, and the interesting *D. Nestor*, between *D. Parishii* and *D. superbum*, was flowered in the same garden at Edgbaston in 1892. *D. Adrasta* (*Pierardii* × *superbum*), *D. Mentor* (*primulinum* × *superbum*) and *D. rhodostoma* (*sanguinolentum* × *superbum*) are other hybrids.

Connecting the allied *D. Pierardii* we have the hybrid between it and *D. Parishii* known as *D. rhodopterygium*, which, with *D. polyplebium*, have been imported as natural hybrids. *J. O'B.*

## A VISIT TO HOLLAND.

To horticulturists, a visit to Holland invariably proves interesting, because the Dutch people are clever gardeners, and horticulture is one of their chief industries. For choice, Spring is the best time to make a visit, and, if the trip is made when the bulbs are in flower, the visitor will find a feast of colour spread out for him, wherever he may go, throughout the bulb-growing district, which has Leyden for its centre. If beautiful arrangements of bulbous plants are anticipated, there will be disappointment. The Dutch growers cultivate bulbs as other folks may grow Wheat or Potatoes, by scores of acres, and it is their good fortune that the crops they cultivate produce flowers of many hues.

There are miles upon miles of bulb farms in Holland, and, when Hyacinths are in bloom, the railway journey from the Hague or Rotterdam to Amsterdam is a trip through fairyland, but a somewhat formal fairyland, as great areas of brilliant colour—all in blocks or "slabs"—are arranged on either side for a considerable part of the way. Sometimes the colour is broken up into patchwork, like the gorgeous colouring of some old-time quilt cover; at others, where some happy chance has graded the blue shades from the daintiest porcelain to the most intense blue-black, the scene is wonderful; but best of all is a large area of bright, clear blue, as though a bit of brilliant sky had come down to rest among the dykes and Poplars of the Netherlands.

Before the Hyacinths are at their best, the Daffodils take up the story and add all shades of yellow, from palest lemon to deepest gold. Blocks of King Alfred, several acres in extent, or of Van Waveren's Giant, or Golden Spur, or Emperor, are wonderful; but if a trip is taken by motor-car around Leyden, Haarlem, Hillegom, Lisse, Sassenheim, Noordwyk, Binnendyk, and other places where bulb-growing is the chief business, eyes will be tired at the close of day and turn gratefully from Hyacinths, Daffodils, and Tulips to green trees and pastures.

A visitor who has the *entrée* of the Dutch bulb farms in spring runs two risks—one is that of being made colour-blind by the surfeit of colour, and the other is that of giving offence to some of the good ladies whose hospitality is hountiful. The capacity of an ordinary person becomes strained after from six to a dozen calls have been made in one day, and at each house a table is prepared for his coming. Every bulb-grower appears to have at least one excellent motor-car, and his good wife a table continuously spread before her husband's friends and customers.

Familiarity does not breed contempt in Holland, as regards flowers, for in the Spring time those who live in the large towns and cities make a point of visiting the bulb districts on one or more occasions, and it is one of the sights of Holland to observe thousands of people travelling by cycle, motor, tram, or railway to the bulb district on a Sunday, and no less interesting to watch them returning in the afternoon or evening with wreaths of flowers over their shoulders, on the handlebars of cycles, and around the roofs, doors, and bonnets of motor-cars. Moreover, during this pageantry of blossom, the tramcars in most of the towns within the bulb-growing area are furnished daily with blooms set in vases fixed inside the cars, while almost every shopkeeper at the Hague, in Leyden and Haarlem, no matter what his wares, decorates his windows with Daffodils, Hyacinths, or Tulips. In short, the bulb-growing district is thoroughly well advertised in these and other ways by means of the flowers the bulbs produce.

But not all the Dutch horticulturists are bulb-growers. Many readers are acquainted with the Bookoop district, where conditions appear to be especially favourable to the growth and multiplication of Rhododendrons, Azaleas, Roses, and a great variety of other trees and shrubs. Unfortunately, circumstances prevented me from visiting this interesting place.

Fortunately, I was able to pay a long-

deferred visit to the little township of Aalsmeer, famous for its Lilac. Here, within about a score of years, a wonderful industry has been built up, until now, each winter and spring, sprays of forced Lilac are produced and distributed over a considerable part of Europe. Intensive cultivation plays its part, as the Lilac plants are given every attention out-of-doors for two years after forcing, before forcing is attempted again. In the glasshouses these prepared plants, chiefly of the *Mdme. Lemoine* variety, are set as thickly as their root masses permit. Little or no shading is given, and the French method of darkening the forcing houses does not obtain here. Nor are abundant heat and a saturated atmosphere provided; indeed, heating by means of hot-water pipes is rarely practised, but upright stoves are used, generally two inside each house, and the growers maintain that the fairly dry heat thus produced is the best for the forcing of Lilac. The proof is seen in long stems carrying two or three graceful heads of bloom which last so well that they are beautiful for a week or ten days after reaching Covent Garden, if put in water as soon as the long boxes are unpacked.

Many thousands of these especially grown Lilacs are forced each year in Aalsmeer, and the cultivators are not merely two or three people who conduct large businesses, but there are scores of growers, and most of them live and have their compact little establishments on one side or other of the canal which is virtually the main street of Aalsmeer. There is such an abundance of water in this district that almost every nursery is separated from its neighbour by a small canal. Communication across these canals is by means of a swing-bridge arrangement, and, if the bridge is "against you," there is no real difficulty, because a long rod with a hook at the end is sure to be found close by, and with it the visitor pulls the bridge round, replaces the pole, and walks over, not forgetting by a deft push with his foot to "shut the gate."

Under the guidance of Mr. Mensing, many of these nurseries were visited, and found to contain, besides Lilac, excellent cultures of Hydrangeas, Begonias, Cyclamen, Primulas, and Roses.

Surprising as are the quantities of forced Lilac, not less so is the manner of marketing the flowers. The market is a large building, well lighted and of light structure—about the size of the London Scottish Drill Hall at Buckingham Gate, where the R.H.S. meetings used to be held. Into this building the flowers are brought and laid out in bunches on movable four-wheeled stalls, each two-tiered, like a dinner waggon. These are arranged in regular rows down the market building, and each grower's contribution is booked, item by item, on a sheet especially designed for the purpose, and this "invoice," which accompanies the flowers, has columns wherein in due course are placed the sale price and the number of the purchaser.

But where are the buyers? To find them it is necessary to follow a porter who wheels one of these flower-laden waggons into a side building. Here, on a sharp-pitched gallery constructed on flower-pot-stand lines, but quite substantial, the buyers sit, each with a notebook and pencil. The only noise beyond an occasional observation in undertone is the voice of the one salesman who sells for all the growers, as the whole of the business connected with the marketing of the flowers is done on co-operative lines.

The method of sale is by Dutch auction. Facing the tiers of buyers is a huge dial with a large, ever-moving hand. Round the dial, near its circumference, are figures representing values and ranging from a very low price to a high one. Within this circle of figures is a large square, composed of small squares which correspond with the number of seats in the buyers' gallery. Each little square is numbered, and has its own tiny electric light. The porter displays a bunch of Lilac. The hand on the dial, commencing at a value the salesman considers full high, swings steadily along on the downward scale, when it sud-

denly halts, and at the same moment a tiny light appears on one of the little squares. The salesman, who watches the dial and has his back to the buyers, observes in a steady monotone that Number 10 has purchased the lot for, say, sixpence a spike, and, while he gives this information, his clerk makes the necessary entries, the porter places a numbered card on the lot and passes to the next. The secret of the whole business is that each buyer has an electric push-knob in the hook-board in front of his seat, and, directly the hand on the dial is reaching the figure he deems it worth while to buy at, he presses the button, the hand stops, and the light appears in the square bearing the same number as his seat in the gallery. There is no noise, no bustle, and rarely any excitement beyond a little sigh when a buyer is lucky enough to purchase a good lot at a low rate, while his brethren are hoping the hand will drop another point. Moreover, the business is done quickly, and a dozen sales are effected in the time it has taken a reader to read this paragraph.

As soon as one waggon-load is sold, it is pushed back into the market hall, and thence the contents are taken into the packing sheds attached to the market, where the flowers are packed for transit to Amsterdam, Copenhagen, Brussels, Paris, London, or elsewhere. It is in these sheds that everybody hustles, as trains and boats will not wait beyond the appointed time, even for the beautiful Lilac from Aalsmeer. Sometimes, when supplies are heavy, the sale may continue beyond midday, and even on occasion to so late as 2 p.m., but generally it finishes in the forenoon.

It is a novel experience to watch a big sale of flowers by Dutch auction, to be allowed to press a button just to "see how it works," and to enjoy a market breakfast of new rolls, exquisite butter, delightful cheese, and hot milk (price 8d.). But for clearing huge quantities of flowers in a short time Aalsmeer cannot hold a candle to Covent Garden, although for peacefulness and orderliness Aalsmeer market wins every time. C. H. C.

## FORESTRY.

### THE OAK LEAF ROLLER MOTH.

SELDOM in a long experience of woodlands in the home counties have I noticed so widespread, persistent and severe attacks of the Oak leaf roller moth (*Tortrix viridana*) as during the present season. Having to deal with the trees on several estates from Kent to Berkshire, I must admit that only on a few occasions before have I noticed so great an amount of damage caused by the caterpillar of this moth as may now be seen, trees, whether isolated or in woods and plantations, sheltered or exposed, being attacked in the same wholesale manner.

In many parts the Oak trees are already entirely stripped of their leaves, and, unless for the greyish, spider-like webs with which the brownish twigs are thickly covered, wear quite a wintry appearance. From the first attack till the full-sized tree is completely stripped is only a question of ten or twelve days, though young Oaks may, and often are, entirely divested of their leaves in less than a week. So numerous are the caterpillars that when beneath an affected tree on a still, warm day, a persistent ticking sound, caused by the pests gnawing the leaves, may be distinctly heard. The Oak leaf roller moth is so well known, owing to the rolled-up appearance of attacked leaves and the method of suspension in mid-air of the tiny green caterpillar, that a description is unnecessary. On various occasions, particularly in the case of the trees in Epping Forest, the question whether the repeated loss of the leaves has an injurious effect on the health of these has arisen, but so far as can be seen this is not the case, at least to any appreciable extent. For the past thirty years the writer has had to do with the trees on a well-wooded estate in Kent where the attacks of the moth have occurred almost annually, but so far as can be seen

at present the trees have not suffered at all in health, and the second growth of leaves is equally robust and of as vivid a colour as were those originally produced. This is particularly emphasised in the case of several standard ornamental Oak trees growing on the lawn by the dwelling-house, which, owing to their being severely attacked many years ago, were at that time the subject of much concern, but to-day these trees are quite as healthy as was the case at least three decades ago.

Little can be done in the way of dealing with a plague of these caterpillars, especially when trees over a wide area are attacked, though in the case of single specimens spraying with an insecticide will assist in keeping the pest in bounds, but the expense of this preventive, added to the cost of application, renders treatment of an infested area quite out of the question. Sometimes the excessive number of the Oak leaf roller moth proves the means of its extinction, the foliage being devoured before the caterpillars are fully fed; while, as is usual at the season of attack, parasitic flies and ichneumons destroy them wholesale. By encouraging such birds as the starling, rook and sparrow, the numbers of caterpillars may be greatly reduced, and the occupants of a rookery will frequently in a few hours clear the pest from the trees over a considerable area of woodlands. On the Holwood estate, in Kent, I have frequently seen the trees in a young plantation of Oak almost black with starlings feeding on the caterpillar. Some observers are under the impression that the Oak leaf roller moth is most abundant where the trees grow closest together, and when we consider that both wind and rain destroy numbers of the insect, the fact of isolated trees, which are most exposed to storms, being comparatively free from attack is not to be wondered at. *A. D. Webster.*

## CULTURAL MEMORANDA.

### SUMMER WORK AMONGST FRUIT TREES.

The dry weather of the past weeks, following the drought of last summer, has greatly taxed all fruit trees, and no efforts should be spared to give the trees all the assistance possible. Those growing on poor or light soils will be greatly benefited by copious waterings where this is practicable, and the watering should be followed by good mulchings of well-decayed manure to help conserve the moisture. Young trees especially require attention in this respect, as much of their future success will depend on how they go through this second dry season.

It is unwise to allow young fruit trees to carry large crops of fruit, as this might cripple them for several seasons. Where the fruits have set freely, remove all the small and badly-placed specimens, and thin the remainder to a fair average crop.

Trees planted last autumn should not be allowed to fruit this season; rather let them make as much wood growth as possible, which is not likely to be much if the dry weather continues. Pay strict attention to the summer pruning of all trees in order to allow as much light and air as possible to reach the fruit, and also to mature the wood for next season. It is advisable to summer prune on two occasions, dealing with half the shoots at each time. Prune the shoots to three or four buds and pinch out the points of the leaders. Trees infested with aphid and other insect pests should be syringed in the late afternoons with Quassia extract, as much depends on keeping them clean. Quassia extract is quite harmless, but should not be used on trees where the fruit is approaching ripeness, as it is very bitter.

Fruit trees on walls, such as Peaches and Apricots, will be much benefited by a daily syringing with the garden engine to promote a healthy growth and keep red spider in check. Gather all the fruits as soon as they are ready, to relieve the trees and enable them to perfect their growth for next season.

Watering and feeding should be continued

after the fruit is gathered, more especially in the case of wall trees, as these rarely get sufficient water naturally. Attend to the trees again before the autumn, and remove any secondary growths that may have been made; also tie or nail all shoots needed for extension and filling blank spaces. Trees that fruit on wood of the previous year should have the growths tied securely, and as much of the basal wood as possible trained in. All weak shoots and breast wood—that is, those growing at right angles from the wall—should be cut out, and only sufficient of the other shoots left to furnish the tree and cover the wall.

Bush fruits, such as Gooseberries and Red and Black Currants, should be watered, if necessary, although these will withstand dry weather better than most other fruits. Attention, however, should be paid to keeping them clean, and when the fruit is gathered the new growths may be thinned out if the branches are too thick, and the leaders of Red and White Currants may be shortened. In the case of the Black Currant, some of the old wood may be cut out altogether to encourage as much young wood as possible to develop. Gooseberry bushes may be thinned, and the side shoots cut back to form spurs. If this is done they will require much less pruning in the winter. Raspberries need a moist, rich soil, and should be watered and mulched if necessary; some of the roots grow near the surface, therefore it is necessary to keep the ground moist near the surface. Cut out the old growths as soon as the fruits are gathered so that the young shoots may make strong canes.

Strawberries are benefited by constant hoeing in early spring, and as soon as hot weather arrives the plants should be mulched with long stable litter. Strawberries growing in light soils should be watered to assist the berries to swell to a large size; but on heavily manured, rich soils this may not be necessary if the plants were mulched early, as advised. Keep all runners picked off, if they are not required for making fresh beds, as these weaken the parent plant, especially in dry seasons such as we are now experiencing. Watering should be done thoroughly in all cases, as a little applied to the surface only encourages the roots to grow upwards, to become dried up by the sun and air. Pond or rain water that has been exposed to the warmth of the sun is best for use, if procurable. Cold water from a tap or well applied to trees in hot weather would probably do more harm than good, causing mildew and other diseases to appear. Where water is scarce the next best thing is to keep the surface of the ground well hoed, and mulched with manure to keep it as cool as possible.—*R. W. Thatcher, Carlton Park Gardens, Market Harboro'.*

## FRUIT REGISTER.

### APPLE ENCORE.

THE keeping qualities of Apple Encore should recommend the variety to be planted in most gardens. Here, at The Node, Welwyn, this Apple keeps in firm condition until the month of June, and is one of our latest Apples in use. Encore is a vigorous, upright grower, and was raised by the late Mr. Chas. Ross and introduced in 1908. It has received the First-Class Certificate of the Royal Horticultural Society. Very young trees are rather shy in bearing, but once well established they crop very freely. The tree, being a vigorous grower, often needs root-pruning to bring it into bearing in its early stages. *T. Pateman, The Node Gardens, Welwyn.*

### APPLES—CODLIN.

MANY years ago, before Blenheim Pippin, or King of the Pippins, had a name, Codlin was a household word the length and breadth of the land.

Springrove Codlin is one of the best of all the Codlins. The fruit is of medium size, with greenish-yellow skin, tinged with orange on the side next to the sun. The flesh is soft,

greenish-yellow, sub-acid, with an agreeable aroma. This Apple is in season from July to September.

Dutch Codlin is a very large fruit of oblong shape, and has prominent angles. The eye is small and deep, the stalk short and thick. The skin is yellow, changing to orange colour when ripe, and the flesh is white.

The tree is a strong grower, and does well as a half standard.

English Codlin is an old and valuable variety, and one usually propagated from off-shoots; I have seen large branches pulled or wrenched off a bush tree, planted with a spade and left to grow, which they did quite happily.

Carlisle Codlin is a fruit of medium size, and of first quality. The skin is pale yellow; the flesh white, tender and juicy, with a brisk aroma, and the cooking qualities are first rate. It is in season from September to November.

Mank's Codlin is an Irish Apple of great merit, it being most productive season after season. The fruit is of medium size, oval, and most regular in shape of all the Codlin family. The skin is coloured pale yellow, with a deeper shade towards the sun. The flesh is yellowish-white, the juice sub-acid, with an aromatic flavour. The season is August to early November.

Nelson's Codlin is a king amongst the Codlins, its fruit being very large, handsome and useful. The fruit is of first quality, of a rich yellow colour, thickly interspersed with dark dots. The flesh is yellowish-white, delicate, tender, sugary, and useful for either dessert or culinary purposes. The season is August to November. *Pomona.*

## HOME CORRESPONDENCE.

[The Editors do not hold themselves responsible for the opinions expressed by correspondents.]

**The Late Mr. F. Clarke.**—The notice on p. 328 records the death of one of our best gardeners, Mr. F. Clarke, late of Lowther Castle, who retired from Lord Lonsdale's service about seven years since. The very large flower gardens at Lowther were always kept in excellent order by him, but, being so far from London, were not seen by so many persons as others, and were seldom heard of. It has been my good fortune to see them, in company with Mr. Clarke, and to notice the keen interest he took in keeping them in good order and in carrying out the various alterations which were made from time to time.

Very large numbers of bedding-out plants were used to brighten up the large lawns, and the whole scene, situated among the Cumberland hills, was magnificent. Since my visit private gardens have suffered great losses in the way of floral adornment, especially in such fine gardens as those which my late friend managed so well for forty years. *W. H. Divers, Westdean, Hook, near Surbiton.*

**Fungus, Fungous, Fungoid, or Fungal Diseases?**—Which adjective is correct? To me it seems that, when the disease is produced by a true fungus, fungous and fungoid are wrong, and should be discarded, and that the choice lies between fungus and fungal. To speak of a fungus or a fungal disease in such a case seems quite correct, but a fungous or fungoid disease may mean a disease caused by something having the character or nature of, or resembling, a fungus without being one. In his *Glossary of Botanic Terms*, Mr. B. Daydon Jackson gives the following definitions: fungal, relating to fungi; Fungous (or fungose), (1) spongy in texture, (2) relating to a fungus, (3) produced by a fungus; Fungoid, pertaining to a fungus; Fungoid Parasites, parasites which are fungi. Dr. Lindley used the term fungal (Fungal Alliance), and Mr. Hiley also uses it in the title of his book, *The Fungal Diseases of the Common Larch*. In, I think, all his works on forestry, the late Dr. John Nisbet used the term fungoid, and it is very commonly used by other writers. *A. D. Richardson, 34, St. Andrew Square, Edinburgh.*

## SOCIETIES.

### ROYAL HORTICULTURAL.

JUNE 27 AND 28.—The exhibition held on these dates at Vincent Square was an admirable one, and the display of hardy flowers, Begonias and Carnations provided glorious colouring, while a large number of novelties added considerable interest to the meeting. The Floral Committee had an arduous task in judging the forty-three groups exhibited and the fifty-nine flowers and plants submitted for awards.

#### Orchid Committee.

*Present:* Sir Jeremiah Colman, Bart. (in the chair), Prince Shimadzu, Messrs. Jas. O'Brien (hon. Secretary), Gurney Wilson, Arthur Dye, Fred K. Sander, H. T. Pitt, W. J. Kaye, Pantia Ralli, E. R. Ashton, J. Wilson Potter, Frederick J. Hanbury, S. W. Flory, Stuart H. Low, H. G. Alexander, and C. J. Lucas.

Messrs. STUART LOW AND Co., Jarvisbrook, Sussex staged a fine group, for which a Silver-Gilt Flora Medal was awarded. The background was of fine plants of *Laelio-Cattleya Canhamiana*, varying from white with rose purple lip, to rose with claret lip. With these were good selections of *Cattleya Warszewiczii* and *C. Mendelii*. *C. Mendelii* Sunray is a very remarkable form and a distinct novelty; its large petals have a broad band of purple matching the maroon purple of the lip. New hybrids in this group were *Brasso-Laelio-Cattleya Ancona* (B. L. Jessopii × L. C. luminosa) with clear yellow flower; and *Odontioda Virgil* (Odm. Rolfeae × Oda. St. Fuscien), a showy flower with yellow ground heavily blotched and veined with dark red. The group was largely composed of species of *Dendrobium*, including the white and purple *D. superbum* Huttonii (see Fig. 6), *D. Parishii*, of good type, the blue *D. Victoria Regina*, and other *Dendrobies*, both species and hybrids. *Phalaenopsis amabilis*, *Vanda coeruleus*, *Eria amica*, *Masdevallia tridactylites*, *Trichopilia tortilis*, and various *Oncidiums*, with the fine bronzy scarlet *Oncidioda* Stuart Low, were also well shown.

Messrs. SANDERS, St. Albans, were awarded a Silver Flora Medal for a good and excellently well arranged group, in which elevated plants of the yellow *Cattleya citrina* between good forms of *Cattleya Mossiae*, *Laelio-Cattleyas*, and *Odontoglossums* were very effective. The returning interest in rare species was seen in a very interesting selection, including *Laelia Gouldiana*, the yellow and purple *Eulophia streptopetala*, *Epidendrum Parkinsonianum*, *Aërides virens*, and other *Aërides*; a selection of *Dendrobiums*, *Masdevallias* and allied species.

Messrs. CHARLESWORTH AND Co., Haywards Heath, showed some excellent specimens, the central plant being a grand example of *Coelogyne burfordiensis* (pandurata × asperata) with seven spikes, each with from twelve to fifteen large, pale emerald green flowers with blackish marks on the lip, and for which a Cultural Commendation was given. Other fine Orchids were *Miltonia Charlesworthii* with four spikes; the superb *Sophro-Laelio-Cattleya* Prince Hirohito, for which a First-Class Certificate and Gold Medal has already been awarded; *Laelio-Cattleya* General Maude, a fine flower; and *Odontoglossum Ithone*.

#### Floral Committee.

*Present:* Messrs. H. B. May (in the chair), D. B. Crane, W. P. Thomson, W. B. Gingell, Arthur Turner, M. C. Allwood, C. R. Fielder, W. Howe, G. Harrow, John Heal, J. W. Barr, G. Reuthe, W. J. Bean, R. C. Notcutt, E. A. Bowles, Sydney Morris, H. V. Warrender, G. W. Loder, Jas. Hudson, W. B. Cranfield, C. Williams, J. F. McLeod, J. T. Bennett Poë, Chas. E. Pearson, R. W. Wallace, and H. J. Jones.

#### FIRST-CLASS CERTIFICATES.

*Anemone glaucophylla*.—A new, distinct and beautiful species, which, if hardy and a good grower, is sure of a welcome in gardens. The plant shown had deeply divided leaves, light

green, but with little trace of glaucous colouring. The inflorescences, about a yard high, carried one expanded flower and two buds. The flower was five inches in diameter, of light mauve colour, with a satiny sheen. Raised from seeds sent home by Forrest. Shown by Col. STEPHENSON CLARKE, Cuckfield.

*Rhododendron discolor*.—An exquisitely beautiful *Rhododendron*, with dark green leaves that are pale glaucous green on the underside. The widely expanded flowers have slightly recurving lobes, prettily waved. The throat is yellowish green, but the rest of the flower is white or blush and even pink in some forms. Slightly fragrant. Shown by the DIRECTOR, Royal Gardens, Kew.

#### AWARD OF MERIT.

*Campanula rotundifolia Jenkinsii*.—This charming *Campanula* was raised by the late Mr. E. J. Jenkins, who considered it to be one of the best plants he had raised. The narrow foliage scarcely corresponds to the specific name. The flowers, of the usual size and form, are freely borne on slender erect stems and are pure white. Shown by Mr. H. J. JONES, Lewisham.

*Gaillardia Kn-ght Errant*.—In this variety the two or three rows of ray florets are very broad and flat; light golden yellow with a very reddish base. Shown by Mr. DOWNER.

*Gaillardia Yeoman*.—A bold and handsome variety, with three rows of broad ray florets. The colour is rich golden yellow, with blood crimson centre. Shown by Mr. G. R. DOWNER, Chichester.

*Begonia Aurora*.—A large, double-flowered variety of excellent, rounded form; the colour is yellow, edged with golden apricot.

*Begonia Stella*.—A glorious drooping variety and a grand plant for a hanging basket, in which form it was admirably shown. The double flowers are of a rich red hue.

*Begonia Venus*.—An elegant drooping variety with double white flowers, but the flowers are not heavy. A fine *Begonia* for a hanging basket.

*Begonia Eunice*.—Another drooping variety and a fine basket plant; colour, soft rich pink. These four *Begonias* were shown by Messrs. BLACKMORE AND LANGDON, Bath.

*Dianthus Prichardii* var. *Donnicottii*.—A lovely single Pink, with slightly fringed petals. The colour is deep scarlet-crimson with a deep velvety crimson centre. Very handsome and free. Shown by Mr. MAURICE PRICHARD, Christchurch.

*Carnation E. G. Quick*.—This finely formed border variety is of deep slaty heliotrope colour. Shown by Mr. JAS. DOUGLAS, Great Bookham.

*Rose Jacquiline*.—A hybrid briar Rose, free-flowering, with neat dark foliage, and semi-double flowers of rich salmon-pink hue heavily shaded with gold; very effective. Faintly fragrant. Shown by Messrs. WM. PAUL AND SON, Waltham Cross.

*Delphinium Mrs. F. T. Neighbour*.—One of the prettiest *Delphiniums* of recent introduction, as its semi-double flowers open out well and are of a clear and beautiful sky-blue colour. Shown by Mr. FRED SMITH, Weybridge.

*Philadelphus Coup d'Argent*.—One of the most graceful and beautiful of *Philadelphuses*, the elegant branches, with narrowly lanceolate leaves, carrying numbers of flat, single, pure white flowers; fragrant. Shown by Sir W. LAWRENCE, Bt. (gr. Mr. J. Brown), Burford Lodge, Dorking.

*Buddleia alternifolia*.—This graceful, free-flowering hardy shrub is blooming in several gardens just now and shows some variation. In its best form it is a graceful shrub, about 12 feet high, with an abundance of slender arching growths, which at this season of the year are wreathed with small *Lantana*-like flowers of soft mauve colour, and sweetly scented. Many of the branches have blooms along two or three feet of their length. The narrow alternate leaves are green above and grey beneath. Sent home by Farrar as his No. 100, this *Buddleia* has now been on trial for some time. It is scarcely so bold and effective as *B. variabilis*, but as a shrub for cultivation near water it appears likely to win a place for itself. Shown by the Hon. VICARY GIBBS, Aldenham

House, Elstree; and by LIONEL DE ROTHSCHILD, Esq., Exbury, Southampton.

*Esculus indica*.—The Indian Horse Chestnut known also as *Pavia indica*, Wallich, and figured under this latter name in the *Bot. Mag.*, t. 5117, is a handsome tree. It has compound leaves composed of 5-7 long leaflets, shining green above. The erect spikes are a foot or more in length and about five inches wide; the flowers are white or pale pink, and the inner pair of the four petals have a yellow or rose-red blotch at the base. In *Trees and Shrubs Hardy in the British Isles*, Mr. W. J. Bean expresses the opinion that *Esculus indica* is one of the most magnificent of all temperate trees, and equalling the common Horse Chestnut in size and beauty. He refers to a specimen 70 feet high at Barton, Suffolk, introduced by Col. Bumbury in 1851, but we understand this fine specimen no longer exists. At Kew good seeds have been produced and seedlings raised therefrom. Shown by the DIRECTOR, Royal Gardens, Kew.

*Cornus capitata*.—An old species known in gardens as *Benthamia fragifera* and represented in Cornwall and the warmer parts of Ireland by large trees. The branch shown had flagged so badly that the beauty of the sulphur-coloured bracts was lost. Shown by C. J. LUCAS, Esq., Warham Court, Horsham.

#### GROUPS.

*Delphiniums* were a great feature of the show, and these were represented by many tall, well-flowered spikes. In the large collection by Messrs. KELWAY AND SON there were James William Kelway, large dark purple blooms with a white eye; Smoke of War, Gaby Deslys, Geraldine Kelway and Sir Alfred Keogh (Silver Flora Medal). The collection by Messrs. R. H. BATH, LTD., was especially noteworthy for the clear colour and excellence of the pale blue sorts, such as Baldersage, Musis sacrum, The Knight and Ellen Terry, though many other sorts were also worthy of admiration (Silver Banksian Medal). The darker sorts were most prominent in an exhibit by Mr. W. WELLS, Junr., and of these Lord Curzon, Cossack and Mr. H. Kaye were particularly good (Silver Banksian Medal).

Messrs. G. G. WHITELEGG AND Co., LTD., had many *Delphiniums* of merit and various Irises (Bronze Banksian Medal). *Delphiniums* and *Gaillardias* were shown by Mr. G. R. DOWNER (Bronze Banksian Medal). Messrs. BUNYARD AND Co. had various *Delphiniums* with Iris Monnier, I. ochroaurea and others. (Silver Banksian Medal).

Many excellent spikes of *Delphiniums* were arranged by Messrs. BLACKMORE AND LANGDON, Robert Cox and Dusky Monarch, of dark blue colour, Queen of Bath, Queen Mary and Mrs. Townley Parker, light blue, Lorenzo de Medici and Mrs. Shirley, mauve shades, were very handsome (Silver Flora Medal).

General border flowers were present in great variety, and of a higher order of merit than might have been expected after the long drought. The CHALK HILL NURSERY Co. showed many useful varieties, and included a good specimen of *Edelweiss* and some of their large *Mimulus* (Bronze Banksian Medal). Messrs. LADHAMS, LTD., included a splendid plant of *Ethiopia speciosa grandiflora* with an excellent collection, and, in the annex, had many desirable border Pinks (Silver Flora Medal). Messrs. WATERER, SON, AND CRISP included the brilliant scarlet *Verbena chamaedrifolia* and *Armeria Bees' Ruby* in their collection (Silver Flora Medal).

A pleasant little rock garden was made and appropriately planted by Messrs. WM. CUTBUSH AND SON (Silver Banksian Medal). Many dwarf *Campanulas* with other border flowers were shown by Messrs. R. TUCKER AND SON (Bronze Flora Medal). Mr. AMOS PERRY had a large batch of the semi-double *Coreopsis grandiflora* Perry's var. (Bronze Banksian Medal). Border flowers were also shown by Messrs. MAXWELL AND BEALE (Bronze Banksian Medal), Mr. CLARENCE ELLIOTT, the MISSES HOPKINS, Mr. MAURICE PRICHARD (Silver Flora Medal), Mr. G. W. MILLER (Bronze Flora Medal), Mr. G.

REUTHE (Bronze Flora Medal), and Mr. DIXON also showed various hardy flowers.

A large and very meritorious collection of Sweet Peas was delightfully arranged by Messrs. SUTTON AND SONS. The tall stamens of such sorts as Doris, Doris Usher, Hawmark Pink and Mrs. Tom Jones enabled their great decorative value to be easily appraised, while smaller, though quite large collections of Orange Perfection, Gladys, Adelaide, Picture and May Unwin were equally beautiful (Silver-Gilt Banksian Medal).

In a smaller, but particularly good selection of Sweet Peas Messrs. R. BOLTON AND SON displayed excellent vases of such sorts as Picture, Tangerine Improved, Comrade and Elsie Dene (Bronze Flora Medal).

Just inside the entrance Mr. H. J. JONES had a large collection of well-grown Hydrangeas and herbaceous Phloxes. All were growing in relatively small pots, and the Phloxes were particularly fine, whilst the Hydrangeas bore large, shapely heads of bloom. The following are the names of a few of the many good Phloxes on view: John Meakings, Mrs. Bevil Fortescue, Mrs. H. J. Jones, Florrie Freeman, Selma and Mia Ruys (Silver-Gilt Banksian Medal).

Messrs. HILLIER AND SONS made a pretty little water garden in a corner space by the stairs. There was a pool with excellent blooms of such Nymphaeas as Gladstoniana, atropurpurea, flammea and Escarboucle (Silver Banksian Medal).

An interesting collection of hardy shrubs was arranged by Mr. CHAS. TURNER. Amongst the many valuable species we noted Ochra multiflora and Neilla (Spiraea) Torreyi in fruit and Tilia asplenifolia and Ligustrum Iboti (Silver Banksian Medal). Some well-flowered bushes of Kalmia latifolia were shown by Mr. T. LEWIS (Bronze Banksian Medal). Messrs. CHEAL AND CO. showed English Irises and Dahlias, with hardy flowers (Bronze Flora Medal).

Dame ALICE GODMAN (gr. Mr. C. Savegar), South Lodge, Horsham, showed an interesting set of seedlings of Rhododendron discolor and sprays of Styrax Wilsonii. An excellent collection of named English Irises was staged by Messrs. BARR AND SON, who also showed many Delphiniums (Silver Banksian Medal).

Roses, mostly those of garden and decorative value, were fairly plentiful. Mr. W. PAUL included the dark crimson Walter C. Clark, of which he had some exceedingly fragrant blooms. Gloria, a new H.T. of full shape and deep pink colour, Mrs. Hy. Morse, Columbia and Paul's Scarlet Climber were also prominent varieties (Silver Flora Medal). Under the clock Messrs. F. CANT AND CO. showed Mrs. Alfred Wist, Golden Emblem, C. V. Haworth, Mrs. Rosabel Walker, Golden Ophelia, with other good sorts (Bronze Flora Medal). The Rev. J. H. PEMBERTON had a collection which included several good climbing varieties.

Stove and Greenhouse plants were more numerous than usual at this time of the year. At the end of the hall, next to Sutton's Sweet Peas, there was a collection of Crotons from A. P. BRANDT, Esq. (gr. Mr. J. W. BARRS), Bletchingley, Surrey, which were admirable in their clear growth and excellent colouring. A great variety were shown, including Evansianus, Queen Victoria, Lady Zetland, and Juliet Russell (Silver-Gilt Flora Medal).

A goodly collection of Caladiums was arranged by Messrs. JOHN PEED AND SON, who also had many plants of a good strain of Streptocarpus and two batches of double-flowered Petunias. The latter were Holly Greenfield, rich pink, and Mrs. John Campbell, velvety blue (Silver Flora Medal).

An excellent collection of miscellaneous stove plants was attractively arranged by Messrs. L. and R. RUSSELL, LTD. The plants all illustrated splendid cultivation, and included such kinds as Dracaenas in great variety, Caladiums, Anthuriums, Medinilla magnifica, Nepenthes, Tabernaemontana and Cissus discolor (Silver Flora Medal). A long stretch of tabling was filled with an admirable collection of Streptocarpus by Messrs. R. and G. CUTHBERT. The plants were all of the large-flowered type, and bore

an unusual quantity of bloom, illustrating a very desirable strain (Silver-Gilt Banksian Medal).

Excellent tuberous-rooted Begonias were staged by Messrs. BASTIN AND SON. They were mostly of such double-flowered sorts as Lady Bell, for which they received an Award of Merit at the previous meeting, Mrs. Reg. Caulfield, Lady Diana Cooper and Mrs. W. Churchill. The pretty crested singles and graceful basket Begonias were also well represented (Silver Flora Medal).

The customary collections of greenhouse Carnations were contributed by Mr. C. ENGLMANN (Silver Banksian Medal), and Messrs. ALLWOOD BROS. (Silver Flora Medal), the latter adding quantities of their Dianthus Allwoodii. Mr. J. DOUGLAS showed a good collection of border Carnations, which included Sunshine, rich yellow; Saladin, mauve with scarlet stripes; Miss Elizabeth Shiffner, Linkman, White Clove and the deep crimson Sir Brunetto (Silver Banksian Medal).

Messrs. CARTER, PAGE AND CO. showed Irises, Violas and Dahlias (Silver Flora Medal).

#### Fruit and Vegetable Committee.

Present: Messrs. J. Cheal (in the chair), E. A. Bunyard, W. Poupart, H. S. Rivers, P. C. M. Veitch, Geo. F. Tinley, W. Jefferies, S. B. Dicks, J. Wilson, J. C. Allgrove, T. Pateman, E. Beckett, P. A. Tuckett, H. Markham, E. Merryweather, E. Neal, W. Bates, W. H. Divers, and the Rev. W. Wilks.

Mr. Alan N. Rawes, Fruit Experiment Officer at Wisley, has been appointed Secretary of this Committee, in succession to the late Mr. S. T. Wright.

#### AWARD OF MERIT.

*Cherry Peggy Rivers*.—This new early Cherry is stated to be a seedling from Bigarreau Gros Coeuret and ripens at the same time as Governor Wood, which it greatly resembles, but the foliage is darker. The great value of the new variety is that the fruit does not split, as is frequently the case with Governor Wood, out-of-doors. Shown by Messrs. T. RIVERS AND SON.

#### GROUPS.

Messrs. T. RIVERS AND SON showed a corner group of Cherry trees in pots, all superb specimens and bearing large crops of luscious fruits. The varieties were Frogmore Bigarreau, Governor Wood, Early Rivers, and the new Peggy Rivers (Silver-Gilt Hogg Medal).

Varieties of Broad Beans, representing those for which Awards of Merit were recommended by the sub-committee on the 25th ult., were shown, from the WISLEY GARDENS. The trial comprised some eighty-three varieties, and the seed was sown on February 27. The following sorts were those recommended for Awards of Merit: Multiple, White Edge Early Large, Early White-Edged, Shirley Long Pod, Broad Windsor Selected, Giant White Windsor Improved, Exhibition, Champion Long Pod, Hangdown Selected, and Green Leviathan.

Messrs. SUTTON AND SONS showed new types of dwarf Broad Beans, a white seeded variety about one foot in height, and a green seeded sort, which only grows about nine inches tall. They were the progeny of Dwarf Gem crossed with Exhibition Long Pod.

Messrs. H. CHAPMAN, LTD., Rye, showed a very large podded form of Broad Bean, of a bushy habit of growth and very prolific cropping, of the Aquadulce or Seville type. The variety was recommended for trial at Wisley.

Mr. G. APPLETON, Northwick, showed a Rhubarb named Appleton Red. It is of the Paragon type and, like Paragon, is said never to run to seed.

#### STREATHAM ROSE AND SWEET PEA.

A SMALL but altogether successful exhibition was held in the Congregational Hall, Streatham, on the 24th ult., by the Streatham and District Rose and Sweet Pea Society.

In the open class for twenty-four Roses, distinct, the Championship was won by Messrs.

FRANK CANT AND CO., Colchester, who had excellent blooms of H. V. Machin, J. B. Clark, F. K. Draschki, and other first-rate varieties. There were six entrants, Mr. G. PRINCE, Oxford, winning second prize, and Messrs. PRIOR AND SONS, Colchester, third prize. For eighteen Tea and Noisette Roses, distinct, Mr. PRINCE won first prize, showing many excellent blooms, including Mme. Jules Gravereaux and Maman Cochet; second, Messrs. D. PRIOR AND SONS, and third Messrs. F. CANT AND CO. The Norman Rogers Challenge Cup for the best twelve blooms shown by amateurs was won by Mr. M. COXHEAD, and the Streatham Amateur Challenge Cup for six blooms, distinct, was won by Mr. A. E. COXHEAD, Ambleside Avenue, while Mr. T. J. GARRATT won first prize in another class for six blooms.

The Streatham Traders' Challenge Cup for six bunches of Sweet Peas, distinct, was won by Mr. W. MARTINEAU, The Chestnuts, Boxmoor, while in the open classes the premier award for twelve bunches was won with magnificent flowers by Mr. A. E. USHER, The Gardens, Rauston, Blandford, Dorset. Mr. J. B. PROCTER, Ellison Road, Streatham, had the best vase of twenty-five sprays of Sweet Peas, and won in a very close competition among ten exhibitors. Mr. A. CURTIS, a local grower, won the cup for six bunches of Sweet Peas.

In local classes Mrs. DYER, Benlah Hill, won first prize for a decorative basket of flowers with a very charming arrangement of blue Delphiniums and pink Paeonies. Mrs. DYER also had the best bowl of Roses, while Mrs. A. KING had the best vase of garden flowers in one section, and Mr. TAYLOR, St. Mark's Road, had the best vase of garden flowers in the local section. In each of these two latter classes the competition was extremely keen, and the numerous exhibits made a fine contribution to the general display.

Messrs. B. R. CANT AND SONS, Messrs. CHAPLIN BROS., and Mr. PRINCE each put up excellent non-competitive displays of Roses that added greatly to the effect and interest of the exhibition.

#### ROYAL CALEDONIAN HORTICULTURAL.

JUNE 6.—The ordinary monthly meeting of this Society was held at 5, St. Andrew Square, Edinburgh, on this date, Mr. David King, President, in the chair.

Sir Herbert Maxwell, Bart., Monreith, read a paper entitled, "Cultural Notes on Rhododendrons." We were not yet in a position, he said, to gauge the full affluence of the Rhododendron family. The number of new species introduced from China by Henry, Wilson, Forrest, Farrer, and others, amounted to many hundreds, ranging from the humble creeping forms to R. giganteum, which attained a height of 80 feet. Some of these species were of high ornamental merit, but many were of little more than botanical interest. It had been found that, with the exception of the dwarf species which grew above the limit of forest growth (12,000 to 15,000 feet) in Western China, which take the place there of Heather in Western Europe, most species of Rhododendron from high altitudes flourish and flower freely in the milder districts in this country if they are protected against wind. As to hardiness, a safe test was found in R. arboreum. Where that species flourished, most of the new kinds have nothing to fear from the British winter, provided they have protection against wind. Winter cold was not, however, what they had most to fear in this country. Most of the Asiatic species came from high altitudes (5,000 to 15,000 feet), where the winter temperature brought them to complete rest for several months, whereas a typical British winter consisted of long spells of mild, wet weather, causing the buds of sensitive species to swell and push, to be blackened and killed by frost in March and April. In the mild climate of the west coast of Scotland, 100 feet above sea level, with Sir Herbert the beautiful Chinese species, R. oreodoxa, started into growth in February in 1921, and had all the young shoots destroyed in April, whereas at Dawyck,

in Peebleshire, a cold district, 600 feet above the sea, the plants were kept dormant, and put forth new growth after the danger from frost was past. Sir Herbert also referred to the inability of Rhododendrons to thrive, or even live, in soil which contained more than a faint trace of lime, and of attempts which had been made to grow them on the chalk formation by excavating huge beds and filling them with peaty soil, where they only thrive until the water from the chalk filtered into the soil. It occasioned much surprise, therefore, when Messrs. Wilson and Forrest and other collectors reported the discovery of many species growing luxuriantly on limestone, but Mr. Forrest discovered that these plants had the under surface of their leaves, and in some cases the young growth, covered by the mycelium of the fungus which is usually found on the roots of the Rhododendron and other plants, and that this is killed when the roots are brought into contact with lime, and the Rhododendron dies of starvation when it is deprived of the services of its humble ally. The fungus, therefore, changes its habitat and becomes a mycophyllon instead of a mycorrhiza, the obvious inference being that, as it is unable to encounter the lime, it changes its location and repays the plant for its lodging there by free nitrogen drawn from the air instead of fixed nitrogen drawn from the soil.

In dealing with their cultivation, Sir Herbert confined his remarks to a few special points applying to natural species, leaving aside garden hybrids. All except those with very small leaves were, he said, naturally woodland species, and to ensure their vigorous development they should be partially screened from full sunlight. Open woodland glades afforded the ideal position for them, otherwise a north or north-west exposure was best, provided they had shelter from wind, but the small-leaved species from the Asiatic mountains did best in open exposures. In forming collections of some of the natural species, he emphasised the necessity for plenty of space, and said it would be well to act on the precept enunciated by the owner of perhaps the largest collection of Rhododendrons in Cornwall, who told him years ago to "place each plant in such a position that you will be able to ride round it thirty years later." With the more vigorous kinds, it was the only way to avoid disappointment, and as an illustration of this, he referred to a specimen of *R. campanulatum*, at Leny, in Perthshire, raised from seed in 1823, which was now 30 feet high and 150 feet in circumference. The larger Asiatic species should never be planted nearer to each other than 60 feet, and 100 feet was not too much. But the ground which they were intended to ultimately occupy could be planted with hybrid Rhododendrons and Azaleas, which flower when they are of small size, as well as other flowering shrubs, in order to temporarily furnish the ground.

The annual application of a liberal mulch of freshly-fallen leaves, 1 foot thick, in November, which should be allowed to decay *in situ*, was recommended in order to protect the root system against such agencies as drought, deficiency of nourishment, etc. Farmyard manure as a mulch was, Sir Herbert thought, if not mischievous, superfluous. Although Rhododendrons thrive in good peat, the Asiatic species were not acquainted with it until they were brought to this country. In their native homes they subsist on the leaf mould of the forest soil. Nevertheless, peat of the right sort was an admirable ingredient in a compost, and it possessed the great advantage over leaf-mould in that it did not harbour slugs and injurious insects. Peat dug from a moss flow, however, which is full of humic acid, should be exposed to sun and rain for six months, and well pulverised before use. The sand used should be sharp and rather coarse. Sea sand, which consisted largely of triturated shells, contained lime, and was unsuitable for Rhododendrons, but where it was chiefly composed of grains of quartz, it exerted no chemical action on them.

The exhibits were:—Rhododendrons, from Sir HERBERT MAXWELL, Bart.; Rhododendrons, from Mr. W. G. PRIE, Dalhousie Castle, Midlothian; Darwin Tulips, from the

MARCHIONESS OF TWEEDALE, Yester, Haddington (Silver Medal); Darwin Tulips, from Messrs. DOBBIE AND CO., Edinburgh (Silver Medal); Aquilegias and Chimonanthus fragrans, from Mr. JOHN DOWNIE, Edinburgh (Cultural Certificate); Cheiranthus Allionii, from Messrs. J. GRIEVE AND SONS, Edinburgh.

TRADE NOTE.

A REMARKABLE catalogue of quite unusual form and size has reached us from Messrs. T. Bath and Co., Savoy Street, Strand. It is like a large newspaper, and consists of twenty pages crowded with illustrations of garden tools and requisites, garden seats, summer houses, tea houses, bungalows, poultry appliances, bee hives, and a host of other things connected with the equipment of the garden and the farm, in addition to household furniture, and other goods of varying interest and usefulness.

ANSWERS TO CORRESPONDENTS.

APPLE SHOOTS INFESTED WITH RED INSECTS: *B. C.* The shoots are infested with red spider which may be destroyed by spraying with a weak insecticide.

ASTERS DISEASED: *J. H. J., Notts.* The Asters are suffering from the Black Neck or Wilt Disease, caused by a fungus (*Phytophthora sp.*) present in the plant. All diseased plants should be lifted and burnt, and healthy plants sprayed with Bordeaux mixture.

LABURNUM WITH THREE TYPES OF FLOWERS: *W. P.* The flowering shoots from your Laburnum represent the type, Laburnum vulgare, yellow; Cytisus purpureus, and the multi-coloured form known as Adami. This is a case of a graft hybrid in which Cytisus purpureus grafted on the common Laburnum has resulted in the form known as Adami. It is one of the classical examples of a graft hybrid to which reference is made on p. 3 (see also *Gard. Chron.*, September 24, 1904).

NAMES OF PLANTS: *F. O.* Bignonia Tweediana (Brazil).—*A. F. E.* (1) *Aubrietia deltoidea* var.; (2) *A. d. violacea*; (3) *Camassia esculenta*; (4) *Aethionema iberideum*.—*H. C. M.* The tree is *Aesculus Pavia*, syn. *Pavia rubra* (Red Buckeye), and the blue flower *Saintpaulia ionantha*, a greenhouse plant.—*Gardener, Herts.* *Cercis Siliquastrum*. *L. S. A.* 1. *Robinia Pseud-acacia*; 2. *Spiraea brachybotrys*; 3. *Philadelphus coronarius*.—*Enquirer.* 1. Unable to identify; 2. *Raphiolepis ovata*; 3. *Lonicera involucrata*.—*A. Wilson.* *Crataegus orientalis*.—*P. E. N.* *Linaria purpurea*.—*R. S. L.* Probably *Arum Dracunculoides*, but we cannot determine the specimen in the absence of inflorescence.—*H. F. W.* *Xanthoxera sorbifolia*. *J. K.* *Pancreatum calathinum*.

RUSCUS ACULEATUS FRUITING: *J. J. S.* The Butchers' Broom commonly fruits in the south of England, and sprays with the fruits on them are sometimes marketed in Covent Garden. We have noticed the plant fruiting freely in the neighbourhood of Oxshott, Surrey.

ST. BRIGID ANEMONE: *E. W.* The only Irish firm we know which specialises in St. Brigid Anemones is Messrs. Reamsbottom and Co., Alderborough Nursery, King's County; but we do not think they have a London address.

VIOLA CUTTINGS: *R. H. H.* It is advisable to take off some of the lower leaves and the stipules before inserting the cuttings in the soil, as they might set up decay. Sever the shoots just below the node with a sharp knife, and use plenty of sand and grit in the soil in which they are to be rooted.

REMARKS.—The Strawberry season has had its usual effect on the demand for other fruits, and prices have fallen considerably. Ample stocks of Australasian Apples are on offer at easier rates. Bananas are quoted lower, and not in much demand. Oranges and Lemons are a slow trade. Apricots from Spain have sold freely at lower prices. Plums and Greengages from the same source are selling moderately freely. A fair quantity of English Cherries is arriving each day, the reduced values encouraging a good demand. Gooseberries have been a drag on the market, large quantities arriving from Holland, and prices are accordingly very low. French Black Currants have been in demand, and are selling freely. English hothouse fruits, such as Grapes, Peaches, Nectarines, Figs and Melons, are in good supply, and except in the case of Melons, good prices are being obtained for the choicer qualities of these fruits. Strawberries are moderately plentiful, supplies from both Hampshire and Kent selling for the most part at satisfactory prices. New Potatoes from all sources are plentiful and cheap. Forced Beans are lower in price. Mushrooms are plentiful, and Peas are in good request, but Cabbages and other greens are quoted at very low rates.

Plants in Pots, etc.: Average Wholesale Prices.

REMARKS.—There is no great demand for any particular subject and, generally, the supplies exceed the demand, while there is a further reduction in the prices for all outdoor blooms. Achillea, The Pearl, and Alstromeria are now available. There has been an abundant supply of Liliun longiflorum, and a few blooms of Liliun lancifolium are available. Canterbury Bells, Delphiniums, Gladstoll, Gaillardias, Larkspurs, white and coloured Stocks, are all being received in excellent condition. English Irises are arriving in good condition, also *Statico sinuata* and *caebiosus caucasicus*. The quantities of foliage are also sufficient to meet all requirements. Asparagus plumosus, A. Sprengeri, Adiantum (Maideahair Fern), and large consignments of Smilax are available. The last is arriving from Guernsey, and the price fluctuates, there being none from home growers.

GARDENING APPOINTMENTS.

Mr. J. Roberts, previously Gardener to C. H. LOMAX, Esq., Grove Park, Yoxford, Suffolk, as Gardener to Col. HAMMOND, C.B.E., Coldham Hall, Bury St. Edmunds, Suffolk.

Mr. D. Milne, for the past thirteen months Foreman at Cromlix, Dunblane, as Gardener to E. BALFOUR, Esq., Balmirrie, Markinch, Fifeshire. (Thanks for 2/6 for R.G.O.F. Box.—Eds.)

Mr. Charles T. Farmer, for the past eleven years Gardener to LORD ASTWON, Woodlawn, Co. Galway, Ireland, as Gardener to LORD GLENARTHUR, Fullerton House, Troon, Ayrshire.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 62.1°.

### ACTUAL TEMPERATURE:—

Gardeners' Chronicle Office, 5, Tavistock Street, Covent Garden, London, Wednesday, July 5, 10 a.m. Bar. 29.9; temp. 61°. Weather—Fine.

### On Planting in Times of Drought.

The sudden transition of winter to summer weather which occurred this year and the almost complete absence of rain made gardening operations difficult and laborious. Gardeners who are in charge of well-established gardens are generally so experienced and resourceful that, although the conditions this year have greatly tried their ingenuity and powers of work, they have been able to overcome in large measure the difficulties of the present season. Less experienced gardeners, however, have complained bitterly that they could not get their plants "out," and also that their seed beds have failed. A case of this kind came under our observation recently. A young and keen gardener was complaining bitterly that he could not plant out his Antirrhinums, Cauliflowers, Leeks, Celery and other garden and kitchen garden crops. He was devoting much of his time to watering, but the results were not in proportion to his efforts. The soil was bone dry at the surface although, being of a heavy kind, there was plenty of mois-

ture underneath. Two facts escaped his notice, or at all events his application. One, that by consolidating the soil it is possible to facilitate a rise of water from the deeper levels to the upper crust—a practice which, of course, is applied generally by farmers and gardeners when making a seed bed. The other, that where comparatively small breadths of ground have to be sown or planted the dry weather may be disregarded, provided that water and litter are available; the former to prepare the seed- or plant-bed, the latter to cover the transplanted plants or the sown seed. In the case under notice there were both plenty of water and hay—the latter from meadows adjoining the garden. When he had grasped these simple ideas the gardener set to work, and planted out his plants, watering before and after planting, and covering them with a light, loose layer of freshly made and nearly dry hay. The result was satisfactory. The plants in the warm soil soon took hold and grew sturdily through the mulch. Then the hay was drawn aside, and the ground was well hoed; but instead of hoeing to produce a fine tilth the surface, when it was no longer too moist, was gently but firmly consolidated so as to encourage the rise of water in the soil. When the plants had become thoroughly established the ground was hoed again to a fine tilth and the mulch of hay put back.

Although to every experienced gardener devices such as these are the common-places of cultivation, it is, nevertheless, worth while to point out to the less experienced that a garden is far less at the mercy of weather than is a farm where large breadths are cultivated. So much to heart has the lesson he learned been laid that the young gardener has now made up his arrears of planting, and even the rock walls which were waiting for their plants are now planted, and, until rain came, looked more like haystacks than wall gardens. Standing above the wall at one corner is a recently planted Rhododendron of considerable size turned out from a pot, and through its thatch of hay the young growths pushed sturdily despite the hot, dry weather.

Imperial Fruit Show, 1922.—The Imperial Fruit Show organised by the *Daily Mail*, to be held at the Crystal Palace from October 27 to November 4, will include classes for amateur as well as for commercial growers. Prizes to the value of £3,000 are offered for competition. The show has been divided into the following sections: Kent and Southern Counties; Eastern and Northern; West and Midlands; Ireland; Channel Islands; Great Britain; Overseas; and British Empire. In the sections for home-grown and Channel Islands fruit, there are classes for Apples, Pears, Tomatoes, and Grapes. The Irish section comprises six classes—three for cooking and three for dessert Apples. Apples and Pears make up the classes in the Overseas section, while the British Empire section provides for two classes of Apples (in which home growers can compete), four classes for Oranges, and two classes for Grapes. Beside money prizes, forty-three gold medals, forty-three silver medals, forty-three bronze medals and twenty-six cups and other trophies are offered. All commercial entry forms must reach the Secretary, Imperial Fruit Show, 130, Fleet Street, London, E.C.4, on or before Monday, October 2, 1922. In the case of Canadian exhibits, entry forms and fees must be delivered or sent to the Imperial Exhibition Department, Fruit Branch, Department of Agriculture, Ottawa, and marked "Imperial Fruit Show," on or before September 25, 1922. In the case of South African exhibits, all entry forms and fees must reach the Chief Division of Horticulture, Department of Agriculture, Pretoria, on or before September 5, 1922. All

amateur entry forms must reach the Secretary, Imperial Fruit Show, 130, Fleet Street, E.C.4, on or before Saturday, October 14, 1922.

An Educational Garden at Reading.—Dr. Hurry's "Educational Garden" at Westfield, Reading, which contains numerous plants used in the preparation of medicines, foods, fibres and dyes, will be open to the public free of charge on July 12, 15 and 16, between the hours of 3 and 6 p.m. There is also a museum of Economic Botany in which are exhibited commercial products derived from the plants grown in the garden.

The North of England Horticultural Society's Show.—The hon. secretary informs us that the date of the show has been provisionally fixed for October 11, 12, and 13. The Harrogate Chamber of Trade have guaranteed the prize list of £100, and will be running a shopping week or carnival simultaneously with the exhibition. A champion cup, valued at £15 15s., is offered for the best exhibit of fruit, and is open to growers in England, Wales and Scotland.

### Conveyance of Plants by Passenger Train.—

We are very pleased to be able to report the success of the efforts made through the medium of the Chamber of Horticulture to secure better conditions for the conveyance of plants by passenger train. Our readers are aware a deputation of growers placed their case before the railway authorities on the occasion of a recent conference at the Railway Clearing House (see p. 2, and also p. 297, Vol. LXXI). The points put forward at the interview have been carefully considered by the various railway companies, who have agreed that plants, flowers and Orchids in less than truck loads, in soil, or in soil in pots, above one foot in height, when not packed in substantial crates or wooden boxes, so constructed as to admit of other traffic being loaded on top thereof, be charged as follows: Company's Risk—general parcels' scale, including collection and delivery within the usual limits at places where arrangements for these services are in operation. Owner's Risk—owner's risk scale of rates, including delivery within the usual limits at places where arrangements for this service are in operation. The railway authorities have further agreed to reinstate special rates for plants and flowers in soil, or in soil in pots, on the basis of the rates in operation in 1914, increased by 75 per cent. Where these special rates are required application must be made to the companies concerned. All these revised rates and conditions came into operation on July 1. Not only is this good news for the horticultural trade in general and for the cultivators of plants for market in particular, but it also affords considerable relief to those who wish to convey plants over considerable distances for exhibition purposes, including the Royal Horticultural Society's shows.

Health Certificates for Imported Plants.—The experience gained during the past season of the working of the Destructive Insects and Pests Order of 1921, which came into operation on October 1 last, has enabled the Ministry of Agriculture to review the regulations governing the entry of plants, etc., into England and Wales, and to frame new regulations in order to meet certain practical difficulties which have arisen. The whole matter has been considered in consultation with the Departments of Agriculture for Scotland and Ireland, and as a result the Destructive Insects and Pests Order of 1922 has been issued, which comes into operation on July 1. The new regulations maintain the principle that imported plants, etc., must be accompanied by a health certificate, but it will not be necessary for a copy of the certificate to be affixed to each package as heretofore. Two copies of the certificate must, however, be sent with the papers relating to the consignment. One of these should be sent by the importer to the consignee; the other will be retained by the Customs authorities. Experience has shown that the examination of uncertified consignments at the port of landing cannot usually be conveniently carried out, and, if any consignments should arrive without the prescribed health certificates, they

will not be held up at the port, but will be allowed to proceed to their destination, where they must be detained until the contents have been examined by an inspector of the Ministry and pronounced to be healthy, or until a notification has been received from the Ministry that the goods may be distributed. The importer is liable for the cost of any inspection in such cases, and care should be taken, therefore, when placing orders for plants abroad, to insist that a health certificate shall accompany the plants.

**Glasgow International Flower Show.**—We understand that excellent progress is being made with the arrangements for the great International Flower Show, to be held in the Kelvin Hall, Glasgow, on August 30 and 31, and September 1 and 2 next. Our readers will remember that the promoters of this exhibition are the Corporation of the City of Glasgow, and the Glasgow and West of Scotland Horticultural Society, a combination that is sufficient augury for its success. The Royal Horticultural Society will send a deputation consisting of the President, Lord Lambourne; the Secretary, Mr. W. R. Dykes; Col. F. R. S. Balfour, Mr. W. Cuthbertson, Mr. G. W. Loder and the Rev. W. Wilks. This deputation will make awards on behalf of the Royal Horticultural Society to meritorious exhibits. British nurserymen are taking a keen interest in the event, and already no fewer than thirty-two firms have applied for space for the purpose of staging non-competitive displays.

**National Sweet Pea Society.**—This Society's twenty-second annual exhibition will be held in the Winter Garden, Devonshire Park, Eastbourne, on the 12th and 13th inst., in conjunction with the exhibition of the Eastbourne Horticultural Society. Her Royal Highness, Princess Alice, Countess of Athlone, will open the exhibition at 2.30 p.m. on July 12. An official luncheon will be held in the Indian Pavilion at 1 p.m., and in the evening a dinner and reunion will be held, also in the Indian Pavilion, when Mrs. Macnamara, President of the National Sweet Pea Society, will preside. His Worship the Mayor of Eastbourne, Ald. H. W. Keary, and Sir Charles O'Brien Harding, President of the Eastbourne Horticultural Society, have expressed their intention of being present. After the dinner, Mrs. Macnamara will distribute the cups and trophies to the successful competitors. The National Sweet Pea Society's trials at the University College Gardens, Reading, have been judged by the Floral Committee and are now open to inspection by members, who should notify the Superintendent, Mr. Cobb, of their intention to view them. We understand that only one Award of Merit has been granted this season, to a bright salmon-coloured American variety, the name of which has not yet transpired.

**Commercial Fruit Show in 1923.**—Representations have been made to the Ministry of Agriculture by the Eastern Counties Commercial Fruit Growers' Association as to the desirability of holding a fruit show in 1923, in one of the large towns in the north of England, e.g., Manchester. Being always anxious to do everything possible to encourage movements likely to lead to the increased consumption of home-grown produce, the Ministry has accordingly arranged for a public conference to be held at 10, Whitehall Place, at 2 p.m., on Thursday, the 20th inst., when an opportunity will be given for a free and full discussion of the subject by those interested in the growing, marketing, and distributing of fruit. No special invitations for the conference will be issued.

**Elstree Flower Show.**—Mr. Edwin Beckett informs us that on the occasion of the Elstree and District Flower Show, which will be held on Saturday, the 15th inst., in Aldenham Park, the gardens and grounds of Aldenham House will, by permission of the Hon. Vicary Gibbs, be open to visitors. Many horticulturists will doubtless take the opportunity of inspecting this famous establishment, and those travelling from London should book from St. Pancras Station, on the Midland Railway, to Radlett, where special conveyances will be

waiting to conduct them to the gates of Aldenham Park. Elstree Show is one of the most interesting of the small horticultural exhibitions. Sweet Peas, Roses, and hardy border flowers are prominent features of this show, and there is always a large display of vegetables from Aldenham House Gardens.

**Wright Memorial Fund.**—Mr. W. R. Dykes, secretary of the Royal Horticultural Society, writes:—"As there is some doubt as to the purpose of this fund, I have been asked to state that its object is to purchase an annuity for Mrs. Wright. It is hoped that a considerable sum will be raised in order that this may be possible."

**Mr. James Melrose.**—Horticulturists who have visited the Grand Yorkshire Gala over a period of many years, either as exhibitors or judges, have come to regard Mr. James Melrose, J.P., as the father of the great York show. On the rare occasions when Mr. Melrose has been absent, everyone officially connected with the show has regretted his inability to attend. But these occasions have been very rare, for, despite his years, which are more than ninety, he has wonderfully good health. At the exhibition held in Bootham Park, on June 14-16 last, Mr. Melrose carried out his

MR. JAMES MELROSE, J.P., PRESIDENT OF THE GRAND YORKSHIRE GALA.

duties as President, and presided over the luncheon given to judges and exhibitors, with a vigour which would have done credit to a man thirty years his junior. Mr. Melrose attended the meeting held in York over sixty years ago, when a few enthusiasts conceived the idea of starting a flower show in that city, and promptly acted upon it. From small beginnings the show has grown in extent and interest until now it is one of the finest annual horticultural events held in the British Isles, and through all its changes, its good seasons and its bad ones—the whole exhibition was blown down by a terrific gale some years ago.—Mr. Melrose has been associated with its fortunes, and his optimism, founded on long experience, has proved invaluable to the governing body on many occasions. Mr. Melrose is a great lover of plants and flowers, and his connection with an exhibition from its institution to its diamond jubilee is probably unique in the annals of horticulture.

**Potato Trials at Reading.**—A party of Potato experts paid a visit to Messrs. Sutton and Sons' trial grounds at Reading, on the 27th ult., for the purpose of inspecting the firm's extensive trials of Potatoes, which include about fifty specially selected seedlings not yet offered to the public. Of these seedlings numbers are

being tested at Ormskirk, and promise to be immune to Wart disease. The visitors were greatly interested in the varieties, and in the methods Messrs. Sutton and Sons adopt to secure true and clean seed Potatoes. Among those present were Mr. P. G. Dallinger, chief inspector of the Potato department of the Ministry of Agriculture; Mr. G. C. Gough, divisional inspector of the Ministry; and Mr. G. P. Berry, technical adviser in horticulture to the Ministry.

**Gift of Orchids to Kew.**—Sir George Holford, Westonbirt, has presented a valuable collection of Orchids to Kew to help make good the serious loss experienced last year, due to the use of water impregnated with salt, the sea water at high tides having contaminated the water supply of the garden. Sir George Holford has on previous occasions contributed generously to the Kew collections, and this last gift is estimated to be worth several thousand pounds.

**National Potato Exhibition, 1922.**—The annual exhibition will be held at the Artillery Drill Hall, Sheffield, in conjunction with the annual exhibition of the Sheffield Chrysanthemum Society, on Friday and Saturday, November 10th and 11th, 1922. Schedules may be obtained from Mr. W. H. Morter, Cannon Hill Park, Birmingham.

**Legacy to a Gardener.**—The Right Hon. Augusta Clementine Baroness Blythwood, of Dunally Lodge, Shepperton-on-Thames, and formerly of Blythwood House, Renfrew, who died on March 23rd, left a legacy of £300 to her gardener, Mr. H. Goldhawk, and one year's wages to her garden labourers of two years' service and not under notice. She also left legacies to her other servants.

**A New Horticultural Bulletin.**—The Chamber of Horticulture is to be congratulated on the first number of its *Bulletin*, which it will issue quarterly, a sign, as Sir Arthur Griffith-Boscawen, Minister of Agriculture, states, of the vigour with which the organisation is being conducted. Much of the literary matter refers to the work done by the Chamber, and deals with such subjects as the tax on British flowers imported into France; co-operative advertising; the rates for transit of pot plants by passenger train, and various Orders affecting the horticultural industry. Articles on "Experiments on Cultural Methods of Controlling Onion Fly," by Mr. A. Roebuck, and on "Commercial Carnation Culture," by Mr. C. Engelmann, will appeal especially to practical men, and there are interesting articles on "Science and Research in Horticulture," by Sir Daniel Hall, and on "Railway Inquiry and Trade Organisation," by Mr. H. W. Goodall, Secretary of the National Federation of Fruit and Potato Trades' Associations, Ltd. There is an excellent reproduction of the portrait presented to Mr. George Monro by the Chamber, with an account of the annual dinner at the Hotel Cecil on May 3 last, at which the presentation was made. Items on legal matters and statements made in Parliament on subjects affecting the horticultural industry will be interesting guides to the horticultural trader on many aspects of his business, whilst subjects that call for reform, such as reduction of taxation on industry, postal rates, and improved transport facilities, are included in the Parliamentary programme of the Chamber. A close perusal of the pages shows that the Chamber is watching the interests of horticulture very closely, and that it is deserving of a much fuller support than it receives from all sections of the horticultural industry.

**Appointments at Kew.**—We understand that the position of Assistant Curator at Kew, as hitherto existing, is to be discontinued and, instead, the foreman in charge of the several departments at the Royal Botanic Gardens will each become an Assistant Curator. Those who will enjoy this more dignified title are Mr. J. Coult, Decorative Department; Mr. Walter Irving, Herbaceous Department; Mr. A. Osborn, Arboretum Department; Mr. C. P. Raffill, Temperate Department, and Mr. T. W. Taylor, Tropical Department.

**A Metropolitan Vegetable and Flower Show.**  
 —A competitive exhibition of vegetables and flowers will be held under the patronage of the Worshipful Company of Gardeners and under the auspices of the Vacant Land Cultivation Society, the National Union of Allotment Holders, and the London Gardens' Guild at the Guildhall, on September 2. The show will be opened by Lord Leverhulme. There are thirty-six classes, and the prizes are mostly monetary; a silver cup is offered by the Worshipful Company of Gardeners to the society which obtains the highest number of points in the classes for a collection of vegetables and six varieties of Potatoes respectively. The freedom of the Worshipful Company of Gardeners is offered to the exhibitor who obtains the highest number of points for all the exhibits, including fruits and flowers. The Hon. Secretary is Mr. R. Sudell, 61, Penrose Street, S.E.17.

**Appointments for the Ensuing Week.**—Monday, July 10.—United Horticultural Benefit and Provident Society's meeting; Bath Gardeners' Society's meeting. Tuesday, July 11.—Royal Horticultural Society's Committees meet; lecture by Commander G. Silver on "The uses of Cellulose in the Garden"; National Carnation and Picotee Society's show; Wolverhampton Floral Fête (3 days); Saltaire, Shipley and District Rose Society's show (2 days); National Rose Society's provincial show at Wakefield. Wednesday, July 12.—Ipswich and East of England Horticultural Society's show (prov.); East Anglian Horticultural Society's meeting; Sheffield Chrysanthemum Society's meeting; National Sweet Pea Society's annual show in the Winter Garden, Devonshire Park, Eastbourne (two days); Richmond Horticultural Society's show. Thursday, July 13.—Bristol and District Gardeners' Association's meeting; Woodford Horticultural Society's show; Manchester and North of England Orchid Society's meeting. Friday, July 14.—Paisley Florists' Society's meeting; North Lonsdale Rose Society's show. Saturday, July 15.—Elstree and District Horticultural Society's show at Aldenham Park.

"The Gardeners' Chronicle" Seventy-Five Years Ago.—Writing for the "Chronicle." It has been wisely observed that "Knowledge is nothing but as it is communicated." By imparting to others we enrich ourselves. He who waits until truth receives its due homage from the world, may wait until the tide of human agency ebbs finally away for ever, and he who neglects present opportunities will inevitably be found a loiterer upon the shore of that vast ocean of truth which lies before him. They who seek the grounds of their responsibility as instructors of others, have only to resolve the question into one of moral obligation, and from it they will derive a motive and an impulse to exertion equal to their highest capacity; though with Newton in intellect, they rise to the investigation of distant worlds, or with Milton in inspiration, or with Handel in harmony, they soar into the third heavens of poetry and song. He who has once opened a fountain of truth can never close it again, and he who is living to himself is defeating the great end of his existence. The communication of knowledge constitutes one of the highest sources of human enjoyment, but they who revile it in the character and example of others, know nothing of its regenerating influence in their own. The preceding remarks are intended as an answer to the oft-recurring question: "Why do you give away your knowledge by writing in the *Chronicle*?" They who are accustomed to complain of other people's liberality, seldom question their own aright, and probably forget that, though some minds, like small streams, can afford to lose nothing, there are others which, like majestic rivers, can impart of their abundance, and remain unimpoverished.—W. Wood, Fishergate Nurseries, York.

**Publications Received.**—*Vines: Useful Hints for Amateurs.* By Douglas Wood, Homewood Hall, Sturry, Kent. *The Gardener: A New Geographic.* By A. T. Shearman, Beech Villa, West Cowes, Isle of Wight.

NOTICES OF BOOKS.

Indian Timbers.\*

FOR a long time the standard work on Indian Timbers by Mr. J. S. Gamble has been out of print, and impossible to obtain even second-hand. We are grateful to the Secretary of State for India, who has recently published a reprint of the second edition of this valuable work, unaltered except for the addition of two short appendices, containing notes and descriptions of a few timbers which were sent to Mr. Gamble in late years.

This work is well known to all who are interested in the structure of wood, and in the

pocket lens, magnifying from 5 to 20 times. This will not serve, however, to distinguish accurately sections of Coniferous woods, which often require to be examined with a high power. We may here note a curious error in the *Manual*, pp. 695, 718, where it is said that resin canals are absent in the wood of the Indian species of Spruce, and present in the wood of the Indian Silver Firs. This is not the case, for in India, as elsewhere, resin canals occur in the normal wood of Picea, and do not occur in that of Abies. The sporadic occurrence of resin canals in the latter genus as a result of injury, need not mislead, as these are irregular in size and form and only appear in an odd ring.

FIG. 7.—ANEMONE GLAUCOPHYLLA; R.H.S. FIRST-CLASS CERTIFICATE, JUNE 27, 1922 (SEE P. 12).

accurate distinction of the various species. It is impossible to get away from the necessity of making accurate investigations of useful timbers. During the war, woods entering into the construction of aeroplanes were submitted to rigorous scientific tests, as a matter of stern duty, for the substitution of an inferior species would have meant horrible accidents. In almost all branches of wood utilisation, scientific knowledge of timbers would be of financial benefit to the user.

Mr. Stone's little *Guide to the Identification of Useful Timbers*, can be consulted if Mr. Gamble's introductory remarks on structure are not detailed enough for the beginner. Mr. Gamble claims that he notices only characters which are capable of being observed with a

It is to be hoped that the publication of this book will help to stimulate an interest in Indian timbers, which are now being pushed much more than formerly on the London market. Some of the woods are remarkable for beauty, as will be remembered by those who visited the Empire Timber Exhibition at the Holland Park Skating Rink, in July, 1920. Furniture, panelling, parquet flooring, and a crowd of miscellaneous articles were shown, made of woods from India, which had been previously unknown, or at any rate little appreciated in the European timber trade. A. Henry.

"Country Life" Booklets.—Three booklets of garden interest in the "Country Life" Booklets series have been sent us by the publishers. They are entitled: *Border Carnations and Cloves*, by Mr. James Douglas; *Tomato Cultivation under Glass and Outdoors*, by Mr. R. V. Giffard Woolley; and *Pot Plants and How to Preserve Them*, by W. Truelove. The price of these useful little books is only 9d. each.

\* *A Manual of Indian Timbers.* An account of the Growth, Distribution, and Uses of the Trees and Shrubs of India and Ceylon, with descriptions of their Wood-Structure. By J. S. Gamble. Reprint of Second edition, with some additions and corrections. Pp. XXVI., 868; 20 plates. (London, Sampson Low, Marston & Co., Ltd., 1922). £3 3s. net.

## The Week's Work.

### THE ORCHID HOUSES.

By J. T. BARBER, Gardener to His Grace the DUKE of MARIACROUGE, K.G., Blenheim Palace, Woodstock, Oxon.

**East Indian House.**—Orchids which enjoy the temperature of the East Indian House include *Angraecum sesquipedale*, *A. Ellisii* and *A. arcuatum*. Although these plants are found in different parts of the world, they are all more or less natives of tropical regions, hence the necessity of growing them in the warmest house. Those that have started into growth and in need of attention as regards repotting should be attended to immediately new roots are observed. The plants all delight in a moist, tropical atmosphere whilst making their growth, but sun-light and fresh air should be admitted with discretion. These evergreen plants are not capable of withstanding strong sunshine, and if exposed to too much, will soon assume a sickly, spotted, and unhealthy appearance. Some need more shade than others, hence the necessity of closely observing the progress of each individual plant, especially those that are rare, as many of these subjects may not again be imported for some years. The whole of these epiphytal Orchids succeed well in live *Sphagnum*-moss.

**Coelogyne pandurata.**—Of all the beautiful members of the genus *Coelogyne* there is none to compare with this fine species, and especially the best varieties of it. It usually flowers in May and June, from partially developed pseudo-bulbs, and its emerald green flowers have black markings which form a most striking contrast in colouring. From the time that growth begins, usually in December, or early in January, until the flowers have faded and the growth is matured, the plant should never be allowed to become dry. When the new pseudo-bulb is completed, the water supply should be decreased, as, should the supply be over liberal, the pseudo-bulbs may decay. It should be grown in the warmest house at all seasons, and does best in a shallow Orchid pan, filled with a clean, open, fibrous compost. This Orchid should be kept shaded during the summer, and should never be subjected to a low temperature. It delights in a moist, humid atmosphere whilst making its growth, and may be frequently sprayed or syringed as a preventive against red spider, which will attack the leaves, these being of a somewhat coriaceous nature. The best season to repan or repot the plant is when the young growth is about to develop roots. The roots being rather large, the compost should be used in a fairly rough state. The usual precautions of applying water to newly potted plants must be strictly adhered to with this plant, or failure may occur.

### FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Liagfield, Surrey.

**Melons.**—Young plants should be available for use as vacancies in the pits and frames occur. Melon seed will germinate freely now, and the best results are obtained when the plants are put out early, say, when the first rough leaf is about two inches wide. Melon culture is easy after May, the main requirements of the plants being a good bottom-heat, sound, calcareous loam, mixed with old lime rubble as compost, and common-sense attention in airing and watering. With attention to these details the plants will grow without a check, and the foliage will not ripen before the fruits. For frame culture late in the season the compost should always be on the poor side, as it is much easier to feed the roots than suppress strong growth. The bottom-heat should be brisk and steady, especially when the fruits are finish-

ing, as declining bottom-heat and flooding the soil with water when the fruits are ripening results in the flavour of late Melons being inferior. The weather of the latter part of May and up to the present has been all that could be desired for Melons, but conditions may change, hence the importance of maintaining the necessary warmth by adding fresh manure on the outsides of the frame when necessary, and covering the glass at night with mats.

**Early Vineries.**—The vines in the earliest houses will now be clear of bunches, and should be copiously syringed rather late on fine evenings. A little soft soap and sulphur should be added to the water for syringing if spider or mildew has been troublesome. Inside borders, which have been allowed to get, rather dry, should be restored, without loss of time, to a thoroughly moist condition, but, before watering, the surface should be lightly pricked over to ensure an even distribution of the water. If the vines are young and vigorous, clear water only will suffice, but for older vines, which make weaker wood and but few laterals, use a liquid fertiliser. The mulching material should be allowed to remain in position; where this has not been used, fresh stable litter should be placed over the surface to prevent evaporation. If the covering still remains intact on outside borders, it may now be reduced in depth, but some inches should be allowed to remain, and water from the hose, provided the rains have not been sufficient, applied liberally to it. Ventilation on a liberal scale, both day and night, will now be necessary. Plenty of fresh air and the use of the syringe will play an important part in the ripening of the wood.

**Succession Vineries.**—Houses containing ripe Grapes should be kept cool and airy, and where black varieties are losing colour, slightly shaded for a few hours on bright days. White Grapes, on the contrary, cannot have too much light, provided they do not burn. The borders and floors may be liberally damped and the walls syringed frequently. A change to damp and dull weather when air cannot be admitted freely will necessitate a much drier treatment, otherwise the berries of such varieties as *Madresfield Court* may crack.

### THE KITCHEN GARDEN.

By JAMES E. HATFIELD, Gardener to JOHN BRENNAND, Esq., Baldersby Park, Thirsk, Yorkshire.

**Coleworts.**—Make a sowing of *Roset's Colewort* to obtain plants for setting out later.

**Broad Beans.**—The plants should be tipped as soon as a goodly number of flowers have set. Black *Aphis* should be checked by syringing with *Quassia* extract before the insects have time to multiply.

**French Beans.**—Sowings should be made for late crops of French Beans within the next fortnight. If the ground is dry, soak the seed for a few hours before setting them in drills that should be well watered.

**Peas.**—Quick-growing early varieties should be sown now to supply late crops. The seed should be sown thinly, for if sown thickly the plants become crowded and are then susceptible to attacks of mildew. The seedlings should be protected from birds, which are often most troublesome at this season of the year.

**Cucumbers.**—A sowing of Cucumbers should be made now to keep up the supply of fruits well into the autumn. Plants in full bearing should be kept well thinned, as the growths quickly become crowded. Rich top dressings of old manure should be applied to the roots, and the atmosphere of the house or frame kept charged with moisture.

**Parsley.**—Make a sowing of Parsley now in drills, thinly, to form the winter supply. Where two or three light, portable frames are available, sow in drills the width of the frame, which may then be placed over the bed in the autumn.

### HARDY FRUIT GARDEN.

By H. MARHAM, Gardener to the EARL of STRAFFORD, Wrotham Park, Barnet.

**Figs.**—Where the roots of Fig trees are much restricted water should be applied at intervals, especially if the trees are large and bearing heavy crops. The roots and growth will be greatly benefited by a good mulching of decayed cow manure, placed over the soil before soaking the borders with water. Attend to Fig trees trained on walls, and remove all superfluous growth, also weak and ill-placed shoots; some of the shoots may be stopped, but sufficient sturdy, young growths should be neatly secured their full length to the walls for filling the space and for fruiting next year. If the present crop is a heavy one some of the fruits may be pulled off, leaving the best and sufficient for a full crop. *Brown Turkey* is one of the best varieties for outdoor cultivation.

**Strawberries.**—Old, forced plants that were put out some time ago should be kept supplied with moisture and the surface of the beds mulched. If the soil is good and mulching material scarce, keep the surface soil loose by hoeing it at intervals; this will help to retain the moisture and assist the growth of the plants considerably. New stock should be obtained from the nurseryman at reasonable intervals; if any is required this season, the order should be forwarded at once, so that the plants may be dispatched as early as possible.

**Morello Cherries.**—Should the young shoots of Morello Cherries become infested with black *aphis*, syringe the foliage with *Quassia* extract or nicotine wash. As a rule, these trees are trained in fan shape, and the fruits are produced on young wood similar to that of the Peach, so that an ample number of healthy shoots should be neatly secured in the position most needed both for fruiting and filling the space. Train each shoot as straightly as possible, leaving ample room in the ties or shreds for the bark to swell. Endeavour to keep the whole of the trees from the bottom to the top rather thinly furnished with young fruiting wood. Some of the shoots that are not required may be shortened to within a few buds of the base, and these, when shortened more closely at the winter pruning, will furnish a good supply of fruit.

**Raspberries.**—The canes should be covered with netting to protect the fruits from birds. Before doing this, remove superfluous young canes, and secure to the trellises, so far as is possible, those that will be required to take the place of the present fruiting canes as soon as the crop has been gathered. Place a mulch, if necessary, along the rows, and water the roots copiously with liquid manure. This will greatly assist the plants to form large berries and lengthen the season as well as increase the strength of the young canes.

### PLANTS UNDER GLASS.

By T. PATEMAN, Gardener to Sir C. NALL-CAIN, Bart., The Node, Codicote, Welwyn, Hertfordshire.

**Propagating.**—Plants used for furnishing, such as *Panicum*, *Selaginellas* in variety and *Tradescantia* may still be propagated. Cuttings of these plants will root very easily at this season, and young specimens are always useful for decorative purposes.

**Stocks.**—Autumn-flowering and winter-flowering Stocks may be sown now and again during the last week in August to prolong the season of flowering. A beautiful show of these flowers may be obtained during the autumn and spring. In fact, if suitable varieties are chosen they may be had in flower practically all the year round by sowing seed at intervals during the spring and summer. Some of the best varieties suited for pot cultivation are *Sutton's All-the-Year-Round*, *Beauty of Nice*, *Christmas Pink*, *Carter's Perpetual Royal Purple*, and *Queen Alexandra*. Stock seed germinates very quickly, and at this season of the year fire heat is not required for the raising of seedling Stocks. The seedpans

should be stood in a cold frame and the soil in them shaded from bright sunshine until germination takes place, when the seedlings should be gradually exposed to the light. When the seedlings are large enough to handle they may be pricked out singly into small 60-sized pots, or three may be placed in each receptacle and grown on intact. Stocks are very partial to lime, and a liberal quantity of old mortar rubble should be mixed with the soil in which they are grown.

**Souvenir de la Malmaison Carnation.**—By this date most of the Malmaison Carnations have passed out of flower, and preparations should be made for the layering of the plants to raise fresh stock. To obtain good plants it is necessary to take layers from young, healthy specimens and not from plants that have been grown on for two seasons. The plants may be layered in a cold frame, and a good depth of soil is necessary to admit of carrying out the work successfully.

### THE FLOWER GARDEN.

By EDWIN BECKETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Hertfordshire.

**The Rockery and Rock Edges.**—Many of the plants in the rock garden have finished flowering, and the stronger growing subjects may need to be kept in bounds, or they may smother their smaller growing neighbours. Aubrietias, Violas and trailing Phloxes need special attention in this direction, and *Lithospermum prostratum* is another vigorous grower. Such plants should be well trimmed back after flowering, in order that new growth may develop from near the root stocks to replace the old growths, and not break from the ends of old shoots, which would mean a rambling and ragged plant of poor appearance. Further, this cutting back should result in a good quantity of fine, sturdy growths, suitable for propagating as cuttings, for from now onwards the propagator should be busy raising new stock. Care should be taken that alpinists do not suffer from lack of moisture in summer, and it is an excellent plan to give the rockery and rock edges a good sprinkling with water each evening, after hot days, to ensure a cool root run for the plants.

**Perpetual Flowering Carnations.**—These, when they have finished their period under glass, should be stood out of doors to harden off, and at this season may be planted out in the open. Lift them carefully from the pots, disturbing the roots as little as possible, and plant in rich, light soil in rows. Place a neat stick to each plant, and secure the sticks themselves by tying them to a string run along the rows from stakes set well in at the ends of the rows. Tie the plants carefully, and loop in the growths with a strand of raffia; when this is finished, well soak the roots with water, after lightly hoeing the surface of the soil, and then mulch the ground with long, stable litter. If this work is done carefully and thoroughly, and the plants given good attention afterwards, they will yield a plentiful crop of flowers.

### PLANTS NEW OR NOTEWORTHY.

#### AESCULUS INDICA.

ALTHOUGH the beautiful Indian Horse Chestnut was first introduced by Colonel H. Bunbury, from the North-West Himalayas, in 1851, very few flowering trees appear to exist in the British Isles. The original tree, some 70 feet in height, is probably still thriving at Barton, in Suffolk.

Cut specimens from a tree flowering in the Royal Botanic Gardens, Kew, were given an Award of Merit at the meeting of the Royal Horticultural Society on Tuesday, June 27. This it is to be hoped will induce planters to find a place in their pleasure grounds for a very beautiful tree. Flowering during the second half of June and early July, it is four or five weeks later than the common Horse-Chestnut. It has the familiar white flower with a red and yellow blotch, but on a longer, more slender (cylindrical) panicle (see Fig. 8), up to

12 to 15 inches long and 4 to 4½ inches wide at the base. The shining dark green leaves, mostly consisting of seven leaflets, give the trees the character of almost sub-tropical luxuriance.

#### RHODODENDRON DISCOLOR.

AMONG the many new species introduced from China during the past twenty-five years, many *Rhododendron* cultivators consider *R. discolor* (Fig. 10) to be one of the most valuable acquisitions. Not only is it a useful evergreen, and a beautiful flowering shrub, but being at its best during the second half of June, hybridists are finding the species valuable in the breeding of a race of free-blooming hybrids which will be at

it is desirable, perhaps necessary, to plant this species in the open woodland, or under similar conditions—but not in dense shade—where the plants will have ample shelter from the mid-day sun.

For the introduction of *R. discolor* to our gardens, we are indebted to Mr. E. H. Wilson, who first sent home seeds from Szechuan, in 1900, when collecting on behalf of Messrs. James Veitch and Sons, and, later, also from Western Hupeh. He describes it as a common *Rhododendron* of the woods growing up to an elevation of 7,500 feet. It forms a robust, strong-growing, evergreen bush up to 20 feet high. Normal leaves are 5 inches to 8 inches long, and 2 inches

FIG. 8.—INFLORESCENCE AND FOLIAGE OF *AESCULUS INDICA*.

their best about mid-summer. There is a wealth of flowers during May, and the first half of June, but, at least in the south, there is little of value after this date. True, there are *R. maximum* and *R. brachycarpum*, but breeders have found these of little value, though they are hoping for much from *R. auriculatum*, also from China. This species does not flower until August, but at Kew it lacks the free-flowering character which is such a valuable trait of *R. discolor*.

Flowering towards the end of June, and making its growth during July, the subject of this note is in marked contrast to the majority of the Himalayan *Rhododendrons*, which flower and start into growth early, consequently there is some difficulty in affording the plants shelter from spring frosts. Blooming and growing late, this trouble does not arise with *R. discolor*, but

to 3 inches wide, but robust young leaves on vigorous shoots are sometimes nearly 1 foot long, and 4 inches wide; oblong or narrowly oval, they taper almost equally at both ends, are dark green above and pale green beneath. The flowers vary very considerably in size, and in colour from white to pale pink, often with a mauve tint. The open, funnel-shaped flowers are 6-7 lobed, the largest 5-5½ inches across, and have a pleasing fragrance.

*R. discolor* belongs to the *R. Fortunei* group, but it is later flowering than that species, has longer leaves, those on *R. Fortunei* being heart-shaped at the base, and the calyx, though small, is more conspicuous than in *R. Fortunei*.

*R. discolor* received the First-Class Certificate of the Royal Horticultural Society on Tuesday, June 27, when flowers were exhibited from the Royal Botanic Gardens, Kew. A. O.

## EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, W.C.2.

Local News.—Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturalists.

Letters for Publication, as well as specimens of plants for naming, should be addressed to the EDITORS, 5, Tavistock Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

## GARDENERS' CALENDARS.

No. 1.—EVELYN, MILLER, ABERCROMBIE.

I HAVE never seen any article, book, or pamphlet which deals exclusively with this particular branch of gardening bibliography. It seems a strange omission, considering the great and prolonged popularity of these books, and also how our greatest and most famous practical gardeners have in a sort of orderly sequence given them to an appreciative world.

Take these four men—John Evelyn, Philip Miller, John Abercrombie, and Joseph Paxton; it would be difficult to select another four to excel them in what may be called a working knowledge of plants and gardens, yet each of them thought it worth his while to devote a certain part of a busy life to the writing of a Gardener's Calendar. How well they read the wants of their fellow-gardeners of less experience than themselves is to be seen in the number of editions or reprints that each separate work went through before it ceased to be. These were righteous books if any books ever have been. They were the efforts of the strong to see their weaker brethren over the stile of comparative ignorance. They are the divided cloaks of garden St. Martins given to horticulture to clothe the dry bones of the small knowledge which some of her devotees possessed. Hence it is a particularly beneficent work on the part of the proprietors of *The Gardeners' Chronicle* to continue to keep Paxton's *Calendar of Garden Operations* up to date in such simple fashion that even cottage gardeners, allotment holders, and amateur gardeners may have an easily understood and at the same time a reliable help at hand against the time of need.

We will never know if Evelyn evolved the idea of a *Kalendarium Hortense* (1664) (Fig. 9) out of his own brain and by a happy inspiration hit upon the very thing that was wanted (editions prove the need); or whether he got the hint from Thomas Tusser, who in his famous *Five Hundred Points in Husbandry* (1562) warns the good housewife when to sow her Peas or gather her Strawberry plants from the woodlands.

"Sow peason and beans on the wane of the moon;

Who soweth them sooner, he soweth too soon."  
(February Husbandry.)

"Wife, into thy garden, and set me a plot,  
With strawberry roots, of the best to be got;  
Such growing abroad, among thorns in the wood,

Well chosen and picked, prove excellent good."  
(September's Husbandry.)

Or whether the idea came from the *Royal Ordering of Gardens*, of Bacon, who in his famous essay *On Gardens* pointed out the beauties of the different seasons:—

"For December and January and the latter part of November you must take such things as are green all Winter: Holly, Ivy, Bayes, Juniper, Cypress-trees, Eugh, Pine-Apple-trees, Fir-trees, Rosemary, Lavender, Periwinkle, the White, the Purple and the Blew. . . . In May and June comes Pincks of all sorts, especially the blush Pinck, Roses of all kinds, except the Musk, which comes later, Hony-Suckles, Strawberies, Bugloss, Columbines, the French Marygold, etc., etc.," and so on through the months.

Whether the idea came from Tusser or Bacon, or whether it was wholly Evelyn's own, we will never know. However it arose, it

speaks volumes for the clear vision and far-sightedness of the man who in the midst of an exceptionally busy life made time to write this little book, which he himself cannot have regarded as the least of his many works, for on the title-page of his *Acetaria, A Discourse of Sallets*, published in 1699, he thought fit to describe himself, not as the author of his much larger work, *Sylva*, but as "Author of the *Kalendarium*." Another fact which proves his estimation of it is that he dedicated the work to his friend Cowley, the poet:—"To Abraham Cowley, Esq. Sir, This Hortulam Kalendar is yours." My copy is one of the eighth edition (1691), and immediately after the dedication there is

letter to Lady Sunderland, dated August 4, 1690, he states that the *Kalendarium*, on the reputation of his worthy friend Mr. Cowley, "has survived seven impressions."

I must at this point beg leave to make two asides. First, that it will always be a great feather in Cowley's cap that he was able to win the regard and affection of such a man as Evelyn. This one fact alone should silence critics who affect to see in all Cowley's references to the country and garden nothing but insincerity and make-believe. Secondly, that it is surely rather a big omission in the *Dictionary of National Biography*, under John Evelyn, to find no reference to what is surely one of the largest books that has never been

FIG. 9.—FRONTISPIECE TO EVELYN'S "KALENDARIVM HORTENSE."

printed "The Garden, to J. Evelyn, Esq.," which commences with words which are often quoted, "I never had any other Desire so strong and so like Covetousness, as that one which I have had always that I might be Master at last of a small House and large Garden," and the poem proper contains that most celebrated verse beginning:

"Methinks I see great Diocletian walk

In the Salonian Garden's rural shade."

I am unable to say which edition of the *Kalendarium* first contained Evelyn's dedication of the work to Cowley and its counterpart, Cowley's poem, "The Garden," which in turn was dedicated to Evelyn, but they are not found in the first (1644), which was bound up with the *Sylva*, just in the same way as many years later Paxton's *Calendar* first saw the light of day in the pages of *The Gardeners' Chronicle* (1842), but I expect they are to be found in a very much earlier one than the eighth, from which I have quoted, as in a

written, the *Elysium Britannicum*, or, The plan of a Royal Garden, in which the *Acetaria* already mentioned and the *Kalendarium* were to figure as single chapters. What a book it would have been! In one chapter alone, gardens in Italy, Flanders, France, Germany, Turkey, America, and England (in all over a hundred and fifty) were to be described, not to mention "miraculous and extraordinary gardens found upon huge fishes' backs, men grown over with flowers, etc." Read, too, the title of another chapter, for the contents of which he sought the help of Dr. Browne (Sir Thomas Browne), of Norwich—"Chapter V. Of Crowns, Chaplets, Garlands, Festoons, Encarpa, Flower-Pots, Nosegays, Poesies, Deckings, and other Flowery Poms." Yes, it would have been a book, magnificent, illuminative, and one before which all others would fall down and do homage. The *Kalendarium* was to be one of this great company.

The next in chronological order of my four selected "giants" is Philip Miller, who lived

in the first half of the eighteenth century. One is tempted to make use of the very ancient phrase, "too well known to need any description," and at once pass on to say something about his calendar, which is our point of contact with him in this article. Philip Miller was born in 1691 and died in 1771. He held the official position of gardener to the Apothecaries' Company at their garden at Chelsea, but it was through the publication of his great epoch-making work, *The Gardener's Dictionary*, of which a greater than he wrote, "*Non est Lexicon Hortulanorum sed Botanicorum*," that he became famous, a fame which grew with the years until in the end he was the acknowledged uncrowned king of the gardening world, "*Hortulanorum princeps*." Again, like Evelyn, this wonderful genius considered it well worth his while to write a calendar. He had "exhibited in his *Gardener's Dictionary*, under the heads of each respective month, a calendar of the works necessary to be done in the Kitchen, Fruit and Flower-Gardens." This, his friends told him, would be much more useful if he would publish it separately in a small volume at a reasonable figure. He, accordingly, "set about the work," and, in order to make it as complete and useful as possible, he went over his garden notes, making additions and corrections wherever necessary, and for convenience of reference he disposed the months according to their order of time, and not in the alphabetical order he was obliged to observe in his *Dictionary*.

While he was busy preparing the book for publication, it came to his ears that it was the "ungenerous intention of some persons to publish something of this nature from his *Dictionary*." Not wishing to be forestalled, he accordingly hurried on with his work as fast as he could, with the result that what I believe was the first edition of his calendar as an independent work appeared in 1732. It is perplexing to find that four authorities of repute each give a different date, viz., 1724, 1731, 1732, and 1734, for the first edition. This discrepancy is perhaps accounted for when it is remembered how this calendar was born in the *Dictionary*, thus making it to some extent a question of choice which should be considered to be the first edition. Miller's Calendar held its own for a long time, and that, too, during a period when calendars were very much the vogue. During the eighteenth century it would be safe to say somewhere between twenty and thirty authors broke out into this form of garden literature. What one author says of himself, "that he is not discouraged by the number of similar books already extant," is obviously true of all; but, however many they may have been, all were, so to speak, swallowed up in the course of time by those of John Abercrombie, whose greater work, *Every Man His Own Gardener*, originally published in 1767,\* was still popular when the nineteenth century was well over fifty years old, and whose smaller *Gardener's Pocket Journal*, which was first brought out in 1791, is said to have had a greater sale than any other horticultural work that had hitherto appeared *Joseph Jacob*.

### GARDEN NOTES FROM S.W. SCOTLAND.

AMONG the multitude of Roses that glorify the month of June, I venture to mention two specially deserving notice. The first is a recent acquisition from China, *Rosa Fargesii*, which, if it be a distinct species, closely resembles *R. Moyesii* in every respect except the colour of the petals, which is a peculiarly luminous carmine. The other is the climbing variety of Nabonnand's old H.T. hybrid, Papa Gontier. The dwarf type of this Rose is only of moderate vigour: it is remarkable, therefore, that the climbing form has reached a height of 18 feet on a south wall, and at the moment of writing (June 26) is covered with large, cherry-

coloured blossoms. It is also a good autumn flower.

Among upwards of eighty species of *Allium* enumerated in the *New Hand List* of 1902, few have found general favour with amateurs owing to the all-pervading odour of Garlic, which renders the cut flowers objectionable to sensitive nostrils. Nevertheless, there are a few kinds which I should be very sorry to dismiss from the herbaceous border. Two of these are now flowering profusely, namely, *A. sub-hirsutum*, from Southern Europe, bearing a cloud of starry white blossom, and the North American *A. acuminatum*, carrying flat heads of rosy-lavender flowers. Both species grow to a height of about 18 inches and carry themselves well. My favourite in the genus is *A. sphaerocephalum*, with globular heads of dark crimson, borne quite erect on wiry stems, 2½ feet high; but that species does not flower here until August.

A new-comer here is flowering for the first

### ORCHID NOTES AND GLEANINGS.

#### ODONTIODA BERMELETTE.

CLIVE COOKSON, Esq., Nether Warden, Hexham-on-Tyne (gr., Mr. W. J. Stables), sends a flower of this exceptionally fine *Odontioda*, originally raised by C. J. Phillips, Esq., at Sevenoaks, between *Odontioda Charlesworthii* and *Odontoglossum Her Majesty*, the grand unrecorded hybrid for which the raisers, Messrs. Charlesworth, gained a First-Class Certificate at the great International Show of 1912.

The flower sent us is of the size and form of *Odontoglossum crispum*; the sepals and petals are dark mahogany red, with a violet shade. The lip is very broad in the upper part, and has an undulated margin, the colour being rosy mauve. The crest and base of the lip has some light yellow lines.

FIG. 10.—RHODODENDRON DISCOLOR (SEE P. 19).

time and proves to be a herb of much merit. This is *Mimulus Bertonianus*, with blossoms resembling those of *Incarvillea Delavayi*, of soft crimson colour, with a hairy yellow throat and rows of darkest crimson dots to guide insect visitors to the nectary. I know nothing about the origin of this species, nor where I obtained it; but it is infinitely superior both in colour and habit to the old *M. Lewisii*.

Another new-comer I received last year in a gift from a generous lady, *Perezia multiflora*, which, though a native of Brazil, came through 9° of frost in April unharmed. It is a Composite, bearing on very succulent branching stems, two feet high, quantities of lavender blossoms with yellow central florets. *Lilium columbianum*, the gift of another good friend, is flowering here for the first time. Of modest stature, it bears its Turk's-cap flowers of soft, yet vivid, orange-yellow, mottled with dark purple, on stems about 15 inches high. *Herbert Maxwell, Monroith*.

**The Wall Garden at Keir, Perthshire.**—An excellent example of gardening on a built wall is to be seen in General Stirling's garden at Keir. It reminds me of a very beautiful wall garden at Pollok, Glasgow, the property of General Stirling's brother, Sir John Stirling Maxwell, one which is well known to lovers of rock plants. *Visitor*.

#### LAELIO-CATTELEYA SOUTHFIELD GEM.

W. WATERS BUTLER, Esq., Southfield, Edgbaston, sends a flower of his charming new hybrid raised between L.C. Martinetti (*C. Mossiae* × *L. tenebrosa*) and L.C. Ganymode Southfield variety (*C. Schröderae* × *L. Latona*). It is a very worthy addition to the favourite class which includes L.C. Thyone and the still nearer L.C. Oriflamme (*L.C. Thyone* × *C. Rex*) of Messrs. Armstrong and Brown.

L.C. Southfield Gem has flowers of fine form and substance; the sepals and petals are bright Buttercup yellow, without a shade of any other colour, and the crimped and slightly fringed lip violet crimson, changing to a lighter tint towards the margin, which is cream colour. The base of the lip is yellow, with several reddish violet lines. The parentage is complex, but each of the four species included in its ancestry is indicated in some degree in the hybrid.

#### SEED SOWING.

MANY seed pods are approaching maturity, and directly the seed is ripe, it should be sown in prepared pots, or around the base of an established plant of the same family.

The raising of seedling Orchids is most fascinating work, and wherever exceptional varieties of Orchids exist, their hybridisation should be attempted. *B.*

\* Again, various authorities give different dates. How came this discrepancy? *J. J.*

## INDOOR PLANTS.

## PALMS.

No plants cultivated under glass are better adapted for purposes of decoration, whether in the mansion, the conservatory, or the ordinary living room of the humbler classes than Palms. Many of the hardier kinds are well suited for plunging out-of-doors in sheltered situations during the summer with good effect. They are, to all intents and purposes, the most useful of all foliage plants, by reason of their light and graceful habit and long lasting qualities. To recommend the extensive cultivation of so ornamental and generally useful a class of plant as Palms would, by those acquainted with their charming and valuable qualities, be deemed almost superfluous. Yet before the introduction of *Kentia Belmoreana*, *K. Forsteriana*, *Cocos Weddelliana*, and a few other choice kinds in the early 'seventies of the last century, they were scarcely to be found in this country save in a very few exceptionally large establishments or botanic gardens.

The most gigantic members of the race may be cultivated and enjoyed in any ordinary warm greenhouse or conservatory of moderate dimensions for nearly a life-time without fear of their outgrowing their position. Few other plants give so rich and tropical an affect as Palms. They are indispensable in house and ball-room decorations, while the beauty and grace of many species render them invaluable as table plants. Their utility in a small state is well known, particularly so in the case of the light and more elegant kinds. At the present time *Kentias*, *Cocos*, *Phoenix*, and others are grown by the tens of thousands for market on account of their well-known durability, usefulness, and light and graceful appearance. They endure the atmosphere of rooms in which coal-gas is consumed better than almost any other plant, and require much less attention, provided they are not allowed to get dry at the roots. Their cultivation generally is extremely easy, the matter of temperature being of the first consideration. The next point to be observed, besides occasionally repotting, and cleansing of the foliage, is to give them liberal supplies of water at all times, with a moist atmosphere, especially when in active growth during the summer.

Generally speaking, Palms may be divided into two classes, those of a light and graceful habit, which may be grown in small pots, or as specimens 20 to 30 feet high, and others of a hardier constitution, with more bushy, compact growth and dwarfer in habit. These last thrive well in a cooler atmosphere during the winter, and are most suitable for plunging out-of-doors in sheltered situations throughout the summer, where they give a tropical effect to their surroundings. The following include the most useful of the light, graceful kinds:—

**KENTIA BELMOREANA.**—This fine Palm is admirably adapted for exhibition purposes, or the ornamentation of the conservatory, mansion, or ball-room. It is very elegant and graceful in habit, and may be grown in thumb pots or in 2½-inch to 3-inch pots, 9 inches to 12 inches high. Such specimens are suitable for furnishing small vases. The plants may also be grown as large specimens, some 20 to 30 feet high.

**KENTIA FORSTERIANA** somewhat resembles *K. Belmoreana*, but is more robust in its habit of growth, and the leaves are broader in all their parts. This Palm requires similar treatment to *K. Belmoreana*.

**COCOS WEDDELLIANA** (see Fig. 11).—This is the most graceful Palm introduced, and the most useful for small drawing-room vases. It makes beautiful specimens 2 feet to 3 feet high when grown in pots 5 inches to 6 inches in diameter.

**COCOS FLEXUOSA.**—This is a particularly light and graceful Palm, invaluable for decoration when it becomes 8 feet to 15 feet high, but is not characteristic in a small state.

**GEONOMA GRACILIS.**—This is an elegant, dwarf-growing Palm of very graceful habit, somewhat resembling the beautiful *Cocos Weddelliana*. It

is a most useful plant for the dinner table, as well as general decorative purposes.

**PHOENIX ROEBELINII.**—The newer *Phoenix Roebelinii* is a very distinct and beautiful species remarkable for its light, compact, graceful, drooping habit, and is most valuable as a dinner-table plant, or as a specimen in an ordinary living-room.

**PHOENIX RECLINATA** is a good plant for living-rooms, being light and graceful in habit.

**ARECA LUTESCENS** is another useful Palm, very ornamental and effective.

**SEAFORTHIA ELEGANS** is a graceful Palm when grown into half specimen or specimen size.

FIG. 11.—COCOS WEDDELLIANA.

This Palm is not so much utilised as formerly, as the *Kentias* and *Cocos* are more lasting.

All these Palms, when in a small state, require a moist atmosphere, and a temperature from 65° to 70°. As they get larger and are required for use a temperature of 55° to 60°, with atmospheric moisture, is sufficient to harden them for general decorative purposes. They do not require large pots, as they stand better when grown in comparatively small receptacles, with plenty of roots that should not be allowed to get dry. Syringe the plants on two or three occasions daily in hot weather. A little liquid manure is beneficial to them when growing in a warm house.

They may be raised from imported seed sown in heat, in pans or well drained pots. As soon as the seedlings are 2 inches to 3 inches high they should be potted singly in thumb pots and placed in a warm temperature.

The best compost for Palms is a rich fibrous loam mixed with a little peat or leaf mould, well-rotted cow manure and silver sand.

The following do well in a low temperature of 40° to 45°, and are suitable for standing in corridors, halls, or cool rooms, where they will remain in good condition for a long time, if given proper attention in watering and kept clean. Many of them are almost hardy in sheltered situations, requiring only slight protection during severe weather. Amongst the best are *Chamaerops excelsa*, *C. Fortunei*, *Areca sapida*, *Corypha australis*, *Latania borbonica*, *Rhapis flabelliformis*, *Phoenix rupicola*, *P. canariensis*, and *P. dactylifera* (the Date Palm).

There are many other choice kinds suitable for collections, such as *Stevensonia grandifolia*, *Sabal*

*Blackburniana*, *Pritchardia grandis*, *P. pacifica*, *Licuala grandis*, *Latania aurea*, *Euterpe edulis*, *Thrinax elegans*, *Kentia canterburyana*, and *Versaffeltia splendida*, but there would be a difficulty in procuring some of them.

Cycads and *Zamias* are foliage plants intermediate in character between Ferns and Palms. They make fine subjects for the decoration of greenhouses and conservatories, and in the summer they are admirable for the adornment of terrace gardens and walks, to which they lend a charm unattainable with any other plant. Their gracefully recurved and deeply and regularly pinnate leaves also give them a good position amongst exhibition plants. They are easy of culture, requiring very little attention, and will succeed in an ordinary warm greenhouse or conservatory. They may be increased by suckers. Cycads should be grown in a rich, loamy soil; a free drainage is essential for these plants, which should not be overpotted. They will grow well in a winter temperature of 50° to 55° and a summer temperature of 60° to 70°. *John Neal.*

## TREES AND SHRUBS.

### A FINE BED OF ANDROMEDAS.

WHILST on a brief visit to Havering-atte-Bower recently, I was privileged to see a very fine bed of *Andromedas* growing in Havering Park, the beautiful estate, wherein is situated the home of Mrs. C. McIntosh. The plants were in full flower, producing a fine picture. The bed was planted about the years 1867 to 1870, and comprises a number of plants which now form a well furnished group at least 50 yards in circumference, the height of the plants being 9 feet in several cases. They have evidently discovered an ideal rooting medium, and those of us who know how difficult it is to even persuade some of the less fastidious members of the *Ericaceae* to grow where the rooting-medium is not peaty, will naturally feel rather envious of Mrs. McIntosh in her possession of such lovely examples of plants of the Heath family, making fine, vigorous growth.

Havering Park is situated at a fairly high point above the town of Romford, and the water supply is a serious proposition, and one which last season was very acute, yet, despite this handicap, one sees on every hand magnificent collections of *Rhododendrons*, and allied plants, of which the bed of *Andromedas* is probably the very finest gem, with their pretty racemes of Lily-of-the-Valley-like flowers. *E. Beckett.*

### VERONICA BALFOURLIANA.

THE above shrubby species was introduced from New Zealand in the form of seeds to the Edinburgh Botanic Garden, where it was first flowered and from whence it was figured and described in the *Botanical Magazine*, t. 7,556, by the late Sir Joseph Hooker. No one seems to have gathered it since in New Zealand. Even Cheeseman had to quote the original description for his *Manual of the New Zealand Flora*, as he had never seen a specimen. Under certain conditions it will make a bush 3 ft. high, but indoors 18 in. to 2 ft. seems to be about its range. The species is closely allied to *V. Traversii*, but is dwarfer, with short leaves having a reddish-brown margin, and closer habit of growth. The flowers are purplish-blue, not white as in the last-named. The bark of the shoots is also of a dark purple, so that altogether it does not resemble *V. Traversii* very closely to a casual observer. In the group to which it belongs the racemes of flowers are said to be rarely branched, but quite a good percentage of the racemes have one to three side branches when the plant grows out of doors. I have branching racemes of *V. Traversii*, but they are quite uncommon. *V. Balfouriana* has withstood the frosts of several past winters unprotected. The hybrid *V. Guthrieana* sometimes does service for it, but that seldom exceeds 6 in. in height, and the flowers are larger and of a deeper blue. *J. F.*

## HARDY FLOWER BORDER.

### DIVIDING AND REPLANTING PYRETHRUMS, IRISES, AND PAEONIES.

It needs not to be said that hardy plants become too big to fulfil the object of having them in a garden—the object of producing a profusion of flowers of good quality—and before they become so crowded with growths it is important to divide and replant them. At this season the chief plants that demand attention in this way are *Pyrethrums*, *Irises* of the *Pogoniris* section, and herbaceous *Paeonies*. Though it is difficult to find time for work of this kind at present, it is not impossible where there is the will. The labour involved may be spread over more than one season by doing one kind in one year, another in a second, and yet another in a third, though work of this kind is more rapidly overtaken when it is all done at once or in detail. I grow single *Pyrethrums* only, and these

are ready first to operate on. The soil of sizable clumps is apt to become very hard and dry by the time flowering is over, unless a more than usually copious rainfall moistens it. Usually it may be necessary to soak the clumps for 24 hours previous to dividing them, when it is easily accomplished without damaging either foliage or roots. Each clump should be torn into halves by means of two forks working against each other. Then the soil can be washed from the roots, and the pieces separated by hand and into sizes according to the wish of the operator. They should be planted, according to the nature of the soil, from  $\frac{1}{2}$  inch to 1 inch lower than the spring of the leaves, and a reasonable quantity of manure should be worked into the soil when planting. One soaking of water will generally be sufficient. In beds for cutting not less than 9 inches should be allowed for interspaces.

well as downward, so firming each tightly. The distance to plant should be not less than 1 foot apart. As to watering, that, of course, depends on the weather, but never more than a very slight application to each set is required, and that only till root action has become vigorous. A thick mulch of rotted manure should not be omitted, and renewed annually.

Later than these, *Paeonies* are ready to be divided. It may be found necessary to soak old plants in water similarly to *Pyrethrums*, and in any case it is worth while to wash most of the soil off the roots previous to breaking them up. Here, again, two forks should be employed, not only to halve them, but also to subdivide them into smaller pieces fit to plant. *Paeonies* are gross feeders, and the ground for a fresh plantation should be manured to a depth of 6 inches with rotted

FIG. 12.—ROSE MRS. HENRY BOWLES: SEE AWARDS BY THE NATIONAL ROSE SOCIETY, p. 25.

In northern gardens, June planting of *Irises* is not possible, because they are, unless of the earlier sorts, still in flower, nor are their new roots formed till the next month, so that, at the earliest, division must not be attempted until July. I have established them successfully with all the old rhizomes and their roots removed, but probably most will incline to leave an inch or two of rhizome with its roots, which, however superfluous otherwise, at least helps to steady the young plant until new roots in sufficient number are produced to effect that object. Sometimes a quite short stick may be required for ensuring stability, especially when the blades are very strong. The soil, if at all loose, should be slightly firmed before planting, and, as the rhizomes run along the surface, planting should be only deep enough to give the pieces a grip of the soil. When set, all that is needed to firm them is a slight pressure with the tip of one's boot, the pressure being a little forward as

cow-dung, and in addition to that a thick layer applied to the surface and worked in while the operation is proceeded with. The stems of the leaves should be tied together to prevent breakage, and every care taken to save the roots, the washing of which will be found of great advantage to that end. Once planted, a stout stake is needed to which to tie the plants, and an abundant supply of water poured about each to moisten the ground all round and to a fair depth. A thick mulch of cow-dung should be applied to the plants each spring before growth pushes, an inch or two of soil being previously scraped off and returned on top to prevent birds from scratching and to hide the dung. I should have added that at least 3 feet should separate the plants when setting them out, and to preserve the flowering stems from growing crooked a ring of string supported on sticks should be run around the large plants before the stems are much in evidence. *R. P. Brotherston.*

## MESEMBRYANTHEMUM AND SOME NEW GENERA SEPARATED FROM IT.

(Continued from page 8.)

36. *C. pusillum*, N. E. Br. Growths 4-7 lines long,  $2\frac{1}{2}$ - $3\frac{1}{2}$  lines broad and 2-3 lines thick, obconic, varying from nearly circular to elliptic-oblong at the convex top (as type D, but much smaller), greyish-green, marked with irregular brownish-crimson (or in sunless seasons dark green) lines. Flowers not seen. *M. pusillum*, N. E. Br., in *Journ. Linn. Soc. Bot.*, v. 45, p. 99.

South Africa. Locality and collector unknown.

This is closely allied to *C. labyrinthum*, but seems to be distinct by its rather smaller growths, which have a greater tendency to be circular in outline, and are marked with fewer and less crowded lines.

37. *C. signatum*, N. E. Br. Growths 4-7 lines long,  $3\frac{1}{2}$ -5 lines broad and  $2\frac{1}{2}$ -4 lines thick, obconic, with the flattish or but slightly convex or faintly notched top often somewhat overhanging the sides (type G), and oblong or elliptic in outline, somewhat grey-green, marked in a labyrinth-like manner with rather crowded, irregular, dark brownish-purple lines, or in winter-time deep grass-green with the markings of a darker green. Flowers not seen. *M. signatum*, N. E. Br., in *Journ. Linn. Soc. Bot.*, v. 45, p. 100.

South Africa. Locality unknown, Pillans.

This is allied to *C. labyrinthum* and *O. pusillum*, but is distinguished at sight by the growths being more tapering to the base and the top flatter and often inclined to overhang the sides.

38. *C. minusculum*, N. E. Br. Growth 3-5 lines long,  $3\frac{1}{2}$  lines broad and  $2\frac{1}{2}$ - $3\frac{1}{2}$  lines thick, obovoid, elliptic in outline at the convex top, often slightly notched at the orifice (somewhat as type D, but much smaller), at first bright green, becoming dull green and often suffused with purple, very minutely and densely dotted with white, with the orifice surrounded at a little distance from it by a somewhat diamond-shaped dark green or dark purple ring, and outside of the ring are some irregular dark purple or dark green disconnected lines. Calyx 4-lobed. Corolla 8-15 lines in diameter, expanding in daytime irrespective of sunshine; tube 5-6 lines long, dull orange below, fading into yellow at the top; petals of two kinds, an outer series of 16-20, widely spreading linear-spathulate, obtuse, and  $1\frac{1}{2}$  line broad, bright magenta, shading into light yellow at the base, and an inner series of 5-6 small and very acute petals that are sometimes magenta and sometimes (on the same plant) orange-yellow tipped with purple. Stamens 6-8 included in the corolla-tube, yellow. Style  $\frac{1}{2}$  line long; stigmas 4, less than  $\frac{1}{2}$  line long, dark orange. *M. minusculum*, N. E. Br., in *Kew Bull.*, 1913, p. 118.

Clanwilliam Div., near Clanwilliam, Pillans.

This is one of the most beautiful species in this genus, the prettily marked growths and the richly coloured flowers, which are much larger than the growths, make it a very attractive plant.

39. *C. paxillum*, N. E. Br. (Fig. 13). Growths 5-7 lines long,  $3\frac{1}{2}$ -6 lines broad and  $3\frac{1}{4}$  lines thick, obconic, convex, with a small transverse notch at the centre of the oblong or elliptic-oblong top (type E), varying from chalky-green or pale greyish-green to dull green, marked with separate dots and lines formed of confluent dots of purple-brown or dark green, usually a line extends from each side of the orifice over the top, and the other lines and dots are irregularly scattered on the other part, or there is a series of three lines radiating from each side of the orifice. Calyx 4-lobed. Corolla 4-7 lines in diameter, expanding in the evening, closed during the day, scentless, tube about as long as the calyx; petals 20-26, lax, whitish or very pale straw-coloured. Stamens 16-20, with the upper anthers shortly exerted, pale yellow. Style  $\frac{1}{2}$ -1 line long; stigmas 4, shorter than the stamens, about  $1\frac{1}{2}$  line long, plumose-filiform, greenish. *M. paxillum*, N. E. Br., in *Journ. Linn. Soc. Bot.*, v. 45, p. 97 (1920).

South Africa. Locality unknown, Pillans.

40. *C. bulbum*, N. E. Br. Growths 5-6 lines

long,  $2\frac{1}{4}$  lines broad and  $2\frac{1}{2}$ - $3\frac{1}{2}$  lines thick, obconic, elliptic to nearly circular in outline at the convex top, glaucous-green, with a few short lines formed of connected dots and a few separate dots of a rather darker dull green, but not very conspicuous. Calyx 4-lobed, entirely dull reddish. Corolla about 7 lines in diameter, expanding in the evening; tube not exceeding the calyx; petals whitish. Stamens shortly exerted; anthers light yellow. Ovary dome-shaped on the top. Style less than  $\frac{1}{2}$  line long; stigmas

FIG. 13.—*CONOPHYTUM PAXILLUM* N. E. BR. NATURAL SIZE; PHOTOGRAPHED AT 8 P.M.

4. nearly twice as long as the style, slightly thickened upwards.

Laingsburg Div., near Laingsburg, Pole Evans, 6916 A. N. E. Brown.

(To be continued.)

## THE ROSE GARDEN.

### THE ROSE TRIALS AT BAGATELLE.

THE annual meeting of jurors appointed to inspect and judge the new Roses at Bagatelle, Paris, met at 9 a.m. on the 15th ult. As usual, the jury was international in character, including five British, two Dutch, and one American, the remainder being prominent French Rose growers.

Unfortunately, owing to the heat of May the Roses were almost entirely over, only a few flowers were to be seen, indeed, there were so few that the Jury discussed the question of postponing judgment until September next. It was, however, decided to inspect the plants as they were and to deal with the question of awards after inspection.

After examining the fifty-two varieties under trial the French members suggested that a Gold Medal should be awarded to the best introduction by a raiser other than French, and the award to the best French novelty deferred until September next.

The variety selected for the Gold Medal was *Elvira Aramayo* (Messrs. Loomans and Son, Holland). This is brightly coloured, somewhat in the style of the *Queen Alexandra*; the bloom was almost over and did not seem to possess much substance, but judging from the growth it would appear to be free flowering.

The best of the French introductions as they appeared on the date of inspection was *Jules Tarbart* (Barbier and Co.), a *Pernetiana* Rose of vigorous growth and with good foliage; the bloom is large, full and well-formed; colour salmon-pink with coppery coral centre. This, as seen at Orleans, was superb. Next came *Jacotte*, a *Wichuraiana* hybrid of undoubted superiority as seen at Orleans, where it covered a pole quite eight feet in height and was a mass of bloom from base to summit. The colour is beautiful and novel, being an orange-yellow toning to deep copper, tinted coppery red. *Madeline Pacaud* (Chambard) is a medium-sized flower in the *Madame Léon Pain* style of colour; this was not of great merit as seen growing.

*Geisha*, an orange-yellow sport from *Madame Edouard Herriot*, resembles *Cambrai*. *Madame*

*Edouard Herriot Panachee* is a striped sport from *Madame E. Herriot*. Neither of these appealed to me. *Toison d'Or* (*Pernet Ducher*), apricot-yellow, shaded orange red, was only partly developed, so that it was impossible to form a correct opinion of its merit.

As already mentioned, most of the Roses were over, and the decision to make a second examination in September next was a wise one, and it is hoped the plants will be in such condition as to admit of forming an opinion of their worth. Unfortunately the soil at Bagatelle is not by any means suited to the successful growth of Roses, and consequently it is not possible under present conditions for Roses planted there to do themselves justice, especially in a dry season such as we have passed through. The staff had endeavoured by a good mulching of manure and frequent applications of water to counteract the weather, but with very little effect.—N.

### ROSES AT DRYNHAM.

OUR Rose garden is exceedingly beautiful just now. We planted some four hundred new bushes last season, and they have all done exceedingly well in their first year. Our soil is very light, but we plant in good Kentish loam, with bone meal and soot as manure. Our fifteen hundred Rose bushes are all comparatively free from aphids this season. They were sprayed with nicotine insecticide on two occasions. It was quite different last season, when we had to spray on many occasions to keep the aphides under. I find spraying with clear water from 6 p.m. to 8 p.m. is of very great benefit to the plants. Pillar and Rambler varieties have been exceedingly fine this season, as also have *R. Moyesii* and *R. Fargesii*, species which are not always particularly free in blooming. Amongst the very large number of Roses grown in these gardens, the following have done best:—*Cheerful*, *W. C. Gaunt*, *Mon. Paul Lédé*, *Pharisæer*, *Cambria*, *Mathilda Liegarde*, *Daily Mail*, *White Maman Cochet*, *Ed. Bohane*, *Mme. Antoine Mari*, *Golden Ophelia*, *Mme. Abel Chatenay*, *Mme. Léon Pain*, *Lady Hillingdon*, *Hugh Dickson*, *Red Letter Day*, *Mélanie Soupert*, *Prince de Bulgarie*, *Rosa Moyesii*, *Persian*, *Frau Karl Druschki*, *Caroline Testout*, *Mme. Ravary*, *Lady Pirrie*, *Lyon*, *Mme. Jean Dupuy*, *Marie Van Houtte*, *Rêve d'Or*, *Irish Elegance*, *Flame of Fire*, *Comtesse du Cayla*, and *Mme. Eugène Resal*. *W. A. Cook*, *Drynam Gardens*, *Walton-on-Thames*.

## THE BULB GARDEN.

### SCILLA CAMPANULATA AND S. NUTANS.

THE Spanish (*campanulata*) and the English (*nutans*) Wood Hyacinths are literally all over my garden. The Wood Hyacinths are allowed to seed as they like and to grow as they like. It is surprising how many shades of blue and pink (?) have turned up. If I wished I could also select many different types of habit. Not only do *Scilla nutans* and *S. campanulata* differ from one another, the first-named bearing its flowers in the form of a bishop's crozier and the last-named in candelabra fashion, but the seedlings of each one differ amongst themselves. Just before the war began I started to select a few of the best, but that has been quite given up, I regret to say; all the same it shows there are possibilities.

My present purpose in this note is two-fold (1) to say that Wood Hyacinths should be left undisturbed as much as possible. They become taller and finer in every respect with age; (2) to advocate their use with tall, May-flowering Tulips in bedding. Such combinations as these look fine: (a) *Moonlight* and a blue Wood Hyacinth; (b) *Euterpe* and a pink Wood Hyacinth; (c) *Golden Bronze* with a white; (d) *Edmée* or *Baronne de la Tonnaye* with a blue; and so on. Those to whom the idea is novel will be surprised at its effectiveness if they will give it a trial and choose their combinations with discretion. First-sized bulbs only should be used in order to get the best results. *Joseph Jacob*.

HOME CORRESPONDENCE.

[The Editors do not hold themselves responsible for the opinions expressed by correspondents.]

**Giant Larches.**—I was much interested in the correspondence on pages 258, 294, and 337, vol. lxxi, relating to giant Larches at Dunkeld, Arniston, and Aberystwyth, that has arisen out of my note. I have received a communication from Dr. Henry giving some useful information upon Larches; he states that isolated Larches rarely reach over 100 ft. in height. The Dunkeld parent Larches are about 100 ft. high, while in the plantations at Dunkeld, the height runs to 125 ft. He also states it is difficult to give more than an approximation of the age of a tree, as the rate of growth will depend on the soil and other circumstances. He also observes that he had just received particulars of a Larch cut down at Kentock, near Cupar-Fife; it was 104 ft. high and 9 ft. 2 in. girth at 3 ft. from the ground, and the rings on the stump showed it to be 152 years old. Starting from the centre of the tree and taking one half of the stump, the number of rings are given in years, and the years in inches, thus we get, starting from the centre, 20 years, 2½ inches; 60 years, 3 inches; 35 years, 3 inches, 20 years, 2 inches; 21 years, 4 inches; bark 3 inches. Total number of inches from centre to the outside wood 14½ inches, this does not include the bark. Dr. Henry considers the Coombe House, Croydon, Larches may be about 150 years old, as they may have grown a little faster than the one at Kentock. This estimate appears to me to be as nearly correct as possible. Several of the specimens at Coombe House have no doubt finished their growth in height, as their tops are bare of growth and bend over in the shape of a whip; they are not dead, otherwise they would break off; they appear to be green and tough, yet without foliage for about four or five feet. In this neighbourhood Larches have suffered from disease, but I do not consider these giants have been affected in any way by it. We have lost several specimens lately, but this I attribute to the drainage system of Croydon, causing several specimens of various trees to die through dearth of water at their roots. *Mark Mills.*

**Digitalis purpurea monstrosa.**—Times out of mind a strain of seed of Foxglove has been obtainable, which gives a large terminal, regular flower of a purple colour. Seeds are now obtainable that give white flowers and several shades of rose. I have examined a white one that has neither shading nor spots of purple. The flowers have a slight shade of cream when young, otherwise the variety is a pure albino. The regular, terminal flower has twenty shallow lobes and sixteen stamens, so that it really consists of four flowers in union. There are eighteen to twenty lobes to the calyx, which is variously fissured, the deeper ones resembling the numerous bracts present. Two of the lobes are white. The regular flower of this old garden curiosity is, therefore, fasciated. It continues to interest people who have not seen it before. The top flower opens long before the raceme has completed its growth. *J. F.*

**Gypsophila paniculata fl. pl.**—At present there are two large plants of this variety here, and if the present stock in gardens originated from a single plant, it is remarkable how these should differ in foliage and in flowering. The foliage of one is glaucous, that of the other light green, so distinctly different that one might take them for separate forms. In flowering one is earlier than the other, the later of the two usually not being so regular in flowering as to be fully open when stopped by the cold of late autumn. Next to there having been two forms of double, would it be possible that the stocks—no doubt seedling singles—have influenced the plants to the extent these exhibit? Both are of great value as decorative plants, and long sprays—two or three feet in length—are employed here for vase furnishing, in conjunction with other seasonable border flowers. *R. P. Brotherston, Tynningham Gardens.*

SOCIETIES.

NATIONAL ROSE.

JUNE 29.—Fortunately, about ten days of cool weather preceded the date of the National Rose Society's show at Regent's Park, consequently flowers were in excellent condition on the show day. Had the earlier tropical weather continued the show would not have been a success, whereas, thanks to the altered conditions, it was one of the finest displays of Roses seen for many years. Competition was good, especially in the larger classes, and the flowers were of good size, form and colour. Rain fell at intervals during the day, but this did not appear to have any effect upon the attendance.

New Roses exhibited for medal or other awards were numerous, and the tent wherein these seedlings and sports were staged was, as usual,

exhibition, garden and bedding purposes. The colour is golden yellow, shaded with coppery red; very effective. Shown by Rev. J. H. PEMBERTON, Havering.

**Lady Verey.**—A dwarf bedding or garden Rose.—It is a Hybrid Tea of clear, rich shell-pink colour, of beautiful form in the bud stage, while the open blooms are of medium size and a trifle thin. A very pretty Rose, but apparently lacking fragrance. Shown by Mr. ELISHA HICKS, Twyford.

**Alice Amos.**—This is a dwarf polyantha variety and apparently very free-flowering. The flowers are single, 1½ inch to 2 inches wide, rich reddish rose with whitish centre. The blooms remind one of those of American Pillar, but they are smaller and brighter. The raisers state that this variety flowers freely in the autumn. Foliage small, dull green, leathery. Shown by Messrs. D. PRIOR AND SONS.

FIG. 14.—ROSE CAPTAIN KILBEE STUART.

thronged with visitors. The way in which the new Roses were criticised by the visitors was evidence of the keenness with which a host of amateurs are cultivating the Queen of Flowers.

Awards.

GOLD MEDALS.

**Mrs. Henry Bowles.**—A large, finely formed Hybrid Tea variety, with broad petals that make up a substantial bloom of exhibition style. The colour is rich pink, flushed with carmine. Foliage dark and shining. Slightly fragrant. Gained a Certificate of Merit in 1921 (See Fig. 12). Shown by Messrs. CHAPLIN BROTHERS, Waltham Cross.

**Capt. Kilbee Stuart** (see Fig. 14).—This velvety crimson scarlet variety has been shown on numerous occasions, and is already fairly well known to Rose enthusiasts. The large-petalled flowers are shapely and will reach exhibition size. Stems long and sturdy; foliage very dark and leathery. Richly fragrant. Shown and raised by Messrs. ALEX. DICKSON AND SONS, Newtownards.

CERTIFICATES OF MERIT.

**Ruth.**—This Hybrid Tea Rose is of globular form, and the variety is said to be useful for

**J. G. Glassford.**—For its wonderful fragrance this Rose deserves wide cultivation, but it has also the merit of good form and large size, while its cherry red colouring is most attractive, though some flowers indicated that in some kinds of weather the outer petals may fade to an unpleasant magenta. It is a perpetual-flowering Hybrid Tea Rose of much merit. Shown by Messrs. HUGH DICKSON, LTD., Belfast.

**Bessie Chaplin.**—A vigorous, large-flowered Hybrid Tea Rose, with very full blooms which often resemble in shape the fine old La France. The colour is silvery pink, but not so silvery as in the case of La France. Shown by Messrs. CHAPLIN BROS.

**Lady Roundway.**—A gorgeous Pernetiana Rose shown for the first time. If this should prove to be an easily grown and free-flowering bedding variety it cannot fail to become popular. The colour, rich golden orange, is arresting. Leaves dark and shining. Raised and shown by Messrs. B. R. CANT AND SONS.

**Innocence.**—A lovely single Rose of vigorous habit, and said to be perpetual-flowering. The blooms are 4½ inches in diameter and composed of broad, rounded petals, white, faintly tinted blush at the margins. The buds are of pretty

and pointed shape, cream yellow, and this colour persists until the blooms are fully expanded. Sweetly fragrant, with Tea Rose scent. Shown by MESSRS. CHAPLIN BROS., Waltham Cross.

#### SILVER MEDAL BLOOMS.

The customary Silver Medals were awarded to the following as being the best blooms of their respective types in the two sections:—

**NURSERYMEN'S CLASSES:**—H. P., Louise Crette, shown by MESSRS. G. and H. BURCH; H. T., Mrs. George Marriott, shown by MESSRS. ALEX. DICKSON AND SONS; T., Mrs. Campbell Hall, shown by Mr. GEORGE PRINCE.

**AMATEURS' CLASSES:**—H. P., Candeur Lyonnaise, shown by Mr. S. W. BURGESS; H. T., Mildred Grant, shown by Mr. A. R. REEVES; T., W. R. Smith, shown by Rev. F. R. BURNSIDE.

#### NURSERYMEN'S CLASSES.

The championship class for exhibition Roses was again a great triumph for MESSRS. ALEX. DICKSON AND SONS, who, for the second year in succession, won the coveted trophy with a superb collection. MESSRS. ALEX. DICKSON AND SONS also repeated their last year's success in the class for thirty-two distinct trebles, and in the whole of their 168 Roses there was not a single weak bloom. Mr. ELISHA J. HICKS is to be congratulated on winning the Group Championship for three successive years.

As stated above, the Nurserymen's Challenge Trophy, with a Gold Medal and money prize, was won by MESSRS. ALEX. DICKSON AND SONS with a superb collection. This was characterised by blooms of even size, freshness and rich colouring. The seventy-two distinct varieties included such sterling sorts as Mrs. G. Marriott (the Silver Medal H. T. Rose), Archie Gray, Mildred Grant, Marjorie Bulkeley, Snow Queen, Florence Pemberton, Dean Hole and Lady Inchiquin, though all were deserving of mention. MESSRS. HUGH DICKSON, LTD., were a very good second; their choicest blooms were Gorgeous, Mildred Grant, Alex. Emslie, Mrs. G. Marriott, Pink Pearl, E. Godfrey Brown and Mrs. J. Laing. MESSRS. D. PRIOR AND SON, who were third, had very fine examples of Gorgeous, Snow Queen, George Dickson and Florence Forrester.

Of the splendid first-prize collection of 32 distinct varieties, three blooms of each, by MESSRS. ALEX. DICKSON AND SONS, the very best were Mrs. G. Marriott, Edward Bohane, Mrs. Fred. Searle, Molly Bligh, Dean Hole and Lady Barham. MESSRS. B. R. CANT AND SONS were second, and their outstanding sets were of Gorgeous, Lemon Pillar, H. V. Machin, Hugh Dickson and Edith Cavell; MESSRS. D. PRIOR AND SON were third.

Competition was not quite so good in the class for 48 exhibition varieties, nor was the quality of the same high standard as in the former classes, but Mr. GEORGE PRINCE, who won the first prize, had very fine blooms of Edith Cavell, Golden Emblem, Mrs. E. Mawley, Margaret Dickson Hamill and Modesty. In the second prize exhibit of Mr. CHAS. GREGORY there were especially good blooms of George Dickson, Lyon Rose and William Shean. Mr. HENRY DREW was third.

In the extra class, for 24 distinct varieties, first prize was won by Mr. JOHN PIGG with a praiseworthy collection, which included White Maman Cochet, Col. Oswald Fitzgerald, Mrs. W. J. Grant, H. V. Machin and Golden Emblem. MESSRS. CHAPLIN BROS. were second with such sorts as J. B. Clarke, George Dickson and Florence Pemberton. Mr. HENRY DREW proved to be the winner in the class for 8 varieties, three blooms of each, and of his good sets, Golden Emblem, Gorgeous, Mrs. R. D. McClure and Margaret Dickson Hamill were the very best. Mr. CHAS. GREGORY was second, and MESSRS. G. and H. BURCH were third.

Tea and Noisette Roses showed signs of damage by the weather, and in some instances the colouring was only moderately good. The best 18 varieties were by Mr. GEORGE PRINCE, who had Auguste Comte, Mrs. H. Taylor, White Maman Cochet and Mrs. Campbell Hall. Mr. HENRY DREW, with such as W. R. Smith, Mr. Foley

Hobb and Lady Plymouth, was second; and MESSRS. D. PRIOR AND SON, who had very good examples of Madame Jules Gravereaux and Maman Cochet, were third.

The Kilbee Stuart Cup, for 12 blooms of new Roses distributed since January 1, 1918, resulted in an interesting competition, and was won by Mr. GEORGE PRINCE, who had good examples of J. G. Glassford, Mrs. Lamplough, Mrs. Darlington, Princess Victoria and Edith Cavell. MESSRS. HUGH DICKSON, LTD., showing Mrs. J. R. Allen, Marjorie Bulkeley, Alex. Emslie and Margaret M. Wylie, amongst their twelve, were second. The 12 best blooms of any single new Rose were of the silvery pink Marjorie Bulkeley, by MESSRS. HUGH DICKSON, LTD.; vivid blooms of The Queen Alexandra Rose, by Mr. ELISHA J. HICKS, were second; and the rich pink, Mrs. Henry Morse, by MESSRS. G. and H. BURCH, were third. Showing good blooms of Earl Beatty, a very fragrant bright crimson, much of Château de Clos Vougeot type, and the bright Waltham Crimson, MESSRS. CHAPLIN BROS. were awarded the first prize for two baskets of new Roses not yet in commerce.

The baskets of Decorative Roses were fully equal to those at any of the former shows. The best seven baskets of distinct varieties were shown by MESSRS. CHAPLIN BROS., who repeated their success of last year with superb arrangements of such varieties as Isobel, Col. Oswald Fitzgerald, Mrs. Henry Bowles, K. of K., and Golden Emblem. MESSRS. ALEX. DICKSON AND SONS were a good second with, amongst other varieties, Sunstar, K. of K., Lady Inchiquin, Betty Uprichard and Margaret Dickson Hamill. Mr. MATTOCK had the best three baskets, showing Mrs. Henry Morse, Los Angeles and Château de Clos Vougeot. Mr. CHAS. GREGORY was a good second with Golden Emblem, Christine and Emma Wright.

There were also classes for single baskets of any one variety of the several types. The best H.P. was Snow Queen, shown by MESSRS. CHAPLIN BROS., and MESSRS. D. PRIOR AND SON were second with the same variety. In the H.T. Class, Mr. G. PRINCE was first with Edith Cavell, and MESSRS. W. and J. BROWN were second with George Dickson. The best basket of T. Roses was that of Madame Jules Gravereaux, by MESSRS. D. PRIOR AND SON, while MESSRS. W. and J. BROWN, with Mrs. Foley Hobbs, were second.

#### GROUPS OF ROSES.

The congratulations of all rosarians will go to Mr. ELISHA J. HICKS, who, for the third successive year, has secured the Championship Trophy, Gold Medal and First Prize in the large group class. This most meritorious exhibit was of high quality decorative Roses arranged with the skill now expected from Mr. HICKS. The cross arches of such as Red Letter Day, associated with Blush Rambler and Joanna Bridge with Aviateur Bleriot were a distinct feature of these large collections, and he also showed excellent stands of Hoosier Beauty, Ethel James, Columbia, Ophelia, Lady Hillingdon, Mrs. Henry Sawyer, with many other valuable sorts. MESSRS. B. R. CANT AND SONS, who were a worthy second, set up their collection on more conventional lines, showing excellent large vases of Paul's Scarlet Climber, American Pillar, Emily Gray, Flame of Fire, Lady Pirrie, and Christine, amongst a great many varieties.

MESSRS. CHAPLIN BROS. won premier honour in the class for a group 20 ft. by 4 ft., amid very strong competition, and their arrangement was noteworthy for the glowing colours of the massed varieties. Mrs. Henry Bowles, George Dickson, Ophelia and Paul's Scarlet Climber are the names of only a few of the sorts so well shown. MESSRS. A. J. and C. ALLEN were a good second, and their outstanding sorts were Golden Emblem, Ophelia, Mrs. Henry Morse and K. of K.

The 36 vases of distinct varieties which won the A. C. Turner Cup for MESSRS. F. CANT AND CO. were of very high quality. They included Moonlight, Miss Ada Francis and Braiswick Charm of the Cluster Roses with The Queen

Alexandra Rose, Cambria, and Donald McDonald of the larger double varieties. Mr. MATTOCK was second, and his best blooms were of Constance, Mr. Curmook Sawday, Rayon d'Or and Mrs. Redford. MESSRS. J. JEFFRIES AND SON were third. MESSRS. W. and J. BROWN had the best 12 vases of the useful dwarf Polyantha Roses and included beautiful sprays of Etoile de Mai, Perle d'Or, Mrs. W. H. CUTBUSH, Léonie Lamesch and Baby Tausendschön. Mr. JOHN MATTOCK was second and in his fine collection, the vase of Rödhätte was very prominent. With an excellent collection MESSRS. CHAPLIN BROS. were first in the class for 18 vases of decorative Roses.

#### AMATEURS' CLASSES.

As in the nurserymen's section history repeated itself with the amateurs for the Championship Trophy, Gold Medal and First Prize were won for the second time in succession by Mr. H. L. WETTERN, Oxted. His was a particularly good board of 36 exhibition blooms and included superb flowers of Hugh Dickson, Avoca, George Dickson, Her Majesty, Freda, Mrs. W. J. Welch and Mrs. F. Denison. Dr. R. E. TURNBULL, Colchester, was second, but his blooms, though shapely and of good size, showed traces of the inclement weather. His best sorts were Mrs. Edward Mawley, Hugh Dickson, H. V. Machin and Lyon Rose. Mr. JOHN HART, Potter's Bar, had the best 24 exhibition varieties, and these also were a trifle weather stained, though otherwise, very good indeed. The outstanding sorts were Gorgeous, J. L. Mock, Joseph Welch and Mildred Grant. Dr. TURNBULL was second in this class, which he won last year, showing Rev. F. Page-Roberts, Mrs. G. Marriott and Lemon Pillar of good quality.

The class for 12 distinct blooms brought very good competition, and the first prize exhibit by Mr. J. E. RAYER, Worcester, was excellent; it included Mrs. G. Marriott, Candeur Lyonnaise, Madame Jules Gravereaux and Mrs. Theodore Roosevelt. Dr. T. E. PALLETT, Earls Colne, the second prizewinner, had good blooms of George Dickson, Mrs. Henry Morse and Lemon Pillar. Dr. PALLETT, took chief honours in the very strong class for 8 varieties, 3 blooms of each; his triplets of Mildred Grant, Mrs. G. Marriott and Mrs. W. J. Welch were excellent. Mr. G. SPEIGHT, Market Harborough, was second. In the class for growers of fewer than 1,000 plants, Mr. F. H. FIELDGATE, Colchester, staged 12 splendid blooms of such varieties as Lady Barham, Candeur Lyonnaise and Mrs. J. Laing. Mrs. HENRY BALFOUR, Oxford, was a very good second. Mr. FIELDGATE also won first prize with 8 splendid triplets of such sorts as Mrs. J. H. Welch and George Dickson. Mr. R. DE V. PRYOR, Hitchin, was the most successful exhibitor of 12 varieties in the section for growers of fewer than 500 plants, and Mr. F. G. HAYES took first prize in the similar class for 6 varieties, 3 blooms of each, while Mr. RAYER, with Snow Queen, won first prize for 6 blooms of any one variety.

The best 24 distinct blooms in the extra class for amateurs who grow their own Roses were Mr. G. SPEIGHT's, who had admirable blooms of Dean Hole, Lady Barham, George Dickson and E. Burnett.

The metropolitan classes illustrated the fact that, within the prescribed radius, practically all varieties may be grown successfully. The first winner of the Williamson Challenge Cup was Mr. JOHN ROFF, Wood Green.

Baskets of Roses were very popular with the Amateurs and the many excellent examples were very pleasing. The first prize-winners were Mr. G. SAWDAY, High Wycombe, with Hugh Dickson in the class for one variety, and Mr. G. MARRIOTT, who was first in the three remaining classes, where he had excellent baskets of Lyon Rose, Mrs. Foley Hobbs, and Los Angeles. Mr. MARRIOTT was first also in the class for an arrangement of Roses on a space 5 ft. by 3 ft., where he had beautiful vases of K. of K., Lady Pirrie, The Queen Alexandra Rose, Flame of Fire and Golden Emblem, and he had the best 12 varieties. Dr. M. LACROZE

was second with a generous display, though rather heavily arranged.

Tea and Noisette Roses on the chief stands were exceptionally good. The Rev. F. K. BURNSIDE won the Trophy and Gold Medal with beautiful blooms of such as W. R. Smith, Madame C. Soupert, Mrs. Foley Hobbs and Medea. Mr. W. E. MOORE, showing splendid blooms of Auguste Comte, Alex. Hill Gray and Mrs. Foley Hobbs, was first in the class for 9 Tea or Noisette varieties.

#### DECORATIVE CLASSES.

The decorations of cut Roses were all staged in one large, beautifully light tent, and there was ample space for the comfort of visitors. The main displays were of decorated tables, in four classes, the combined number of exhibits totalling thirty-four.

The nurserymen's classes included one for a dinner table decoration of cut Roses, lightly arranged with Rose foliage only. Six competed in this class, and the first prize was awarded to Mrs. MAY, Waltham Cross, for an elegant arrangement of Ophelia Roses in a large centre bowl and four smaller ones at the corners. The foliage employed was of Rose Willmottiae and R. rubrifolia; 2nd, Mrs. ARTHUR R. BIDE, "Highlands," Guildford Road, Farnham, who employed Emma Wright, a semi-double coppery-red variety; 3rd, Miss PEMBERTON, Havering-atte-Bower, with a new, semi-double, warm rosy-red variety named The Adjutant, which was most dainty and the equal to any for freshness, colour, simplicity and utility, as such a decoration would be possible for an actual dinner table arrangement.

The three classes for decorated tables of Roses in the amateurs' section attracted twenty-eight competitors. There were nine entries in the class for single-flowered Roses, which lend themselves admirably for dainty arrangement in bowls and vases. The first prize was awarded to Mrs. COURTNEY PAGE, Earldoms, Ridgeway, Enfield, for Irish Elegance, relieved with long sprays of Rosa Willmottiae in one large, centre bowl, and eight smaller ones; 2nd, Mrs. BARTON, Chappel, with Isabelle, but too much material for practical purposes; 3rd, Mrs. OAKLEY FISHER, Barrow, with Mrs. Foley Hobbs, a most dainty decoration of a tall vase in the centre, surrounded with eight tiny vases and one at either corner.

The class in which single Roses were excluded was well contested by eight exhibitors, the premier award going to Mrs. COURTNEY PAGE for a charming decoration of Madame Butterfly, the centre piece being a perfect bowl of Roses. The use of yellow vases was very daring and not to everybody's taste, but the result was the best of its kind in the show, for the yellow base of the blooms gave perfect harmony to the scheme; 2nd, Mrs. ALEX. ROBINSON, Bourne End, with Ophelia; 3rd, Mrs. OAKLEY FISHER, Harrow, with Golden Emblem.

In the class for a decorated table, the Roses to be grown by the exhibitor, there were eleven competitors, and the first prize was won by Mrs. BARTON, for Padre, Sunstar and Irish Elegance varieties, which harmonised in tone; 2nd, Mrs. COURTNEY PAGE; 3rd, Mrs. EDGAR BURNETT, Southampton.

The best low bowl of Roses was shown by Mrs. BARTON; the first prize for a bowl of mixed Roses was awarded to Mrs. OAKLEY FISHER, but as only Ophelia was employed, the exhibit did not seem to agree with the conditions of the schedule; Mrs. EDGAR BURNETT excelled in the class for a bowl of cut Roses arranged with Rose foliage only, with Irish Elegance. The best vase of Roses, Ophelia, was shown by Miss ETHEL JAMES, Abingdon. Mrs. SIDGWICK, Ingatstone, had the best bowl of Roses in the class for lady amateurs who have never won a first prize in the decorative section of these shows, with Mrs. Tate variety.

#### NON-COMPETITIVE EXHIBITS.

The corridor was, as usual, filled with non-competitive exhibits. Messrs. ALLWOOD BROS. had a magnificent display of Carnations of all types, including a large number of their new

perpetual border varieties. Messrs. ANDREW IRELAND AND HITCHCOCK, Marks Tey, showed Sweet Peas of outstanding quality, the varieties including many novelties, such as Lord Lascelles, pale lavender; Gloriosa, scarlet; and Le Mahdi, aniline blue. Messrs. DOBBIE AND Co., had also a magnificent exhibit of Sweet Peas, in which we noticed the new varieties, Renown, cerise; George Shawyer, light salmon; and Dignity, pink on a cream ground.

Messrs. CARTER PAGE AND Co. provided a very pleasing group of English Irises, Dahlias, Pansies, and Antirrhinums. Messrs. R. H. BATH made a very striking display with tall spikes of Delphiniums. Messrs. STUART LOW AND Co. had an imposing exhibit of Roses and Carnations, whilst Messrs. J. CHEAL AND SONS showed a collection of their pretty Star Dahlias. Messrs. ISAAC HOUSE AND SON exhibited new Gaillardias and forms of Scabiosa caucasica. Messrs. MAXWELL AND BEALE and the Misses HOPKINS showed collections of alpines.

#### GARDENERS' ROYAL BENEVOLENT INSTITUTION.

THE seventy-seventh anniversary festival dinner of the Gardeners' Royal Benevolent Institution, held in the Grocers' Hall, City, on Tuesday, June 27th, to which a brief reference was made in our last issue, was the occasion of many generous gifts, resulting, as we announced on page 2, in a total collection of £3,000, in aid of this excellent gardening charity.

The toast of the evening, "The Gardeners' Royal Benevolent Institution," was proposed by the chairman, Lord Lambourne, who stated that he always had deep sympathy with the Institution, which was one he desired to help with every assistance in his power, but he did not claim to possess the charm of manner of their treasurer, Sir Harry J. Veitch, who everyone regretted was not present with them that evening. He read a letter from Sir Harry expressing deep regret at his absence in consequence of illness, but his heart would be with them that evening and he wished them a full measure of success. Lord Lambourne expressed the hope that the cause which Sir Harry Veitch had so much at heart would not suffer on account of his absence. He then proceeded to give some particulars of the fund and stated that 250 old and infirm gardeners or gardeners' widows were receiving pensions, the oldest of whom was ninety-three years of age. They had a waiting list of thirty applicants. In 1921 the fund was enabled to benefit 335 persons, and the sum necessary to carry on this good work annually was £5,500, to which the assured income did not contribute more than £1,000. Lord Lambourne said: "We have all to tread the path of life which, when it begins, seems delightful, and both sides of it seem bordered with flowers. Then comes middle life with responsibilities and worries. We find amongst our flowers a Bramble, a Thistle or a weed. Afterwards comes old age, when we have before us the last hill to climb, and we look back and see others who have fallen by the way. The cry comes from these for help, and there is no greater delight in life than assisting those who have fallen. Some of us have had nothing but joy and flowers, while others have nothing but misery all the time." "I appeal," he said, "to-night, for those who need help, and you who respond will be rewarded by our Father in Heaven."

Col. Sir J. S. Young, C.V.O., responded. He stated that in his capacity as almoner of the Worshipful Company of Gardeners he had had to look closely into the merits of the Institution, with the result that there is at this moment awaiting signature a deed assuring in perpetuity the maintenance of one pensioner to the fund. He referred to the love of flowers by all classes, from the King downwards. They had seen recently that the Prince of Wales had his path strewn with flowers and on the same day Queen Alexandra was appealing with Roses for help for the hospitals. Princess Mary had placed her bridal bouquet on the Cenotaph in recognition of the services of the glorious dead, and quite recently showers of flowers

came from all classes to solace the widow of one of our greatest soldiers who had lost his life by cruel tragedy. He appealed to his hearers for their benefactions in aid of the workers who plant and sow, in their old age.

The toast of the "Visitors" was proposed by Mr. H. J. Greenwood. To the visitors, he said, was due in large measure the success of the evening, and he hoped that they would be so impressed by their surroundings as to give generous support to the fund. He expressed his gratitude to the Master and Wardens of the Worshipful Company of Grocers for loaning them their beautiful hall for the dinner. In responding, Lt.-Col. R. K. Harvey, Master of the Worshipful Company of Grocers, stated: "I am a visitor in my own ball and I feel somewhat a stranger, but your applause makes me feel at home." On behalf of the visitors he expressed his thanks for the hospitality they had all enjoyed.

A vote of thanks proposed by Sir J. Colman, Bart., concluded the proceedings.

A programme of vocal and instrumental music was rendered by artistes under the direction of Mr. C. Davis-Brook, M.A., A.R.C.M.

The total amount raised, including the chairman's (Lord Lambourne's) personal donation, amounted to nearly £3,000.

Amongst the contributors were the following:—Sir Harry J. Veitch, V.M.H., £105; Messrs. Rothschild and Sons, £135; Messrs. Sutton and Sons, £105; Messrs. Hurst and Son, £100; Mr. Edward White, V.M.H., £50; Messrs. R. W. Wallace and Co., Ltd., £50; Messrs. Wood and Son, Ltd., £50; Mr. G. H. Richards, £42; Mr. W. E. Wallace, £32; Mr. A. MacKellar, V.M.H., £31 10s.; Sir Jeremiah Colman, V.M.H., £26 5s.; Mr. H. G. Alexander, £26; Mr. J. W. H. Barr, £25; Messrs. Waterer, Sons, and Crisp, Ltd., £21; Mr. Geo. Swift, £21; Major Churcher, £21; Mr. John Heal, V.M.H., £21; Mr. Whitpain Nutting, £20; Mr. J. B. Slade, £18 18s.; Mr. Chas. H. Curtis (including £5 5s. from the *Gardeners' Chronicle*, Ltd.), £17; Mr. P. C. M. Veitch, J.P., V.M.H., £16 16s.; Mr. Owen Thomas, V.M.H., £16 16s.; Messrs. Barr and Sons, £15 15s.; Mr. T. Finch, £14 14s.; and Mr. W. L. Corry, £13 13s.

The following contributed £10 10s. each:—Col. Sir John Smith Young, C.V.O., Mr. John W. Hope, C.B.E. (Master of the Fruiterers' Company), Messrs. W. J. Jefferies and Son, Mr. W. J. Jefferies, Mr. H. J. Jones, Mr. J. F. McLeod, Mr. S. M. Segar, Mr. M. Larsen, Mr. Ed. Harriss, Mr. Arthur Dye and Mr. Arthur Turner. Sums of £5 5s. each were received from Messrs. W. Cutbush and Son, Sir J. Agg-Gardner, Lord Treowen, Mr. J. M. Bridgeford, Mr. A. Howard, Mr. A. Dawkins, Mr. J. C. Allgrove, Mr. W. A. Bilney, V.M.H., Mr. Martin Mash, Mr. E. T. Willis, Mr. W. H. Page, Mr. A. J. Monro, Mr. Arthur Bedford and Mr. H. W. Nutting.

Major E. G. Monro's list of £760 included the following amounts:—Mr. James Sweet, V.M.H., £25, and £10 10s. each from Mr. A. Watkins, Messrs. A. Stevens, Ltd., Messrs. E. Stevens, Ltd., Mr. J. P. Rochford, Mr. Bernard Rochford, Major E. G. Monro and Messrs. Geo. Monro, Ltd.; £7 7s., Mr. Raymond Rochford and Mr. John Rochford; £5 5s. each from Messrs. Thos. Rochford and Sons, Messrs. Cobby, Kay and Co., Messrs. Lowe and Shawyer, Ltd., Mr. P. G. Small, Mr. H. O. Larsen, Mr. A. Baker, Mr. F. Ridley and Mrs. Ridley; and £500 from the brothers—Major E. G. Monro, Geo. Monro, and Bert J. Monro.

Mr. John Collingridge's list, amounting to £230, included the following: £10 10s. each from Mr. John Collingridge, Mr. A. Bird, Messrs. C. P. Kinnell and Co., Mr. Jas. Kinnell, Mr. W. Maxwell, Mr. Edward Laxton, Mr. A. Harris, and Mr. F. H. Mills; £5 5s. each from Messrs. W. T. Ware and Co., Ltd., Messrs. Slaymaker and Co., Mr. J. Butler, Mr. P. G. Small, Mr. A. Dimmock, Mr. C. Langman, Mr. J. Linford, Mr. D. Ingamells, Mr. Bruce L. Gibson, Mr. Geo. Prickett, Mr. J. Collingridge, jun., and Mrs. Butchart.

A handsome contribution was promised also from Mr. Reginald Cory.

## Obituary.

**William Icton.**—We deeply regret to learn of the death of Mr. William Icton, of Putney, which took place on Saturday, July 1. Mr. Icton had been ailing for some considerable time, but was only seriously ill about a week. Amongst market growers, as well as among horticultural traders in general, Mr. Icton was well known, as he had been in business at Granard Nursery, Putney Park Lane, Putney, since 1868. As a cultivator, he will be best remembered for his long association with the retarding and forcing of the Lily-of-the-Valley for the London market, in which he was particularly successful. Mr. Icton was always a keen supporter of the horticultural charities, and for over thirty years was a member of the Committee of the Gardeners' Royal Benevolent Institution. He lost one son during the war, but his second son, Mr. Hubert Icton, conducts the business from which his father retired only so late as February last. To the widow and family we extend our deepest sympathy in the great loss they have sustained. The funeral took place at Putney Vale on Wednesday, the 5th inst.

**William Lockhart.**—Sincere regret will be felt in horticultural and fruit-growing circles on learning of the death of Mr. William Lockhart, head of the firm of William Lockhart and Co., wholesale fruit and flower merchants, Virginia Street, Aberdeen, which took place at his residence, Craigeubucker Cottage, Aberdeen, on Sunday morning, July 1. Mr. Lockhart, who was only fifty-two years of age, was a native of Dumfriesshire, and started business in Aberdeen twenty-three years ago. During those years he built up an extensive fruit-selling business and became a well-known and highly-esteemed figure in the wholesale fruit trade of Aberdeen. Few were better known in the Glasgow market and in English fruit-growing centres, from whence he introduced fruits and flowers of all kinds, thus helping greatly to extend and establish the fruit trade in Aberdeen. His great hobby was Rose growing, and for specimens of his favourite flower he gained most of the leading honours at the Edinburgh, Glasgow, and Aberdeen shows. Mr. Lockhart held the office of president of the Aberdeen Horticultural Society. He is survived by his widow and only son, Dr. R. D. Lockhart, Lecturer in Anatomy at the University of Aberdeen.

## NEW HORTICULTURAL INVENTIONS.

### LATEST PATENT APPLICATIONS.

- 15,960.—Brook, F.—Hand-tool for making holes for planting, etc. June 8.  
15,615.—Harrison, C. J.—Device for cutting and lifting sods. June 6.  
15,746.—Okey, W.—Frames for protection or/and intensive cultivation of plants. June 6.  
14,996.—Cornish, H. J.—Horticultural barrow. May 29.  
15,325.—Propert, A. H.—Seed-sowers. May 31.  
14,753.—Barnes, H. J. W.—Edging strips for gardens, paths, etc. May 25.

### SPECIFICATIONS PUBLISHED LAST MONTH.

- 180,380.—Pugh, Ltd., C. H.—Power-driven lawn mowers.  
180,139.—Rennie, J.—Device for trapping bees that through disease are incapable of flying.  
180,180.—Browning, R. G.—Treatment of nitrates, particularly those used for fertiliser purposes.  
179,746.—Ward, W.—Adjustable plant support.  
179,446.—Savage, A. J.—Hand-tool for cultivating and scarifying land.

Messrs. Rayner and Co. will obtain printed copies of the published specifications, and forward on post free for the official price of 1s. each.

This list is specially compiled for the *Gardeners' Chronicle* by Messrs. Rayner and Co., registered patent agents, of 5, Chancery Lane, London, from whom all information relating to patents, trade-marks and designs can be obtained gratuitously.

## ANSWERS TO CORRESPONDENTS.

**AMERICAN GOOSEBERRY MILDEW: M. A. B.** Your Gooseberries are suffering from a very bad attack of American Gooseberry mildew. You should notify the appearance of this disease to the nearest representative of the Ministry of Agriculture.

**AMPELOPSIS VEITCHII DYING: W. G.** Several fungi were present in the specimen you sent. All diseased parts of the plants should be removed and destroyed by burning.

**APPLE AND PEAR TREES UNHEALTHY: E. E. B.** There is no fungus present on the clusters of blossom you send. It is not unusual for the decaying flowers of both Apples and Pears to become matted together when they have not been fertilised. The mildew on the Apple foliage is the common Apple mildew. Spray the leaves next season early in the spring with lime sulphur; you will probably find that the foliage will grow out of this condition later. The woolly substance that resembles mealy bug is American blight, or woolly aphid.

**BATH WATER FOR HARDY PERENNIALS: C. N.** Water used for the bath, or for hand-washing in a lavatory basin, may be used with advantage for moistening the soil about the roots of herbaceous plants. The amount of soap used is not likely to have any untoward effect; indeed, it is more likely to have a beneficial effect upon the plants. Moreover, the use of such water during a dry period will relieve the demand for water for domestic uses. Have you tried *Nepeta Mussinii* as an edging plant?

**DISEASED TULIP LEAVES: J. T. S.** The Tulip leaves are affected with "fire," a common disease, due to *Botrytis parasitica*. It is advisable to remove all infected foliage and lift the bulbs early. On no account should the bulbs be left in the ground another year: by so doing the growth comes away quickly to be damaged by weather in the early spring, and the plants are then more readily affected with this fungus. By removing the foliage now the bulbs generally escape infection, but as a precautionary measure it is wise to soak them in a solution of liver of sulphur (1 oz. to 3 galls. of water) for a couple of hours. The bulbs should be planted on fresh ground during November.

**FIG TREE UNHEALTHY: J. P. S.** The unhealthy condition of your Fig tree is not due to organic disease caused by a fungus; the trouble must be looked for in some wrong cultural treatment.

**INSECT ON CURRANT LEAVES: E. G. H.** The insects on your currant leaves are larvae of the Lady Bird, which is beneficial and not harmful to plants.

**NAMES OF PLANTS: X. Y. Z.** A form of *Iris sibirica*.

**SOUVENIR DE LA MALMAISON CARNATIONS DYING: T.** There is the mycelium ("spawn") of some fungus (perhaps a *Fusarium*) in the plants. Dig up and burn the diseased specimens.

**SWEET PEA INFLORESCENCE WITH NINE FLOWERS: A. T.** The abnormal number of flowers on your Sweet Pea spike is due to fasciation; apparently two spikes have united together.

**WHITE FLY: G. G.** Try the specific recommended by Mr. Chilcott on page 326. See also *Gard. Chron.* December 10, 1921, p. 295.

**Communications Received.**—P. R. S.—A. B. H.—W. D.—A. E. W.—T. H.—S. F. & Co.—E. B.—G. W. R.

## MARKETS.

COVENT GARDEN, Tuesday, July 4th, 1922.

### Fruit and Vegetables

REMARKS.—A rather better demand for most fruits has ruled during the past week. Choice fruits such as Peaches, Nectarines, Grapes, Melons and Figs, have moved well, although in some instances values have slightly receded. Australasian Apples are a steady trade. Strawberries are not so heavy in supply, the main source now being Kent. After a relapse in price due to arrivals from Holland, home grown Gooseberries are quoted higher. Moderate supplies of Black Currants are coming to hand from Holland and France, with a few home grown. Oranges are a better trade. Bananas meet a poor inquiry, probably due to the competition of other fruits. Green vegetables are still comparatively cheap. French Beans show a slightly improved trade. Mushrooms are plentiful, and show considerable variation in values. Tomatoes are not so plentiful, the dull, cold weather checking supplies, and a large proportion arriving is very hard. Cucumbers have an improving tendency. A small quantity of Worcester and Devon Asparagus continues to be marketed, and realises comparatively high prices. New Potatoes are much easier in price.

### Cut Flowers, etc.: Average Wholesale Prices.

REMARKS.—Supplies have shortened considerably; the unfavourable weather has checked the supply of all outdoor blooms, prices for which are a little firmer this morning. *Lilium longiflorum* has suddenly advanced in price, owing to a shorter supply, but *L. lancifolium album* is now more plentiful, and *L. lancifolium rubrum* is again available in the market, but is still dear owing to a limited supply. All best Roses show a tendency to rise in price; indoor blooms are again arriving in a better condition owing to the cooler weather. The principal sorts on sale are Madame Abel Chateauy, Liberty, Hoosier Beauty, Columbia, Melody, Opheia, Madame Butterfly, Molly Sharma Crawford, Frau Karl Druschki, Sunburst, Richmond, Mrs J. Laing and General McArthur. Carnations are abundant, and ordinary varieties are disposed of at a very low price, at the close of the market, although best blooms are still in good demand. Like many other subjects, Sweet Peas are becoming dearer for best blooms. The large salmon coloured *Glaucolus*, Prince of Wales and Halley, also Giant White *Glaucolus*, are amongst the most attractive lines just now. The Bride (white) is getting scarce, small consignments of these blooms are now being received from Holland, which is also sending us large quantities of *Iris anglica*; these flowers, being cut in the bud stage, arrive here in excellent condition. Good white flowers are in shorter supply. *Achillea* The Pearl and double white Stocks are selling more freely, and inquiries are already being made for Asters.

**Agricultural Research and the Farmer.**

The Ministry of Agriculture has performed a service both opportune and of the utmost value to the community in preparing in readable form a summary of the investigations which are being carried out at the present time under its auspices by the several Agricultural and Horticultural Research Stations in England and Wales. The booklet\* in which the summary is published has been compiled by Mr. V. E. Wilkins, B.Sc., of the Ministry of Agriculture, who is to be congratulated on the able way in which he has discharged a very difficult task. Although this account of contemporary agricultural research has been written mainly for the benefit of the layman, it will prove of great interest to cultivators generally, and it is to be hoped that everyone concerned with the work of growing crops will procure and peruse a copy of the work. There is none but will be the wiser from its study, and although, in accordance with the plan, much of the text is concerned with research in progress, with respect to which the final results cannot yet

be stated, nevertheless, the alert reader will discover that many hints of great practical value are to be gained from its pages. Take, for example, the story of fascinating interest of the progress which has been made in the manufacture of organic manure from straw. This work, which has been carried out at Rothamsted, has already demonstrated that suitably treated straw may be converted into manure of equal or all but equal value to farm-yard manure. Incidentally, this line of work has converted the experimenters to the view which horticulturists have never abandoned, namely, that no artificials, though they may effectually supplement farm-yard dung, can replace it. In the course of these researches it was found that the natural formation of farm-yard manure depends on two agencies, both bacterial in nature. Of these agencies, one consists in nitrogen fixing organisms which, operating in the medium of the manure heap, add to the amount of organic nitrogen in the straw by bringing atmospheric nitrogen into combination. These nitrogen fixers alone, however, do not suffice to rot the manure sufficiently to make it useful on the land. If they alone are present the "rotting" remains incomplete. The complete decomposition to the manure stage is effected in nature and may be effected artificially by another group of organisms which decompose the cellulose of which straw is largely composed. These organisms, however, require for their activity a supply of nitrogenous food. The investigators have found that this supply may be provided in the form of sulphate of ammonia. On the basis of these discoveries a large scale method of manure manufacture has been designed which, although it has not been used for a sufficient time to enable a confident statement to be made of its efficiency, bids fair to prove successful. The method, which any gardener who can obtain straw can try on a small scale, is as follows. When stacking, a certain amount of chalk is mixed with the straw, which is then sprinkled with water, little by little, till enough has been added almost to saturate it. Sulphate of ammonia dissolved in water is then added—apparently, however, only in small quantity. The stage of nitrogen absorption occupies about three weeks, after which time the manure can be left exposed to the air without risk of loss of its valuable nitrogen contents. Although in the present stage of these investigations the actual quantity of sulphate of ammonia cannot be stated, and although it is already proved that too much or too little is apt to interfere with the rotting process, nevertheless, we think that gardeners might take note of the facts with a view to applying them cautiously to the compost heap. Another method of compensating for the increasing difficulty of procuring adequate supplies of farm-yard manure which is touched on briefly in the report is the old method of green manuring. Experiments in this subject are being carried out at Rothamsted, Woburn and Wisley, and it is to be hoped that by the next issue of this publication, results will have been obtained which will enable gardeners to apply this method more generally and successfully than it is possible to do in the present state of knowledge. In this brief notice it is not possible to do more than refer to one or two of the many interesting lines of research which the booklet records. We shall hope, however, on a future occasion to draw the attention of our readers to other of the chief investigations which it records. Many who read its pages will wish that the stories told therein were more complete, but they should remember that the prime object of this record of research is to awaken

interest and that fuller detailed accounts are available in the *Journal of the Ministry of Agriculture* and in the several periodicals which are devoted to the publication of the results of agricultural and horticultural research. To have attempted to supply more details would, we think, have defeated the object of this work, namely, to provide cultivators with a readable and simple account of work in progress—an account of the stewardship of the Ministry. It is a good account and for it we are deeply grateful.

**Report of the Hardy Fruit Crops.**—Following our usual practice, we hope to publish in August statistical tables showing the condition of the hardy fruit crops in the United Kingdom. As many changes have occurred in the charge of gardens during the past few years, it is possible that some of those who previously contributed to our report may have changed their addresses, and we shall be pleased if these and any other readers especially concerned in fruit growing will make immediate application to the Editors for one of the forms.

**R.H.S. Gardens Club Outing.**—On Saturday, the 8th inst., the past and present members of the staff of the Royal Horticultural Society met at the establishment of Messrs. Carter and Co., Raynes Park, London, by the kind invitation of the firm. They were brought from the station by a large automobile provided by Messrs. J. Carter and Co., and received by Mr. F. A. Gardiner, their representative. The members were conducted in five parties through the trial grounds, under the guidance of as many employees. A fine putting green of two years' standing claimed attention, after which something like 1,115 trials of Peas were inspected. All sections of the Pea were included, from the first-class garden varieties to *Lotus Tetragonolobus* (*Asparagus Pea*), *Cicer arietinum* (*Chick Pea*), and the *Mummy Pea*. The trials of Broad Beans were also extensive and interesting. Carnations, annuals, Wheat, Oats and lawn grasses were all inspected more or less according to the bent of the visitors. Plots showed lawns for various purposes, and the various species, sown separately, gave ample opportunity for seeing what growth they could make. The offices, seed warehouses, both below and above the ground level, were all in turn inspected, the whole forming one very extensive, rectangular building, which is a prominent object from the London and South Western Railway. The machinery for cleaning seeds claimed the keen attention of most of the visitors. Tea was provided by the firm, and this was followed by the annual meeting and the election of officers, under the presidency of Mr. F. J. Chittenden.

**Trial of Spring Cabbages.**—The Holland Horticultural Committee is again arranging to carry out trials of Spring Cabbages at the Agricultural Institute, Kirton, Boston. These trials have been visited by growers from all parts of England during the past two years. Those who desire to send varieties for trial are asked to forward four ounces of seed of each variety to the Institute at Kirton.

**Alsatian Potash.**—The production of Alsatian potash during the year 1921 shows a considerable decrease as compared with 1920, as noted by the following figures: Crude salt—1913, 355,341 metric tons; 1918, 333,500 tons; 1919, 591,571 tons; 1920, 1,203,000 tons; 1921, 895,744 tons; pure potash ( $K_2O$ )—1913, 58,000 metric tons; 1918, 55,700 tons; 1919, 98,000 tons; 1920, 192,480 tons; 1921, 146,355 tons.

**Elms at the Arnold Arboretum.**—According to the *Bulletin of Popular Information*, vol. viii., No. 13, issued by the Arnold Arboretum, the arboretum contains sixty-six different Elms and includes all the known species with the exception of the four Himalayan Elms and the Mexican Elm, which are not in cultivation, and two species from the southern United States which are not hardy there. With few exceptions the

\* *Agricultural Research and the Farmer*.—A Record of Recent Achievement, by V. E. Wilkins, B.Sc., London. Published by His Majesty's Stationery Office. 2/6 net.

important and interesting varieties and hybrids are represented in the collection. Many of the plants are still too small to produce fruit or to show the habit of mature trees, but as a whole the collection offers a good opportunity for the study of the leaves and branchlets of Elm trees.

**The Royal Society of Arts.**—Now that the Society's house in John Street, Adelphi, has become the permanent property of the Society, the Council are anxious to make it as convenient and attractive as possible for the Fellows. They desire to restore it, so far as is compatible with modern requirements, to the state in which it was left by its architects, the Brothers Adam. With this end in view they have appointed Mr. Arthur T. Bolton, F.R.I.B.A., Curator of the Soane Museum, to take charge of the renovations. It is hoped to make the library into a handsome and comfortable club room; the Great Hall will be entirely redecorated and provided with a new system of ventilation; and the entrance hall will be considerably enlarged and improved. The heating and lighting throughout the building will receive very careful attention, and every effort will be made to encourage Fellows who desire to use the Library and Reading Room.

**Horticultural Exhibition in Berlin.**—The German Horticultural Society is arranging a great centenary Horticultural Exhibition to be held in August and September, 1922, in the beautiful Bellevue Castle grounds in Berlin. There is to be a reception for foreign guests on the evening of Thursday, August 31, arranged by the Greater Berlin Group of the Association of German Florists, and a large portion of the exhibition will be devoted to the florists' art.

**A New Rose Stock.**—The Dutch firm of Messrs. Jac. Smits and Co., Naarden, are said to have raised a new stock suitable for Roses, between *Rosa canina* and *R. rugosa*. It is claimed that the new stock surpasses *rugosa* in that it is suitable for all soils and, moreover, makes so stout a stem that no stakes are required. *Rosa rugosa* is now largely employed by some nurserymen in this country for the propagation of standard Roses, but there are differences of opinion as to its value for the purpose.

**Mr. William Watson, V.M.H.—An Appreciation by Sir Frederick W. Moore.**—Where fixed laws and regulations exist with little or no elasticity there are bound to be cases of hardship. The retirement of William Watson from the position of Curator of the Royal Gardens, Kew, illustrates this, although the loss and hardship will be more severely felt by the garden than by the man who retires after 43 years' service. Mr. Watson has in every way "done his bit," and by his practical work and by his writings left a mark on horticulture which can never be effaced. On the occasion of my first official visit to Kew in 1879 I was introduced to Watson, who had just taken up the position held by Mr. R. Irwin Lynch, and from then up to the present date I have been privileged to be on terms of intimate friendship with him, a friendship which I prize and value and from which I have derived lasting benefits. During my horticultural career two men struck me as outstanding in the originality and soundness of their views on plants, on cultivation, and as possessing an almost prophetic instinct as to the merits or demerits of a new plant. One was the late Mr. Tom Smith, of Newry, the other was Mr. Wm. Watson. Each of them was also a most interesting conversationalist, possessing strong and original opinions on matters outside horticulture, and each fearlessly and frankly supported his views. I have spent many happy hours listening to them. In these "outside" matters Smith was the more practical, Watson the more idealistic, but none the less sincere; in fact this sincerity of conviction, and constant exposition and advocacy of what he considered to be right cannot have been helpful to his material welfare or peaceful existence. Still, knowing this, he persevered with undiminished ardour, and with a certain

defiant stubbornness said to be an inheritance of Lancastrians. The welfare and advancement of gardeners, the betterment of their position socially and financially, providing means and methods of interchange of views, and of mutual help and support, were the great objects of his solicitude for over a quarter of a century, and although some questioned his methods none questioned his sincerity. With these objects in view Watson, amongst other things, started a cricket club for the young gardeners at Kew, and a tennis club for the staff. He organised the Kew Guild, was honorary secretary of it, and edited its *Journal* for some ten years, and for many years was Chairman of the Kew Mutual Improvement Society. In 1904, with characteristic energy and thoroughness, he helped to found and start the British Gardeners' Association, acting as hon. secretary for some time, and although it soon became evident to him that many so-called friendships were being affected and that his action did not meet with very cordial approval in "official quarters," with that stubbornness before alluded to, and in this

MR. WILLIAM WATSON, V.M.H.

instance stimulated by sincere conviction, he tenaciously stuck to his guns. The success achieved by the Association was largely due to Watson. On the practical side of gardening there can be no question or doubt as to the eminent and authoritative position attained by Watson. His training was sound and practical. Born in Garston in March, 1858, he was taken from school at the age of 13 and apprenticed in the propagating department of Messrs. R. P. Ker and Sons, Nurserymen, Liverpool. On leaving them he went to Messrs. Davies and Sons, to Messrs. C. Pennell and Sons, and then to Messrs. Hugh Low and Co., of Clapton, where at the age of 19 he was made foreman over the hard-wooded department, at that time about the most important branch of that world-famed establishment. In July, 1879, he went from Clapton to Kew as principal foreman and propagator. In 1886 he was promoted to be Assistant Curator, and on July 1, 1901, on Nicholson's retirement, he became Curator, a position he has occupied from that date until May 31 last with credit to himself and benefit to Kew. Mr. Watson felt that a Botanical Garden should not merely be a home for collections of plants, but that it should cater for as wide a circle of the public as possible, illustrating, both indoor and outdoor, the best methods of cultivating and of grouping plants, so as to make the garden not only scientifically

instructive but bright and attractive. Many new plants which became of much commercial importance were first brought into prominence through bold groups exhibited at Kew. That Watson's efforts met with the approval of his superiors is best demonstrated by quoting the following from Sir Joseph Hooker, taken from the *Botanical Magazine*, Vol. 130, 1904:—"To William Watson, A.L.S., F.R.H.S., Curator, Royal Botanic Gardens, Kew. Dear Mr. Watson,—The dedication to you of the last volume of the *Botanical Magazine*, which I am privileged to conduct, gives me welcome opportunity of expressing my sense of the value of the services which you have rendered to this work during your Curatorship of the Royal Botanic Garden. This is due to the skill and knowledge which you have devoted to raising and flowering an unprecedentedly large proportion of the rare, interesting, and beautiful plants portrayed in the last twenty volumes of the *Magazine*, and to the valuable information which you have so often given me of the habits, history and mode of culture of these and of many other species whose portraits accompany them. In conclusion, let me congratulate you on the recognition you have so fairly earned as an authority on the culture of Cacti, Palms, Aloes, Agaves and other large groups of plants, in your study of which you have displayed as accurate a knowledge of their physiological characteristics as of their requirements under cultivation. Believe me, very sincerely yours, Jos. D. Hooker, The Camp, Sunningdale, December 1, 1904." Sir Joseph Hooker's successor, Sir W. Thiselton Dyer, continued to encourage these efforts, and Watson responded to these encouragements. Ably seconded by men such as W. J. Bean and W. Irving, Kew was developed into what we see it to-day, an institution unrivalled by any other botanic garden, and one of which the nation has every reason to be proud. Although so fully occupied by the official and practical work of his office, Watson found time for study and observation of many special groups of plants, and as a writer on horticultural subjects he made his mark as definitely and inefaceably as he did on the practical side. The older gardeners remember the charming and attractive style of the articles on gardening matters written by the late Mr. F. W. Burbidge. Watson's style reminds me strongly of Burbidge's, and yet there is a distinct difference, Watson is terser and his facts more clearly stated; and there is no ambiguity or uncertainty. His views and conclusions are original, and are fearlessly stated, often with wit and humour, sometimes one might almost say defiantly. I find that many who know him, and others who do not, are unaware of the extent and variety of his writings. In the horticultural Press his name has been familiar to readers for many years. He wrote many of the articles which accompanied the coloured plates in *The Garden* when edited and owned by Mr. William Robinson. For a long period his letters and articles have appeared in the *Gardeners' Chronicle*. He succeeded the late Mr. F. W. Burbidge as horticultural editor of *The Field*, a position which he still holds. Further, he was general editor of the new edition of *Thompson's Gardener's Assistant*, 1900, a position which entailed an immense amount of thoughtful work. Amongst the books written by him are *Cactus Culture*, *Orchids for Amateurs*, *Rhododendrons and Climbing Plants*. This imperfect list justifies my statement above, that as a writer Watson has made his mark. To all these activities has to be added his experimental work in plant breeding; for instance, his *Streptocarpus* hybrids. I have written at length, but the space occupied is all too little to do justice to one of the most able and remarkable men we have had in the realm of gardening during the present generation. I gratefully acknowledge the valuable and practical advice and assistance I have had from him, and I will always treasure the memories of the pleasant times we had together in England, Ireland, and on the Continent, a continuance of which I look forward to.

**Moles in the Garden.**—Although moles feed entirely on earth worms and grubs, they are very destructive pests in gardens through displacing plants and burying seeds so deeply that they fail to germinate, besides spoiling lawns with their burrowing. Mole traps are not always a certain method of destroying them, as the traps require to be set by a very experienced mole catcher, but the following poisons are stated in *Garden Magazine*, U.S.A., to be effective methods of getting rid of these unwelcome visitors in gardens:—Unroasted Peanuts, first dipped in white of an egg and then liberally sprinkled with Paris green and allowed to dry, or raisins rolled in strychnine. The strychnine should not be handled, as it is a virulent poison, but the raisins may be manipulated with a stick. When the Peanuts and raisins are dry, they should be dropped at intervals of a few feet into the tunnels through openings made with a broom handle and the soil then pressed down again with the foot.

**Tasmanian Apples.**—An exhibit of Apples from the orchards of Mr. Frank Walker, Lalla, Launceston, Tasmania, has occupied a prominent place in Australia House during the past week or so. The fruits are of excellent quality and include some well-known sorts, such as Jonathan, Crofton, Sturmer Pippin and London Pippin, the first two of which are extensively imported into this country from America. There are other excellent varieties which are quite new to us, including Tasma, a very large, deep crimson variety with a big open eye of the Blenheim type. This is a splendid Apple for packing, and the fruits were as solid and fresh looking after their long journey as though they had just been gathered. Another very deeply coloured Apple named Hoover is also a very solid, heavy fruit. Statesman is a very pretty rosy-red Apple of medium size and yellow on the shaded side. Cleopatra is wholly of a pale yellow colour and a very attractive variety. The Apple-growing industry is extending in Tasmania, especially in the region of the River Tamar, and the Tasmanian growers are developing a market for their surplus crop in the home country.

**Argenteuil Asparagus.**—An Asparagus fête was held at Argenteuil on the 9th inst., to celebrate the one hundredth anniversary of the production of this crop in the district. The celebrations included the election of an Asparagus "Queen," who presided over the proceedings, and an immense bunch of Asparagus was borne in front of her triumphal car.

**Appointments for the Ensuing Week.**—Tuesday, July 18: Royal Scottish Arboreal Society's exhibition of Forestry (3 days).—Wednesday, July 19: North Elmham Flower show; Liverpool Horticultural Society's show (2 days); Hereford and West of England Rose Society's show.—Thursday, July 20: Walsall Horticultural Society's show (3 days); Royal Scottish Arboreal Society's meeting.—Friday, July 21: Eastbourne Horticultural Society's meeting; Birmingham Horticultural Society's show (2 days).—Saturday, July 22: Falkirk Rose show.

"The Gardeners' Chronicle" Seventy-five Years Ago.—*A New British Plant.*—A very curious discovery has lately been made by Miss Wilkins, of Westbury, of a new British plant belonging to the genus *Simethis* of Kunth. This lady, while botanising at Bournemouth, in Hampshire, met with a considerable quantity of it, amongst Heath and Furze, in a lonely spot more than two miles from Bourne. "When in perfection, the petals are quite expanded and of a snowy whiteness, so that an inexperienced observer might almost mistake it for an *Ornithogalum*; but the filaments are very different, being so woolly." It is evidently allied to the plants collected by Professor Kunth under the name of *Simethis bicolor*, hitherto observed in Portugal, the Pyrenees, Sardinia, and the Barbary coast, but whether it is identical with any of them, or a new species, the specimens that we have received do not enable us to determine. It should be compared with the *Athericum ericetorum* of Bergeret. *Gard. Chron.* July 17, 1847.

**THE ROSE GARDEN.**

**SEASONABLE WORK.**

WATCH the plants carefully for pests, particularly for mildew on all classes of Roses, and red spider on climbers on walls, which spreads rapidly in hot, sunny weather. Red spider weaves a very fine web on the underside of the leaves, which very soon turn yellow and die. It is best combated out-of-doors by spraying, at a few days' interval, with either paraffin emulsion or liver of sulphur, and the attack against it should be commenced as soon as it is noticed, or it will rapidly cause considerable damage, especially if the climatic conditions are at all favourable to it.

The trees and bushes, being in full flower, require feeding from time to time, to attain the best results and prolong the season of bloom, and to this end applications of liquid manure should be given, alternating this stimulant occasionally with a dressing of a reliable artificial manure, which should be well watered into the

**HARDY FLOWER BORDER.**

**SISYMBRIUM STRICTISSIMUM.**

I DESIRE to direct the attention of readers to a fine border plant, but one which is seldom met in gardens. This is *Sisymbrium strictissimum*, a hardy, herbaceous plant from Central Europe. It flowers from the middle of June to about the middle of July, bearing large, handsome, erect, pyramidal or paniculate clusters of flowers.

The individual flowers are small, but very numerous and of a bright golden yellow colour. It is clear the species belongs to the Order Cruciferae, as the flowers are composed of a calyx with four separate, oblong, yellow sepals, and a corolla with four reflexed, tongue-shaped petals; but especially do the four long and two short stamens also indicate the family of the plant. The leaves are soft green above and pale green beneath, oblong and acuminate.

The flowering time of *Sisymbrium strictissimum* makes it a plant which can be associated

FIG. 15.—ROSE ALICE AMOS. NATIONAL ROSE SOCIETY'S CERTIFICATE OF MERIT, JUNE 29 (SEE P. 25).

soil. Keep the plants well supplied with clear water at the roots, especially in very dry weather, and remove faded blooms.

Rambler Roses should be pruned when their flowering period is over. All Ramblers flower best on strong, young growths made the previous season, and with that in view, remove the old wood, cutting it well back to the ground, only leaving one or two "eyes," from which new growth will spring. Any of the older wood that may be left, owing to sparsity of new growth, should be shortened to the point where a strong, healthy, young growth is making progress, but if there are sufficient already forming for next season, then it is better to shorten the old growths right back, so as to encourage the development of new shoots from the base. These instructions do not, of course, apply to Climbing Teas, Hybrid Teas, and Hybrid Perpetuals, which should be spring pruned.

Where Briars have been grown for the purpose, the propagation of new stock, by means of budding, should be commenced this month. Select buds that have not swollen up, on shoots that are almost ripe, a condition that may generally be assured by selecting shoots that have flowered about ten days previously. Remove the bud carefully, and after inserting it in the stock, tie it in position, firmly but not tightly, so as to prevent it slipping or moving. *B.*

with other early flowering subjects, such as dark and light blue Delphiniums; white, pink, and yellow Eremuri; white and silvery-pink Chinese Paeonies; blue Campanulas and the cream white Spiraea Aruncus, which flower about the same time and make fine groups. Its height allows *S. strictissimum* to be used in the back row of the flower border, but its elegant habit permits it to be placed with advantage in the middle row, even though the flowers rise above the surrounding plants—indeed, this adds charm to the grouping. Because of its somewhat uncommon and charming appearance, its bright and strong colour, and its ease of cultivation, I can heartily recommend this very handsome, free-flowering, and quite hardy plant to all lovers of flowers. *A. J. van Laren, Botanic Gardens, Amsterdam.*

**CYNOGLOSSUM AMABILE.**

*CYNOGLOSSUM AMABILE*, which has much finer flowers than *C. furcatum*, appears to be but little known, although the plant was described by Stapf and Drummond in the *Kew Bulletin* so long ago as 1906. I noticed some excellent plants of this pretty perennial at the meeting of the Royal Horticultural Society on June 17, but I do not remember ever having seen the plant in gardens. The inflorescence takes the form of a tall, lax spike, and the flowers are of Forget-Me-Not blue colour. *P. R.*

## The Week's Work.

### THE ORCHID HOUSES.

By J. T. BARKER, Gardener to His Grace the  
DUKE OF MABLBOROUGH, K.G., Blenheim Palace,  
Woodstock, Oxon.

**Oncidium.**—Many of the cool-growing Oncidiums, such as *O. Forbesii*, *O. crispum*, *O. Gardneri*, *O. concolor*, and *O. Marshallianum* may require repotting, which should be done when the young growths are from 3 inches to 4 inches in height and about to develop fresh roots. The flowers of these species are produced on pendulous racemes, and when in bloom these Orchids are delightful objects. They may never be imported in quantity again, hence the necessity of taking care of those that are still in cultivation. They all succeed in shallow pans, and resort having a large amount of compost placed about their roots; therefore moderate-sized pans should be used, furnished with a good supply of drainage material. A similar compost to that used for *Odontoglossums* will suit their requirements, but slightly more half-decayed leaves may be added. *O. macranthum* and allied species that are developing their long flower spikes should be given water at the roots whenever they become dry, until the flowers open. The few hybrids raised in this section all succeed under the same conditions as their parents, and it is a pity that so little progress has been made in their culture as compared with most other groups. The inflorescences of all Oncidiums should be removed soon after all the flowers are fully developed, as they exhaust the energies of the plant.

**Warm-House Oncidiums.**—The warmer-growing Oncidiums, such as *O. luridum*, *O. Lanceanum*, *O. carthaginense*, and others of this section may also be afforded fresh rooting material as they reach the desired condition. It is useless to attempt the cultivation of any Orchids in a sour, decomposed compost, hence the advisability of repotting any plants in this condition at their proper season. These plants revel in a light position in the warmest house, and whilst the roots are growing actively they should have liberal supplies of moisture. The plants may be sprayed freely during bright days, but during their resting season water should be supplied sparingly, as the thick, fleshy leaves are capable of withstanding a reasonable amount of drought without injury. Oncidiums include some of the most beautiful and interesting of Orchids, although they are not seen in the same quantity as in pre-war days. Their flowers are most useful for all kinds of decoration.

### THE FLOWER GARDEN.

By EDWIN BECKETT, Gardener to the Hon. VICARY  
GIBBS, Aldenham House, Hertfordshire.

**Seed Saving.**—Many hardy plants have already formed their seed pods, and these should be carefully saved when ripe with a view to raising fresh plants. Seed which is small in size such as that of many Alpine and rock garden plants, should, for preference, be sown when it is ripe in pots of good sandy compost and germinated in cold frames, for the germination is more likely to prove satisfactory than if the seed is stored for a time. Raising seedlings of such subjects as *Phloxes*, *Delphiniums* and *Asters* forms a very pleasant diversion in a garden, as, where space permits for raising the plants in large batches, there is always the prospect of finding amongst the seedlings some which will prove a big advance on those already in cultivation.

**Sweet Peas.**—The spring drought has proved very trying to these plants, and for the most part growth has not been free. The roots should be given plenty of water, substituting this occasionally with weak liquid manure. Remove the first flowers in order to promote growth, and cut away all faded blossom to prevent the seed pods forming.

**Spring Bedding Plants.**—Where these have not yet been placed in their summer and winter quarters, they should be planted now, in order that they may get well established, and grow on healthily before the winter arrives, otherwise, in the colder and more boisterous months of autumn, with frosty spells later, they may not succeed.

**Summer Bedding.**—The beds should be examined carefully from time to time, in order that the plants may be effectively trained by tying, etc. Trailing subjects, such as *Violas*, should be pegged down as is considered desirable, and where carpet bedding is employed, the different plants should be firmly kept within their own bounds, and not permitted to grow into one another, otherwise the sharpness of the design will soon disappear, and only an uninteresting, blurred effect will be presented by the bed.

**Wild Garden.**—Many large estates have semi-cultivated or wild gardens, where the garden proper gradually merges into pasture land or wooded areas, and in which many charming flowering subjects are to be found, also individual specimens of choicer trees than in the ordinary woodland, and big, rough beds of various shrubs, etc. These areas should, at this period of the year, receive a certain measure of attention, where the time and labour can be applied to them, so as to keep order amongst the plants, curbing the too rampant growers, shaping somewhat those that require this attention, and generally making the whole of tidy appearance, whilst not destroying the rustic character which distinguishes it and renders it so pleasing in contrast to the more formal flower gardens and shrubberies. One point that needs attention in connection with this work is the clearing away of grass and strong growing weeds from around the smaller and weaker-growing plants set out in the wild garden, so that these do not get choked and destroyed by the weeds.

### FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY,  
M.P., Ford Manor, Lingfield, Surrey.

**Pot Strawberries.**—Strawberry runners are very scarce, and to have stout plants with ripe crowns fit for forcing in November, runners should be rooted at once and assisted to develop with all speed. Strawberry plants will grow in almost any free, rich soil, but the staple should be a heavy, calcareous loam, made pervious to the free passage of water by the addition of old lime rubble, bone dust, oyster shells and charcoal. As the compost should be made very firm, it cannot be used in too dry a state, and for this reason is the better for being mixed a month before it is required for use. If five inch pots are used, these may be filled to within half an inch of the rims, the runners placed in position and pegged firmly in the soil. Such crowns, thoroughly ripened, invariably produce fine trusses of bloom, and this mode of preparation costs a minimum of trouble, and is preferable to layering in small pots. Watering is an important detail, as the pots quickly become filled with roots. Weak liquid manure is of great benefit, from the time the plants are detached until they show signs of ripening. The best position for the plants during the summer is in the open away from any shade. If placed about six inches apart, the pots will, to a certain extent, shade each other. Later kinds require to be layered in six inch pots. The compost for these should be a little heavier, as the roots will penetrate the hardest comest when potted in a dry condition. The crocks used for drainage should be clean and well placed, as worms are sometimes troublesome, hence the advantage of sprinkling a little soot over the crocks, and also in the compost. Where service water is plentiful, it is very tempting to use it, but unless the water is soft and warm, the less it is used over the leaves the better.

### THE KITCHEN GARDEN.

By JAMES E. HATHAWAY, Gardener to JOHN BRENNAND,  
Esq., Baldersby Park, Thirsk, Yorkshire.

**Globe Artichokes.**—These plants are growing and cropping freely, and should be given plenty of liquid manure and heavy waterings. If the plants are allowed to get dry the heads grow small and tough. Mulch liberally between the rows with half-rotted manure.

**Celery.**—If Celery is required early, earthing up should be commenced, but the late crops should not be earthed up until the plants have nearly completed their growth, as the stems will bleach in about 7 or 8 weeks. First remove decaying leaves and side shoots, then well soak the roots with water, but do not place the earth in position until the plants are dry. This work is best done by two men and a boy, as no soil should be allowed to get into the centre of the plant. Only a little soil should be added at one time, and it is best to add more every fortnight. Take care not to cover the centres of the plants, or they may become crippled. Give the plants frequent dressings of soot and lime, and plenty of water.

**Turnips.**—Make sowings of Green Top or red varieties of Turnips. Thoroughly moisten the soil before sowing, and encourage the seedlings to develop as quickly as possible to get beyond the stage when the fly attacks them. A watch should also be kept for birds, as they will pull out the seeds as they begin to germinate. Another sowing should be made in a fortnight's time.

**Broccoli.**—The early kinds of Broccoli should be transplanted at once, and the main crop as soon as the early crops of Peas are over, or on the site of an old Strawberry bed. Leave this ground firm, as the plants grow sturdily in compact soil. Allow a space of two feet six inches between the rows and set the plants two feet apart in the rows, as the more they are open to the air the more hardy will they become.

**Spinach.**—Sow a batch of Prickly Spinach in well-manured land.

### PLANTS UNDER GLASS.

By T. PAYEAM, Gardener to Sir C. NALL-CAIN, Bart.,  
The Node, Codicote, Welwyn, Hertfordshire.

**Layering Carnations.**—Before commencing to insert the layers, remove all weak growths and strip off all the lower leaves on the shoots. See that the roots are thoroughly moist before turning the plants out of their receptacles. Plenty of sand should be incorporated with the soil, and the layer made firm and secure by means of a small peg. Keep the soil in a moist condition and shade the plants from sunshine. If a frame is used it should be kept fairly close for a week or ten days, but after this time the lights may be removed in the evening, when the plants will benefit by the night dew. Replace the lights during the day, and use a shading if necessary. At this period of the year red spider often proves troublesome to Carnations; to keep this pest in check it is advisable during hot weather to syringe the plants twice daily. An occasional spraying with soot water or 1 oz. of common salt to two gallons of water will do much to keep this pest in check.

**Primula malacoides.**—Seed of this *Primula*, and its improved forms, should be sown to obtain plants for flowering in the winter and early spring. This dainty *Primula* is invaluable for greenhouse decoration and is easily grown, provided it is given very cool treatment. It will be found to thrive best in a very cool greenhouse near the roof-glass, where only sufficient fire heat is used to exclude frost. The seed may be sown either in pots or pans filled with a light, open compost, and will germinate very quickly in a cool plant house. Cover the seeds lightly and shade the seed pan from bright sunshine. Careful attention to watering at all stages of growth is necessary, otherwise the seedlings will damp readily; on the contrary, guard against excessive dryness at the root.

**Euphorbia jacquinaeflora.**—The earliest-rooted cuttings of this Euphorbia are growing freely and will soon be ready for their final potting. Where a good, open loam is available the compost for this potting may consist of three parts loam and one part peat, with sufficient sand added to render the compost porous. The plants will grow well in a light pit, where a night temperature of 60° is maintained, a little fire heat being necessary when the weather turns damp and cold. After potting secure each plant to a short stake. Keep the surroundings damp by syringing between the pots twice daily during very hot weather. Careful attention must be given to airing of the pit at all times to prevent cold draughts.

**HARDY FRUIT GARDEN.**

By H. MAREHAM, Gardener to the EARL OF STRAFFORD, Wrotham Park, Barnet.

**Plums.**—Plum trees are making strong, healthy young shoots, and some of the varieties are bearing good crops of fruit. The pruning and regulating of the new growths should be done and all the leaders made secure before they are damaged by high winds. Do not fasten them too tightly, but allow ample room for the swelling of the bark. Retain young shoots at intervals, and secure them to the walls between the older branches for fruiting in a couple of years' time, as it is from these young growths that the best fruits are usually produced. Shorten all the foreright shoots to about the fifth leaf from the base and give the trees a thorough cleansing before the fruits get too forward. Where the crops are heavy some amount of thinning should be done to allow of full development of those left to ripen. The thinning of the fruits may be done at intervals and, if large enough, those removed may be used for farts. See that the roots are well supplied with water and liquid manure at intervals.

**Grafts.**—Examine recently grafted trees with care to ascertain if the union is perfectly completed, and if that is found to be satisfactory, remove the binding materials and make the grafts secure against wind. A good plan is to tie pieces of Bamboo canes to the stock and to fasten the grafts to the canes. As growth advances, remove all shoots which may have developed from the stock, but if any of the grafts have failed, retain a few of the best of the young shoots and bud them with suitable varieties.

**Watering and Mulching.**—The present is a good time to thoroughly soak the roots of all fruit trees in bearing with liquid manure. This stimulant will greatly assist the trees to build up strong, fruitful buds for next year's crop, and also assist the present crop to develop. Some Apple trees are bearing satisfactory crops, namely, Bramley's Seedling, Newton Wonder, and Old Winter Nonsuch, but many Apple trees in these gardens are without a single fruit.

**ORCHID NOTES AND GLEANINGS.**

**DENDROBIUM LITUIFLORUM AND ALLIES.**

**DENDROBIUM LITUIFLORUM** is one of the showiest and most beautiful of the genus, and it will be well now to call attention to its merits on account of its approaching scarcity and the strange fact that, notwithstanding the evident possibilities of its use in the hands of the hybridist, only two crosses of it, both of great beauty, have been made. But no cross has been effected with either of its near allies, which, although bearing smaller blooms than *D. lituiflorum*, might give exceptionally good results, as do many of the smaller species in other genera.

*D. lituiflorum*, Lindl. (*Gard. Chron.*, 1856, p. 372), widely distributed in Arracan, Assam, Burma, and other uplands in India, first became known by its flowering in 1856 in the collection of the late Robert Hanbury, at The Poles, Ware. It was also recorded by Reichen-

bach as *D. Hauburyanum*, and a dwarf form of it as *D. Freemanii* in gardens.

The type has slender stems one to two feet in length, and bearing on the upper part, in fascicles of generally two or three, showy blooms, each over two inches across, the sepals and petals being tinged with amethyst purple and the labellum having a tubular base with a broadly expanded trumpet-shaped lip, ruby purple on a white zone, the margin being rose purple. A pure white variety flowered with the late Sir Trevor Lawrence in 1881, and both forms have gained the R.H.S. First-Class Certificate. There is much variation in the form and size of the flowers of the varieties from different localities, but all are worthy subjects, as their showy flowers are delicately fragrant.

In habit it resembles *D. transparens*, and bears an abundance of similar flowers, which are white, tipped with amethyst purple, the lip having a yellow blotch at the base, often greenish yellow, which suggested the name for the variety once known as *D. mesochlorum*.

All the foregoing are spring-flowering, and have the Violet scent in some degree.

*D. crystallinum*, a native of Arracan, Burma, and other Indian uplands, although having specific differences, especially in its peculiarly elongated anther-case, with crystalline papillae on the surface, may well be classed in this section, as it has the same general appearance and needs similar cultural conditions. Its slender stems bear a profusion of white flowers tipped with magenta, and with yellow base to the lip.

FIG. 16.—MALE PLANT OF MACROZAMIA PEROFFSKYANA WITH CONE (SEE P. 35).

The hybrids of typical *D. lituiflorum* are *D. micans* (Wardianum × *lituiflorum*), for which Messrs. J. Veitch and Sons obtained a F.C.C., March 26, 1889; and *D. Corningianum* (*lituiflorum* × *nobile*), raised in the United States of America and flowered in 1876.

*D. transparens*, known from Wallich's description for many years, was first sent to Messrs. J. Veitch and Sons in 1852 by their collector, Thomas Lobb, who found it plentiful in the lower Himalayan zone, the plants he collected being obtained in the Garrow Hills at 5,000 feet above sea-level. It is dwarfier than *D. lituiflorum*, and bears white flowers tinged with mauve, about an inch and a half across, the lip being streaked and tinged with purple.

*D. marmoratum*, Rehb. f. (*Gard. Chron.*, 1875, p. 492) is from a high altitude in Burma and like a dwarf variety of *D. transparens*.

*D. amoenum*, Lindl. (*Gen. et Sp. Orch.*, p. 78, 1831), was one of the earliest Dendrobies recorded, but was not known in gardens until 1874, when it flowered with Mr. Wm. Bull, of Chelsea, on plants collected by Major-General Berkeley from trees on a range of hills in a temperate region of the Himalayas.

With these may be included *D. Boxallii* and *D. gratiosissimum* Rehb. (*D. Bullenianum*, *Bot. Mag.*, t. 5652), both of which have always been rare, and the two hybrids, *D. Aeneas* (*crystallinum* × *mouilliforme*), and *D. Statterianum*, Hort. (*crystallinum* × *Bensoniae*).

In the matter of culture these are all easy to grow, like many other Dendrobiums, if a moist, warm temperature is provided in the growing season, and a decided rest in a temperate house or dry fruit house is afforded after the leaves fade and fall. J. O'B.

**LAELIO-CATTLEYA BENITA.**

VARIETIES of this charming cross between *Cattleya Schröderae* alba and *Laelio-Cattleya Fascinator-Mossiae* alba, raised by Messrs. Charlesworth, Haywards Heath, have been flowering in several forms during the past month, the best selected, large, pure white forms of *L.-C. Benita* alba being of great purity and fine size and shape.

Although the cross was made between specially selected pure white forms, the small batch gave several examples with delicate pink tint on the labellum, but none reverted to the darker tint of the original type.

### EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, W.C.2.

Local News.—Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Letters for Publication, as well as specimens of plants for naming, should be addressed to the EDITORS, 5, Tavistock Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Editors and Publisher.—Our correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication or referring to the Literary department, and all plants to be named, should be directed to the EDITORS. The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.

Special Notice to Correspondents.—The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.

## MR. KINGDON WARD'S SIXTH EXPEDITION IN ASIA.\*

No. 19.—ON THE RHODODENDRON MOORLAND.

ON our return from the Shun-lu, we spent five rainy days in Mu-li, and then, on July 4, set out to see what we could find east of the Litang River. From the monastery to the wooden bridge is a descent of about 2,000 feet. Besides the rose-red *Malvacea* *Primula* already referred to, there was a queer little *Aristolochia*, twining itself amongst the grass, and a cream coloured *Chirita* just coming into flower; the gorge of the Litang River was quite the last place in which I should have looked for a *Chirita*, or a *Begonia* either, yet we found one of the latter in a wet ravine.

Conspicuous right down here, wherever trickling water and shade were to be found together, was the crimson *Candelabra* bog *Primula* previously alluded to. It is quite common at about 7,000 feet altitude given the required conditions, and so far as other species of *Primula* are concerned, has the ground entirely to itself. This is certainly not usual with the *Candelabras*, nor, indeed, with any marsh *Primulas* which usually share the ground. However, later, we found this species much higher—at about 11,000 feet, in fact, and here it grew with *P. pseudosikkimensis* and a mauve flowered *Nivalis* *Primula*. Even here, though, it was inclined to withdraw the hem of its garment, so to speak, and keep to itself; it was greedy, too, and demanded most of the ground. Its chief merit, perhaps, lies in the fact that it is a late flowering species, beginning to open when many of the *Primulas* are already fading away.

After crossing the Litang River, we began the ascent of the opposite slope on a big slant, soon entering the Pine forest; then crossing a spur, we dropped down into a tributary valley, eventually camping a few hundred feet above Mu-li. The bottom of the valley was fairly well forested, and under the trees grew a pretty *Roscoea* with large, pale lemon flowers. There were two species of *Arisaema* growing hereabouts, which were of particular interest. One was a big plant with a tall, umbrella-like leaf composed of many leaflets arranged in a circle, but hanging down; and each leaflet was drawn out at the apex into a long drip-tip, very like that seen in *Ficus religiosa*, only longer. The second species was a much smaller plant, and in this the spadix was drawn out into a long whip or flagellum, trailing on the ground as in *A. speciosum*, from Sikkim. It is common to find the spathe so provided, but I had never

before seen the spadix contrived in this way. Here, then, we see the same structure in leaf, spathe and spadix, and the conclusion is almost irresistible that it is simply a drip-tip. It is, however, rather astonishing to find such elaborate precautions taken in a region like this, where the rainfall is not great; for that matter, it is puzzling to find so many species of *Arisaema*, and in such variety—a genus one associates more with the wetter, jungly regions bordering on Burma. There are at least a dozen species in the Mu-li district, probably more, found at all altitudes. However, in favour of the drip-tip theory—negative evidence, I admit—it may be pointed out that the species which grow down in the dry river gorges are not so provided either on leaves, spathe or spadix, and the spathe stands wide open.

Continuing up the valley next day, we presently ascended by a precipitous ridge to a grassy meadow, where *Primula* *Littoniana* was poking up its crimson spires, and changing to lilac below as the flowers opened. *Leeches* swarmed on the road here. They haunted the stones in the middle of the path, and, swinging round in circles, attached themselves to the ponies' fetlocks. This is quite a different species to the one commonly met with on the North East Frontier of Burma, and its tactics, too, are different, in accordance with the changed conditions. The latter sit on the leaves which line the narrow jungle paths, and either drop on the traveller from above, or attach themselves as he brushes through the dense vegetation. On the comparatively wide tracks in mountainous country this procedure would be useless.

The meadows were yellow with a rather tall, handsome *Potentilla*—the same that I had seen on the grass-land plateau of Eastern Tibet in 1911. The forest, comprising *Alies*, Oak, and a few species of *Rhododendron*, none of them big, was draped with Lichen, and looked very uninviting. In time, we reached the last grassy slope leading to the summit ridge—grassy and not shrub-clad because facing south. A yellow *Cremathodium* swarmed here, but though there were plenty of flowers there was little variety. We now turned northwards along the ridge, which was clothed with *Rhododendron*. A small rose-pink *Androsace* carpeted the ground in open places, and a remarkable species of *Cynoglossum*, with large, Prussian-blue flowers with purple eye, grew in the shade.

About this time it began to pour with rain, and by the time we got out of the forest on to the open moorland we were drenched and shivering. Making camp under such conditions was a sorry affair, but we found a dry knoll, the water streaming down the hill-sides all round us; however, dense mist prevented us from seeing much. What we did see was quite pleasing. *Rheum Alexandrae* was a wonderful sight up here, its tall, creamy pagodas rising in every direction. *Primulas* revelled in the bogs—mostly *P. secundiflora* and *P. pseudosikkimensis*; but there was also a charming *Nivalis*, its tall stems, whitened with meal, bearing fine heads of flowers, rose pink or lilac; it was, too, deliciously fragrant. Every marsh was crowded with a violet *Iris*, whose fat seed pods, of dusky purple, were as striking as the flowers themselves.

After a night of unremitting rain, we broke camp in dense mist and started again over the bleak moorland with its carpet of dwarf *Rhododendron*, comprising but four species. Frothing streams hurried down the slopes, spilling over and wandering in a dozen marshy rills, every one embowered with flowers.

We came presently to a wide, shallow valley, where yak fed over the emerald green turf; and at a herder's tent drank sour yak milk. Then, climbing again, we returned to the moorland, the altitude here being between 14,000 feet and 15,000 feet. In the marshes an *Omphalogramma* *Primula* was in fruit—possibly *P. vincaeflora* again, and a *Cochlearia* in flower. Amongst the *Rhododendrons* grew masses of a purplish-violet *Aster* (perhaps *A. stacticifolius*), an undershrub no higher than the *Rhododendrons* themselves, covered with blooms; and every bank was purple with the tiny *Soldanel-*

loid *Primula*, a most variable and baffling plant with its numerous microforms. The rain ceased for a time, and high, rocky ranges showed up in the east; on either side, the ridge along which we were travelling fell away into broad, shallow grass-land valleys which rapidly narrowed and became choked with forest. It was impossible to tell just which streams flowed to the Litang River and which to the Yalung, but we were more or less on the crest of the divide. Crossing a lofty pass, we now began to descend, and came down into a grassy valley, obviously at some previous time glaciated.

A conspicuous plant here on steep, stony, shrub-clad slopes was a tall Lily with rather small, pale purple flowers. In favourable situations it grows six feet high, bearing over a dozen blooms. An enormous *Rheum*, fully eight feet high, the bulky stem rising from a nest of huge *Rhubarb*-like leaves was also a conspicuous object; it requires shelter, keeping close amongst the shrubs, but does not mind the rude, stony slopes below the cliffs. We did not stay in this valley, but climbed out of it by a slanting path, and turning the shoulder of a great mountain, ascended to the moorland again, finally pitching camp in a meadow of *Rheum Alexandrae*. Before this, however, we had found one more treasure, another *Muscarioid* *Primula* with fine heads of deep violet, fragrant flowers. It grew on the sheltered slopes, amongst low scrub and broken rock, a plant here and a plant there, or occasionally in small colonies. But it was not common, and extensive search (interrupted by the popping up of two fat hares, which were chased to no purpose) did not reveal more than thirty or forty plants. Nearly all the *Muscarioids* are worth growing for their sweet fragrance and quaint form, as well as for their rich colouring, which is more often than not deep violet; and this plant was no exception. Later, we found a little plant of this section which was certainly queer and of botanical interest, but of no more horticultural merit than *P. Watsonii*. Of the non-violet flowered species, *P. Littoniana* is amazing both for its long spikes and scarlet bracts; while a lilac, or almost white flowered species I found—possibly *P. conica*—is as pleasing as any.

I came across a rather gross species in shady woods edging a torrent; it was already fruiting, and appeared to have purplish or mauve flowers, in moderately long spikes, and might be an acquisition. Yet another species, with violet flowers and very short leaves arranged in a tight rosette, was peculiar for the lax arrangement of the flowers in the spike. It grew on a rocky south-facing slope, covered with a dense thicket of shrubs—rather a strange situation for such a find; but then, it was a strange plant. This was the seventh *Muscarioid* of our collection, but we found less than a dozen plants of it. On the whole, we had every reason to be satisfied with our *Muscarioids*. *F. Kingdon Ward*.

## PLANTS FROM THE ANTIPODES.

SIR H. MAXWELL and Mr. Lynch have raised a very complex subject, on another branch of which I should like to say a few words. The reason why some plants natives of the Antipodes will not acclimatise themselves, whilst others will do so when brought to the changed seasons of this country, is very difficult, if not impossible, to account for, and I think we are obliged to fall back on what the late Professor Huxley called "a verbal anodyne to blind us to our own ignorance," and to say that it is due to constitution, using the word for plants in exactly the same sense as we use it for human beings.

Let us consider a few cases from South America, where alone in the Antipodes I have been able to observe the natural conditions under which plants grow. First let me state that I never heard of any difficulty in acclimatizing plants from the Northern Hemisphere either in South America, South Africa, or Australasia; on the contrary, many of them

\* The previous articles by Mr. Kingdon Ward were published in our issues of May 14, June 18, July 23, August 20, September 3, October 8, October 29, 1921; January 7, January 21, March 11, March 25, April 8, April 23, May 6, May 20, June 3, June 17, and July 1, 1922.

seem as much at home as the natives which they often supersede. Take the case of trees: some, such as the Araucaria and Chilean Beech, grow here and produce fertile seed as well as in Chile; others, such as Fitzroya or Saxegoth, though they grow under less favoured conditions in Chile, either die or remain stunted in this country. Among herbaceous plants *Mutisia decurrens*, so well described by Mr. Coutts in your issue of June 3 (p. 286) is a good illustration. I have seen this plant thriving at the two places he refers to where it grows best in this country, namely, Killerton, in South Devon, and at Edinburgh under very dissimilar conditions, and I have entirely failed to grow it myself either indoors or out, as I believe Mr. Coutts has failed at Kew.

Of the many beautiful alpine *Mutisias* which I have seen in the Andes of Chile not one has ever been grown in England, and the same is true, I think, of the Andean *Gentians*, as it certainly is of the remarkable terrestrial *Orchids* which I took so much pains to collect and bring home. No gardener that I know of, past or present, has been able to keep them alive more than two or three years, and yet their natural conditions are far more like ours than those of the South African *Disa grandiflora*. But there are plants from the Andes which it seems impossible to kill if the drainage is good, such as *Tropaeolum polyphyllum* or *Caecolaria polyrhiza*, both of which bid fair to become weeds in my garden. Among the bulbous plants it is just the same: *Habranthus pratensis* and *Triteleia uniflora* will grow almost anywhere, whilst *Tecophilaea cyanocrocus* will grow only in a few select spots, and many others equally beautiful, such as *Placea ornata*, will not grow at all. *Astroemerias*, which ought to grow in winter, have here completely changed their season and increase rapidly, whilst many plants which grow with them in Chile refuse to adapt themselves, and this is equally true of many Chilean shrubs, though no doubt temperature has much influence on their success or failure in Europe.

Among South African species equally striking illustrations are furnished by plants quite unlike in habit and structure. So far as I know, there is not a single Heath, shrub, or tree native of South Africa that will live outside at all, though many are cultivated with success under glass and live to a great age, quite unaffected, it seems, by the change of season. This is equally true of most herbaceous plants, though a few, such as *Kniphofias*, are quite hardy and happy, though they are naturally sub-evergreen. *Galtonia candicans* is equally indifferent to our coldest and wettest, as it is to our hottest and driest seasons. *Belladonna Lilies*, though they still try to grow through the winter, when their leaves are usually injured by frost, continue to thrive, increase, and produce ripe seed when they get such a chance as 1921 gave them. The *Barberton Daisy*, though reputed tender, is quite hardy at the foot of a wall here, and flowers continuously for three or four months, though it is almost a solitary instance among South African plants of that character. But for one such case as this it is easy to mention ten of plants from the same districts apparently similar in character and structure which have defied, and I believe always will defy, the skill of the most experienced growers.

Of Australasian plants I have neither time nor knowledge to speak, but I do hope that Major Dorrien-Smith, whose knowledge of them at home is exceptional, and whose garden at Scilly contains more than any garden in Europe, will give us the benefit of his opinions and experiences on this interesting and difficult subject. If any place can prove that Antipodean plants from all three continents do acclimatise and grow here it is his garden at Tresco, where if a hotanist were dropped from the sky and saw the rocks covered with a dense growth of *Mesembryanthemums*, *Agapanthus*, and innumerable New Zealand and South American plants, he would never believe he was in Europe. *H. J. Elwes, Colesborne.*

PLANTS NEW OR NOTEWORTHY.

STYRAX HEMSLEYANUM.

THIS Chinese *Styrax* is proving a valuable addition to our list of choice trees and shrubs. It was discovered by Prof. Augustine Henry in 1888, but for its introduction to our gardens we are indebted to Mr. E. H. Wilson, who collected seeds in Szechuan in 1900. These were raised in the Coombe Wood Nursery of Messrs. J. Veitch and Sons, where the first plant flowered in 1909, and from which the figure published in the *Bot Mag.*, tab. 8,339, was made. Mr. Wilson also records this *Styrax* as growing in Hupeh.

A deciduous tree or large bush 20 to 30 feet in height, it is said to have whitish bark in a wild state. Mr. W. J. Bean records a vigorous young tree 10 to 12 feet in height in 1914 at Caerhays, Cornwall. The striking obovate leaves are 3½ to 5 inches long and 3 to 3½ inches wide. The pure white flowers are produced

trunk is 3 ft. high and 1 ft. in diameter at the base. It is growing in the Palm House here among many allied genera and species in conditions common to tropical plants generally.

There is a figure of *Macrozamia Peroffskeyana* in Regel's *Gartenflora*, t. 660, showing a female cone and the whole plant on a much reduced scale. At page 227 of the same volume (1870) the plant is described, and the author hazards the opinion that "it is the finest and most imposing Cycad cultivated in European gardens."

Regel describes it as *Lepidozamia Peroffskeyana*; by other authorities it has been called *Encephalartos Denisoni*, *Macrozamia Denisonii*, *Catakidozamia Macleayi*, and *Zamia Macleayi*, under which last name it was obtained from Messrs. Sander. Professor Chamberlain, in his delightful book, *The Living Cycads*, does not mention the specific name *Peroffskeyana*, but he refers to *Macrozamia Denisoni*, which he saw growing on Tambourine

FIG. 17.—STYRAX HEMSLEYANA.

8 to 20 together in June, on branched axillary or terminal panicles 3 to 6 inches long (see Fig. 17). The individual blossoms are about 1 inch across and pleasingly fragrant.

Seeds ripen in this country and provide the best means of increase, but if these are not available, some of the lower branches may be layered. In common with other species of *Styrax*, *S. Hemsleyanum* thrives best in a sheltered position, either against a wall or with protection from surrounding shrubs. The plants thrive in a well-drained loamy soil to which, when planting, it is desirable to add leaf-mould and peat if available. *A. O.*

MACROZAMIA PEROFFSKYANA.

A MALE plant of this handsome Cycad has recently flowered at Glasnevin, and, as may be seen from the illustration (Fig. 16), the cone is of ample proportions. I did not measure it accurately, but it was roughly eighteen inches high and nearly half as much in diameter.

The plant was purchased from Messrs. Sander, of St. Albans, in June, 1904, and has grown well in the interval. The leaves now have a spread of 10½ feet and individual leaves measure up to 7 feet in length. The

Mountain, west of Brisbane. *J. W. Besant, Glasnevin.*

CATALPA FARGESII.

ONE of the most recent *Catalpas* to bloom in this country is *C. Fargesii*. It had not flowered anywhere in cultivation till 1914 at least, although introduced to France late in last century. The flowers are of good size for the genus, but not produced in anything like the numbers borne by the older introduction, *C. bignonioides*. They are densely spotted all over the outer and inner face with purple, on a white ground, but the appearance is pink to the naked eye a little way off. There are also two yellow patches in the throat, though these are not conspicuous. The leaves are small as *Catalpas* go, being only 3-4 in. long, exclusive of the stalk, with a long point. A marked botanical distinction is that the leaves, young shoots and calyx are covered with branched or stellate hairs, as in many of the *Malvaceae*. There is also an oval brown patch on either side of the base of the midrib beneath, and these patches are thickly covered with glands. They are not mentioned in descriptions, and one would like to know what purpose they serve. The tree flowered recently at Aldenham House, Elstree. *J. F.*

## TREES AND SHRUBS.

### FREMONTIA CALIFORNICA, TORREY.

PERHAPS the most striking plant at the moment in this garden is *Fremontia californica*. The plant, 14 feet high, and planted in 1917, has flowered for three consecutive years, and is now a mass of golden blossom.

Mr. Bean states in *Trees and Shrubs Hardy in the British Isles*: "that the species has flowers 2 to 2½ ins. across, produced singly on short stalks. There are no petals, the bright golden calyx being the conspicuous part of the flower; it is at first widely cup-shaped, has five rounded divisions, and is densely downy outside and very hairy in the centre inside. Stamens united in a short column, dividing at the top into five radiating arms ⅓ in. long. Ovary conical, with a slender style." The description, "roundish divisions," corresponds with the drawing there given (p. 576), but scarcely with the flowers on the tree here: for a typical sepal here is long and pointed; moreover, at no stage of the opened flower do the sepals overlap, as in the drawing, so as to form a continuous calyx, but are, on the contrary, widely separate and divergent, as will be seen from the flowers I enclose. This suggests that there may be two forms of this flower.

The stigma is not differentiated from the style, which appears to end in a simple sharp tip; but under the magnifying glass this is seen to be separated into minuter points, which doubtless have the function of a stigma, since the plant produces seed.

After a flower has been open for a few days it is noticeable, in some cases, that the united bases of the stamens have split and allowed of the protrusion of a dense tuft of whitish "hair," which until this time has been hidden beneath them; this appears to surround the head of the ovary, and to be sticky and honey-catching. What can its function be in that position?

There is at Leonardslee a specimen of this plant trained against the wall; but, to my thinking, it is more effective when not so trained, but merely sheltered by a wall and allowed to grow naturally, with drooping branches.—*Aubyn Trevor-Battye, Ashford Chase, Hants.*

[We compared the flowers received from Mr. A. Trevor-Battye with the illustration in Mr. Bean's book and found that the fresh flowers were more stellate and the sepals divergent and more pointed than those illustrated. Perhaps there are two forms, as suggested by our correspondent, whose flowers we sent to Mr. Bean, with a request for his observations thereon. Mr. Bean's reply is given below.—*EBS.*]

There is evidently considerable variation in the flowers of *Fremontia californica*. In the *Bot. Mag.* figure (t. 5591) the flowers are of the same shape as in the figure in my book—that is to say, the lobes of the perianth slightly overlap. In Mr. Trevor-Battye's flowers they are well separated. I have been to the Herbarium and find some of the wild specimens approximate his in the perianth lobes being well apart—none, however, quite so widely. The lobes are also more slenderly pointed. Mr. Trevor-Battye's plant seems to represent a distinct and handsome form.—*W. J. Bean.*

## THE ALPINE GARDEN.

### ROCK GARDENS AT THE MOUNT, IFIELD.

MR. AND MRS. OSWALD M. COURAGE have very charming gardens and grounds attached to their residence, The Mount, Ifield, Sussex, and both are keen horticulturists. The rock and water garden is extremely pleasing, and alpine is a great hobby of Mrs. Courage; the constructive formation of the rock garden was carried out under her supervision, and the arranging and planting done entirely by herself. There is no doubt but that rock gardens are most fascinating to those that have a real love of plants. Mrs. Courage has made a

study of alpine and their requirements as to soil and positions most suitable for the various species and varieties, and has become quite conversant with these interesting and popular plants. She is always pleased to show her garden to anyone interested in rock plants, and a visit is always most pleasant and instructive. The following plants, with many others, are doing splendidly:—*Acantholimon venustum*, *Geranium argenteum*, *Ramonda pyrenaica*, *Erodium guttatum*, *Campanula muralis*, *C. pumila*, *C. pumila* Miss Willmott, *Gnaphalium Leontopodium*, *Erythraea diffusa*, *Lithospermum Heavenly Blue*, *L. intermedia*, *Dianthus alpinus*, *D. neglectus*, *Calamintha alpina*, *Veronica Bidwillii*, *Aethionema grandiflora*, *Androsace lanuginosa*, *A. Chumbyi*, *Gentiana verna*, *G. acaulis*, *Onosma taurica*, and *Saxifragas* in variety. These alpine are all tastefully arranged with suitable rock shrubs, and the environment lends to the beauty of the place, the whole forming a glorious colour scheme of natural beauty. *R. H. Holton*

### PRIMULA JULIAE.

From early April and throughout the greater part of May *Primula Juliae* is a charming acquisition in the garden. This pleasing species, which is of Corsican origin, when planted in large masses on damp, shady slopes, cannot fail to attract attention. The striking colour of the flowers, which somewhat resembles *Fire King Aubrieta* (though somewhat richer), contrasts with the dark earth. Its culture is of the simplest when planted in leaf-mould and rich pond mud, and it is surprising how rapidly it grows into enormous clumps; here they spread over three feet and four feet. I find the best time to plant is during August and early September, and, like other *Primulas*, a light mulch of leaf-mould during the early winter proves beneficial to *P. Juliae*. To anyone who has been disappointed with *P. Juliae* through trying to grow it in a hot position on the rock garden, I would advise them to give it a trial as stated above. *R. H. Crockford, Weston Park Gardens, Stevenage.*

## FLORISTS' FLOWERS.

### SOUVENIR DE LA MALMAISON CARNATIONS.

IN spite of the improvement in Carnations of the perpetual flowering section, the old *Souvenir de la Malmaison* type has still the advantage where size and fragrance are concerned, and, as these qualities are coupled with a splendid habit, the plants serve many purposes when in bloom. A well-grown specimen, such as the one illustrated in Fig. 18, is a fine ornament in the plant houses, and will supply excellent flowers for use as cut blooms. In common with all indoor Carnations, the best results follow where a house can be set apart for them, because at certain times of the year they call for conditions which cannot be freely provided when there are other occupants to consider. Moreover, open-air treatment for long together is out of the question. The foliage, though apparently strong, is quickly affected by damp, and the protection of glass is essential for practically the year round to enable the leaves to retain their texture and resist disease. It is for this reason that spraying with liquids for the destruction of red spider should not be overdone, for at each application the foliage is softened, and, when this happens in late summer, no worse start for winter could be imagined. Unfortunately, the interior of many modern glasshouses is totally unsuited to easy plant-growing; instead, they are ideal places for the breeding of pests.

Unless the conditions are so near natural as a glass roof will permit, plants, and especially Malmaisons, fail to do the grower full credit. To obviate the necessity for combating red spider—for under fair treatment it is the only pest that is difficult to eradicate—

the benches should be made of slates, so that they may be covered with a moisture-retaining material, and there should be as much earthy floor space as possible, which, however, need not be bare of greenery of some kind. Under such conditions, and however hot the weather, there is always a sense of coolness felt on entering the house, and it is this alone that makes for healthy, clean growth.

At one time this season's display of Malmaisons promised to be over rather earlier than usual, but the recent dull weather has enabled the blooms of later plants to last longer than the first. It is, however, a mistake to shade unnecessarily for the sake of a few flowers. The sooner a return can be made to the ordinary treatment—shading is only necessary to break fierce sunshine—the stronger will be the new growths. Plants, however, which have had to be grouped under a heavy shade will be benefited by being stood in the open in fine weather for a few days, as this will stiffen the shoots and make for easier layering.

Where specimens in 8-inch or 10-inch pots are required, the best of those now in 5-inch or 6-inch receptacles should be potted shortly after the flowers are cut. See that the pots are clean and well crocked. Malmaisons do best in loams inclining to the heavy side, but made porous with the addition of broken bricks, mortar rubble, and wood ash. A suitable mixture, where yellow loam of this description is available, consists of four parts soil to one of leaf-mould, with sufficient of the ingredient just mentioned to ensure porosity, after firm ramming. Bone meal and a little Carnation fertiliser are also helpful. See that the roots are quite moist before turning them out of the pots, and, when potting, do not bury the stem any deeper than before. It should not be necessary to water the plants for a few days afterwards, but, until the roots have had time to establish themselves in the new soil, keep the house somewhat close and shaded, and damp freely the surroundings of the plants, gradually returning to the normal treatment of admitting as much air as possible, both day and night.

It is always necessary to discard a certain number of old plants annually, and increasing the stock by layering is an essential operation, to be completed, if possible, before August. Cold frames, in which a good layer of sandy soil has been placed, answer the purpose best. Select healthy plants, and, after turning them out of the pots, plunge them on their sides in order that the growths may be spread out evenly. A sharp knife is essential, and, when pegging down the layers, see that the cut is not closed, as it is from the tongue that the roots develop. It takes about six weeks for the layers to become well rooted, and in the meantime the frames should be kept rather close and shaded, and the soil moist. A week or so before potting them, sever the layers from the parent plants and increase the amount of ventilation. Pots 3 inches in diameter are large enough, and, after potting them, return the plants to the frame, keeping it close until they have fully recovered from the disturbance. If, through any cause, the root action does not warrant potting into 5-inch or 6-inch pots in October, defer the operation until the new year. During winter, very little progress, beyond a thickening of the stem is noticeable. Keep the roots on the dry side, and maintain a dry, airy atmosphere by employing just sufficient heat to dispel dampness, and to keep the temperature between 45° and 50°. Before the year has far advanced, the flower stems begin to grow, and, when growth is fully active, occasional applications of a concentrated fertiliser are beneficial.

There are many fine varieties in addition to the popular Princess of Wales. *Duchess of Westminster*, rose pink, is an early bloomer, and such as *H. J. Jones*, *Maggie Hodgson*, *Lady Mary Hope*, *Marchioness of Londonderry*, and *The Colonel* are worthy a place. Amongst perpetual Malmaison varieties, *Mrs. C. F. Raphael*, though not new, is one of the best. *Y. G.*

## SOCIETIES.

### MANCHESTER AND NORTH OF ENGLAND ORCHID.

JUNE 1.—*Committee present:* The Rev. J. Crombleholme (in the chair), Messrs. R. Ashworth, B. J. Beckton, A. Burns, A. Coningsby, D. A. Cowan, J. C. Cowan, A. T. Cussens, J. Cypher, J. Evans, W. Giles, A. Hanmer, J. Howes, J. Jackson, A. Keeling, D. McLeod, E. W. Thompson, and H. Arthur, Secretary.

#### FIRST-CLASS CERTIFICATES.

*Sophro-Laelio-Cattleya Meuse*, West Point var. A flower of fine shape with sepals and petals deep mauve colour and lip deep purple; *Odontoglossum crispum Mariette*. A fine variety of the Dom type. *Brasso-Cattleya Albion* var. *Bianca* (B.-C. Thorntonii alba × C. Trianae alba). A well-shaped flower with white sepals and petals, also white lip with a blotch of magenta. *Laelio-Cattleya Teucra gloriosa* (L.-C. Martinetii × C. Messiae). Flower large, sepals and petals very dark, and lip deep reddish purple. From S. GRATIX, Esq.

*Dendrobium Butterfly* (chessingtonense × Ainsworthii). Flower yellow with black centre; and *Miltonia Horridgeana* (Bleuana Stevensii × Lyoth). Sepals white and petals white, suffused with rose, with a black mask. From Capt. W. HORRIDGE.

*Miltonia Hyeana* var. *The Queen* (Bleuana Stevensii × G. W. Owen). A large, almost pure white flower with large, black mask. From P. SMITH, Esq.

*Odontioda Joiceyii splendens* (Odm. promerens × Oda. Coronation). A spike carrying fourteen large and well-shaped flowers with large, regular blotches of intense colour, the outer edges being deep pink, and the flat lip with deep blotch. From J. and A. McBEAN.

#### AWARDS OF MERIT.

*Odontoglossum eximillus superbum* and *Odontioda Hiawatha Edgemoor* var. From A. HANMER, Esq. *Odm. crispum West Point Amazon*. From Mrs. GRATIX. *Odm. promerens xanthotes West Point* var. From S. GRATIX, Esq.

#### GROUPS.

S. GRATIX, Esq., West Point (gr. Mr. J. Howes), was awarded a Silver-Gilt Medal for a group of Orchids in variety. Capt. W. HORRIDGE, Bury (gr. Mr. A. Coningsby) was awarded a Silver Medal for a miscellaneous group. Messrs. J. CYPHER AND SONS were also awarded a Silver Medal for a group of Orchids.

THURSDAY, JUNE 22.—*Committee present:* A. T. Cussens, Esq. (in the chair), Messrs. A. Coningsby, D. A. Cowan, A. G. Ellwood, W. Giles, J. Howes, A. Keeling, D. McLeod, E. W. Thompson, and H. Arthur.

#### FIRST-CLASS CERTIFICATES.

*Brasso-Laelio-Cattleya Jupiter* var. *Rotunda*. Flower of large size and even colour; *Odontoglossum Doreen* var. *Royal Purple*, a variety with rich purple flowers; *Cypripedium Goveianum Gratrixianum*; from S. GRATIX, Esq. *Odontoglossum eximillus* var. *The Prince*, sepals and petals rich reddish brown with a white margin; *Odm. Penelope Edgemoor* var., a well formed flower having distinct heliotrope spots; from A. HANMER, Esq. *Odm. Gorizia giganteum*; from P. SMITH, Esq.

#### AWARDS OF MERIT.

*Cattleya Brenda* var. *Snowdon*; *Odm. Centaur* (Ernestii × Georgius Rex); *Cypripedium Enchantress* (Curtisii Sanderæ × Alma Geveart); *C. niveum* var. *Emerald* and *C. niveum* var. *Gratrixiae*; from S. GRATIX, Esq. *Odontoglossum Faustina superba*, *O. Orosius magnifica* and *O. Doreen Edgemoor* var.; from A. HANMER, Esq.

#### GROUPS

S. GRATIX, Esq., West Point (gr. Mr. J. Howes), staged a group in variety for which a Silver-gilt medal was awarded.

A. HANMER, Esq., Buxton (gr. Mr. G. Giles), was awarded a large Silver medal for a group of *Odontoglossums* and *Odontiodas* in variety.

### WINDSOR, ETON AND DISTRICT ROSE AND HORTICULTURAL.

AUGUST 1.—The twenty-ninth annual show of the above society was held on the slopes of Windsor Castle on this date. Roses have long been a feature of the Windsor shows, and the present occasion was no exception to the rule. Following their great triumph at the N.R.S. show on the previous Thursday, Messrs. ALEX. DICKSON AND SONS added to their laurels by winning the King's Challenge Cup, and also the first prize for 12 varieties, 3 blooms of each, with superb collections. Of their 48 blooms in the premier class, Archie Gray, Capt. Kilbee Stuart, Marcella, Gorgeous, Edgar M. Burnett, Mrs. Henry Morse, Mrs. W. J. Grant, Candeur

of any H.P. or H.T. Rose, while Lady Ashtown, shown by Messrs. D. PRIOR AND SON, was a good second. Messrs. D. PRIOR AND SON were easily first with splendid blooms of Madame Jules Gravereaux in the class for 12 Tea or Noisette blooms, and they also secured premier honours with Snow Queen and George Dickson in the class for 12 blooms each of any crimson or white variety. The latter class was strongly contested, and Messrs. F. CANT AND Co. were a good second with their new Henry Vevard and Mrs. Cornwallis West.

The class for 12 bunches of decorative Roses was very attractive. Mr. GEORGE LILLEY was first with excellent vases of such varieties as Isobel, Margaret Dickson Hamill and Lady

FIG. 19.—BEGONIA VENUS. R.H.S. AWARD OF MERIT, JUNE 27 (SEE P. 12)

Lyonnais, Lord Allenby, Lohengrin and Lady Inchiquin were perhaps the very best. Messrs. F. CANT AND Co. were a good second, and their outstanding sorts were Gorgeous, Golden Emblem, C. V. Haworth, Snow Queen, St. Helena, Mrs. W. J. Grant, Mrs. G. Marriott and Mrs. J. H. Welch. Messrs. B. R. CANT AND SONS, who were third, included good blooms of Colcestria, Lyon Rose, George Dickson and Mr. A. Hartmann.

The very best of the 12 excellent triplets shown by Messrs. ALEX. DICKSON AND SONS were Lord Allenby, Gorgeous, Mrs. G. Marriott, St. Helena and Mrs. Henry Morse. In the second prize collection of Messrs. F. CANT AND Co. there were good blooms of Gorgeous, Mrs. Theodore Roosevelt and Henry Vevard, a new fragrant crimson variety. Messrs. D. PRIOR AND SON were third, and they had excellent triplets of George Dickson and Madame Jules Gravereaux.

Augustus Hartmann, shown by Messrs. B. R. CANT AND SONS, proved to be the best variety in the class for 12 blooms

Pirrie, while Messrs. F. CANT AND Co. showing such brightly-coloured sorts as Red Cross, Red Star, K. of K. and W. C. Gaunt, were second.

#### AMATEURS' CLASSES.

Dr. T. E. PALLET had a great day in the open amateurs' classes, for he won the "Windsor," the "Islet," and the "Lady Julia Follett" challenge cups, and was also first with the Tea and Noisette varieties, and in each instance with really admirable blooms, the quality of which may be realised by the fact that his bloom of George Dickson won the N.R.S. silver-gilt medal as being the best bloom in the show. Other of his remarkable blooms were Coronation, Lemon Pillar, Mrs. Henry Morse, Mrs. Campbell Hall, W. R. Smith and Mrs. Feley Hobbs. The best 12 blooms in the class for growers of fewer than 1,000 plants were shown by Mrs. HENRY BALFOUR, who had excellent specimens of George Dickson, Mrs. Feley Hobbs and H. V. Machin.

W. C. ROMAINE, Esq., the founder of the society, won premier honours in the local amateurs' classes, and there was great competition

for the "Pool" and the "Tea and Noisette" challenge cups, which were both won by F. A. GOVETT, Esq., who, with Candeur Lyonnaise (H.P.) and Maman Cochet (T.) won the N.R.S. bronze medals offered for the best blooms of these types in the local classes. With George Dickson Mr. W. C. ROMINE won the H.T. bronze medal, and he won first prizes in the classes for 6 blooms each of any H.P. or H.T., and T. or N. Roses.

As in the open section, the decorative Roses were exceedingly meritorious, and the 6 bunches which won the first prize for Mrs. F. W. SAUNDERS were admirable. They included Una, American Pillar and Paul's Scarlet Climber. The R.H.S. Banksian Medal, for the best bunch of decorative Roses in the amateurs' classes, was won by Mr. H. J. STOKES with a charming vase of Irish Elegance.

The Prince of Wales Cup, offered for the best 18 bunches of Sweet Peas, is usually keenly competed for, but on the present occasion SIR RANDOLPH BAKER (gr., Mr. A. E. Usher) found no competitor, and was awarded the cup for a splendid collection of such sorts as Hebe, Hilda, Tangerine, Mrs. Tom Jones, Mrs. A. Hitchcock and La France. He was also awarded the first prize in the class for 12 bunches, where the outstanding sorts were Royal Purple and Great Scot. Mrs. F. CHARLTON, who used Rose Ethel James with great taste, won the first prize in the dinner-table competition, and, with Madame A. Chatenay, was equally successful in the decorated basket class.

Vegetables generally were poorly represented, but there were several excellent collections. The society's prize and the special prize offered by Messrs. J. Carter and Co. were both won by Miss E. HENDERSON, who showed very good Peas, Broad Beans and Onions. The special prize offered by Messrs. Sutton and Sons was won by Mr. E. BALDWIN, who had excellent Selected Duke of Albany Peas, Best of All Tomatos and very white Cauliflower.

The trade exhibits were a great feature of the show, and were greatly appreciated by the public as well as by the executive. Mr. CHAS. TURNER had large collections of Roses and general flowering shrubs, including splendid Philadelphus in great variety, Spiraea Billardii, and Neilla Torreyi, with many excellent border flowers; while in another tent he had a fascinating group of well-grown Malmaison Carnations of such sorts as Old Blush, Princess of Wales and Lady Middleton. Mr. J. C. ALLCROVE included in an attractive collection of herbaceous flowers a fine group of stately Eremurus, many Delphiniums, Iris Monneri, Pentstemons and plenty of Roses. He also had fruiting canes of Pyne's Royal Raspberry and a collection of trained Gooseberries and Currants in pots. Mr. ELISHA J. HICKS exhibited Roses; Messrs. WATERED, SONS AND CRISP showed Roses and various border flowers; while Mr. BIDE staged a large number of good Sweet Peas of such sorts as Crimson Queen, Elegance and Tangerine.

A very pretty group of border plants and alpines, with Nymphaeas, in a little pool, was contributed by Messrs. BARR AND SON. Amongst their many Irises were Iris monspur, Monneri and spuria varieties. Messrs. J. PIPER AND SON arranged Roses, with Delphiniums and other border flowers.

### THE OXFORD COMMEMORATION SHOW.

This society held its first show of the year in the Trinity College Gardens, on Tuesday, June 27. Although rain threatened in the morning, the afternoon was beautifully fine, and visitors were able to enjoy in the open a programme of music rendered by the band of the 2nd Life Guards.

In the class for stove and greenhouse plants, Messrs. J. CYPHER AND SONS, Cheltenham, won the first prize for a good collection of choice subjects.

The exhibits of Roses were exceptionally good. Mr. G. PRINCE, Longworth, was placed first with a well-displayed group of choice varieties.

Mr. HENRY DREW, Longworth, had also an effective group of Roses, and was awarded the second prize. In the open class for cut Roses Mr. PRINCE won premier honours. In another class for cut Roses Mr. H. BALFOUR, of Headington, was a first-prize winner. Messrs WEST AND SON won first prize for twelve bunches of Sweet Peas, outstanding varieties being Picture, Jean Ireland, Hugh Dickson, Royal Purple, Sunproof Crimson and R. F. Felton. Mr. MATTOCK was awarded the second prize in this class. A bank of hardy perennials, shown by Mr. J. JOHNSON, was awarded a first prize. The same exhibitor staged a very choice collection of Carnations, the pick of the stand being White Wonder, Laddie, and Scarlet Corolla. A very fine exhibit of Lilium Harrisii, staged by Messrs. WEST AND SON, was deservedly placed first, the blooms being particularly good. The Vegetable and Fruit Classes were not strongly contested, although some exceptionally fine produce was staged. Brig-General MILLER, Shotover Park (gr., Mr. A. Whiting), secured first prize for white Grapes, Peaches and Strawberries, and Mr. A. E. BRADSHAW was successful for Tomatos and Cucumbers. For a collection of vegetables, Mr. T. ALDER was placed first, and Mr. A. E. BRADSHAW second.

### NON-COMPETITIVE EXHIBITS.

Mr. F. C. LEVETT won, for the second time, a challenge cup presented by Councillor L. Alden, Esq. (offered for the best non-competitive trade display). Mr. R. TUCKER had a good exhibit not for competition. In the centre of the vegetable tent Mrs. MORRELL, Headington Hill Hall (gr., Mr. A. Gibson), staged a very graceful, light and effective group of choice plants not for competition, which included Miltonias, Clarkias, Caladiums, Crotons, Souvenir de la Malmaison Carnations and some fine Gloxinias. This exhibit was awarded a Gold Medal. Mrs. Morrell is deserving of thanks and praise for all the good she does in anything pertaining to horticulture. Messrs. JAMES CARTER AND Co., Raynes Park, exhibited, not for competition, a bold, well-staged group of vegetables. Mr. A. ROWLES had a pleasing group of various plants and sundries.

### ROYAL HORTICULTURAL.

JULY 11 AND 12.—The usual fortnightly meeting was held on Tuesday last in the Vincent Square Hall. The exhibition was not so fine as some of the recent ones, the falling-off being most noticeable amongst Orchids, while doubtless many Sweet Pea growers were reserving their efforts for the National Society's show at Eastbourne on the Wednesday and Thursday following. Neither the Orchid Committee nor the Fruit and Vegetable Committee made any awards to novelties, but several were recommended by the Floral Committee. Lilies, Roses, Japanese Irises, Carnations, Border Pinks and stove and greenhouse plants were the chief subjects shown. The annual show of the Southern section of the National Carnation and Picotee Society was held in conjunction with the R.H.S. meeting.

### Orchid Committee.

Present: Sir Jeremiah Colman, Bart. (in the chair), Prince Shimadzu, Messrs. Jas. O'Brien (hon. secretary), Pantia Ralli, W. J. Kaye, E. R. Ashton, J. Wilson Potter, Frederick J. Hanbury, Gurney Wilson, S. W. Flory, Stuart H. Low, H. G. Alexander, H. T. Pitt, G. J. Lucas, Arthur Dye and Fred K. Sander.

The Chairman read the following communication from the Secretary, which it is hoped will do much to meet a difficulty generally experienced by Orchid exhibitors:—

"Dear Sir,—I am desired by the President and Council to inform you that they have decided that written application may be made for leave to remove, at 5 p.m., on the first day of a two-days show, special plants submitted for award. It is hoped that a sparing use will be made of this privilege and that application will only be made in cases of urgent necessity.

"The written application will, if leave is granted, be initialled by me and will then serve as a certificate to allow the plant to be taken out of the building.—W. R. Dykes, Secretary."

Mr. THURGOOD, gardener to H. T. Pitt, Esq., Rosslyn, Stamford Hill, was awarded Cultural Commendations for a fine plant of *Platycodon filiformis* with over thirty of its elegant drooping sprays of yellow flowers; and for a grand specimen of *Bulbophyllum macrobulbum* J. J. Smith with a dense cluster of twenty fleshy, Stapelia-like flowers of cream colour, densely spotted with chocolate red. The comparatively small pseudo-bulbs bore long, fleshy leaves and gave evidence of perfect health. The plant had previously received an Award of Merit under the provisional name *B. Balfourianum*.

### Groups.

H. T. PITT, Esq., Rosslyn, Stamford Hill, was awarded a Silver Flora Medal for a very interesting group in which were noted a good selection of *Odontoglossums* with some bright scarlet *Odontiodas*. Species of botanical interest were *Catasetum fimbriatum*, *Chondrorhyncha Chestertonii*, a grand specimen of *Miltonia Phalaenopsis*, *Vanda teres*, *Angulea Ruckeri*, and several rare *Epidendrums*.

MESSRS. CHARLESWORTH AND Co., Hayward's Heath, were awarded a Silver Flora medal for an exceptionally good group of white *Cattleyas*, every specimen being finely grown and well flowered. Twelve varieties of their fine *Cattleya Hesta* (*Suzanne Hye de Crom* × *Warszewiczii* Fr. M. Beyrodt) were shown, all with white sepals and petals, and with labellums having various shades of violet. *C. Muriel* (*Dusseldorferi* Undine × *Mendelii* alba) bore two strong spikes of white flowers, and several *C. Stuartii* (*Mendelii* alba × *Mossiae* *Reineckiana*) bore many good white flowers and some with a pink tint on the lip. Messrs. FLORY AND BLACK, Slough, showed good examples of *Disas*, *Disa Luna* bore a stout spike of pretty rosy mauve flowers with large bluish-white galea; *D. Blackii* (*Luna* × *grandiflora*) had larger and darker flowers. *D. Italia* (*Blackii* × *grandiflora*) was still nearer the latter parent; the new *D. Julia* A. Stuckey (*Italia* × *grandiflora*) with its scarlet segments and large rose-striped galea closely approaches *D. grandiflora*, but is said to be much easier to grow. The progressive hybridising in these *Disas* is very interesting.

MESSRS. J. and A. McBEAN, Cooksbridge, showed a very fine specimen of their *Cattleya Falco gloriosa* (*Dupreana* × *Dowiana*) with a spike of four large and perfectly shaped flowers, the sepals and petals of which are violet-mauve and the broad, crimped lip ruby-crimson in front, the disc being chrome yellow with some purple lines at the base. The fine form of *O. Warneri* in *C. Dupreana* is evident in this showy hybrid. Messrs. McBEAN also showed *Odontoglossum Doreen* var. *Rotunda* (*eximium* × *Empress of India*) of perfect shape and finely blotched.

### Floral Committee.

Present: Messrs. H. B. May (in the chair), D. B. Crane, W. P. Thomson, H. J. Jones, H. P. Warrender, J. W. Barr, S. P. Morris, G. Reuthe, John Heal, Amos Perry, C. R. Fielder, John Jennings, W. B. Gingell, C. E. Pearson, H. R. Darlington, J. T. Bennett-Poë, W. J. Bean, R. C. Notcutt, Jas. Hudson, Reginald Cory, J. F. McLeod, and A. Turner.

### AWARDS OF MERIT.

*Begonia Sir J. Reid*.—A splendid double-flowered tuberous-rooted variety. The Camellia-shaped blooms, which were of bright orange colour, were freely produced, and an additional attraction was the well-marked foliage. Shown by Messrs. BLACKMORE AND LANGDON.

*Clematis Species*.—The award to this graceful free-flowering species was subject to its being named in the near future. It bears long, elegant sprays of smallish white flowers. The four narrow sepals give a pretty star-like appearance. The smooth oblong Pea-green foliage has a glaucous hue. Shown by the Rev. W. WILKS.

*Eschscholzia crimson-carmine*.—A brilliantly beautiful annual. The colour is well described by the varietal name and its beauty is enhanced

by the small white centre. Shown by Mr. W. H. GARDINER.

*Lilium gloriosum*.—This is the most vigorous of the many *L. pardalinum* hybrids which have been raised by Mr. Perry. The tall stem bears plenty of pointed, pale orange-coloured flowers which are freely spotted with rich crimson. Shown by Mr. AMOS PERRY.

*Rose Kew Rambler*.—An elegant, free-flowering variety raised at Kew by crossing the Chinese species *R. Soulieana* with the variety *Hiwatha*. It possesses more than a suggestion of the glaucous hue of the Chinese species, while the flowers are borne in longer sprays and are larger than those of either parent. It is suggestive of a pale American Pillar, but the exact shade more nearly approaches that of the Wild Rose. There is a bold, white centre to the flowers, and the buds are a bright pink. Shown by the DIRECTOR, Royal Gardens, Kew.

*Hypericum species*.—As with the *Clematis*, this award is subject to naming. It is much like a brighter *H. patulum* Henryi, and is a desirable garden plant; very free-flowering and of good bushy habit. Shown by LIONEL DE ROTHSCHILD, Esq.

*Rhododendron auriculatum var.*—This is a nearly pure white variety of the pale rosy-pink species discovered by Mr. A. Henry in W. Hupeh, and introduced by Mr. Wilson in 1900. Well-formed trusses were shown, which bore large, widely expanded blooms. The stalks as well as the flowers are white, and they are plentifully furnished with white hairs on the stalk and outside of the petals. The upper surfaces of the leaves are a pleasing green, while below they are somewhat silvery. Shown by the Hon. H. McLAREN.

*R. discolor, pink variety*.—Except in colour, which is a pleasant soft pink, this is identical with the type which was illustrated in last week's *Gard. Chron.* (see fig. 10). Also shown by the Hon. H. McLAREN.

#### CULTURAL COMMENTATION.

*Magnolia macrophylla*.—A magnificent bloom of this, the largest of all the *Magnolias*, was shown, accompanied by leaves nearly 2 feet long. It is a native of the South-Eastern United States, and the globular bloom was over 5 inches across and of creamy white colour. Shown by LIONEL DE ROTHSCHILD, Esq.

#### GROUPS.

The most imposing exhibit in the hall was the splendidly arranged collection of stove and greenhouse plants by Messrs. L. R. RUSSELL, LTD. There were many *Caladiums*, including the old favourite *C. argyrifolium*, which has become quite a rare plant. *Codiaeums*, *Acalyphas*, *Anthuriums*, a well-flowered specimen of *Dipladenia amabilis* and others, all displayed the first-class cultivation associated with Messrs. RUSSELL'S plants (Silver-Gilt Flora Medal). Carnations were an important feature of the show, and these were shown by Messrs. ALLWOOD BROS. (Silver Flora Medal), who besides many perennials had a large quantity of *Dianthus Allwoodii*; and Mr. C. ENGELMANN (Silver Banksian Medal).

Roses were also freely exhibited. Messrs. PAUL, LTD., showed beautiful vases of such sorts as Paul's Scarlet Climber, Madame Edouard Herriot and the very dark fragrant Dinah (Silver Flora Medal). The Rev. J. H. PEMBERTON included many free-flowering sorts, of which Danaë, Prosperity, Vanity and Havering Rambler are a selection (Silver-Gilt Banksian Medal). The deep yellow and orange coloured varieties, such as Margaret Dickson Hamill, Golden Emblem, Independence Day and Rayon d'Or, were well shown by Messrs. WATERER, SONS and CRISP (Silver-Gilt Banksian Medal). In a collection by Messrs. D. PRIOR and SON, Caroline Testout, Lady Pirrie and Modesty were very prominent (Bronze Flora Medal). At one end of a fascinating collection Messrs. F. CANT and Co. had a large vase of the very fragrant Red Star, while The Queen Alexandra Rose and C. V. Haworth were also well shown.

Of the many collections of hardy border flowers none attracted more attention than the large quantity of *Lilium candidum* shown by Messrs. BARR and SONS. Associated with these were

vases of *Alströmérias*, *Salvia Turkestanica* and Sweet Lavender (Silver Banksian Medal). On the opposite side of the entrance Mr. AMOS PERRY showed a number of his interesting hybrids of *Lilium pardalinum* and *L. regale*. For the most part they were unnamed, though a deep orange-coloured hybrid and *L. Pardal-Parryi* of rich orange colour spotted with chocolate were of striking appearance. The effect of these Lilies rising above many hardy Ferns was excellent (Silver Banksian Medal).

Japanese Irises, in good sorts, were included in a general exhibit by Messrs. W. H. ROGERS and SON, who also had a good vase of *Callistemon speciosus* (Silver Banksian Medal). Messrs. G. G. WHITELEGG, LTD., also showed a good assortment of Japanese Irises with *Astilbes* (Bronze Flora Medal).

Especially good spikes of *Delphinium* were staged by Messrs. BLACKMORE and LANGDON, who, in another part of the hall, had some excellent tuberous-rooted *Begonias*, of which *Lady Rhondda*, salmon pink, and *Lord Lambourne*, orange apricot, were prominent. Amongst the *Delphiniums* were *Queen of Bath* and *Mrs. Townley Parker*, pale blue, and *Mrs. H. Kaye*, very dark blue (Silver-Gilt Banksian Medal).

Mr. H. J. JONES filled a corner of the hall with excellent herbaceous *Phlox*. Besides the sorts we greatly admired at the previous meeting, he had *Maculata Alpha*, a magnificent white, *Jules Sandeau*, *Mrs. Scholten*, *W. Watson* and *The Captain* (Silver-Gilt Banksian Medal). A large quantity of *Lavatera Olbia rosea* was shown by Messrs. LADHAMS, LTD., who also had many garden Pinks and *Anothera Golden Glow* (Silver-Gilt Banksian Medal).

Garden Pinks were excellent in the exhibit of Mr. M. PRICHARD, as also were various *Verbascums*, *Phloxes* and *Alströméria aurantiaca* (Silver-Gilt Banksian Medal). Mr. G. REUTHE arranged his customary collection of hardy border plants and shrubs (Silver-Gilt Banksian Medal). Border flowers in variety were contributed by Mr. W. WELLS, Junr. (Silver Banksian Medal); Messrs. R. TUCKER and SON, who had many pots of *Campanula Bellardi*, *Miranda* and *C. pusilla* Miss Willmott (Silver Banksian Medal); and Messrs. G. JACKMAN and SONS, who gave prominence to a quantity of *Helenium Crimson Beauty*, which is of brighter colour than *H. cupreum* (Silver Banksian Medal).

Other exhibitors of hardy flowers were Mr. YANDELL, who showed many *Violas* in boxes of sand (Silver Flora Medal), Messrs. R. H. BATH, LTD. (Bronze Flora Medal), Messrs. RICH and Co., and Messrs. MAXWELL and BEALE, who made a small rockery (Bronze Banksian Medal). Mr. F. C. WOOD, who included *Violas* and various alpinas (Bronze Banksian Medal), Messrs. JOHN FORBES, LTD., who had *Phloxes*, *Violas* and *Delphiniums* (Bronze Banksian Medal), Mr. R. C. DOWNER (Bronze Banksian Medal), and the Misses HOPKINS, who made and planted a small rockery.

Border Carnations of great excellence were staged by Mr. J. DOUGLAS. His blooms were all of good form and size, while many possessed the delicious Old Clove scent. The most prominent of the many varieties were *Fair Ellen*, *Bookham Rose*, *Gordon Douglas*, *Lieut. Shackleton* and *Maroon Clove* (Silver Flora Medal).

Messrs. LOWE and GIBSON gave the place of honour in their collection of border Carnations *Mary Murray* (see National Carnation Society awards), and also had good examples of *Lady Shackleton*, a giant fancy, *Kathie Moore*, *Skirmisher*, *Border Yellow* and the fragrant *Surrey Clove* (Silver Banksian Medal).

#### Fruit and Vegetable Committee.

Present: Messrs. C. G. A. NIX (chairman), Geo. F. Timlev, G. Berry, E. Merryweather, G. Reynolds, E. Neal, II. Prince, T. Pateman, W. Bates and Rev. W. Wilks.

A seedling, unnamed, black Cherry of the Waterloo type was submitted by Mr. YATES, Cone Lodge, Iver, Buckinghamshire, for award. The flesh is very solid and the stone is relatively a small one. Mr. Berry stated that the variety is very prolific and a most promising Cherry for market purposes. It was decided to ask Mr. Yates to name the variety and to

supply fuller particulars. Messrs. G. G. WHITELEGG and Co. showed a new Red Currant named *Orpington Prolific*, a cross between *Comet* and *Raby Castle*. The variety was referred to *Wisley* for trial, as were also two seedling Peas shown by Messrs. J. CARTER and Co.; both were raised from *Superb* crossed with *Quite Content*; the earlier sort grows one and a half feet high, and the other, which is a second-early, two feet. The pods are exceptionally large for dwarfs. This firm was awarded a Silver Knightian Medal for twenty-three varieties of Broad Beans, including two dwarf kinds, *Royal Dwarf Fan*, a white seeded form, and *Beck's Green Gem*, green seeded. The two finest varieties were *Leviathan White* and *Mammoth Windsor White*; the most prolific cropper was *Market Garden Windsor*, a sort intermediate between the *Long Pod* and *Windsor* types. They had also a very fine type of *Windsor*, with four-seeded pods, named *Home-stead Green Windsor*.

Messrs. G. G. WHITELEGG and Co. made a small group with the new varieties of Red Currants *Little Croft Beauty*, *Orpington Prolific* and *Improved Red Dutch*. Mr. F. WALKER showed varieties of Apples from his Tasmanian orchards, to which reference is made on page 31. The exhibit was awarded a Bronze Hogg Medal.

#### NATIONAL CARNATION AND PICOTEE.

##### SOUTHERN SECTION.

The annual show, which was held in conjunction with the R.H.S. meeting, did not attract many competitors, but the exhibits were generally of great excellence. The *Cartwright Challenge Cup* was again won by Mr. J. DOUGLAS, while Miss SHIFFNER also repeated her success with the *Martin Smith Memorial Challenge Cup* in the Second Division, and Mr. E. W. PAINTER won the *Edmund Charrington Challenge Cup* in the Third Division.

##### FIRST-CLASS CERTIFICATES.

*Mary Murray*.—A splendid canary yellow variety of good size and borne on such long, stout stalks that artificial support would seem unnecessary. The foliage is very good indeed, and it is a free-flowering sort—quite the best of its colour. Shown by Messrs. LOWE and GIBSON.

*Snowflake*.—A milky white variety of great excellence. The blooms are of medium size, perfect form, and the foliage is also very good. For purity of colour and substance of petal this variety is unsurpassed. Shown by Mr. J. DOUGLAS.

##### OPEN CLASSES.

Mr. R. MORTON, Woodside Park, was the only exhibitor of 6 Bizarres and Flakes in vases, and was awarded the first prize for a good collection, which included *Master Fred* (Premier Bizarre bloom), *George Morland* and *Meteor*.

Mr. JAMES DOUGLAS was similarly awarded the first prize for 6 vases of distinct varieties of (a) *Selfs*, (b) *Fancies* (yellow or buff), (c) *Fancies* (other than yellow or buff), and (d) *Clove Scented*. His excellent blooms included (a) *Snowflake* (Premier White Self), *Grenadier*, *Salmon Clove*, *Marechal Niel*, (b) *Viceroy* (Premier yellow ground Fancy), *R. Kelso*, *Lieut. Shackleton* and *Highland Mary* (c) *Steerforth* (Premier white ground Fancy), *Sir D. Haig*, (d) *Scarlet Clove* and *King of Cloves*.

Classes 34 to 44 were "Open to All," and, while their object or requirements were not stated on the exhibitor's cards or in the schedule, we assume they were colour classes. Mr. J. DOUGLAS won the first prize with *Cherry Blossom*, *Albion*, *King of Cloves* and *Scarlet Clove*. *Eclipse*, *Kelso* and *Margaret Keep*, while Miss SHIFFNER was equally successful with *Border Yellow*, *Effie Deans* and *Grey Douglas*.

##### AMATEURS' CLASSES.

Mr. J. J. KEEN, Southampton, won first prizes for (a) 3 varieties, *Bizarres* and *Flakes*, (b) *Picotees* (white ground), and (c) *Picotees* (yellow ground). The best of his very good blooms were (a) *Huntsman* (Premier seedling scarlet flake), *Master Fred*, (b) *Ganymede* (Premier heavy-edged Picotee), and (c) *Eclipse* (Premier light-edged Picotee).

Miss ELIZABETH SHIFFNER, Lewes, was particularly successful in these second division classes, winning first prizes for (a) 3 varieties, Fancies (yellow or buff ground), (b) Fancies (other than yellow or buff), (c) Picotees, and (d) Clove Scented. Miss SHIFFNER also won all the seven first prizes in the colour classes with excellent vases of the following: The White Fox, Border Yellow, Elizabeth Shuffner (buff or terracotta), Fujiyama (red or scarlet), Gordon Douglas (dark red or maroon), Mrs. R. P. Smith (pink or rose), and Grey Douglas (any other colour).

In the third division of the amateurs' classes Mr. E. W. PAINTER, Brentford, was the most successful exhibitor. He won nearly all the first prizes, showing very good blooms of such sorts as Gordon Douglas, Grey Douglas, Sam Weller and Lord Steyne. Mr. G. CHARRINGTON was first in the class for 3 yellow ground Picotees.

The best three vases of flowers grown in the open border were shown by Miss J. B. WELLS, Clapham, while the best single vase was by Mr. E. J. LOWE, Cricklewood.

### ROYAL AGRICULTURAL SHOW.

It is not many years ago that the Royal Agricultural Society decided to add to the attractions of its annual gathering a horticultural section of the exhibition, and that the step was a wise one which has met with the most generous appreciation is proved by the thousands of visitors who pay an extra charge to see its glories. Since the institution of the flower show there has been steady improvement in quality and extent, and that held between July 4th and 8th at Cambridge, was the finest of the series. The exhibits were displayed in two immense tents each having central staging and side benches, with abundance of space for locomotion in between. The general effect was that of formal masses of brilliant colour relieved here and there by groups of softer hues.

The one objection appears to be the rigidity of the lines, and it is difficult to see a way out of it. However, we look to Mr. Peter Blair, who has managed the shows so admirably and with such conspicuous success up to now, to see whether it is not possible to break away from the severely formal to the wisely controlled informal which will lead to the artistically picturesque. Mr. Blair is as keen as possible to help the growers who come to make the show and it is quite certain that if he could devise a scheme under which arrangements, while conforming to necessary rules for the convenience of the visitors, might deviate from the straight lines which now prevail, the exhibitors would heartily welcome it, while the public would learn what can be done with flowers in the creation of decorative effect when the artistic hand and eye are allowed free play.

Those who sent Roses and Sweet Peas must have had special favour from the clerk of the weather, for they were simply magnificent. There were colour, substance, form and size, with scarcely a trace of coarseness, and, almost without exception, the blooms were beautifully displayed.

In the competitive class for a collection of cut Roses Mr. THOS. ROBINSON, Nottingham, had a stand which was perfect in artistic effect, while the blooms shown by Messrs. A. J. AND C. ALLEN were conspicuous for remarkable quality. Messrs. R. BOLTON AND SON, Raythorne End, Essex, combined quality of blooms with delightful arrangement in their winning collection of Sweet Peas, as also did Mr. C. ENGELMANN, Saffron Walden, with perpetual Carnations. The collections of hardy perennial plants and cut blooms were excellent so far as the quality of the material was concerned, but they lost points generally through the diligence with which the packing in was done. Messrs. W. ARTINDALE AND SON, Sheffield, Messrs. HARKNESS AND SONS, and Messrs. G. GIBSON AND Co., both of Bedale, were all in good form. Messrs. J. CYPHER AND SONS, and Mr. W. A. HOLMES, Chesterfield, entered the lists with charming groups, while Messrs. BLACKMORE AND LANGDON, Twer-ton-on-Avon, were almost unfairly dazzling

with their tuberous Begonias, tempered somewhat by their adjacent collection of grand Delphiniums.

Handsomely meritorious as were the competitive classes, the non-competitive exhibits constituted the solid ground-work of the show, for they were at once numerous and well above the average for quality. Messrs. A. DICKSON AND SONS, Newtownards; Messrs. DOBBIE AND Co., Edinburgh; Messrs. A. IRELAND AND HITCHCOCK, Marks Tey; Messrs. SUTTON AND SONS, Reading; Messrs. ED. WEBB AND SON, Stourbridge; and Messrs. R. BOLTON AND SON did their respective duties with Sweet Peas; while Messrs. LAXTON BROS., Messrs. R. HARKNESS AND Co., Hitchin; Messrs. WOOD AND INGRAM, Huntingdon; Messrs. A. J. AND C. ALLEN, Norwich; Messrs. J. BURRELL AND Co., Cambridge; Messrs. B. R. CANT AND Co., Colchester; Messrs. A. DICKSON AND SONS; Messrs. DANIELS BROS., Norwich; and the Rev. J. H. PEMBERTON, Havering-atte-Bower, rendered splendid assistance with Roses.

Among those who sent hardy flowers or plants were Mr. R. C. NOTCUTT, Woodbridge; Messrs. R. H. BATH, Wisbech; Messrs. I. HOUSE AND SON, Westbury-on-Trym; Messrs. W. ARTINDALE AND SON; Messrs. BAKERS, Wolverhampton; the CHALKHILL NURSERIES, LTD., Reading; Mr. JOHN FORBES, Hawick; and Messrs. R. WALLACE AND Co., Tunbridge Wells. Very beautiful Carnations came from Messrs. ALLWOOD BROS., Haywards Heath; Messrs. K. LUXFORD AND Co., Harlow; and Mr. H. LAKE-MAN, Thornton Heath. Messrs. PULHAM AND SON, Elsenham, arranged a charming little rockery; Mr. H. N. ELLISON, West Bromwich, staged splendidly grown Ferns and Palms; and Miss THOMPSON, Handsworth, Birmingham, showed an interesting collection of Cacti.

Fruit trees in pots were sent by Messrs. J. VERT AND SONS, Saffron Walden; Messrs. SEABROOK AND SONS, Chelmsford; the KING'S ACRE NURSERIES, LTD., Hereford; and Sir CARL MEYER; while Messrs. SUTTON AND SONS showed superb Melons and Messrs. LAXTON BROS. splendid Strawberries. Messrs. SUTTON AND SONS also showed numerous dishes of admirably grown and staged vegetables. Outside the great tents Messrs. LAXTON BROS. had a bed of fruit trees and Mr. C. ENGELMANN two beds of Carnations.

### NATIONAL VIOLA AND PANSY.

THE monthly meeting and show of this Society was held at the Crown Hotel, Birmingham, on Wednesday, July 5. Mr. H. J. Milner occupied the chair, and there were 30 members present, including the hon. secretaries. Mr. W. W. Staples, treasurer of the Society since its formation, and who is connected with several other horticultural organisations in the Midlands, gave his "Reminiscences," many of which were on the humorous side. The greater part of the evening was taken up with business and arrangements for the annual show, to be held on July 28 and 29, at the Botanical Gardens, Edgbaston, Birmingham.

A fair number of exhibits were staged for the members' monthly medal competition, awards being made as follows:—Open Vases (Violas): 1st, Mr. W. H. C. TOOBY-DESMOND, Moseley. Open Boards (Violas): 1st, Mr. W. H. TOOBY-DESMOND. Amateur Vases (Violas): 1st, Mr. S. BUSHILL, Birmingham. Amateur Boards (Violas): 1st, Mr. A. HOLBROOK, Harborne. Amateur Boards (Pansies): 1st, Mr. THOS. H. JUSTICE, Wolverhampton. Novice Vases (Violas): 1st, Mr. F. DENNIS, Birchfields.

The Floral Committee met at 8 p.m. Present: Mr. H. Milner, in the chair, and Messrs. W. Allison, F. Barnett, W. H. C. Tooby-Desmond, and Hon. Secretary, H. F. Carter. A First-Class Certificate was awarded to Mr. A. CARTER for a seedling Viola named Mrs. A. Carter, described by the Committee as a dense purple ground, marbled and streaked with French grey and carmine. The flower has a neat eye, and is considered to be a new break in fancies. Mr. CARTER was awarded 1st prize in the Amateur Seedling Class for this Viola at last year's annual show.

### WOLVERHAMPTON FLORAL FETE.

THE thirtieth floral fête, held at Wolverhampton, took place on July 11, 12 and 13, and, as usual, its venue was the beautiful West Park, an open space of which the Midland town is justifiably proud. On this occasion the National Rose Society held its Provincial Show in conjunction with the fête, and the combination produced the finest exhibition yet held in Wolverhampton. The Roses were superb, and we hope to report upon them in our next issue, with special reference to the new seedlings which were exhibited in a tent by themselves. The chief features of the fête were the grand groups of plants, the specimen plants, the displays of hardy flowers and the floral decorations. Big tents are provided and there is ample space for the crowds of visitors, for whom, in addition to the plants, flowers, fruits and vegetables, various sports and outdoor attractions are provided. Mr. Alderman Jeffis, Chairman of the General Committee; Mr. F. T. Beck, Chairman of the Horticultural Committee, and Mr. G. W. Martin, the Secretary, deserve congratulations on the admirable arrangements made for exhibitors and visitors.

### GROUPS.

There were three noble entries in the principal class for a group of flowering foliage plants, arranged on a space 25 ft. by 12 ft. Messrs. J. CYPHER AND SONS, Cheltenham, secured the premier award of £40 with a beautiful group of attractive and well-grown plants disposed most artistically. A low double arch formed the centre of the background, and this was furnished with Codiaeums, Fuchsia triphylla, and Humea elegans, with Palms behind. Humea elegans was used as dot plants with elegant effect, and the slender spikes of Francoa ramosa harmonised with it. Vantage points were distinguished by specimens of Codiaeums, while Odontoglossums, Ixoras, Miltonias, Laelias, Cattleyas and Anthuriums were used freely in the ground work in association with Ferns, Rex Begonias, and Nandina domestica, while Selaginella and Nertera depressa were used as an edging. Sir G. H. KENRICK (gr. Mr. J. V. Macdonald), Edgbaston, was a capital second prize-winner, and he used Miltonias and tall Codiaeums with great effect; 3rd Mr. R. MANNING, Dudley.

In the class for a large group of foliage plants Messrs. J. CYPHER AND SONS were again the winners of the chief prize, and won with a handsome arrangement, but scarcely so bright as some of their exhibits we have seen; Codiaeums, Acalyphas, Dracaenas, Anthuriums, Palms, Nandina domestica and Japanese Maples were the leading subjects. Sir G. H. KENRICK, 2nd; Mr. W. R. MANNING, 3rd.

A handsome group of Clerodendron Balfouriana arranged over equally good examples of C. fallax, won for the Cheltenham firm the first prize in the class for a group of one kind of flowering plant. Mr. A. S. DUNTON, Penn, 2nd, with Astilbes; Sir G. H. KENRICK, 3rd with Hydrangeas.

Messrs. J. CYPHER AND SONS led in the class for fifteen specimen plants, and showed medium sized, finely flowered examples of Clerodendron Balfouriana, Statice profusa, S. intermedia, Ixora coccinea, and I. Regina; 2nd, Mr. MANNING, Dudley. Mr. G. MASON (gr. Mr. T. Clark), Penn, had the best dozen flowering plants of one kind, winning with Hydrangeas; 2nd, Major S. THOMPSON, Oaken, with Begonias. Mr. Mason was also successful in a small group class.

Two collections of decorative plants and cut flowers were arranged, and produced a pleasing effect; the best of the two was arranged by Messrs. CYPHER AND SONS, Mr. R. MANNING coming second.

### Floral Arrangements.

Two classes were provided for table decorations, and in the open one the competition was very keen. The principal award was made in favour of Mr. W. J. GRESSON, Severn, Stoke, who had a beautifully light design in Oncidiums, Francoa ramosa and Gloriosa Rothschildiana; the colour scheme was brilliant and daring. Sir G. H. KENRICK came 2nd also with Orchids, his arrangement being a handsome, but subdued

one of Miltonias, Phalaenopsis, Odontoglossums, and Vanda teres; 3rd, H. WATSON SMITH, Esq. (gr. Mr. H. Davis), Stourbridge.

In the Amateurs' Class, Mrs. COURTNEY PAGE, wife of the N.R.S. Secretary, won first place with a low design of bowls of a gorgeous Rose of the Queen Alexandra type; 2nd, Mr. R. W. HOSIER, Wettenhall, for a fine arrangement of Ophelia Rose; 3rd, Mrs. COLSTON HALE, Warminster, with Sweet Peas and Carnations; a trifle too freely used.

Bouquets were good, and in the class for a hand bouquet Mr. A. ADSHEAD, Gatley, led with a handsome design in bright-hued Orchids and Anthuriums; Mr. C. VICKERS, Leicester, 2nd, with an Orchid design, a trifle heavy. Mr. A. ADSHEAD was very successful in the class for a bridal bouquet and two bridesmaids' bouquets, and here he showed charming designs in white Orchids, and two bouquets of fine red Carnations. Mr. C. VICKERS, 2nd, with Orchids and yellow Carnations. Mr. C. VICKERS led in the class for a featherweight bouquet, a pleasing arrangement of Orchids and Anthuriums.

Mr. W. GRESSON and Sir G. H. KENRICK were placed first and second respectively in a class for a stand of cut flowers. Mr. H. E. FENTON, Walsall, showed the best bowl of Roses, the variety being the ever-popular Ophelia.

**Sweet Peas.**

No doubt the fact that the N.S.P.S. show was to take place on the following day at Eastbourne was responsible for a slight falling off in the exhibits of Sweet Peas—generally a very fine feature at Wolverhampton. In the leading class for a dozen bunches distinct, Mr. F. R. MINSHALL, Market Drayton, won first place with capital flowers of Constance Hinton, Picture, Royal Purple, Daisybud, La France, Mrs. Tom Jones, Royal Scot and other first-rate sorts. The blooms were large and fresh, but their arrangement in fan-shaped bunches was not pleasing; 2nd, Mr. D. GREEN, Wolverhampton (gr. Mr. Thorneycroft). Mr. J. T. FINNEY, Stone, won first prize for six bunches of distinct varieties.

Mr. A. S. DUNTON contributed the best collection of eighteen bunches of Sweet Peas, winning with fine flowers and showing Mrs. T. Jones, Royal Purple and Mascotts Helio, in fine form. Mr. H. WATSON SMITH led in a special class for six bunches, and Mr. H. BUCKLEY, Stone, had the best twelve bunches, distinct.

**Hardy Flowers.**

The sum of £20 was offered as 1st prize for a collection of hardy flowers arranged on a space 25 ft. by 7 ft. There were three competitors, and Messrs. HARKNESS AND SON, Bedale, won chief position with a very fine display in which were Delphiniums, Mulleins, Gaillardias, Lilliums, Gladioli, Poppies (too closely packed), Campanulas and other good border plants; 2nd Mr. R. PRICHARD, Christchurch, who had a great variety of subjects, and included a collection of beautiful Pinks, a selection of Kniphofias, Romneya Coulteri, Delphiniums, etc., but did not finish off the front of his exhibit so well as did the first prize winner; 3rd, Messrs. GIBSON AND SON, Bedale. These three groups made an imposing and interesting display.

For a collection of a dozen bunches of hardy flowers, Mr. F. A. COOKE, Tettenhall, was easily first in a good competition where popular kinds figured. He was also first prize winner in the class for a collection of hardy flowers arranged on a space 8 ft. by 4 ft.; here there were three entrants, two of whom packed their blooms too tightly together.

Mr. M. PRICHARD led for a collection of Delphiniums, and Messrs. HARKNESS AND SON came second, but in each case it appeared that the exhibitors had insufficient time to properly arrange their flowers. Messrs. GIBSON AND SON were awarded first prize for a spike of a new seedling Delphinium, winning with a rich blue, white centred variety, with large, widely expanded blooms.

Mr. T. B. ADAMS, Compton (gr., Mr. Walker), showed the best collection of a dozen kinds of hardy flowers, a pleasing arrangement of Lillium elegans, Spiraea Aruncus, English Iris, Gaillardias, Delphiniums and Roses; 2nd H. WATSON SMITH, Esq. (gr., Mr. H. Davies), Stoneleigh.

Violas were admirably shown, and Mr. T. H. JUSTICE, Wolverhampton, led in a keen competition in a class for six varieties, with grand show flowers; 2nd, Mr. S. CARLESS.

There appeared to be only one exhibit of a group of Hardy Annuals, and this, awarded a first prize, was shown by Mr. A. S. DUNTON. Such a class should receive more attention from exhibitors, as it could be made a very interesting feature. For a group of bedding plants the chief award was won by Mr. E. LOWE, Stanstead, who had a very formal arrangement of Pelargoniums and Begonias, edged with Pyrothrum and Echeverias—not a very original design; 2nd, Mr. A. S. DUNTON.

Mr. C. WALL, Bath, was the only exhibitor of a display of Carnations, and he thoroughly deserved the first prize awarded him. His arrangement was bold and effective, and his flowers of popular perpetual varieties were of excellent size and colour. Mr. F. BAYLISS, Walsall, led for a dozen blooms of border Carnations, with very clean, shapely flowers; and also for a dozen fancy border Carnations.

**Vegetables.**

Considering the season, vegetables were fairly well represented. In Messrs. Sutton's class for a collection of six distinct kinds, Mr. W. J. GRESSON was first prize-winner, and Mr. G. H. HICKMAN, Cookley, 2nd. Mr. GRESSON was equally successful in an open class and in the class provided by Messrs. Webb and Sons, as well as in the amateurs' class for six kinds, and in every case he staged capital produce.

**Non-Competitive.**

Needless to state, the non-competitive exhibits were numerous and added greatly to the excellent beauty and interest of the fête. The three outstanding displays were those of Messrs. BAKERS, Wolverhampton—a formal garden with sunken centre and handsome borders of hardy flowers; Messrs. DOBBIE AND CO., who showed a fine lot of Roses; and Messrs. E. WEBB AND SONS, Stourbridge, who displayed vegetables, Begonias and annuals in good style.

*Large Gold Medal.* To Messrs. BAKERS, Wolverhampton; to Messrs. DOBBIE AND CO., Edinburgh; and to Messrs. E. WEBB AND SONS, Stourbridge.

*Gold Medal.* To Mr. H. ELLISON, West Bromwich, for Ferns and Cacti; to Messrs. STUART LOW AND CO., Enfield, for Orchids and Carnations; and to Messrs. J. E. KNIGHT AND SONS, for floral designs.

*Silver Medal.* To Messrs. JARMAN AND CO., Chard, for Pelargoniums and Sweet Sultans; to Messrs. ISAAC HOUSE AND SON, for Scabious in variety; to Mr. W. WELLS, jun., Merstham, for hardy flowers; and to Mr. E. MURRELL, Shrewsbury, for Roses.

*Bronze Medal.* To Miss TROMPSON, Wandsworth, for succulent plants; and to Messrs. MAXWELL AND BEALE, for alpine plants.

**GENERAL BULB GROWERS' OF HAARLEM (HOLLAND).**

THE different Floral Committees have made the following Awards at their meetings during the winter and spring of 1921-2:—

**FORCING.—CERTIFICATES.**

*Narcissus Ajax Moonlight.*—Perianth white, trumpet creamy-yellow. Shown by Mr. P. VAN DEURSEN, at Sassenheim.

*N. bicolor Olivier Cromwell.*—White perianth with yellow trumpet. Shown by Messrs. EGGINK BROS., at Voorschoten.

*N. Campmerelli odorus giganteum.*—Deep golden-yellow, firm flower. Shown by Mr. P. VAN DEURSEN, at Sassenheim.

*N. Cervantes.*—Yellow, perianth not closed, trumpet somewhat deeper yellow. Shown by Messrs. BYVOET BROS., at Overveen.

*Tulip (Darwin) Le Nôtre.*—Striking rose, Shown by Messrs. EGGINK BROS., at Voorschoten.

*Tulip (Breeder) Panorama.*—Deep mahogany-red coloured. Shown by Messrs. EGGINK BROS., at Voorschoten, and Mr. NIC. BOS, at Katwyk-on-Rhine.

**FIRST-CLASS CERTIFICATES.**

*Tulip (Darwin) Laura.*—Bright violet with white centre, large white border. Shown by Messrs. C. G. VAN TUBERGEN, JUNR., at Haarlem.

*Tulip (Parot) Fantasy.*—Deeply lacinated rose, with green splashes outside. Shown by VEREENIGDE BLOEMBOLLENCULTUREN, LTD., at Noordwyk.

*Iris pallida Emprress of India.*—Large flower, standards light violet with sky-blue shading, fragrant. Introduced by Mr. G. LUBBE THZ., at Oegstgeest.

**AWARDS OF MERIT.**

*Eranthis Tubergens Var.*—(Eranthis cilicica × E. hymnalis), soft yellow, free flowering. Shown by Messrs. C. G. VAN TUBERGEN, JUNR., at Haarlem.

*Narcissus Adelaide.*—Perianth and trumpet both white, cylindric trumpet, perianth firm. Raised by Messrs. E. H. KRELAGE AND SON, Haarlem.

*N. Ajax Grand Frazier.*—Perianth and trumpet soft sulphur-yellow, large petals, border recurved and notched, very large flower. Raised by Messrs. C. G. VAN TUBERGEN, JUNR., Haarlem.

*N. Ajax Pile of Gold.*—Deep unicoloured golden-yellow, very firm. Raised by Messrs. C. G. VAN TUBERGEN, JUNR., Haarlem.

*N. Burri Glad Eye.*—Creamy-white perianth, cup orange-scarlet, centre canary-yellow, flat. Shown by VEREENIGDE BLOEMBOLLENCULTUREN, Noordwyk.

*N. bicolor The Queen.*—Large creamy-white perianth, trumpet soft yellow, border notched. Raised by Messrs. E. H. KRELAGE AND SON, at Haarlem.

*N. incomparabilis Alceste.*—Cup bright yellow with white perianth, large petals forming a star. Shown by Messrs. C. G. VAN TUBERGEN, JUNR., at Haarlem.

*N. incomparabilis Red Cross.*—Perianth soft yellow, large cup dark yellow coloured, border orange shade, big flower. Raised by VEREENIGDE BLOEMBOLLENCULTUREN, LTD., at Noordwyk.

*N. incomparabilis Selycette.*—White perianth with large petals, cup canary-yellow, wide and recurved. Raised by Messrs. E. H. KRELAGE AND SON, Haarlem.

*N. Leedsii Her Grace.*—Creamy-white perianth, cup light sulphur-yellow becoming white, rather long and wide. Shown by Messrs. C. G. VAN TUBERGEN, JUNR., at Haarlem.

*N. Leedsii Prof. Westerdijk.*—Cup soft pale yellow, perianth ivory-white, large petals. Shown by Messrs. E. H. KRELAGE AND SON, at Haarlem.

*N. Poetoz Brimstone.*—Soft sulphur-yellow perianth, crown light citron-yellow, large flowering. Raised by Messrs. DE GOEDE BROS., Beverwyk.

*N. Poetaz Diadem.*—Milk white perianth, crown bright yellow with orange border, large flower stalk. Raised by Messrs. DE GOEDE BROS., at Beverwyk.

*N. Primrose Perfection.*—Unicoloured, soft yellow with peculiar glow, flower medium-size. Raised by Messrs. E. H. KRELAGE AND SON, at Haarlem.

*N. triandrus hybridus Gertrude.*—Unicoloured, citron-yellow, wide and rather long, petals somewhat curled. Shown by Messrs. VAN ZONNEVELD AND PHILIPPO BROS., Sassenheim.

*Tulip (Breeder) St. James.*—Deep wine-red with bronze border. Shown by Messrs. EGGINK BROS., Voorschoten.

*Tulip (Cottage) Mrs. Hoog.*—Soft creamy-yellow, points sulphur-yellow. Shown by Messrs. C. G. VAN TUBERGEN, JUNR., Haarlem.

*Tulip (Mendel) April Queen.*—(Duc van Thol × Darwin), light lilac rose. Shown by Messrs. E. H. KRELAGE AND SON, Haarlem.

*Tulip (Mendel) Early Beauty.*—(Duc van Thol × Darwin) bright carmine-rose. Shown by Messrs. E. H. KRELAGE AND SON, Haarlem.

*Tulip (single late) Gesneriana Advance.*—(Tulipa gesneriana spatulata × Tubergiana), bright scarlet with blue centre, outside

greyish-white with violet glow. Shown by Messrs. C. G. VAN TUBERGEN, JUNR., Haarlem.

*Tulip (single early) Fortuna*.—Lilac rose. Shown by Mr. C. J. KIEFT, Heiloo.

*Tulipa Eichleri*.—Bright scarlet with gleaming black spots, light yellow centre. Imported from Asia by Messrs. C. G. VAN TUBERGEN, JUNR., at Haarlem.

*Iris (Dutch) The First*.—(*Iris tingitana* × *filifolia*), light blue standards, falls somewhat lighter, very early. Shown by VEREENIGDE BLOEMBOLLENCULTUREN, LTD., Noordwyk.

*I. (Dutch) Vermeer*.—White, standards green shaded, rather yellow round the centre, deep-yellow spot. Shown by Messrs. C. G. VAN TUBERGEN, JUNR., Haarlem.

*I. (Dutch) Wouwerman*.—Standards sulphur-yellow, falls deep golden-yellow with orange-red spot. Shown by Messrs. C. G. VAN TUBERGEN, JUNR., Haarlem.

*I. filifolia E. B. Garnier*.—Standards dark indigo-blue, falls light grayish-blue. Shown by VEREENIGDE BLOEMBOLLENCULTUREN, LTD., Noordwyk.

*I. filifolia J. D. de Heem*.—Standards soft mauve-blue, falls soft pearl-blue with bright yellow stripe. Shown by VEREENIGDE BLOEMBOLLENCULTUREN, LTD., Noordwyk.

*I. filifolia A. L. Koster*.—White, centre rather creamy-yellow, yellow spot. Shown by DE VEREENIGDE BLOEMBOLLENCULTUREN, LTD., Noordwyk.

*I. Regelio-Cyclus Asporina*.—Soft violet standards, veined dark purplish-red with large coloured brown-purple spot.

*I. Regelio-Cyclus Clotto*.—Very dark violet standards, falls short, velvety black brownish-purple with blackish-brown spot.

## Obituary.

**Thomas Hatton**.—We learn with deep regret of the death of Mr. Thomas Hatton, who for many years was gardener at "Badgemore," Henley-on-Thames. He died on June 9, in New York, after a serious operation. He leaves a widow, two daughters and one son.

## NEW HORTICULTURAL INVENTIONS.

### ABSTRACT PUBLISHED LAST MONTH.

**Packing Plants** (Patent No. 178,327).—A patent has been granted in this country to Mr. J. Nissen, of 165, Obere Lichtenplatzenstrasse, Tolleturn, Barmen, Germany, for a machine for packing the roots of living plants. The roots are enclosed with the necessary earth and straw in wire or thread netting. The root is held by a holder above a base-plate which carries, in arms, the bearings of shafts on which are mounted wire guiding-levers. The shafts are actuated from a planetary system of pinions connected by shafts to pinions gearing with bevel-gears. The wire is supplied from bobbins and is guided to the ends of the levers through eyes. The wire having been twisted together from the previous operation, the device is rotated by means of a hand-rail; the gear being prevented from rotating in one direction by a pawl, the pinions actuate the levers to place the wires about the root. After the levers have made half a revolution, the rotation of the device is reversed. The gear being free to rotate in this direction, the levers are not rotated about the shafts, and the wires were consequently placed round the neck of the root. The rotation of the device is again reversed until the levers have returned to their positions, this completing a network of wire about the root. On reversal again the ends of the wires are twisted and are cut off. In a modification, the root is held in a vertically movable carrier, and the wire-guiding levers are mounted on vertical axes in the rotary machine frame. In another modification, the wire guiding levers are mounted on vertical pivots and are actuated by the action of pins and slots in outward extensions thereof.

## ANSWERS TO CORRESPONDENTS.

**BEEF LEAVES DAMAGED:** *H. P. K.* The leaves have been damaged by the leaf miner insect, which you will find present beneath the skin if you hold the leaf up to the light. As the grubs are present in the tissue below the skin, spraying is of no avail, and the only method is to destroy the pest by pinching between the finger and thumb or by piercing it with a needle. Next season spray the plants early with some distasteful solution, such as quassia extract, in order to deter the mother insect from laying her eggs on the leaves.

**CATERPILLAR ON OAK:** *J. E.* The Caterpillar to which you refer (the Oak leaf roller Moth) is very plentiful this year; see *Gard. Chron.*, July 1, 1922, p. 10.

**CLUB ROOT:** *W. A. R.* As the soil is so badly infected with the disease, the ground should not be planted with Brassicas or Turnips, but it would not affect such crops as Carrot, Beet, or members of the Pea and Bean family. Your suggestion to grow Strawberries might be followed, and, by the time the ground was cleared of the Strawberries, it might then be possible to grow members of the Brassica family again.

**GRAPES SCALDED:** *Urgent.* Scalding is due to the action of sunlight upon foliage and berries wet with condensed moisture. Theinery should be ventilated early in the morning so that the moisture is dispersed before brilliant sunshine can act through it, as through a lens, on the tender tissues. The chief point to observe in the prevention of scalding is to open the ventilators very slightly, early in the morning, and steadily increase the amount of ventilation through the day in bright and warm weather.

**MILDEW ON VINES:** *W. J. S.* Syringe the Vines immediately, in sunny weather, with sulphur mixed with water. First make a paste by mixing the sulphur with a little soapy water and then dilute sufficiently to enable the syringe to draw it up. The sulphur will do no permanent harm to the berries so long as the shade temperature does not exceed 80°. The sulphur may be syringed off with soft water in a fortnight's time.

**NAMES OF PLANTS:** *J. L.* 1, *Saxifraga Gemm. var. gracilis*; 2, *S. Hostii*; 3, *Ornithogalum umbellatum*; 4, *Saxifraga Gemm. var. dentata*; 5, *Scilla peruviana*; 6, *Sedum praealtum*; 7, *Enonymus japonicus variegatum*; 8, *Aesculus flava*.—*G. M. P.* 7, *Rhododendrons Minnie*; 2, Mrs. F. Hankey; 3, Mrs. Mendel; 4, Bruce Finlay; 5, Charles Mason; 6, Mrs. J. P. Lade; 7, *Marchioness of Lansdowne*; 8, *Martin Hope Sutton*; 9, *John Waterer*; 10, *Coral Star*; 11, *Barclayanum*.—*A. H. and A. Y. L.* *Arum Drauculanum*.—*T. A. V.* 1, *Scilla italica*; 2, *Stachys lanata*; 3, *Erigeron philadelphicus*; 4, a variety of the *Iris pallida* section.—*J. T.* 1, *Scilla italica*; 2, *Ranunculus acris flore pleno*; 3, *Veronica gentianoides*; 4, *Gnaphalium lanatum*; 5, *Erigeron speciosus*.—*J. A. C.* *Tecophilaea cyanocrocus*.—*W. L.* We cannot undertake to name varieties of florists' flowers.—*E. C.* 1, *Abutilon vitifolium*; 2, *Acer palmatum sanguineum*; 3, *A. p. aureum*; 4, *A. Negundo variegata*; 5, *Phlox fruticosa*; 6, a variety of *Helianthemum* (rock Rose).—*G. B.* 1, *Muscari comosum monstrosum*; 2, *Crataegus nacetifolia*.—*W. J. P.* *Cynosurus echinatus* (Rough Dog's Tail Grass).

**PEACH AND NECTARINE FRUITS FAILING TO SWELL:** *W. H. B.* Probably the growth of your Peach trees is too vigorous. Examine the roots early in October and bring them nearer the surface, adding plenty of old lime rubble in the compost. Also examine the border and make sure that the trees have not suffered for want of water at the roots. Absence of fire heat is not the cause of the fruits dropping, provided the house was ventilated carefully.

**REMARKS.**—The cold, wet weather has resulted in fewer consignments of home-grown produce, and also adversely affected the demand. At the time of writing the prospects are more promising for better trade. Choice fruits, such as Grapes, Peaches, Nectarines, Melons and Figs have an easier tendency in some instances, due to increased quantities. A fair inquiry is being maintained for satisfactory parcels of Australasian Apples, the season for which is now finishing. A fairly brisk demand is ruling for Black Currants from all sources. Raspberries and Red Currants are also selling well. Bananas show little fluctuation in values. Cherries are in fair demand, but a large proportion of the fruit is cracked and unfit for further transit, which tends to restrict values. Forced Beans are a short supply and inquired for. The few outdoor Beans available are realising good prices. The wet weather has resulted in very large supplies of field Mushrooms, and these being so plentiful the values of forced Mushrooms have seriously depreciated. Green vegetables are plentiful and cheap. Lettuces, unfortunately for the producers, are practically unsaleable. Potatoes are considerably cheaper; heavy quantities of Dutch tubers are quoted at low rates.

### Out Flowers.

**REMARKS.**—Carnations and Roses are the most plentiful of flowers; the supplies of the former exceed the demand. The quantities of all outdoor blooms have been considerably reduced by the unfavourable weather of the past few days. Gladioli, Giant White Breuchleyensis, Hally and Prince of Wales (salmon) are amongst the most attractive lines. Large consignments of these blooms are arriving from Holland, including large quantities of The Bride variety. *Statie sinuata*, in white, mauve and yellow colours, is arriving in better condition. The first consignment of *Statie latifolia* was a sale last week, also *Gypsophila paniculata*. *Astromerita beguini* to make a bigger show. *Lilium longiflorum* still holds firm in price; *L. lanceifolium album* and *L. l. rubrum* are more numerous. Asters have appeared in the market, but only a few, and good blooms are fetching high prices.

### GARDENING APPOINTMENTS.

**Mr. J. Roberts**, previously Gardener to C. H. LOMAX Esq., Grove Park, Yorkford, Suffolk, as Gardener to COLONEL H. E. HAMRO, C.B.E., Coldham Hall, Bury St. Edmunds, Suffolk.

**Mr. H. F. Zobel**, for ten years Gardener to the late GEORGE BURR, Esq., J.P., at Castle Hill, Rotherfield, Sussex, as Gardener to G. W. GORON, Esq., J.P., Southwood House, Hildesborough, Kent. (Thanks for 2s. for R.G.O.F. Box.—Eds.)

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 63.2°.

ACTUAL TEMPERATURE:—

Gardeners' Chronicle Office, 5, Tavistock Street, Covent Garden, London, Wednesday, July 19, 10 a.m. Bar. 30.2; temp. 62°. Weather—Fine.

The Carrot's Crimson Eye.

Along the railway banks, by the roadside, and in the dry pastures, the white flowers of the Carrot are in evidence, and to the student of botany they have a great fascination, for the plant represents the wild condition of one of our best-known indigenous vegetables. Under cultivation the root has been made juicy, succulent and sugary. The Carrot belongs to the Order Umbelliferae, and for this reason it demands attention, for a plant cannot have attained to so great distinction all in a day. It must have a history, and that a long and eventful one. The word "umbel" was chosen, as anyone may see, on account of the shape of the inflorescence which spreads out like an umbrella, and the two words are derived from the Latin *umbra*. It is, as a rule, quite easy to distinguish an Umbellifer from any other plant. "As a rule," be it observed, for there are a few exceptions. The novice who does not at once recognise that the Sea Holly, the Sanicle, the Penny-wort, or the Astrantia are Umbellifers, may be excused, but with few exceptions all the remaining plants of this order found in England have their flowers in compound umbels, usually white, occasionally yellow, and at times with a greenish or else a pinkish tinge. The Order is a large one. We find some fifty genera in this country alone, or nearly one-third of the whole Order. There are about seventy native species, which is a twentieth part of those which have been described. The Carrot, however, has one distinctive mark, and this exceptional badge makes it particularly

interesting. In its heart we may see a blossom which is distinct from all the rest. It is thus described by quaint old Gerard: "The floures are little, and stand upon broad spoked tuftes, of a white color, of which tuft of floures the middlemost part is of a deep purple." Withering, however, states, the "flowers are white, except the central floret, which is deep crimson." At times it is a vinous red, but in any case, it is conspicuous by reason of its colour. In the Hogweed, the Goutweed, the Parsnip, Parsley, or any other wild Umbellifer, we will fail to find the crimson eye. This is the one fact on which we focus attention. What means the Carrot's crimson eye? The colour of the eye is always significant, be it black, blue, red or otherwise. How are we to explain this striking phenomenon? Volumes have been written on the colours of flowers, and yet the subject is not exhausted. There are still many problems unsolved, and that of the Carrot's crimson eye is one. There is the biologist, for example, who considers colour is very largely a question of nutrition. Rich colours are exhaustive, and with large umbels the plants cannot supply their blossoms with the foodstuff necessary to colour the whole of the inflorescence, but the central floret, being near the heart of things, gets the fullest measure, and so turns crimson. That is one theory. Another theory is that the colour represents nature's beautiful device of adorning the decadent, but in the present case this does not apply. There is also the theory that the crimson eye is a response to the call of certain insect visitors who want a more striking colour scheme. It suggests that the Carrot is about to attempt higher flights, and will some day don the purple. But if that were so, why does not the cultivated Carrot show a crimson inflorescence? Grant Allen tells us that this family is a difficult one to deal with satisfactorily, and he refuses to look the Carrot in the eye. Lubbock wonders whether the neutral tints of the Umbelliferous flowers have any connection with the number of different kinds of insects by which they are visited. What insects do we find in search of honey on a Carrot? "In the common Carrot, where the honey is quite exposed, 13 in a hundred visitors are bees, 3 are butterflies or moths, 31 are flies, and 53 belong to other orders." Such are the figures supplied by one of the German authorities, but the present writer has not verified them. The theory that the richly-coloured floret is a freak will not hold. It is not sporadic; it has been recorded for hundreds of years and is found in every locality where the plant flourishes, no matter what the soil or season. There remains, so far as our observation goes, one other theory worthy of mention. It is that the crimson eye is representative of a glory which has departed; the last faint reminder of the days when the Carrot was clothed in crimson or clad in purple. It would take too long to follow out all the lines of argument, but the following observations are according to this theory. In the long ago, the Carrot produced highly coloured flowers which were scattered at intervals over the straggling flower-stalk. In the battle for life it was necessary to adopt a better means of securing insect visitors. Thus the umbel was evolved, and the expensive habit of producing coloured petals given up. True the umbel did not possess the aristocratic appearance which belonged to the earlier state, but there are times when appearances must be sacrificed to save life. The Carrot, however, was unwilling to sacrifice every heirloom, and just as the new poor retain the seal when the

coat of arms has vanished, so the Carrot bugs to its heart one single ruby from its ancestral coronet. To show that in this theory there is a possible solution of the question, two facts may be adduced. The first is that a plant is sometimes found in which the central umbellule (and not merely its innermost floret) is crimson. The second is that many years ago it was reported from Penzance that the umbel sometimes contains flowers which are entirely red.

Ghent Quinquennial Exhibition.

The decision of the Council of the Société Royale d'Agriculture et de Botanique de Gand to hold a great exhibition at Ghent in 1923, is one which has been received with great pleasure by horticulturists in this country, because many pleasant memories attach to quinquennial exhibitions of bygone years, and also because it is a token that Belgian horticulturists have sufficiently recovered from the effects of the war to undertake the organisation of an exhibition, which, judging from past experience, will be one of the largest held in Europe. In former years the great Ghent shows attracted horticultural traders from all parts of Europe and from America, as new and rare plants were invariably an important feature. Although new tropical plants of horticultural value are rarely seen nowadays and the demand for them has fallen off, we hope that in 1923 novelties among plants and flowers of these and other kinds will be as numerous as formerly and not less valuable and interesting. We have before us a schedule of the exhibition to be held in Ghent from April 14 to April 22, 1923. It is a booklet extending to 108 pages, in which are printed no fewer than 778 classes, together with the rules for exhibitors and the names of the officials. The exhibition will be held under the special patronage of His Majesty King Albert of Belgium. Once again M. Alexis Callier is President; M. Albert Ceuterick, Vice-President; M. Lucien de Cock, General Secretary; M. Robert Delmotte, Assistant Secretary and M. Maurice Duquesnoy, Treasurer. M. Henri de Wilde, Director of Open Spaces and plantations of Ghent, will plan the exhibition on artistic lines. The Council is composed of MM. le Comte Andre de Kerchove de Denterghem, Arthur de Smet, Romain de Smet, Maurice Lippens, Théophile Morel de Westgaver, Charles Pynaert, Francois Spae, Louis Van Houtte and Maurice Verdonek. Sir Geo. Holford, Sir W. Thiselton-Dyer and Sir Harry J. Veitch are the British members of honour. The classes are divided into twenty-eight groups, i.e., for New Plants, Orchids, Stove and Greenhouse Plants, Aroids, Palms, Cycads and Pandanus, Ferns, Miscellaneous Flowering and Foliage Plants, Specimen Plants, Hard-wooded Plants, Roses, Herbaceous Flowers, Carnations, Bulbous Plants, Tuberos-rooted Plants, Azalea indica varieties, Camellias, Mollis, and Ghent Azaleas, Ornamental Plants, Succulent Plants, Conifers, Fruits, Genetics, Florists' Art, and Horticultural Industries. To secure publicity for the exhibition the Council has appointed a Press Commission upon which we find the names of the principal horticultural journalists of this country and of France. We trust that the exhibition will be the success its promoters anticipate, and that it will prove an advance upon the seventeen quinquennial exhibitions previously held by the Ghent Society, which was founded in 1806 and has done a vast amount of excellent work in extending horticulture in its own land and also in the whole of Europe.

**Retirement of Mr. W. Tilling from Heaton Park.**—The Manchester Parks Committee is about to lose the services of Mr. William Tilling, their head gardener at Heaton Park, on his retirement under the superannuation scheme. Mr. Tilling is a native of Gloucester and has been at Heaton Park for more than forty years. He was gardener to the former owner, the Earl of Wilton, and when the park was purchased by the citizens of Manchester some twenty years ago he was appointed to the superintendency under the corporation. Always a most courteous and obliging official, he was held in great respect and esteem by all classes, and in particular by the staff under his control, who have made him a parting gift in the form of a handsome oak timepiece, together with a pair of silver vases for Mrs. Tilling. He carries with him into retirement the good wishes of the Manchester Parks Committee and of all with whom he has come into contact.

**Presentation to a Head Gardener.**—A representative gathering of residents in the Tardebigge district met in the Village Hall on the evening of the 8th inst. to present Mr. J. J. Graham, late head gardener to the Earl of Plymouth, at Hewell Grange, with a handsome gold watch and chain as a token of esteem and appreciation of the work he had done amongst them during his seven years' residence at Hewell. The Earl of Plymouth, who had been asked to make the presentation, travelled from London specially for the occasion. After several speakers had testified as to the excellent record of Mr. Graham, the Earl expressed the pleasure and honour he felt at having been asked to make the presentation. He voiced the feeling not only of himself, but of the whole neighbourhood, when he said how deeply they regretted his leaving them. He pointed out, however, that although old ties must be broken, no one could deprive them of the delight Mr. Graham had been while among them, and although they were losing him they would still have happy memories of the past. He paid tribute to the excellent service Mr. Graham had rendered to the whole community at Tardebigge, rich and poor alike. Mr. Graham, in a few well-chosen words, expressed his gratitude to the Earl and all the friends for their great kindness to him. Mr. Graham has recently been appointed by the Manchester Parks Committee to take charge of Heaton Park, the largest and most important of their public parks. He is succeeded at Hewell by Mr. F. Molyneux, late general foreman at the Royal Gardens, Sandringham.

**The World's Requirements of Nitrogen.**—An interesting estimate of the nitrogen requirements of the cultivated soils of the world is cited in the *International Review of the Science and Practice of Agriculture* (*Monthly Bulletin of Agricultural Intelligence*, XII., 10, October, 1921). According to estimates and reckonings, the nitrogen requirement, in terms of nitrate of soda, by the cultivated regions of the world is about eight and three-quarter million tons annually. They receive at present only some two and three-quarter million tons.

**Rhus Toxicodendron and Other Poisonous Species.**—The well-known poisonous effects of various species of *Rhus* have recently been investigated by Mr. McNair, whose results published in the *American Journal of Botany* (VIII., No. 5), indicate that the poison is non-volatile and is contained in the resinous sap. The skin irritation which the poison produces may develop only after a long latent period, and hence there is apt to be a difficulty in diagnosis. The paper contains an exhaustive bibliography on the subject of *Rhus* poisoning.

**Self-sterility in Apples.**—Tests carried out in Sweden\* indicate that in that country self-sterile Apples include Belle de Boskoop, Bismarck, Cox's Pomona, Wellington; and that Lane's Prince Albert is partially self-sterile; and that Lord Grosvenor develops parthenocarpic fruit (i.e., without fertilisation) as also in a limited extent does Keswick Codlin.

**Mr. E. Gilman.**—Another old gardening association is about to be broken, as Mr. E. Gilman, so long gardener to the Earl of Shrewsbury and Talbot, at Ingestre Hall, Stafford, is retiring, after a period of service extending over forty-six years. Mr. Gilman belongs to a school of gardeners of which only a few now remain, and thirty or more years ago he made fame for himself in the Midlands as a grower and exhibitor of Chrysanthemums at the time when big blooms were at the height of their popularity. As a grower and exhibitor of fruit, notably Grapes and Peaches, Mr. Gilman also excelled, and in addition he was responsible for raising several good varieties of Melons and Tomatos. Mr. Gilman commenced his gardening career at the age of fourteen, in the gardens of John Cruso, Esq., Leek, and after remaining there for three years, he entered service under Mr. Rabone, at Woodseat, Uttoxeter, where this celebrated gardener was then producing Grapes of remarkable quality and creating a considerable sensation in the gardening world. A little later, Mr. Rabone became head gardener at Alton Towers, and young Gilman soon joined him, and stayed with him one year.

MR. EDWIN GILMAN.

From Alton, he was sent by Mr. Rabone to Coombe Abbey, where he received further training in fruit and plant cultivation under Mr. William Miller. Here he remained for three years, and then went to the famous Trentham Gardens, at the time when Mr. Zakok Stevens was the Duke of Sutherland's gardener. From Trentham Mr. Gilman went as gardener to Sir Henry Edwardes, Wootton Hall, Derbyshire, a beautiful place, where he obtained experience that qualified him for the more onerous duties of gardener to the Earl of Shrewsbury, at Ingestre Hall, Stafford, an appointment he took up in 1876. After twenty years service at Ingestre, Mr. Gilman also took charge of the famous gardens at Alton Towers, another of the Earl's residences, and the improvements he made during the time he lived at Alton testified to his ability as a gardener and organiser. Returning again to Ingestre to live, Mr. Gilman not only remained in charge of both establishments, but he made a new garden for his employer at Goring-on-Thames. With so many responsibilities on his shoulders, it was not unnatural that Mr. Gilman should drop out as an exhibitor and as a member of the Fruit and Vegetable Committee of the R.H.S., but his gardening enthusiasm never lapsed, and whatever his hand found to do was done well. In connection with Mr. Gilman's well-earned retirement it is regrettable that the glory has departed—tem-

porarily, at any rate—from the two once famous establishments over which he had charge, owing to circumstances following on the death of the late Earl. In severing his connection with the gardens he loved, Mr. Gilman must feel these things, but his nature is optimistic, and he goes to his new home on the borders of Cannock Chase with the good wishes of his many gardening friends.

**The Packing of Soft Fruits.**—At the conference of fruit-package manufacturers, held at the Imperial Fruit Show last year, the Controller of Horticulture promised to convene a further conference to consider the possibility of the introduction of a standard package for the transport of Strawberries and other soft fruit. This conference will be held at the office of the Ministry at No. 10, Whitehall Place, on Tuesday, the 25th instant, at 2.30 p.m.

**National Association of Cemetery Superintendents.**—The seventh annual congress of the National Association of Cemetery Superintendents was held at Birmingham on the 10th, 11th, and 12th inst. The delegates were welcomed to the city by Mr. R. R. Gelling, chairman of the Parks and Cemeteries Committee. The morning session was occupied with the submission of the secretary's and treasurer's reports and balance sheet and the election of officers for the ensuing year. During the afternoon the congress considered and adopted a motion to enlarge the activities of the association by amending the qualification for membership so as to admit the election of parks superintendents and assistant superintendents. The congress on the second day considered the advisability of publishing the activities of the association either in a monthly or quarterly magazine, but owing to financial considerations the idea was not found practicable. A paper was read by Mr. Harry Robertson, manager of York Cemetery Company, on "Should the Association Adopt a National Programme?" During the afternoon visits of inspection were paid to Witton and Handsworth Cemeteries. On the third day the association was addressed by Mr. L. Hill, general secretary of the National Association of Local Government Officers, on the Superannuation Bill. The remainder of the session was devoted to questions and answers on matters connected with cemeteries and their management. During the afternoon visits were paid to Yardley, Brandwood End, and Lodge Hill Cemeteries under the guidance of Mr. W. H. Morter, chief officer of the Birmingham Parks and Cemeteries Department. The secretary of the association is Mr. W. A. Cochrane, Hamstead Cemetery Office, West Hampstead, N.W.6.

**Ormskirk Potato Trials, 1922.**—The summer inspection of the Ministry of Agriculture's Wart Disease Immunity Trials at the Potato Testing Station of the National Institute of Agricultural Botany, Lathom, Ormskirk, will take place on Thursday, August 24. Attendance on that day will be by invitation from the Institute, but the Trial Grounds will be open on August 25 and 26 to all interested in Potato growing. The extensive plots of Potatoes planted at the Station include a large number of varieties from Australia, France, and other foreign countries, and also a considerable number of seedlings from Breeding Institutions, Potato raisers and others. There is also an interesting historical section. Trials for other purposes are being carried out by the Institute, which this year has again undertaken Potato Maturity Trials and has planted a large number of Demonstration Plots of most commercial varieties of immune Potatoes.

**Home-grown Bulbs.**—Mr. W. R. Dykes, secretary of the Royal Horticultural Society, informs us that there will be no dry-bulb show at the Royal Horticultural Society this year, but exhibits of home-grown bulbs will be welcomed at the meetings on August 9 and 22. Applications for space should be made in the ordinary way a week before the meetings, and be accompanied by a declaration that the whole of the produce to be shown has been grown in the British Isles.

\* *Monthly Bulletin of Agricultural Intelligence*, XII., 10, October, 1921. International Institution of Agriculture.

**Magnesium Sulphate as a Fertiliser.**—According to the *Chemiker Zeitung*, XIV., No. 56, May 10, 1921, magnesium sulphate has a markedly beneficial effect on crop production when used as a fertiliser in conjunction with potassium salts and the usual nitrogenous and phosphatic fertilisers. The effect in a series of cultivations of Potatoes was to increase yields by a small definite amount—about two per cent. Although the effect on the Potato crop of magnesium is much less considerable than that of potassium, it is by no means to be ignored. The yields obtained without the use of potassium was in this series of experiments 202\* quintals per hectare, with chloride of potassium 244, with sulphate of potassium 250 and with potassium and magnesium sulphates 253.

**Appointments for the Ensuing Week.**—Tuesday, July 25: Royal Horticultural Society's Committees meet; lecture by Dr. A. B. Rendle on "Plants of Interest Exhibited"; Bath and West and Southern Counties Society's Council meeting. Wednesday, July 26: Irish Gardeners' Association's meeting; Cardiff and County Flower show (two days); Whitchurch and District Horticultural Society's annual exhibition; Elgin Horticultural Society's meeting; Hayward's Heath Horticultural Society's show (two days); Welsh National Agricultural Society's Horticultural show on the Racecourse, Wrexham (three days). Thursday, July 27: Bristol and District Gardeners' Association's meeting; Royal Botanic Society's meeting. Friday, July 28: Paisley Florists' Society's meeting; Midland Carnation and Picotee Society's show (two days). Saturday, July 29: National Viola and Pansy Society's exhibition; Newburgh Flower show.

**"The Gardeners' Chronicle" Seventy-five Years Ago.**—*Exhibition at Chiswick.*—The exhibition season of 1847 was terminated on Saturday last by the meeting in the garden of the Horticultural Society. The day, although ushered in with a tempest, proved enjoyable in the afternoon, and 6,827 visitors found their way to Chiswick. We have no space for an account of the music, which was enchanting, from the variety introduced into its arrangements, and the large area over which the movements of the bands extended; and we must refer to the witnesses of the gay scene for a description of the beauty of his Grace the Duke of Devonshire's grounds, of the noble lawn, the rich parterres, and the majestic timber there. We can only dwell upon the novel features of the exhibition in the Horticultural Society's Garden. Conspicuous among them was Messrs. Veitch's plant of *Medinilla speciosa*, a *Melastomad* from Java, with broad, concave, fleshy leaves, and large bunches of semi-transparent pink flowers, which seemed as if carved from crystal. Then came an *Aerides* from Sir George Larpent, resembling *maculosum*, and perhaps a variety of it, but with a lip of the deepest crimson. Of an inferior rank, but beautiful, were Kuhl's *Dendrobe*, a pink-flowered species, in the way of *D. secundum*, and a beautiful Brazilian *Oncid*, the form of whose flowers might have satisfied the fastidiousness of a florist. The two last are from Messrs. Veitch, who also produced an orange *Ixora*, called the Javan, which will probably be a fine show species. A prize was also awarded to a little specimen of a blue-flowered *Leadwort* from Shanghai, quite distinct from all in gardens, and likely to be a valuable bedding-out plant; it has been received by Sir George Larpent, whose gardener, Mr. Eyles, has succeeded in raising it. Another remarkable part of the exhibition was a collection of thirty-five different Palms from Messrs. Loddiges. This occupied a large circular table, and excited much attention. We do not, however, think that plants of this description are capable of producing a striking effect when mixed with others. *Gard. Chron.*, July 24, 1847.

**Publications Received.**—*Science in Diet.* By K. Monteath. A thesis on Vegetarianism with a table of food values. Second edition. Messrs. Chapman and Wilson, Coney Street, York. Price 4d. post free.

\* A quintal = 100 kilograms = 220.49 lb., and a hectare = 2.47 acres.

## THE ALPINE GARDEN.

### PATRINIA PALMATA.

Not many of the *Patrinias* which have been in cultivation are ever likely to achieve lasting popularity, and there are only a very few indeed which are destined to be favoured by the cultivator of alpine flowers, who has now an almost bewildering choice of charming plants with which to furnish the rock garden. *Patrinias* belong to the natural order Valerianaceae, and mostly possess a share of the comparative coarseness of the family. *P. palmata*, which, as I know it, is a dwarf plant about 9 in. high; does not wholly agree with the description of the plant by the late Mr. Reginald Farrer, for he classes *P. palmata* with several others

FIG. 20.—LILIUM GLORIOSUM: R.H.S. AWARD OF MERIT, JULY 11 (SEE P. 41).

as "being too precisely Valerian-like in tall stem and loose habit to be fitted in the garden for any place more choice than the wilder parts where *Paradisea* is growing among the *Astrantias* and *Campanula rhomboidalis*." I have not found the plant to exceed the height of 9 in., while it is even less in stature if grown in a dry moraine, where it flourishes excellently. It may not be a choice, but it is a pleasing plant, with palmately divided, glossy green leaves and heads of golden-yellow bloom. In the moraine it thrives well, spreading a little and giving plenty of flower. I think it prefers a dry soil.

### CAMPANULA PUNCTATA.

BUT rarely met with, yet a good Bellflower of considerable beauty and interest, is that known as *Campanula punctata*, which comes from North Asia, and ought to be a free and easy grower in these islands, but, unfortunately, proves none too long-lived in numerous gardens. Its habit would suggest that it would present no difficulty, as it seems to delight in spreading and

sending up little stems bearing its rather neat leaves, and eventually producing handsome bells, but it frequently dies off, much to our disappointment. Indeed, some have considered it only a biennial, although it is not such, but a true perennial. It needs, experienced cultivators agree in asserting, a dryish and sunny place, but even there it is not always that *C. punctata* will prove perennial. Therefore it is not so much seen as its beauty deserves. The stems are about a foot high, inclined to arch over, and bear several large, drooping bells of a pinky-white outside, white inside, and beautifully spotted in the interior like a Foxglove. Its full beauty is not seen until the inside of the flowers is examined. Some think that the distinct Bellflowers named *C. Burghaltii* and *C. Van Houttei*, have *C. punctata* as one of their parents, but others class them as hybrids or descendants in the direct line of *C. latifolia*. It looks as if *C. punctata* was one of the parents, with, possibly, *C. latifolia* as the other. *S. A.*

### TROPAEOLUM POLYPHYLLUM.

At the end of June and early in July, this showy, hardy perennial was one mass of yellow flowers, trailing over and among the rocky boulders. The long, prostrate growths furnished with grey-green foliage were well over 4 feet in length and studded with golden bossoms. This plant is known as the Indian Rock Cress, and by this one can easily imagine that it requires a hot, sunny position. I never remember seeing it quite so fine as this season, and undoubtedly this is due to the heat and drought of last summer and autumn. When planting this perennial, it is wise to place it near or between the rocks. It will then quickly send its creeping stems in all directions. It is important that the soil should be well drained, unless the slope be fairly sharp, as it resents stagnant moisture at the roots. When once established, it should be left undisturbed. The foliage dies down in the early autumn, and growth does not appear again until about early May, when the soil begins to get warm; thus it is wise to mark the site to avoid any danger of the plants being lifted. *R. H. Crockford, Weston Park Gardens, Stevenage.*

## ORCHID NOTES AND GLEANINGS.

### DENDROBIUM NOBILE.

*DENDROBIUM nobile*, Lindl. *Gen. et Sp. Orch.*, p. 86 (1831), one of the oldest and still one of the most deservedly popular species, first became known in British gardens through a plant of it flowering in Messrs. Loddige's nursery in 1837, the small specimen having been brought from China by the late Mr. John Russel Reeves. Since then it has been imported frequently from Southern China, and a wide range in North and North-East India. It was collected by Gibson in the Khasia Hills at an altitude of about 4,000 feet and sent to Chatsworth in 1837. The range of its distribution being great, wonderful variation in the flowers results, and while the typical form, with its amethyst-purple tinted sepals and petals, is the most commonly seen, there are forms varying from the pure white variety *album*, through various shades to the now well-known *D. nobile nobiliss*, with its richly coloured flowers four inches across, described by Reichenbach in *Gard. Chron.*, 1882, p. 366, and which is yet one of the finest of *Dendrobiums*.

Scores of varieties have received distinctive names, and all are fine and easily distinguishable from each other, two of the most interesting being the peloric *D. nobile Cooksonianum*, which appeared in several gardens, with petals resembling the *labellum* in colour; and the singular *D. nobile burfordiense*, in which the lateral sepals partake of the colouring of the lip.

Probably no *Dendrobium* has played so useful a part in gardens as *D. nobile* during the eighty years or so in which it has been a familiar object. It has been grown, and should still be grown, in gardens where Orchids are not made a speciality, the adaptability of its

requirements rendering its culture possible in any gardens where a warm glass house exists. Its time of flowering may also be extended by treating some of the plants differently from the rest. In *Gard. Chron.*, November 2, 1901, particulars were given of very successful results from outdoor treatment in summer, and similar experience with it and other Orchids in the late Dr. Smee's garden at Hackbridge have frequently been noted.

But in the main the old prescription of a warm, moist temperature during the season of growth and a long, cool, dry period during the resting time are details to be relied on for success. On those lines the old collections produced huge specimens, those of the Rucker collection at Wandsworth, and the Holford collection at Westonbirt often bearing close on 1,000 flowers at a time.

The tufted habit of growth of *D. nobile*, which admits of a practically unlimited number of pseudo-bulbs to a single specimen, accounts for the possibility of such giants, and in regard to them one may note an important point in which modern cultivators have surpassed the old growers.

Many years ago it was the custom to leave all the old stems until they passed away after being useless and unsightly for a considerable time. The modern cultivator prunes his *Dendrobium*s and other Orchids, removing all old pseudo-bulbs before they become unsightly, and in the case of *D. nobile* and some others using the stems for propagating young plants of such varieties as are required.

#### ALLIES OF DENDROBIUM NOBILE.

*Dendrobium Linawianum*, a native of China and Japan, was first introduced by the Horticultural Society in 1823. It was known and figured generally as *D. moniliforme*, a name now known to belong to the Japanese species formerly called *D. japonicum*. In growth and flower it may be likened to a small form of *D. nobile*, the disc of the lip having but two small, purple spots. It is interesting as being one of the parents of the first hybrid *Dendrobium*, *D. Dominianum* (*Linawianum* × *nobile*), recorded as early as 1864, but not described until in *Gard. Chron.*, 1878, p. 202. It is quite intermediate between the parent species, and with its *D. Linawianum* parent has been used in a dozen other crosses, while *D. nobile* has been applied directly to about forty other species and hybrids.

*Dendrobium Regium*, a native of Lower Hindustan, described by Dr. Prain in the *Journal of the Asiatic Society*, lxxi, p. 89, and which first flowered in the Royal Botanic Garden, Calcutta, in 1901, flowered at Kew in 1904, and was soon fairly represented in gardens, both the late Sir Trevor Lawrence and Messrs. Charlesworth and Co. obtaining First-Class Certificates for it on August 6, 1907. It is a beautiful species, closely related to *D. nobile*, but quite distinct from it, having more equally arranged segments of clear amethyst pink on a white ground, and a differently shaped lip without the dark zone, differences which render it easily recognised.

It is a charming species, not yet sufficiently well known, and with good prospects to the hybridiser.

So far, Sir Jeremiah Colman, Bart., is the only grower who has proved hybrids of it, his *D. alpha* (*enosum* × *Regium*) (1910); *D. Royal Princess* (*aureum* × *Regium*) and *D. Royal Sovereign* (*Curtisii* × *Regium*) (1912); and *D. Prince Arthur* (*Euryalus* × *Regium*) (1919) being very handsome hybrids, showing much of *D. Regium*.

*Dendrobium tortile*, *D. Hildebrandii* and the many hybrids produced from them, and *D. nobile*, come into this section. They are all most floriferous and, although their flowers do not compare favourably with good *D. nobile* or *D. Regium*, they are excellent for decorative purposes, especially *D. Wigandiae* and *D. Wigandianum* and their progeny. All show the elegant arrangement of the flowers, as in *D. tortile*, to which *D. Hildebrandii* is closely allied; so also does *D. Dartoisianum*, from Indo-China (*Bot. Mag.*, t. 8352). *J. O'R.*

## THE HISTORY OF THE MOSS ROSE.

### A CRITIQUE.

IN a short article on the origin of the Moss Rose, which appeared in the *Gardeners' Chronicle* for September 24 last, and which in a more elaborated form was published in the *Journal of the R.H.S.*, vol. xlvii., part I, an attempt was made by Major Hurst to trace the history of this old, popular, floral favourite. More recently, in the *Rose Annual* for 1922, that gentleman gave us, with but few variations, notes on the history of that flower which are in substance a repetition of the previous articles.

I make no claim to a qualification for dealing with that part of the history which is essentially botanical, and leave that entirely outside my consideration, but from the purely literary and historical aspect it seems that a few critical comments on the evidence upon which the author of those three articles has relied, together with a few other items of additional material which do not appear to have come under his notice, may serve to put a somewhat different complexion upon the history of the Moss Rose compiled by him, with the result that we shall ultimately arrive at a closer approximation to the true facts.

Major Hurst has gathered together from many sources, more or less authentic, a quantity of information, to a large extent second-hand, and in some cases it would seem that he has failed to get a proper grip of his material; while in others he has undoubtedly drawn conclusions from false or insufficient premises, as there will be but little difficulty in demonstrating, and thus in more than one important point the value of his researches has been neutralised.

When surveying the accumulation of literary and historic material that lies before me, after going through and verifying the facts and data comprised in Major Hurst's articles, I can only regret that a writer with the wide floricultural knowledge and consummate literary skill of the late Shirley Hibberd has not had the handling of it. We should then have seen the raw material and plain facts deftly woven by a practised hand into a harmonious whole, and should have had presented to us, replete with every needful accessory of detail, that which might justly claim to be a history, fascinating and holding the reader, as was the rule when that great writer undertook the task of historical floral investigation, beneath the spell of his inimitable style.

The three separate articles referred to in the opening paragraph cannot in the space at disposal be treated individually, and there is really no object in doing so. Major Hurst has collected a series of quotations and extracts from various authorities without making any serious endeavour, in some instances, either to prove or disprove their accuracy. The mere gathering together of a collection of quotations, or of facts, chronological or cultural, without any apparent or definite object is not a history. Book titles are here and there misquoted. Some of the authorities upon which Major Hurst seems to have relied implicitly can easily be proved to be unworthy of the trust he reposes in them, and consequently the result is scrappy and disjointed.

In examining the early authorities on Rose history one is bound to concur in the expression of opinion that a careful search reveals no evidence in support of the oft-repeated statements in English horticultural literature of the 19th century, that the Moss Rose was introduced from Holland in 1596. One of the earliest modern writers to say so is Thomas Rivers, junr., in the *Rose Amateurs' Guide*, 1837. It would serve no useful purpose to enumerate the various authors who followed suit. One of the latest is the Rev. J. H. Pemberton in his recent work, *Roses*. Even the eminent English rosarian William Paul, in 1845, says, "on the authority of botanists," without naming them, "the year 1596 saw several species of Roses introduced to England, among

them being the Moss (*R. centifolia muscosa*)." Neither Mr. Pemberton, nor Mr. Paul, nor indeed any other writer who makes this assertion enlightens us as to the name, English or Latin, that this supposed original Moss Rose bore nor in what old work the fact is recorded, but in passing it may be observed that the name was most assuredly not *muscosa*, for as a specific name it will be seen later that the word was not used in connection with a Rose for many years afterwards. Instead of accepting such unsupported statements modern writers ought to have been more cautious, and have gone back to contemporary authorities and subjected such statements to a practical test.

It is astonishing to anyone accustomed to research work to read in the Rev. J. H. Pemberton's book on Roses such a paragraph as this—"the common Moss, which came from Holland in 1596 . . . and it is remarkable that no varieties of the Moss were in cultivation between 1596 and the end of the eighteenth century." That very fact alone when once ascertained, and it can be without much difficulty, ought to have raised in the author's mind the question: Was it really a Moss Rose that was introduced in the year named? and is it possible that so distinct and so singularly beautiful and attractive a variety of a popular garden favourite, such as the Rose has always been, could in those far-off times when flowers were much less numerous than in these later days, have been obliterated; or if actually introduced as alleged that it could have been utterly ignored by every writer on Roses for upwards of a century? Major Hurst, with the same idea in mind, expresses it well when he remarks that the Moss Rose is a variation so striking that it could hardly fail to be noticed by the most casual observer. No! the thing is inconceivable, and the plain truth or the matter is that the Moss Rose was never imported into this country either from Holland or elsewhere in, or prior to, 1596, despite the bald and unsubstantiated reiteration of modern Rose writers.

It is no part of my present purpose to contradict without reason or to affirm without proof. There is far too much of that kind of so-called argument in horticultural literature, and such methods may be left to those persons who are content to copy the errors of their predecessors, and thus spare themselves the trouble of embarking upon a course of independent original research!

In pursuance of this intention I shall first of all deal with the mystic date of 1596, and that as briefly as the importance of it will permit, and then follow on in their proper sequence with some of the other questionable points that arise on a perusal of Major Hurst's compilations. Students of horticultural literature will need no reminding that in that year John Gerard published a *Catalogue of Plants* which he had collected, and were then growing in his garden at Holborn. Among them are enumerated sixteen different kinds of Roses, some, if not all, of which had long been in cultivation in this country before coming into his hands. They are all more or less fully described, and fourteen of them are figured in his *Herbal*. Among them is one called *R. holosericea*, or in current English of the period, the Velvet Rose. At one time it was considered that *R. holosericea* was identical with the Moss Rose, but this opinion has been abandoned as indicated in a footnote to Major Hurst's article in the *Journal of the R.H.S.*, and also in another one to his article in the *Rose Annual*.

It may usefully be observed at this juncture that, in some of the old books published after the actual introduction of the Moss Rose, both the Velvet Rose and the Moss are given as separate varieties. Thus in *Furber's Catalogue* in the 1724 edition of Miller's Dictionary, they are both entered separately. In *The Compleat Florist*, 1740, the *Catalogus Plantarum*, 1750, and other similar publications the coloured figures of these two Roses depict varieties that are quite dissimilar. *C. Harman Payne*.

(To be continued.)

**PLANTS NEW OR NOTEWORTHY.**

**EUONYMUS WILSONII, SPRAGUE.**

PREVIOUS to the introduction of this species, *Euonymus japonica* and its varieties and allies, amongst which must be included *E. radicans*, were the only hardy evergreen Spindle-trees in cultivation. It is very distinct from them, and represents a curious group in the genus with prickly fruits. According to Mr. Wilson's note on one of the labels of the specimens of his own collecting, he appears to have found it as a kind of climber and growing up to 20 feet high. But, so far as I have seen, it promises under cultivation to be a loose-habited bush rather than a climber. Its leaves are of leathery texture, 5 to 6 inches long, 1 to 1½ inch wide, of lanceolate outline, with a long, slender point and very shallowly toothed. Like the young shoots and other parts of the plant, they are quite devoid of pubescence. The flowers are pale green, produced in densely furnished cymes. The sprays exhibited by the Hon. Vicary Gibbs at the R.H.S. Show on June 7 and 8 were very profuse in blossom and quite ornamental (Fig. 21). It is much to be hoped that fruits will develop at Aldenham, for I do not think they have yet been seen on cultivated plants, and they are very curious and probably effective in colour. Judging by the few fruits on Mr. Wilson's specimens in the Kew Herbarium, the capsules appear to be yellow, and they are thickly set with awl-shaped spines about ¼ inch long.

This shrub is evidently quite hardy, and may be propagated by cuttings taken in July or August and put in a close, gently heated frame. Probably its profusion of blossom this year is due to the heat of 1921, and, so far as I know, Mr. Vicary Gibbs is the first to have had it in flower. It is a native of Mount Omi, in Western China, and was discovered and introduced to the Coombe Wood Nursery in 1904 by Mr. E. H. Wilson.—W. J. B.

**HYBRID OLEARIAS.**

THE interesting correspondence by Sir Herbert Maxwell and Mr. Irwin Lynch on the behaviour of plants from the southern hemisphere in northern gardens is worth following up. In the wonderful collection of Sir John Ross, of Bladensburg, at Rostrevor, two strange *Olearias* appeared spontaneously some years ago. The conditions there are peculiarly suited to New Zealand plants and to some Australian ones also. One of the apparent hybrids shows evidence of being a product of *Olearia arvicenniaefolia* × *Olearia nitida*. It forms a handsome shrub of rapid growth, producing its flower heads abundantly in June from the axils of the leaves on shoots of the previous year.

The ray florets number about seven to each head, and are pure white, half an inch in length and about 1-12 of an inch broad; the involucre consists of four series of imbricated softly hairy scales. The leaves vary from 1½ in. to 3 in. long and from ½ in. to 1 in. wide, tapering to both ends, the base ending in a petiole about half an inch in length; the upper surface is dark green, while the lower surface is clothed with a dense, dull white tomentum, the margin being remotely and irregularly toothed.

The other hybrid is supposed to be the result of a cross between *O. argophylla* and *O. macrodonta*. It is a somewhat stouter shrub, with larger leaves (Fig. 23, p. 53), more numerous and smaller flower heads, produced in a more or less corymbose manner. The larger leaves are up to 4 in. long and 1½ in. wide, tapered to both ends, but more sharply towards the apex, while the base is often oblique; the petiole is nearly ¾ in. long. The upper surface is at first pilose, but later becomes glossy green, the lower surface remaining densely coated with a yellowish-white tomentum. The margins are coarsely toothed, and approximate in this respect to *O. macrodonta*.

The parentage of both hybrids is largely inferred from the fact that the parents are

growing in proximity to the position in which each hybrid was found.

Of the four species mentioned, it will be noticed that three are natives of New Zealand, while the fourth, *O. argophylla*, is Australian. The size of the leaves is taken from plants growing at Glasnevin, but under more favourable conditions they might easily be much larger. J. W. Besant, Glasnevin.

**TREES AND SHRUBS.**

**GYMNOCLADUS CANADENSIS.**

ALTHOUGH recorded as being first introduced to Britain by Archibald, Duke of Argyll, in 1743, and planted at Whitton, Middlesex, very few large specimens of *Gymnocladus canadensis* exist

among the first to fall in autumn, though the leaf-stalks remain until later. The leaves are bipinnate, 1 to 3 ft. long and 9 to 24 in. wide, with from 4 to 10 or 11 pairs of leaflets. With few exceptions the trees are dioecious, the Kayhough specimen having staminate flowers borne in a racemose corymb, while the flowers on pistillate trees are arranged on a larger raceme.

A second species of *Gymnocladus*, *G. chinensis*, Baillon, is, as the name suggests, a native of China. It is, however, on the borderland of hardiness, and only suitable for planting in the mildest parts of the country. Both species are best propagated by means of imported seeds, which are not difficult to obtain. Among a consignment of seeds recently received at Kew from China was a packet of the *Gymnocladus*, the seeds germinating freely.—A. O.

FIG. 21.—EUONYMUS WILSONII.

to-day in our gardens. The flowering of a tree about 50 ft. in height at Kayhough, Kew Gardens Road, Kew, is my reason for writing this note and drawing attention to a tree with very ornamental foliage. Planted by the late Mr. Charles Wright in 1878, when it was said to be twenty-two years old from seed, his daughter, the present owner, is justly proud of this tree, and also of a beautiful specimen of *Taxodium distichum* planted at the same time, still carrying many of the cones produced last year.

*G. canadensis*—the Kentucky Coffee—is a native of North America, and, though found over a wide area, it is nowhere common. Some of the native trees exceed 100 ft. in height. The tallest tree in this country is said to be one at Claremont, between 60 and 70 ft. in height. An attractive foliage tree in summer, *Gymnocladus canadensis* is also readily recognised in winter by its ragged wood with few branches and thick branchlets. Its leaves unfold late in spring, but they are nevertheless

**KOELREUTERIA PANICULATA.**

ONE of the best shrubs for town planting is *Koelreuteria paniculata*, which was introduced to this country from Northern China in 1765. In its native country it is a small tree; but here it generally attains a height of from eight to twelve feet. The shrub is hardy in, perhaps, every part of the British Isles, but it will give the best results if placed in a sheltered corner, and planted in a rich soil. Under these conditions it will grow and flower freely, and although in its growth it is rather irregular, it is certainly well worthy of a place in the garden. It is remarkable alike for its flowers in summer and its foliage in autumn, and these two qualities render it a valuable aid in ornamental planting. The bright yellow flowers, which are produced in large panicles during July and August, stand out well above the foliage, while in the autumn the leaves assume beautiful tints of yellow, bronze, and purple. Robert H. Jeffers.

## The Week's Work.

### THE ORCHID HOUSES.

By J. T. BARKER, Gardener to His Grace the Duke of Marlborough, K.G., Blenheim Palace, Woodstock, Oxon.

**Miltonia.**—*Miltonia vexillaria*, its many varieties, and the numerous hybrids derived from them, comprise the most showy and popular members of the genus. They are mostly vigorous and very floriferous under good treatment, and their flowers will remain on the plants in good condition for a considerable time, and make a considerable display over a long period. When growing strongly they often start into growth before the flowering period is over; therefore, the roots should never be allowed to suffer for the want of water, even whilst the plants are at rest. Those plants which produced their flowers early in the season, and were rested as advised previously, are commencing to grow actively, and those that require fresh rooting material may have attention at this season, soon after new growth commences. I find that it repays to re-plant these plants annually, for, if the compost becomes decayed, a general decline in the plants occurs. Young, vigorous plants that require more root room should be shifted into larger pots, or pans, which I prefer, with as little root disturbance as possible. Exhausted plants, or those that have lost their centres, are best divided, and potted afresh in small receptacles, to make specimens next year, thereby keeping up a succession of young and vigorous plants. The best potting material should be used, and it is advisable to separate it thoroughly of all earthy particles. A suitable potting compost consists of equal parts of *Osmunda* fibre, *Al* fibre, and *Sphagnum*-moss, with some half-decayed broken leaves added. The pots, or pans, should be half-filled with drainage material, as these plants are purely surface rooters, and in no case should they be over-potted. Potting should be done moderately firmly, bringing the heads of the live moss to the surface to eventually grow and make a green, cool surface.

**Treatment after Potting.**—After they are re-potted the plants should be placed together in a house, where an intermediate temperature is maintained, staged in full exposure to the light to prevent them becoming drawn, and kept shaded from strong sunshine. The supply of water at the roots during the early stages of growth is of great importance, as if too much is given the roots will die and the plants receive a check. The cause and effect of too little or too much moisture is much the same; hence the necessity of careful observation on the cultivator's part. On bright days slight spraying overhead will be most beneficial, and be the means of keeping the plants in a clean and healthy condition. With the aid of the late summer blooming forms and the autumn flowering ones, it is possible to maintain a display of these beautiful flowers for fully six months of the year. The re-potting of the late flowering varieties is best deferred to a later period, but as they succeed in similar material and under the same conditions, their culture is similar, except that, being later in making their growth, they require attention accordingly. Un-suitable atmospheric conditions should be avoided. Too much heat will result in an attack of thrip and other insect pests, and the young growth will damp and fall off in cold, damp conditions.

### THE KITCHEN GARDEN.

By JAMES E. HATHAWAY, Gardener to JOHN BRENNAND, Esq., Baldersby Park, Thirsk, Yorkshire.

**Cabbage.**—A small sowing of Cabbage should be made in late districts. Sow the seed in drills made one foot apart and well cover it. Scatter a good dressing of wood ash on the soil, as this will help to deter insects; if

birds are troublesome cover the seed bed with a net. Ellam's Early and Sutton's April are two of the best sorts for present sowing.

**Onions.**—The recent heavy rains and cold nights have been favourable to attacks of mildew, which should be checked immediately by dusting the rows with lime and soot, and also flowers of sulphur when the foliage is damp.

**Swedes.**—The garden varieties of Swede are very useful late in the season. The seed should now be sown in drills made 18 inches apart on ground which has been recently cleared of early Potatoes. As soon as the plants are growing freely, give them a dressing of artificial manure.

**Vegetable Marrow.**—Marrow plants are growing and cropping freely, and the roots should have liberal supplies of liquid manure made from sheep or deer droppings, soaked in a tub of water.

**Brussels Sprouts.**—The early plants of this vegetable are growing freely, and if they show signs of falling over support them by placing earth up to the stems or by stakes. Keep the ground free from weeds, stirring the soil freely with the Dutch hoe.

**Shallots.**—These bulbous plants are now ripe and should be harvested and laid on open trellises to become thoroughly dry. If allowed to remain in the ground the plants will commence to make fresh growth.

### PLANTS UNDER GLASS.

By T. PATEMAN, Gardener to Sir C. NALL-CMUN, Bart., The Node, Codicote, Welwyn, Hertfordshire.

**Euphorbia pulcherrima.**—The earliest-rooted plants of *Poinsettia* should now be ready for their final potting, and the same treatment may be extended to these plants as was advised for *Euphorbia jacquinaeflora*.

**Chrysanthemums.**—Plants intended to produce large blooms, that are growing in their summer quarters, should be given every attention with regard to tying the young shoots to prevent them from being broken by high winds. The shoots should be examined frequently, and all side growths removed as they appear. The receptacles are now becoming well filled with roots and it will be found necessary to examine the plants three or four times daily during hot, dry weather for watering. A little soot water applied to the roots at intervals will be found to be very beneficial to the plants. Earwigs are sometimes troublesome, and means should be taken to trap these pests. Bean stalks cut into pieces nine inches long form one of the best traps for earwigs, which should be blown out of the Bean stalks every morning into a vessel containing an insecticide.

**Winter Flowering Begonias.**—The earliest rooted cuttings of *Begonias* belonging to the tuberous section, such as *Optima*, *Elatior* and *Exquisite*, may now be potted for the last time in 6 inch receptacles, which is the most useful size for these plants. Where a good fibrous loam is obtainable, the compost for this potting may consist of three parts loam and one part leaf mould and manure from a spent Mushroom bed, the last after it has been passed through a fine sieve. A little bone meal and sufficient sand to render the compost porous should be added. The plants should be grown in an intermediate temperature and kept shaded from the direct rays of the sun. Syringe between the pots twice daily on all hot days, and fumigate the house occasionally to destroy mite and other pests that check the growth of these plants.

**Begonia Gloire de Lorraine.**—The earliest rooted plants of this *Begonia* are growing freely, and the growths should be supported by small, neat stakes. Later inserted cuttings of this useful *Begonia* should receive attention with regard to potting, as they become ready; if grown in large 60-sized pots and fed judiciously they will make useful plants for decorating purposes, and are particularly suitable for placing in small ornamental bowls in the dwelling rooms.

### HARDY FRUIT GARDEN.

By H. MARHAM, Gardener to the EARL OF STRAFFORD, Wrotham Park, Barnet.

**Strawberry Beds.**—As soon as the plants have been cleared of their fruits remove the litter and gather up the nets, which, when perfectly dry, should be stored in a dry, airy shed. The beds should then be weeded, the plants trimmed of the runners and all superfluous growths, and the soil lightly forked over, and then well manured, to encourage the development of strong, fruitful crowns for next year. In deep, mellow soils where the plants are apt to grow too strongly manure should be used sparingly, but it may be liberally applied on light, shallow land. The heavy rains have suited the plants, and that, together with a thorough cleaning of the bed, should prove very beneficial to the plants in building up good growth and making strong crowns. I usually destroy a certain number of the oldest plants each year, and plant afresh a given number to meet the requirements. A change of stock is necessary occasionally.

**Thinning Fruits.**—Peach trees cropping heavily should have their fruits reduced to the number required to ripen on each tree. Young trees making strong wood may be allowed to carry heavy crops, but older trees covering a large amount of wall space should not be over-cropped, as not only will the fruits be small in size and wanting in flavour, but the trees are liable to be crippled for next season. Peach shoots should be trained thinly; those of medium growth with strong, green, leathery foliage, free from red spider and thoroughly matured, are the best for cropping.

**Summer Pruning.**—This work should be undertaken, but do not prune the shoots too severely at this season, as this results in the buds forming fresh shoots instead of remaining dormant until next spring. All shoots required for furnishing the trees, where space is vacant, should be neatly attached to the walls or trellises. Stop and rub off all gross growths, and thin out some of the other shoots that are not wanted, in order that light and air may reach those remaining. Where young trees are making strong, gross shoots, hard pruning will not bring the wood into fruitful bearing.

### FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Lieut.-Col. SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

**Composts.**—If a good supply of loam has not been secured, no further time should be lost in getting it cut and stacked, and provided it is intended solely for use in the orchard house, proper correctives and fertilisers may be added in layers. Whether wireworm is suspected to be present in the turves or not, a liberal dusting of soot should not be omitted. Old lime rubble and burnt earth may be added to heavy loams, whilst marl and old cow manure will improve light, sandy soils. The latter may be further improved by liberally pouring liquid manure over the stack; indeed, on must loams this fertiliser might be used with advantage.

**Peaches.**—As the trees in early and succession houses are cleared of their fruits, prompt attention to pruning, cleansing, and re-arrangement of the shoots will be necessary. All superfluous wood which has borne fruit should be cut away. The borders may be lightly forked over to ensure an even distribution of water to the roots, and mulched or otherwise, according to the vigour or weakness of the trees. If the wood is fairly strong and the foliage good, it is best to err on the safe side and withhold rich stimulants. On the contrary, if the trees from age or over-cropping show signs of weakness, they may be stimulated with such fertilisers as diluted liquid manure and soot water. The trees must be kept clean by occasional syringings with insecticide and liberal evening syringings with pure water. From this time forward, the ventilators may be left constantly open.

**Succession Peach Houses.**—Trees with fruits that are swelling fast need an abundance of water at the roots, and should be syringed thoroughly twice daily with soft water. It is better to reduce the syringing to once a day than to use water charged with lime on woolly skinned Peaches. It is more than probable that the long spell of drought may be followed by the opposite extreme. If so, soft water should also be applied freely to the roots of inside borders, no matter how recently they may have been watered. An abundance of air should be admitted from the time the fruits begin to colour, and their size may be increased by pinching the points of these shoots which in due course will be removed. The complete closing of the house at this time of the year is not absolutely necessary, as, with syringing, the atmosphere may be kept charged with moisture without excluding all the fresh air. If the fruits from these houses are intended to precede the supply from open walls, the trees should now be well thinned and the shoots tied down, otherwise the young growths may be allowed freedom for some time longer, as Peaches not only make slower progress, but produce the finest fruit under the natural shade of their own foliage. All borders, inside or out, should be well mulched with fresh stable manure. By adopting this plan and adding a little fresh material at short intervals, the moisture constantly arising from it keeps the foliage clean and healthy, and reduces the necessity for direct syringing to one operation on the hottest days.

### THE FLOWER GARDEN.

By EDWIN BECKETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Hertfordshire.

**Ornamental Crabs.**—To the ornamental Crabs referred to in my notes in the issue of June 24, may be added *Pyrus Malus transitoria toringoides*, which was sent home by Mr. E. H. Wilson. The plant has pretty, Hawthorn-like foliage, and develops a wealth of pale pink blossoms, which are succeeded by small Cherry-like fruits in abundance. Many more quite distinct sorts, each with its own particular beauty, might be mentioned. There are also hybrids of garden and nursery raising, which, though pretty in flower, are chiefly attractive in the autumn, when in fruit; of these probably the pick are P. M. Veitch's Scarlet, P. M. Cheal's Crimson, P. M. John Downie, three sorts with fine deep red coloured fruits, and P. M. Montreal Beauty, with very large fruit of blending yellow and red tones. With these may well be joined P. M. *baccata* (the Siberian Crab), of which there is a yellow-fruited as well as a red-fruited form.

**Propagation.**—The raising of fresh Alpine plants and shrubs to replace old worn out specimens should be undertaken now. It is little short of wonderful the variety of plants that may be raised in this way in an ordinary cold frame. The bulk of our hardy plants at Aldenham are propagated in this way and largely during the present month. Well-drained, 48-sized pots filled with a good compost of loam with which is incorporated a plentiful amount of sand, the whole moist, but not wet, should be prepared, and into these the cuttings should be dibbled, making them firm at the base but loose at the collar. In the case of shrubs we generally commence with such subjects as *Philadelphus*, *Deutzias* and *Diervillias*, starting with those which make strong, young shoots, which ripen quickly, for once the wood gets ripe it is not easy to strike the cuttings. The propagation of *Viburnums*, *Verenicas*, *Genistas*, *Abelias*, *Ceanothus*, *Cytisus*, *Cistus*, and *Forsythias* follows in quick succession, and then the rooting of various other kinds, such as *Escallonias*, *Enonymus*, *Loniceras*, *Buxus*, and many others follow, working right through each group once the work has started, to the end, and leaving such items as *Ligustrums*, *Loniceras* of the Honeysuckle group; *Poplars*, *Salix*, and similar classes for propagation during a later period of the year.

### THE ROSE GARDEN.

#### THE ROSE TRIALS AT BAGATELLE.

THE report of the trials of the new Roses at Bagatelle which was published in your issue of July 8, is one that demands the attention of all rosarians. Those who were present at the trials last season stated that they were almost a farce. The soil, of course, was very dry as the result of drought, and the Roses were simply not in a condition to be judged. Despite this, the jurors went on with their work and made awards in the usual way. The trials should have been postponed for another year. The varieties simply did not get justice. This season a similar state of affairs has to be recorded.

Your correspondent (see page 24) states that only a few flowers were to be seen, but the jury decided to go on and make awards. A Gold Medal was awarded to a variety named

### GARDENERS' CALENDARS.

I THINK I can approximately answer the Rev. Joseph Jacob's query so far as it concerns Evelyn's dedication of this *Kalendarium* to Cowley. Before doing so it may be permissible to inquire did the first edition (1664) have for its frontispiece the picture Fig. 9, on page 20. I think that must be doubtful, for so far as my knowledge goes, the first edition of the *Kalendarium Hortense* appeared in Evelyn's *Sylva* in folio, and was not issued in separate form. The separate and independent issues of the *Kalendarium* were either 8vo or 16mo in form. My copy of the *Kalendarium Hortense* is "the third Edition, with many useful Additions," and is dated MDCLXIX. The Epistle Dedicatory is evidently that of the second edition and begins as follows: "To Abraham Cowley, Esq. Sir,—This Second Edition of my Hortulan Kalendar is

FIG. 22.—ROSE LADY ROUNDWAY; NATIONAL ROSE SOCIETY'S CERTIFICATE OF MERIT, JUNE 29 (SEE P. 25).

*Elvira Aramayo*, which was sent in by a Dutch firm of nurserymen. Your correspondent also states that its bloom was almost over and did not seem to possess much substance. The raisers of this Rose had it staged for a Gold Medal award at the recent show of the National Rose Society at Regent's Park. It was unanimously turned down. It was indeed a poor thing, and a long, long way behind the calibre and dignity of Roses as we expect them to be in these days. It has, nevertheless, received a Gold Medal after trial at Bagatelle. One of the jurors at Bagatelle has described the place as "a barren sand-heap," and states the soil is totally unsuited for the cultivation of Roses.

I have advised Mons. Forestier that my firm can no longer send Roses for trial at Bagatelle, and that as conditions are at present it is only a waste of time and money. I received a reply from Seville that he is at present there on holiday, but that he will write me fully on his return to Paris. In the meantime, he informs me that a further inspection of the Roses will be made in September. That is all very well, but what of the Roses that were turned down last season? They never had a chance, for they were never seen in condition. They were literally burned out of the ground. Raisers can have no confidence in Bagatelle unless matters are very materially altered. *George M. Taylor, Edinburgh.*

yours," etc. Cowley's poem must have been added to some subsequent edition, as also was the frontispiece, for so far as I can discover, no issue of the *Kalendarium* is credited in the bibliographies with a frontispiece until the 8th (1691). With regard to that illustration, of course, Mr. Jacob is aware that it originally formed the frontispiece to the *Jardinier Francois*, by Nicolas de Bonnefons, a 12mo, published first in 1651. John Evelyn translated that work into English, which ran into several editions. He called it *The French Gardiner*. I have two editions, one dated 1658, and the other 1675. In each of these volumes Evelyn reproduces as the frontispiece Bonnefons' picture, but in the process of reproduction has reversed it. I had no idea that Evelyn also used this picture for the frontispiece of an edition of the *Kalendarium*, the only apparent difference between that and the original being in the label where "*Kalendarium Hortense*" is substituted for "*Le Jardinier Francois*." Some of these title pages were by artists of no mean ability. It has often occurred to me that it would be a most instructive and interesting work of exceptional utility if Mr. Jacob, or some other equally enthusiastic bibliophile were one day to give us a book containing examples in photogravure, or other similar process, of some of the rare old frontispieces and title pages. *C. H. P.*

### EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, W.C.2.

Local News.—Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

## CALCEOLARIAS

CALCEOLARIAS comprise annuals, herbaceous perennials, and shrubby perennials. Of the annual kinds *Calceolaria scabiosaefolia* is probably the best decorative species, but is apt, through self-seeding, to become a weed. It was introduced exactly a century ago, as also, in the same year, were several shrubby species, of which *C. rugosa* and *C. integrifolia* are the best. These and a few others kept their place in flower gardens till at least 40 years later. *C. Fothergillii*, the first of the herbaceous section, was introduced as early as 1777, but it was not until after the year 1822, when *C. corymbosa* was introduced, that Calceolarias engaged the attention of gardeners. In 1830 a series of hybrids was raised from herbaceous species, several of which were distributed by Young's, of Epsom, in the succeeding year, that named after himself being the pick, and it was long grown afterwards, though, judged by the coloured figure of it, the variety was a very poor one. This and a few more, the names of which Paxton, along with one or two more hybrids raised by others in the same year, included among the species in his *Botanical Dictionary*. Young's varieties were raised by one Morrison, gardener to Lord President Hope of Granton. He anticipated Darwin by cherishing and acting on the theory that a crossed plant would produce more seeds than a self-fertilised one, and it was in putting that theory into practice that these varieties were raised. Their appearance seems to have caused a commotion among botanists, and Professor Grahame, of the Edinburgh Botanic Gardens, contributed an article to a scientific journal upon their history and evolution. It is noteworthy, too, that most of these hybrids displayed spots and blotches, and were certainly the forerunners of the florists' section of later years.

All sections were cultivated under glass, plants of the shrubby section having been grown to five feet across (that was the day of specimen plants!). It was long before the propagation of these was understood, it being usual to strike cuttings in August in heated frames, a fair description of the process being detailed in *The Gardeners' Chronicle* for 1845. Five years earlier, at the beginning of flower massing, such species as *C. rugosa*, *C. integrifolia*, *C. viscosissima* and *C. salviaefolia* were being employed to furnish beds in flower gardens, and in 1845, according to Paxton, *C. amplexicaulis* was introduced. In *Hortus Veitchii* the date is given "about 1849." The plant, however, was distributed all over the country before that year, and was figured in the *Botanical Magazine*, t. 4,350, in 1847. Probably, therefore, Paxton was correct in the date. *C. amplexicaulis* is a fine species, and is only surpassed by *C. Burbidgei* and *C. Chibranii*. I have frequently had standards of it in the open up to 5 feet or 6 feet in height. These were produced from cuttings inserted in September, stood in cold frames till November, and after that the plants were wintered in a heated structure, to be grown on rapidly in the spring and planted out in May. Along with Prince of Orange, a later dark variety, it is the least hardy of the shrubby section. For long it retained its popularity as a bedding plant, most growers pegging down the somewhat straggly shoots. In the Glasgow Park a dwarf variety of similar colour used to be largely grown, by name, I think, Eastwood Gem. About the middle of the century, Sultan, Kentish Hero and Kayii were popular sorts, and a little later the long-time popular *aurea floribunda*, while in 1862 *C. equari-*

sis was greeted as the finest plant ever put into the hands of flower gardeners. A year or two later Ambassador, from Lang of Kirkcaldy, caused a great sensation, and I recollect how every scrap was propagated, the chief bed in the garden furnished with it, but the said bed was the failure of the year! In 1856 Calceolarias were attacked by a disease in the stems that decimated stock almost everywhere. After a while the disease lost its virulence, and again the Calceolaria looked up, to be, some 30 years later, once again attacked. I tried to overcome the disease by planting out in March, but finally *C. amplexicaulis* alone could be depended upon to withstand it. One of my men, on taking up a situation, had an amusing experience through introducing this practice. The old men on the estate, where previously Calceolarias had been prepared for planting in pots, assured him all would be killed, and he no doubt rose many degrees in their estimation when the success of the experiment proved him to be not the fool they thought.

With the exception of the two sorts above noted as somewhat tender, the best time to take cuttings is October, to be rooted in cold frames and freely ventilated after the beginning of the year. In spring, cuttings strike almost as readily as Verbenas, but under less hot conditions. The herbaceous section has all along been that favoured by florists, and we find the usual clash of opinion between Glenny and raisers as to the points to be aimed for in the obtaining of improved varieties. Glenny's objective was a flower perfectly globular in form, if small. Gaines and others affected as large a flower as possible, though less inflated, and therefore deficient in the property that Glenny esteemed so much. The controversy died out long ago, and also it is long ago since florists had the round and large flower in conjunction. The many coloured illustrations in the florists' magazines of that period show small flowers with markings of no great beauty, yet in the course of another 20 years plants bearing flowers of the type we are all familiar with had become general. The earlier strains, moreover, were not so amenable to cultivation as the later, in which something of the shrubby section had been introduced. And also gardeners, up to the middle of the century, propagated named varieties by means of cuttings and layers, novelties appearing every year from Green, the grower of mammoth plants, and a few others. Up to 1870 this practice was not yet obsolete. Roots were freely produced on basal growths, more especially when they were covered with some light compost kept moist and the plants kept cool and shaded. A little earlier than the middle of the century the whole system of cultivation was altered, and altered for the better, by growers for Covent Garden market. They grew them entirely from seed, annually selecting some of the finest seedlings for seed production, and each year making an advance in the quality of the flowers, till finally it was not worth while to cultivate Calceolarias by any other method.

As already stated, the early growers erred in coddling the plants, being unaware that in their native habitats—the western slopes of the Andes—they revelled in damp, shaded positions. Given similar conditions under cultivation, these difficulties do not materialise. Seeds may be sown at any time from July to September; in July to provide the largest plants. The seeds are merely sprinkled on the sandy surface of the previously moistened compost, pressed very gently down, protected by a sheet of glass, and the receptacle stood on a cool, moist bottom in a shaded position, or even in a frame out of reach of sunshine; the seedlings are attended to, pricking them out and potting as required till danger of frost is imminent, and during winter keeping them in a low temperature, only just above freezing point during frost. Paradoxical as it may seem, while moisture is essential, they succeed best when not over-watered. I had at one time to

grow Calceolarias in a garden in which was a detached span pit of low pitch heated by a flue which was used only to keep out frost. Therein the plants were watered only at long intervals, and thrived exceedingly while the insects that usually prey upon them never put in an appearance. The final potting should be done in February. At that time the lower shoots should be pegged down to give them more space to develop. R. P. Brotherston.

## MR. KINGDON WARD'S SIXTH EXPEDITION IN ASIA.

No. 20.—THE LITANG-YALUNG DIVIDE.

We spent the next three days in camp on the moorland, ascending in search of flowers; but it was not till the evening of the third day, when we descended to the village in the valley, that we began to find new ones. Now that the rain had come, drenching the mountains with cold water, there was a distinct lull in the appearance of new plants, though all those which had already ventured to peer above ground started at the shock as if it were the touch of a spur, and grew amazingly. There are two great flowering periods in these mountains of Western China—early spring, when melting snow supplies the water (May), and autumn, when the reluctant sun shines out again and warms a saturated world, calling the Gentians and Saxifrages out of the ground (September).

There was, however, one fine plant above our camp, as beautiful as anything we had seen yet. This was a violet-flowered *Meconopsis* of the *Primulina* section, growing in a remote valley head on a grassy slope. The central scape, about six inches high, rising from a rosette of leaves, terminated in a single, large, nodding flower of shimmering violet silk, tossed by the wind and battered by the rain, but splendid despite all. From the axils of the leaves rose two or three shorter scapes surrounding the central one; but these were not as yet in flower. The curiously bent stigma and slender, obconic capsule were distinguishing features. There was a fairly large group of these beautiful Poppies here, some growing on the steaming, grass-clad slope, others springing up amongst the boulders, perhaps two or three dozen plants in all. Later, I found a few plants in fruit amongst dwarf *Rhododendron* scrub on the open moorland, but the species is certainly rare, at least in this locality.

The section *Primulina* contains some of the most lovely Sino-Himalayan blue Poppies, and the addition of this charming plant—for it conforms to none of the eight known species—will surely be welcome to horticulturists. Unfortunately, it seems to be monacarpic.

On the evening of the third day in this rather bleak camp, we descended to the village in the valley, not far distant. As soon as we got down to the torrent we began to find flowers in unexpected numbers. One of the first was *Primula Cockburniana*, hiding its rich orange flowers and mealy white pedicels in thickets of high grass and Bamboo, as though it could not brook the sunlight; there was little chance of its getting any at this season. *P. Cockburniana* is a *Tatsienlu* plant, so we really were getting into the Szechuan flora, though more than a hundred miles of mountains still separated us from *Tatsienlu*.

In the high meadow, in deep shade—quite a different situation to that taken up by *P. vincaeflora*—we found scattered plants of another *Omphalogramma* *Primula* in fruit. The plants were very tall, the capsules small, and the leaves narrow; the flowers we were left to speculate on. It might, of course, be *P. Franchetii*, known from *Tatsienlu*; but most of the *Omphalogrammas* seem to have a restricted range, so that it might equally well be something new.

\* The previous articles by Mr. Kingdon Ward were published in our issues of May 14, June 13, July 21, August 20, September 3, October 8, October 29, 1921; January 7, January 21, March 11, March 25, April 8, April 23, May 6, May 20, June 3, June 17, July 1 and July 15, 1922.

A tall, slender *Codonopsis* with bloodshot, nodding flowers crowded the meadows by the streamside, and further on we came to clumps of Iris with queer slate-blue flowers, both standards and falls being very narrow; violet Irises also grew here in profusion.

The stream was lined with trees of *Hippophaë rhamnoides*, which in autumn would, I knew, be a fine sight. Masses of *Primulas*, familiar to us ever since our arrival in the country, crowded the marshes. It was here, under the *Hippophaë* trees, that we found a rather coarse *Muscarioid Primula*, new to me; but its flowering time was already past. We spent three days at a little Hsigan village here near the valley head and 11,000 feet above the sea. For dirt, gloom and smells, a Hsigan house will hold its own with most Tibetan competitors; how I longed for the commodious houses of the Chung-tien Tibetans!

The valley here began to split up, and there were meadows fringing the stream, where a host of brilliantly coloured flowers grew rankly. A cloud of blue *Cynoglossum* occupied one territory, followed by a galaxy of crimson *Pedicularis*, against a background of golden *Potentilla*. Everywhere the little crimson spires of *Primula Littoniana* (or maybe *P. Vialii*) were pricking through the ruck.

We also found another dwarf *Rhododendron* here, possibly two, the second being a form of *R. racemosum*; but these, of course, were long past flowering. Had the weather been at all kindly disposed, we should have seen snow peaks in one direction or another from above our village; but though we did, indeed, have intervals without rain, it was always far too cloudy to see even the nearer mountains. The Campanulaceae were now coming into their own; besides the species of *Codonopsis* referred to, a second species with lavender-blue bells, changing to dusky purple at the base, grew in masses on the moorland. Two species of *Campanula* were also in flower, one a plant of the limestone, very like our own Harebell—the Bluebell of Scotland—but more dwarf, the second a tall, untidy thing with flowers of uncertain violet growing on rocky outcrops at lower altitudes. But it was not till the middle of August that the *Campanulas* attained to the height of their power, when all the twining species of *Codonopsis* and the alpine *Campanulas* were in full bloom. They heralded the beginning of autumn, which season pays scant respect to dates in Chinese Tibet.

On July 13 we started back for Mu-li, following the same route as before. The road is never quite the same going as coming, and one reason for this is certainly that on the return journey you are traversing fresh those parts of the route which on the outward journey you traversed in a somewhat faded condition.

We found *Primula septemloba*—or a dwarf form of it—in the wooded valley, and the little *Soldanelloid Primula* everywhere.

On July 16 we were back in Mu-li with our spoil; the rose-flowered *Malvacea Primula* by the bridge was now a fine sight, and it was during the next few days that we found the other two *Malvaceae* already referred to, one of them undoubtedly being *P. blattariformis*.

Although Mu-li is situated in a dry region, it would be a great mistake to suppose that it does not rain there. On the contrary, it rains very thoroughly in the wet season, and for six weeks on end it did scarcely anything else. Its dryness consists in the fact that the rainy season is short, and that there is a long dry season. There is a second wet season, but as this occurs in the winter, it is of little assistance to the vegetation, except indirectly.

Where there are snow peaks in the vicinity, it must rain fairly heavily at times, and the mountain ranges surrounding Mu-li get their fair share. During five days spent at Mu-li on our return from the Shui-lu (June 29-July 3), over an inch and a half of rain fell, most of it during the night. Throughout July and the first week of August it rained steadily, generally at night in the valley, by day on the mountains, or, rather, day and night on the mountains. Between July 18 and 23 at Mu-li I recorded 2.4 in. of rain, while ten days' rainfall in the mountains accounted for

another 4.7 inches. This, of course, is slight enough when compared with the rainfall in the southern and western parts of Yunnan. I dare say we had on an average 12 or 14 inches of rain in July, but it varied considerably in different localities. Anyhow, this rainfall, coming in the vegetative season, is sufficient to support a moderately rich flora on the mountains, with a certain amount of thin forest on the sheltered slopes. There is no temperate rain forest, such as is met with on the North-East Frontier of Burma, nothing but mixed forest below, or woods of scrubby Oak, and Conifer forest above.

There are even a few plants of Indo-Malayan affinities—species of *Strobilanthes*, *Begonia*, *Impatiens* and *Hedychium*, genera which are enormously developed along the Burma frontier. Are these waifs which have arrived here fortuitously, or are they the remnant of a once more extensive representation? The fact that the whole of this region is extensively glaciated, and hence that the rainfall must

NOTES FROM WISLEY.

ALTHOUGH the spectacular effects of the spring and early summer have run their appointed course, Wisley Gardens are full of interest. On every hand serene content with the change in the weather is the chief impression one obtains from a tour of the gardens. Roses are effective and the *Viola* and Sweet Pea trials provide an interesting study.

The herbaceous borders are chiefly devoted to late blooming plants, and for the moment have little colour. One plant, however, makes a bright patch—*Glacium flavum* var. *tricolor*—which is similar to our Sea Poppy, but 3 ft. high and with orange-coloured flowers.

Throughout the gardens many species of *Campanula* are in flower. On some of the ditch banks are masses of the pale blue *Campanula lactiflora*, behind which are the pink blossoms of *Rosa rugosa*. Near by is *C. latifolia* and its still more handsome variety *alba*.

FIG. 23.—A HYBRID OLEARIA: *O. ARGOPHYLLA* X *MACRODONTA*? (SEE P. 49).

once have been far heavier, inevitably leads to the latter conclusion. I even found on the limestone cliffs—and at no great altitude, either, 10,000 feet—during the first week of August, one of those really dwarf *Rhododendrons*, only a few inches high, with the flowers borne in pairs on long pedicels; a group almost peculiar to the mountain tops of the high ranges further west, enjoying a heavy rainfall. This plant, which was in flower, apparently for the second time, had a flat, almost rotate corolla, standing on edge—there is a little plant with rather larger flowers from the North-East Frontier of Burma which closely resembles it in habit. My Mu-li species, however, has flowers of a gorgeous Plum colour when seen by reflected light, but blood-red when seen with the sunlight streaming through it. And this is obviously the way to grow it, on a cliff edge high up against the sky.

This discovery brought our *Rhododendrons* up to over twenty species from the neighbourhood; and I dare say continued search would in time yield as many again; but they form a very different assemblage to these found even so near as Ta-li-fu or A-tun-tzu, and are strikingly less in numbers. The rain continuing, we returned to Glacier Lake Camp on July 23, going by easy stages. *P. Kingdon Ward*.

In the rock garden our native Harebell is much in evidence, and also the variety *hirsuta*, which is a much finer plant, bearing large flowers on erect stems a foot high. Many plants of *Rampion* (*Campanula Rapunculus*), *C. rapunculoides*, and *C. glomerata* are to be seen scattered about the rock garden. A beautiful little gem is Farrer's *Campanula Billardieri* *Miranda*, which grows about four inches high and has nodding bells of a very pale greyish blue.

Another good plant is a bright, crimson-flowered form of *Thymus Serpyllum*, which attracted the notice of the Director, and was sent to the gardens. Two rock pinks deserve mention, *Dianthus Old Rose* and *D. Gladys Cranfield*, the latter having flowers of a warm shade of pink with a dark crimson centre. Among the shrubs on the rock garden *Philadelphus purpureo-maculatus* with its purple-splashed blossoms is flowering well. In the wood the groups of *Lilium giganteum* are flowering, but are rather short in the stem owing to lack of moisture. In a heated tank in front of the laboratory is the Berlin variety of *Nymphaea stellata*. This plant is something of a barometer, as if a fine day is ahead the blue flowers are closed in the early morning, but if rain is imminent, they open very early. *J. E. G. White*.

## MESEMBRYANTHEMUM AND SOME NEW GENERA SEPARATED FROM IT.

(Continued from page 24.)

41. *C. petraeum*, N. E. Br. (Fig. 24). Growths 5-6 lines long, 2-3 lines broad and 1½-2 lines thick, obconic, convex and elliptic in outline at the top, glaucous-green or slightly bluish-green, marked in a somewhat regular manner with interrupted or continuous lines of confluent blackish-purple or very dark green dots; one such line usually extends over the middle of the top from each side of the orifice, and branching from or disconnected with this central line on each side are two simple or forked lines and one or two separate dots. Calyx 4-lobed. Corolla only seen in a dried state apparently about 3

FIG. 24.—*CONOPHYTUM PETRAEUM*, N. E. BR. NATURAL SIZE.

lines in diameter, with about 25 petals, probably whitish, in the dried flower seen usually marked with from 1-3 linear glands. Stamens all with exerted yellow anthers. Style about ½ line long; stigmas 4, about ½ line long, slightly thickened upwards.

Laingsburg Div., near Laingsburg, Pole Evans.

42. *C. vagum*, N. E. Br. (Fig. 25). Growths under cultivation variable in size and form, 5-7 lines long, 3-6 lines broad and 2½-5 lines thick, some, as viewed from above, regularly elliptic in outline, others more or less distinctly six-angled, the angulation seems chiefly confined to the larger growths, obconic, with the top slightly convex and the larger growths slightly keeled, smooth, glaucous-green or greyish-green, with about 3 dots on each side of the orifice, behind the middle dot on each side extends a straight line of more or less connected dots, towards the middle angles, and on each side of that line at a little distance from it are one or two dots or a diverging line of dots directed towards the lateral angles, all dark purple-brown. Calyx 5-lobed, with the tube 2 lines long, and partly exerted. Corolla 7-10 lines in diameter, expanding in the evening, not scented, closed during the day; tube not longer than the calyx; petals 26-31 in 1-2 series, very lax, widely spreading, 3-4 lines long, very narrowly linear, acute, white. Stamens about 20, in 3 series, all more or less exerted from the corolla-tube; anthers light yellow. Style, half a line long; stigmas 5, erect, 1 line long, not nearly reaching to the lower anthers, filiform.

South Africa. Locality unknown. This species was sent to me by Prof. P. MacOwan, in 1878.

43. *C. scitulum*, N. E. Br. Growths 6-7 lines long, 4-7 lines broad, and 3½-6½ lines thick, obconic, somewhat convex at the broadly elliptic top (type E), with or without a slight transverse notch at the centre, greyish-green, tinted with purple on the sides and marked on the top in a map-like manner with branching and more or less connected lines of a dark purple-brown or violet-brown colour, or (if not

exposed to the sun) dark green. Calyx 4-lobed. Corolla 3-8 lines in diameter, expanding in the evening, scentless; tube equalling or longer than the calyx; petals 30-35 in 2-3 series, milk-white. Stamens 15-20; anthers all more or less exerted, creamy-white or very pale yellowish. Style 1 line long; stigmas 4, rising to the base of the anthers, 1½-2 lines long, whitish.—*M. scitulum*, N. E. Br., in *Journ. Linn. Soc. Bot.*, v. 45, p. 100.

South Africa. Locality and collector unknown.

44. *C. uvaeforme*, N. E. Br. Growths subglobose or grape-shaped, resembling the green grape called "Muscadine," pale green, with small, slightly confluent dots of a darker green.—*M. uvaeforme*, Haw., *Rev. Pl. Succ.*, p. 84.

South Africa. Locality and collector unknown.

The above description, copied from Haworth's account of it, is all that is known of this plant. I have not seen any plant that can be referred to it.

### EEE.

Growths distinctly obovate, with or without a slight ridge or keel extending from the orifice to the top of the convex lobule on each side of it, and often with the slopes of the notch on each side of the ridge more or less flattened. (Types O-Q). Species 45-49.

The six species comprising this small group are very similar in appearance and very difficult to discriminate by characters that can be set down in words, yet when seen growing side by side, can easily be distinguished. They all expand their flowers in the evening, or late in the afternoon, and the flowers of all the species are very pleasantly scented, something like Cloves, and of some shade of pink, except those of *C. placitum*, which vary from white to pink. The stamens (except in *C. placitum*) are numerous (50 or more) and whitish, with the upper series of anthers visible at the mouth of the corolla-tube. But the size, shape, and general character of the flower of each species seems to be constantly different from that of the other species. So that in the following descriptions none of the above general characters are mentioned.

45. *C. ficiforme*, N. E. Br. (Fig. 26). Growths 6½-12 lines long, 5-9 lines broad, and

FIG. 25.—*CONOPHYTUM VAGUM*, N. E. BR. PHOTOGRAPHED AT 8 P.M. NATURAL SIZE.

4½-7½ lines thick, without or with only a faint ridge on the faces of the notch, which is not so deep as in the other species (type O.), light greyish green or somewhat glaucous-green, sometimes tinted with purple on the basal part, and thickly covered on the top with moderately large dark green conspicuous dots, all separate or a few of them more or less confluent into a short line, extending from the centre of the orifice on each side over the top, and a confluent line of them around the orifice. Calyx 4-lobed; tube much exerted. Corolla 10-12 lines in diameter; tube at first not longer than the calyx, finally exceeding it, white; petals 30-40 in few series, the outer finally recurved, the others

widely spreading, white for about one-fourth of their length at the base, the upper part bright pink. Stamens numerous in 3-4 series, with the

FIG. 26.—*CONOPHYTUM FICIFORME*, N. E. BR.

white anthers of the upper series just exerted. Style and stigmas imperfectly developed in the only flower examined.—*M. ficiforme*, Haw., *Rev. Pl. Succ.*, p. 83 (1823); N. E. Br., in *Gard. Chron.*, 1876, p. 743, and 1886, v. XXV., p. 373, Fig. 73.

Worcester Div. Near Worcester, Cooper.

The locality from which the original plant came is unknown, but it may very well have been the same as where Cooper collected it. Haworth states that he received it from Salm Dyck, in 1819, and there is a drawing at Kew of a plant of *M. ficiforme*, stated to have been received from Haworth in 1824, that is labelled as having been received from Bowie, "who says it grows on the rocks of Kogmans Kloof and Lange Kloof." I suspect these localities to have been given by Bowie from memory, and I much doubt their being correct. At any rate, the plant here described is the same as that figured in the Kew drawing, which must be taken to represent the type. *N. E. Brown.*

(To be continued.)

## HEDGES AND THEIR MANAGEMENT.

For all practical purposes hedges may be divided into two kinds, useful and ornamental, the former being chiefly in use for protective purposes and keeping farm stock in bounds, and the latter in connection with private grounds, and for garden sub-divisions where ornament and not utility is of first importance. For plantation fences and field boundaries the Hawthorn, Beech and Hornbeam are mainly employed, while for purely ornamental purposes and where resisting properties are of little moment, the list of suitable shrubs is a long one, and includes, amongst others, several species of Berberis, the Box, Aucuba, Yew, Holly and Privet, in fact, almost any shrub that fancy dictates may be used. Where strength, hardihood and shelter are concerned no other shrub that I know can equal the common Hawthorn as a hedge plant, and for this reason it is more extensively used than any other in the formation of estate and farm fences. It

is of stout, stubborn growth, perfectly hardy, of fairly rapid growth, not at all subject to disease, long-lived, and readily propagated. Though by no means particular as to the quality of soil in which it is planted, the Thorn delights in a rather rich, brown loam, but detests in a marked degree stagnant moisture, and attains its greatest perfection at not too high an altitude. Few shrubs so well repay good treatment as the Thorn, and for this reason thorough preparation of the ground where it is to be planted is a point of great importance. The ground along the line of fence should be trenched or dug deeply, and thoroughly loosened to a depth of 18 inches or 2 feet; if of poor quality, a quantity of thoroughly decomposed farmyard manure may be added, and the whole left in a roughly-turned-up condition for a month or longer before planting is done.

Where it is intended to form a hedge in rather damp, low-lying ground it is advisable to plant slightly above the level of the surrounding ground, so that when trenching or digging is being carried out a slight mound may be raised along the proposed line of fence. Autumn, immediately after the fall of the leaf, is the best time to transplant the Thorn, when stout, well-rooted plants about 15 inches in height should be used. The usual method of planting is to stretch a line along the prepared surface of the soil, close to which a V-shaped trench of sufficient depth to permit of the roots being inserted and spread out, should be opened. Plant in a single line, which is preferable to the double row, about 8 inches apart, replacing the soil in the trench and tramping it firmly.

Both the Beech and Hornbeam make satisfactory hedges, and thrive better than the Thorn on exposed, high-lying ground, an advantage with the Beech being that a great proportion of the leaves are retained throughout the winter, thus rendering it valuable for shelter at that time. It is, however, subject to disease and insect attack. Compared with the Thorn, the Beech lacks rigidity, and is thus a less valuable farm fence, and this is true also of the Hornbeam, which, however, in stiff soils approaching clay, will thrive in a satisfactory manner.

Both the Holly and Yew are excellent hedge plants, but are most suitable for ornamental gardening, although the latter should be out of the reach of farm stock. Gorse or Furze hedges are valuable on poor, gravelly or sandy soils, at high altitudes, and on the Welsh and Scotch hill-sides are largely employed as subdivision fences. For the top of a dyke or sunk fence they are specially useful, and may be quickly raised from seed, 1 lb. of which will sow 100 yards of fence. In order to keep the Gorse healthy and bushy, pruning should be done immediately after the period of flowering, and cutting the plants down to ground level every third or fourth year is to be recommended. The Blackthorn and Myrobella Plum have been recommended for hedging purpose, but they are not employed to any great extent.

Ornamental hedges, as before stated, may be formed of almost any shrub that fancy dictates, and in Cornwall even the Escallonia is highly valued for that purpose; near the sea, at Penzance, I saw hedges of this shrub that were perfect wedges over 6 feet high and fully 4 feet thick. At Penrhyn Castle, in Wales, both the Hydrangea and hardy Fuchsia are employed for a like purpose, and not far distant hedges of the Tamarisk and Myrtle are not uncommon. In a young state especially, *Berberis Darwinii* makes one of the most beautiful hedge plants, and is especially valuable for subdivision purposes, but should be allowed to produce its flowers, and the same may be said of the Laurustinus, Sweet Briar and many other of the ornamental type of shrubs.

Amongst Coniferous trees several are in constant use as fences, including Lawson's Cypress, the American *Arborvitae*, *Retinospora plumosa* and *Thuja gigantea*. At Ken Wood there is a perfect hedge of the common Oak, and at Holwood, in Kent, the Mediterranean

Heath makes a capital boundary hedge of not too rampant growth, while at Oxford *Gaultheria* is largely employed in that way.

The after-management of hedges consists mainly in keeping the ground around the roots of the plants in a clean condition, for weeds rob the soil of nourishment, choke, and sometimes kill out the young plants and prevent the free access of rain to the roots.

Elder should never be allowed to luxuriate in a hedge of any kind, as it quickly kills out its neighbours, as do also the Ivy and *Honeysuckle*. After three years' growth the hedge may be trimmed into shape with a sharp switching knife, and annually afterwards the same operation may be engaged in, but with the exception of cleaning and pruning, a well-formed hedge should require but little attention for many years. Should the hedge at a later period show signs of becoming thin and gappy through soil exhaustion, the roots should receive a top-dressing of thoroughly decomposed farmyard manure, while plants that have died outright should be made good by inserting stout, well-rooted plants in their stead. *A. D. Webster.*

### PERMAIN APPLES AND POMME-POIRE.

SINCE writing on this subject (*Gard. Chron.*, June 24, 1922, p. 336), I have had access to the classic work of Julien de Paulmier (*De Vitis et Pomaceo; traduit en Français par J. de Cahaignes, réimprimé par E. Travers, Rouen, 1896*), which affords a very suggestive idea as to how the connection between Apple and Pear arose and led to the spelling of pearmain for permain and parmain. Many attempts have been made to explain it by pretended resemblance in shape and size, for instance, Hogg's insupportable *Pyrus magnus* or Great Pear Apple, and in respect to quality, Manger's (1780) plea for an Apple having the worth of a Pear.
