INDEX OF CONTENTS.

JANUARY TO JUNE, 1877.

A

- ABIES, distinguishing characters of, 178
 Abies Engelmanni, 651, 792-821; A. Fraseri, 147; A. Menziesii, 48, 214, 565, 691, 725, 750; A. Menziesii and A. Engelmanni, 790; A. nobilis, 255
 Abies Parryana at Knapp Hill, 758
 Abbey Hall, the gardens at, 367
 Abutilon Darwinii chromosome, 598; A. roseiflorum, 622
 Acacia dealbata, 81
 Academy exhibition, the Royal, 619
 Acclimatization, notes on, 474
 Acer Van Volxemii, 71
 Adenium oblongum, hints from the seed of, 695
 Adiantum Capillus-Veneris var. comense, 504, 567; A. concinnum Flemingii, 695; A. gracillimum, 686, 690; A. negundoense, 12; A. palmatum, 40; A. scolopium, 115; A. Williamsii, 571
 Aerialis crassifolium, 593, 633; A. A. Fieldingii, 136
 Africa, note on Palm seeds from, 344
 Agave, review of the genus, 179, 303, 368, 527, 620, 717
 Agave agapantha, 777; A. cochlearis, 718; A. Demeisteriana, 620; A. Deserti, 717; A. filifera, 393; A. filifera var. filamentosa, 393; A. Giesbreghtii, 620; A. Gilbeyi, 621; A. heteracantha, 369; A. Hookeri, 718; A. horrida, 621; A. Kerchovei, 527; A. latissima, 718; A. lophantha, 368; A. lophantha var. concinnescens, 368; A. macrantha, 621; A. macrodonata, 621; A. Nissou, 527; A. parviflora, 393; A. Paeonickii, 621; A. Poesgelieri, 527; A. Rocelliana, 527; A. Salmaiana, 718; A. schiediana, 51, 393; A. schiediana var. 393; A. Schottii, 393; A. Sartorii, 621; A. Shawii, 717; A. splendens, 369; A. triangularis, 621; A. univittata, 368; A. Vanderlinnii, 621; A. Victoria reginae, 528; A. xylantha, 527
 Agave Elieceniana, flowering at Kew, 621
 Agave americana flowering at Tesco Abbey, 820
 Agaves, hybrid, list of, 439
 Agricultural Benevolent Institution, the, 727
 Agricultural statistics, 141
 Agriculture and gardening in Costa Rica, 449, 494
 Agriculture, insects injurious to, 310
 Albert Memorial, Mr. Walls' design for covering the, 436
 Aloe, fresh water, of the Cape of Good Hope, 668
 Algeria and the South of France, vegetation in, 146; locusts in, 694
 Algerian species of *Crocus* and *Fritillaria*, 45
 Alwrick Castle, the rainfall at, 116
 Aloe roseo-cincta, A. Hanburyana, 792
 Alpina nutans, 692
 Alps, the Wetterstein of the, 473
 Alocchya glauca, 753
 Amaranth, seedling, 665; A. Princess Trust, 219; A. Storr's Beauty, 487
 Amateur gardening, see Supplement, May 12, and Supplement, June 9
 American and Italian Tulroses, 147
 American blight on Apple trees, whole oil a cure for, 341
 American blight on the Auricularia, 537
 American fruit supply, the, 491
 American Oaks, North, 410
 American plants at Knapp Hill, on the, 59, 727
 American Potatoes, 244
 America, the fruit crops in, 147; the potato crop in, 221; Wine raising in, 436
 Americanium Palmii, 139
 Amsterdam Botanic Garden, 529
 Amsterdam and Haarlem, 10, 462
 American International Horticultural Exhibition, the, 468; the best thing at the, 536; the Congress at, 212
 Amsterdam, Tulip literature at, 567
 Anemone, on the road to, 377
 Anemone sempervivens, 751
 Anderson, Mr. A., with portrait, 529
 Andrews, Mr. James, death of, 24
 Anemone fulgens, 82, 312; A. nemorosa, 1, 500
 Anglesia, rainfall in 1876 at Bodogran in, 148
 Anglia, East, the fruit crops of, 695; and the weather in, 600
 Angolan Florarum, Welwitsch's, 509
 Annuals, hints from the horse-barden, 693
 Annuals, a gigantic garden of, 810; Messrs. Carter & Co.'s show of, 814
 Anthurium Andraeanum, 654; A. Brownii, 525; A. Decharlieri, 622, 765; A. Schreuzmann Wardii, 412; A. spathuliphyllum, 652
 Antigonon yacinae, 784, 789
 Antipodal Hyacinths, 591, 632
 Antirrhinum at Pinkhill, 76
 Ants, 281
 Antwerp, the town of, 337; M. Charles Van Geert's nursery at, 527
 Aotus gracillima, 726
 APRIARY.—Bee-master, how and when to become a, 431; drones, do bees mass on, 414; drones, massacre of, 594; honey in dromed coila, 722; Ligurian or Italian bees, 658; swarms, new, 753
 Apples, Baldwin and Lady, in Gurnsey, 662; *Capilla Bianca*, 729; Cox's Orange Pippin, 655; Pippin, 662
 Apple tree, nature and cure of canker 10, 146
 Apple trees, whole oil a cure for American blight on, 344
 Aralia Brodiaei, 568, 691
 Aquatic culture, the, 373
 Aquilegia chrysantha, 622
 Aquilegia, new hybrid, 739
 Aralia filicoides, 369, 571
 Arancaria Cookii in New Caledonia, 85
 Arboretum and shrubbery for Berlin, 245
 Arctostaphylos, 379
 Arctic Expedition, survey in the, 372
 Arisa Hostii, 760
 Arischoke, the Jerusalem, on the origin of, 146
 Artificial flowers and fruit, 335
 Ash and the Oak, the, 632
 Ash trees, the, 276, 295, 791
 Asia, Central, Melons from, 303
 Asparagus, a quick method of forcing, 83
 Asparagus, 626, 595
 Aspects of horticulture, 139, 201, 303
 Aspidiotus pandani, 732
 Assam, Potato culture in, 178
 Asterabad, vegetable products of, 655
 Athens, letter from, 395
 Atholia, a tour round, 651
 Atmospheric moisture in Orchid-houses, 624
 Athuria coarctata, 694
 Athuria, the 249; and the Polyanthus, 338, 402
 Auricularia Society's southern show, the National, 173
 Auricularia, the American blight on the, 537
 Auricularia Topsy, 12
 Auricularia, nearly-leaved, 475; on potting, 475; soil, 475
 Auricularia, the Kirby Marnard, 470; at Loxford Hall, 497
 Australia, 219, in spring, 174
 Australian Cereals, 483
 Austria, social standing of gardeners in, 144
 Auburn planed Potatoes, 52
 Azalea, Dodder on an, 314
 Azalea Mrs. Carmichael, 313
 Azaleas, Ghent, on the origin of, 18
 Azaleas, propagating, 766
 Bedfordshire, plants of, 179
 Beech trees, the, No. 629
 Beekeeper, how and when to become a, 434
 Bees, Ligurian or Italian, 658; the scarcity of Holly berries and, 83
 Beetle, the Colorado, 333, 669
 Beetles, injurious, 771
 Begonia Gloire de St. Louis, 739
 Beisfeld Gardens, Wandersmeer, 536
 Ben Nevis, notes of a botanical excursion 10, 131
 Berlin, arboretum and shrubbery for, 245
 Berlin Horticultural Society, 470
 Berries, Holly, scarcity of, 53, 143
 Betwixt Newydd, resuscitated Yew at, 215
 Bigonias, on the culture of, 105
 Bilbergia horrida; B. Lihonina, 752; B. speciosa, 138; B. viridifolia, 133
 Birch, white-knots on the, 249
 Birds and Flowers, 469
 Birds-nests, do not rob, 438
 Birds, protection of, 534; the sports of, 146
 Birmingham Botanical Gardens, 573
 Blackberries, 116
 Blackthorn in bloom on January 9, 83
 Blair Athole, 683, 729
 Blair Athole plants, 729, 761
 Blue Glass, growth of Vines under, 759
 Blue Mountains, 732
 Boboli gardens, Florence, the, 173
 Boiler, the Endless Pile's Impact, 374
 Bolts, the heating power of, 438
 Bophophyllum Fendleri, 752
 Bollea celestis, 366
 Bonarea Carder, 112
 Bone-dust per acre, 119
 Books for villa gardeners, Supplement, May 12
 BOOKS, Notices of.—Agrostographia, 412; Alnutt's The Cactus and other Tropical Succulents, 249; Artistic Arrangements, Supplement, May 12; Artistic Decorations for Ballrooms, &c., Supplement, May 12; Bernardini's L'Afrique Centrale, 539; Bevan's British and Continental Industries, 407; Brown's A Plea for the Creation of a School of Forestry in connection with the Arboretum at Edinburgh, 603; Brown's Forests and Moisture, 413; Bulletin d'Arboriculture, 184; Burdige's Cultivated Plants their Propagation and Improvement, 372; Cassell's Familiar Wild Flowers, 208; Christy's Forage Plants, 157; Church's Food: some Account of its Sources, Contents and Uses, 412; Compendio di Flora Italiana, 413; Cordier's Les Champignons, 151; Coutance's L'Olivier, 721; Darwin's Cactus and Soil Fertilization of Plants, 276 (see Fertilization); Dupuis's Les Papillons, 151; Eweis' Monograph of the Geous Liliaceae, 438, 603; Gardener, the, 23, 208; Gallien's The Forces of Nature, 497; Hulme's Familiar Wild Flowers, 443; Hume's Cactus, 412; Journal of Forestry, the, 603; Journal of the Bath and West of England Society, 345; Journal of the Linnean Society, 345; Kingstons' Horticulturalism of Animals, Birds, Fishes, and Meteorology, 443; King's the Window Observer's Supplement, May 12; Kolb's Theorie des Gartenbaus, 656; Lange's Souvenir de l'ancien Jardin Botanique, 497; Marshall's Birding in India, 497; Mollison's The New Practical Window Gardener, Supplement, May 12; Mueller's Select Plants readily eligible for Industrial Culture or Naturalisation in Victoria, 412; Murray's Economic Entomology, 249, 404; Natural History Journal, the, Supplement, May 12; Notes on Observations of Injurious Insects, 603; Nurseryman's Directory, the, 345; Philology, 443; Quin's Garden Recipes, Supplement, May 12; Riley's Potato Fests, 181; Rivers' The Miniature Fruit Garden, Supplement, May 12; Schibler's Die Pflanzenwelt Norwegens, &c., 475; Smiles' The Life of Scotch Naturalist, 411; Smith's Mushrooms and Toadstools, 23; Stackhouse's Hardy Plants for Little Front Gardens, Supplement, May 12; Stormonth's Etymological and Pronouncing Dictionary, 184; Thome's Structural and Physiological Botany, 208; Victorian Year Book, the, 412; Villa Gardener, the, 54, 208, 345; Vogl's Les Aliments, 412; Waldheim's Aperçu Systematique des Utilisations, 222; Whigston's Agricultural Text Book, 816
 Books, relating to Tulips at Amsterdam, 392
 Borderland, on the Hollando-Belgian, 338
 Borders, Vines, 59; why are inside borders rootless, 150

 Bournefontaine, Raikes' Fan, Supplement, June 9
 Bournefontaine Winter Garden, the, 77
 Boxes, hatching, 53
 Boxwood, outside window, 507
 Brassica, Potato spritting, 149
 Brassica Napus, 247; hereditary deformity in, 436
 Bread, the A. death of, 438; memoir on (with portrait), 625
 Britain, on the gardens and gardeners of, 146
 Broccoli, in Cornwall, 51; Veitch's self-protecting autumn, 22, 83, 213
 Broughton, the late A. (with portrait), 625
 Brussels Botanic Garden, 623
 Brussels Sprouts, 129
 Buckley fund, the, 180
 Bull heads of Haarlem, the, 526, 559
 Bull season of 1876, the, 10
 Bulrush and the Reed, the, 747, 779
 Butcher's, the, 106, 495
 Burial grounds, our, 728
 Burrs, and bad variations in trees, 311
 Butterfly, the first, 184; the clouded yellow, 826
 C
 CBSALPINIA brevifolia, 215
 Calanthe vesita rubro-cerulea gigantea, 219; *Leopoldina*, 752
 Calceolaria, herbaceous, 605, 725
 California, Rain culture in, 778; the Wheat, 412
 Calliphora subcaudata, 622
 Calceola esculenta, 12; var. Leitchiana, 725
 Cambridge, Mass., notes from, 47
 Camellia blooms from the open-air, 244
 Camellia disease, a curious, 628
 Camellia Martiana Gaches, 758; reticulata, at Chiswick House, 695
 Camellia, on the renovation of the, 607
 Campbell, Mr. A., death of, 419
 Campanula Allionii, 762; *x* C. Hausmannii, 1, 60; Rapunculid, 819
 Campanulaceous plant, a remarkable, 146
 Canker, on the culture and use of, in Apple trees, 146
 Caper Spurge, the, 762
 Carbolic acid and paraffin, 51
 Carbolic acid, absorption of, by plants, 146

- Curatima pratensis*, as a salad herb, 758
Cuscuta, fungoid Christmas, 29, 53
 Cult. International Horticultural Ex-
 hibition, 342
 Carnation show in London, the proposal,
 634
 Caratoun Souvenir de la Malmaison, 563,
 604, 604
 Carnations and Picotees, exhibition of,
 604
 Carnations, tree, Guelder Rose, and Rose
 Perfection, 313
 Carnivorous properties of Zonal Pelar-
 gium, 604
 Carob tree, the, 705; in Portugal, 144
 Carpet bedding, and the plants used in it,
 604
 Carpeting, May 12 (with coloured
 plate)
 Carse Trees, 298
 Caserta, the cascade at, 628
 Cassiniana Gnomus, 622; C. scabra, 220,
 304
 Cattleya Schilleriana, 752; C. Skinneri
 729, 810
 Cauliflowers, 82
 Ceasothus, hardness of, 703, 82
 Celars of Lebanon, the, 39, 147, 150
 Cells, the red, at Inverary, 212
 Cells, on the culture of, 663; in market
 gardens, 665
 Celis australis, 413
 Centaurea Lacyanus, 270
 Ceratonia Siliqua, 144, 765
 Cereals, development of, from northern
 80
 Cereals, our, 663
 Ceylon, climate, 713
 Chafers, 476
 Chalk castle, 823
 Chalk soils, lime for, 438
 Chameroops Fortunei, 466
 Chemical vapours, expiration of Thistles
 79, 112
 Chenopodium Bonus-Henricus, 694
 Cherry, a double-blossomed, 628
 Cherry the Marquis, as a standard, 630
 Cheshire, the Primrose in, 507
 Chicomby or Witloof, as grown in Belgium,
 48
 Chinese arbutaceous, 568
 Chiviswick House, bedding-out at, 470;
 Camellia reticulata at, 500
 Chionodoxa fragrans, 377, 490
 Chionodoxa cordatum splendens, 150,
 500
 Christmas cards, unanswerable, 503
 Chionodoxa, the, 503
 Church decoration, "A May" for, 593
 Chusan Fams, on, 468
 Cinchona, 478; on the culture of in India,
 212
 Cinchona febrifuge, the new, 725
 Cinchona studies, by Otto Kuntze, 663
 Cinchona tree, planting of, 212
 Cinerarias, double, 662, 665; new double
 white, 810; Mary and Thomas Winter,
 213
 Clifton, the Phenomenon at, 212
 Clematis Aurora, 442; C. caucayica, for
 making wreaths, 82
 Clematis, Messrs. Jackson's exhibition
 of, 628
 Clematis, the wild, 534
 Ceanothus puniceus, 438
 Climate and productions of Turkestan,
 306
 Climate of Russia, 534
 Climbing plants, 278
 Climbing Seedling Grape, the so-called,
 84
 Cochin in the Canaries, 92
 Codonopsis Jacquiniana, 599, 747
 Cockle, the, 729, 704; destruction
 caused by, on the Continent, 405; kill-
 ing, 430
 Codonopsis in Queensland, the, 636
 Codonopsis Devoiana, 534
 Colymbone cristata, 247, 278, 303, 595
 Coffee, cultivation and exportation of
 in India, 685
 Coleus Duchesne of Edinburgh, 752
 Colorado Abies Menziesii, 45, 211
 Collet, the, 333, 669; a remedy
 for the, 818
 Columbia, return of Messrs. Carter and
 Sluethworth from, 18
 Colts, the Prickly, in Ceylon, 18; at
 Malabar, 50
- COMMITTEE, THE SCIENTIFIC**—Aspidula
 Latanice, 377; Aquilegia, hybrid,
 734; Asplenium Farleyense, 734;
 Alchoum niger, 377; Auricula, American
 light, on the, 777, 444; Euryco-
 chloa, 210, 313; Berkeley, Rev. M. J.,
 portrait of the, 506; Calliphora
 sp., 85; Cetraria, conchion of 444;
 Cetraria, tree, treated, 632; Citron
 gingered, 444; Coffee diseases, 313,
 377, 444; Crocuses, 85, 210, 313; Cu-
 perianthus Lawsoniana, hermaphrodite
 flowers, 635; Cycad cones, 377;
 Cyclopes, monstrous, 85; Damara
 Rostrata, 206; Daphne Laureola, 85;
 Diostopya Kaki, 85; Doryanthes ex-
 celso, 377; Embria, 85, 210; Encaphal-
 thos villosus, male spike of, 85;
 Erygia, 85; Erythraea, 413; Erythraea gra-
 minis, 634; Eucharis candida of
 gardens, 414; forage, Prickly Pear as,
 210; Eucharis and other bulbous
 plants in flower, 506; Gladiolus dis-
 ease, 414; Hepiathus humilis, 377;
 Homolomena petolata, 210; insects,
 Australia, 85; Japanese books,
 377; Lachenalia, Ck., 377; Larch dis-
 ease, 730; Lillium Thomsoni, 414;
 Males, removal of the male flowers of,
 414; Mentha, 377; Mentha, 730;
 Medlar leaves, diseased, 634; Muscari,
 species of, 377; Mushroom, new variety
 377; 85; 377; 85; 377; 85; 377; 85;
 N. rupeola, 414; Narcissus flies, 730;
 Oak from Fume, 210; Onion snail,
 444, 634; Osiers, diseased, 85; Phylo-
 dactylus, 634; Pinus, exultation from
 the leaves of, 377; plants exhibited, 729;
 Poinciana pulcherrima, 714; pollen,
 action of, on seed, 313; pupa from
 brain, 424; Psoqueira formosa, 794;
 Quercus humilis, 210; Prunus car-
 patica, 313; proceedings of the com-
 mittee, 377; Prunus, monstrous,
 635; Rhododendrons, 506; Rhodod-
 dendron leaves, damaged, 506; sap,
 course of the, 85; scion, 377;
 Sida, 634; 731; seed, action of pollen,
 on, 210; Silene, hybrid, 377; Smea,
 the late Mr. A., 85; Stromboscarus
 rubescens, 414; Trichocera, regent, 85;
 Vine leaves, diseased, 505; Viciae,
 malformed, 634; Wheat, Mummy, 313
- Common lands, enclosure of, 278**
Composts for plants, 185
Concert at Melchet, a, 593
Conifer, discovery of a new, in Europe,
 479
Conifers, on the growth of, in spring, 700
Cordia candida, 752
Crocus, 85
Crocus, winter Broccoli in, 51
Cornilla glauca, 240
Corsican Crocus, 286
Costa Rica, agriculture and gardening in,
 410, 404
Cotoneaster vulgaris, 81
Cottages, on decorating the incornet
gardens of, 278
Cotton, a new variety of, 561, 790; im-
ports of, 20
Courgette, the sap, the, 138
Course of the soap, on the, 181
Covers, game, on planting, 175
Cox's Orange Pippin Apple, 705
Cran, the wooden, 413
Cramb, Mr. A., death of, 604
Crossing Oak, the, 812
Cross, Mustard and, as grown for
market, 24
Crimm aquaticum, 471
Critchley's heat regulator, 468
Crocus and Frigularia, the Algerian
species of, 45
Crocus, Corsican, 246
Crops, how to preserve from rats, 408
Crops, rotation of, and profitable garden-
ing, 476
Croton camptophyllus, 367; C. Earl of
Derby, 367; C. Calcutta, 367; C.
fasciatus, 367; C. Morrif, 210; C.
paradoxus, 367; C. MacArthurii, 377
Croweas, on the culture of, 553
Cucumbers, disease and "Salus," 555, 567,
 792, 818
Cucumber disease, 600; stamped out,
 632, 792
Cultivo, steam, in the garden, 396
Cunningham, Mr. D. W., death of, 539
Curneria Wallisi, 108, 214
Cyananthus labialis, 752
Cyathus, Australian, 413
Cyca media latissima, 210
Cyclamen, a double, 340
Cyclamen, culture, 476
Cyclamen, essay on the, with coloured
plate, Supplement, June 9
Cyclamen growers, bad news for, 470
Cyclamen, the, in C. periculum
compactum magnificum, 210; C. per-
ciculum var. Brillant, 412; C. persicum
var. Euseb, 377
Cydonia japonica flore-alba, 210
Cyperus esculentus, experiments with, 375
Cyprinoides Boxalli, 567; C. Druryi,
 729; C. eurypterus, 729; C. periculum
 naidianum, 207, 728; C. occidentale,
 727; stable, 791
Cyprinoides, hairy, on the culture of,
 604
Cyrtium giganteum Lowianum, 685
- D**
DAHLIAS, new, of 1876, 53; bedding,
 785
Dahlias, propagating, 278; on sending
 out, 530
Daisies, double, 473
- Dale Park, the rainfall at, 116**
Dale testimonial, the, 601
Darlington, California, 761
Darwin, Mr., presentation of a testimonial
to, 241 (see Fertilisation)
Davidsonia, the, 493, 567
Davidsonia prietii, 493
Decorative plants: hardy Ferns, 503
Deformity in Brassica Napus, recalcitrant,
 503
Deinostedia davallides Youngii, 313, 377
Dendrobium Ainsworthii, 754; D. arach-
noctylichum, 330; D. crassinode, 281;
D. distichum, 313; D. forbesianum, 313; D.

NEW SEED CATALOGUE For SPRING, 1877.

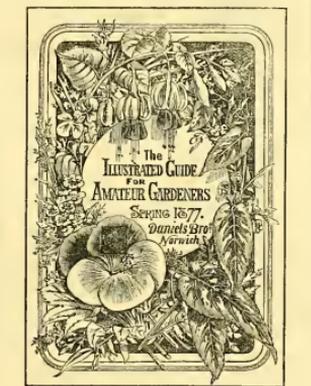

All intending Purchasers of choice Kitchen Garden or Flower Seeds should send for a copy of the Illustrated Guide for Amateur Gardeners, which will be found the most complete, useful, and beautiful Seed Catalogue ever published.

Price 1s., Post-free. Gratis to Customers or intending Purchasers.

The Illustrated Guide for Amateur Gardeners, Spring, 1877.

Contains 112 pages of beautifully illustrated Letters, with two superbly finished Coloured Plates, Original Articles on the Rearing and Cultivation of various Garden Crops and Flowers, and complete Instructions for the successful Management of the Kitchen and Flower Gardens throughout the year, together with a Select List of choice Kitchen Garden and Flower Seeds, Seed Potatos, &c.

The most practical and comprehensive Guide for the Amateur yet issued, and should be read by every one having a garden.

OPINIONS FROM THE PRESS.

"The inside is quite in character with the beauty of the exterior, and we do not know of a more useful or important garden guide to lie on the drawing-room table."—Vita Gardener. "This is the most careful and best executed thing of the kind that we ever remember having seen, and would be an ornament to any room."—The Country. "This superbly illuminated and handsomely illustrated annual is something more than a mere catalogue of seeds and plants, inasmuch as it contains the most copious and carefully written instructions for horticulture. The Guide is quite a work of art as well as a compendium of garden work."—Norfolk News. "The calendar for the kitchen garden will be found most useful. The hints for the rotation of crops are at once comprehensive and practical."—Land and Water. "The most chaste and beautiful catalogue we have ever seen."—Lloyd's London News. "The flower garden calendar, written expressly for this publication, will be especially useful for all lovers of flowers."—The Record. "Profusely illustrated, and the coloured plates which verify the average of book illustrations."—Liverpool Mercury.

DANIELS BROS., The Royal Norfolk Seed Establishment, NORWICH.

MR. WILLIAM BULL has just received an importation from California several thousands of the best kinds of **LILIES** indigenous to that country, and can supply them by the dozen, hundred or thousand. The Californian Lilies being perfectly hardy, are beautiful objects when planted or grouped in beds, borders or shrubberies; they are also extremely handsome when grown in pots for decorating the greenhouse or conservatory.

Establishment for New and Rare Plants, King's Road, Chelsea, London, S.W.

LILIUUM AURATUM.—Fine Bulbs of this "Queen of Lilies" can now be supplied at 6d., 1s., 1s. 6d., 2s., and 3s. each; and English Bulbs, at 1s., 1s. 6d., 2s., and 3s. each. Sample of two bulbs, postage 6d. extra; more cannot be sent by post. Good selection of Lilies 1s., 2s., and 3s. per dozen. Price List on application. Post-office orders payable at Finchbury Street, E.C.
WILM. GORDON, Lily, Bulb, and Plant Importer, 10, Cullum Street, E.C.

BEGONIA FREBELI.

First-class Certificate, Royal Hort. Society, August 4, 1875.
Silver Medal, Lyons, September 11, 1875.
Gold Medal, International Exhibition, Cologne, August, 1875, as the best new flowering plant.

This is undoubtedly the finest novelty in Bulbs offered to date seasons, and a discovery of Mr. H. Roetz, when travelling through the Pyrenean Mountains. As a being between 800 and 10,000 feet he came upon a patch in full bloom, the effects of which he has since described as being actually dazzling, and the grandest display he had ever witnessed. The individual flowers of this plant measure over 2 inches across, are produced in great masses, and are of a more intense and brighter vivid scarlet than the well-known German "Jean Saisie".
The bulb may be potted in the same manner as a Hyacinth, or as any ordinary autumn bulb, started steadily into growth, they will produce a brilliant display in the conservatory. We believe the plant to be hardy, or nearly so, and when planted out it will flourish and bloom during the summer out-of-doors. To the great beauty of the flowers is added the attraction of a very fine and noble foliage. See also description in *Gardener's Chronicle*, October 31, p. 530.
We have imported extraordinary large native bulbs of this magnificent novelty, which are in finest possible condition, and which will produce an abundance of flowers. Price, each per dozen, will be given by every Seedsmen and Nurseryman. Wholesale prices of Messrs. Hurst & Son, 5, Leadenhall Street, E.C.; and of F. SANDER AND CO., SEED GROWERS, ST. ALBANS.

AVENUE TREES.

PLATANUS OCCIDENTALIS (true), 10 to 12 feet high, and girthing 4 to 8 inches at 4 feet from the ground.
LIMES, 12 to 20 feet high, and girthing 6 to 10 inches at 4 feet from the ground.
POPULUS CANADENSIS NOVA, 15 to 16 feet high, and girthing 6 inches at 4 feet from the ground.

ANTHONY WATERER

Has to offer many thousands of the above. They may be seen growing at Knap Hill. They are straight, handsome, and well rooted, and altogether the finest Trees of the kind to be found in any nursery in Europe.

KNAP HILL NURSERY, WOKING, SURREY.

RICHARD SMITH'S FRUIT LIST

OSBORN & SONS

BEG TO ANNOUNCE THAT THEIR

ANNUAL CATALOGUE OF KITCHEN GARDEN AND FLOWER SEEDS

Is now ready, and will be forwarded post-free to all applicants.

It contains a choice selection of "NOVELTIES" and of the "BEST" and most approved kinds of VEGETABLE and FLOWER SEEDS, including among

VEGETABLE SEEDS—Osborn's Forcing French Bean, which has been proved one of the best and most prolific; Osborn's Select Red Beet (or Dell's Crimson), Osborn's Winter White Broccoli; and among

FLOWER SEEDS—*Pyrethrum aureum laciniatum*, a very distinct and beautifully cut-leaved form of the deservedly popular "Golden Feather." Like its prototype it is perfectly hardy, but of dwarfer habit and more spreading, and is admirably adapted for bedding. It obtained a First-class Certificate at the Meeting of the Royal Horticultural Society, May 3, 1876; and also a First-class Certificate at the Grand Exhibition held at the Westminster Royal Aquarium, May 16 and 17, 1876.

WORDSLEY, STOURBRIDGE.

ODONTOGLOSSUMS.

MR. J. C. STEVENS will SELL by AUCTION, at his Great Rooms, 38, King Street, Covent Garden, W.C., on THURSDAY, January 11, a large importation of the beautiful ODONTOGLOSSUM PESCATOREI, O. TRIUMPHANS, O. HASTILABIUM, O. PHALÆNOPSIS, O. CORONARIUM, just received, ex *Vile*, from the United States of Colombia, in good condition. Collector says the varieties found of O. coronarium are of the most magnificent description, the inflorescence itself, which is very dense, being about 1½ foot high by 9 inches broad, and the flowers individually very large and attractive.

At the same time will be sold some good plants of the handsome O. VEXILLARIUM, O. CIRRHOSUM; several good plants, just breaking into growth, of the new and beautiful SOBRALIA VIRGINALIS; good plants of ODONTOGLOSSUM CRISPUM (ALEX-ANDRÆ), various DENDROBIUMS, and a few choice ESTABLISHED ORCHIDS, including the new white-flowering VANDA UNDULATA, the sweet-scented DENDROBIUMS AMENUM and BARBATULUM, PHALÆNOPSIS SCHILLERIANA, &c.

AUCTION ROOMS AND OFFICES, 38, KING STREET, COVENT GARDEN,
LONDON, W.C.

SPLENDID NEW MELON, 1877.

CHARLES LEE & SON

(Successors to Messrs. J. & C. LEE)

Have the pleasure to announce that they have purchased
the entire Stock of

MANN'S HYBRID GREEN-FLESH MELON,

Which they now offer for the first time.

It has already earned a high reputation in London and the provinces for its many excellent qualities, among which may be mentioned a remarkably high and exquisite flavour at all seasons of the year—perfection of shape and size for dessert—a thin rind and melting flesh, with an overflow of perfumed juice. It is also a heavy cropper, and forces well.

Dr. HOGG has spoken of this excellent Melon in the highest terms, and after tasting it pronounced it a fruit of the highest merit.

Mr. CULVERWELL, of Thorpe Perrow, fellow judge with Mr. FOWLER, of Harewood House, at the Leeds Horticultural Show, where they awarded a First-class Certificate to "Mann's Hybrid Green-flesh Melon," speaks of it as "an exceedingly fine Melon, especially at that early season—the early part of June."

Mr. INGRAM, of Belvoir Castle, writes, in the third week of October, "that in spite of the disadvantage of a long term of gloomy weather, at that season of the year, 'Mann's Hybrid Green-flesh Melon' was sweet, tender in flesh, very juicy, and distinct in character."

Messrs. Charles Lee & Son are now prepared to offer this very useful and delicious new Melon
In Sealed Packets, at 8s. 6d. per Packet.

CHARLES LEE AND SON, HAMMERSMITH, W.

SEEDS OF SUPERIOR QUALITY.

SATURDAY, JANUARY 6, 1877.

TRAINING AND TYING PLANTS.

AS the season when the annual process of retying hard-wooded plants in particular has arrived, it may not be out of place to say a few words on the subject. The very different manner in which pot plants generally, and more especially those of a hard-wooded nature, are now grown from what they were before taken in hand by the exhibiting growers, has necessarily made this work considerably different from what it once was. There are many who will recollect that these subjects were usually seen cramped for years in undersized pots, spring upwards, with a few gaunt branches and bare stems, with perhaps a single stick to support each starveling, which generally exhibited so little in common with its natural form and habit of growth as to be somewhat difficult of recognition. This, be it remembered, was the case with a class of plants which when in a state of Nature mostly assume a low-spreading, bushy habit. This form is so changed by the influence of under-glass cultivation in even the best constructed light-affording houses we can give them, that unless counterbalanced by timely stopping the leading shoots, so as to direct and distribute the sap into the lower lateral branches, a straggling, objectionable growth is the result. When, however, by judicious treatment, a plant is so grown as to consist of a large number of branches, generally of slender character, it naturally follows that these require some support, hence the necessity for sticks and ties; but in the use of these it should ever be borne in mind that they belong to the category of things that are generally designated as necessary evils.

Sticks should never be used in greater numbers than are absolutely necessary to keep the branches sufficiently open to admit the requisite light to the inner portion of the plant, to support it in the shape most conducive to maintain it in a healthy, well-clothed condition of foliage, and to display the flowers to the best advantage. There is one other and very important consideration, that must be taken into account in determining the more or less support that a plant requires; that is, the particular purposes it will be wanted for. Plants that are only intended for home decoration, and have not to be moved about further than from one house to another, need a comparatively small number of sticks, and still fewer ties, than such as, in addition to doing duty at home, have to be conveyed a considerable distance to exhibitions. Such plants as Azaleas, the branches of which are naturally stout enough to support themselves in the desired position, after they have been trained to the desired form and have acquired strength and substance, need very few sticks when only wanted for home use. Eriostemons, again, are comparatively stout-wooded plants, and do not need so much tying as many things; neither do Darwinias (Hedatomas), although each of the strongest shoots will want a stick: the smaller lateral growths do not require securing. Of Epacris, also, the flowering wood looks better when not too stiffly tied; Acrophyllum venosum is another stout-wooded subject, that when not to be moved about much wants no more tying than may be sufficient to preserve the

outline reasonably; the same may be said of *Adenarras*, *Cassia corymbosa*, *Correas*, *Crowcas*, *Diosmas*, *Hoveas*, *Desfontainea spinosa*, *Dillwynia*, *Boronia*, *Plama* indica, *Witsenia corymbosa*, *Statice*, *Melroca* clegans, *Pimeles*, *Pharomomas*, *Mitiraria coccinea*, and the strong-wooded *Heaths*, such as *Cavendishii*, *depressa*, and the *vestitas*, or any others of similar growth, which only need as many sticks and ties as will hold them in position, and keep them furnished with leaf-clad shoots down to the pot. Naturally weak-wooded plants, such as *Droacophyllum gracile*, *Chorozemas*, *Aphelexis*, *Leschenaultia*, *Roella ciliata*, *Swinsonas*, and *Tetrathecas*, must have more support, merely to keep them from hanging about in an untidy manner. There are also very many *Heaths* so weak-wooded that if a considerable number of sticks be not used they cannot be kept in shape at all, even if never moved off the stage of the house in which they are grown.

In the case of plants for exhibition we sometimes see the quantity of sticks used for training carried to such an excess beyond what is really necessary as to make the plants hideous to look upon; and to stamp those who thus torture them as totally devoid of the slightest notion of artistic taste, however capable they may be of so treating their plants as to preserve them in a healthy condition. This over-training is most objectionable when it extends so far as tying flat down the points of the flowering shoots in a horizontal position all over the surface of the plant. The operator may think he secures his aim in displaying the quantity of flower most conspicuously, but it simply makes what otherwise might be a meritorious specimen look wretchedly bad. But although tying should never be carried to such an extent as this, still with plants that have to be subjected to the shaking unavoidable in conveying them to an exhibition in the best constructed vehicle, it is absolutely necessary that as many sticks and ties should be used as will keep every shoot in its proper place, and the whole of the flowers from chafing. Otherwise, even plants with hard flowers, such, for instance, as the *Cavendish Heath*, will be so injured as to turn them black, and with the far greater number of things literally grind them away, and this when only a few miles have to be traversed. It will be needless to say that the evil is much aggravated when long distances have to be gone over. If any one who has not had experience in this matter has any doubts about it, and will just try the experiment of moving a loosely tied plant only a few miles, he will get enlightened on the subject.

Many a gardener has had his exhibiting career cut short through his plants coming home disfigured for want of being sufficiently tied. We have frequently known gentlemen anxious to support horticulture, and also encourage their gardeners, and equally desirous of giving the public an opportunity of seeing fine plants, yet they were so disgusted at the condition in which their plants returned from the shows that they put a stop to exhibiting altogether. The amount of tying indispensable to the safe carriage of flowering plants is much greater than those who have not tried it are aware of; the shoots must of necessity be secured in a way that deprives the plants to a considerable extent of the loose elegance that can be allowed them when they have not to be moved further than necessary for home use. This is what some of those who give us their views upon plant tying, and condemn the work of exhibitors, never appear to be able to comprehend. We are from time to time favoured with the ideas of those who generally indulge in a sweeping tirade against the bad taste displayed by exhibitors in the way they tie their plants. If these would-be critics do not succeed in con-

vincing those they essay to enlighten and who have had ample opportunity of judging in the matter, they at all events manage not only to display a total absence of practical knowledge of the subject they treat upon, but also show their want of ordinary perception in not being able to discriminate betwixt the training necessary to give the plants required for home use, apart from such as have to go through the severe jolting unavoidable from their being moved even a moderate distance.

But, although this operation needs to be so far varied for the different purposes plants are required to fulfil, when they have arrived at a considerable size, yet in the early stages of their existence the training they need is identical. Unless the branches, especially the strongest, are well and regularly tied out in a horizontal position low down from a little above the collar, the foundation for the future specimen can never be satisfactory, inasmuch as the plant will, whilst in a comparatively young state, get bare at the base; but when from the commencement the branches are properly placed so as to distribute them equally in the desired positions, the after-treatment in tying is simple, and should be carried out just so far, and no farther, than the particular purpose the plants are wanted for demands. The support that pot plants in this way require is simply a necessity resulting from the highly artificial conditions we force them to endure; and the more we can conceal the hand of art thus inseparable from their existence, the greater measure of success we attain.

A SPRING TOUR IN ITALY.

THE summer and winter climate and vegetation of the plain of Lombardy present greater contrasts than do our English seasons. A descent from the Alps at midsummer brings you at once into the midst of tall Maizes, fields of ripening Rice, and hedge-way rows of *Mulberries* in luxuriant leafage intertwined with *Vines* which have nearly completed their season's growth.

From the refrigerating influence in winter of the snow-covered Alps forming its northern boundary, little or no difference can be observed up to the middle of March between the spring vegetation of the northern Lombardy plain and that of England, and late frosts even in May occasionally do serious damage. On February 26 heaps of snow were lying in the garden of the grand Hôtel de Turin; the plain of Lombardy was seared and soddened by the winter scarcely over, and *Galanthus nivalis* in the hedgerows and *Eranthis hyemalis* in the fields were the only indications of coming spring.

A night journey from Venice brought me at day-break on February 27 to the head of the Adriatic, with the calm land-locked Gulf of Monfalcone far below the level of the railway to the right, and to the left long parallel ridges of oolitic and cretaceous limestone full of little lakes and waterlogged hollows trend away to the south-east as an irregular stony tableland, the home of a rich and special flora.

This configuration holds good for nearly 300 miles down the east coast of the Adriatic, and has determined the outline of the archipelago of parallel islands off the Dalmatian coast. The isolated hollows or complete rock basins seen on the east side of the railway are not unfrequently in calcareous rocks, and are the result of the gradual dissolution of the limestone through swallow-holes or underground channels, of which the neighbouring cave of Adelsberg is a gigantic example. I am informed by Herr Max Leitch that it is in similar hollows that *Lilium dalmanicum* occurs in the neighbourhood of Cattaro, farther south. Monfalcone is interesting to the botanist in being one of the most western habitats of the beautiful *Crocus reticulatus*.

From the flat alluvial plain at the head of the Adriatic the railway gradually ascends the coast Monfalcone to the Nabresina junction, where the line to Trieste branches off. The approach from this point to Trieste is most striking; the line winds down the western face of the escarpment, the vegetation of which is notably different from that of the barren summit. *Salvia humilis* is a most abundant indigenous plant, and several

species of *Euphorbia* clothe the rocks. The steep bank between the railway and the edge of the gulf is densely clothed with plantations of Olive, of unusual vigour and size. Trieste, with its forest of masts, is seen for miles before we reach it, far below us. We pass above the marine villa of the unfortunate Emperor Maximilian, and look down hundreds of feet into the Adriatic waters, now quiet and smooth as glass, in the early morning dotted over with fishing boats, and fringed with spiral *salix* nets spread out from the shore, and nearly land-locked by the grey outline of the Italian and Italian coast to the west and south. We quickly descend down the escarpment, through tunnels and across viaducts, into the bay port, full of life and dirt, the great maritime outlet of the Austrian empire, through which over twenty millions of import and exports pass during the year.

TRIESTE.

The city stretches up from the water's edge to the foot of the great oolitic escarpment, here about 1000 feet high, flanked by neocomian beds, mostly consisting of dark grey marls, which lie at a high inclination against the upturned edge of the oolitic rocks, forming the limestone plateau known as the Carso.

Chevalier Tommassini, the Governor of Trieste, has formed an interesting little botanical garden on one of the hills overlooking the city. It contains representatives of the local flora and the plants of Istria and Dalmatia. Very few species were yet in flower, but patches of a nearly large *Galanthus*, from the neighbourhood of Pirano, in Istria, formed striking features. The entire plant is quite twice the size of *Galanthus nivalis*, with long perianth segments, and may possibly prove to be distinct. There were also in the garden some of the local *Crocus*, including some brightly coloured varieties of *Crocus Weldenii* just expanding.

On Monday, Feb. 28, M. Tommassini kindly accompanied me on a botanical excursion over the Carso plateau to the east of Trieste, rich in rare plants though few species were yet in flower. It consists for the most part of a great treeless wilderness of limestone, with escarpments facing west and dipping to the east. One of the highest points is known as Mont Spaccato, and on the eastern slopes there are here and there low woods, principally of Oak, the most extensive of which is the Lipizza Forest, but the greater part of the Carso is devoid of arboreal vegetation, except near the villages, where M. Tommassini has established plantations of *Pinus austriaca*, thriving well on the limestone, though not indigenous.

Among the plants of the Carso may be enumerated: *Foenicia peregrina*, *Lilium carniolicum*, *Heliolepis viridis*, *Gagea pusilla*, *Potentilla subcaulis*, and *Fritillaria montana*. The association of the two latter plants is interesting, as they occur in similar association on the Plateau des Rochers above Grassano, 400 miles to the west, though I believe neither species occurs within 300 miles in the intermediate district.

The Carso forms a western starting-point for many species, but it affords a wide eastern distribution. It is the most western habitat of *Crocus reticulatus* (*C. variegatus* of Hoppe and Hornsch), which extends to Podolia, Asia Minor, and the Caucasus. It occurs in profusion in the Lipizza Forest, on Mount Spaccato, and near the villages of Opsina and Prosecco, varying with lilac and white flowers, externally striped. The corn-coats are densely enveloped with wire-like reticulated fibres. Deen Herbert erroneously associated it with the Crimean Cloth of Gold *Crocus* as varieties of the same species, but the two differ materially, not only in the colour of the flowers, but in the character of the corn-coats and the form of the limb, which is much narrower and more acute in *reticulatus* than *susianus*. Opsina is also the habitat of the beautiful diminutive *Crocus albiflorus* of Gay—a miniature form of *Crocus vernus*.

Prosecco, further to the north, is the most western habitat of *Crocus Weldenii*, which extends south-east for several hundred miles down the Dalmatian coast. It has been associated with *C. biflorus* as a variety, but as it resembles the typical form of *biflorus* only in its having somewhat corn-coats, its title to specific rank seems to me very strong. The form of the limb is almost rhombic; the prevailing colour white, but examples occasionally occur beautifully flushed with brilliant lilac and purple. A small form of *Galanthus nivalis* occurs abundantly on the Carso, and *Cyclamen europaeum* in the Lipizza Forest.

On Feb. 29 I made a short excursion by steamer

to Pirano and Stromana in Istria, passing large flocks of wild swans resting on the water. Sturgeon are here most abundant, and we had on board a large cargo of huge spider-like crabs, with legs spanning nearly a yard, which seem to be the prevailing crustaceans of the Adriatic. A walk from Pirano to Stromana afforded nothing of particular interest except the large form of *Galanthus nivalis* observed in M. Tommasini's garden, and *Primula vulgaris* with white flowers. On the evening of the same day

taken from an old drawing by Gerolamo Porro, made in 1501, and preserved in the lecture gallery at Padua—for a copy of which I am indebted to Professor Visiani—represents the original plan of the garden then limited to the circular space. The little geometrical compartments or flower-beds are fenced off by neat stone partitions environing spaces from 2 to 3 feet across, each apparently intended for a single species. The arrangement of the masonry has since been somewhat altered, and made more simple; a conservatory now

Goëthe's reference to the plant is inscribed over the building:—

Giovanni Wolfgang Goethe
Poeta e Naturalista
Di qua trasse nel 1802
Il concetto e le prove
Della sua *Metamorfosi delle Piante*.
Roberto de Visiani
Perche non mancasse a' posteri
La Palma che lo ispirò
Ni ripirava nel 1802.
La vetustà gloriosa.

Many other trees in the garden betray great age,

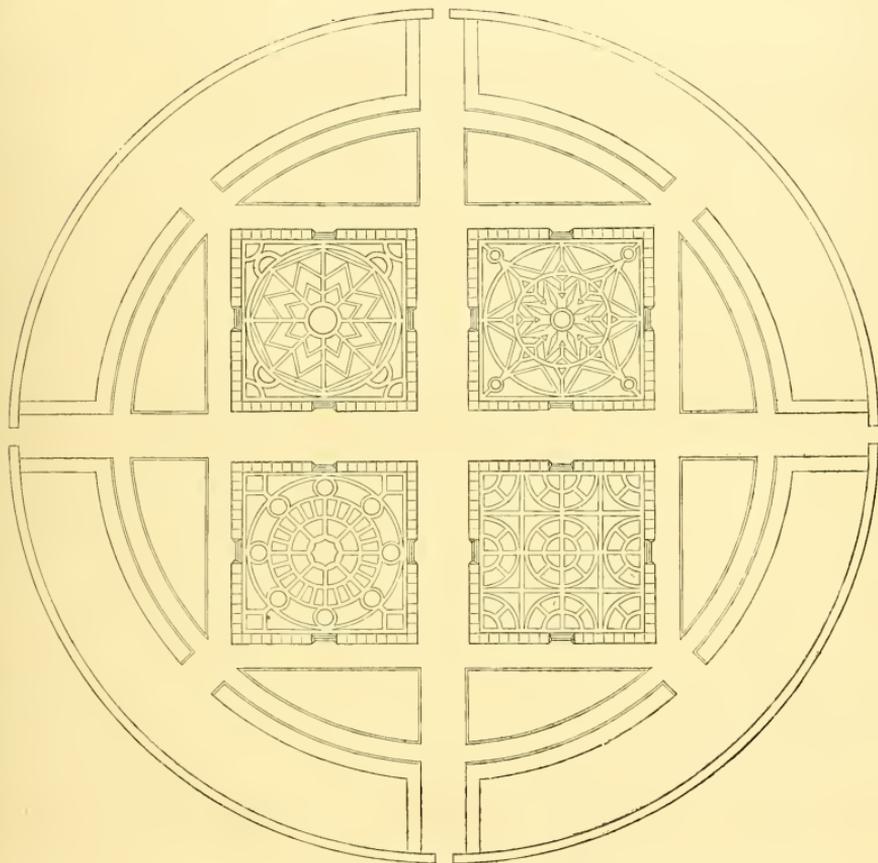

FIG. 1.—ORIGINAL PLAN OF THE BOTANIC GARDEN AT PADUA.

I left Trieste by steamer for Venice, arriving at Padua at 10.30 on the following morning.

PADUA.

A walk of about a mile from the station through the picturesque arcaded streets brings you to the great church of Saint' Antonio, towering over the portals of the little botanical garden (see previous illustration, p. 685, vol. vi.), so interesting to the horticulturists as being the oldest botanical garden in Europe, and as recording the mediæval sentiment of associating stone masonry and gardening, which are here mixed up in a charming manner. The accompanying engraving (fig. 1),

encircles the northern half of the old garden, and the extensions outside the original circle must, judging from the age of the trees, have been made within a few years of the founding of the garden, under the direction of Cisalpino, in 1500.

The garden contains several plants of historic interest—grand specimens of *Bignonia radicans* and *Chamaecyparis humilis*, referred to by Goëthe in the supplement to his essay on *Metamorphoses*, which indicates that he was less of a naturalist than a poet. The Palm is 8½ metres in height, branched into seventeen growing points, and is yet in full vigour, protected by a small conservatory. The following record of

amongst them a huge stump of *Platanus orientalis*, 24 feet in circumference, bearing a little leafage. The dying embers of a life of 180 years, a grand old specimen of *Celtis australis*, is in a similar condition; indeed, the whole place, so interesting in its antiquarian associations, is saddened by an aspect of decay aggravated by present neglect. The untutored tangled growth of a wild garden has its charms, but where the features of the garden are ordered by rigid architectural precision, the utmost neatness of detail is essential to a satisfactory result. Nothing can be more charming than the laying-out of the little circular "garden of simples" at Padua, each prettily formed

compartment intended for a special occupant, and the space grouped pleasantly to the eye, but its disorder as a garden, and the weedy paths and empty spaces, where symmetry and order are essential to the original scheme, is most depressing.

It was also disappointed with the culture in the glass-houses, and the same remark is applicable to every garden I visited in Italy; indeed, the Italians are far behind northern Europe in greenhouse gardening: this is partly due to the bad structure of the houses. Few of them have top lights, and many have glass but on one side; the occupiers under such circumstances are inevitably lanky and drawn up, and bear the aspect of having spent their lives in trying to look out of the front window. One notable exception is the magnificent specimen of *Araucaria excelsa*, which has a pagoda-like structure to itself. It was planted in 1840, and has attained a height of between 50 and 60 feet, symmetrically branched down to the very base. Out-of-doors, even in the south of Italy, the Norfolk Island Pine does not seem to thrive; none of the specimens I saw will compare with those in the Portuguese gardens. Their growth is evidently slower than in Portugal, and when attaining any size they get a rigid unsymmetrical aspect. *Araucaria imbricata* does not seem to flourish, and good symmetrical specimens are seldom seen in Italian gardens.

Of the trees in the garden, *Cupressus pyramidalis* forms striking features within the original circular space, and there are also fine examples of *Cupressus funebris*, *Abies cephalonica*, *A. excelsa*, *Pinus Laricio*, *F. Strobus*, *Taxodium distichum*, *Cedrus Deodara*, with straight undrooping branches, resembling in habit the Cedar of Lebanon; also *Magnolia grandiflora*, *Diospyros virginica*, *Juglans oliviformis* and *J. nigra*, *Cornus glabra*, *Quercus Ilex*, *Q. pedunculata* and *Q. laevis*, 16 feet high. Their orientals is used for framing high fences for shade, and bears close training into wall-like masses. A singular result has been produced by grafting *Tilia argentea* on *Tilia europaea* at about 4 feet from the ground; the trunk of the graft, 2½ feet in diameter, having outgrown the stock of *T. europaea*, which is barely half a yard across, producing a most singular top-heavy appearance.

The little arbutum outside the circular garden contains for us a good collection of trees, but the specimens are long past their prime, and suffering prematurely from want of space; and the dense contiguity of the older trees would render renewal by planting almost impossible without first cutting down the greater part of the original collection. This is a point which seems to have been lost sight of in the planting of almost all the earlier botanical gardens.

From Padua I proceeded *via* Bologna and across the Apennines to Florence, which I reached the same evening, and in my next I purpose sending you a few notes on Florentine gardens. *Geo. Mors.*, R.L.S.

THE BULB SEASON OF 1876.

THE bulb season of 1876 can hardly be considered quite so satisfactory as several of its immediate predecessors. For several years past this branch of trade has been rapidly extending, and notwithstanding the large quantities annually sold to cheap buyers at the various auctions, legitimate traders have had no reason to complain. The choicest and most expensive varieties must always be procured from respectable dealers, while the auctions, by making these articles more widely known, increase the demand for the popular and cheaper sorts.

There are several reasons why there has been a somewhat diminished demand this season, but the principal reason will be found in the general stagnation of trade, and the disquieting war rumours which from time to time have filled all the lucky (?) bondholders with gloomy apprehensions lest some very interesting coupons should be conspicuous by their absence, or at the best appear considerably reduced in value. This was especially the case during the months of August and September, when the first importations of bulbs usually arrive, and the trade is generally brisk. The regular orders meet their usual appearance, but in a somewhat modified form, while the elasticity of trade has been altogether wanting.

Glancing briefly at the principal items, we begin as usual with the Hyacinths. The demand for the choicest varieties has been very limited indeed. The cheaper and better-known named sorts have had a fairly good sale, while the bedding kinds sold very

slowly until the beginning of the present month, when a slight revival in trade became apparent, and most dealers have now cleared out.

Tulips, next in importance, have shared a somewhat similar fate. High-priced sorts have been almost ignored, but the cheaper kinds have sold fairly well. An exception to the general depression is to be found in the demand for the late border section of this handsome order of bulbous plants. For some years past these have been gradually increasing in popular favour, and this year is no exception to the rule.

It would be well if an effort were made to obtain a dwarf habit in these magnificent flowers, seeing that the long fleshy stem on which the flower is borne is liable to be snapped by the first gust of wind, unless a covering (which is generally unsightly) has been provided. Mr. Gridon and his enthusiastic coadjutors in Lancashire might take this matter up, and by this means render a service to the whole of the horticultural world, and enhance the interest in these beautiful flowers.

Narcissi have again become a drug. The somewhat unaccountable increase in the sale of these last year has been fully compensated for by the diminished sale this. The disease afflicting them may have had something to do with it, as it is not very encouraging after paying a long price for a bulb to find it rotten when it should have been gay with bloom.

Crocuses generally have sold very well. It seemed at one time that they would be left on hand, but the contrary has been the case, and it is questionable if such a complete clearance has been effected during the past twenty years. The prices of Crocus have been very moderate, and this may be one reason why they have so readily been sold.

Snowdrops, having for several years steadily increased in price, have at last, like the camel's back, succumbed to the last straw, and the advertisement columns of the *Gardener's Chronicle* best tells the tale of a large surplus as a necessary consequence. Reckless speculators are alone to blame for the mischief which, unfortunately, falls on other shoulders besides their own.

Anemones and Ranunculuses are steadily increasing in popular favour, and have sold very well. The new French varieties of the former are a vast improvement, both in colour and size of bloom, on the Dutch-grown roots hitherto offered.

Amongst miscellaneous flower roots those principally used for early forcing occupy a prominent place. The leading articles are Roman Hyacinths, Narcissus totus albus, *Ilotia japonica*, and Lily of the Valley. The demand for all these increases every year, and does not seem to be liable to the same fluctuations as other branches of the trade.

It is worthy of note that all these produce white flowers, and it is further noteworthy that the white varieties of Hyacinths, Tulips, &c., have been more in demand than any other colours. Why this has happened it is not very easy to define, but the fact doubtless has some significance.

The quality of the bulbs has been generally very sound and good. The hot, dry weather in June and July thoroughly ripened them, and, as far as this is a reliable guide, the results cannot fail to be of a very satisfactory character.

On the whole things might have been worse. A little rest is needful for all things; the check in trade is only of a temporary nature, and should the difficulty not arise from the expansion of civilising and elevating commerce be removed, the love of the truly beautiful, which is fast permeating society in all its classes, will manifest itself with redoubled vigour, and claim larger supplies of these by no means insignificant adjuncts to its full development. *S. E. D.*

WHICH ARE THE BEST LATE GRAPES?

As you invite the opinions of correspondents on the above question I have sent you a few examples of the varieties I consider the best as grown here. The bunches I intend sending you of them are only small, to economise space, but you will be able to judge of the flavour of the berries all the same.

As to the different varieties of the Muscat of Alexandria, there is no doubt but that they are the best-flavoured white Grapes grown; but they can hardly be termed very late Grapes, for it is only in exceptional cases that they keep till the end of January without shrivelling too much.

To commence with the very late Grapes: Lady Downe's, of the black section, is the latest keeping sort grown, but its hard flesh is not relished by some, especially invalids. I have kept it, however, in some seasons, in bottles of water until the middle of June, and in good condition.

I send a bunch of a seedling black Grape raised from a cross between Lady Downe's and West's St. Peter's, and which has the quality of keeping till April good success. It is distinct from any other variety which I know, by the purplish colour of the young wood and midribs of the foliage, and bears bunches something like those of Lady Downe's in having a shoulder nearly as large as the bunch itself. In flavour it resembles West's St. Peter's, but its berries are larger and oval-shaped; they are not however now so well coloured as last year.

West's St. Peter's is still one of the very best late Grapes grown for its delicious vinous flavour, and although not a show Grape, no collection should be without it.

Barchard's Prince is with me an excellent late keeping variety, and in flavour something like those of the St. Peter's section.

The Black Alicante, although one of the finest late show Grapes grown for its fine compact clusters, large berries, and fine jet colour, is yet, as grown by me, never of the flavour of the above-mentioned sorts. It likewise, when it begins to shrivel, seems to lose its sweetness, and gets watery and insipid.

Gros Guillaume, when well ripened, is an excellent keeping Grape, especially if the bunches are not too large, and it is not to be despised for its flavour when kept very late in a dry and equable temperature.

In addition to the late varieties of black Grapes I have sent a small bunch of the Mill Hill Hamburg, a variety of good colour, long with me, and any other of that section, being firm in the flesh, the Hamburgs in general are not very late keepers.

Of the section of the latest keeping white Grapes the Royal Vineyard with me keeps quite plump and good till the end of April. This variety has been discarded by many growers for its hard flesh and flavour, but when well ripened it will be found in March and April very useful both for flavour and variety in the dessert dishes.

Trieblich, which is the best late-keeping white Grapes known, a very vigorous grower, and produces enormous bunches when grown well. I believe some forty years ago I first introduced this variety into general cultivation, having got it from the late Mr. Meard of the village of Welbeck, where it grew originally at Shobden Court, in Herefordshire, where, as I understood him, it was received from Italy. It requires the temperature of the Muscats to ripen it well, and to be kept dry, or its large bunches will get mealy, and the berries soft and damp off.

The old Tokay is a late variety that keeps well with me till March. Its flesh is very firm, and the berries not very highly flavoured, but it is useful when white Grapes are wanted for variety.

Muscats of Alexandria, as above stated, is the best flavoured of all late white Grapes, but it is always shrivelled with me, and used before the others above described are commenced cutting. *William Tillyer.*

The Muscat of Alexandria certainly stands at the head of the list of white Grapes. When comes Royal Vineyard, according to our estimate of the samples sent; and finally, but considerably behind, Trebbiano and Tokay. The black sorts are not so easily placed. Gros Guillaume and the Mill Hill Hamburg, have a certain resemblance in flavour, and will best please those who like sweet Grapes. The seedling named above, with West's St. Peter's, and Barchard's Prince, are more acid, and will suit some palates better than the other sorts. Lady Downe's was not sent, as I believe it is decidedly inferior. Mr. Tillyer's seedling is a fine-looking Grape, one of the best of the above as to preservation, and scarcely, if at all, inferior to West's St. Peter's in flavour. *E. J.*

—Mr. Grieve's experience with late Grapes, as recorded at p. 836, vol. vi., is nearly identical with my own. He has sent me this season two large varieties full of grapes. I have this day tasted and noticed them all. I find Lady Downe's No. 1 both for plumpness and appearance. Black Alicante is firm in berry and bunch, but has just begun to shrivel. Barchard's Prince's berries are much better than all, but that objectionable foxy colour gives one clear and important point to the Alicante. The very look of a bad coloured Grape is hateful, and on this score the Alicante before Mrs. Price's. To please the palate of your employer is no doubt an important item, but to please his eyes is, to my way of thinking, quite preferable. Barbarossa is plump and good, but it is not an accommodating Grape, wanting much more ripening. In white Grapes we have nothing here like Trebbiano. *K. Gilbert, Burghley.*

BOTTOM-HEAT: ITS USE AND ABUSE.

THAT bottom-heat is one of the most powerful and essential aids to growth, few will deny; that it is capable of being used in excess, and applied at the wrong time, must also be admitted; but there does seem a danger of making the abuse of this potent cultural force the occasion of a series of onslaughts on its legitimate use. The several cases recorded by Messrs. Bines, Wildsmith, and, if I remember rightly also a year or two ago by Mr. Tillery, are no doubt vivid illustrations of the evil effects of an excess of bottom-heat applied at the wrong time. In each of them there was a twofold cause of failure—the amount of heat was in excess, as well as itself itself an excess. The excess is proved by the fact of the stronger state or healthier condition of the Vines at the ends of the houses. Supposing, then, that no part of the borders had been made hotter than these two extremities, there is no proof that the bottom-heat would have proved injurious. Without greater precision as to absolute temperature, it is quite a logical and legitimate inference to assume that the fermenting dung and leaves were heated to excess, to the inevitable injury and enfeeblement of the Vines. We ask how exceedingly capricious and even violent the most staid-looking fermenting materials often become within the shortest period of time, and at the most unexpected seasons and places. The term bottom-heat itself needs definition, and the amount of it employed recording, before such failures as those referred to, can assume much scientific importance or practical value. By bottom-heat let us understand, once for all, a temperature equal to that of the air, or 5° Fahr., or at the most 10°, in advance of the atmosphere in which the Vine or other plant was or is resting or growing. Are your able correspondents able to affirm that this difference was not exceeded? If so, then we must either admit the cogency of their reasoning, or find some other and better explanation of their facts. But if not, then it is but reasonable to assume that the evils recited were caused by an excess of bottom-heat, and cannot be accepted as any reasonable argument against its legitimate use.

My friend Mr. Bines will, I am sure, excuse me for finding proof in his article that by bottom-heat he means a good deal of it, in the two or three paragraphs of his lucid paper he writes quite seriously about growing and flowering stove plants better without bottom-heat than with it. From this it is obvious that the "champion cultivator" does not consider an equality of terrestrial and atmospheric heat bottom-heat. Possibly he would say all excess of terrestrial over atmospheric heat was bottom-heat. If so, then almost everything turns on the answer to the questions, How much in excess should the bottom-heat be over the top to prove useful? and at what point in advance of it does it cease to be useful and become injurious? And, further, What was the amount of difference between the temperature of the tops of the plants and the roots in the cases referred to? It may be too much to expect exact data, but without some approximate estimate of the difference, the experiments recorded prove nothing whatever but the injurious effects of an excess of bottom-heat. It is no extravagant supposition to assume that the layer of fermenting materials was as much as 90°, while the heads of the Vines were in a temperature of 45° at starting; and if so, the results would of necessity be as described by your correspondents.

It may be added that most of the zealous advocates of bottom-heat for Vines are quite content with a measure of it, which somehow our friend writes down as none at all. That is the having the roots in the same temperature as the tops, which of course is the happy condition of all above plants.

But another cause of failure is the employment of the bottom-heat at the wrong time. Though it is difficult to point to any season when the roots are at rest, and it would be easy to prove that they are abnormally active at the descent of the sap, yet the natural and extension under the influence of descending fluids is a widely different thing from an abnormal activity of the action set up and sustained by the warmth and the moisture of artificial heat from fermenting materials, two months or so before the tops were ready to start. The difference between the character and union of these two sets of roots, the natural and

unnatural, is as wide as the Poles asunder; the natural roots are vicarious chiefly, the unnatural are selfish wholly; the first serve the Vine, the second feed themselves, the first strengthen, the second weaken. The mission of the first roots is to fill the Vine with strength and all good things; the second empty it and rob it at all points; it may never be forgotten that natural currents, as well as natural functions, may readily be reversed in such plants as the Grape Vine under unnatural conditions. For instance, it is the legitimate function of roots to collect and convey food to and for all parts of the Vine, but develop an abnormal activity in the roots out of season, and they then drain the stems and branches of vital force and available food—for currents are reversible in vegetable tissues without inconvenience, and fluids have the power of flowing in any direction where there is an active outlet. Hence roots started out of season, or so long in advance of the top, finding no demand in a natural direction, set up the business of accretion and extension on their own account—supplies are drawn by the roots downwards, instead of through the tops upwards. The buds and stems are impoverished before starting, and when they do start they have to reverse an established order of policy and practice, arrest a downward current leading to destruction, and establish an upward or constructive growth. To take a favourite illustration in morals—correct enough for our purpose—to train a virtuous child is like starting to develop a character on a clean sheet of paper. To educate a vicious lad there is much of the past to be erased before a start can be made in the right course. It is almost precisely so with the Vine. Start top and bottom almost abreast, and all is smooth sailing. Start the roots long in advance of the top, and all the established currents of life have to be stemmed and turned by the ascending fluids. Nor is it any wonder that the plant should be worsted and weakened in such a struggle. But my point here and now is, that the struggle, and its legitimate results of weakness prove nothing against bottom-heat, only that it was out of season.

The cases as recorded do not even show that bottom-heat was not be applied slightly in advance of top-heat, only that in these cases there was too wide an interval between the two. The whole question, in fact, under this head turns on time, as under the first it resolved itself into one of quantity. It might, for instance, be wise and helpful to apply bottom-heat to the roots of Vines a week or ten days before the tops were started, but it by no means follows that, therefore, it would be wise to subject them to a vapour-bath of steam-fermenting materials one or two months before the command was given to the top, to lose it from the restraining fetters of dry and cold air, and let it go into the warmth of a genial and growing atmosphere.

No, your useful hints upon the nature of evidence, and even the meaning and weight of facts, would teach us better logic than to come to the conclusion that bottom-heat itself was evil, on the slender and even irrelevant basis that it led to failure when used at the wrong time, and to excess. To counsel that outside Vine borders should have no covering at any season, but merely enough to enable them to show off the leaf is quite a long way on the other side of bottom-heat, and virtually recommending that the Vine roots be in a much colder medium than their heads.

In fact, this, as I understand it, is the inference drawn by Mr. Bines from Nature. Nature is many-sided, and has many voices; hence, I assume, my different reading of her teachings in this matter. Nature uses bottom-heat abundantly, and so determined was she to have the roots made one for all warm, that she took special pains not to sensibly warm the air by the passage of the sun's rays through it, but first of all to warm the surface of the earth, and then make that, root-filled as it is, her great warming-pan for the heating of the air. In full view of the fact that heat travels slowly downwards,—which, however, tells both ways in this argument—it is impossible not to see in this simple arrangement that Nature took the most forcible means in her power to keep the roots of plants warm, and experience an experiment alike show that she has provided abundantly of bottom-heat.

It is needless, however, to bear in mind that these views must not be interpreted as advocating an excess of bottom-heat. It will be found in practice that, as near as may be, an equality of terrestrial and celestial heat

results in the strongest growth and the finest produce and if there is to be a difference in degrees of temperature the roots may safely have it within the moderate limits already stated. The chief danger, under our highly artificial modes of treatment—with the heads of our Vines in the tropics, and the roots too often wandering in a half-named state in search of the North Pole—arises, not from heat, but from cold. Hence the present vindication of a wise and prudent use of bottom-heat for Vines. It is found remarkably useful for Vines in pots, and one might have thought that, on the sound principle that what is sauce for the goose is sauce for the gander (how savoury of Christmas the proverb seems), what was so good for Vines in pots would be equally good for Vines out of pots. But it would almost appear as if this were no longer to be accepted as true, and, more, that Nature has herself made a fundamental mistake in providing more bottom-heat for Grape Vines and other plants than was necessary. I trust ever to stand shoulder to shoulder with Nature in declaring that bottom-heat is a right good thing—a strong, useful, healthful, cultural force—though too much of it at the wrong season may prove a very bad thing indeed; and in this determination and these conclusions I hope to have with me all the able cultivators concerned in getting up those cases that seem to point to other conclusions. *D. T. Fish.*

PLANT PORTRAITS.

MESSRS. A. C. VAN EEDEN & Co., of Haarlem, have favoured us with the two parts for 1876 of the *Album van Eden*, which contains faithfully executed chromo-lithographed plates.

TULIPS VAN DER NEER and WOUVERMAN, two early flowering sorts, both large-flowered varieties, the former of a dark rich hue of crimson, and the latter dark violet in colour. Both varieties are described as having "firm, upright stems, and their habit of growth all that can be desired."

LILIUM LONGIFLORUM, a well-known favourite, which the editor alludes to as being admirably adapted for forcing into flower in April and May.

LILIUM CHALCEDONICUM, the two forms found in the trade, one red and partly spotted with black, the other wanting in the latter particular. *L. chalcædonicum* is reported to be not very abundant in Holland, owing to the constant demands from abroad.

IRIS SUSAANA, sometimes called the "Morning Widow of Susa," is beautifully portrayed. "According to Clavius," it was imported from the East to Vienna about six centuries ago, and there soon found its way to the Netherlands, where even at that time people made a great point of collecting plants of foreign origin."

IRIA HYBRIDS, a plate containing several varieties of English origin, varying in colour from white to orange, buff, and dark crimson.

DOUBLE TULIPS MARILLO, COURONNE DES ROSES, AND LA CANDEUR.—The latter is the best known of this trio. Its colour is white, its habit neat and dwarf. Couronne des Roses is mentioned as being a good early variety, and is of a bright rosy shaded pink colour. Marillo is a fine soft rose, darker coloured flowers appearing with age.

TIGRIDIA PAVONIA, which "deserves unquestionably the place of honor among the Tigridias as well for the size of the flowers as for their brilliant colours."

HYACINTHIS MARIE and ALBA MAXIMA, the former single blue, the latter single white. "Alba maxima has bulbs of the first order; and those of Marie are so beautiful, so splendidly formed and large, that it would undoubtedly be readily bought, . . . for the public generally entertain the erroneous idea that the largest bulbs produce the largest flowers, and, as a rule, they are not inclined to believe that a variety, which has always a small bulb, sometimes far outstrips a sort which makes large bulbs."

FERTILISARIA MELÆGRIS, a very pretty and handsomely marked species, for culture in either pots or borders. It is said to be suitable for forcing, and will flourish freely in a rich garden soil with plenty of sand.

POLYANTHUS NARCISSEUS.—This plate contains three varieties, white, sulphur, and primrose, of this well-known plant.

LILIUUM SPECIOSUM ALBUM, a fine white variety, which "will be always worthy of its place, whether grown in pots or planted in the open ground."

CAMASSIA ESCULENTA, a beautiful old, hardy, blue-flowered, bulbous plant, that has not met with such an extended culture as it deserves. It was introduced more than forty years ago by Douglas, who sent it from North-Western America to the Horticultural Society's garden at Chiswick.

— The *Gardeners' Monthly* for December has a coloured illustration of the Californian Palm, *FRITZ-CHARDIA FILIFERA*.

— The January number of the *Revue de l'Horticulture Belge* has a coloured plate of two varieties of GIENET AZALEAS, elsewhere referred to.

— The *Floral Magazine* for December last contains coloured illustrations of

LILIUUM NEILGERRENSE, the beautiful new Indian species figured in our columns last autumn, p. 332.

AURICULA TOSPY (Kay), a self-coloured variety, "and one of the darkest flowers in existence, the paste being of the purest white, the tube of the right size and golden." It was raised in Scotland by the late Mr. Kay.

BONIMAEA CARDELI, a valuable new Amarylloidaceous plant, of recent date, introduced by Mr. Bull from New Granada, and figured in our columns at p. 793, vol. vi. Its portrait, on a reduced scale, will also be found on the Almanac issued to our subscribers to-day.

PENTSTEMONS MRS. A. F. BARON and OCTOORON, both hybrids raised by Messrs. Downie & Laird, of Edinburgh. The former is a very graceful flower, possessing all the perfect qualities of the improved Pentstemon. The flowers are of a soft rose pink colour, with a broad well-defined white tube. Octooron is not so smooth a flower, but by reason of its broad spike and rich dark colour, is a valuable addition to our store of these grand autumn border flowers.

— The current number of the *Florist and Pomologist* contains coloured plates of Rhododendron Princess of Wales and Willson's Queen Victoria Pear.

RHODODENDRON PRINCESS OF WALES is one of a second race of hybrids bred from *R. jasminiflorum* by Messrs. Veitch & Sons, and is the most beautiful of them all. The colour is a soft but brilliant tint of rose-pink, with a pure white throat and tube. As a decorative plant this is a decided acquisition, since in the genial atmosphere of a warm greenhouse, it may be expected to go on growing and flowering indefinitely.

WILLSON'S QUEEN VICTORIA PEAR is an excellent autumn variety, raised about twenty years ago by the late Mr. W. Willson, of Whitby, a well-known florist and Rose grower. The fruit is of about medium size, and of a greenish or pale brownish tint yellow-green colour, with a thin coating of pale but bright russet-brown on the exposed side. The flesh is juicy and sugary, having a strong Pear flavour, blended with a smack of that of Noyeau.

BLUNDERS.

THERE is among the various educational seminaries the school of suffering, where lessons are given to those who will not learn in any other academy. Beginners frequently find out near cuts to knowledge, without taking all the usual steps; and, but for one spoke wanting in the wheel of fortune, all would have gone well, though for want of that little spoke the wheel would not turn to profit. How often do we see that the chalking of the wheels and bands of the spinning-jenny is necessary before it will turn aright. To be sure the machine wanted very little, yet all the rest was useless until that little was got. There may possibly be a royal road to knowledge, especially to horticultural knowledge, "but this the gods in later times perform." A little sulphur and a little heat did good service in Z.'s victory against red-spider, but when neighbour X. copied this recipe, he over-heated the pipes, and the crop of Grapes was ruined; and when the blunder became evident, X. cried for very sorrow—

"But you awe awaits a vinery when
It sees the tears of bearded men;"

and from that day forward, X. would as soon seek the aid of Satan as that of sulphur.

B. was a clever youth, but went astray on the soap question. Like

"Donald Caird, with meikle study,
He caught the gift of making soap;"

got the hot tallow in the wash-house copper, and the hot ley in an iron pot, regardless of the heat of either; and as the fatty acid did not rise in vapour, or give sign or warning as long as it was under 60°, there was a good margin for blundering. But as soon as the ley was put to the tallow it rose in a jet of froth like foam, and first it filled the copper, then the wash-house, and threatened to fill the yard, when B. left, and no doubt "a wiser and a better man he rose the morrow morn."

In the earlier days of horticulture, before hot-water pipes were in vogue, there was in most gardens, from royalty downwards, a good deal of rough firing to be done, and it was nobody's business to direct the drudge that was told off for the stoakehol. Indeed, it is likely enough that lecturing an aspiring youth on the science of combustion would not have been taken in good part, so every one fired after his own fashion, and I generally found the fire the wrong end set, but black enough towards the flue to be heated. It is rather late in the day now to speak of fire-flues, and late hours for young gardeners with the fire-shovel and lantern; but I have more than once seen the furnace bars melted by blundering.

In the culture of Mushrooms it is a good plan to have the command of steam free in the Mushroom-room, and in good hands all goes well; but it is a hackneyed saying that even the coarsest true lovel itself does not always run smooth, neither does the culture of the common Mushroom. I had attached to the Mushroom-house a nice little copper, for the supply of steam; it had a wooden lid, and a zinc spout to carry the steam, the whole being very much like that well-known article called in the North a "sma' still." My fireman had put more fuel on than was needed, and when I walked my rounds I found the wooden lid charred, and in the bottom of the pot, along with the remains of my zinc spout. Fortunately the Mushrooms had not appeared, and no harm was done; but later on, some six or seven years, I had a splendid house of Mushrooms scalded to death by the same blunder, namely, steam in excess.

There are few, among my subjects so little understood as combustion; everybody makes fires, or, at least, mends them, but each has a way of his or her own, and a large commercial business is done with "fire-lighters" whose composition is a profound secret. If you go into some of the restaurants in Liverpool a little before dinner-time, the cloth is laid, and so is the fuel in the grate, but it is all black and cold, when a dapper little maid comes in with a vial of petroleum, and with a quill or small brush sprinkles the lumps of coal, and striking a match—

"Quick as the spark from smitten steel
From nitrous grain the blazing fire,"

—the whole becomes a cheerful blazing fire with no coals used until the business of the house required their services. Powdered resin in good hands is less dangerous than petroleum, in kindling a fire or refreshing one that has gone down—

"Ay, me! what perils do environ
The man that meddles with cold iron."

"Or he that doth our minds unsettle
By burning stones to boil the kettle."

It is related in the jest and tale books of birds who had built their nests too early in the season, that their callow young were killed by frosts; hence the moral—

"Not only choose a proper mate,
But proper time to marry."

The "times and seasons" are the very vitals of horticulture in the northern counties. You cannot trust greenhouse plants out-of-doors before the first week in June, although in the southern counties they risk their bedding-stuff soon after the middle of May; and should severe frost occur, the gardener cannot be blamed, since the practice is general. Now K. was a handy labourer, and so he got employed in a single-handed place; and in his anxiety to do right he laboured early and late, and as far as besoms could go, he kept the place clean. He got rather late with his Onions, Leeks, and Carrots, but would not, as he said, be cast with other things, so he sowed,

* Hudibras.

or rather planted his French Beans in good time; they came up well and quickly, but only to be frosted, and their case was worse by half than frost-ripped Potatos, for they never sprouted the second time. Next year he marked the almanac with two crosses, one the date when the cow should calve, and the other, May 15, the time to plant French Beans—not to blunder a second time.

A West-countryman of my acquaintance got recommended to a head gardener's place, and as the gentleman was showing his new servant the place he asked him what religion he professed, at the same time stating that his religious views would not alter the good opinion he had of him; to which question the gardener replied "that he was not particular." This was a serious blunder, and was taken to mean a total absence of all religious training, and he was paid a month's wages the next morning, and left the place; proving, what I have stated above, that the school of suffering and dearly-bought experience can teach important lessons, long after our school days are gone by, for besides the three "R's" of our Board Schools, and, on the Green of the Archbishop of York, of the Latin and Greek of our Colleges, they do not exhibit models for imitation, however grand their utterances are. In practice, the high moral training is as needful to the gardener as his skill in gardening. The late Dr. Lindley, who knew the state of the English market for gardeners as well, if not better, than any other man, told me that although he was pestered with applications from gardeners for situations, when he wanted a man that could be trusted to manage an important place—fit to be trusted with money and means, and capable of managing himself with care—it was difficult to find one to fit one. Now this is what comes of blunders! *David Sangster.*

New Garden Plants.

ADIANTUM NEOGUINEENSE, sp. n.*

This plant belongs to the same group of species as *A. rhotiopicum*, though differing from it in many important respects, obviously in the sori, which are rounded and entire, and in the rachis, which is continuous at the edges of which meet so as to close the aperture. It is a larger plant of fuller development, the fronds, independent of the stipes, being already, though but recently imported, about 15 inches long, and fully as much in width as the base. The rachis is castaneous, 6 to 8 inches long, and before handling covered with a glutinous bloom on the polished surface. The lower pinnae are themselves three times divided, the rachises of the secondary pinnae and pinnules being remarkably slender and hair-like. The pinnules which terminate both pinnae and pinnules are wedge-shaped at the base, irregular in the outline of the outer margin, being boldly crenate-lobate, the lobes large and entire except when serriform. This lobing is a conspicuous feature, and is more or less observable over the whole frond. The lower pinnules are smaller than the terminal ones, and are of a trapezoid form, but showing more or less of the lobing already referred to. In the fertile parts of the frond these broad rounded lobes are split into three or four narrow, linear, serrate, deep sinuses, in each of which a small sorus is so deeply sunk that the margin of the pinnule is continued around and beyond it. The texture of the frond is pellicled membranaceous, and the colour is a dark green, with a glaucousness—more or less marked—on both surfaces, when mature, but in the young and partially developed state the fronds are of a very pale green. This will no doubt prove a free-growing and also an elegant addition to our ferns. It has been recently obtained from New Guinea by Mr. Goldie, when collecting for Mr. B. S. Williams, of Holloway; and it is from plants now growing in Mr. Williams' collection that we have derived the foregoing particulars of the plant. *T. Moore.*

MASEVALLIA MACRURA, *Reich. fil., supra*, 1874, 40.

My prediction that this curious species would soon appear in gardens is fulfilled very speedily. There it is in England—at Chelsea. It has unusually large leaves for a *Masevallia*. From the articulation of their petiole base to their top they are a span high, and they attain a breadth of two to 3 inches, so that they

* *Adiantum neoguineense*, sp. n.—Fronds spreading, glabrous, deltoid, tri-quadripinnate, pellicled membranaceous, dark olive-green, with a glaucousness on the lower surface. Ultimate pinnules on very fine hair-like stalks, the terminal one cuneate, the lateral ones trifid, averaging about 1/2 inch long, crenate, with the lobes serrate, the lobes small, distinct, about 6-8 to a pinnule, orbicular, entirely sunk in closed sinus, the lobes of the lobes being small, orbicular, with a fine filabellate, about four running into each sinus; stipes castaneous, smooth, glaucous; secondary and tertiary rachises very slender, hair-like.—Hb. New Guinea.

make a very stately impression. Their substance is very stout, and the surface is shining. As to this, they may be compared to the beautiful leaves of *Masdevallia towarensis*, though they are far superior. The flower-stalks are equal to the leaves, perhaps a little shorter sometimes. The cucullate bract stands just at the back of the perigonial tube. It is inclined apparently to show some variation as to the length. The wide tube itself is very short, of firm texture, and slit into an upper and an inferior lip. The upper lip forms a short triangle, extending in a long, strong tail; the inferior lip is longer and broader, dividing in two long, strong, spreading tails. Those tails are light yellow, the bodies themselves of the sepals light

flower, when many are rather dark. This species would appear to be rather rare. It is New Grenadian, and appears to have escaped one of the best *Masdevallia* hunters, Mr. Wallis. The discovery is due once more to M. B. Roel. Then a short-tailed variety was gathered by M. Patin, the young Belgian. Afterwards Mr. Shuttleworth met with it during his first journey, and from his plants Mr. Bull sent me lately. *H. G. Rehb. j.*

ONCIDIUM ELEGANTISSIMUM, n. sp.*

I saw this really elegant plant at Messrs. Veitch's in October last. A glaucous, short, broad, ribbed, two-leaved pseudobulb throws a splendid panicle

yellow of the glorious *Oncidium varicosum* and *O. Rogersii*; the calli of the base with black purplish borders. The anterior limb of lip is beautifully marbled and dotted with light brown, which feature renders it so very pretty, for there is a quiet charm in seeing all those brown dots washed away like clouds to pass into yellow.

This is near another most elegant and nearly unknown plant, Dr. Lindley's *Oncidium Gardneri*—one of the most beautiful of Brazilian Orchids. It is easily understood by its very short claw to the lip, as in this, by the calli being entirely of a purplish black, the two long anterior ones totally covered with small warts, not only with a few marginal ones, as in *O. elegantissimum*.

FIG. 2.—MASDEVALLIA MACRURA.

brownish, with dark purplish brown streaks. There appears to be much variation in the varieties as to the length of the tails. I can affirm this to be so from eighteen specimens at hand—from 6 to little over 4 inches in length. The petals, column, and lip, form, as usual, a small body, yellowish, with purplish dots, the middle lobe of lip being orange-yellow; the petals are rhomboid, blunt, and very thick, now emarginate at apex. Lip three-lobed in the middle, the side lobes blunt, the anterior lobe blunt, recurved, covered with short acute warts; there are two lamellae between the basilar lobes. The column is acute at its top. The greatest curiosity of the flower is kept inside. The chief nerves of the sepals are prominent internally, and covered with numerous blunt warts. Though they are far more conspicuous in the dry specimens, yet they may easily be seen in the fresh

of flowers, very similar to those of *Oncidium curtum*, Lindl., but with far more shining colours, and the lip much shorter in consequence of the unguis being very short, as in *Oncidium Gardneri*, Lindl. Colours are unusually pretty. The sepals are brown, banded with narrow yellow bands. Broad petals, with a few yellow spots. The lip of the brightest

* *Oncidium elegantissimum*, n. sp. (affine *O. Gardneri*, Lindl.) —Sepalo dorsali apiculato oblongo; sepalis lateribus basi connatis unguiculatis, dein albe bilobis oblongis acutis; tepalis cucullatis ovatis extus bilobis emarginatis; labelli auriculis minutis, isthmo brevi; lacina antica dilatata subtrifurca biloba; callo basae triangulari; carina antherogica, area limbo incrassata subcirculari utraque in basi; callis anticae lateraliibus disco levibus, limbo papillois parvis; columna albe angustis subquadrateis. Sepala brunneo flavo fasciata; Tepala brunnea maculis paucis flavis, Labellum pulchre brunneo xanthinum circa limbum lacinae mediae pulchre brunneo guttato fasciatum. *H. G. Rehb. j.*

mum, where those bodies are much smaller. I have just now, after having for nearly two days studied the whole group, finally made out that *Oncidium flabelliferum*, Finel (see *Fraxel's Magazine*, xvi, p. 65, 1859), is nothing but *Oncidium Gardneri*. Both Dr. Lindley and myself never had much trouble with this plant. Dr. Lindley's materials of *Oncidium Gardneri* were not good, so that he named for me a variety of *Oncidium crispum*, Lodd., his *Gardneri*, which troubled me a long while. Only by seeing other specimens of Gardner's No. 442, I understood the plant. I, indeed, had rightly named *Oncidium flabelliferum* for Mr. Linden, 1858 (see C. Koch, *Berliner Allgemeine Gartenzeitung*, p. 379), but from three flowers I had obtained, two were monsters, with two lips, so that I had no well-marked impressions.

Another species, proposed by myself, may be com-

pared to these two species as to colour, *Oncidium* pretiosum. It has a much longer nail (analis, as this is the narrow part between the basilar auricle, and the anterior dilated part), totally different call, and a column with a far more protruded tabula infrastigmatica, which is so very inconspicuous in both *Oncidium Lindleri* and *O. elegantissimum*, which, too, have very short columns. *H. G. Kuhn, f.*

MUSTARD AND CRESS.

FEW people who see and purchase the punnets of small salad, locking so neat and nice in the green-grocer's windows, have a thought of how it is produced further than they suppose it grew somewhere; or have a notion of the magnitude and importance of this branch of market gardening, or the number of people it directly or indirectly gives employment to. It is a branch of gardening which is carried on to a certain extent all the year, but the time of its greatest activity commences with the arrival of the French Lettices in our markets, and continues through the spring and summer months. Shortly after Christmas, therefore, in the places where it is grown, the floors of the early viciaries and other suitable warm houses are prepared for the crop. The seed is frequently wetted and placed in hot situations, to swell and even start before sowing, though this I believe is more with a view of shortening the time the crop occupies the ground, and as a rule one crop a week is taken.

One great labour connected with growing Mustard and Cress is the necessity of having fresh soil for every crop. Each time a crop is cut the whole of the soil used is removed and fresh soil spread for the reception of the seed. It certainly does not require much depth of soil, but still the labour is considerable. The seed having been sown, the whole is covered with mats, shutters or some such contrivance, for to suit the market the stems must be white, and the tops a bright light green; a purple shade in either stem or leaf spoils its sale. When the crop has reached the proper height it is cut with a very sharp, peculiarly-shaped knife, one round or swarth of which is considered a punnet. Some skill is required to gather the salad together in an upright position, to place it in the punnets, and the punnets require to be of an equal size, that they may be comfortably full, not loose or crowded, to fetch the best price in the market. This process is repeated till the season advances and cold frames can be used, and after the cold frames, out-of-doors crops are grown, still taking the same precautions to blanch the stems, and keep the tops light green.

A skillful hand will cut from 1000 to 1200 punnets per day. It is highly important that the seed used shall be of the very finest quality, or the crop will either be too thin, or, what is almost worse, irregular in its growth, some ready to cut, and some just up, in which case the appearance is not only bad, but it starts to rot in the punnets much sooner than if the whole is regular. Three parts of the so-called Mustard is Rape, which is of milder flavour, and, moreover, smooth and white in the stem, whilst Mustard is hairy, and does not keep so well when cut. One grower of my acquaintance pays £3 per week on an average for punnets alone, and uses from 600 bushels to 700 bushels of seed per year. *J. B.*

Natural History.

THE GOATSUCKER.—Your natural history correspondent, in your issue of the 30th ult., gives me very interesting details of an old favourite of mine, the Goatsucker; but as my observations have led me to different conclusions in several items I am led to write in hopes of further information or correction. The "hissing sound" always seemed to me to come from a bird at rest, not when flying, as your correspondent states, or at least if flying it must have been in a very limited area. Also that the "crackling sound" was made by a bird at rest, probably by beating its wings against the branch on which it was sitting; or, what is more probable, by a magnetic state of the pinion feathers in an excited, nervous quiver of the wings. And this not as a "serenade" by the male, but by the female bird with a leaf-year privilege inviting her mate to come and woo.

Your correspondents' views are that it is a timid, easily scared bird. This I have never found to be the case, but on the contrary, daring—not the courage of bravado but a simple trust, a fear no evil, feeling,

In twilight or moonlight it will settle on the road or park drive—a favourite spot with it—and allow one to approach within a few yards, and then with its peculiar, graceful motion, fit on and re-settle, again to fit on your approach; and thus on for a long distance, as if wooing you to follow and fear not. And also in its more aerial flights when food-hunting, it seems not to heed your presence; rather follows than flees.

And again, your correspondent gives as its favourite haunts "beaths, moors, and commons;" not so my experience, for though not seeking the vicinity of water and bustle, it seemed to love the tree-tudded meadow or park around some mansion. Really I differ on so many points with your correspondent that since beginning to write this a doubt flutters across my mind. Can I be mistaken in the bird? But no. However, if I get corrected I shall not have written in vain. *W. Wilson, West Hill, Shanklin.*

Apiary.

DO BEES MASSACRE THE DRONES?—Until I observed Mr. Murray's paper, at p. 714, vol. vi., on the age and death of drone bees, I knew nothing of the doubts of their slaughter by the common bee. However, without going into what writers have said, or the popular belief of such, I merely say if he has wood or glass hives, and peeps into them shortly after the usual swarming time, he may see the bees attacking the drones with fury, especially in half-filled glasses on the tops of the hives. I have doubts if they use their stings in the fracas, they seem only to throttle them with their strong mandibles, in the most vital part, just under the wings, which is the same kind of warfare as among themselves.

However, in mid autumns, at times fresh broods of drones appear. Those have been mistaken for drones which escaped the general slaughter. I have frequently found drone-cells filled with honey, while the adjoining cells of the same combs contained late brood of drones. Indeed that led to my belief, if we had no winters honey-bees would repeat swarming during the year, or at all seasons. In other words, the instinct or habits of bees are not suitable for our field climate. That accounts for beesaying up both honey and pollen more for the present use of the colonies than any foresight of winter. *J. Wighton, Cussy Park.*

Florists' Flowers.

THE NEW FLOWERS OF 1876.—What shall be said generally of the new florists' flowers of the past year? This can be stated with considerable show of truth, that though the circle of possible attainment lying beyond the present sum of achievement narrows as the ideal of perfection is reached, there is yet so much of un-realised conception that we cannot, and dare not rear up any imagined barrier beyond the line of which it is impossible to proceed. It is well that it is so, for as Margaret Fuller somewhat quaintly put it, "Man is a plant of slow growth, and great heat is required to bring out his leaves. He must be promised a boundless futurity to induce him to use aright the present hour. In youth fixing his eyes on those distant worlds of light, he promises himself to attain them; and there find the answer to all his wishes. His eye grows keener as the gaze, a voice from the earth calls it downward, and he finds all his feet." It is as true in the vegetable world as in that of morals; and the true florist does wisely when he puts no limit to possible attainments.

The delicate and beautiful Auricula appropriately heads the list of the distinguished floral products of the year in Kay's Alexander Meikiejohn, a grey-edged flower of great refinement, nearly perfect in all its parts; Mrs. Purvis (Turner), grey-edged; and Gertrude Knight (Turner), grey-edged, may be seen to better advantage—there is the promise of good flowers in them, though as shown they were marred by defects which detracted from their first-class character. In the alpine section the finest flower of the year is Gorton's Mauve Queen, because so perfect as an edged variety; colour deep mauve, shaded off to a pale margin, and white centre. Turner's Bessie Ray is remarkable for its brilliancy of colour, shaded crimson, margined with a brighter hue. Turner's Slough Kival is another edged flower, shaded purple, edged with violet; Charles Lödgar and William Dragg, from the same raiser, are large bold self

alpine, particularly striking, but regarded as "non-descripts" by the Northern Auricula growers.

New Azaleas of a distinct character increase less slowly than they did a few years ago; there was then a wonderful leap forward, which, as is usually the case, has been followed by a corresponding pause. In point of novelty the new double-flowered variety named imbricata, figured at p. 817, vol. v., 1876, tops the newer single varieties of the year. The flowers are as full as those of a Camellia, the white ground tinted with green, and lit up with flakes of carmine. Jean Verveine is one of the pretty edged flowers, the colour reddish salmon, edged with white, a pretty decorative variety. Flambeau is remarkable for its brilliant hose of light crimson; it is most striking in colour, but wanting in the form and substance to which so much value is generally attached. Apollo is a flower of enormous size, dashed with flakes of scarlet on a white ground; a fine conservatory plant.

The tuberous rooted Begonias promise to become as numerous as bedding Pelargoniums, a most formidable list can now be compiled. Vicomesse Doronille (Veitch & Sons), rich dark scarlet; Excelsior (Perkins), bright crimson; and Majestic (Perkins), vermilion-red, have all seen the light; the flowers are large, with broad petals. Several others have been produced, some with delicate colours; in fact, production goes on with rapid strides. The useful decorative Begonias are finding a place in schedules of prizes, and they are charming objects on the exhibition table but some of them carry badly. They are also being employed for bedding purposes. The ornamental leaved stove type, of which E. Rex is an illustration, have been reinforced in Miranda and Otto Foster, raised by Messrs. Veitch & Co., both having handsome, finely divided leaves.

New Carnations and Picotees are confined to the North. They have not been seen southwards but those who saw them at the exhibition of the National Carnation and Picotee Society held at Manchester in August last speak of them in unqualified praise. I have seen some of them growing in the garden of the raiser, Mr. B. Simonte, at Sheffield, and also in the vicarage garden at Kirkby Malzeard, and am bound to bear testimony to their grandly rounded petals, massive substance, the purity of the ground, and the fine marking. Deserving to be mentioned in this record are: Carnations, crimson bizzure, Frank Simonte, Samuel Barlow, John Simonte, scarlet bizzure, Othello, purple flake, James Douglas, scarlet-flake, Rev. F. D. Horner; Picotees, Mrs. Simonte, Mrs. Gorton, and Mrs. F. D. Horner (named in memory of her at rest in the churchyard of Kirkby Malzeard), all three light red-edged flowers; Mrs. Douglas and Silvia, purple-edged. Other new varieties are Picotee rose-edged Miss Turner, and rose-flake Carnation Mrs. Dodwell, raised by Mr. R. Lord, Todmorden; and rose-flake Carnation Mr. E. S. Dodwell, raised by Mr. Thomas Ewary, Bradford. All the foregoing have been awarded First or Second Prizes.

During the last two or three years Carnations have been named and certificated, but we do not appear to hear of them again. Two double varieties, viz., King Alfonso, rosy red, and Prince Imperial, dark violet-purple, were shown by Messrs. E. G. Henderson & Son, as well as a very beautiful and in my view doubtful if the double varieties will ever make much headway; for decorative purposes they were no more near the single flowers—where their value will lie in their suitability for cutting from.

The past year left us a rich legacy of new Clematises, and indeed so rapidly have they increased during the past ten years that it is now a little embarrassing to make a selection of a dozen choice varieties. Messrs. Jackson & Son give us some fine additions to the double variety planted out against sunny south walls, and also a very bold and striking double flake of Connaught, lilac, very large, and well adapted for planting out against conservatory pillars; and Duchess of Edinburgh, pure white, deep and fine. The double variety to be planted out against sunny south walls, with a little protection in winter. Mr. Nurb's Frostens is also double, the flower rosy purple in colour and of great size; a distinct and fine variety. Messrs. Cripps & Son give us two new double varieties in Gertrude Knight and Cyclamen, the latter in the petals; and Venus Victorix, delicate in colour, semi-double, striking in appearance. All the foregoing belong to the patens and languinis sections. Mr. Henry Little, who has done so much in originating high-class varieties of Cyclamens, has produced a fine flower in Purple Gem, the colour crimson heavily shaded with purple. The difficulty of propagating Cyclamens by division of the bulbs interferes with the distribution of a fine variety like this, but Mr. Little's

experience and that of others who grow up to show that rich-coloured flowers almost, if not quite, reproduce themselves from seed. R. D.

(To be continued.)

Garden Operations.

PLANT HOUSES.

GREENHOUSE HARD WOODED PLANTS.—With the present saturated atmosphere it will be necessary to attend particularly to removing any dead leaves, as if not got away they become mouldy very quickly, and will even destroy whole branches. This applies particularly to such things as *Koelia* cistata, *Leontodon* lilioides, &c. It is a good plan to cut away the plants down on their sides to get these decayed leaves away. Less water will be required now than at any other season in the year, but care must be exercised that the plants do not get too dry, or serious harm may be done. Camellias, &c., which have the buds of which have not yet begun to swell, if at all infested with scale should now be cleared. It is a good plan to put a portion of these late-flowering varieties in the north house, so as to still further retard them. In the case of *Camelia* flowers may be had till April or May. With plants that are not so forward as may be desired, and to which a little fire-heat is used, it is necessary to be very careful in the atmosphere here, so that they do not get too dry, or the buds will fall off instead of opening, and they will be over-dry at the roots, or a like result will follow. **Azaleas.**—If any of the earliest forced Azaleas have done blooming, they should at once have a good washing with water, to clear the gam of which has been added to once or twice, and so that means if any trips exist they will be destroyed. After the washing, the plants should be immediately replaced in a temperature such as they have been in, and encouraged to set new growth early; in this way they will be prepared for blooming in the next season. Azaleas that it is deemed desirable to retard, whether for home decoration or for exhibition purposes, should now be put in the north house, where they can be kept cool, as it is their early stages that is retarding, and the most satisfactory carried out. It will be well at the present time to go over the stock of Azaleas and wash them thoroughly with the above mixture; if this is done effectually now they will most probably be little or none the worse at the time they are making their growth; do not wash the tobacco-water off, but let the plants remain laid down on their sides till it has dried on. **Soft-wooded Greenhouse Plants.**—Keep a good look-out for aphides on the stems and leaves of these plants, and as soon as any are discovered take immediate steps for their destruction. For early blooming for conservatory decoration, the old *Calceolaria aurea* floribunda is not surpassed. If grown on from year to year, it will be found very easy to manage, and its fine display. No time should be lost in getting in *Chrysanthemum* cuttings; in a temperature of 45° or 50° they will root readily. Do not cover them with bell or hand-glasses, but let the pots stand on some material that will hold moisture. Conservatory. Everything possible should be done to have the conservatory at this dull time as gay as circumstances will admit. Sweet-scented flowers are always valued, and never more than during the winter months. A few pot plants of plants that will set very early. Heliotropes that have been specially prepared for blooming at this time should be afforded a light position, or their flowers do not open well. *Richardias* as they come into flower should be brought into the conservatory, where, from the distance of some of their flowers, they are very effective. *T. Elaine*.

ORCHIDS.—The depth of winter at first might seem rather premature to cast one's eye along the month that intervene, and take in the display of bloom that should be presented to our view during the spring and early summer months; but though it may be a fair display of bloom, the result is very surprising to the time that is before us, and by forethought, early arrangement and planning, that the desired end can be consistently looked for. At present it will be more the part of the cultivator to be reaping, in a fair display of bloom, the result of his own care and diligence; whilst, however, present attainments are to be enjoyed and rejoiced over, it should also be the aim, by keeping the future in mind, to make the present further the means to greater results and progressive advances. Let us see how the orchids stand with us here. We want, say, a good show of *Dendrobium* in flower during the spring months; presuming that the plants are sufficiently strong, and are matured stock healthy bulbs or stems, the great part of the care now must be directed to a lower temperature than they have hitherto received. *D. fimbriatum*, *moschatum*, *Paxtoni*, *densiflorum*, *Pierardi*, &c., are just a few of those that are best treated in this way. Such as are from 45° to 50° is the regular winter temperature, and but small quantity of water given, they must here

remain for the next two or three months, as the eye may be, until the buds are just showing either at the top of the bulb or along the greater part of their length; then gradually bring them back to the *Dendrobium*-house, where the spikes and flowers will come quickly on, and thus the result will be a much greater display of bloom, which will be finer individually than if the plants had been subjected to a greater heat all through the winter. Another that requires hard treatment to flower well is *Vanda* trees. If a fine growth has been formed during the previous summer, they should also be brought out to the cool, and kept with water for the next two months or more; then, on bringing it back to the East India-house, presuming the growths are strong and thoroughly ripened, it becomes almost a certainty that it will flower. If the plants, however, are but small, the rest recommended will be beneficial to these also, but they should be brought back into heat sooner than the blooming plants, which will cause them to start into growth a little earlier. By this means the more quickly grow into a flowering plant. Carefully look to the plants of *D. crassinode*, *Wardianum*, and *moniliforme*, &c., that are now pushing out their flower-buds; give them a little water at first, then, as the young shoots begin to show, give them a similar quantity of water; the node the display this winter will doubtless be the finest that has ever been seen. Where several plants of this are grown and flowering, carefully make a note of the characteristics of the different varieties, and mark them as they are similar. Some of these many will prove to be much darker in colour, and at the same time the individual blooms will be larger and of finer substance. Where such is the case it is very desirable that the points of difference should be noted and preserved. The very pretty *glossum membranaceum* will now be showing for flower. The beauty and apparent transparency of the flowers cause this to be always admired, and if some of the rose-coloured varieties are grown, and cover at the same time, the beauties of each are better observed. These, however, do not succeed well as a rule, and having tried them under several methods, the one I have found to succeed best is to grow them in sand, and in peat-moss, and hang them in the *Odontoglossum* house. Here, with plenty of water, which quickly runs away, they will make fine bulbs, and flower more freely than when in pots. The night temperatures for this month should be the lowest, and the light the brightest. The following A.M. indicate about the following numbers:—East India-house, 55° to 58°; *Dendrobium*-house, 50° to 55°; *Cattleya*-house, 53° to 55°; *Odontoglossum*-house, 45° to 48°. If only *Dendrobiums* were grown in the house, the temperature should be kept a few degrees lower temperature than that mentioned, but as the collection is almost sure to be a mixed one, and some flowering plants are coming on and others are in flower, the numbers here given will be safer and more satisfactory. *H. Swan, Fillingfield.*

FRUIT HOUSES.

CUCUMBERS.—Until the days begin to increase in length and the sun attains a little more power, a right temperature of 65°, with a corresponding rise of 10° to 15° by day, will be sufficient for the fruiting plants; but where the winter supply is obtained from plants growing in a house divided into several compartments, successions intended for meeting the demand in February may be kept 5° lower until they begin to bear, care being taken that the bottom-heat is not lost. To keep the plants to a bearing stage say till Christmas, from plants thoroughly established in September, the extremely low temperature we sometimes see strongly recommended may answer in mild winters, as the smallest amount of heat will concentrate the plants to a bearing stage; but in severe winters this advice is liable to lead young beginners astray, and it is more than probable the plants will be found weakly and quite unequal to the steady demand which always comes in with the fish season. Where the dry stagnant weather has interfered with the daily ventilation, red-spider and mildew will most likely put in an appearance; if so, the usual remedies without retarding the plants, and the plants to be kept with liberal supplies of tepid liquid manure when required, particularly if they happen to be growing in pots plunged in fermenting Oak leaves or tan. Keep the foliage and young growth always protected from the sun, and the plants must be kept clean. Top-dressings with good turf as the roots appear on the surface. Syringe sparingly for the present, except on fine bright days, when the house is closed about 2 P.M. at a temperature of 55° to 58°. For the present, it will be better for getting up a supply of young plants for early spring work, and for this purpose a good bottom-heat from fermenting materials will be found most conducive to fast and vigorous growth. Let the seed sown singly in small pots, and in a trench near the glass to prevent their becoming drawn, and shift on as they require it. Meantime get together a

good quantity of stable litter and Oak leaves, which should be well broken and mixed in a heap, on a dry bottom in the soil ground, to ferment and sweeten for future use in pits and frames.

ORCHARD-HOUSE.—For some years after the veteran pomologist, Mr. Rivers, introduced the pot system of growing fruit, this department was looked upon by many as an expensive toy; steadily, however, it has worked its way, and if the price of fruit has not been reduced our knowledge of varieties has been greatly increased, as we are now able to grow and taste side by side a great number of kinds in a given space. In large establishments, where the main supply of Peaches and Nectarines is and always will be obtained from trellis-houses and arbors, a selection of early kinds in pots will give one fruit long before it can be obtained from large trees established in borders. Assuming that the trees in the forcing orchard-house were taken in early in December, the buds will be swelling fast, particularly if growing in pots. Daily syringing must be continued until the blossoms begin to open, and even then the atmosphere must be kept too dry. The pots should be well drained (an I favourably placed for the free egress of water, as if fruit trees under the hand are finished, and to increase the chances of a good set of fruit, all ventilators and doors should be set open to keep the house cool, and so retard the swelling and opening of the blossoms until danger of spring frosts has passed away. Where the stock of trees is limited but the plants are good, they should be selected from the nursery—if from the open ground they should be firmly potted and plunged out-of-doors until the buds are ready to open, when they may be taken up and placed in the house, and ripen their growth. *H. Coleman, Easton Castle.*

KITCHEN GARDEN.

One of the most important operations of this month is the getting together as large a quantity of fermenting material as possible; of course the staple of this will be the litter and droppings from the stables, but it may be greatly and advantageously increased by a plentiful admixture of tree leaves. These materials, if frequently and intimately mixed together, will produce a much sweeter compound, and one which will retain a gentle heat much longer than stable manure alone. It is not necessary that the quality of such manure when decayed is equally well suited for garden purposes. With such materials let there be a good-sized hotbed thrown up at once; it will answer many purposes, for although we are in the short, dull days, vegetation will soon be in active movement, and many little crops will have to be started where there is a family of taste to supply and early luxuries are required. Amongst these a small pinch of Celery should be sown thinly in boxes, but it may be sown in trenches, and it is not too early even for very early planting in trenches, but will be found very useful for soups and other flavouring purposes. A pan of *Walcheren Cauliflowers*, to be picked out into boxes before it is too far advanced, will be found very useful for soups, and it is not too early to furnish an early supply where there were failures in the autumn-sown plants. The long continuance of drenching rains during the last month will have been a great hindrance to all operations connected with ground-work. There will therefore be the greater need to concentrate a little extra labour in this department so soon as the weather will serve for wheeling out manure and compost, and digging or trenching up all vacant ground for sowing. It is not too early to furnish as roughly as possible on the surface, so that they may have all the advantage of frosty weather. It may seem almost superfluous, considering the present condition of the soil, to give any reminder about sowing crops in the spring, yet in a few weeks, if the soil may be possible to get in a sowing of Early Mignon and Early Long-pod Beans; the latter will succeed the former in coming in as if sown at the same time. The Peas sown in November will probably be ready for the table in the first week in March, and it may be possible to get in a sowing of Peas, and some dry leaf-mould laid along each side of the rows to form a shelter; the plants likewise may be just covered with the same material. A simple matter, but one requiring attention where neatness is looked for, is the sowing of small pots of *Winter Greens* and leaves on the beds of *Winter Greens* and Broccoli. *John Cox, Redfoss.*

THE

Gardeners' Chronicle.

SATURDAY, JANUARY 6, 1877.

THE institution of a physiological laboratory at Kew, by the munificence of T. P. JODRELL, Esq., affords a fitting occasion for laying before our readers a portrait of one of the founders of vegetable physiology—one who was the direct precursor of BONNET, of DUHAMEL, of DE SAUSSURE—one whose experiments and inferences are still current in the text-books; one, in fact, of whom, together with NEHEMIAH GREW, British science has just reason to be proud. In subsequent issues we purpose giving similar portraits of THOMAS ANDREW KNIGHT, and of other physiologists, to whose labours the gardening world is indebted for a knowledge of the basis on which the intelligent cultivation of plants depends. From the time of KNIGHT down to comparatively recent years, if we except the carefully-devised and laborious experiments of LAWES and GILBERT, comparatively little has been done in vegetable physiology proper by British observers, or at least in that department of it which embraces the study of the mode of working of the plant and its parts, looked at as machines. Botany, or the description and discrimination of one plant from another, including the study of outward conformation and minute anatomical structure, has been studied with zeal and success in this country, but in the particular department we have alluded to we have followed the Germans, the French, and other nationalities to surpass us. There are many indications that this state of things is likely to undergo a change, and it is one which, in the interests of horticulture, is greatly to be desired.

Two hundred years ago, that is to say in September, 1677, was born in the pleasant village of Bokesborough, near Canterbury, STEPHEN HALES, a younger son of a very old Kentish family originally settled at Halden, and a man to be held in honour wherever the life-workings, whether of animals or of plants, are deemed worthy of study. In due time he proceeded to Cambridge, where we are told botany and anatomy together with chemistry formed his "studies of relaxation."

We read of him collecting plants on the Gog-magog Hills, with the aid of RAY's *Catalogue*, accumulating fossils and butterflies, and studying the stars. Entering the Church he became perpetual curate of Teddington, Middlesex, and although he held other preferences he seems to have resided chiefly at the last named village, under whose church tower, built by himself, he was buried in 1761, at the ripe age of 84. Westminster Abbey contains a monument erected to his memory by the Princess Dowager of WALES, in whose establishment he had acted as clerk of the closet. The monument is in the tasteless style of the period, with a Latin inscription, which serves to testify the esteem in which he was held by the "mother of the best of kings," but which is silent as to his services to science. An amiable and benevolent man, he lived, says one of his biographers, not only "a blameless but in a high degree an exemplary life." Withal his career, apart from science, was uneventful and demands no further comment on our parts. What he did in science may be gleaned from a brief enumeration of some only of his principal papers, chiefly communicated to the Royal Society, of which he became a Fellow in 1717. The practical bent of his mind and the scope of his researches will be made so manifest from this enumeration that any lengthened comment will be unnecessary. His first paper contained an account of some experiments on the sun's heat in raising the sap in trees, a paper received with such favour by his contemporaries that, says PETER COLLINSON, to whose account in the *Annual Register* for 1765 we are indebted for some of these details, the request was "like the charge given by PHARAOH's daughter to the mother of MOSES to take care of her son. The result was the publication of STATICAL ESSAYS—*Vegetable Statics*, in 1727, concerning which we shall have more to say in the sequel.

Although he thought it quite consistent with his sacred office to perform experiments on animals which would now-a-days suffice to brand him in the eyes of some people as a vivisector, he was yet humane and careful of the material as of the spiritual welfare of his fellows. "His philosophy was not," says Sir JAS. ED. SMITH, "a barren accumulation for the ignorant to wonder at, for its professor to repose on in sottish self-sufficiency and uselessness, but an inexhaustible bank on which his piety and his benevolence were continually drawing." In accordance with this, we find him addressing a "friendly admonition to the drinkers of brandy and other spirituous liquors," making experiments with a view to find a solvent for stone in the bladder, and for preserving meat in long voyages, for checking fires, for ensuring the due ventilation of ships, mines, prisons, &c. In this latter matter he was so successful that the mortality in the Savoy and Newgate prisons was reduced from fifty or even a hundred in the year to four. He investigated the cause of earthquakes, invented a "seamage to measure unfathomable depths." He devised methods for keeping water and fish sweet with lime-water, also a "cheap and easy way to preserve corn sweet in sacks and heaps, and to sweeten it when musty, and a mode of distilling fresh-water from salt. In 1757 he published in the *Gentleman's Magazine* an easy method of purifying the air, and regulating its heat in Melon frames and hot greenhouses." This was done by inserting a bent pipe into the dung-bed, one orifice of which communicated with the outer air, the other opened in the frame, at the upper end of which were holes to carry off the impure air.

From this mere enumeration we glean a good idea of what manner of man he was. It is satisfactory to find that his merit was recognised. He refused higher preferment in the

Church, but he accepted the honour which the Royal Society conferred on him of a Copley Medal, and English science was honoured in his person in 1753, when HALES was elected one of the eight foreign members of the French Academy of Sciences on the decease of Sir HANS SLOANE.

So much we have gleaned from various sources. The best account of HALES' life and career that we have seen is that by PETER COLLINSON above referred to, and for indicating which we owe our thanks to the Rev. W. W. NEWBOLD.

It behoves us now to allude at somewhat fuller length to the book by HALES which will be longest remembered, and by which his position as a physiologist will be most securely upheld. Almost any text-book will furnish the leading details of HALES' *Statics*. Till a quite recent period HALES' experiments on certain subjects, as here recorded, formed the one source from which later writers took their inspiration. HALES' experiments were repeated and performed in a more or less modified form, and his general results were confirmed. Whether it was the amount of moisture evaporated from a leaf, the amount and force of the current of ascending sap, as measured on the cut surface of a Vine stump, it was—nay is—HALES' experiments which were and are quoted and relied on, and, as we have said, till quite recently but little has been added to what he did nearly two centuries ago. HALES' *magnum opus* is thus entitled:—"The Vegetable Statics; or, an Account of some Statical Experiments on the Sap in Vegetables, being an Essay towards a Natural History of Vegetation; also a Specimen of an Attempt to Analyse the Air by a Great Variety of Chemico-Statical Experiments, which were read at several meetings of the Royal Society." We have spoken of it as a *magnum opus*, and so in some sense it is, though in mere dimensions a small 8vo of a few pages. It appeared in 1726, ISAAC NEWTON being then President of the Royal Society, and it was dedicated to H.R.H. GEORGE PRINCE OF WALES. It passed through several editions, and was translated into the principal European languages. The headings to the chapters, which we transcribe in an abbreviated form, will show in what manner HALES may be said to have laid the foundation of vegetable physiology.

First of all, then, we come to a chapter showing the "quantities of moisture imbibed and perspired by plants and trees."

"2. Experiments whereby to find out the force with which trees imbibe moisture.

"3. Experiments showing the force of the sap in the bleeding season.

"4. Experiments showing the ready lateral motion of the sap, and consequently the lateral communication of the sap vessels. The free passage of it from the small branches towards the stem, as well as from the stem to the branches, with an account of some experiments relating to the circulation or non-circulation of the sap.

"5. Experiments whereby to prove that a considerable quantity of air is inspired by plants.

"6. A specimen of an attempt to analyse the air by chemico-statical experiments, which show in how great a proportion air is brought into the composition of animal, vegetable, and mineral substances, and withal how readily it resumes its elastic state when in the dissolution of those substances it is disengaged from them."

In this last series of researches HALES unwittingly confirmed the researches of BERNAUVE, made about the same time.

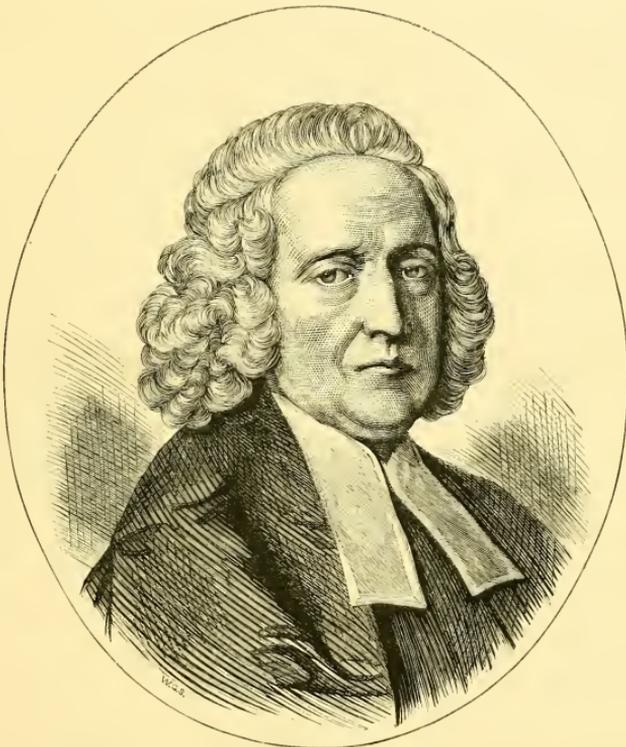

This is not the place to enter into any critical analysis of what HALES did. The above enumeration will suffice, particularly as his experiments and inferences are inwoven into all the more important text-books, and are, even

now, not displaced by more modern research. Our portrait is copied from a fine mezzotint, after a painting by HUDSON.

— WITH our present issue we present our subscribers with a sheet ALMANAC for the present year, designed and engraved by MR. WORTHINGTON SMITH. As on former occasions, the leading idea with the artist has been to reflect in the Almanac a few of the more prominent horticultural novelties, or salient points of interest during the year, and which have been chronicled in our pages. The Kew Supplement,

which is in so far a concession to Mr. WILSON'S scheme. It seems a pity, however, that the Council should have adopted this in so half-hearted a manner. Either let the scheme be adopted in full or let alone. We are well aware of the enormous incubus under which the Council now lies—we are well aware, too, of the labour that the Council has without fee or reward undergone—we recognise that the Council is the most popular of any that we have had for several years, but we must beg them not to succumb to the numbing paralysing influence which the action of the debenture-holders and the Commissioners seem to have induced. The horticultural spirit of the

a bush 10 to 12 feet high, "disregarding both frost and snow, being often covered with flowers from top to bottom, and forming a most beautiful object." At various times during the winter we have been favoured with specimens from Mr. BOSCAWEN, but a few days since, in order to corroborate his opinions still more forcibly, he sent us a large hamperful of the blooms of this delicious Heath. As this was the product of a small garden, it may be judged what would be its profusion in a large establishment. Both Maresfield and Lamorna are comparatively warm localities, though by no means exempt from severe frost and snow. We should be glad to know, from

STEPHEN HALES.

The Founder, in England, of Vegetable Physiology.

and that devoted to the King of the Belgians' conservatory are thus recalled to memory, together with several of the best new plants of the year. The germination and fructification of the Potato fungus, and of allied forms, are appropriately introduced, together with various garden-visitors, of some of whom it may be said in the garden that their room would be preferable to their company. The dates for flower-shows and meetings are as complete as we can make them at so early a period of the year. The mean temperatures are those recorded at Chiswick, on an average of forty years, as revised by Mr. GLAISHER.

— It will be observed that in the circular issued by the Council of the Royal Horticultural Society mention is made at the end of guinea Fellowships,

country is not dead, and it only awaits the earnest well-directed efforts of the Council to lend its aid in the reorganisation of the Society. At the annual meeting, which takes place in a few weeks, we shall hope to hear that the Council has roused itself to a more active policy than has been possible of late.

— We desire to call the attention of our readers to the beauty of ERICA COPONODES, by no means a new plant, but one not sufficiently known. The plant has something of the habit and appearance of E. arborea, but the flowers are larger and more bell-shaped. It was figured in 1835 in the *Botanical Register*, tab. 1698, from specimens supplied to Dr. LINDLEY by Messrs. WOOD, of Maresfield, Sussex, in whose nursery the plant was quite hardy, forming

other correspondents, how the plant fares with them. Where it thrives it is evidently one of the very best hardy winter-flowering shrubs.

— THE POST OFFICE authorities too often act as if they considered the people of this country made for the Post Office, and seem, in particular, to look on the Press of the country with aversion—as their greatest source of annoyance. The officials seem to forget that they are the servants of the public, and that the vexatious and often absurd regulations they make tend to restrict the revenue of the country, to say nothing of the injury done to the Press and to the public in general. Constantly some petty quibble is raised by the obstructiveness of some official whose desire seems to be "how not to do it." The *Printing Times* has

a long article on the subject, most of which we can endorse from our own experience. We trust that the truly childish regulations which are ignored one day, insisted on the next, interpreted to-day this way, tomorrow another way, will be swept away and replaced by a uniform and readily intelligible system. It is not only the annoyance to ourselves and our brethren of the Press which would be thus spared—that is a minor matter—but the labour and cost of the Post Office itself would be reduced, and the revenue at the same time increased. Sarcily the higher officials might be expected to know and put into practice some of the laws of political economy and business management.

— The origin of the GHENT AZALEAS is given in the last number of the *Revue de l'Horticulture Edgée*, by M. VAN HULLE, from which it appears that towards 1825 M. MORTIER, a nurseryman, of Ghent, conceived the idea of retarding the flowering of the early flowering varieties which were likely to be injured by early frosts, by fecundating them with the pollen of later flowering varieties. The experiment succeeded. Not only were flowers of later flowering tendency secured, but flowers of better form and more varied colour and more agreeable fragrance. This variety soon became known as Azalea Mortieriana, the varieties so called having been raised from various crosses between Azalea viscosa, nudiflora, pontica, and calendulacea. Ghent Azaleas are now propagated from seed, the one-year-old seedlings being grafted and treated as Camellias are. They are planted out in leaf-mould, and after two years are in a fit state for sale.

— The *Bulletin of the Belgian Federation of Horticultural Societies* for 1875 contains, in addition to the usual official matter, various articles on physiological subjects, to which we have already called attention. At p. 30 we observe an amusing mistake, which our Belgian friends would do well to correct. The President of the Royal Horticultural Society is stated to be — AVERTON, Esq.! We trace this to a "squib" which was published some time since, but which we hardly expected to see taken up *grand sérieux*. No wonder the poor Royal Horticultural Society is "agonisante."

— We have received from Mr. SINCLAIR, gardener to Sir H. D. INGLYB, Bart., Ripley Castle, Leeds, a copy of his GARDEN DIARY, or, rather, GARDEN ACCOUNT-BOOK. It contains a page for every day in the year, on which is printed the name of each kind of fruit, vegetable, salad, and herb, that is usually grown, with an *L. s. d.* column to show the money value of the quantity sent into the house each day. Cut flowers and plants are treated in the same way, and provision is made for recording the temperature three times a day, and for other observations on the weather, as well as for a few general remarks. Such a book as this should be kept by every gardener, who would find it an excellent check on extravagance either in the kitchen or still-room. The one before us, however, would have been better had the space allowed for the various entries been on a more liberal scale. We may note, too, that through the transposition of a letter the word *Borecole* is misspelt on every page.

— As originator of the ROYAL AGRICULTURAL BENEVOLENT INSTITUTION, Mr. MECHI suggests, in the *Agricultural Gazette*, that at all public agricultural dinners it should be one of the toasts. A good and worthy farmer, the late Mr. CONGREVE, has left to it £1000. We are informed that the late Mr. GEORGE MOORE has also bequeathed to it £1000. Mr. MECHI adds that he fears this very disastrous farmer's year will greatly add to the number of applicants for relief.

— The *Ceylon Times* states that a letter in its issue for December 7 bears testimony to all that has been written of the rapidity of growth of the PRICKLY COMFREY, showing clearly enough that it is a plant specially adapted to the soil and climate of Ceylon. "There should be no reason," says the journal in question, "why it might not be grown successfully on most of the poor waste lands of the low country. Messrs. THOMAS CHRISTY & Co.'s circular, forwarded to us with the letter, says, 'The Comfrey, being a deeply-rooted plant, is independent of weather and climate, for in the driest and hottest

seasons it will afford several heavy cuttings when all other vegetation is either burnt up or at a standstill.' With this plant at their disposal the natives of the poorer districts of the maritime provinces might turn to good account many an unproductive field, many a barren waste. We commend the idea to the Government, which has resolved on establishing an experimental garden at Meerigama, for the special development of products suitable to native industry. A better plant could not be grown for general distribution than the Prickly Comfrey, which might be gradually distributed amongst all villagers applying for cuttings of it."

— THE ENFORT OF ROSES TO PORTUGAL AND ASSAM last year by one of the leading nurserymen in the North of Ireland, is an interesting item in the events of the year. The taste for Rose growing and Rose showing which has sprung up in Portugal lately is, the *Irish Farmer's Gazette* has reason to believe, to be largely attributed to a member of the Crawford family, who is an enthusiastic rosarian, and is now settled on his property in one of the richest wine-producing districts of Portugal. It is to be hoped the cultivation of Roses in Assam will be as successful as has been the cultivation of the Chinese Tea plant in that country.

— Dr. E. GOEZE, we learn from the *Hamburger Gartenzeitung*, has left Lisbon, and taken the post of Inspector of the Botanic Garden at Greifswald.

— SIGNOR ALBERTIS, writing from NEW GUINEA, as quoted in a recent number of *Nature*, says:—"I expect to have about 500 species of dried plants, and between twenty and thirty of living plants, collected far in the interior, many of which I did not get afterwards. I hope Mr. C. MOORE will be satisfied, as I have some fine *Crotoms* and *Palms* among them, also some *Ferns* with variegated leaves, *Orchids*, and several other plants with variegated or spotted foliage, &c., from the very centre of New Guinea." *Adonis*, we are glad to hear, we have recently had the opportunity of inspecting some valuable importations from New Guinea at the nursery of Mr. B. S. WILLIAMS, and of which we hope to be able to say more on another occasion.

— We understand that two of Mr. Wm. BULL's collectors—Messrs. CARDER and SHUTTLEWORTH—have just returned from New Grenada, barely escaping with their lives. The revolution has extended throughout the United States of Colombia to such an extent that the utmost lawlessness now prevails. Mr. CARDER was unfortunately robbed, not only of his money and valuables, but also of his revolver. To escape, we understand, the collectors were obliged to go down the river Magdalena in a small open barge, and the river being unusually swollen, that was a highly dangerous alternative. Holders of the beautiful plants that come from that country, and who have secured good stocks, may be congratulated, as from the nature of the revolution it can scarcely be expected that any plants will be received from that country for some time to come. Many of the most handsome of the cool and comparatively cool *Orchids* now so high in popular estimation are indigenous to the United States of Colombia, such as *Madevella* Harayana, the always beautiful *Odontoglossum crispum* (Alexandra), *Pescatorea* and *Rozellia*, *Cattleya Mendelii*, and the exceedingly handsome *Odontoglossum vexillarium*.

— The Golden *Tuja occidentalis*, named *Vervaneana*, is generally represented as having foliage of a bronzy-yellow colour. There can now be seen at the Royal Nurseries, Ascot, some specimens in which the foliage is of a bright golden colour, and most effective. Perhaps the moist sandy bog of the Ascot Nurseries has something to do with the production of the striking gold of colour. The larger the plants the better character did they appear to possess.

— There seems to be considerable doubt as to whether the EMPIA, the supposed NEW DANCER FOR ORCHID-CROWERS, mentioned in our last issue, has anything to do with the destruction of *Orchid* roots or with the spinning of webs. We were assured that no such insects had been found in the *Orchid*-house from which the plant was originally derived, and that the web was in all probability spun by a species of spider

common in *Orchid*-houses. The subjoined letter from Mr. M. LUCAS will be read with interest, as having been written by one who has made a special study of the group of insects in question. We shall be obliged if any of our readers will forward us specimens of the insect, should they unfortunately discover it in their houses:—

"The notes and figures that appeared in your last number have much interested me; as *Embia* has long been one of my pet groups. Like Professor WESTWOOD I have never seen any but fully legged and absolutely wingless forms; yet from analogy the 'nymph' ought to have rudimentary wings, but not (as regards the mesothoracic wings) like the figure. I share his (impudic) doubts as to whether the *Embia* be a real spider in this case. Professor WESTWOOD has overlooked an important notice on the habits of *Embia*. M. LUCAS, in the *Exploration Scientifique de l'Algérie* (insects), pp. 113-114, says concerning his *Embia mauritanica* that he found the perfect insect in the environs of Algiers in June, living in families in sandy places, and running about rapidly on the stems of large herbaceous plants; not using the wigs when about to be captured. Of the larvae he says they are found under damp stones, and inhabit little silken tunnels, into which they retire when an attempt is made to seize them. They are very active, carnivorous, and not rare in winter. In March he placed several larvae in boxes with insects to feed them. He was not able to watch the transformation, but in one of the boxes he found, many months afterwards, a winged insect fully developed. A larva is noticed by HAGEN as having been found at Athens in November under a stone. I possess a larva of *Embia Solieri*, given to me by Mr. F. ASCOLE, found by him at Hyères, under a stone. I think these notes are sufficient to warrant doubts as to the supposed *Orchid*-destroying propensities of the creature, even supposing that the carnivorous habits attributed to them by M. LUCAS be not strictly correct. Analogy certainly suggests dry and dead vegetable matters as a more probable food; yet we have M. LUCAS' distinct assertion that they are carnivorous. R. M. Lachlan, 39, Lines Grove, Leitham."

— Mr. JOHN LEE having retired from the firm of Messrs. JOHN & CHARLES LEE, the business to long carried on by them has passed into the hands of Messrs. CHARLES LEE & SON, who will in future carry on the general business of the nursery and seed trade, at the Royal Vineyard Nursery, Hammersmith; and at the branch establishments at Feltham, Ealing, and Isleworth. It is the intention of the new firm to rebuild the extensive ranges of glass in the Hammersmith nursery on a new site, a portion of the old nursery being taken up for building purposes.

— A correspondent asks for a description of HANSTEIN'S METHOD OF KENEDING VEGETABLE TISSUES TRANSPARENT. He describes in his *Zoologische Abhandlungen*, heft 1, p. 5. It is very simple. He employed it especially in his investigations on the development of the embryo of phanerogamous plants. To release the embryo from the seed a dilute solution of caustic potash was used, and this rendered the embryo transparent. Very young embryos required only a few seconds' immersion in the solution, and afterwards placing in glycerin to make them transparent, and preserve them in that state. The glycerin was diluted with water and alcohol. Older embryos required longer treatment with the potash solution, and subsequent washing in caustic acid. Sometimes it happens that the preparation is too transparent, and the cell-walls are no longer distinguishable; but this is easily remedied by immersing it in a dilute solution of alum, when the walls become distinctly visible.

— To all concerned in gardening operations, the long-continued rains and stormy weather are becoming serious evils of more than ordinary moment. With the soil in its present waterlogged condition, all really useful and seasonable ground-work is out of the question; indeed, it is only with high, gravelly loams that sifting or planting of any kind is possible. Over vast tracts of the country the water is found within some 12 inches to 18 inches of the surface, but on close clay loams the water lies on the surface in puddles, the heavy rainfall having closed up the pores of the soil by constant friction. To attempt the cultivation of soil so affected would be folly, as the moving would simply result in the conversion of it into lumps of clay, to be baked into the consistence of bricks under the possible March wind. Patience under existing circumstances is an uncoloured virtue,

and one that all having to cultivate land will do well for the present to practise. To those engaged in the cultivation of tender plants under glass, the too common flooded stockholes are grave calamities. It is scarcely probable that whilst the water lies so high in the soil we shall have severe frosts, but with so much moisture in the atmosphere fire-heat is as essential for the reduction of damp as it is to maintain a high temperature. The expectation that we shall have a soft, moist winter, seems even more likely to be verified.

— In one of Messrs. VEITCH'S Orchid-houses is now flowering a charming plant of *MASDEVALLIA TOVARRENSIS*. From a compact tuft of broadly oblong strap-shaped leaves rise no less than twenty-nine flower-spikes, bearing some three, others four, pure white flowers. It is a veritable gem.

THE FRUITS AND VEGETABLES OF 1876.

THE Year 1876 stands almost pre-eminent for the great paucity of its Fruit crop in general, and of new or notable varieties in particular, so that our task of reviewing the acquisitions during the past year is an exceedingly light one. This great scarcity in the case of the outdoor fruits, such as Apples and Pears, is chiefly attributable to the action of the late spring frosts, which were last season of unusually long duration. Notwithstanding this general scarcity, we have the pleasure to record the introduction of a few sterling representative fruits.

Grapes naturally claim our first attention, their cultivation and improvement being specially the property of the British gardener. Here we have in Clive House Seedling a very decided acquisition in the class of late black Grapes. This is a seedling variety raised by a gentleman amateur, D. P. Bell, Esq., of Clive House, Alnwick, which is stated to be a cross between the Black Morocco and another black variety from Wortley. The bunches are large and well shouldered, of much the same appearance as the Alicante; the berries large, ovate in shape, with a dense black bloom. In flavour it has the rich sparkling character of the Morocco, and is very pleasant, so that it is free from the tart setting qualities of that variety, and of good constitution. It will prove to be one of the best late black Grapes, and we congratulate Mr. Bell on his success. We may note also, *en passant*, how well Mr. Pearson's last introduction, "Mrs. Pearson," is proving. It is one of the best white Grapes in cultivation.

Pine-apples merit this season a share of our attention. Seedling Pine-apples are of rare occurrence, and their production is evidence of considerable skill and perseverance. We therefore compliment Mr. Hunter, the very able gardener at Lambton Castle, for his success so far. His new seedling, "Lady Cecilia Lambton," is a large and very handsome fruit, not unlike a good Cayenne. Some fruits exhibited before the Fruit Committee were of fine appearance, but of inferior quality; we have, however, tasted some fruits which were excellent, so that we look forward to its taking a front place, independently of its great size and beauty, which will always recommend it.

Apples furnish us with no novelties of particular note this season, and Pears are nearly equally wanting; yet here we must mention one or two excellent additions, as *Amiral Cecile* and *William's Queen Victoria*—the former one of the richest-flavoured January Pears, the latter a good early autumn sort. Both are of medium size, and well worthy of cultivation.

Of Peaches and Nectarines there is little novelty to record, but attention may be called to some of the older but too little known sorts, such as *Goshawk*, which is one of Mr. Rivers' best seedlings, and is a fine large and excellent sort. Let us mention also *Desse* rather as one of the handsomest and best late Peaches, *tar. 60* little known.

Strawberries are not so prolific of novelty either this season, as usual, the excessive drought having materially interfered with their progress. A great many new Strawberries are annually introduced to us from the Continental raisers, the majority of which are worthless. Of the new English sorts we would especially recommend *Enchantress*, *Excelsior*, *Countess*, &c., all seedlings of Dr. Roden—free

and abundant bearers, of excellent quality, and most distinct.

Melons appeared in plentiful array, as usual, some promising scarlet-fleshed varieties coming from *Kashgar*, of which more may be said anon. Mr. Frisby's *Alexandra Palace* proved to be a first-class, high-flavoured green-flesh.

In the VEGETABLE DEPARTMENT the number of new names annually introduced to notice by our enterprising seedsmen is most confusing. We fail to see the necessity or the policy of this continual application of new and special names to well-known varieties. A new name cannot improve the quality of the article, neither do we believe it can tend to the reputation of its introducer in the long run. A spade is still a spade, and we should prefer to call it so, and the *Ne Plus Ultra* Pea bears a more honourable character by that name than any of its new-fangled aliases will ever attain. Improved selections of vegetables are most meritorious and require distinctive appellations, and it is certainly by careful selection that the high standard of excellence is maintained, so it has apparently become the fashion now to bestow a special name on all carefully saved seeds, whilst the original names are lost sight of. This is a tendency greatly to be deplored and discountenanced.

Amongst Peas, which of late years have been replete with novelty, thanks to the great skill of our hybridists, we have again a few very promising varieties to notice. *Criterion*, of Messrs. Veitch, is a seedling of the late Mr. Standish's, and is an early *de Plus Ultra*, name which it wants no better character. *Sutton's Giant Emerald Marrow* is a novel and very distinct sort, a tall, strong-growing variety, with large pods, and of good quality. It has the peculiar glassy green of the old *Dancerot Rival*. *Charley's Commander-in-Chief* is a large and very fine shew semi-wrinkled green Marrow in appearance like *Sicem*. *Allen's Champion* is a good selection of *Dickson's Favourite*, and *Taber's Market Favourite* is a good selection of the *Essex Rival*, but distinct.

Onions we call special attention to the *Trebons*, which, being a new variety, was proved last season to be so exceptionally good for autumn sowing that it deserves all the notice we can give it. We would also note the *Rocca* as being the best form of the large *Tripoli* section.

Of Kidney Beans we make note of the *Early White Etampe*, as being a very early sort; *Nain Blanc Quarantin*, an excellent second early; *Rachel*, *Yellow Champion*, and *Zebra* are all excellent sorts, if so many varieties are really required.

Cauliflowers there is nothing specially new. In the *Chiswick* trials the *Lenormand* was specially distinct, as was the *Extra Earliest Paris*, which is used for forcing purposes, and little known in this country. The *Early variety* seemed to engulph many of the so-called new varieties of former years. Of Cabbages, *Carter's Heartwell* is a good variety of the *Norpareil*.

Amongst Salads we must not omit to mention the *Whitloof*, or *Brussels Chisney*. This is not a new vegetable, but although extremely common in many parts of the Continent, it was scarcely known or cultivated in this country until the past season. It is of the easiest cultivation, and when blanched like *Seakale* it is excellent as a salad or cooked. Speaking of *Seakale*, we are reminded of a distinct sort cultivated by Messrs. Stuart & Mein, the leaves of which are green, with no purplish colouring, consequently when blanched they are pure white, and although exposed, never assume that purplish tint of the common form. On this account it may prove valuable as a market variety.

Potatoes come last, but are far from being the least of the gardener's charges, or the least deserving of notice. Of late years it is pleasant to note the increasing popularity of this vegetable. Immense interest is now being taken, not only in improved cultivation, but also in the production of improved varieties, both in this country and in America, and the improvement is manifest. From America we have received quite a distinct class, remarkable for their great cropping qualities, and for possessing a peculiar whiteness of flesh. In some seasons and in some situations they are wonderfully good, but when they lose the finer qualities of the English varieties. To overcome this—to blend the good properties of both in one, many of our enterprising men have been endeavouring to cross them, and in this Mr. Bennett, of Enville, has succeeded by producing the *Schoolmaster*, now offered

by Mr. Turner. This is a splendid victory, and a splendid Potato in every sense. It is of the *Regent* appearance—a most extraordinary cropper, and of first-class quality. *Criterion* is very similar to this. *Wyllie Seedling* is a fine handsome Potato. It is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. Of other sorts we mention *Prince Arthur*, referring to the *Lapstone* section; *Lyons Favourite*, which is a variety raised at the village of Wyllie some years ago, and, strangely enough, is scarcely distinguishable from the *American Bessie's Prolific*. assistance cannot be too highly deprecated. I am free to confess that I am not altogether clear in this matter myself, being far too prone to "follow the leader" rather than take a new course; but, having a desire to be free, I have occasionally worked out a theory of my own, and this one of Vine roots is by no means the least interesting. I have no doubt of the originality of discovery that Vines do not make new feeding roots till the buds are expanded, for I doubt not that scores have known this for years; still the general opinion is that root-growth does and must precede leaf development, but to my own satisfaction I have proved that they do not—more, that though they may be made to produce roots in advance of top-growth by the application of heat to the border, yet that such a practice is injurious to the general welfare of the Vines; both border and other, in a remarkable manner with Mr. Baies' experience, and I doubt not that many of your readers could give similar testimony. Still the great majority of gardeners believe in the doctrine of root precedence; hence all labour and anxiety to keep a low temperature in early Vine borders. Like Mr. Baies, I had strongly imbibed the doctrine, and from those whom I believed best calculated to teach it; and it was only after the demonstrative experiment recorded in my vol. 4, that I was fairly given up, and, being wrong tenaciously I held the doctrine, though this occurred some six years ago, I have hardly ever been able to give up the practice of covering early Vine borders, to induce root formation by the heat so generated. However, in the last year, I have merely covered the borders to keep out the cold, doing it as early in the autumn as opportunity offered, with a view of retaining part of the as yet unexhausted summer-heat; and my conviction is, that if outside borders were covered with straw, or other covering would be requisite, though forcing began ever so early. But the question here arises, Why have outside Vine borders at all? Given a plentiful supply of water, and an easy mode of applying it, and why have inside borders for several reasons preferable—1st, they are independent of weather, no covering from cold or protection from wet being required. Liquid and other forms of manure can be more freely applied. 2nd, they are independent of weather, and an equable temperature as compared with the heads of the Vines than can possibly be the case with outside borders; and I am convinced that at least one spoke in the wheel of successful culture is equality of temperature. 3rd, they are independent of weather. I am an advocate for late viney borders being also entirely inside, for the same reasons as those just mentioned. Further, I contend that the orthodox style of Vine borders is founded on a wrong principle—half border inside, and other half outside—one half protected from all weathers, and when the Grapes are ripe, dry as dust, the other half exposed to all the rain that falls, and sometimes perhaps a bound with frost. Put an advocate of such borders in a similar predicament on a cold frosty night, i.e., with one foot outside the blanket and the other safely enclosed in it, and one can fancy how well pleased to have both inside. I know I am treading on tender ground in this matter, and shall probably be met with the reply that perhaps the best Grapes that have ever been grown were from such borders. Granted that they may have been; it does not follow that yours would not have been better if grown on what I term the inside style. I contend that with the roots entirely in, or entirely outside. Again, it is always more pleasant to record successes, than failures, hence the few records of the latter will appear in print; but all will admit that, as regards "one half border inside, and other half outside," though I do not wish to infer, there is just a possibility that "half-and-half" borders may have been accidental to such failures. Certainly as regards myself, if obliged to give a decisive answer, I should without hesitation, and with strong conviction, that it was right, answer in the affirmative. The subject is to me of such deep interest that I am selfish enough to hope that many others will have a say in the matter. *H. W. Williams, Westbury.* Will some of our correspondents write what they think of the roots in outside and inside borders respectively at the same time? Ens.]

Fruiting of the White Jasmine.—Observing in your last number a notice of the extreme rarity of the fruiting of the white Jasmine, I beg to enclose you a specimen which I found this morning in my garden. The fruiting has occurred in the same place in this neighbourhood, I have made the unusual event the excuse for troubling you. *G. Fuller, Gey, The Grange, Eury St. Edmunds, Dec. 31, 1876.*

Late Roses.—Passing to-day (December 31) the residence of Mrs. Jones, widow of the late proprietor of the White Hart Hotel, situated on Milford Hill, Salisbury (rather an exposed situation), I observed that the late autumnal weather had done good. Climbing Forester and Climbing Devoniensis; as on a standard

fastened to the wall a bloom, finely developed, of what in colour exactly resembles the *Madame Rothschild*. It was not nearly enough, however, to speak positively as to the variety. The trees, which face almost due west, are well sheltered from north winds, and effectively protected from wet by widely projecting eaves. To "speak Rose" in December, as in June," seems now-a-days a less ridiculous thing than it was supposed to be in the "degenerate days" of Byron. *C. H.*

Epiphyllum truncatum.—It gave me much pleasure to see the features of an old favourite of mine again appearing in the pages of the *Gardener's Chronicle*; I mean your reprint of engrafted *Cactus lignosus*. It is thirty years ago since the sketch was taken by the late H. Sellenden Ker, Esq., of Chesant, when on a visit to Mrs. Huskisson, at Earham, Sussex, from a plant grown by me and in the company of the fine "Kew's" lively recollection of seeing him sketching and of my placing the plant in better position for the purpose. I had four of these large plants at the time, the two tallest being on stems about 4 feet in height, the heads fully 2 feet in diameter. They had been in the open air, and under Cereus growing under. The other two were of the double section, and had the Cereus mixed, as shown in your illustration. These plants after flowering were allowed to remain in the warm end of the same glass house, and they had been in the open air during that time. In the spring they were moved to the back of a lean-to Orchid-house, and encouraged into growth. The soil they were grown in was similar to that recommended by Mr. Bester at p. 508. The plants were watered with the usual quantity for flowering they were moulded over to the depth of 1½ inch with fowl-dung fresh out of the fowl-house. In the course of a few weeks the roots were seen to draw up over the surface until the mass became white. The plants were then covered with a mat of straw, and removed by poking it up with a pointed stick, and a similar mulching put on. This method served for years without shifting the plants into larger sized pots. Sometimes as many as three or four flowers would grow on the same stem, and the colour of the petals and the mass of bloom they produced was sometimes marvellous. The *Persikia* is a strong free-rooting plant and does not require tampering with by starving cultivation. It was either Mr. Ker or some friend of his who first suggested the subject, and I reproduce the figure of my plant for the frontispiece of his *Theory of Horticulture*, where I think it will be seen to correspond with the figure in the *Gardener's Chronicle*. [Not in the second edition]. *J. Webster, Gordon Castle.*

Fungoid Christmas and New Year's Cards.—Messrs. De la Rue & Co. have this Christmas, among the best of the admirable productions they have issued a set of six [six] Fungoid Christmas or New Year's cards: No. 31. Each card shows a group of fungi, over and about which fairies, elves, little goblins, and witches are disputing themselves. As the groups of Agarics, &c., are copied from nature, and are made up by myself and my friend Mr. W. Wilson Saunders, many fungological friends may reasonably imagine that we have been improperly reducing the higher fungi to this lower (?) level. But this is not so; and for the two groups complete. One of the titles of the cards was from a tree in a shop-window, just as the first I recently knew of a new edition of my *Mushrooms and Toadstools*, with new key plates, &c., was from seeing a criticism of it in a newspaper. This criticism was not even given, but I do not think the publishers have arranged for all details to be right. The first of Messrs. De la Rue's fungoid cards reproduces on its left my figure (now in the British Museum) of *Cantharellus carbonarius*. The natural habitat of *Cantharellus* is wood-sheds; and care is made to grow in a nice grassy place amongst Ferns, and on one pileus is a Dryad with a red feather in her cap. On the right of this card is my *Boletus parasiticus*, Bull (also in the British Museum). On the pileus of one of the two trees grows complete. One of the titles is in the foreground. The fungus upon which the *Boletus* is parasitic is omitted (*Scleroderma*), probably on account of its strong resemblance in my drawing (to the non-fungoid mind) to a lump of horse-dung. My *Boletus* is well reproduced, but I do not think Mr. Wilson Saunders' group of *Cortinarius* cerealesces. *Fr. (Mycological Illustrations, plate 22)*, but Messrs. De la Rue's artist, not having fungus in his heart, has omitted the *cortina* (or veil) from the *Cortinarius*; and the *Boletus* is shown in the foreground. Nine amusing sprites are playing in the foreground. Card No. 3 is a plant I first published as British, viz., *Cortinarius dilapshus*, Fr. My original, now in the British Museum, or the plate in *Mycological Illustrations*, is well reproduced, but I do not think it is omitted from both specimens. Queen Mab is introduced in the foreground directing the cutting down of one of the two fungi by two infant axe-bearing gnomes. Card No. 4, possibly original, is certainly a fungological nondescript. Four elves are dancing on

the pileus of *Agaricus muscarius* (judging from its red colour and its white gills, but that of the Christmas-card fungus is ringless, and clearly pertains to a Mushroom belonging to a different section. In the foreground are three small beings belonging to the world of dreams, and a small original fungus with no characters in particular. Card No. 5 reproduces on its left Mr. Wilson Saunders' illustration of *Coprinus lagopus*, Fr.; a wood nymph and five evil geni of the masculine gender are engaged in overturning one specimen. On the right of this picture is a possible *Tricholoma*, which is original or copied, cannot say. Card No. 6 is a similar fungus with this last occurs on the right of this card, in which five little dream-folk and two witches figure. The witches with their cauldron are concocting Macbethian broth, whilst on the left are three Cereus, and a reproduction of Mr. Saunders' *Agaricus lacrymabundus*, Fr. The characteristic veil is again omitted, which shows that the copyist who has honoured us by reproducing our drawings has not a fungus eye. *W. G. Smith.*

Horse Radish Culture.—An essay on the culture of this root was read at the West Derby Gardeners' Mutual Improvement Society on December 18 by Mr. C. Gore, of West Derby. In this culture may be of service to some of the readers of the *Gardener's Chronicle*. The whole should be lifted in November, and have the long roots cut off, the remainder being laid in in some convenient part of the garden, and covered with a layer of straw, and be selected for planting, and cut to the length of 8 or 10 inches. All the fibres should be cut off to within half an inch of the bottom (the back of an old knife being a good thing for this purpose), then rubbed with a cloth, so that no fibres remain for branching, except at the bottom. The pieces selected should be tied in bundles, and plunged in ashes with their roots exposed till March, when they should be planted in ground that has been well manured, and deeply dug or trenched to the depth of 18 inches. The distance the rows should be 18 inches apart, and the same distance from root to root, a straight stick being used to dibble them in. The holes are lightly filled up, and the rows covered to the depth of 2 inches. Here they should remain till the time mentioned for taking them up, the rootlets being cut off and prepared as above described for next season's planting. An average sized stick was produced for the inspection of the members, and it measured 6 inches in circumference, and 18 inches in length. The soil was very crisp and tender. I have obtained a sample from Mr. Gore, and have sent it for your inspection. *Wm. Bardsley, West Derby, Liverpool.* [A very fine sample: straight, stout, and succulent. Eds.]

Poinsettias.—I can well imagine what a glorious sight your correspondent (see p. 772) must have had at Acton. I believe, as a rule, Poinsettias are grown too much heat. I have some of the best I ever had high, grown in 4½ and 3½ pots. They were put in as cuttings in the last week in July, and when fairly struck, they were taken into the intermediate-house, where they still remain till wanted for decoration. I have measured one best 12-inch which is 17 inches in diameter, with thirty-four scarlet bracted leaves; height 1 foot 6 inches from the pot. Such plants are a welcome addition on the Christmas table. If wanted for decorating rooms, &c., they will last double the time. I have some of the best I ever had colour is much brighter. *T. Ester, Glenhurst, Essex.*

—A good example of what Poinsettias ought to be for decorative purposes may now be seen in the stove at Croxteth Hall, the Earl of Sefton's. The plants were raised in the last week in the last week in spring, in heat, and grown in cold frames during the summer, in 5, 6, and 8-inch pots, and vary in height from 2 to 3 feet. The floral leaves or bracts are brilliant in colour, the heads measuring from 12 to 16 inches in diameter. *William Bardsley, West Derby, Liverpool.*

Rainfall in 1876 at Wallington, Northumberland.—The following is a copy of the monthly register of rainfall kept here during the past year: January, 1.7; February, 3.77; March, 2.77; April, 4.2; May, 1.3; June, 1.86; July, 1.35; August, 1.51; September, 3.82; October, 2.22; November, 3.87; December, 1.95; total, 37.95. The greatest stand is 12 inches above the ground, and 398 feet 6 inches above sea level. The rainfall is recorded every day at 9 a.m. *W. McCumbe, Gr. to Sir W. C. Trevelyan, Bart., Wallington Hall.*

Lardizabala biternata.—In the last number of the *Gardener's Chronicle* you ask for information respecting the hardiness of *Lardizabala biternata*. It has now been growing in my garden on a south wall for five or six years, and has done very well, and is doing thoroughly well, and this year it fruited—two small bunches of Grape-like fruit. I consider it quite hardy, but, as I stated in February last, let no one plant it in preference to *Stamtonia latifolia*, which I am glad to say has this year again fruited on a west

wall. I again repeat that this is, without any exception, the very best hardy evergreen creeper now cultivated in England. *K. K., Tadley, Exeter, Dec. 30.*

Hints to Young Gardeners.—Young gardeners are very frequently alluded to in complimentary terms by the older members of the craft, and many unwarrantable faults laid to their charge. How is this? That there are faults on both sides I know, but I fear the fault-finders will fail to improve the position or proficiency of either. What is wanting is the establishment of a better feeling, and a little more regard for each other's interests. If head gardeners would treat their young men as they would like to be treated themselves, and let their own conduct be an example, it would save them many of the annoyances they complain of, for those who cannot be managed by good words and feelings can rarely be managed at all. It would be well too for young gardeners to remember that there is no occupation that requires more careful energy and forethought than gardening, and that success depends more or less upon the energy and ability of every separate individual employed in the garden, and any extra achievement adds as much to their own reputation as to their employer's satisfaction. I have always made this my rule of conduct, in spite of many discouragements, and I have succeeded beyond my expectation. I have had experience in nurseries, public and private gardens in many counties, and have had to deal with many dispositions, but have never met with such dunces and black sheep as are too often represented. *J. H. Goodacre, Elevation.*

Dwarf Chrysanthemums.—In answer to an enquiry by one of your correspondents, as to whether the dwarf Chrysanthemums exhibited by me at the Liverpool show were from layers or struck from cuttings, I beg to say that they were struck from cuttings taken on August 1st and struck in the same pot they were bloomed in, they having only one stem each, with one bloom to each plant. *W. Tinwood, The Gardens, Allerton Priory.*

Strawberry Growing.—Whilst admitting the importance of soil, climate, and a good variety in the successful growing of Strawberries, I am yet inclined to believe that, with careful cultivation, very fine fruit may be grown in all good garden soils. The great mistake made by many is planting too thickly at first, and allowing the plants to remain from year to year on the same bed. Thus we often find the plants growing together in a tangled mass, and the result is when a pinch of dry weather comes in June or July, they receive a serious check, the quality of the fruit is depressed, and the constitution of the plant weakened, possibly so much so that the plants are unable to mature their fruiting crowns for the following season. Thus the plants go on from bad to worse. Such a "lazy bed" system will fully account for some varieties growing and cropping well for a few years, and then becoming almost barren and the fruit less flavoured. As a grower of from forty to fifty distinct varieties on light soil, in a backward situation, I have adopted the following system of cultivation, and have found little difficulty in growing abundant crops of excellent fruit from most of the varieties I have tried. In fact, judging by the quality of the fruit grown on one-year-old plants, you might be led to suppose that nearly all varieties were equally good, and it is only after a second or third crop of fruit that you are able to distinguish the better qualities of the favourite sorts. A well-grown one-year-old plant will bear abundance of fruit, and the quality and size all that can be desired. My plan is to give the land one thorough cultivation the winter previous to planting, to plant the bed in July on land that has grown a crop of early Potatoes, in rows 30 inches apart, and 15 inches between each plant, with strong, healthy, well-rooted runners taken from one-year-old fruit-bearing plants only; to let the plants stand to bear two, or at the most, three crops of fruit; as soon as the first crop of fruit is gathered to remove every other plant, thus leaving them at a distance of 30 inches apart each way; to keep the hoe constant in working during the summer and autumn months after planting; and to remove all runners as fast as they make their appearance; in early spring to mulch the land with fresh stable manure at the rate of a good barrowful to every twenty plants, and when the plants are in bloom to finish off with a second mulching of clean straw. Thus treated, Strawberries may be grown in almost any situation, and at least a score good varieties may be selected from, any one of which may be cultivated with satisfactory results. *W. Lovell, Watercourse, York.*

Encyphalartos villosus.—We have so recently figured this handsome Cycad that we need add but little to what we have already said on the subject. We avail ourselves, however, of the opportunity pre-

sented to us by Mr. Bull of figuring the male spike. The illustration (fig. 4) is two-thirds the size of Nature, and the colour a beautiful grass-green, frosted over with a silvery bloom like that of a *Plum*. The

FIG. 4.—MALE SPIKE AND FLORAL DETAILS OF ENCYPHALARTOS VILLOsus.

details show side and front views of the anther-scale, together with a section of the same of natural size. Magnified representations are given of the anther, invested with hairs at the base, and of the pollen cells magnified 150 diameters, the latter on the authority of Mr. Worthington Smith. *Eds.]*

The True Service Tree.—It may interest some of your readers to know that the old tree that Professor Buckman speaks of is still alive, and bears from 5 to 8 bushels of fruit annually. It may be of great age, as I see very little difference the last eighteen years. We have both forms here, but the Apple-shaped is a much smaller tree, and a shy bearer. *T. Foster, Glenhurst, Essex.*

The Garibaldi Strawberry.—My attention has been called to the remarks that have appeared for some weeks in your "Home Correspondence" as to this Strawberry. The Garibaldi raised by me about twenty years ago was the only one selected from several hundreds of seedlings, the seed of which was saved principally from Elton and Keens' Seedling, and was sent out by me in the year 1866. Two or three years previous to that date I foolishly let a gentleman's gardener have some of the plants to test, and, contrary to promise, he distributed them amongst a number of his friends, which consequently disheartened me from bringing it prominently before the public until 1866. I enclose a copy of a circular issued by me at that time, from which you will be able to gather a description of my Garibaldi. *Theo. Armstrong, Netherwood, near Longbridge, near Macclesfield, Carlisle.* (From the circular sent to us by Mr. Armstrong we gather that the variety raised by him is "one of the healthiest, hardest, and earliest grown"; it resembles the Elton Pine in colour and size; it ripens earlier, and fruits longer than the Keens' Seedling, and is of a superior flavor; it is an immense cropper, and grows well on exposed situations, and on land where the Keens' Seedling does not grow well." *Eds.]*

As our name has been introduced in connection with the Garibaldi Strawberry controversy, we may state that we got our stock of it from Mr. Thomas Armstrong, Benah Gardens, near Carlisle, in the autumn of 1865. We ordered it after seeing the fruit, and the impression that it was a new variety raised by Mr. Armstrong, who stated that it was earlier, a much greater bearer, and would give a longer season of fruit than Keens' Seedling. We had no knowledge of the previous existence of any variety under the name of Garibaldi. Vicomtesse Héricat de Thury we got for the first time from Mr. Chas. Turner, Slough, in February, 1871, expecting to find it distinct from any we had, but we have no doubt now that it is synonymous with Garibaldi, which we have found to be the most prolific and generally useful Strawberry in our collection. *Dickson & Co., Waterloo Place, Edinburgh.* (Will some of our French friends give us the origin of the Vicomtesse Héricat de Thury? *Eds.]*

Late Grapes: Mrs. Pince's Vagaries.—Mr. Grieve has (see p. 836) undoubtedly made an excellent selection of late Grapes; he has noted also two Vines of Mrs. Pince's Black Muscat growing "in the same house and under the same conditions," one of which has produced black and the other red Grapes. Seeing that this Grape is prone to produce black fruit, which so greatly impairs its value for dessert purposes, it becomes important to ascertain, if possible, the cause of its non-colouring. I should like Mr. Grieve to examine minutely the two Vines to which he has referred. Are they of the same age, excellently cropped, both having the same relative proportion of foliage and fruit, and especially are they from the same source? There must be a cause for one Vine producing black Grapes, and a different cause for the other yielding red fruit. Can Mr. Grieve tell us wherein is this difference, and what is its nature? If he can do so, he will command the thanks of many gardeners who have long been puzzled to account for the caprices of this fine Grape, refusing to appear in a "black dress." He cannot satisfactorily account for the difference in colouring alluded to, would he raise a young Vine from each of his stocks, and tell us, in due time, if the deficiency of colour so common with Mrs. Pince is constitutional and hereditary? Mr. Grieve appears to have an excellent opportunity of settling that important point which, as yet, is a matter of controversy. Some specimens of Mrs. Pince invariably produce Grapes as "black as swags," while others are a constant yield of fruit as "brown as hedges," and no one has yet told us the "reason why." *Enquirer.*

The Royal Horticultural Society.—In common with other Fellows of the Royal Horticultural Society, I have received a copy of the circular spoken of in your last edition. Permit me to make one or two observations respecting it, and to begin, as we write *Eds.]*, so that we may delete £50,000 from our capital account. This is joyful news for the Fellows, only one can scarcely believe that the debenture-

holders have been so generous; but, at least, it is a grand way of settling the difficulty. Is our Council in earnest, or is it a joke? Read one of the earlier paragraphs:—"That this meeting (*i. e.*, of debenture-holders held on November 23, 1876) declines to authorise the surrender of the lease of the grounds to the Commissioners on the terms mentioned in the letter of the Society of November 2, 1876, and the meeting will not authorise a surrender of the lease unless provision be made for the payment of the debenture debt in full, by reasonable instalments, with the interest in the meantime, and that a copy of this resolution be forwarded to the Society." The Council then goes on to say:—"In these circumstances no open appears open to the Council but to confirm their anxiety of the Society's interests. Pray what would our Council make or wish us to believe in these statements? Here they acknowledge beyond all possibility of a doubt that the debenture-holders have some charge on the Society beyond the doubtful payment of some charge upon their surplus income, for there would be no difficulty in proving that, were this said income double its present amount, there could easily be found a proper way of spending it without any real meaning of our charter; and that the debenture-holders have been left, not to the justice, but the generosity of the Council. In lieu of not being in debt, it rather looks as though we had in part mortgaged our lease in some way to the debenture-holders, and it appears to me that it would be much more satisfactory if the Council were to place before the Fellows a succinct statement of affairs at the annual meeting, or before, if possible, in such a way as to be intelligible to brains of such mean capacity as mine, than incur the expense of printing and posting statements which are incredible and if they would favour us with some particulars of our worthy co-partners the Commissioners, and the footing on which we now stand with them; I think it would be of interest to me, who believe we still linger in the Valley of Tears, for a more judicious body of that august body, and their actions for some considerable time, they have been marching to the tune of—

"O who dare meddle w' me,
And who dare meddle w' me!
My name it is little Jack Elliott,
And who dare meddle w' me!"

The proposition of the Council to make the two guinea tickets transferable is most decidedly good; and I am very glad that the Council have decided sooner, though I feel sure that this and the proposed guinea Fellowships will not cause any large influx into our ranks, nor can it be for one moment expected till such time as the whole *raisonne* of the affair is changed. As they refer to the National Institute, I must hang by his own head." Our good fish does not seem to have done so, and we seem to be waiting with bated breath for Blucher's last word.—

"Nostis, sis habens vias von mir gelernt, lernen,
Sie auch von mir abig sterben!"

Robert Prince Glendinning.

Robert Prince Glendinning. Will you condescend to make space for a few remarks on the last clause of the notice to Fellows lately circulated by the Council of the Royal Horticultural Society wherein Guinea Fellowships but without the right of voting are proposed. Judging from the tone of very many letters which I have received country Fellows will be satisfied with semi-Fellowships, those who live at a distance, who will give a guinea to support a society they believe to be useful, though they get little direct good from its proceedings, and who do not expect the honour of full Fellowships will assuredly give the little longer waiting get. The first bid for their support was a guinea Associateship, a guinea part Fellowship is now offered, a full Fellowship is not. The Council have had their backs to the wall; there was great difficulty in keeping old Fellows and in bringing in new ones, even when the South Kensington Garden was well kept up; in its present state of *disability* the difficulty is greatly increased. Let us hope the neighbourhood will generally subscribe, otherwise it is not a pleasant reflection, however economical the expenditure on the garden may be, as long as it is kept open there will be a charge of some £600 a year for rates and taxes, a severe tax for the last of new to be used, and no paid out of horticultural money. I hope that those who believe in guinea Fellowships, and who are canvassing their friends through the country, will not relax their exertions. A year ago I thought we had tried to come to this, but it was led to believe that the Council were likely to undertake it. Judging from the great number of first-class names collected in two months, a year's work would have given us enough Fellows to make us independent of State assistance. By this time, if we were to have completed the necessary number. Strong societies have grown up starting with supporters less in influence and number than we already have. It is now almost necessary to justify the independent course we are taking, though it is not as if it is no longer I who am advocating guinea Fellowships as the

one means of making the Society what it should be—I am merely the mouthpiece of very many of the best and most experienced horticulturalists of the country, of all ranks, who urge me not to let the matter rest till the guinea Fellowships are accomplished. On a former occasion I had got independent action, having means of knowing more of the circumstances of the time than some of my friends had. I was so certain that it was for the interest of the Society that the Council of 1873 should be continued in office, that I was very ready to resign, and I was, I think, circulated the lady Fellows, asking for their proxies to support the Council. One hundred and fifty ladies trusted me with their proxies; twenty more proxies would have carried the vote of confidence, and I am sure, if I had any office, I should have been the arrangement with the Commissioners on the eve of settlement would have been accomplished, with the result that the Society would now have been free from its debenture debt, free from rent, and with a conditional accession of £1,000, then estimated to amount to £1,000, but which last I doubt would have been continued. Therefore, having been proved right once, I claim the inference. I hope that nothing more will be said about turning out the present Council. On my own responsibility, and without any office, I am finding suitable men who would undertake the office. The present work is both unpleasant and thankless. When we get a really good Society with only horticultural work there will be plenty of first-class names to serve. *George F. Wilson, Heatherbank, Wodbridge.*

Veitch's Self-Protecting Autumn Broccoli.—I can fully endorse all that Mr. W. Johnstone stated in your last issue respecting this Broccoli. I have seen it, and get the first water, and I am sure when it becomes known it will be in great request. I have been cutting this variety for the last six weeks, and have this day (January 2) cut six as beautiful heads as any one could wish, from 4 inches to 6 inches in diameter, as clear and white as a curd. In future I intend growing this kind for follow the Autumn Giant. *J. Little, Cheltenham.*

The Potato and its Difficulties.—The Potato question is the "Eastern Question" of cultivators; it may seem easy, but is full of difficulties. How many have tried to get the first water, and I am sure when it becomes known it will be in great request. I have been cutting this variety for the last six weeks, and have this day (January 2) cut six as beautiful heads as any one could wish, from 4 inches to 6 inches in diameter, as clear and white as a curd. In future I intend growing this kind for follow the Autumn Giant. *J. Little, Cheltenham.*

essential oil." Mr. Worthington Smith's promised manure, if we may judge from the hints he has given us, will be of an odorous nature, and perhaps is intended to act on this principle as a disinfectant. A little crude petroleum oil would make it still more fragrant. It will no doubt command a trial. *S. S., Swainwick.*

The Villa Garden.

THE VILLA GARDEN GREENHOUSE.—This heading is selected not so much to serve the purpose of setting forth a few remarks as to its management at this season of the year—for we have but recently dealt with that part of the subject—as for the purpose of pointing out errors that sometimes creep into their construction and position.

The modern builder of Villa residences must have but a limited range of ideas as to the principles required in constructing a house suited to the growth of plants; in fact a house suited to the cultivation of plants appears to be the very thing that he least considers. If the builder sets up a plant structure it is for the purpose of situating the house, and the position is north, east, south, or west, as the fancy suits him. A glass structure is deemed to enhance the appearance of a house, while it certainly increases the assessment or rateable value of a dwelling; therefore, it is deemed politic to erect one. In the case of an ordinary detached Villa residence, it generally comes in at the back of the house, and the back entrance leads through it into the garden, and as such houses generally have a basement floor the house is level with the ground floor, and built up over a coal-hole or cellar, or merely on brick pillars.

And the modern builder goes in for decorative effect, and therefore employs architectural ornamentation, and sometimes there is a heavy wooden roof with elaborate carving, or a roof partly wood and partly glass, but so much of the former, and so little of the latter that it might just as well have been wholly of wood. He has the impression that plants will flourish in any shelter, and not to any circumstances, light or dark; and if such is not the case he cares but little. He has built the greenhouse, and the plants must take care of themselves.

Then, too, he must have some colour about it, and so he employs plenty of green and red glass, and we invariably find that the green is of the greenest, and the red of the reddest; for do not these impart a picturesque appearance to the house whereon the rays of the declining sun fall, and light up with crimson glow and purple radiance the house of glass? But about the plants? we ask, and the reply comes back—"A conservatory is a conservatory, and plants are quite another thing;" and with that one must be satisfied.

A neighbour of ours—a lady, fond of flowers, as most ladies are—some time since took a Villa residence in our neighbourhood, and was much attracted towards the house by one of these variegated conservatories. A friend of hers shortly after gave her a plant of Kennedy monophylla, raised from seed sent home from New Holland by a relative of the lady's, and she naturally attached much importance to the plant. It was placed in the conservatory, which was in a north aspect, and had but little sun, save and except about midsummer, when a little shone upon it in the evenings; and it was not to be wondered at that some little time after the plant was sent home with a request that we would explain the reason of its having become denuded of leaves. The reason was too evident—the dark, cold, sunless quarters it occupied were as detrimental to its well-being as could well be imagined; but a temporary sojourn in a greenhouse soon brought it round again, only to be returned to its inhospitable home, to again decline.

That great essential to the well-being of plants, light, is sacrificed at the shrine of appearance. One builder's conception of what is requisite for plants recalls to mind a circumstance that occurred a few years ago when taking a journey through Ireland. It was within a few days of a horticultural exhibition in the south of the Kingdom, and a gardener accustomed to exhibit Fuchsias had some plants that were quite sufficiently advanced in bloom a few days before the date of exhibition, and he hit upon an expedient for prolonging their flower by placing the plants in a dark cellar. I was asked to inspect them after they had been in the tree or four days, and sorry subjects they presented, for nearly all the leaves had

turned yellow and fallen; and the Hibernian horticulturist was sorely perplexed at the result—one that he had never calculated upon. It was a sad ending to so much pains; the absence of light had upset all his calculations—

"Since light so necessary is to life,
And almost life itself,"

it is obvious that to unnecessarily exclude it was wrong in practice. It can be easily subdued by artificial means; but by no means can you add one iota to the daylight of the dulllest day.

When larger and more roomy conservatories are set up, they are invariably as lean-to's, so that they give exit from a dining and drawing-room. They are much better adapted for the growing of plants, but in looking these eventualities are not considered. They are sometimes raised 5 or 6 feet above the ground level, but quite open beneath; the result is that frost attacks from below as well as at the sides and top. If they could be closed up so as to prevent the admission of cold air on the east, north, or west sides, they would be rendered warmer; as it is, such houses are horribly cold in times of sharp weather. But covering in on any one of the open sides is sometimes difficult, because light would thereby be excluded from reaching the windows of the domestic offices on the basement floor and under the conservatory.

And what occurred in many places on Sunday, December 24, and also as a result of the heavy snow-storm of last winter, should be borne in mind by those whose business it is to construct plant-houses. These lean-to houses are placed immediately beneath the sloping roof of a two and three-storied house, and when a thaw comes, and the snow is dislodged, it sweeps avalanche-like down on to the ill-fated glass roof below, with what result may be well imagined. As long as plant houses with glass roof are placed in such a position this is likely to happen perhaps two or three times during winter. The glass with which these structures are glazed is nearly always of the cheapest.

The proper kind of house, and certainly the most satisfactory in all respects, is that set forth by Mr. William Paul in his *Handybook of Villa Gardening*. He says: "Waiving the question of mere outward show, I will venture to describe a house capable of producing and preserving plants, and suited to the requirements of a Villa Garden. First it should be span-roofed, the ends placed north and south, divided in the middle to form two compartments, one of which may be kept warmer than the other and used as a propagating and forcing house in winter and spring. A walk, 2 or 3 feet wide, running down the centre, with raised benches on either side, and 4 feet in width, on which to stage plants, is a very convenient and economical arrangement. The stages should be of slate, because cooler, cleaner, and more durable than wood. The paths may be paved with York stone or bricks. A slate cistern, fixed at one end, or beneath the stage inside, to receive the rain from the house, will save much labour, and place ready to your hand water of a suitable temperature, and of the best quality. This is the sort of house for real utility, adapted for rearing and forcing a number of plants at a small cost."

For any purpose, even if wanted for hardy plants only, this is the best kind of house. It need not be far away from the dwelling, and an asphalt, brick, stone, or well-kept gravelled path will enable the house to be reached in all weathers without inconvenience. It is sure to be in the line of sight of the sun, and away from the chance of harm from the snow-fall from the roof.

Notices of Books.

MESSES, HARDWICKE & BOGUE have issued a third edition of Mr. Worthington Smith's useful little book on *Mushrooms and Toadstools*—how to distinguish easily the differences between edible and poisonous fungi, with figures of twenty-nine edible and thirty-one poisonous species. When any one (especially if he be, as the author of this little book is, zealous) has attained considerable knowledge and experience of any subject, he is rather apt to ignore the deficient attention and defective apprehension of those who have paid no heed to the subject, and seriously to underestimate the amount of necessity of the public in general. We allude to this matter for the reason that

the present little volume contains two uncoloured lithographs of edible and poisonous fungi respectively. Now when deprived of its natural colour, as on fig. 1, on the plate of edible Mushrooms, *Agaricus rubescens* resembles very closely fig. 13 on the plate of poisonous Mushrooms (*Agaricus Muscarius*). Indeed the ordinarily brown warty cap of the former may frequently be replaced by one of a red hue. Compare also fig. 2, *Boletus edulis*, with fig. 27 on the poisonous sheet, *B. satanas*. Of course the mycophagous artist will say, and say truly, that people should read his book as well as look at his pictures; but then, as he himself admits, and also very truly, people are so stupid. Be this as it may, we are satisfied that danger often arises from the would-be fungus eater not having at hand the means of comparison. He gathers one fungus, which from his imperfect knowledge he infers to be such and such a species, because it presents some more or less near similitude to it; but if he could have placed before him the real thing, with the counterfeit, he would be able to detect the difference instantly. Uncoloured plates, such as those in the book before us, do not convey to the uninitiated sufficient marks of distinction. We would, therefore, strongly recommend the beginner not to trust to the uncoloured representations in this book (in so doing we are far from imputing aught against the artist's designs), but to procure the coloured figures by the same artist, and issued by the same publisher. Again we may suggest to Mr. Smith (always in the interest of the stupid people, who cause some inconvenience to others when they happen to poison themselves) the expediency of depicting the edible species side by side on the same plate with dangerous species, for which they might possibly be mistaken. The comparatively frequent occurrence of disasters from mistaking *Aconite* for *Horse Radish*, however, leads us to fear that, until people are trained to observe for themselves, no assistance that can be rendered by others will be of much service unless it be in administering antidotes.

ROYAL HORTICULTURAL SOCIETY'S COMMITTEES FOR 1877.

Dec. 28.—Overcast, dull, wet, miserable day. Very mild. Strong S.W. wind.

29.—Overcast, dull, with occasional rain. Mild. Gale at night.

30.—Fine at 9 A.M., overcast. Dull and wet till evening; then fine. Windy. Mild.

31.—Fine, bright, with strong gusts of wind. Very mild. Clear at 9 A.M., overcast; fine till 7 P.M. Gale of wind.

Jan. 1.—Fine, bright, and pleasant till 7 P.M., then dull and wet.

2.—Fine, bright, and pleasant till 7 P.M., then dull and wet.

3.—A dull, wet day. Pleasant till 7 P.M. Mild.

LONDON: Barometer.—During the week ending Saturday, December 30, in the vicinity of London, the reading of the barometer at the level of the sea increased from 29.39 inches at the beginning of the week to 30.19 inches by the morning of the 26th, decreased to 29.68 inches by the afternoon of the 26th, increased to 29.53 inches by the morning of the 27th, decreased to 29.44 inches by the evening of the same day, increased to 29.66 inches by the early morning of the 30th, decreased to 29.36 inches by the afternoon of the same day, and was 29.50 inches at the end of the week. The mean reading for the week at sea level was 29.72 inches, being 0.55 inch above that of the preceding week, and 0.35 inch below the average.

Temperature.—The highest temperatures of the air observed by day ranged from 58° on the 28th to 55° on the 26th; the mean for the week was 50°. The lowest temperatures of the air observed by night varied from 29½° on the 26th to 50° on the 28th; the mean value for the week was 38½°. The mean daily range of temperature in the week was 9½°. The greatest range in the day was 22½° on the 27th, and the least 3½° on the 24th.

The mean daily temperatures of the air, and the departures from their respective averages were as follows:—Dec. 24th, 34.3°, 3° 9' above; 25th, 34.5°, 5.0° above; 26th, 32.4°, 2.9° below; 27th, 31.1°, 1.1° below; 28th, 53.5°, + 16°; 29th, 51.1°, + 13.7°; 30th, 50.1°, + 12.8°. The mean temperature of the air for the week was 43.6°, being 5.9° above the average of sixty years' observations.

The highest readings of a thermometer with blackened bulb in vacuo, placed in sun's rays, were 61° on the 30th, 58½° on the 28th, and 57° on the 20th; on the 24th the reading did not rise above 35½°. The lowest reading of a thermometer on grass, with its bulb exposed to the sky, were 30½° on the 26th, 31½° on the 24th, and 32° on the 25th; the mean value for the week was 36½°.

Wind.—The direction of the wind was from the S.W., and its strength strong. The weather during the week was very dull and wet, and the sky generally overcast; and the first three days of the week were cold, but the last four very mild.

Rain.—Rain on every day in the week; the amount collected was 1.84 inch.

The Mean Reading of the Barometer for the Month of December was 29.309 inches, being 0.496 inch below the average of the preceding thirty-five years, and during this period of thirty-five years there has been no monthly reading in December so low as that of the present December; the nearest approach was 29.279 inches in December, 1868.

The Mean Temperature of the Air for December was 44.4°, and the mean range 10.5°; there are only nine instances of a mean temperature equal to or exceeding 44½° in December.

The Total Fall of Rain during the Month of December was 5.92 inches, and there is no instance hitherto in 1815 when the fall of rain in December was so large as in the present month; the nearest approach was in the

year 1868, when it was 5.4 inches. Rain fell on twenty-five days during the month, being thirteen days more than the average number for December.

ENGLAND: Temperature.—The highest temperatures of the air observed by day were 58° at Blackheath and 57° at Truro, Cambridge, Norwich, and Nottingham; at Sunderland 54° was the highest temperature. The mean value from all stations was 55½°. The lowest temperatures of the air observed by night was 24½° at both Bristol and Wolverhampton; at Truro and Brighton 23° was the lowest temperature. The general mean from all stations was 28½°. The range of temperature in the week was the greatest at Bristol, 34½°, and the least at Brighton, 22°. The mean range from all stations was 27½°.

The mean of the seven highest day temperatures was the highest at Truro, 53°, and the lowest at Bradford, 41½°; the mean from all stations was 46½°. The mean of the seven low night temperatures was the lowest at Wolverhampton, 31½°, and the highest at Truro and Plymouth, both 41°; the mean value from all stations was 36½°. The mean daily range of temperature was the least at Bradford, 6½°, and the greatest at Eccles, 13½°; the mean daily range of temperature from all stations was 10½°.

The mean temperature of the air for the week from all stations was 40½°, being 3° lower than the value for the corresponding week in 1875. The highest was 46½°, at Truro, and the lowest 37½°, at Wolverhampton.

Rain.—Rain fell on five or six days in the week at most stations, and at no station was the fall less than 1 inch. The amounts, however, varied from 3½ inches at Truro, 2½ at Plymouth, 2½ at Bristol, to 1 inch at Wolverhampton, Nottingham, and Liverpool. The general average fall over the country was 1½ inch nearly.

The weather during the week was dull and wet, and the sky generally overcast. The weather was cold on the first three days, and very mild on the last four days.

Gales and floods have again been experienced all over the country, resulting in great loss, and many wrecks have occurred.

SCOTLAND: Temperature.—The highest temperatures of the air varied from 48½° at Leith to 43° at Dundee; the mean value from all stations was 45½°. The lowest temperatures of the air ranged from 26° at Perth to 31½° at Aberdeen; the general mean from all stations was 28½°. The mean range of temperature from all stations in the week was 17°.

The mean temperature of the air for the week from all stations was 36½°, being 4½° below that of England, and 8° below the value for the corresponding week in 1875. The highest occurred at Aberdeen and Leith—both 47½°—and the lowest at Paisley and Perth—both 35½°.

Rain and Snow.—The fall of snow and rain was large everywhere, the greatest fall in the week was rather more than 3 inches at Perth, and the least fall about 1½ inch at both Edinburgh and Leith; the average fall over the country was 2½ inches.

DUBLIN.—The highest temperature of the air was 56°, the lowest 34½°, the range 21½, the mean 44½, and the rainfall 1½ inch.

Law Notes.

DELAY IN TRANSIT.—At the last sitting of the Clerkenwell County Court before the Christmas vacation, the case of *Rowe v. The Great Northern Railway Company* was heard before the presiding Judge, Gordon Whitbread, Esq., in which the plaintiff, a salesman, sued the Company to recover the sum of £5, the loss he had sustained in consequence of the want of prompt delivery of three tons of Kent Regent Potatoes, which had been consigned to him from York, and which had not reached the terminus in London at King's Cross in time for a purchaser for whom he had ordered them. Mr. Williams, solicitor, appeared for the plaintiff, and Mr. Harmsworth as standing counsel for the Company. The plaintiff said he was a wholesale salesman at King's Cross, and ordered the goods in question to reach London on Friday, November 17, in order to meet the requirements of a customer on the following morning's (Saturday) market. They, however, did not reach King's Cross till late on Saturday, and during his men had left work, and were not virtually in his possession till early on Monday morn-

ing, and his customer in the meantime got supplied elsewhere, whereby he had lost the sale of the goods, and estimated his loss at the price now sued for.

In reply to question put, the plaintiff said he considered the wholesale first price of the Potatoes were from £5 to £6 a ton, and that £5 profit on the lot was a very reasonable one. Two of the plaintiff's servants were called, who proved leaving their work on the Saturday, at which time no delivery of the goods was made. This evidence completed the plaintiff's case, when the Counsel addressed the Court as some length, urging the non-liability of the Company on the following grounds.

In the first place, the Company did not hold themselves responsible by their bye-laws for reasonable delay, and he would be in a position to prove from witnesses he should call that the goods were not at the York goods station in time to be despatched with the goods train which would reach King's Cross Station in time on Friday evening, and would call the goods manager and checker from York for that purpose; but even should the question of damages arise, which he did not apprehend, they could be merely nominal, as the charge the plaintiff had made was a most excessive one.

The goods manager and checker attended from York, who both stated that the goods arrived two hours after the goods train, by which they would have reached King's Cross on Friday evening had left. This being the defendant's case, his Honor ruled in favour of the Company, who did not apply for costs.

LANDLORD AND TENANT.—A case, just decided by Mr. Justice Lindley, at Manchester, is of some public interest as defining the position of tenants holding non-repairing leases. The landlord, in this instance, had covenanted to keep the roof, windows, main timbers, and exterior of the house in an effectual state of repair. After a time, water frequently penetrated through the roof to such an extent that the tenant was obliged to remove his wife to the kitchen, while many of his goods were completely spoilt. On this being represented to the landlord's agent, he empowered the tenant to get some one to execute the repairs, previously forwarding an estimate of their cost. The tenant failed to find any person who could give such an estimate, and therefore had the repairs executed by a tradesman, who, on receipt of the bill, deducted the amount he had so spent, and tendered the balance. This was refused by the agent, who thereupon put in an execution, and sold off all the property on the premises under distraint. These proceedings resulted in an action before Justice Lindley, which terminated in favour of the tenant. The jury held that, while the landlord had a right to his rent, £30, he must pay to the tenant £7, 2s. 6d. for repairs, £5 for damage done by rain-water, and £65 for illegal distraint, less £5 15s. 4d., the amount realised by the sale. The important point in this decision is that it sanctions the execution of repairs by non-repairing tenants, at the cost of their landlords, when the latter either fail to perform the duty, or are guilty of unjustifiable delay. *Widder.*

Obituary.

The death is recorded, on December 17th last, at his residence, Penrose Street, Walworth, of Mr. JAMES ANDREWS, the well known floral artist, aged 75 years.

Variorum.

THE ANNUAL MEETING OF THE BISHOP AUCKLAND FLORAL AND HORTICULTURAL SOCIETY was held a few days ago, and from the balance-sheet read at the meeting it appears that the society had to sustain a loss of just over £300 on the last year's show, the takings in the way of admission to the park having fallen considerably short of the usual sum. This deficiency is attributed to the causes heretofore mentioned, and the committee had no control—the great depression in trade in the North, and the somewhat unfavourable character of the weather. Notwithstanding this loss there is still a balance in hand of £292 7s. 7d. At this meeting it was resolved that a good portion of this sum should be invested for the benefit of the society, but in order to have a complete legal control over money so invested it was further resolved to take steps to have the society registered as an industrial society under the provisions of the Acts of Parliament relative to these societies. Registration can be completed at a small expense, and then the society will be

Pansies and Violas, Bedding.
THOMAS S. WARE'S AUTUMN CATALOGUE of the above, including Carnations, Picotees, Pinks, Fuchsias, Pelvexes, Delphiniums, Roses, and others, for Immediate Planting, is now ready, free upon application.
 Hale Farm Nurseries, Tottenham, London.

LARGE TREE BOX and EVERGREEN HOLLY.—Haudsons, bushy, and well-rooted, will transplant with good balls of earth, 5, 6, 7, and 8 feet high. The above species better than any other in the vegetable trade. An inspection invited. Price on application to
 T. JACKSON AND SON, Nurseries, Kingston, Surrey.

To the Trade and Others.
FRANCIS & ARTHUR DICKSON & SONS have to offer strong healthy plants as under-noted, viz.:
 ANTHURUM SCHERZERIANUM,
 ADIANTUM GRACILE,
 ADIANTUM VEITCHII,
 ASPLENIDIUM COLEMANI,
 BLECHNUM CORCOWADENSE,
 LOMARIA GIBBA.
 Prices and full particulars on application.
 The "Upton" Nurseries, Chester.

SURPLUS STOCK.
ROSES, common or Red Moss, own roots, strong, 2s. 6d. per 100.
CABRAGE, or Red PROVENCE, own roots, strong, 4s. per 100.
AUSTRIAN BIRAR, Harrisoni, own roots, strong, 4s. per 100.
 Fernia Yellow, own roots, strong, 4s. per 100.
FELICITE PERPETUELLE, climbing, own roots, strong, 2s. per 100.
MANETTI STOCKS, own roots, strong, 4s. per 100.
 N.B.—The above are all guaranteed to be true.
 GEORGE GRAY AND SON, Chertsey, Surrey.

PORTUGAL LAURELS.—Fine bushy plants, from 2 to 4 feet high, also standards of the same on stems, 2 to 4 feet, with finely shaped heads, 2 to 4 feet in diameter. **IRISH YEW,** 4 to 7 feet; English do., 4 to 6 feet; **GREEN HOLLIES,** 3 to 6 feet; **ROSE,** 2 to 4 feet; **SYRINGAS,** 3 to 5 feet; **PURNIA LILACS,** 4 to 5 feet; **DEUTZIA** **ORANGE FLORE-ROUGE,** 4 to 6 feet. The above are all fine plants, and in good movable condition. Price and all particulars on application to
 ALEXANDER DANCER, The Nurseries, Fulham, S.W.

POTATOS (SNOWFLAKE), cheap—a quantity of this delicious variety for sale, at 10d. per cwt. The stock is perfectly true, grown on light soil, and is seed imported last year from France, but the skins are very rough from wireworm. As good for seed purposes as our best samples.
PRICKLE COMPLY, a most valuable permanent forage plant; may be cut six times a year, producing 120 tons rich feed per acre. Cultural instructions and price on application.
ASPARAGUS, forcing, strong crowns, 5s. per 100.
ASPARAGUS, S. B. S. D. CONNOVEY'S COLossal (our own saving), a considerable quantity for sale.
CABBAGE SEED, FREEMAN'S MASSIVE DRUMHEAD, 4s. per bushel, our own sowing.
 C. R. FREEMAN, Seedsmn, Norwich.

COCOANUT FIBRE REFUSE.—Products from Cold, Frost, &c.—No Russia Mats needed. Use a layer of FIBRE REFUSE, 3d. per bushel, 100 for 20s.; truck, 40s. for any rail or wharf. As supplied to Messrs. Carter & Sons, Veitch & Sons, Bull, Wills, Ewing, Daniels Bros., Dixon & Co., Dickson & Sons, Herr, Schmidt, Germany; Martin Muller, Strasburg, &c.
 W. H. BENTOTE, Fibre Maker, Lausanne Road, Nunehead, London, S. E.

COCOANUT FIBRE REFUSE, newly made.—Reduced price, 20 bushels, 6s. 8d.; 100, 20s.; or Truck-load, 40s. Delivered free to any rail in London. J. STEVENS AND CO., Fibre Works, High Street, Battersea, S.W.

Fibrous Peat for Orchids, &c.
BROWN FIBROUS PEAT, best quality for Orchids, Store Plants, &c., 1s. 6d. per truck. **BLACK FIBROUS PEAT,** for Road and Garden, 1s. 6d. per truck. Heaths, American Moss, 1s. 7d. per ton.
DELICIOUS on rail, 1s. 6d. per ton, or Farnborough, S.W. R., by the truck-load. Sample sack, 5d. each.
FRESH SPHAGNUM, 10s. 6d. per sack.
 WALKER AND CO., Farnborough Station, Hants.

PEAT.—A few hundred tons of superior Peat, delivered at either of the Farnborough Stations on the South-Western or South-Eastern Railways, at 1s. 7d. a ton.
 W. TARKY, Eastiff, Isington, Surrey.

ODAMS' MANURES, FOR ALL CROPS.
 Manufactured by the NITRO-PHOSPHATE and ODAMS' CHEMICAL MANURE COMPANY (LIMITED), consisting of Tenant-Farmers occupying upwards of 120,000 acres of Land. **MANAGING DIRECTOR—JAMES ODAMS.**
Sub-Manager and Secretary—W. H. HAMM.
CHIEF OFFICE—100, Finchurch Street, London, E.C.
WESTERN COUNTIES BRANCH—Queen Street, Exeter.
 Particulars will be forwarded on application to the Secretary, Or may be had of the Local Agents.

GISHURST COMPOUND.—Used by many of the leading Gardeners since 1859, against Red Spider, Mildew, Thrips, Greenfly, and other blights, and solutions of from 1 to 2 ounces to the gallon of water, and of from 4 to 10 ounces as a winter dressing for Vines and Fruit Trees. Has obtained many preparations and is the most effective. Sold Retail by Seedsmen in Boxes, 1s., 2s., and 10s. 6d. Wholesale by PRICE'S PATENT CANDLE COMPANY (LIMITED).

MATS.—Archangel, Petersburg, Packing RAFFIA for tying, TRAINING STICKS, BAMBOO CANES, &c. Before purchasing send for prices to
 C. J. BLACKBURN AND CO., Cox's Quay, Lower Thames Street, London, E.C.

RUSSIA MATS.—A large stock of Archangel and Petersburg, for Covering and Packing (price on application for Archangel)—Petersburg, 60s. to 100s. per 100; superior close-woven, 40s., 50s., and 55s. per 100; Packing Mats at 20s., 25s., and 35s. per 100; and all other descriptions of Mats at equally low rates, at
 J. BLACKBURN AND SONS, 4 and 5, Wormwood Street, London, E.C.

RUSSIA MATS, for Covering Garden Frames.—ANDERSON'S TAGANROG MATS are the cheapest and most durable. Price List, which gives the size of every class of Mat, forwarded post-free on application.
 JAS. T. ANDERSON, 7, Commercial Street, Shoreditch, London, E.C.

* Price Lists, with further particulars of WIRE NETTING, IRON FENCING, POUCH FENCES, DIAMOND and other TRELLIS WORK, on application.

J. B. BROWN & CO.,
 Offices—90, CANNON STREET, LONDON.

The FRENCH SYSTEM of WIRING GARDEN WALLS, &c., FOR TRAINING FRUIT TREES.

GALVANIZED EYED NAILS for Stretching Wires, one at each end of wall, 1s. 10d. per dozen. Smaller Size for supporting the wire, every 10 feet, 10d. per dozen. Smaller Sizes, not recommended, 6d. per dozen.
GALVANIZED IRON RAIDISSEURS, for Tightening Wires, one to the centre of each wire, 2s. 6d. per dozen.
KEYS for Winding, 4d. each.
SCREWS and NUTS, neater than Raidisseurs, 3s. 6d. per dozen.
NO. 14 GALVANIZED WIRE, 10 inches apart, 2s. per 100 yds.
 * Prices of IRON TRELLIS or ESPALIER for TRAINING FRUIT TREES on the FRENCH SYSTEM, on application.

J. B. BROWN & CO.,
 90, CANNON STREET, LONDON, E.C.

F. T. ARCHER'S "FRIGI DOMO."—Patronized by Her Majesty the Queen, for Windsor Castle and Frogmore Gardens, the late Sir J. Flaxton, and the late Professor Lindley, &c.
 MADE OF PREPARED HAIR and WOOL.
 A perfect non-conductor of heat or cold, keeping a fixed temperature where it is applied. A good covering for Fish and Forcing Frames.

PROTECTION from COLD WINDS and MORNING FROSTS.
 "FRIGI DOMO" NETTING, 2 yards wide, 17. 1d. and 1s. 10d. per yard.
 "FRIGI DOMO" CANVAS, 3 yards wide 2s. 10d. per yard run.
 3 yards wide 2s. 10d. per yard.
 4 yards wide 3s. 2d. per yard.

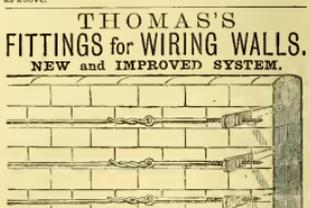

ELISHA T. ARCHER, only Maker of "Frigi Domo," Brockley, near Hill, London, S. E., and all Florists and Seedsmen. All goods carriage paid to London.
 NOTICE.—REMOVED from 3, CANNON STREET, CITY.

Garden Wall Wiring.

R. HOLLIDAY, PRACTICAL WIREWORKER, 12, 13, Fenchurch Terrace, Notting Hill Gate, London, W., begs to call the attention of all Gardeners who are about to have their Garden Walls Wired to his system of Wiring Walls, as being superior to all others for neatness, strength, and durability.
FOR NEATNESS.—Because all the Wires are kept perfectly tight, without the use of the Raidisseur.
FOR STRENGTH.—Because very much stronger Wire can be used, therefore not liable to be drawn out of the horizontal line by the branches of trees.
FOR DURABILITY.—Because, being able to use the strong Wire, it is not so likely to be eaten through with the galvanism as the thin Wire, as used in the French system.
 The above engraving is an example of one system of Wiring Garden Walls. We have recently completed the Wiring of the New Garden Walls for the Marquis of Salisbury, Hatfield House. The Walls are 12 feet high and 753 yards long, wired on both sides; making a total length of 1506 yards—our system being chosen in preference to any other.
 Illustrated Catalogues of Garden and Conservatory Wirework, Rabbit-proof Hurdle Fencing, &c., may be had on application as above.

THOMAS'S FITTINGS for WIRING WALLS.
NEW AND IMPROVED SYSTEM.

The following prices give the total cost of each line of wire, including hoists, straining bolt, intermediate guiding eyes, 10 feet apart, and best quality galvanized wire.
 Length of Wall—100 yds. 40 yds. 60 yds. 80 yds. 100 yds.
 No. 14 Gauge Wire 1 1 1 1 8 2 2 2 8 3 2
 No. 13 " " " " 1 1 1 1 1 2 2 2 6 3 1 3 8
 Illustrated Lists, with full particulars of the above, and Fittings for Espalier Trainers, on your economic principles, free on application.
 Five per cent. discount allowed for prompt cash on orders amounting to 50s. and upwards.
Special quotations for larger quantities.

FOREST TREES and SHRUBS.

ANNUAL CATALOGUE NOW READY.

THE LAWSON SEED & NURSERY COMPANY

(LIMITED),
 EDINBURGH and LONDON,

Will forward their newly published List free to any address upon application.

The Stock of Seedling and Transplanted FOREST TREES, SHRUBS, and COVERT PLANTS is most extensive, and in unusually fine condition.

SPECIAL OFFERS TO LARGE BUYERS WHEN REQUESTED.

W. G. SMITH & CO., HORTICULTURAL ENGINEERS, Victoria Works, Bury St. Edmunds.

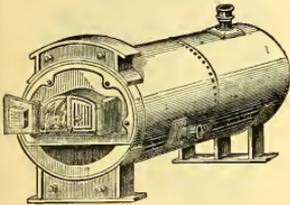

SOLE MANUFACTURERS OF BEARD'S PATENT METALLIC NON-CONDUCTING GLASS-HOUSES. — The Glass is fixed between two layers of prepared felt. The Ventilators are worked by a simple mechanical contrivance, and the whole structure is screwed together so as to render it quite portable. HEATING APPARATUS IN ALL ITS BRANCHES. ORNAMENTAL CONSERVATORIES and HORTICULTURAL BUILDINGS of EVERY DESCRIPTION. — For lightness, elegance and durability, these Houses cannot be surpassed. The best materials only are used in their construction. Great improvements have recently been made, to obviate the objections to iron houses. Very extensive works on this principle have been satisfactorily executed. An Illustrated Catalogue forwarded post-free on application.

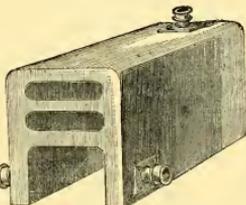

THE THAMES BANK IRON COMPANY, Old Barge Wharf, Upper Ground Street, London.

Rosher's Garden Edging Tiles. THE ABOVE and many other PATTERNS are made in materials of great durability. The various sorts are especially suited for KITCHEN GARDENS, as they require no Sticks or Insects, take up little room, and, once put down, incur no further labour or expense, as do "crown" Edgings, consequently being much cheaper. GARDEN VASES, FOUNTAINS, &c., in Artificial Stone, very durable and of superior finish, and in great variety of design. F. ROSHER and CO., Manufacturers, Upper Ground Street, Blackfriars, King's Road, Chelsea, S.W. Agents for LOOKER'S PATENT "ACME FRAMES," PLANT COVERS and PROPAGATING BOXES; also for FOXLEY'S PATENT BEADED GARDEN WALL BRICKS. Illustrated Price Lists free by post. The Trade supplied.

ORNAMENTAL PAVING TILES, for Conservatories, Halls, Corridors, Balconies, &c., from 40 per square yard upwards. Pattern Sheets, of plain or more elaborate designs, with prices, sent for selection. WHITE GLAZED TILES, for Lining Walls of Dairies, Larders, Kitchens, Kitchens, Baths, &c. Grooved and other Scaled Paving of great durability. Wall Copings, Drain Pipes and Tiles of all kinds. Roofing Tiles in great variety. Slates, Cement, &c. F. ROSHER and CO., Brick and Tile Merchants. See addresses above.

SILVER SAND, fine or coarse grain as desired. Prices by Post per ton or truck-load, on Wharf in London, or delivered direct from Pits to any Railway Station. Samples of Sand free by post. FLINTS and BRICK BURNS for Rockeries or Ferneries. KENT PEAS or LOAM supplied at lowest rates in any quantities.

F. ROSHER and CO.—Addresses see above. N.B.—Orders promptly executed by Rail or to Wharves. A Liberal Discount to the Trade.

Oil Paint No Longer Necessary.

HILL and SMITH'S BLACK VARNISH for Preserving Ironwork, Wood, or Stone. This Varnish is an excellent substitute for oil paint on all outdoor work, while it is fully twice as cheap. It was introduced upwards of thirty years ago by the advertisers, and its genuine good quality, notwithstanding a host of unprincipled imitators, is fully attested by its constantly increasing sale. It may be applied by an ordinary labourer, requires no mixing or thinning, and is used cold. It is used in the grounds at Windsor Castle, New Gardens, and at the seats of many hundreds of the Nobility and Gentry, from whom the most flattering testimonials have been received, which HILL & SMITH will forward on application. Sold in casks of about 30 gallons each, at 1s. 6d. per gallon, at the Manufactory; or 1s. 6d. per gallon carriage paid to any Station in the Kingdom.

UNDISCOURAGED TESTIMONIAL. Glanville, Littlehampton, Chichester, Nov. 27, 1873—"Mr. Lloyd Lloyd encloses cheque for £3 3s, amount due to Messrs. Hill & Smith, and he considers the Black Varnish one of the most useful things he ever possessed." Apply to HILL and SMITH, Briery Hill, Ironworks, near Dudley; and 115, Queen Victoria Street, London, E.C., from whom only it can be obtained. CAUTION.—Beware lately come to the knowledge of Hill & Smith that persons of the name are being offered by unprincipled dealers at a slight reduction in price, they would especially draw attention to the fact that every cask of their Varnish is regularly marked with their name and address, without which none is genuine.

JOHN MATTHEWS, The Royal Pottery, Weston-super-Mare, Manufacturer of TERRA COTTA VASES, FOUNTAINS, ITALIAN BASKETS, BORDER TILES, GARDENERS' superior quality, from 4 to 30 inches diameter, stand the frost and seldom turn green. ORCHID, FEEN, SEED, and STRIKING PANS, RHENISH and SEAKALE POTS, &c. Price List 200s. free. Sheets of Design, 6d. Books of Design, 1s.

LASCELLES' PATENT BENT WOOD CONSERVATORIES and GREENHOUSES—All Gardeners know that Wood is better than Iron for Plant Growing, and by the above system a handsome curved lighter can be erected as cheaply as a plain straight one. The curved house is more durable, stronger, higher in construction, and no bent glass is required. **W. H. LASCELLES**, 172, Bonhill Row, London, E.C., will supply Drawings and Estimates free of charge.

BELGIAN GLASS for GREENHOUSES, &c., Can be obtained in all sizes and qualities, of

They are the neatest, cheapest, most effective, and durable of any extant.

Descriptive Illustrated Price List may be had sent on application to

THOMAS GREEN and SON, Smithfield Ironworks, Leeds; and 54 and 55, Blackfriars Road, London, S.E.

LIMEKILN HEATING.

This System of HEATING WINTER GARDENS, CONSERVATORIES, ORANGERIES, FERNERIES, VINERIES, FORCING HOUSES, PINERIES, CUCUMBER, MELON and MUSHROOM HOUSES, STOVES, PITTS, &c.—also for WARMING MANSIONS, PUBLIC BUILDINGS, FACTORIES, &c., is steadily making progress in public estimation, effecting as it does

Great Economy of Fuel and Steadiness of Heating Power,

and rendering the hitherto onerous duties of Stoker comparatively light—no night stoking whatever being necessary.

List of Places where the System is in Operation, with full address in each case, will be sent free on application.

Gentlemen and Gardeners wishing to adopt this System will then be enabled to view the Apparatus nearest to their own Establishments, or write to the Gardener, and thus get independent testimony as to the value of this method of Heating.

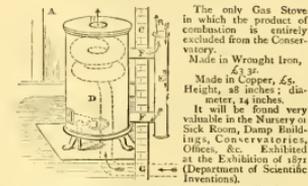

Estimates will be submitted, on receipt of Particulars, free of charge.

FULL PARTICULARS POST-FREE.

Cowan Patents Company (Limited), 21, WHITEHALL PLACE, LONDON, S.W., and The Vineyard, Garston, near Liverpool.

GEORGE'S PATENT CALORIGEN,

FOR Warming and Ventilating Small Conservatories.

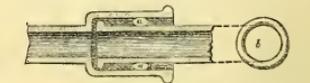

Illustrated Prospectuses and Testimonials on application. **J. F. FARWIG and CO.**, 36, Queen Street, Cheapside, E.C. This Stove introduces a strong current of warmed (not burnt) fresh air.

POWELL'S PATENT STEAM PLOUGH and CULTIVATOR may be SEEN at WORK in every Agricultural County in England.

For particulars apply to **JOHN FOWLER and CO.**, 71, Cornhill, London, E.C., and Steam Plough Works, Leeds.

JAMES LYNE HANCOCK'S Improved India-rubber Socket-rings FOR THE JOINTS of HOT-WATER PIPES.

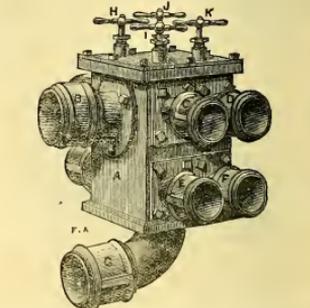

Description of Sketches.— A. The Rubber Ring as rolled into the Socket. B. The Ring before inserted in the Pipe. These Rings are made any size to order. All ordinary sizes are kept in stock.

I Illustrated Price List on application.

J. L. HANCOCK, VULCANISED INDIA-RUBBER WORKS, 256, GOSWELL ROAD, LONDON, E.C.

CRITCHLEY'S PATENT HEAT REGULATOR,

AN APPARATUS for REGULATING the HEAT in HORTICULTURAL BUILDINGS.

A, Iron Box fitted up water-tight. B, Pipe for Supply of Water from Boiler. C, D, Pipes for Circulating Hot Water. E, F, Pipes for Return of Water to Iron Box. G, Pipe for Returning Water to Boiler. H, J, K, L, Piston Rods for Opening and Closing Valves.

The advantages of this Regulator are that houses may be kept at different degrees of heat, or the circulation of water and heat entirely stopped in one part and not in others. It may be fitted with as many valves as required, and is particularly adapted for forcing houses where top and bottom heat is used. It may be fixed in any part of the apparatus most suitable for working, without regard to the position of the Boiler.

The following Testimonial has been received:—

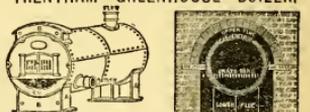

"Berkeley Castle, April 12, 1875. "Gentlemen,—I am happy to inform you, now that the late severe winter is past, that the Hot Water Apparatus erected by you does its work to my entire satisfaction. As to the two Heat Regulators, which represent thirty valves. I have had ample opportunities of precisely proving them, and unhesitatingly admit they are far superior to any other valve in fact, I think it the greatest improvement that has come out for horticultural purposes.

"I am, Gentlemen, yours truly, "R. H. CROWEY, "Gardener to the Right Hon. Lord Fitzharding."

Estimates and Plans furnished for Warming Greenhouses, Mansions and Public Buildings. Orders attended to in any part of the Kingdom, and guaranteed to answer their intended purposes.

MESSRS. CRITCHLEY, Horticultural Engineers and Builders, HERBORNE PLACE, CHELTENHAM.

STEVENS' TRENTHAM GREENHOUSE BOILER,

After long experience, has proved the most SIMPLE, ECONOMICAL, EFFECTIVE and LASTING BOILER extant; recently improved. For Illustrations, with full particulars, apply to the Sole Makers,

F. & J. SILVERSTER, HOT-WATER ENGINEERS, &c., &c., Castle Hill Works, Newcastle, Staffordshire.

Our Boilers are the only ones made with the sanction and under the inspection of the inventor, Mr. Stevens—all others being bad imitations.

T. H. P. DENNIS & COMPANY.

Motto, "Art with Economy" as applied to Conservatories.

HORTICULTURAL BUILDINGS OF ALL DESCRIPTIONS & HOT-WATER HEATING APPARATUS

ERECTED AND FITTED IN ALL PARTS OF THE KINGDOM. ESTIMATES GRATIS.

Show Rooms: MANSION HOUSE BUILDINGS, LONDON, E.C.,
where full-sized Specimens of Greenhouses, &c., and Hot-water Apparatus at work can be inspected.

Works: CHELMSFORD.

MESSENGER & COMPANY, CONTRACTORS, MIDLAND HORTICULTURAL BUILDING AND HOT-WATER ENGINEERING WORKS, LOUGHBOROUGH,

See to call attention to the above illustration, which shows a very advantageous arrangement of Glasshouses which has been adopted for several important Works on M. & Co.'s recommendation.

Only thoroughly well-seasoned timber used. Glasshouses erected on Messenger's patent principles are, owing to mechanical arrangements, very strong, most durable, in cost and maintenance. Messenger's Patent Boilers, Flexible Jointed Hot-water Pipes and Valves, are now in use in many thousands of instances, with the greatest light, elegant; perfect efficiency for purpose intended is guaranteed, are economical success. Particulars on application.

Plans and Estimates forwarded. Ladies and Gentlemen waited upon. The Plans of Architects and others carried out. Illustrated Circular Free.

THE GARDENERS' CHRONICLE

VOLUME for JANUARY to JUNE, 1876.

W. RICHARDS, 41, Wellington Street, Strand, W.C.

Price 6d.

THE GARDENER:

A Monthly Magazine of Horticulture and Floriculture.
 Edited by DAVID DRAGON, Gardener to His Grace the Duke
 of Buccleuch, Drumlanrig; Author of "The Handy Book of the
 Flower Garden," "The Handy Book of Fruit Culture under
 Glass," &c.; assisted by a Staff of Practical Gardeners through-
 out the United Kingdom. Yearly subscription, 6s. or 6s. free by
 post, 7s. Payable in advance.

The publishers of "The Gardener" have much pleasure in
 announcing that arrangements have been made by the Editor for
 the ensuing year, which they hope will much extend the use-
 fulness of that periodical both to Amateurs and Professional
 Gardeners.

In addition to articles of the usual miscellaneous class—such
 as possible of a thoroughly practical character, special
 series of papers by thoroughly competent contributors are
 promised on such subjects as the following:—

Hardy Fruit Culture in all its Branches.
 Everything New and Valuable in Florists' Flowers.
 Conservatory and Room Decoration.
 Reports on Horticulture in London, and all Novelties of
 Interest that may Appear There.

A Series of Lessons on Drawing for Young Gardeners,
 with Illustrations.

Culture and Directions for Amateurs on Every Department
 of Horticulture.

Notes and Comments on Subjects of General Interest
 Discussed in the Gardening Periodicals, &c.

Published by WILLIAM BLACKWOOD AND SONS,
 77, PATERNOSTER ROW, LONDON; and 45, GEORGE STREET,
 EDINBURGH. Supplied by all Booksellers and Newsmen.

Belgian.

BULLETIN D'ARBOICULTURE de

FLORICULTURE, et de CULTURE MARA-
 CHÈRE. A monthly horticultural work, with superb Coloured
 Plates and Illustrations. Published since 1855 by F.
 BURVENCH, E. PYNART, E. ROEGHANS, and H. J. VAN
 HULLE, Professor in the Horticultural School of the Belgian
 Government at Ghent. Post paid per annum.

H. J. VAN HULLE, Botanical Gardens, Ghent, Belgium.

Every Saturday, price 4d., by Post, 4½d.

WANT PLACES.

B. S. WILLIAMS, having at the present time several very excellent GARDENERS upon his Register, is desirous of placing them in Situations where they are required, and will be glad to undertake, at the same time to intimate that when a Gardener is applied for that the filling of the situation should be left with him, as that which is the most necessary correspondence, to the Victoria and Paradise Nurseries, Upper Holloway, London, N.

Head Gardeners. JOHN LAING can at present recommend several very excellent and practical Men, of tested ability and first-rate character. Ladies and Gentlemen in WANT of GARDENERS and BAILIFFS, or GARDENERS for first-rate Establishments in Single-hand Situations, can be sought, and have full particulars by applying at St. James Park and Rutland Park Nurseries, 47, Pall Mall, London, S.E.

GARDENER (HEAD).—Age 32, married, no family; first-class capabilities. 45s Bonus to any one procuring a situation as above.—A. E., 115, High Street, St. John's Wood, N.W.

GARDENER (HEAD), where several Men are kept.—Age 35; twenty-one years' practical experience in all branches of the profession; eight years with present employer.—R. M. Wats, 79, Southgate Street, Gloucester.

GARDENER (HEAD).—Age 28; Scotch; experienced in all branches of the profession. Twelve years' references.—A. M., William Nicol, 112, Bishopgate Street, London, E.C.

GARDENER (HEAD).—Age 36, married; twenty-two years' good practical experience. Good character. Death of employer cause of leaving.—J. P., 6, Cecil Street, Elm Lane, Hove, Sussex, London, N.

GARDENER (HEAD), where three or more are kept.—Well recommended by the Proprietors of a Gentleman's Establishment, Fruit, Vegetables, Flowers, &c.—R. H. Wats, 79, Southgate Street, Gloucester.

GARDENER (HEAD).—Age 38, married, one child (age 12); well up in the profession. Upwards of twenty years' practical experience in good places—eight years in head.—L. G. Mr. Wats, 79, Southgate Street, Gloucester. References unexceptionable.—L. G. 20, Stamford Street, London, E.C.

GARDENER (HEAD), where any Number or Gentlemen, where several men are kept. Married, no incumbency; thoroughly competent and well versed in all the duties of a Gardener to any lady or Gentlemen requiring the same. In last situation, and first-class references can be given. No objection to Meadow Land and Stock.—J. B., Cape Cottage, Lutteridge, Kent.

GARDENER (HEAD, WORKING), age 25.—A GENTLEMAN wishes to recommend his late Gardener as above, thoroughly competent both Inside and Out.—J. T., 10, St. James Street, Brighton, Sussex.

GARDENER (HEAD, WORKING), where two or more are kept.—Age 29, well up in the profession, in or out of Lancashire.—T. CREAMER, 6, Hayden's News, Portobello Road, Notting Hill, London, S.W.

GARDENER (HEAD, WORKING).—Middle-aged, single, well recommended by the Proprietors of all branches of the profession. Can be highly recommended, as a honest, sober, and trustworthy man.—J. W. GOLDIE, Leigh Lodge, near Healy Wood, near Melkham, Wilt.

GARDENER (HEAD, WORKING), married. Five and a half years' good personal character.—W. B. 30, College Street, Putney, Surrey.

GARDENER.—The Rev. CARUS WILSON, New Milverton Vicarage, Leamington, wishes to recommend a Gardener to any lady or Gentlemen requiring the services of a good practical man.—Address as above.

GARDENER.—Mr. MILFORD, Gardener to R. L. Lopes, Esq., wishes to recommend his Foreman to any lady or Gentlemen requiring the services of a good Gardener, and will answer all questions by letter and expeditiously. Neighbourhood of London preferred.—GARDENER, Richmond Park, near Melkham, Wilt.

GARDENER (SINGLE-HANDED), or where two or three are kept.—Age 27; single. Good character.—H. B., 67, Woodbine Grove, Penge, S.E.

GARDENER (SECOND, or SINGLE-HANDED).—Age 26; has been accustomed to good places. Character and references investigated.—J. P., Princes Cottage, Alexander Road, Egham, Surrey.

GARDENER (SECOND), in a good establishment.—Good knowledge of the Management of Vines, and of other Fruit and Flowering Plants. Highly preferred. Good reference. State particulars, and wages given, to—W. H. S., The Gardens, Ham Manor, Angering, Sussex.

GARDENER (SECOND), where three or four are kept.—Age 21; good knowledge of Stone and Greenhouse Plants, Vines, Flower and Kitchen Garden, &c.—Good character.—J. S., The Lodge, Cranston House, Cranston, Surrey.

JOURNEYMAN, in the Houses.—Age 22; has had seven years' experience under Glass, Growing Plants and Fruit, good references.—G. M., Post-office, Moulton, Northampton.

FOREMAN.—Good experience in Planting and Laying-out Grounds, from Plans or otherwise, or Abattoirs.—J. M. Mann, Stationer, Elgin Road, Maidstone, Kent, N.W.

FOREMAN.—Age 26; has had twelve years' practical experience, and is well up in the Growing of Stone and Greenhouse Plants, Vines, &c.—No small choice references.—H. J. J. Dudman Terrace, Chelsea, London, S.W.

FOREMAN, or SECOND, in a Nobleman's or Gentleman's Garden.—Age 23; good knowledge of Stone and Greenhouse Plants, Vines, and Laid Fencing, &c.—Good character.—Y. Z., J. Sturgeon's, Walmore Court, near Gloucester.

TO NURSERYMEN.—Age 20; wishes an engagement in a good Nursery. Has had four years' practical experience in the Nursery trade.—G. S., 84, Allison Street, Hallow, Hasting, Sussex.

IMPROVER, in a Nobleman's or Gentleman's Garden, where he would be called to attend to Gardening.—Age 21; would not object to pay a Premium.—T. G., Green Hill, Kingstington, Newton Abbot, Devon.

HOMESTEWARD or HEAD GARDENER and NURSEMAN, in a Nobleman's Garden, requiring the services of a thoroughly practical man. Will shortly be disengaged, and be pleased to treat for either of the above situations.—Apply, stating references as to character, to—Harber Terrace, Stoke Newington Green, N.

To the Seed Trade.—Age 21; three years' experience in the Trade. Good references. London preferred.—W. SMITH, The Birches, Peckham Rye, London, S.E.

TO NURSERYMEN and SEEDSMEN.—A Gentleman has at present a situation vacant in a SHOPMAN, or CLERK in a Seed or Nursery Business, First-class references.—K. W., Strouton Lodge, Cotham, Bristol.

TO FLORISTS, &c.—A young Lady desires to re-engage in a Florist's or Flower and Fruit Garden, thoroughly understands the Business. London preferred. Good references.—M. L., Castle Hill, Woodbridge, Suffolk.

P P P S C C O C A O. GRATEFUL-COMFORTING.

By a thorough knowledge of the natural laws which govern the operations of digestion and nutrition, and by a judicious application of the fine properties of well-selected Cocoa, Mr. Bp's has provided our breakfast tables with a delicately-flavoured beverage which saves us many heavy doctor's bills. It is by the judicious use of such articles of diet that a constitution may be gradually built up until strong enough to resist every tendency to disease. Hundreds of subtle maladies are floating around us ready to attack wherever there is a weak point. We may escape many a danger which a single cup of Bp's Coffee will prevent. It is worth trying, and will surely do you good.—Solely sold in packets, labelled, 'Solely Serravallo's Genoa.'—JAMES EPFS and CO., Homoeopathic Chemists, 48, Threadneedle Street, E.C., and 179, Piccadilly, London, S.W.

KINAHAN'S LL WHISKY. Kinahan & Co. find that, through the recommendation of the Medical Profession, the demand for their CELEBRATED OLD SCOTCH WHISKY is increasing.

It is very great, and mixed with pleasure the following Analysis by Dr. HAYDEN'S has been made:—The analysed samples of this well-known and popular Whisky. They are soft and mellow to the taste, aromatic and coherent to the smell. The Whisky is of a fine quality, and is of the highest quality of very excellent quality. The Medical Profession may feel full confidence in its purity and quality of this Whisky. 20, Great Fitzroy Street, Oxford Street, London, W.

DINNFERD'S FLUID MAGNESIA. The best remedy for ACIDITY OF THE STOMACH, HEADACHE, BRUISES, PAIN IN THE BACK, COLIC, and INDIGESTION, and the best agent for delicate Constitutions, Ladies, Children, and Infants.

DINNER, 179, New Bond Street, London, and all Chemists.

DR. LOCKOCK'S PULMONIC WAFFERS. "I shall always consider it my duty to recommend them as a safe and effectual remedy for Coughs and Chest Complaints, and for all the various Affections of the Lungs, such as Asthma, Consumption, Bronchitis, Croup, Colds, Rheumatism, and all Hysterical and Nervous Complaints arising from a cold in the Head."—Price 1s. 6d. per box.

HOLLOWAY'S PILLS. The resources of Medicine and Chemistry are long and fruitfully tried before they yielded a remedy which could overcome Disorders of the Stomach and Nerves, all Professor Holloway's Pills are a system that has been tried in the safest and surest correctives of indigestion, heartburn, flatulency, acidity, and all the various Affections of the Stomach, and of the bowels, and declining strength. Holloway's Pills supersede all irregular action of the body, and so strengthen the system that it is able to resist every ailment the patient net at all shaken. This is the grand aim and object of the Pills, and the only method of attaining it without damaging the constitution, by the remedy given, as this end obtained by Holloway's Pills.

CHARLES LEE AND SON,

SUCCESSORS TO

MESSRS. JOHN & CHARLES LEE,

OF THE

ROYAL VINEYARD NURSERY, HAMMERSMITH, W.,

BEG TO ANNOUNCE THAT, IN CONSEQUENCE OF THE

RETIREMENT OF MR. JOHN LEE

from the Business, they have taken over the entire NURSERY and SEED TRADE so successfully carried on for many years by the late Firm, and they trust the same liberal patronage so long given to Messrs. JOHN & CHARLES LEE will be continued to the New Firm.

CHARLES LEE & SON

pledge themselves to devote all their energy to Raising First-class Stock in every Department, which the large resources at their command will enable them to supply with considerable advantage to the Public both as regards quality and price.

With a view to a more extensive production of STOVE and GREENHOUSE PLANTS of the best quality they intend to almost entirely rebuild their extensive ranges of glass on a new site, a portion of the old Nursery being taken up for building purposes.

All Orders to be addressed to

CHARLES LEE & SON,

ROYAL VINEYARD NURSERY, HAMMERSMITH, W.,

where the general business of the Nursery and Seed Trade will be carried on; or to

Mr. DIXON, Feltham Nursery,

Mr. CANNON, Ealing Nursery,

Mr. WEBB, Arboretum,

Mr. MARSLER, Wood Lane,

} Isleworth.

 Seedling Nurseries, Wisbech.

PYRUS or CYDONIA, the NEW JAPAN APPLE or QUINCE—This gorgeous hardy scented May-flowering fruit tree ripened a fine crop of its golden, deliciously delicious fruit, and especially big strong, although the general failure of our common Apple crop. The jam made is most delicious, which may be tasted at the nursery, or sample sent to those who really take an interest in the delicacies of the dinner-table.
 Original plants 2s. and 15s. each, younger 10s., 7s. 6d., and 5s. each.
WILLIAM MAULE AND SONS, The Nurseries, Bristol.

Splendid New Melon, 1877.
CHARLES LEE AND SON (Successors to Messrs J. & C. Lee) have the pleasure to announce that they have purchased the entire Stock of MANN'S HYBRID GREENISH MELON, which is not only a most excellent variety, but 'tis time it has already earned a high reputation in London and the provinces for its many excellent qualities, among which may be mentioned a remarkably big and exceedingly big strong, all seasons of the year—perfection of shape and size for dessert—a thin rind and melting flesh, with an overflow of perfumed juice. It is also a heavy cropper, and forces well.
 Dr. Hogg has spoken of this excellent Melon in the highest terms and after tasting it pronounced it a fruit of the highest merit.

Mr. CULVERWELL, of Thorpe House, fellow judge with Mr. FLOWERS, of Harlow Wood, at the Leeds Horticultural Show, where they awarded a First-class Certificate to "Mann's Hybrid Green-fleshed Melon" as being the most excellent specimen of the Melon, especially at that early season the 25th party of June.
 Mr. INGRAM, of Belvoir Castle, writes, in the third week of October, "that in spite of the disadvantage of a long term of gloomy weather, at that season of the year, Mann's Hybrid Green-fleshed Melon" was a very tender in fruit, very juicy and distinct in character.
 Messrs. Charles Lee and Son are now prepared to offer this very useful and delicious New Melon in special packets, at 5s. 6d. per packet.
CHARLES LEE AND SON, Hammarwich, W.

SPECIAL OFFERS TO LARGE BUYERS WHEN REQUESTED.

SPEED'S VINE AND ROSE MILDEW ANNIHILATOR.

JAMES VEITCH & SONS,
ROYAL EXOTIC NURSERY, KING'S ROAD, CHELSEA, S.W.,

Have much pleasure in offering this excellent preparation for the destruction of Mildew. It proves to be perfectly harmless to the Grape Vine, the Rose, and the Peach when applied to the youngest and most tender foliage, and the fruit itself may be dressed with perfect impunity in any state, even before the thinning period, and there are few things more sensitive than the cuticle of young Grapes in the early stage of their growth.

It kills the Mildew instantaneously, and can be rinsed off within a few minutes of being applied, leaving no smell or sediment, or other traces of its application.

It is not poisonous to Animals, although it is instant death to all Fungi.

Experiments were made on a piece of Mushroom spawn, and one puff of the spray distributor on its little active thread-like mycelium shrivelled it up as if charred. As it kills the fungus in a resting state as well as in an active state, there is every reason to hope that it may be found useful in checking diseases of the Potato, the Hollyhock, &c., that are caused by Fungi.

The following Testimonials have been received:—

From ROBERT HOGG, Esq., LL.D., F.L.S., &c., *Phonological Director of the Royal Horticultural Society.*

"I have great pleasure in bearing my testimony to the magical effect which your mixture has upon the Mildew of the Vine. When I was at Chatsworth a few months ago, the application of the mixture, through a spray distributor, on the foliage of the Vioes, was so destructive and so instantaneous as to leave no doubt on my mind as to its perfect efficacy in destroying the Mildew. On examining the foliage with a magnifying glass after the application, I could find no trace of the disease."

From Mr. WILLIAM THOMSON, *Tweed Vineyard, Clovenfords.*

"I tested Mr. Speed's remedy for Mildew this last summer, when staying for a few weeks at Chatsworth, and in my life I never saw a more radical remedy for any such pest. One puff of the spray distributor cleared the leaf of a Vine badly affected with Mildew, during the last no harm, and I believe it can be safely applied to the most tender plant, as well as the fruit of the Vine. I believe it will completely supersede the use of sulphur for destroying Mildew on Peaches, Roses, and Healths, and all other plants liable to attack by Mildew, and that it will prove a great boon to horticulture."

From Mr. STEVENS, *Gardener to His Grace the Duke of Sutherland, Freetown.*

"I have much pleasure in bearing testimony to the efficacy of your liquid for destroying Mildew upon Vines. I saw the liquid applied with a spray distributor, in one of the vintages at Chatsworth, to some badly infested leaves, and upon examining them early the following morning they were perfectly free from Mildew. If the liquid will destroy Mildew on Roses, Hops, &c., as completely as in this instance, it will be a most valuable article of commerce."

From Mr. HARRISON, *Knowsley Gardens.*

"Your Mildew mixture seems effectually to prevent the spread of Mildew. It is also very cleanly in use, being almost without smell, and leaving little or no sediment behind it unless used very strong, and even then it is easily rinsed off with a little clean water."

From Mr. JAMES ANDERSON, *Nurseryman, Mendocomb.*

"The solution prepared by Mr. Speed is the most effective that has come under my cognisance. By simply blowing the spray through a pipe on any leaf affected with Mildew the destruction of the fungus is complete, without the slightest injury to the most tender leaf. For the Stove, Greenhouse, and Rockery, or Peach-house, or even for the Nursery out-of-doors, this solution will undoubtedly prove invaluable, all that seems necessary to guard against is that the leaves operated upon should be as dry as possible."

Sold in Bottles, at 2s., 3s., 6d., 6s., and 10s. each; to make 1 Quart, ½-Gallon, 1 Gallon, or 2 Gallons, ready for use.

Price to the Trade on application to J. VEITCH & SONS, Sole Wholesale Agents.

GARDEN AND FLOWER SEEDS.

THOMAS METHVEN & SONS

BEG TO INTIMATE THAT THEIR DESCRIPTIVE PRICED

CATALOGUE OF KITCHEN GARDEN and FLOWER SEEDS, IMPLEMENTS, &c., for 1877,

Is now ready, and will be forwarded free on application.

THE NURSERY AND SEED BUSINESS

So successfully conducted for a number of years by the late Mr. JOHN INGRAM, will be continued to be carried on in its various branches, as heretofore, by his Widow and Two Sons, in the name of WOOD and INGRAM, who respectfully solicit a continuance of the kind and liberal patronage which has been given for a lengthened period to their Establishment.

THE NURSERIES, HUNTINGDON.—January, 1877.

JEFFERIES' LITTLE QUEEN COS LETTUCE,

Per Packet, 1s. 6d.,

Is the Earliest, Best Flavoured and Best Coloured Lettuce in cultivation.

MR. EARLEY, *The Gardens, Valentines*, says:—"Your Little Queen Lettuce proved a good selection, although the weather was very adverse to the trial."
MR. MEADES, *Gr. to the Rt. Hon. Viscount Barrington, Bucket Park*, says:—"Your Little Queen Lettuce is a capital variety, as hard as a stone, and has kept well from running to seed this dry summer."

MR. FARR, *Gr. to Sir R. Knightley, Bart., Pawley Park*, says:—"Your Little Lettuce has proved a very useful one, although the season had been very trying for that class of stuff; its early hearting and crisp sweet flavour are sufficient to recommend it to all who are desirous of a small but good Lettuce."

A Packet of this excellent Lettuce will be included in all our Collections of Vegetable Seeds.

JEFFERIES' HALF GUINEA COLLECTION OF VEGETABLE SEEDS,
JEFFERIES' GUINEA COLLECTION OF VEGETABLE SEEDS,

Moore's Duke of Edinburgh Cucumber.
J. MONRO begs to inform the Trade, &c., that he has SOLD the ENTIRE STOCK of Seed of the above-named Cucumber to Messrs. CARTER and CO., The Queen's Seedsmen, 237 and 238, High Holborn, London, W.C.; and as no other Cucumber is grown by J. Monro, those having it from the above-named Firm are bound to have it true.
Foster's Box, January 2, 1877.

The Best Scarlet-fleshed Melon.

SUTTON'S HERO OF BATH.
From Mr. W. Wisnith, *Gr. to the Right Hon. Viscount Eversley*:—"I consider your Hero of Bath the best scarlet-fleshed Melon yet in commerce, being A 1 in quality, appearance, and product of the soil. Your Hero, as it is called, had a prejudice against scarlet-fleshed Melons, pronounces this variety superior."
From Thomas Lockie, *Gr. to the Right Hon. Lord Ocho Fitzgerald, Aquart st.*:—"I consider your Hero of Bath Melon the best I have ever seen of the scarlet-fleshed class. It is very handsome, of good constitution, and excellent in flavour."
Price 2s. 6d. per packet.

SUTTON AND SONS, The Queen's Seedsmen, Reading.

SPECIAL OFFER

OF FOREST, FRUIT, ORNAMENTAL TREES, &c.
PINUS AUSTRIACA, well furnished, 3 to 4 feet, 12s. per 100; 4 to 6 feet, 20s. per 100.

EVERY DESCRIPTION OF HORTICULTURAL and AGRICULTURAL SEEDS, SEED POTATOS of finest quality, both Home-grown and Imported.

CHARLES SHARPE and CO., Seed Farmers, Stamford, and 21, New Seed Market, Mark Lane, London, E.C. All letters address Stamford.

OSBORN & SONS

BEG TO ANNOUNCE THAT THEIR

ANNUAL CATALOGUE OF KITCHEN GARDEN and FLOWER SEEDS

Is now ready, and will be forwarded post-free to all applicants.

It contains a choice selection of "NOVELTIES" and of the "BEST" and most approved kinds of VEGETABLE and FLOWER SEEDS, including among

VEGETABLE SEEDS—Osborn's Forcing French Bean, which has been proved one of the best and most prolific; Osborn's Select Red Beet (or Dell's Crimson), Osborn's Winter White Broccoli; and among

FLOWER SEEDS—Pyrethrum aureum laciniatum, a very distinct and beautifully cut-leaved form of the deservedly popular "Golden Feather." Like its prototype it is perfectly hardy, but of dwarfer habit and more spreading, and is admirably adapted for bedding. It obtained a First-class Certificate at the Meeting of the Royal Horticultural Society, May 3, 1876; and also a First-class Certificate at the Grand Exhibition held at the Westminster Royal Aquarium, May 16 and 17, 1876.

FULHAM NURSERIES, LONDON, S.W.

NEW SEED CATALOGUE

For SPRING, 1877.

All intending Purchasers of choice Kitchen Garden or Flower Seeds should send for a copy of the *Illustrated Guide for Amateur Gardeners*, which will be found the most complete, useful, and beautiful Seed Catalogue ever published.

Price 1s., Post-free.

Gratis to Customers or intending Purchasers.

The Illustrated Guide for Amateur Gardeners, Spring, 1877,

Contains 112 pages of beautifully illustrated Letterpress, with two superbly finished Coloured Plates, Original Articles on the Rearing and Cultivation of various Garden Crops and Flowers, and complete Instructions for the successful Management of the Kitchen and Flower Gardens throughout the year, together with a Select List of choice Kitchen Garden and Flower Seeds, Seed Potatoes, &c.

The most practical and comprehensive Guide for the Amateur yet issued, and should be read by every one having a garden.

OPINIONS FROM THE PRESS.

"The inside is quite in character with the beauty of the exterior, and we do not know of a more useful or beautiful garden guide to lie on the drawing-room table."—*Villa Gardner*.

"This is the most tasteful and best executed thing of the kind that I ever remember having seen, and would be an ornament to any room."—*The Country*.

"This superbly illuminated and handsomely illustrated annual is something more than a mere catalogue of seeds and plants, inasmuch as it contains the most copious and carefully written instructions for horticulture. The Guide is quite a work of art as well as a compendium of garden work."—*Norfolk News*.

"The calendar for the kitchen garden will be found most useful. The hints for the rearing of crops are at once comprehensive and practical."—*Land and Water*.

"The most choice and beautiful catalogue we have ever seen."—*Lord's London News*.

"The flower garden calendar, written expressly for this publication, will be especially useful for all lovers of flowers."—*The Record*.

"Profusely illustrated, and the coloured plates are quite beyond the average of book illustrations."—*Liverpool Mercury*.

NORWICH.

FIRST-CLASS NURSERY STOCK.

JAS. BACKHOUSE & SON

Begin to offer the following, of which they have an extra stock:—

FOREST and ORNAMENTAL TREES and SHRUBS.

ABIES DOUGLASHI, extra transplanted, 2 to 3 feet, 100r.; 3 to 4 feet, 120r. per 100

ARBORVITÆ, American or common, 2 to 3 feet, fine, 27s. 6d. per 100

" Chinese, transplanted, 9 to 12 inches, 15s. per 100

ASH, Mountain, 6 to 7 feet, 60r. per 100; 8r. per 100; 7 to 8 feet, 12s. 6d. per 100

ARUNDO CONSPICUA, an elegant Grass, 18s. per dozen

BERBERIS DARWINII, extra transplanted, 12 to 18 inches, 12s. per 100; 17s. 6d. per 100

" WALLICHII, extra transplanted, 12 to 18 inches, 25s. per 100

BROOM, common, 1-yr. seedling, 9s. per 100; 12. 6d. per 100

" bushy, transplanted, 30s. per 100; 6s. per 100

" Spanish, transplanted, 70s. per 100; 9s. per 100

CEDAR, Red, 1½ to 2 feet, 2s. per dozen, 30s. per 100; to 3 feet, 7s. per dozen, 50s. per 100

ELM, English, from seed, 6 to 7 feet, 60r. per 100; 12s. 6d. per 100; 7 to 8 feet, 25s. per 100

" " grafted, 3 to 4 feet, 27s. 6d. per 100; 5 to 6 feet, 40s. per 100

" " grafted of ornamental sorts, 6 to 30s. per dozen

" Wych, 1½ to 4½ feet, 40s. per 100; 6s. per 100; 5 to 7 feet, 12s. 6d. per 100; 7 to 8 feet, 25s. per 100

" Weeping, 6 to 9 feet stems, good heads, 30s. to 35s. per dozen

EUONYMUS RADICANS VARIEGATUS, excellent dwarf shrub for edgings or borders, 25s. per 100; 4s. 6d. per dozen

JUNIPERUS TRIPARTITA, a fine branching semi-erect Juniper, well adapted for covering banks, &c.; 1½ to 2 feet, bushy, 10s. 6d. per dozen; 2 to 2½ feet, bushy, 16s. per dozen

LIBOCERUS DECURRENS, 2 to 3 feet, 18s. per dozen

ERICA CARNEA ALBA (White Spring Heath), 15s. per dozen; hardy sorts, good variety, 40s. per 100; 6s. per dozen

LIMES, from layers, 3 to 4 feet, 26s. per 100; 2s. 6d. per dozen; 4 to 5 feet, 20s. per 100; 3s. per dozen; 8 to 9 feet, 100r. per 100; 15s. per dozen

LILAC, Common, 2 to 3 feet, 18s. per 100; 3s. per dozen

" White, 2 to 3 feet, 25s. per 100; 5s. per dozen

MAPLE, Norway, 6 to 8 feet, 12s. 6d. per 100; 2s. 6d. per dozen; 8 to 10 feet, 25s. per 100; 5s. per dozen

HORNBEAM, 3 to 4 feet, 35s. per 100; 5s. per 100

PICEA NOBILIS, 2 to 2½ feet, fine stout plants, 200s. per 100; 20s. per dozen; 2½ to 3 feet, do., 180s. per 100; 4s. per dozen; 3 to 3½ feet, do., 330s. per 100; 5s. 6d. per dozen

POPLAR, Black Italian, 10 to 12 feet, 30s. per 100; 6s. per dozen; 15 to 18 feet, extra, 21s. per dozen

" Lombardy, 2 to 3 feet, 25s. per 100; 5s. per 100; 3 to 4 feet, 45s. per 100; 6s. per 100; 4 to 5 feet, 60s. per 100; 8s. per 100; 5 to 7 feet, 90s. per 100; 12s. 6d. per 100; 2s. 6d. per dozen; 7 to 8 feet, 20s. per 100; 4s. per dozen

PRUNUS SINENSIS ALBA-FLENA, strong, 18s. per dozen

THUJA VERANANSA, 9 to 12 inches, 60s. per 100; 9s. per dozen

THUJOPSIS DOBERATA and VARIEGATA, 9 to 12 inches, 80s. per 100; 12s. per dozen; 12 to 15 inches, 200s. per 100; 18s. per dozen; 15 to 18 inches, 24s. per dozen

VINCA ACUTILOBA (Italian Periwinkle)—A fine addition to the number of bushy creepers, and will be especially valuable for clothing banks or rockwork. It is of compact and bushy growth, with shining deep green leaves, and pale lilac or French-white flowers, 2s. 6d. each; 24s. per dozen

YUCCA CONSPICUA, extra fine stout plants, 2 to 2½ feet, 5s. to 7s. 6d. each. Highly ornamental for vases, centres of flower-beds, &c.

FLOWERING SHRUBS, of sorts, in good variety, and strong plants, 4s. to 8s. per dozen

For prices of LARCH, SCOTCH and SPRUCE FIRS, and other Forest Trees, see Catalogue, which will be sent on application.

FRUIT TREES.

VINES, strong planting cans, leading sorts, 2s. to 7s. 6d. each

FIGS, strong, of sorts, 3s. 6d. to 7s. 6d. each

APPLES, pyramid or bush, with fruit-buds, extra transplanted, 2s. 6d. each

CHERRIES, best sorts, fine maidens, 10s. per dozen

dwarf trained, 30s. to 45s. per dozen

CURRENTS and GOOSEBERRIES, good useful sorts, 2s. per dozen, 12s. 6d. per 100; large prize sorts, 4s. per dozen, 25s. per 100

PEARS, of sorts, dwarf-trained, strong, 2s. 6d. to 5s. each

" " of sorts, on Quinces, 12s. 6d. to 25s. each

" 2-yr. seedling, extra fine. Price to the Trade on application

PLUMS, Victoria, half-standards, 12. 6d. each, 12s. per dozen

" dwarf-trained, of sorts, 2s. 6d. to 3s. 6d. each

ROSES.

STANDARDS and HALF-STANDARDS, fine named sorts, our selection, 15s. per dozen, 105s. per 100

DWARF, of fine named sorts, our selection, 9s. per dozen, 65s. per 100

LISTS ON APPLICATION.

WORDSLEY, STOURBRIDGE.

LILIES.—LILIES.

MR. WILLIAM BULL,

Being an annual importer of many thousands of Liliums direct from their native habitats in various parts of the world, can supply all the choicest sorts at very moderate prices.

Good and varied selections can be made by Mr. W. B. at 18s., 30s. and 42s. per dozen.

The following Handsome and Choice Hardy kinds can be recommended:—

AURATUM.—Consignments of many thousands have now arrived, and the bulbs are in magnificent condition, so that they are offered at the following low prices—18s. and 30s. per dozen; extra-sized bulbs 3s. 6d. each.

BLOOMERIANUM OCELLATUM.—An extremely handsome hardy Lily, producing large flowers of a rich tawny orange colour, spotted near to the tip of the perianth segments with blackish crimson. 3s. and 7s. 6d. each.

ELEGANS SPLENDIDUM.—Bright orange spotted with black; a very showy and attractive variety. 3s. 6d. each.

HUMBOLDTII.—A splendid species, from Humboldt County, California; it is quite hardy, and produces large golden-yellow flowers, which are spotted with purple. One of the best of modern introductions. It has been awarded a First-class Certificate by the Floral Committee of the Royal Horticultural Society. 3s. 6d. and 5s. each.

MONADELPHUM SOZOVITZIANUM.—Rich citron colour, spotted with black; flowers most deliciously fragrant. One of the best of Lilies. 2s. 6d. and 3s. 6d. each.

NEILGERRENSE.—This magnificent Lily is by far the finest of its section. The flowers are deliciously fragrant, and of great substance; the Collector writes that it bears as many as seven flowers on a stem, each flower of the marvellous length of 1 foot. They range in colour from pure white to numerous shades of various varieties having pink flower-tubes. 5s., 7s. 6d. and 10s. 6d. each.

NEILGERRENSE TUBIFLORUM.—A handsome and distinct variety of the preceding. 10s. 6d. and 15s. each.

PARDALINUM (puberulum).—A very beautiful hardy Lily, freely producing its fine flowers, which are of a rich golden-orange colour, attractively spotted with maroon-purple. 3s. 6d. and 5s. each.

PARVUM.—A pretty Californian Lily; flowers recurved, canary-yellow, slightly spotted. 3s. 6d. and 5s. each.

PURPUREUM.—This is a beautiful and distinct Californian Lily. It produces very fragrant flowers; the petals on opening are of a light colour, changing to a delicate purple; densely spotted, 3s. 6d. and 5s. each.

TIGRINUM FLORE-PLENO.—This attractive variety produces beautiful double flowers of a bright orange-scarlet colour; it has been introduced from Japan, and is a distinct and extremely handsome variety. 3s. 6d. and 5s. each.

TIGRINUM JUCUNDUM.—(Maximowiczii).—A very bright and cheerful-looking Japanese Lily; flowers light cinnamon-colour, marked on the lower half of the segments with black dots. 3s. and 7s. 6d. each.

WALLICHIANUM.—This is an extremely handsome species; the flowers are very large, deliciously fragrant, and of a delicate creamy-white colour. 7s. 6d. and 10s. 6d. each.

WASHINGTONIANUM.—This noble Lily inhabits the western slope of the California Sierra Nevada; it grows six to twelve, to eighteen large flowers on a stem; white, slightly flushed with lilac, and sweet-scented. 3s. 6d. and 5s. each.

LILIES BY THE 100 OR 1000,

For planting in Borders, Strubberies, among Rhododendrons, massing in beds, or grouping among Shrubs.

As Mr. WILLIAM BULL annually imports immense numbers from their native habitats, he can offer choice and new Lilies, also the well-known celebrated showy sorts, at very low prices when taken in quantity. Special quotations on application.

Good and varied selections can be made by Mr. W. B. at 18s., 30s. and 42s. per dozen.

Mr. WILLIAM BULL has just received an importation from California of many thousands of Calochortus oropsis, Cyclocheilus, Brodiaea, Tritis, Callipellis, Erythronium, Bioceras, and Fritillarias. Prices per dozen or 100 on application.

SATURDAY, JANUARY 13, 1877.

THE CEDARS OF LEBANON.

WHEN Seth, the son of Adam, was sent by his dying parent to fetch the "oil of mercy" from Paradise, he saw from the gate of that glorious garden, which an angel opened for him without permitting him to enter, a Cedar of Lebanon, with branches borne high towards Heaven. The tree seemed to typify the great disaster of Adam's early career. It stood there stricken and leafless, and yet suggesting hope—for the legend is of Christian origin—since a child in glittering raiment was seated on its top, the symbol of hope for all future generations.

This ancient legend—the dream, perhaps, of a Syrian hermit—shows that the Cedar of Lebanon, the timber tree of the Temple built on Zion, was held in highest estimation, and exercised the fancy. The story proceeds that Seth received from the angel three seeds of that tree which he beheld still standing upon the spot where sin had been first committed, but standing there blasted and dead. He carried the seeds home, placed them in the mouth of the dead Adam, and so buried them. And here the natural history of the legend is at fault, for the three seeds, ripened on the same tree in Paradise, produced three trees of different kinds. The truth is, the Cedar of Lebanon, the Cypress, and the Pine, which grew from those seeds, were held in equal estimation by the recluse who dreamt this legend, and therefore the same marvellous, though inconsistent origin was claimed for them all. Their future history is curious. Growing on the grave of Adam in Hebron, they were afterwards most carefully protected by Abraham, Moses, and David. After their removal to Jerusalem, the Psalms were composed beneath them; and in due time, when they had grown together and united into one giant tree, they, or it—for it was now one tree, a Cedar of Lebanon—was felled by Solomon for the purpose of being preserved for ever as a beam in the Temple. But the design failed; the king's carpenters found themselves utterly unable to manage the mighty beam. They raised it to its intended position, and found it too long. They sawed it, and it then proved too short. They spliced it, and again found it wrong. It was evidently intended for another, perhaps a more sacred office, and they laid it aside in the Temple to bide its time. While waiting for its appointed hour, the beam was on one occasion improperly made use of by a woman named Maxmella, who took the liberty of sitting on it, and presently found her garments on fire. Instantly she raised a cry, and feeling the flames severely, she invoked the aid of Christ, and was immediately driven from the city and stoned, becoming in her death a pro-Christian martyr.

In the course of an eventful history the pre-destined beam became a bridge over Cedron, and being then thrown into the Pool of Bethesda, it proved the cause of its healing virtues. Finally, it became the Cross, was buried in Calvary, exhumed by the Empress Helena, chopped up by a corrupt Church, and distributed.

Other inconsistencies in the history of this famous tree are the enormous weight of the relics of the true Cross as disposed of by the Mediaeval Church, and the fact that most of the relics are of Oak, which has always grown freely in the grounds of Italian and English ecclesi-

astics, and which does not grow in Hebron, except the evergreen species. The above story is suggestive in many ways.

In Evelyn's *Silva* of 1664 he does not mention the Cedar of Lebanon, and we may therefore be sure that it had not then descended from its Syrian mountain to the congenial level of the banks of the Thames, in our higher latitude. It was first planted largely by John, Duke of Argyle, the friend of Jeanie Deans. The noble grove at Whitton Park, near Twickenham, was planted by him, and the seeds, which he distributed among his friends, produced the existing ornaments of several sites at Fulham, Richmond, and other neighbourhoods, and established the Cedar of Lebanon in the various gardens on the Thames, where it is still an ornament that may be often observed.

One of the oldest, if not the oldest, Cedars of Lebanon in England is that standing in Bretby Park, Derbyshire, on the east front of the Hall. The gardeners' accounts prove this tree to have been planted in February, 1676. The girth of its trunk, at 4 feet, is 15 feet 8 inches; and so far as we could judge the size of the trunk is not much less at 15 feet or 16 feet, where it divides. From this point the main stem runs up 50 or 60 feet. The spread of the two longest lateral branches is about 100 feet. This tall Cedar has lost many limbs, and is now only scantily provided. The stump of every lost limb has been carefully sealed with lead, and each remaining branch is supported by chains.

There is a legend that a limb of this tree falls at the death of a member of the family. On Maundy Thursday, 1773, when the Cedar in the park was nearly a hundred years old, a friend called to see Lord Chesterfield. He was dying. "Give Dayroles a chair" were his last words, and no doubt the Cedar lost a large limb, for the departed Earl, who died true to his principles, whispering faintly those courteous words with his latest breath, was far beyond the average of men, and greater than his detractors. That fine gentleman of a manifold accomplishments was the despicable individual that the delightful poet Cowper, a morbid man and by no means an impartial judge of men, imagined him.

His life was one of many sacrifices. He poured forth the fruit of his experience with infinite pains for a son to whom he was devoted, and the youth died almost before entering the great world. The old Cedar must have lost a heavy branch. It has lost many since, and the family history has been a mournful one. The last Earl died a young man and childless, on reaching home after a visit. His sister was the wife of Lord Carnarvon, and her death will be remembered. The fall of these recent limbs has left the old tree a wreck—a lofty and noble trunk, almost naked except a few remaining branches on the top, supported by artificial means.

It is said there are seven trees remaining of the forest thinned for the building of Solomon's Temple, and the girth of the largest is 45 feet. [Of late years other forests of the same tree have been discovered, see our volume for 1866, p. 876. EDS.] There is a Cedar of Lebanon at Wilton Abbey 26 feet in circumference at 1 foot from the ground; there are famous trees, too, at Strathfieldsaye, Sion House, and Shobdon.

In England this type of indestructibility produces only second-rate timber. In Palestine fragments of particular value were kept in Cedar boxes by preference, and there was a common saying in reference to articles of value that they were worthy to be cased in Cedar. Not only was the wood extremely durable, but it was of rapid growth, and in Hebrew families it was not uncommon for the parents of a child to plant a Cedar of Lebanon at his birth, to be cut down for the construction of a bedstead at his marriage. In England, where colliers marry at eighteen, and farm labourers at twenty, and the middle-class at twenty-five, there are no trees of strength and toughness which would in like manner overtake the wedding-day, so as to be adapted to the purpose above suggested. *H. Evershed.*

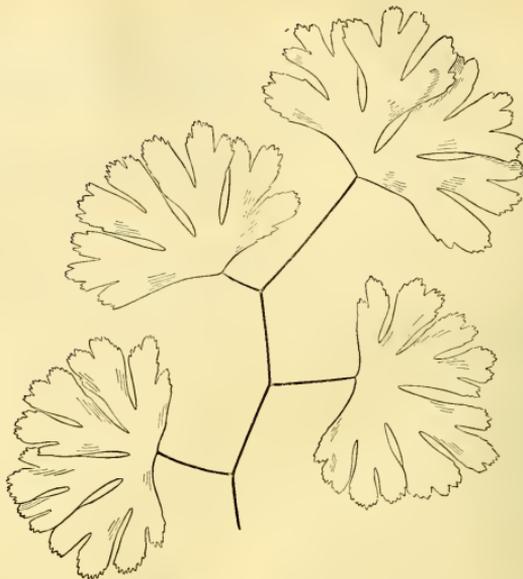

FIG. 5.—ADIANTUM PALMATUM, SHOWING HABIT. (1 NAT. SIZE.)

New Garden Plants.

ONCIDIUM CRISPUM (Lodd.) OLIVACEUM.
I found last autumn a very rich display of *Oncidium crispum* (Lodd.) in the nursery of Messrs. Veitch, and those gentlemen were in a state of despair as to the endless quantity of varieties. As to me I felt much pleased by what I regard as a most interesting variety. It has no Horse-Chestnut-brown in it at all. It is olive-green over and over. The area at the base of the anterior lacinia of the lip is finely yellow, and the

calli, column, wings, and a few blotches at lips base are beautifully black-purple. The combination of these colours makes an unusually nice impression. *H. G. Rebb. f.*

ADIANTUM PALMATUM, sp. n.*

The species of this group of palmate-pinnated Maiden-hairs have been much misunderstood. Being all once considered as one, they have been classed with

* *Adiantum palmatum*, sp. n.—Froonds scrambling or scandent, elongate-oblong, narrowed to the apex, tripinnate;

FIG. 6.—ADIANTUM SPECIOSUM (½ NAT. SIZE.)

A. Feei, as forming a scandent group; but this at least does not apply to *A. speciosum*. The first to be named was the *A. digitatum* of Presl, a plant of which specimens, presumably correct, are in the Kew Herbarium. The *A. speciosum* of Hooker, described and figured in *Species Filicum* (ii., 45, t. 85 c) came next, and this appears to be well represented by living plants, which have been sent out under this name by Messrs. Veitch & Sons. These two were thrown together under the name of *A. digitatum*, in the *Synopsis Filicum* of Hooker and Baker

pinnales distinct, the lower ones obliquely deltid, the posterior side being broadest; ultimate pinnales large, smooth, distant, distinctly stipitate, the stalks 1—2 inch long, in outline varying from obovate wedge-shaped to semi-orbicular, but all palmately cleft half-way to the base or more, and varying in breadth from about 1 inch to 2½ inch; sort oblong, variable in length, situate at the tips of the segments, usually one to each; indusium glabrous, entire; veins forked, 6—8 to each ultimate segment; stipes smooth, dark castaneous, the rachises also smooth and of the same colour, flexuose.—Hab. Chimborazo and Peru.

(p. 125), and a third species included with them, the latter being that here called *A. palmatum*. The three plants are of course near allies, but they are distinct enough for all practical purposes. *A. digitatum* is by comparison smaller in its parts, and of a much neater aspect than the rest, and, so far as can be judged from the specimens referred to—one from the Berlin Herbarium, where *A. digitatum* originated, and another from M. Glazion—it would seem to be altogether a smaller and a dwarfer-growing plant. *A. speciosum* is of much stouter habit than this *A. digitatum*, and produces broadly and abruptly triangular spreading fronds, 2 feet long and 20 inches broad, the large pinnales of which, and at least the ultimate rachides, are downy; while in the *A. palmatum* now described, the fronds are narrow, elongate, reaching 3½ feet in height, and about 10 inches in breadth, apparently almost, if not quite, indefinite in evolution, and having the rachides and the pinnales everywhere quite smooth, the ultimate rachides being distinctly flexuose.

A. palmatum is cultivated by Messrs. Veitch & Sons, and by Mr. B. S. Williams, of Holloway, to both of whom we are indebted for specimens. Our best examples are from the former, and were gathered by one of their collectors at a high elevation on Chimborazo, where the plant is noted as being rare. This specimen, which may not include the whole of the rachides, is 3 feet 6 inches long, and indicates a scrambling habit, though not perhaps strictly scandent. The rhizome is creeping, and the fronds are of an indefinitely elongated form. A very noticeable feature in the plant is the flexuose or zig-zag character of the rachides, most marked near the apex of the fronds, and in the rachides of the primary pinnae. The pinnales are herbaceous in texture, smooth, large, from 1 inch to 1½ inch in breadth, distant, and very distinctly stalked, the stalks varying from ½ to ¾ of an inch; the terminal ones are usually wedge-shaped, while the lateral ones are usually truncate at the base, so as to become semicircular in outline; they are deeply cut down into from three to

five large lobes, which are again more or less parted, an oblong sorus terminating each of the divisions in the fertile portions. When there are two, the tips of the segments are shallowly toothed. The fronds are deciduous. It will be a very elegant garden plant, as the accompanying illustration shows (fig. 5). We understand that it thrives best in a cool stove temperature, and does not require much water. We have seen it growing vigorously in a house entirely without fire-heat. Our figures were derived from one of Mr. Williams' plants, which we are informed were collected in Peru, by M. Roez.

A specimen, as we have said, was imported by Messrs. Veitch & Sons, and is represented by our accompanying figure 6. It has a creeping rhizome, from which arise stout triangular deciduous fronds, with a lamina nearly as broad as long, and very distinct in character from the elongated lamina of the fronds of *A. palmatum*. The fronds are at least tripinnate, the lowest pinnule fully to inches long, with the first anterior pinnule 2 inches long, and the first posterior one 4 inches, thus forming an unequal-sided triangle. The ultimate pinnules on fronds of this size are from 1 to 1½ inch across, the terminal one being wedge-shaped at the base, and the others more or less truncate, but in the more leafy fronds of a younger stage of development there are often pinnules of 2 or 3 inches in breadth. The pinnules are deeply lobed in about three or four divisions, the lobes themselves being again deeply parted, and the sori oblong, crossing the tips of these ulterior lobes. The pinnules are covered with short dense hairs, which give them a woolly feel. Messrs. Veitch's plants were introduced from Peru. *T. M.*

THE FERTILISATION OF PLANTS.

MR. DARWIN'S new book,* like its predecessors, is a perfect mine of facts and generalisations; and it has been no easy task to digest it. I, however, pursue endeavouring to give as concisely as possible some of the chief facts and conclusions which are of more special value to horticulturists.

In an introductory chapter Mr. Darwin describes the plans pursued, which were as follows. Confining his observations almost entirely to cultivated and conspicuous flowers, he protected by a net the parent plants. Several flowers were fertilised with their own pollen, the seedlings resulting being called "self-fertilised plants." Other flowers on the same plant, the stamens not being removed, so that Nature might be closely followed, were fertilised with pollen from a distinct plant of the same stock, growing, however, under the same conditions. Their seedlings he calls "intercrossed plants." I shall limit the word "crossed" to plants derived by a cross of an entirely new stock. As the two kinds came up, whenever one of each kind appeared simultaneously, they were planted one on each side of a pot. Proceeding thus until from six to twenty or more pairs were established, the remaining seedlings were planted thickly in a large pot or in the open ground, often thus having to struggle for existence, with results to be mentioned hereafter. Conditions of soil, light, moisture, &c., were made as exactly alike as possible.

To determine the results, the relative heights of the fully-grown plants were compared, and a long table in a chapter viii. gives the means for fifty or more species of thirty orders; the height of the intercrossed being fixed at 100—the mean of all the self-fertilised is 87. Mr. Darwin, however, omits certain cases which are more favourable to the latter kind; thus, while inserting all ten generations of *Ipomoea*, he omits all mention of the wonderful self-fertilising and tall variety he named "Hero." Again, of *Mimulus*, while inserting the first to the third generations, he omits the fourth to the seventh inclusive, when the self-fertilised exceeded the intercrossed in height; for while the average difference in the first three generations is shown by the proportion of 100 : 65, in the subsequent years the ratios were as 100 : 110, 100 : 126, and even as 100 : 137; neither has he inserted the second year's growth of *Eschscholtzia*, viz., 100 : 100, nor that of *Lobelia fulgens*, viz., 100 : 167—the self-fertilised being in these vastly superior to the intercrossed! Had our author added these—and I cannot see any good reason for their omission—the resulting mean ratio would have been as 100 : 118! Height, however, as Mr. Darwin confesses, is not always a satisfactory nor even trustworthy test; for it

shows only one element of vigour; and if a plant be unnaturally "drawn," as occurred with *Dianthus*, not even that. The weight of the entire plant, had it been possible to ascertain it in all cases, would have been more desirable. Some few plants were weighed, and a table (B) is added, and the difference is often striking. Thus the height of intercrossed plants of *Brassica oleracea* is to that of the self-fertilised as 100 : 95; that is practically the same; but their respective weights were as 100 : 37; giving a difference between the percentages of fifty-eight! That difference is exceptionally great; for if we take the eleven plants that were weighed, a similar difference between the weights and heights of the mean is twenty-six. Unfortunately weighing could not be always done; and as might be expected, the height in some cases gave adverse results, i.e., the self-fertilised grew exceptionally taller than the intercrossed. The reverse, however, was the general rule. Hence it is concluded that intercrossed plants grow under the same conditions have, at least for the first few generations, a decided advantage; unless the plant, like *Pisum sativum*, has been cultivated for many years and propagated solely by self-fertilisation, for in such a case intercrossing does no good. This advantage is shown in the greater vigour of the intercrossed, especially among the first few, though it does not always show itself from the very first; the self-fertilised seedlings being often equal to or taller than the others; but soon after the preliminary stage is past, then the intercrossed begin to surpass their rivals, and ultimately even greater luxuriance, darker foliage, greater fertility, and brighter tints in the flowers. But after several generations of close interbreeding, the latter become more uniform in colour. This fact is associated with another—viz., that although intercrossing is beneficial at first, subsequently it does no good at all; and then decidedly intercrossed and related plants become equal to, if not inferior to, plants of the same kind which have been repeatedly self-fertilised. Mr. Darwin more than once attributes the slight differences between certain self-fertilised and intercrossed plants to the deterioration of the latter through constant inbreeding; but he does not observe that actual self-fertilisation is a still closer form of inbreeding; hence such results tell in favour of the "lasting" powers of self-fertilisation—that they have not deteriorated, at all events, in the same ratio as the intercrossed. This, again, is analogous to the fact that intercrossing distinct flowers of the same plant often does no good, or the given results inferior to self-fertilisation; excepting in the case of some nearly self-sterile plants. Thus, Mr. Darwin speaks of *Ipomoea*—"That the self-fertilised plants grew a little taller, were heavier and generally flowered before those derived from a cross between two flowers on the same plant." A few cases, such as *Digitalis*, *Eschscholtzia*, *Corydalis* alba and *Oncidium* are mentioned, in which a slight advantage accrued to the offspring of flowers fertilised with pollen from others on the same plant. It is an observable fact that these four plants are nearly self-sterile, so that it would seem that the flowers on the same plant had become more and more highly individualised in some way, though it would be dangerous to generalise from so few cases, especially as it was not the case with some other self-sterile plants. An interesting case, not recorded by Mr. Darwin, is the *Victoria* regia, which is said to have yielded 25 seeds only when naturally self-fertilised; 60 when artificially self-fertilised; 100, when by pollen from a different flower on the same plant, and as many as 300 seeds when intercrossed with pollen from a separate one.

The third series of experiments brought out the most important result of all—that when either intercrossed or self-fertilised plants were crossed with pollen from plants raised from an entirely new stock, the ancestors of which had grown at quite different localities, then the resulting "crossed plants" vastly superseded the self-fertilised, and very greatly, though to a less extent, the intercrossed plants of nearly related origin. Every element of vigour was usually enhanced, and colours became much more varied and pronounced. These experiments thus strongly corroborate the value of seed growers and propagators, of introducing fresh seed from distant localities. Here, then, we may see how Nature brings to her aid various means to effect this. Insects do the first office in intercrossing the closely related plants growing in the same district; and the strong persistency in Nature would imply that all the individuals of a species growing in the same

locality were not only closely related, but were seldom crossed with pollen brought from a great distance. This is the first step in the progress of improvement. As the species spread into other areas, birds, especially, perhaps, "of passage," will carry about seeds from different stocks, and having introduced them into new areas, insects will then fertilise the old long-residents by means of the newly bird-imported seedlings; while the fact that insects and birds often feed more or less exclusively on one and the same kind of plant respectively, will favour such crossing. Illustrations will be hereafter given of the benefits which result from crossing distinct stocks.

It may be interesting to the reader to know that Dean Herbert long ago anticipated these results of Mr. Darwin, for he says (*Amateur's Notebook*, p. 371)—"I have inclined to think that I have derived advantage from impregnating the flowers from which I wished to obtain seed with pollen from another individual of the same variety, or, at least, from another flower rather than its own . . . and especially from an individual grown in a different soil or aspect."

Though self-fertilisation does not usually produce such marked results as intercrossing, nor the latter such benefit as crossing with a distinct stock, yet it must not be supposed that, therefore, plants cannot fertilise themselves. The known number of self-sterile plants is very small, i.e., plants in which the flower's own pollen is not a sufficient stimulus; and even these would probably become self-fertile under certain climatal conditions, as some are known to do, especially on the reduction of temperature. Moreover, in several instances amongst Mr. Darwin's experiments the self-fertilised were more prolific and more vigorous than the intercrossed and in some genera highly self-sterile forms appeared and transmitted their self-fertilising properties to their descendants; so that, as was the case with *Hero* in *Ipomoea*, they did not even profit from a cross with a distinct stock! Then again many plants possess "deistogenous" flowers as the *Violet*; i.e., minute nearly apetalous and closed flower-buds, which produce an abundance of good seed; while on the other hand conspicuous flowers adapted for intercrossing often set no seed at all in the absence of insects. Lastly, a considerable number of our wild genera with very inconspicuous self-fertilising flowers, such as Chickweed, Knotweed, Fumitory, &c., are abundant in individuals, prolific, and very rapid seeders, vigorous in growth for their size, and when transplanted into other regions of the globe, as *Polygonum aviculare* into New Zealand, grow to much larger dimensions, and, what is more remarkable, completely invert the rule, so that Mr. Darwin's observations on cultivated plant—[or for they set out the native population, and are wonderfully vigorous in the struggle for life! On the other hand Mr. Darwin's experiments on cultivated plants clearly show the great superiority of intercrossed, and especially crossed, plants when under competition with self-fertilised individuals. Mr. Darwin, though often speaking of the "evils" of self-fertilisation (a term which I hope to show requires a relative interpretation only), is obliged to confess "that self-fertilisation is in some measure more beneficial than 'crossing,' and under certain advantages, and this is only to be acquired by different constitutions in the parents."

Some horticultural importance lies in the fact that the colouring of self-fertilised plants always tends to become extremely uniform in successive generations. This tendency already appeared in the later generations of closely related intercrossed plants subjected to the same environing conditions; but it is even more marked in the case of self-fertilised plants; and an obvious fact issues out of this—that if horticulturists wish to retain and render permanent any particular "strain," they should carefully select it, and then endeavour to fix it by securing self-fertilisation as much as possible, accompanied by entire freedom from competition.

The first chapter of Mr. Darwin's work being introductory, is followed by five chapters in which are recorded the results of his experiments on a large series of plants, the seventh chapter containing tables and a summary of these results. I propose in the next communication to select some of the more interesting cases. The subsequent contributions to the *Gardener's Chronicle* will treat of the various matters dealt with by Mr. Darwin in the remaining five chapters of the book. *George Huxley.*

(To be continued.)

*Cross and Self-Fertilisation of Plants. By C. Darwin. Murray.

A PLEA FOR THE SPECIALIST.

IN your issue of December 16 you favour us with your views on the "number of special societies that are springing up on all sides."

With your opening paragraph I believe you will have an almost, if not quite, universal sympathy, and few so sensitive, or however obtunded, may discern their normal condition, will object to the gentle banter you bestow upon them; but to the closing propositions of your article I feel bound to take exception. Thus you say, "Let a man be a specialist by all means if he likes, but before he bands with others in what we may call a corporate capacity . . . let him be thoroughly well versed in general horticulture." This appears to me, unless interpreted in so narrow a sense, as liable to fritter away its meaning to involve a paradox. As well might we say "let no man study anything unless perfectly informed upon a subject to be studied." As a matter of fact in my experience the specialist, whether of horticulture or floriculture, becomes versed in general horticulture as the result of his specialism, not as a necessary introduction thereto; and he bands himself with others in a corporate capacity, not alone to extend his special acquisitions, but for the acquisition of that knowledge collateral to and lying around every point of his field of specialism, whether it be large or whether it be small.

Going back over a large number of years, I can recall few instances where the cultivators and development of special tastes have been injurious, and none where the really earnest, devoted florist, has not been catholic in his sympathies, though his circumstances utterly forbid his attempting "general horticulture;" and so far from assenting to your proposition that the cultivator of the Rose, the Tulip, the Auricula, or the Carnation, in the gratification of his tastes and opportunities is not "promoting some great and worthy object, such as horticulture, for instance," I holdily assert, that every one who adds aught to our knowledge of those subjects, or to the development of beauty in the subjects themselves, adds to horticulture, and may be said to deserve well of his country. Throw away the work of the specialist, and there, indeed, would be horticulture?

It is quite true there is nothing "in the cultivation of Roses, Auriculas, Carnations, Tulips, &c., that differs aught in broad general principles from the culture of any other plant," but I cannot admit that, because in the, as I hope, passing paralysis of the central body—which, if vital and vivacious, would make such action unnecessary—florists join together and organize shows of horticulture, they specially affect, they largely "degrade horticulture, with its widely beneficent aim, its hopeful future, its philosophic basis, into a mere affair of prize-money and flower shows." An acquaintance such as I have had with special shows and their results would lead the writer, I am confident, to a different conclusion. He would find no degradation of horticulture in them, and as for its being an affair of prize money, the florist who thought to make money by such means would be simple indeed.

But speaking with a commercial experience of upwards of forty years, and, therefore, of many men, I say to you, "I know many more matters of mercenary feeling!" It is his greatest delight to share the objects of his care and regard with his brother florists, no matter what may be the difference, for he knows none, no special degree, but he instinctively turns from the pretender.

For myself, and I doubt not I may assert the same for others taking action for the promotion of these special shows, I shall be indeed thankful when the necessity for such action has no existence. But where around London, save for this special action, can you point me to a field for a display of the Auricula, the Rose, or the Carnation, or a point for the gathering together of the growers thereof, and the interchange of kindly feeling beneficent alike to the man and the subjects of his regard? And surely, whilst it has hitherto been, and as I think is likely ever to be, that the mighty mass of workers in every direction must be specialists, you would not harshly deprive them of the delight which is their garden. Adopting a phrase from Macaulay, I may say the culture and study of the Carnation and Pictote has been "beaten in sickness, wearied in poverty, society in solitude" to me, and I doubt not a similar romance has been known to others—many others—of my brother specialists.

Work by all means, and with the utmost energy, to remove the occasion, and the developments of specialism; but do not involve the specialist in condemnation, because he refuses to stand still when, from its faults or misfortunes, or both, the central body is paralysed and helpless. E. S. Dodsoll.

THE NEW PLANTS OF 1876.

IN taking a retrospective view of the new plants of the past year, we find as usual that stove subjects predominate. This circumstance we suppose must be attributable to the generally more brilliant foliage and inflorescence of tropical as compared with temperate plants, and which fact we may believe induces the introducers of novelties to send their collectors into those countries which yield them subjects likely to be appreciated in these luxurious times. It is to the enterprise of these gentlemen—of whom Messrs. Veitch, Bull, Lowe, Williams, &c., in this country, and Messrs. J. & F. Hooton, Verschaffel and Jacob-Makoy in Belgium stand in the foremost rank—we are now mainly indebted for these introductions from foreign lands; and taking into account the enormous expense and the personal risks encountered in this adding to our home enjoyments, the horticultural world may well accord its heartiest thanks and warmest support to those who, at such risk, cater to enhance its pleasures.

FLOWERING STOVE PLANTS.

Of the flowering section of stove plants there is nothing very startling to record, though there are several of fully average importance. Taking them in alphabetical order, we have first to note *Aphelandra Smitzii*, a showy Peruvian *Acanthoid*, with the costa and main ribs white, and the branches surmounted each by a spike of dazzling scarlet flowers issuing from crimson bracts. In the same category come *Episcia Luciani*, a Columbian Gesneriad, with fascicles of bright red pubescent salver-shaped flowers; *Eranthem roseum*, an *Acanthoid* erect habit, with bell-shaped, pinkish-lavender, and spikes of purplish red flowers, having a long, slender arching stem introduced from the Amazon district; *Griffinia ornata*, a Brazilian *Amaryllid*, of winter-blooming habit, with broad, elliptic, petiole leaves, and large umbels of delicate purplish lilac flowers, on compressed scapes; *Hibiscus Collieri*, a shrubby Malvaceae from Polynesia, of the rose-stained type, with large double yellow flowers, stamens at the base with crimson; *Ixora regina*, a splendid variety, with bright orange-scarlet flowers passing to yellow, and growing in dense massive heads; and, finally, *Urthezia Endresti*, a West Indian *Lentibularioid*, remarkable, like its close ally, *U. montana*, for simulating when in blossom the aspect of an Orchid; in this case the leaves are lance-shaped, and the flowers freely produced, of a pretty lilac colour with a yellow paler, those of *montana* being white. Practically, Messrs. Veitch's splendid *Poinsettia pulcherrima plenissima* is a plant of 1876, since it is only distributed in that year, but its existence was made known sufficiently early in the previous year to permit of its being included in our summary of the novelties of 1875. We have heard of this plant having in some instances been disappointing, but, if really so, it may well be attributed to temporary weakness arising from the excessive multiplication which was found necessary to meet the demand for it.

FINE-FOLIAGED STOVE PLANTS.

The choice among stove plants cultivated for the beauty or interest in their foliage, is larger, but here again there is no one subject sufficiently prominent to be singled out for special remark, and we shall therefore take them in alphabetical order. This arrangement gives the precedence to *Aralias*, and certainly in numbers, perhaps in merit, they are entitled to this distinction. We have here first M. Linden's *Aralia gracillima* (doubtless a form of Veitchii), in which the toothletted leaflets of the slender digitate leaves are reduced to the narrowest dimensions; then come *Aralia elegantissima*, a plant of similar character, but with broader narrow lanceolate toothletted leaflets, which are slightly drooping, and of a deep green colour shaded with brown, the midrib being ivory-white; the New Caledonian *Aralia splendensissima*, a densely-leaved plant, with long pinnate leaves, having about eleven pairs of opposite entire or lobed shining undulated leaflets; and *Aralia ficifolia*, *alias spectabilis*, from

the South Sea Islands, a very handsome plant, having bright green pinnate-pinnatifid leaves, the leaflets lanceolate-ovate, and the segments lobulate. These *Aralias* are all extremely valuable decorative plants, and M. Linden's diminutive *A. gracillima* is indeed quite a gem, and must not be confounded with a simple-leaved plant sent out under the same name by Mr. Bull. *Alcaosia Johnsoni*, another acquisition of the year, shown at Brussels, is remarkable for its erect arrow-shaped dark green leaves, which are veined with red, and supported by purple-mottled stalks furnished with short prickles arranged in groups and spiral lines. *Cildemia vittata* is an erect-growing Peruvian Malvaceae, and the segments of its leaves of a rich metallic blue, with a central bar of white. *Carmeria Wallisii*, of which we intend to publish a figure shortly, is a remarkably elegant dwarfish plant from New Grenada, with the oblique oblong-elliptic leaves freely marbled with angular blotches of white. *Crotons* are still pouring in, but we are not able to report any that exceed in beauty those already known, or introduce novelty of character like the *C. Diemeil* and *C. trilobus* of last year. The best are *C. Macraecaeus*, *C. Mortii*, *C. Andreanus*, and *C. Mooreanus*. *Dieffenbachia* is still a favourite, and *Colandrea* plants, is of a distinct type from those in general cultivation, being of dwarf habit, with spreading lanceolate-oblong leaves of a satiny green, marked with a broad feather central band of white. *Draenas* have been well represented throughout the year by the novelties introduced by Messrs. Wills, Linden, Bull, Veitch and Williams, but unfortunately their number is embarrassing; and singularly enough those of a very distinct type, having a salmon or flame-red tint conspicuous in their variegation, giving them quite a novel, and, as it seems to us, a very ornamental aspect, have failed to win the suffrages of plant judges; but some of Mr. Wills' high-coloured narrow-leaved types will, however, be found invaluable as decorative plants both for tables and plant-houses. *Maranta Massangana*, a Brazilian species, is a beautiful addition to the dwarf forms of this ornamental family; its leaves are spreading, roundish-oblong, flat, of a rich velvety maroon, marked through the centre with a green silvery band and vein-like lines running out to the lower margin. *Philodendron Holtzmanii* is a striking plant with deflexed lance-lobed leaves, of a bluish-green, the young leaves of an beautifully puce-coloured (see 1876, p. 365, vol. vi). *Phyllanthus roseo-pictus*, a South Sea Islander—evidently of the same specific type as that called *P. nitrosus*, with much of the foliage pure white, and *P. atropurpureus*, with the growths similarly of a dark purple—is the prettiest of the triad, the stems of the young shoots being purple, and the small ovate leaves green, blotched with white, and suffused with crimson. The climbing *Smilax Shuttleworthii* is one of the plants sent home by Mr. Shuttleworth, who has just returned from the large country with his life in his hands (see p. 18); it has a green cordate leaves of a deep green colour, mottled with dull grey on the face, and of a purple hue at the back.

PALMS.

Certainly one of the most beautiful of the novelties among Palms is one which M. Linden calls *Kenia gracillima*, introduced by M. Linden from New Caledonia, and recently figured in *L'Illustration Horticole* (t. 253), and which, as it is, as it were, the true leaf, might well bear the name of *Kenia gracillima*. It is said to have a slender stem as that of an orchid's finger, and extremely elegant fronds about 2 feet long, with an ovate, pinnately-parted limb of about twelve distinct narrow linear, drooping, pointed segments, almost rivaling *Cocco Weddelliana* in graceful beauty, and at the same time very distinct. *Kenia Linderi* has the young leaves coloured red in *Welfia regia*, and is of stout and vigorous habit, the mature fronds being of a deep green, with reddish brown varnished stalks. Two handsome new Palms have been introduced by Mr. Bull from the United States of Colombia, *Prinz Geronimo Grantii*—named by Mr. Carder, who, as related at p. 18, comes home stripped of all his belongings, in company with Mr. Shuttleworth—has erect pinnately-parted leaves, with broad segments varying in width; the other is *Chamædorea formosa*, which is also pinnately divided in a more symmetrical manner with numerous narrow linear-lanceolate pinnae, 18 inches long. It may be noted that the Californian Fan Palm, introduced under the name of *Brahea filamentosa*, has now the generally accepted name of *Prinz Geronimo Grantii*, whatever name, it is a most welcome and ornamental plant, thoroughly adapted for greenhouse culture. T. Moore.

(To be continued.)

MRS. PINCE'S BLACK MUSCAT GRAPE.

I CAN hardly hope to accomplish the task which your correspondent "Enquirer" (p. 21) has assigned me, viz., pointing out the cause of this excellent late variety of Grape so frequently failing to take on the desired colour, or declining to appear in a "black dress," as your correspondent so well puts it.

I will, however, endeavour to answer some of the questions he asks, and will even venture to hazard a conjecture as to what I consider likely to be at least one of the causes of the non-colouring of the fruit of this useful and delicious variety.

"Enquirer" asks if the Vines are referred to "are of the same age similarly cropped, both having the same relative proportion of foliage and fruit, and especially are they from the same source?" As regards the first question, or as regards the first and last portion of this compound question, the Vines are of the same age, and are also from the same source, being each the produce of scions taken from the same plant, which was procured direct from Mr. Pince's establishment soon after the variety in question was distributed; each was grafted upon similar stocks, viz., the well-known West's St. Peter's variety. The two Vines are to all appearances equally healthy, and there is no perceptible difference in the condition of their leaves; but one of the Vines certainly bore a heavier crop than the other, and the Vine which bore the lighter crop was that which produced the best-coloured fruit. In stating that one of the Vines bore a heavier crop than the other I do not wish to infer that it carried an unduly heavy crop, more particularly when compared with the crops borne by other varieties in the same house, such as Lady Downe's, Alicante, and West's St. Peter's, of which ripened and coloured their fruit as well as could be desired. But a weight of fruit which might not be a too heavy crop for any of the varieties just named, might nevertheless be so for a Vine of similar dimensions with the Mrs. Pince's variety, which may inherit from its parents (one of which was the Muscat of Alexandria) some innate constitutional weakness, which prevents it from being able to properly colour its fruit when subjected to the strain of anything approaching to a very heavy crop; so that I feel constrained to consider over-cropping, or allowing the Vines to carry a greater weight of fruit than the health and strength of the plants appear to justify, as a fruitful cause of this fine variety so frequently failing to properly colour its fruit.

The weight of fruit which may with propriety be left upon any given plant must, of course, be left to the judgment of the cultivator, who ought to be guided in the matter by the more or less vigorous and healthy condition of the same; and I am inclined to think that in the case of the Mrs. Pince's Grape a moderately light crop will generally mean well coloured fruit, and *vice versa*. It is all very well to say that the fox-coloured fruit of this variety is equal in point of flavour to the black, which is in many instances really the case; but, as Mr. Gilbert very wisely says, it is quite as necessary to please the eye as it is to please the palate.

It has been suggested that this Grape may require a higher temperature, viz., the temperature of the Muscat-house, to induce it to ripen and colour to perfection. This may be so, but as far as my experience in the matter goes, this has not been found to be necessary; but it must be borne in mind that the natural soil here is light, and of a dry, warm nature, and this circumstance doubtlessly operates more favourably in the ripening of certain fruits than would those of a soil of a cold and wet character. Soon after Mrs. Pince's Grape was introduced I was engaged in planting a winery for the purpose of furnishing a late supply of fruit, and having formed a favourable opinion of this variety from what I had heard respecting its good qualities, I procured a plant of it, as I have already stated, direct from Mr. Pince. This I planted under the central rafter of the house, under each of the other rafters a plant of the Lady Downe's Grape was planted, the roots being placed in a prepared border outside. I am no advocate for giving the roots of Vines the option or choice of remaining inside or going out, but prefer to know for certain as to their whereabouts.

From the plant of Mrs. Pince's Muscat in the centre of the house two rods were taken, which, during the first, or, it may be during the second season, reached to the top of the house, and were then brought to a hori-

zontal position, along the front of the house, and from these rods a shoot was trained vertically under the centre of each light, and, as has already been said, a rod of the Lady Downe's variety was trained under each of the rafters—the object of this arrangement being that, in the event of the Mrs. Pince variety proving as valuable as was expected, the plants of Lady Downe's might be removed, and the one plant of Mrs. Pince's might be allowed to occupy the entire house.

This intention, however, has not as yet been carried out, as the two ladies continue to thrive so well in the company of each other, that it has not been thought advisable to disturb them. The house containing them is what we consider our latest, and the crop is still entire, and is what I suppose may be considered as a regular (but not a heavy crop) of medium-sized bunches, which as yet (January 9) shows no symptoms of shrivelling or decay. The fruit of Mrs. Pince's is in all respects as well-ripened and coloured as that of Lady Downe's, and I cannot perceive a fox-coloured berry in the house. A somewhat close inspection is necessary to distinguish the one sort from the other, the fruit of Mrs. Pince's being quite as black as that of Lady Downe's. The house they occupy is only furnished with a common fire-brick, which was only used for about ten days or a fortnight during the time the Vines were in bloom, and occasionally during the present wet and damp weather, in order to keep the atmosphere of the house as dry as possible; so that it does not appear that a high temperature is absolutely necessary to thoroughly ripen and colour either of the varieties in question. P. Griev, Cuford, Bury St. Edmunds.

THE CULTURE OF WOOD IN LINCOLNSHIRE.

THROUGH the courtesy of Mr. Fitzalan Howard, who, with his brother, Mr. Frederick C. Howard, carries on the growth and manufacture of this curious and now little known article of commerce, I early in December last, had the pleasure (although in a teeming rain) of walking over the farm and of inspecting the process of manufacture. Mr. Howard also kindly afforded me full information as to the course of culture, and the after-treatment adopted in preparing it for market.

For more than a century the cultivation of Wood (or "Woad," as it is called by the labourers) has been carried on by the Howard family, and some twenty years ago the father of the Messrs. Howard, who now conduct the business, purchased about 100 acres of land at Parson Drive, a village about 5 miles from Wisbeach, for the express purpose of growing Woad, to which place he moved the necessary mill, ranges, &c., required in its manufacture.

The plant itself (*Isatis tinctoria*) is a hardy biennial, with a fusiform fibrous root, and smooth branching stem, rising to the height of 3 or 4 feet when flowering; but it is the plant in its first year's growth with which I have to treat, and it seldom then attains a greater height than 12 inches. Mr. Howard says that it is on record that it has reached 15 inches on soil most unusually rich, and in a season favourable to its growth, but the average is to be put down at from 8 to 10 inches. Being a most exhaustive crop, none but the richest and best soils are suited to its successful cultivation; it is therefore never grown on any but the best old pasture land. From this fact, and that the demand for the manufactured article is very limited, the area annually devoted to the crop is not extensive; indeed, with the exception of some two or three growers in Lincolnshire, and one, the Messrs. Howard are the only persons engaged in the trade.

The first point, therefore, is to obtain soil adapted for its growth, and as landlords seldom will sanction the breaking up of old bullock pastures (the only land on which it can be grown to advantage), the Howards, as before mentioned, have been obliged to purchase land for the purpose at about £100 to £120 per acre. This point, taken in connection with the fact that after six years of cropping even the best soils become exhausted, makes the rent stand at a very high figure to start with.

Early in the spring the land is prepared by first breaking up the sward, and ploughing the land into stretches 12 feet wide, and by working it into a solid and fine condition. At the end of April the seed is drilled (about 3 bushels per acre), with an ordinary

6-foot corn drill with eight coulters, 9 inches between the rows, thus giving sixteen rows of the plant, or one round with the drill, on a stretch. Sometimes, when the land has been cropped for four or five years, and wants refreshing, about 4 cwt. of artificial manure per acre is drilled with the seed.

As soon as the plants have developed the third leaf-rolling is commenced, being most essential that the crop be kept clean. This work is carried out by families employed on the farm, to whom the several operations of weeding and cropping are put out at so much per acre. In weeding, a short-handled, broad spud, made for the purpose, is used, the labourer carefully chopping up all weeds and drawing them into the furrows between the stretches. It is a curious fact that, notwithstanding the utmost care, the small Nettle can never be entirely eradicated, and each year it gives an immense amount of trouble to the labourer. Chickweed, also, is a boon companion of the Nettle, and is almost as great a nuisance to the Woad grower.

At the end of July, or as soon as the plants are sufficiently ripe, which condition is known by the under leaves beginning to assume a yellow tint, the first gathering, or "cropping" is commenced. This operation is performed by persons upon their knees, who carefully twist off the leaves of the plant, and deposit them free from dirt into large wicker baskets—some what like overgrown Apple skeps—and they are at once conveyed by men to carts to be taken to the Woad-mill, where the following course of treatment is adopted. Before, however, I can fairly explain the operation of grinding, it is necessary that I should roughly describe a Woad-mill. First, then, imagine a small equineum circus, 30 feet in diameter, paved with Yorkshire slabs; beyond this circle upon a platform some 18 inches higher than the slabs, three horses, each yoked to a large wooden wheel, 8 feet in diameter, and about 2 feet wide, shod with iron bars, like the paddles of a steam ploughing engine, slowly walk round. The Woad leaves having been tipped from the cart into the mill, are thus placed in contact with the wheels which, weighing 10 or 12 tons, reduce them to a pulp, this being removed from the mill it is thrown into heaps to drain some of the watery juice away from it, after which the process of "balling" commences. This work is also put out, and is paid for at so much per ton of dried and manufactured Woad, the pulp being worked up into lumps about the size of Cocoa-nuts. These balls are then carried to the "range," or drying shed, which is a long and lofty wooden structure open on all sides, with a rough, weather-proof roof, under which five tiers of watted hurdles, called "flakes," about 3 feet under each other, are placed, and on these the Woad balls are laid out singly to dry. In ordinary seasons this is completed in about three weeks or a month, after which they are put into "pens" until they are crushed, the particulars of which process are described further on.

The first cropping over, the land is again carefully weeded, often twice or three times, and the second "cropping" is generally taken and "balled" before November 23, when "yard work" begins, and it is from this point that the chief art of the Woad-man is called to account, for upon the successful crushing and "balling" of the Woad the value of the product is estimated. The crushing (of the balls) is performed in the mill, in the same manner as the grinding of the leaves, after which the dried matter is thrown on to a floor, to the depth of about 2 feet, called "the couch," where fermentation is carried on, the process being completed in about eight weeks, a constant turning of the mass being necessary, and more or less water being added, as the heat may be excessive or otherwise.

The smell of Woad when "in couch" is very strong, and is so disagreeable, but I believe that it is not unhealthy, for I am told that "Woad-men live as long as they like," or, at any rate, to a good old age.

Mr. Howard says that many years ago the rector of the parish where his father was then growing Woad expressed his dissatisfaction at Mr. Howard's assessment of the value of the crop of Woad in his payment of tithes, so his father measured off a tenth of the field, and left it with "his reverence" to harvest and utilize as he thought well. Of course, the rector could do nothing with it, and in after years, when Mr. Howard's valuation was taken without question, Times have altered since then, and so have parsons, for Mr. Jackson, the present vicar of Parson Drive,

although his dining-room windows open on to the "range" and "couch" of Mr. Howard's Wood farm, from whence sometimes proceeds anything but a savoury odour, yet never complains, but counts Mr. Howard as his best if not his sweetest neighbour. *Wibeach, in the "Agricultural Gazette."*

THE ALGERIAN SPECIES OF CROCUS AND FRITILLARIA.

As far back as the *Flora Atlantica* of Desfontaines, the first volume of which was published in 1798, a Crocus has been recorded from Algeria. By Desfontaines the plant was referred to *vernus*. Of this, till the present year, I have never been able to obtain sight of a satisfactory specimen. Having been engaged lately at Kew in incorporating with the general herbarium the Algerine collection of the late Giles Munby, which after his death was presented by his family to the herbarium of the Royal Gardens, I was very

diameter, with thick tunics, which are entirely composed of fine parallel fibres. Leaves four, contemporary with the flower in December, rising up to a level with it at the flowering time, narrow linear, with strongly revolute margins and a distinct white central band. Top of the flower 4 inches above the top of the corolla. Proper spathe one-veined. Perianth-tube dull purplish, protruded $\frac{1}{2}$ —1 inch from the spathe. Perianth-lobes 1 inch long, the equal obovate obtuse segments $\frac{1}{2}$ — $\frac{3}{4}$ inch broad, whitish, with three faint lilac stripes all down; throat glabrous, concolorous. Stamens half as long as the limb; anther yellow, twice as long as the filit glabrous filament. Pistil rising to the top of the anthers, orange-yellow, the three short cuneate forks strongly toothed on the upper edge.

Mr. Munby's specimens were gathered by M. Pomel in December, 1855, at Rass el Assoua, near Gharrouban, and it is to be hoped that laying the matter before the readers of the *Gardeners' Chronicle* may be the means of the plant being refound and made fully known.

At the same time I should like to call attention to

and the same plant, which I would now name and describe as follows:—

Fritillaria Munbyi, Baker, n. sp.—Bulb globose, $\frac{1}{2}$ — $\frac{3}{4}$ inch in diameter, with membranous tunics. Primal leaves (produced before the flowering-stem appears) oblong, acute, $1\frac{1}{2}$ —2 inches long, narrowed to a distinct petiole, which is longer than the blade. Flowering-stem 1—1 $\frac{1}{2}$ foot long, slender, glabrous, ending in a single drooping flower. Leaves 3—5 to a stem, scattered over the upper half of it, all alternate, or the uppermost opposite or very rarely ternate, 2—3 inches long, the upper ones linear, the lower ones lanceolate, $\frac{3}{4}$ —1 inch broad. Perianth campanulate, 12—15 lines long, dark violet-purple, obscurely tessellated on the face, and sometimes banded down the back with green, the outer three oblong, $\frac{1}{2}$ — $\frac{3}{4}$ inch broad, the three inner obovate, $\frac{3}{4}$ —1 inch broad, all furnished with an obscure greenish oblong nectary above the claw. Stamens half as long as the perianth. Anthers oblong, a third as long as the glabrous filaments. Ovary clavate, under $\frac{1}{2}$ inch long; entire part of the style as long as the ovary; three subulate stigmatic forks half as long. Capsule obovate-oblong, under 1 inch long, furnished with a distinct neck, obtusely rounded on the sides. Seeds discoid,

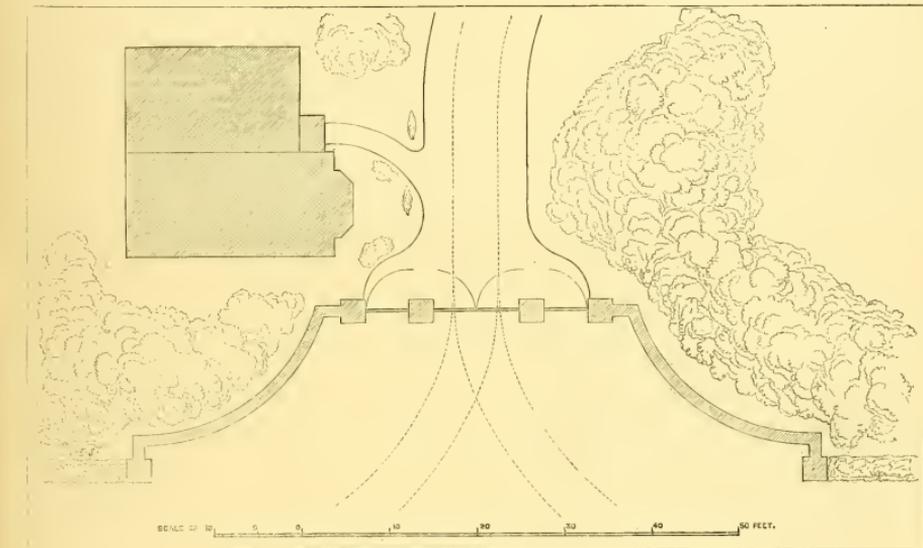

FIG. 7.—DESIGN FOR A PARK ENTRANCE.

pleased to find that it contained three intelligible specimens of an Algerine Crocus. In the second edition of Munby's *Algerine Catalogue* the genus is dealt with as follows:—

- "*Crocus vernus*, Linn. ? Ex Desfontaines.
- "*Crocus verticor*, Gawl. ? Regio Atlantis Provinciae Oran, rarissimus; Gharrouban."

The plant contained in the herbarium seems to have been lately regarded by Mr. Munby as *C. Salzmanni*, but the probability seems to be that these three names, as far as Algeria is concerned, all refer to one and the same plant, and that there is only one Crocus in the country. This plant I have no hesitation in regarding as a new and undescribed endemic species, which should be placed amongst the autumn-flowers of the section *Odonostigma*, next to *C. Salzmanni*, from which it differs materially both in corolla-coats and perianth-limb, resembling in the former *C. vernus*, and in the latter some of the forms of *C. biflorus* more than anything else. The following is as full a description as I can give without palliating the specimens in pieces.

C. algeriensis, Baker, n. sp.—Corm ovoid, $\frac{1}{2}$ inch in

the genus *Fritillaria* as represented in Algeria. The following is what is said about it in the last edition of Munby's *Catalogue*—

- "*Fritillaria montana*, Hoppe ? ; *F. pyrenaica*, Munby, Fl. Alg., non Gawl. ; *F. Melegria*, Desf. ? n. n. Linn. ; Oran, rather rare (*au nova species*).
- "*F. messanaensis*, Rafin. High plateau of the province of Algiers, rare (Boghar)."

In the second part of Munby's fasciculus of Algerian plants, published in 1851, under No. 33 are given specimens of a *Fritillaria* which is named *montana*. In my monograph of the genus, published in vol. xiv. of the *Journal of the Linnean Society*, I have described a plant under the name of *F. lusitanica* var. *algeriensis*. After studying the full material in Mr. Munby's herbarium, in the shape of specimens both in flower and fruit, and a coloured drawing evidently made from the living plant, I am led to conclude that all the specimens in his herbarium are identical with my *lusitanica algeriensis*, and that it is an endemic Algerine species, closely allied to, and intermediate between, *lusitanica*, *pyrenaica* and *messanaensis*, and to suspect strongly that all the foregoing names belong to one

$\frac{3}{4}$ —4 lines broad, pale brown, with a thick, distinct border.

The plant flowers in February. The specimens I have seen are from "Oran, in collibus herbosis" (Munby), "Oran, montagnes" (Dow), "Petite nord du Djebel-Santo, près d'Oran" (Balansa, Fl. Alg. 1852, No. 223), and "ad plantium Rass el Assoua, Gharrouban, Flemeun" (Munby, the same station as that of the Crocus). For garden purposes the more southern *Fritillarias*—*pyrenaica*, *lusitanica*, and *messanaensis*—and now let us add *Munbyi* (which I see from the herbarium that Mr. Munby had in his garden at Wood Green in 1874, and which therefore is very likely in existence in a living state somewhere in the country now, and not improbably may be in our Kew set of the genus)—are to my appreciation far less ornamental than our English *Melegria*. *J. G. Baker.*

A PARK ENTRANCE.

The annexed (fig. 7) is a plan of entrance well adapted to a first-class mansion. It was arranged for a gentleman living in one of the home counties. It faces a road running parallel to it; hence the necessity of setting the gate well back, so that an easy means of

ingress and egress might be obtained. In this plan there is a central entrance for carriages, and two side entrances for pedestrians. Should the gates be of iron it would be necessary to make the carriage gates in two parts. If wood be preferred, one gate will be sufficient.

It is quite lamentable to see so many fine domains in different parts of the country with entrances quite unsuitable and out of keeping with the surroundings; in many cases, indeed, scarcely fit for a modern farmyard. It is to be hoped that these sketches may induce proprietors, having entrances of this mean, unbecoming character, to improve them. An entrance should be a kind of preface to the place, and explain pretty well what we may expect to find, as to matters of taste and fitness in the park and the gardens. *G. Eyles, 44, Eardley Crescent, South Kensington.*

Forestry.

THE last number of the *Indian Forester* contains an article putting in a very clear way the views of those who advocate the sending of students to Germany or France to study in the forest schools. We extract a portion of the article, which is sure to arrest attention. We cannot, however, see any reason why a good grounding in theoretical and practical forestry may not be obtained whenever the proper organisation is established in Scotland or elsewhere within easy access of woodland. This obtained, the pupil would be in a better condition to profit by a visit to Germany than he is now. After all, in the case of youths of this description it is the training they receive, which, together with their natural intelligence, is the main point. The circumstances with which they have to deal in India are so different from those which they have to encounter in Europe, that a good grounding in general principles is all that can be effected here, whether in Germany or in Scotland.

"Of large areas of natural forest, often subjected to a long course of previous ill-treatment, and now destined to be used for a commercial trade, it is to be seen, the country is absolutely dependent (both as regards local and export consumption) for a variety of products, the British forester knows absolutely nothing. No such areas exist in the country, and consequently no forester in Great Britain has ever been called on to treat such areas either theoretically or practically.

"British foresters, and *d fortiori* British botanists who are not foresters, are therefore completely out of count when attempting to argue on the requirements of training in a service destined to deal with large tracts of forest land of this class.

"It is perfectly true that botany (systematic and physiological), surveying, the arts of draining, planting, thinning, felling, &c., are of the highest importance, but they are only detached parts of a subject, and do not cover the mere fact that the great points—the 'weightier matters' of the law, viz., the preparation of 'working schemes' for forests, and the treatment of forest on the system of natural regeneration, are not even alluded to in the curriculum of studies, is not only insufficient in itself to prove what I above argue regarding the necessary incapacity of foresters to only handle a subject, and understand our Indian requirements, but shows further that, if the forest officer came out ever so well trained in the proposed course, he would still be ignorant of his chief duties.

"It must not be supposed that I am casting any slur on the well deserved reputation of many English and Scotch foresters in their own line. It is not the British forester's fault that he is not a large student of natural forest to deal with, no rights and privileges to be provided for, no immense tracts once stocked with valuable timber which have to be led back into a condition of productiveness, and so forth, any more than it is the fault of England that it does not produce the silks of Lyons or the tobacco of Havana. And therefore I cannot conceive why it should be resented by any one as a hard saying that British forestry is incompetent for Indian requirements.

"We go to France and Germany, where there are schools teaching forest management (in the enlarged sense of the term), not because we love foreign things and despise those at home, but just as we go to foreign markets because there we produce what we do not. We do not think it a reproach in the one case, why should we in the other?"

"Of course I am fully aware of the difficulties of the New Forestry question and of the rights of common, &c., which have to be dealt with in proceedings under the Enclosure Acts; but that is quite a different thing from managing forests with a view to the yield of different classes of materials for right holders and communities having rights.

Foreign Correspondence.

MOTOLA, NEAR MENTONE: *Jan. 1, 1877.*—I send you a list of plants I find in flower here in my garden to-day, which may interest your readers; as I have no greenhouse they are all in the open air. Abundant rains have fallen during the month of December, and the weather being now sunny and genial, vegetation in the gardens and surrounding country here is very promising. The crops of wine and Olives have been poor, but Lemons are plentiful, though the price is low and unmercantable. *Thomas Hansbury.*

Plants Growing in the Open Air in the Garden of the Palazzo Orsini, Motola, near Mentone, in Flower on Jan. 1.

Abutilon var.	Geranium (many sp.)
Acacia leucophylla	Globularia alypum
" lophata speciosa	Gonolobus macranthus
" obliqua	Hardenbergia myosiphilis
" retinoides	Helleborus viridis
Aitonia cespitosa	Heliosiphon
Aloe africana	Helleborus sempervirens
" cilicaria	Helleborus cuneifolia
" futescens	Jasminum azoricum
Adiantum strimmaricum	" nudiflorum
Anthriscum var.	Juncus acrotes
Artemisia Andrachne	Klema nerifolia
" arvensis	Knautia sicula
Arum Arisarum	Lavandula multifida
Aster argophyllus	" pinata
" ciliatus	Lycium europaeum
" maritimus	Linum trigycum
Bougainvillea glabra	Malva sp.
Wartecucula	Loganum scandens
Borvordia leiantha	Lobelia fragrans
Borvordia leucantha	Malvastrum Barlayana
" madagascariensis	Mesembryanthemum aureum
" salicifolia	" perfoliatum
Celastrus andrewsii	Monticola arvensis
Cassia grandiflora	Narcissus (many sp.)
Cassipouira quindivilis	Othonna carnea
" crotolaria	" trigularis
Cestrum roseum	Pachyphorum bracteatum
Chamaecrista	Passiflora racemosa
Chimonanthus fragrans	" vesperitidis
Chrysanthemum frutescens	Petunia (var.)
Colonia scandens	Phytolacca decandria
Coletia spinosa	Plumbago capensis
Conyza glauca	Polygala virgata
Convolvulus africanus	Portulaca oleracea
" floridus	Rhoeo coccinea
" mauritanicus	Rosa (many sp.)
Correa alba	Commersonia oclinalis
" aurata	Salvia anapa
Cotyledon macranthum	" Grahami
" luridum	" leucorrhoea
" macranthum	" microcarpa
Cyperus strigosus	" semibrata
Cytinus ferox	" splendens
" glaberrimus	Sonchus oleraceus
Diplopappus filifolius	" angulatus
" glaberrimus	" longifolius
Echeveria metallica	" polycephalus
Eriophora japonica	Solanum robustum
Eriophora japonica	" verbasciforme
Euphorbia alata	Sporobolus africanus
Euphorbia globulus	Stapelia quinquerviridis
Euphorbia globulus	Taccaea maritima
Fabiana imbricata	" mollissima
	Terna capensis
	Tenifolium retusa
	Veronica (sp.)
	Vincis (sp.)

OUTACAMUND, Dec. 15, 1876: *Lilium neilgherrense*.—Mr. Elwes, in his notes on *Lilium neilgherrense*, which appeared in the *Gardener's Chronicle* of September 9 last, mentions that there are three varieties of this Lily. No less than four very distinct varieties are found within 15 miles circuit of this place. This difference in character is probably caused in a large measure by the different aspects and situations in which this plant is found. When it is explained that the hills on the western slopes of the Neilgherri range are frequently 400 inches, whereas on the northern side of the mountains the rainfall is often as little as 50 inches, the different circumstances under which the plant grows will fully account for it varying so much in character as to have been figured by Wight in his *Icones Plantarum Indiarum Orientalium* as three different Lilies.

Wight's figure, No. 2031-32, is the grand form of *Lilium neilgherrense*, colour pure white, found on precipitous rocks 8000 feet above the level of the sea, in situations where there is a heavy rainfall. It is not at all uncommon to find this with six flowers on a stem, each flower 1 foot long. It flowers a month earlier than the other varieties. Wight's figure, No. 2033-34, "tabularum," is also a very fine Lily, and is widely distributed. It varies in colour, the flower-tube is longer, and the leaves also are much longer than the leaves of the large variety. Of this plant there are two very distinct forms, one yellow and one white.

Wight's No. 2035 is a small variety, it grows at Kuthully, the driest part of the hills, and instead of choosing the crevices of the rocks it is found grow-

ing in loam on the sides of the hill, not more than 4000 feet above the level of the sea. The petals are very much recurved, and this led Wight to suppose it to be *L. Wallichianum*. The stem is very leafy, the leaves are very narrow, and it invariably bears a single flower on each stem. This variety does not form on the roots of the forest which are so numerous in the other varieties. Mr. Elwes seems to have some information regarding a pink variety; there is no variety which can be properly called pink. There is a fourth variety, with very dark stems, and the dark marks on the stems are carried up the exterior of the flower-tube, giving a pinkish colour to the outside of the flower, but the flower itself is pure white. It is a charming variety, and rather scarce.

These last two varieties flower very late, not beginning to flower until November; this is probably owing to their being found generally on the northern slopes, where there is little sun and a small rainfall.

At the Royal Horticultural Society's show on November 28, the Hon. and Rev. J. T. Boscaewen exhibited a plant of *Lilium neilgherrense* in flower. It would be interesting to those engaged in the culture of Lilies to note whether this was one of the late-flowering varieties above noticed.

Flowering, as this Lily does, from August to December, it will repay any trouble there may be in growing it. It remains to be seen whether the varieties given above will retain their distinct characters under cultivation, or whether the whole will become blended into one form when grown without the varying conditions of rainfall and climate which are peculiar to the different districts of the Neilgherry Hills. *E. S. B.*

Natural History.

THE GOATSUCKER.—As this locality is a favourite resort of the goatsucker (*Caprimulgus europaeus*) I have for a period of nearly fifty years had an opportunity of observing the habits of this very remarkable and interesting bird. It is to be regretted that the original name, "goatsucker," given to it by Aristotle in the days of old, is still retained, as it is apt to create an idea in the minds of the ignorant that the bird is one of destructive propensity, and ill-omened, whereas, if there is one bird more than another that ought to be fostered and protected it is the goatsucker, or, as we familiarly call it at home, and which is by far the most appropriate name, "nighthjar." It arrives every year about the last week in April, and leaves again the last week in September. Very few birds are of more service to mankind than the nighthjar, and of such value do I esteem them that I would rather give £5 than one should be destroyed. To sit and watch

their graceful flight, and quick gyrations during a warm summer's evening, when fades the glimmering landscape on the night, "is always most amusing to myself and to my friends, and is not very shy birds, and is usually undisturbed or shot at will take but little notice of persons moving about. They feed wholly on moths and insects caught on the wing, and during the season they must, of course, devour an immense quantity. They rarely voluntarily take to flight in the day-time, but immediately the sun sinks below the horizon the expected and well-known *chur-r* is heard, very similar to a spinning-wheel and quite as loud. This sound they continually emit for an hour after sunset, and at greater intervals during the night until sunrise, after which they are never seen unless accidentally disturbed, as they always rest on the ground in the day-time, when they fit a short distance and settle again. The very singular burring or spinning sound is sometimes sustained for many minutes together, and always when settling on a bank, post, tree, or other convenient perch, when the head is croached downward and almost brought on a level with their feet. It would not be possible for the same sound to be emitted while on the wing. During their aerial flight they utter a loud and distinct cry, which may be either playfulness, a love-note, or a warning of danger. They also produce a great and noisy rattling sound by clapping their wings smartly together over their back.

The nighthjar makes no nest, but selects a retired spot on the ground, generally beneath a bank of Furze, Heath, or Fern. The eggs, two in number, are a greyish white colour, singularly marked with dark irregular spots, and may easily be mistaken for stones of a peculiar character, which abound on heath-land. The young birds, too, when hatched, and until they

can almost fly, have a very peculiar appearance, not unlike speckled toads, which assimilates them with the colour of the soil, and, doubtless, protects them in a great measure from their natural enemies. Their favourite breeding haunts are decidedly "heath-lands, moors, and commons," but for food they affect cultivated grounds, "tree-studded meadows," parks, and places where it is easily obtained, and, among the ancients, *W. R. Rogers, Red Lodge Nursery, Southampton.*

Garden Operations.

PLANT HOUSES.

PLANT STOVE.—It is time now to see about starting some Allamandas. If A. Henderson and A. Chelson are grown, begin with them first. In the case of full-sized specimens, the same may be cut back to the same point as last year. Allamandas ought to be repotted at the time they are pruned, and they should have one-half of the old soil taken away. There is no better way of doing this than by using an iron bar with a pointed stick, after which they must be soaked in tepid water for some hours, as if this is not done it is difficult to get them into the proper state as to moisture; let them drain awhile, and then pot them. Good loam is the best for them, to which add about one-third manure and rotten dung, and water, and will keep the whole porous. Make the soil very solid in the pots, as they like it firmer than most things. Put them near the glass, and syringe daily overhead. A plant or two of *Clorodendron Balfourianum* should also be started at once, in this case, however, unless more pot-room is required, the roots must not be disturbed, and when potting is necessary only remove the crocks from the bottom of the ball. It will be found to succeed best at the coolest end of the house, or in a night temperature of 55°; keep it well covered—close up to the glass; brought on in this way the flowers are very useful for cutting, being in both colour and form distinct. Of *Diplantheis* likewise a few plants should now be pushed on. Where it is desirable not to start at some time yet, the *Allamanda*, *Bougainvillea*, or *Clorodendrons* of the above-named section, it is much better to keep them dormant by putting them at the coolest end of the stove, and only giving them as much water as will prevent the bark from becoming so dry, and is sometimes better to subject them to a lower temperature. *Anthurium Scherzerianum* is frequently kept on growing all the year round, which is not a good plan. It is much benefited by a rest in a temperature of not more than 50° a night for six or eight weeks, when it is allowed growth, whilst here withholding water, but not letting the leaves shrivel. Any specimens that have completed their growth should be treated as described. A few *Achimenes* and *Gloxinias* which should now be started. As soon as they begin to grow they must have the light possible by putting them on shelves close to the roof, or in some similar place. If this is not done their flowers will be very soft, and worthless for using in a cut state. Where root climbers are grown they must not be allowed to keep too much light from the plants under them; this will be prevented by thinning the branches out and cutting back those that are to remain. Give a good light position to *Aphelandra cristata* and *A. nitens*, by so doing the colour of the flowers will be improved. Plants of *Gastonia*, *Strobilanthus*, *Strobilanthes citrodora*, which are the two most useful species, that are coming into bloom, should be put at the coolest end of the house, and have only enough water to the roots to keep the plants in a healthy growing state, and none overhead; the flowers will be more lasting treated in this way. *Eucharis americana* and *Amantophyllum minimum* ought also to have a place where their opening flowers will receive the least possible amount of moisture. Put *Hyacinths*, *Crocus*, early *Tulips*, *Ranunculus*, *Rubus*, *Primula*, *Hyacinthus*, *Scilla*, *Lily of the Valley*, and *Prunella* in heat regularly to keep up a supply. It is well to remember that these things last much longer in bloom when they are not brought on in a very high temperature. They will be saved further on if all insects are as far as possible kept under now. If dry weather it is not well to have much moisture in the atmosphere here at the present time; neither should the plants be excited into growth by being kept too warm; managed thus, they will make better growth later on. *Leuco-stegia* and *Avallaria*, that cast their leaves, ought to be kept a little drier at the root in the winter, but this must not be carried too far, or they will be injured, and consequently make weak growth. The entire stock should be gone over and thoroughly cleaned from insects before active growth commences. *T. Baint.*

FLOWER GARDEN.

The extremely wet weather we have is unfavourable for getting forward with ground-work, but much may be done with sweeping the lawns, raking leaves from

under the shrubs, &c. Where the turf has settled down in places and left the surface uneven, this is a good time to have it put to rights, as work of this kind is not so much to be feared as it is usually made out to be. It is also more favourable for the purpose than when the drying winds of spring set in. Proceed by cutting and rolling back the turf, and make the ground up to the level with sand or poor soil; this prevents the grass from growing too vigorously, and it always has a tendency to do. After the ground is made firm and levelled with a rake, roll back the turf and settle it down with the back of a spade, or the wooden beater, then run the roller over it, and all is finished. Let the grass and gravel walks be frequently rolled, and give a clean and finished appearance. Shrubby borders and clumps may be thinned where getting too crowded, and the thin places filled up with the plants that are removed, the ground dug over, and all left as orderly as possible. Where planting has to be done here have the ground well trenched; this requires more labour at the time, but plants and trees always succeed better and give more satisfaction to employer and planter. Roses expected to do well must be planted in well-prepared ground. If the soil is light, it will be necessary to make a good manure and planting much the surface with manure; this will enrich the ground and help to protect the roots. Any tender plants left unprotected had better have a covering of Fern litter, Spruce branches, or anything convenient, for the weather may be expected. *T. Blair, Strathall Park.*

FRUIT HOUSES.

STRAWBERRIES IN POTS.—A supplementary batch of these plants should be placed in heat of a similar nature to that recommended in the Calendar for December, but rather 50, in anticipation of having to meet the ordinary demand, and to make up for defective plants from amongst the early started ones. In order to keep up a good supply of ripe fruit through the spring months, a batch of these plants should now be introduced into heat every fortnight or three weeks. No time to introduce into heat other than those highly esteemed varieties, British Queen, Sir Charles Napier, and President. Let the former lots of plants have every requisite attention, an abundant supply of water being essential when necessary, and the pruning should be done in the usual manner. The fruit commences. The moist and suitable condition provided by the use of sods, or soil in well drained pans beneath the pots is one to be commended, inasmuch as it frequently sustains the plant when the weather is so drying and so hot. It is well to keep the plants which are in growth free from the attacks of the green-fly, either by fumigation or otherwise dipping the foliage of the plants in a solution of tobacco or quassia water. *George T. Miles, Myreside Abbey.*

VINES.—Early houses started in November and December will now require daily attention and care. The rules for disbudding, stopping and tying having been so frequently laid down in former Calendars, I will assume that all these operations have been regularly performed, and that there is still a considerable space of trellis available for covering with young growth. When Vines break and start away evenly, I prefer pinching back to the third or fourth joint beyond the fruit, and afterwards allowing the first set of leading laterals to grow unchecked until every portion of the trellis is covered with foliage, when the strongest shoots are again pinched, and prevented over-crowding. The dull, dark weather which has so long prevailed being unfavourable to hard forcing, the night temperature should be allowed to range low, until we have a change to brighter days. The supply of water should also be reduced, and the soil kept dry. Remove all surplus branches as soon as the best can be distinguished; assist shy-setting kinds by means of artificial fertilisation, and thin when the berries attain the size of No. 6 shot. The pruning of all house Vines, which the frost has been so far from being brought to a close, and advantage taken of the unfavourable weather for getting the Vines washed and painted with the usual composition, the houses thoroughly cleaned, inside borders cleared of all rubbish, and well watered, and the plants treated with good turfy loam and crushed bones. The outside borders, too, as a rule the worst managed borders in a garden, may also be exposed to the influence of rains by the removal of shutters or other means of protection, allowing a slight covering of litter or Fern to keep out frost. Look over late Grapes and remove all decaying berries. Do not allow the house to fall below 45°, and to prevent condensation on the berries always keep it a few degrees above the outside temperature.

MELONS.—To have ripe Melons in May need's should now be sown and plunged in the bottom-deep of 80, and the glass may be consistent, to prevent the young plants from becoming "drawn" when they appear above the soil. To specify kinds would be useless, as every grower now stakes his reputation on this or that hybrid or hero of his own raising. For

general purposes, early or late, in houses or in frames. I may, however, safely assert that I have not yet found anything better than *Victory of Bath* Improved, for the introduction on which every gardener is indebted to Mr. Gilbert, of Burghley. Those who have the convenience of especially heated hot-water pits will experience but little difficulty in raising sturdy plants; but where fermenting materials alone have to be depended on, with the exception of every garden, it is not to be devoted to their preparation. Assuming that a good supply of fermenting horse dung and Oak leaves have been thrown up into a heap, well-turned, worked, and sweetened, a bed should be made up for a single light frame, care being taken that the lining may be placed round it at once; a good body of old tan or leaf-mould, 12 inches thick, should be laid over the surface of the bed, and when warmed through the seeds may be sown in single rows, and plunged or otherwise. The best frame for this purpose are those made on the old McPhail plan, using 2-inch deal for the outside shell, with a lining of 4-inch boards tugged together to form a cavity 1 inch in width, open at the bottom for the admission of heat, but closely made up of inside boards, and the inside frames made upon this principle I have seen Cucumbers cut on March 9. The next point, equally important, is the preparation of the soil, and fortunate are those who, acting upon our advice, have laid up a good store of soil for this purpose, for which this has not been done, no time should be lost in getting a supply into a dry vinery, where it can be brought into condition by exposure to light and warmth. *W. Coleman, Eastnor Castle.*

HARDY FRUIT GARDEN.

Notwithstanding all that has been said and written against pruning hardy orchard fruits, most cultivators are agreed as to its necessity and the beneficial effects it has on the quality and produce. There is no one better able to form a sound judgment on matters of this kind than those who cater for the public, and I have to get a living profit out of what they grow, and if we go to the best managed establishments we there find, not trees and bushes left to themselves, but skillfully thinned and pruned and bristling all over with fruit-buds. It does not necessarily follow that the pruning should be done in the same manner as the branches, as in many cases that would have the effect of inducing a greater number of strong rank shoots to put forth, and no doubt much of the satisfactory state we see trees in the most notable market gardens arises in a great measure from the care and attention they undergo by the deep digging that takes place in the cultivation of the land within a short distance of their stems, the effect of which is to largely increase the number of their fibres; and as it is to these that we must look as a means to produce fertility, it often becomes necessary to attack the trees below. This being so, any that are of a gross, unfruitful habit should at once have their roots laid bare, and such as have penetrated the subsoil severed with a sharp knife, and then be raised and laid in a more horizontal position, so that what fibres they make may feed near the surface. In the case of trees that have been long planted, this interference with the main roots should not be carried to extremes so as to cause a severe check all at once, and to avoid this it will be better to operate on one side only, leaving the other to be effected at some future time, a twelvemonth or two years hence. If the natural soil appears to be too close and stiff, or of an unsatisfactory character, fresh cut turf loam should be in part substituted, but on no account ought leaf-mould or other decomposing vegetable matter to be used as a corrective, for sooner or later it is sure to produce fungus, and if this gets hold of the roots it at once brings on decrepitude and ill-health, and eventually destroys the trees altogether. would use the same care in proceeding with trees in an unsatisfactory state to examine them at once, and, if they find this destructive agent has got possession of the border, to clear away the soil as far as the roots extend and renew it altogether, clearing the fungus from them by the use of the preceding recipe. It is to be noted at the same time that have not plenty of young feeders attached. In shallow, light lands, resting on a sandy bottom, I have found an admixture of clay or marl of great value in sustaining the trees during dry weather, and in the case of trees that are going to fruit that they would otherwise have been unable to do, unless assisted by a free use of the water-pot. It is surprising how retentive of moisture clay is when buried in small nodules on ground of an opposite description. Many of the old-fashioned trees in a loam for renovating exhausted fruit trees may be able to substitute clay for it, which if used in moderation and properly mixed up with the soil in the lower portion of the border will have a most beneficial effect, and last for a great number of years. In regard to top-pruning of orchard trees, it is a thing to be done, and if they are properly thinned, that the main branches do not cross each other or become too crowded to shut out light and air and cause a weak spindly growth. *F. Shappard, Woburn.*

THE
Gardeners' Chronicle.

SATURDAY, JANUARY 13, 1877.

APPOINTMENTS FOR THE ENSUING WEEK.

Royal Horticultural Society. Meeting of
Wednesday, Jan. 17. { Scientific Committee, at 4 P.M.
Sale of Fruit Trees, Shrubs, and Bulbs, at
Stevens' Rooms.
Thursday, Jan. 18. { Meeting of the Linnean Society, at 8 P.M.
Sale of Orchids and Lilies, at Stevens'
Rooms.

WE have most of us in youth been told that the reason why policemen on duty wear a badge on the sleeve of their coats is to enable them to distinguish between their right hand and their left. At first sight it would seem as if this discrimination were no difficult matter, but the discrepancy of opinion on the subject that one meets with in books is soon calculated to un deceive one. Of course, in spite of the unvarnished policeman story, no difference of opinion exists as to which is the right and which the left side of one's own body. We do not hesitate for a moment in deciding which is the right and which the left hand of our neighbour. The starting point is certain, it is only when we come to the consequences that ensue from it, and from the different point of view taken by different observers, that the difficulty is met with; which way, for instance, do the hands of a watch turn, from right to left, or from left to right? What is a right-handed, what a left-handed screw?

The answers to these questions depend, of course, upon the position of the observer, or the way in which the object is viewed, and no common agreement exists as to viewing such objects from a definite point of view. Among plants we have, as every one knows, the leaves arranged in one or more series of spiral curves, beautifully exemplified in the leaves of the Screw Pine (Pandanus), in the scales of Fir cones, or in the rosettes of the House Leek, &c. Similarly we often see the lobes of the corolla in flowers twisted, some in one direction, some in another. Or, again, take the case of twining plants. Some twine regularly and constantly one way, others as constantly curve in the opposite direction.

In describing these curves writers make use of the expressions "dextrorse," or right-handed, and "sinistrorse," or left-handed, according as the direction is from the left hand to the right, or from the right to the left. This would be intelligible enough if those who use the terms would always specify in what sense they use them; but still better would it be if all would use the terms in the same manner. As it is, among those whose business it is to describe plants opposite practices prevail, and as these practices are carried out by authorities of equal reputation it is idle to point to Dr. So-and-so for justification because Professor This-and-that is exactly of the opposite persuasion. In the case of a twining plant, for instance, the observer may imagine himself in the centre of the coil—the stem around which the plant twines from his right hand, beginning from below, and going upwards across the front of the body towards the left hand. But as the coil winds round his back, it, of course, proceeds from left to right, so that here, unless the position of the observer be specified and well understood, confusion may arise. The other way of considering the matter is to suppose the observer standing in which direction the spiral lines ascend, whether from the right or from the left. Scarcely two books agree in this matter, and sometimes the confusion is intensified by some writers meaning by a right-handed or "dextrorse" spiral one that goes from the

right to the left, while others use the term in exactly the opposite signification; and so, of course, with the terms left-handed or sinistrorse. How difficult it is to secure agreement even on such simple matters is shown by the fact that such authorities as BENTHAM and HOOKER suppose the observer to be outside and opposite the coil, using, therefore, the terms dextrorse, or right-handed, and sinistrorse or left-handed, in precisely the opposite way to that intended by the great law-giver LINNÆUS. At a recent, or at least at a not very remote meeting of the Linnean Society, the question was discussed, and MR. BENTHAM then advocated the mode of using the terms we have just mentioned, and DARWIN in his *Climbing Plants* adopts the same course.

It was, therefore, with some interest that we observed that at the June meeting of the Botanical Society of France, M. A. DE CANDOLLE followed exactly the opposite plan, but, what is better, he gave his reasons for so doing. In accordance with many English writers, M. DE CANDOLLE supposes himself in the centre of the coil, and looking down in front of him, sees the coil ascend from his right to his left hand, or *vice versa*, as the case may be. His reasons for so doing are these:—That LINNÆUS adopted this rule, and has been followed by the elder DE CANDOLLE, MOHL, PALM, and A. BRAUN, and other observers. This rule, then, has at least the *prestige* of priority, however widely some may have departed from their allegiance. Another reason given by M. DE CANDOLLE is founded on the practice of the learned Professor of Berlin (A. BRAUN), to whose authority in such matters the highest deference is due. Professor BRAUN remarks that the best way to follow in determining the direction of a spiral is to follow the indications of the object itself. It is the animal or plant itself which ascends or descends, or goes to the right or to the left. Again, in the case of an animal, the position of the observer is of no consequence; we distinguish the right and left sides of the animal, not from our position with relation to it, but according to the conformation of the animal itself. The animal cannot speak to us and tell us which is his left and which his right flank, but we speaking animals are able to do so. A drill-sergeant, says M. DE CANDOLLE, in giving the command "right wheel" does not expect his men to turn to his own right, but he expresses himself as if he were in the position of the men whose movements he directs. So in the case of a river, the universal practice is to call the left bank that to the left hand of an observer supposed to be proceeding from the source of the stream to its outfall in the sea; following, therefore, the natural onward course of the stream. For these reasons, which appear to us to be sound, M. DE CANDOLLE advises those who have to deal with twining plants and other spiral growths to be guided in the use of terms by the direction in which the plant itself is growing, and the advice is so reasonable that we could wish it were henceforth universally followed, but so difficult is it to secure uniformity of practice that we do not look forward with any confidence to so desirable a result.

— OUR central illustration (fig. 8) represents two tropical Australian CYCADS growing in the Botanic Garden at Brisbane, under the charge of Mr. W. HILL. That opposite the right of the reader is *Macrozamia Mackenzii*, that to the left M. Miquelii. The two species are botanically similar, but for garden purposes are different in habit and general appearance. They are admirably suited for the decoration of warm conservatories, and would, like some of their allies, form noble plants in the subtropical garden. The fronds or leaves of both forms are elongate and deeply divided into very numerous linear segments, of a deep green colour, thickened at the base. The rachis or common stalk is slightly flattened, and more or less covered with hair downwards. We shall have more to say concerning them on another occasion.

— The gentlemen recommended by the COUNCIL of the ROYAL HORTICULTURAL SOCIETY to fill the vacancies for the ensuing year caused by the retirement of MR. ROBERT WARNER, the Hon. and Rev. J. T. BOSCAWEN, and Sir TREVOR LAWRENCE, Bart., from the Council, are Sir CHARLES STRICKLAND, Bart., Messrs. H. J. ELWES and T. M. SHUTTLEWORTH.

— The culture of Chicory as a salad under the Flemish name of WITLOOF has, strange to say, only recently been introduced among us. The Brussels market gardeners, it appears, grow it in trenches, covered with 6 to 8 inches of soil; but M. DE VENTER, as recorded in the *Monitor Horticole Belges*, grows it on what is called a *hatter* or quicker method. At the base of an east wall a bed of old tan is made, about 8 inches thick and 7 feet in width. In this tan are plunged, side by side, the roots, previously shortened to a length of about 5 inches. They are covered with the tan to the depth of 7 to 8 inches, and over the tan is spread a layer of dung, between 2 and 3 feet in thickness. In this manner longer and better heads are said to be produced in a fortnight than in double the time according to the ordinary method.

— We are much gratified to hear that our old correspondent, MR. WIGHTON, the gardener at Cossey Park, has lately been presented with a valuable purse of money by his employer, Lord STAFFORD, as a testimonial of respect for long service in his lordship's family. It is always pleasing to hear of such kindners, which exemplifies the good feeling that should exist between masters and servants, and we congratulate our correspondent on his success in having given satisfaction for so long a period to so kind-hearted and appreciative an employer.

— We have received from MR. STEPHEN BROWN, of Weston-super-Mare, a few sprays of an EUONYMUS, which he obtained a few years ago from a green sport of the variegated form of *Euonymus radicans*, to which it has clearly reverted. MR. BROWN states that it grows very rapidly, and soon covers a large space on a wall, where it must have a very pretty effect during the winter months, being covered with beautiful orange seeds. The foliage is in places very slightly stained with white variegation, but not sufficient to be noticed except by close examination.

— One of the most charming of all the Spruces is the COLORADO ABIES MENZIESII, of which some small examples may be seen in Mr. A. WATERERS' nursery at Knap Hill. Two very beautiful selected trees of this now Fir are growing in the garden of Professor C. S. SARGENT, at Brookline, near Boston. These trees are from 7 to 8 feet high, with the symmetrical growth of typical *A. Menziesii*, but specially remarkable for the bright blue glaucous hue of the entire plant, which as a blue is as bright and striking as is the green of the Knap Hill Cypress, *Cupressus Lawsoniana erecta* variegata. The tree is indeed, on account of its soft glaucous hue, and naturally symmetrical habit, one of the most lovely that can be imagined.

— The report of the Council of the ROYAL MANCHESTER BOTANICAL and HORTICULTURAL SOCIETY, to be read at the forty-ninth annual meeting of proprietors, to be held on Monday next, congratulates the shareholders on the improved circumstances of the Society. The financial statement shows that the mortgage to the Lancashire Insurance Company, which has stood at £5000 for the last twenty-five years, is now reduced to £1000. This favourable change has been brought about by means of donations, and the establishment of Life Memberships. The exhibitions held during the past year were very satisfactory from the horticultural point of view, the exhibits being very meritorious in nearly all the sections; but the depression of trade and the unfavourable weather prevented such a satisfactory financial result as the Council have had to lay before the shareholders in connection with previous exhibitions, and in addition to these circumstances influences have also been at work to draw visitors in another direction. For seven years prior to the opening of Manley Hall the average profits upon the Whitson week exhibitions were £600 per annum;

for the two years that Manley Hall has been open the profits on the Whitsun week exhibitions have been £300 per annum. The musical promenades formerly yielded a profit of from £80 to £100 per annum, for the last two years they have not paid expenses. The Town Hall shows have become an important feature in the Society's proceedings, and the increasing interest evinced has induced the Council to arrange for holding three exhibitions of the same character during the ensuing year. It is proposed that an exhibition of window plants and cottage garden

— Twenty sheep, the property of Mr. SAVILL ONLEY, of Stisted Hall, near Braintree, have been poisoned by eating poisonous shrubs in the garden, into which they got access on Saturday night last, in consequence of the park gate being left open. Nearly a whole flock of 100 entered the garden, and as they were all in lamb it is feared there may be still further losses.

— One of the sublimest things in Nature is found in the ROAR OF THE STORM amidst the branches of

and pastime of the raging storm. In her beautiful poem of the Pilgrim Fathers, Mrs HEMANS tells how the

"Woods against a stormy sky,
Their giant branches toss;"

perhaps in deciduous trees nothing affords more complete compensation for the loss of the summer foliage than the watching of the motion of the spray produced by the passing winds. With a background of deep blue cloud lit up by the lurid light emitted from a sun bathed in moisture, there is then

FIG. 8.—AUSTRALIAN SPECIES OF MACROZAMIA. (SEE P. 43.)

produce, grown in and around Manchester and Salford, be held in the gardens, on August 4 and 6 next, the prizes offered to consist mainly of articles for household use; and the Council desire to record their grateful acknowledgments to several ladies and gentlemen who have already promised useful articles to be competed for on that occasion. The suggested arrangements for the year 1877 are—Floral and horticultural meeting, Town Hall, March 20; Auricula show, Town Hall, April 27; National Horticultural Exhibition at the Gardens, May 18 to 25 (inclusive); special exhibition for cottagers at the Gardens, August 4 to 6; exhibition of Chrysanthemums and fruits at the Town Hall, November 27 and 28.

GIGANTIC TREES. Sometimes the sound resembles that emitted by an army of wild bulls, and anon it is lulled into a gentle and soothing murmur; but to all who love trees and woods the sounds alike are sweet music, varying like the notes of an organ from the sweetest symphonies to the crash and thunder of a grand chorus. Not less effective, however, is the motion excited under fine deciduous trees when leafless in winter, under the influence of a fierce and sweeping gale. An imprisoned giant lashing his mighty arms in impotent rage affords but a weak illustration of the magnificence and grandeur displayed by some lofty Oak or Elm, as firmly fixed in the earth it yet has its monster branches bent hither and thither, the sport

and elegance displayed that might well inspire some worthy poet. Wild, wet and stormy as the past weather has been, it has not left us without something to admire.

— Some idea may be gained of the extent of the disasters caused by the PHYLLOXERA by a recent report of M. DUCHARTRE, of the Central Horticultural Society of France, in which the learned Professor of the Sorbonne details the results of his examinations in various districts of France. Where the invasion of the insect took place first some years ago no traces are now left, for the Vine itself has disappeared! and no traces are apparent that the regions in question were

once wine-growing districts. Where the destroying influences are still at work the spectacle is heart-rending (*navrant*). In many places American Vines are being planted rapidly, these so far not being attacked by the *Phylloxera*, and on these it is intended to graft the European kinds. It must be remembered, however, that this immunity does not extend to all the American kinds, but principally, as shown by M. PLANCHON, to those Vines derived from *Vitis rotundifolia* (*alida vulpina*), from which the Scuppernon, Thomas, Flowers, and other American varieties have been derived. These Vines require much heat to ripen their fruit, and their juice requires the addition of sugar to be converted into palatable wine.

— Chance GROUPINGS OF PLANTS not unfrequently turn out to be more effective than combinations upon which much study has been bestowed. A case of this sort has been mentioned to us by Mr. WATERER as having been observed by him during his recent trip to America. A group of double white Primroses was surrounded by a broad belt of *Omphalodes verna*, and both were doing well, flowering freely and at the same period. Though this was associated by mere accident, the combination proved to be most beautiful.

— We are informed that Mr. ROBERT AUGUSTUS ARNOTT retired on December 31, from his engagement with Messrs. CHARLES SHARPE & Co., of Slensford, and is now associated with Mr. WM. BAXTER SMITH and Mr. JAMES WATT, the partners of the old established firm of LITTLE & BALLANTYNE, seedsmen and nurserymen, Carlisle.

— The next meeting of the INSTITUTION OF SURVEYORS will be held on Monday evening, January 15, when a paper will be read by Mr. W. T. MARRIOTT, entitled "Riparian Rights." The chair to be taken at 8 o'clock.

— The following SPECIAL EXHIBITIONS will be held on the dates given in the gardens of the Royal Botanic Society, Regent's Park:—*Clematis*, by Messrs. GEORGE JACKMAN & SON, of Woking, from May 22; Rhododendrons and American Plants, by Mr. ANTHONY WATERER, Knap Hill, from June 1; and flowering and fine-foliaged plants, by Messrs. JAMES CARTER & Co., High Holborn, from June 27 to July 12.

— We learn from Messrs. J. BLACKBURN & SONS' circular that the stock of RUSSIA MATS is quite cleared out in Russia, and, as a proof of this, the quotations for next year's shipments will be higher than last. Stocks are nearly exhausted in England, and they cannot be replenished for the next six to eight months; prices in the meantime must therefore advance still higher.

— The total number of bales of COTTON imported during the twelve months ending with December 31, are 3,615,627; comprising 2,098,078 of American, 315,835 of Brazilian, 759,508 of East India, 335,209 of Egyptian, and 106,097 of miscellaneous. The number of bales exported during the same time are 513,127, comprising 10,113 of American, 17,130 of Brazilian, 364,321 of East India, 9495 of Egyptian, and 13,039 of miscellaneous.

— There is this year promise of a more ABUNDANT BLOOM on the AMERICAN PLANTS than has ever before been known. At Knap Hill almost every plant is full of buds, so that, if no mishaps intervene, the blossoming period may be expected to be a glorious one—one to be made a note of.

— A correspondent of REGEL'S *Gartenflora*, writing from Nikita, in the Crimea, states that there is a tree of *XANTHO CERAS SORBIFOLIA* at Karasson which is at least fifty years old, and another in his own garden twenty years old, so that it cannot be regarded as a new introduction. In the Crimea this small ornamental tree flourishes admirably, producing annually a profusion of beautiful white flowers, and sometimes ripening its seed. It is strange that so distinct a thing should have escaped observation so long. If the writer is not mistaken—and he seems to entertain no doubt as to the identity of his trees—*Xanthoceras sorbifolia* was probably introduced by

some member of the Russian Embassy from North China, or possibly it has a wider range of distribution than was supposed. *Chamaerops excelsa* is also quite hardy in the same region, and ripens its fruit.

— It will be remembered that we published a short time ago an account of the vegetable productions of Japan; and Dr. VIDAL stated there that the JAPANESE always ate their PEACHES in an unripe state. In the *Gartenflora* Dr. REGEL says in some remarks on Japanese fruit trees, that Dr. MAKIMOWICZ informs him that the Japanese regard a ripe Peach as "rotten"! We remember eating with great relish in our younger days Green Gooseberries and Apples, and a variety of other equally delicious fruits; but only so long as there were no ripe ones. A green Peach, however, would have been about the place to draw the line, even then, when scarcely anything came amiss.

— The *Bulletin* of the French Society for Acclimatization for October contains a long account of the HISTORY and USES of the TRUE JABORANDI, *PILOCARPUS PINNATUS*. It appears that its introduction, or rather re-introduction, is due to a Brazilian, Dr. CONTINHO, who brought some leaves of it for his personal use about two years ago. He attended Professor GUELE's lectures, and when speaking of sudorifics the learned Professor of the Faculty of Medicine observed that no drug in use really deserves the name. This statement induced Dr. CONTINHO to bring the *Jaborandi* into notice. The report in the publication referred to is a lengthy one, giving the results of the most important experiments made with this drug by eminent physicians. The physiological action of infusions, chemical composition, and the physiological action of the peculiar alkaloid pilocarpine are detailed. P. simplex gave similar results. It is not only a powerful sudorific, but an equally active sialagogue.

— *RETINOSPORA FILIFERA GRACILIS* is one of those plants that has been much condemned because of its somewhat abrupt and mossy style of growth, and its sending forth the pendulous habit is graceful and elegant. It is a plant that cultivators have left too much to itself, and then it apt to grow bushy and ugly in appearance. A judicious employment of the pruning-knife would keep these bunches somewhat cut away, and when this is done the plant will put forth leading shoots which soon augment its height and elegant appearance. There are among the Japanese plants which Mr. FORTUNE introduced many things of an extremely interesting character that are in great danger of falling into oblivion. Their pigny appearance and slow growth are much against their recognition, but what an interesting group might be made of them were they arranged in a cold conservatory, either planted out in suitable soil or potted and cultivated in pots; or a collection might be made of them in a small garden, where they could not fail to be a perennial source of pleasure.

— The following extract is taken from a letter recently received by Messrs. THOMAS CHRISTY & Co. from Mr. CHARLES DRAKE, of the Culford Coffee Estate, Vythry, South Wynard, Malabar:—

"The Fricky Comfrey is doing remarkably well. Some of the forward plants are now larger round than a very large Cabbage. Next week I intend commencing to feed some of our stock on the leaves, which I might have done at least a month ago, but waited so long they might make roots as well as leaves. This fact speaks for itself, since I have not left England five months yet; six weeks of these were spent on the voyage, and it was quite a month after I arrived on the estate before the roots were all planted. I notice, as you remarked, that they flourish better in shade, where you are sure of a plant on all soils, but I dressed our land so well with manure that although you are in a cooler water after day to a tropical sun, little or no difference is noticeable between those in shade and those in the sun. I am sure if some of our English farmers knew of it, they would, neither they nor any cowkeeper would do without it. I have already fed some of our cattle occasionally with it myself, mixed with grass, and a decided improvement is noticeable, and much as cattle are averse to *Euphorbia*, they will follow me for it in preference to grass or grain."

— At a time when much interest is centred on the PRODUCTION and CONSUMPTION of SUGAR, owing to the rapid rise in the price of this most useful commodity, it is satisfactory to hear of the extension of the cultivation of the Sugar-cane in any country

where it is likely to succeed. Thus we learn from China that in the neighbourhood of Swatow the cultivation is extending, and is likely to continue to do so. Though the sugar is sent to the port of Canton, and to Britain, a large quantity is sent to other ports, and during the year 1875 the exports showed an increase of 170,000 piculs above those of the previous year.

Home Correspondence.

Lily of the Valley.—There has been a good deal said lately on the superiority of the French Lilies of the Valley over those imported from Belgium; but is this borne out by facts? My impression is that it is not so, and I am inclined to think that this cry in favour of the French variety is attributable only to the plan they have adopted in growing the fine early flowers we see so often. I have tried, you a few spikes from English-grown crowns, which I flatter myself are fair, and not so far-fetched. They were forced two years ago this season, and when out of flower were planted out. About five weeks ago they were taken up again, the flowering crowns selected and placed singly in boxes in order to be fitted for sale. I have not cut on the 1st inst. *George Thomson, Crystal Palace, Sydenham*. [The flowers received were quite first-rate. Eds.]

Bambusa Ragamowski.—Having examined the leaves sent by Mr. Wheeler's interesting notice, published in issue for Dec. 30, I have been able to identify them with *Bambusa tessellata* of my monograph. Consequently, I suppose that is the name which the plant ought to bear, as I cannot ascertain, after diligent enquiries, that the name of B. Ragamowski has ever been published. The Rev. Mr. N. ELIACOMBE of Eaton Vicarage, has also sent me specimens of leaves rather larger than Mr. Wheeler's, in fact, exactly corresponding in size with those described by me in my monograph, namely, 14 foot long and about 3 inches broad. The plants can readily be recognised by the tomentose line on one side of the midrib running nearly the whole length of the leaf on the underside, this line being always on the longer side of the leaf. *William Murray*.

The Web of the Embia.—The insect recently engraved in the *Gardeners' Chronicle* undoubtedly weaves a web which must not be confused with the web of the spider. The specimen illustrated was sent for engraving in a large pill-box, and on its arrival a web had been woven inside, attaching the lid to the body of the box. The insect was then very lively and rapid in its movements, ever and anon retreating into a small loose silken den or tunnel it had woven for itself at the bottom of the box. From this den it chloroform stifled the quick movements of the insect, and then the engraving was made direct from a camera-lucida reflection from the microscope. *J. G. S.* [Mr. Michael has favoured us with an inspection of the web. The insect does not doubt that the insect does spin a web. The whole matter is one of great interest, and we are glad to learn that it is being investigated by the most competent entomologists. Eds.]

Limelike Heating.—The Cowan Patents Company's advertisement fell into my hands the other day, and in it I find it stated that the piping heated at Emo Park is 2000 feet. In a letter from Mr. Ennis, the gardener, which appeared in the *Gardeners' Chronicle* of September 30, he stated that the kiln had heated 1000 and 1000 feet of 4-inch piping attached. How does Mr. Ennis explain this discrepancy? *Viri Amator*. [Mr. Ennis informs us that his statement is quite correct. The error rests with the Cowan Company, and it perhaps arose thus. Before the system was adopted there was about 200 feet of 4-inch piping in the range of plant and fruit houses at Emo Park, but finding that the heat was so powerful, a range 350 feet long, in which there is a flow and return 4-inch pipe, was attached. This added 200 feet more, and with another 150 feet, used for connecting the one range with the other, makes the total amount between 3000 and 4000 feet, as stated. After some fourteen months' trial, Mr. Ennis informs us that he cannot speak too highly of the system of heating, and will be happy to show the apparatus to any one who may call at Emo Park. Eds.]

The Glastonbury Thorn.—One of the discomfited consequent on a mild winter is that our attention is arrested by ridiculous lists of plants in flower. It is one thing to record, fairly and honestly, a successful season, and quite another to adulterate the record with details that prove the reporter to be destitute of the experience requisite to intelligent reporting. In a list of plants in flower at Christmas, lately published in an important daily paper, the first item mentioned was the "evil flowering" *Adonis vernalis* *Sensu vulgaris*. There was never a winter known

to the present generation in which the Grandseul did not flower in the intervals of frost, and even during an hour or two of summer. In the latter case the region is remarkably so, or so of frost. About one-third of the plants enumerated as having been in late wondrously in flower, may be assigned to the same category as the Grandseul, and amongst the remaining two-thirds very few indeed were of sufficient interest to require any special notice. What can it matter to any one that the common Chickweed, the common sow Thistle, and the red dead Nettle, were showing a few flowers at the close of the year? They range from here to 82° north latitude, and are always registered in flower, and in fruit, stiff as steel, and then only three or four days of a temperature somewhat above the freezing point will make them gay with flowers once more. Vegetation is at this moment remarkably quiet, considering the range of the thermometer for two months past; but in the latter days of December I saw young Lime trees brightly spangled with golden-green leaves, and a Horbeam under my sanctum window threatened to go ahead, but changed its mind in time, and is now as still as a stone.

Two things in the way of "focal phenomena" have, however, interested me an occasional "tour of my garden." On December 25, our new-fangled Christmas Day, I found a glorious sheet of the blue flowers of Scilla biflora in a very cold, damp corner; and on January 6, the red old Christmas Day, and only one Christmas Day in this connection, my Glastonbury Thorn was in flower. It is the first time in all my days that I have been blessed with the Christmas flowers of this holy tree. And I must say in the way of a particularly interesting to me remarkably buxom appearance, being more densely laden with flowers than I have ever seen it before, and with such a wealth of bright new leafage as makes a sheen of springtime in the cold, damp shrubbery wherein the tree is located. The sample sent me now says that the tree carried all the flowers of last year, a little the worse for wear, while the new leaves are conspicuously forward and of the most delicious tint of tender green, and every twig bristles with clusters of swelling flower-buds, the expansion of which is scarcely to be wondered at. As a matter of course the few flowers I found on Christmas Day were claimed by pious pilgrims, and as it was enough for me to have seen them, I could but hope those who obtained permanent possession would find it worth while to fruit them. It is, however, to be observed that this precocious Crataegus is so rarely met with, although there is not a more interesting garden tree in cultivation, and as regards its beauty it is an advance on the common Thorn in several respects, its leafage being much richer, so that if planted in a hedge, it would make a most beautiful one. It is, however, this "swallow dares." Having seen Joseph's Staff in flower on the festival of the Nativity I shall hope to see it in fruit some day, for hitherto I have never seen a berry on the Glastonbury Thorn. *Shirley Hibbard, Sole Newington, Jan. 8.*

The Rainfall of 1876.—I have been looking at Mr. McCombe's account of the rainfall in 1876 at Wallington, Northumberland (see p. 20), and the total amount for the year there appears to be nearly 11 inches in excess of what fell in this part of Suffolk. Thinking it possible that you may consider it interesting to your readers to know something of the rainfalls of various and distant parts of the country, I have appended a statement of the rainfalls of the various months as recorded at this place:—January, 1.80 inch; February, 2.50 inches; March, 2.25 inches; April, 2.27 inches; May, 3.00 inch; June, 2.75 inches; July, 4.39 inch; August, 1.71 inch; September, 4.45 inches; October, 0.84 inch; November, 2.59 inches; December, 3.97 inches; a total rainfall for the year, 27.16 inches. The rain gauge stands 16 inches in diameter, with a funnel 1 1/2 inches in diameter, which with measurer was supplied by Casella, of Histon Garden, London. The rain is measured each day at 9 A.M. *P. Grieco, Culford, Eury St. Edmunds.*

Cotonaster vulgaris.—This rare plant is still to be found on the Great Ouzes Head. In company with a friend a few days back I saw it growing in two distinct places. It is much resembled by sheep, who devour every leaf that it can obtain, which makes the plant now difficult to find. There is one fine plant growing in the centre of a White Birch, very healthy. *Thomas Shortt, Landisdon, Jan. 8.*

Erica codonodes.—This Heath has been very handsome here all through December. I do not remember to have seen it before February in previous years. Can you inform me if it is really a native of the West of Scotland, as stated in Paxton's *Flora*, or *cal. Dictionary*? *H. K. [No. South of Europe. Eds.]*

The Weather.—Up to the time I now write (January 9) the weather continues to be mild and wet. During the first week of the year upwards of an inch

of rain fell, and the minimum temperature seldom falls under 40°, vegetation is consequently in an unusually forward condition. The bloom-buds on Apricot trees are here about to unfold their petals, while the ends of young shoots are furnished with perfectly developed leaves; Filbert bushes are already in full flower, Roses are almost in leaf, and in covers the Elder has already made shoots of considerable length. It is much to be feared that a change in the weather, which will undoubtedly take place before long, may have a very serious effect upon fruit trees, more particularly the Apricot. *P. Grieco, Culford, Eury St. Edmunds.*

Winter Broccoli in Cornwall.—The market gardeners around here have been cutting their first Broccoli since November, and will finish before the end of the present month, when they will commence on their second variety, which will last until the end of March. I may say that from twenty to thirty railway trucks leave here daily for London and the northern markets—price in the field is from 1s. 3d. to 1s. 6d. per dozen. The seed of this Broccoli is sown in the end of February, and the plants are put out at the end of March. I believe that this variety would succeed further up if sown early enough, and the seed obtained from some of the growers, who, by-the-by, are very careful in parting with it. The variety is large, and perfectly white and distinct. *H. Roberts, Giddeford, Penzance.*

Premature Growth of Vine Roots.—I quite agree with Mr. Wildsmith that it is a bad practice to induce Vines or any plants to make roots when the plants are without leaves; I thus pointed out in your volume for 1874, p. 719. I have long known that Vines left to themselves do not make new roots until they have made leaves, but I cannot agree with Mr. Wildsmith that inside borders are the best for either early or late forced Vines. You cannot keep the soil so sweet and healthy for the roots in an inside border as when it is exposed to the influence of the outward air; but let the Vines decide the point. I assert that you cannot keep the roots of Vines in an inside border if they can get out, and they will overcome almost insurmountable difficulties to attain their purpose. If they find themselves so comfortable inside, why do they struggle to get out? *M. Henderson.*

Flowering of Agave schottigera.—It my interest some of your readers to know that in our collections we have fine plants of Agave schottigera—one at home, one at Regent's Park, and two at the Alexandra Palace, which are all flowering at once. The tendency to flower at the same time proves to me that they are all from one set of seeds, though we got them from very different sources. At first they were very different in their development, but with age they have lost these differences, and have assumed the common type. They are about seven years old. *F. Crawford, Gr. to F. T. Pocock, Esq., Salisbury House, Jan. 4.*

Paraffin and Carbolic Acid.—Your correspondent "F. C. N." does well in being cautious in recommending paraffin oil as a dressing for fruit trees, for nothing can be more destructive to the bark—it completely destroys it wherever it touches. I consider paraffin oil and carbolic acid equally dangerous. If your correspondent would try a bottle of Bridgford's Antiseptic Liquid, he would find nothing so effectual, and it is quite safe; it is a compound of sulphur, and does not burn the skin. It can be procured at any of the principal seed warehouses. *C. W. B.*

Fruiting of the Common White Jasmine.—Mr. W. Wilson has called your attention to the fruiting of this Jasmine at General Sir F. Gray's. I beg to be permitted to express my gratification in seeing the seeds, as Mr. Hamilton kindly gave me a few dozen, and every one of them grew. *Thomas Rixon, South Hill Park, Bracknell.*

Which are the Best Late Grapes?—In my opinion Mrs. Pince's Black Muscat stands first as a fine peeper. It is excellent for use, and, as a rule, those who do not succeed well with it, I would say, Don't overcrop, and use plenty of charcoal in the formation of the border, and it will colour all right. I use it quite fine from the bottom of the charcoal heaps after the burners have left a little dirt on the top. I think when you asked the name of the Grape she was eating into a flower-pot that the result would be as it has turned out—such a first-class Grape. Lady Downe's is the next best with me; but, singular enough, it never keeps so well as the former, and it has such a good flavour. West's is, perhaps, keeps pretty well, and is very fresh and brisk in flavour. Gros Guillaume should always be grafted on the Hamburg, when it is easily managed, and is a very useful late Grape. The finest I

ever saw of this [kind was at Chiswick, where the roots ran over an arch which covered the hot-water pipes, and was trained to a large house. White Lady Downe's I dug up, and so I have Royal Vineyard, for it neither set well nor kept well. Our soil is stiff, the rainfall considerable, and the situation 400 feet above the sea. Perhaps these three things had something to do with its failure, but White Tokay does very well, and is not bad eating after Christmas. Waltham Cross I have planted; it grows capitally, which is saying a good deal after the poor figure some of our new Vines have cut in growth. I have not fruited it. Snow's Muscat, a Hamburg, and its relative was preserved as an old variety, at Harrington House, Fulham; it was propagated by the late James Lane and the late Mr. Snow, of West Park, who sold it jointly to Mr. Henderson, Pine-apple Place, for an incredible sum. The late Sir Joseph Paxton and my late lamented friend, Mr. Thomas Osborn, of the Fulham Nurseries, and many others, believed it to be nothing more nor less than the old Black Muscat. It is a delicate Grape, only fit for a mid-season fruit, and then when grafted on the Hamburg. Gros Colman is a noble-looking Grape and keeps well, but is only third-rate in flavour. Raisin de Calabre is a late-keeping white Grape, and not bad as to flavour. *F. Rux, Eridge Castle.*

I was rather surprised to read in your last issue that Mr. Grieve had sown his favourite Grape, Black Alicante, third on his list. In my opinion it far exceeds other varieties in its late keeping qualities, but no doubt soil and situation have something to do with it. Mr. Grieve writes that it has become shrivelled long before there are any indications of this taking place in the fruit of Lady Downe's or Mrs. Pince's Black Muscat? I certainly cannot give it that character here, for I know of no Grape that will keep so long without shrivelling, or carry a bloom so long as it does. I am sure that it has the finest flavour. I cut a house of Grapes here on December 15, 1875, bottled, and hung them up in the Grape-room, and on May 17, 1876, I had bunches of Alicante hanging without a shrivelled berry in them, and the bloom as good as on the day they were cut. Mrs. Pince's Lady Downe's began to shrivel long before. *F. Brown, Lasham, Grantham.*

The results of the inquiry respecting the most useful varieties of late keeping Grapes best suited to the various localities, has been published in the *Gardener's Chronicle* of December 23, 1876, regarding spent Hops, I beg to make a few remarks on the results of a lengthened experience. I live near a farm 2 miles south of Edinburgh, of which my father is land steward, and have been engaged in agriculture as well as horticulture. I will briefly state two different trials I have seen spent Hops undergo. Four years ago, when Hops were first introduced on the farm referred to, it was spread over the ground at the rate of 35 tons per acre, and ploughed in in autumn, and the Potato crop was a failure, owing to frost, when lifted it was found, to the disappointment of all concerned, that the tubers were small in size, deficient in quality, and a remarkably poor crop, while the stalks, when measured, were found to be 4 feet in length. Another trial was made similar to that mentioned by G. A. Dains, was tried the following year: the ground was ploughed in autumn, and in spring, when the drills were made and the Hops spread in them, the sets were placed thereon and covered in; exactly the same result was witnessed when lifted as already alluded to, but ever since it was mixed with other composites it has done very well, so that in my opinion, and that of practical farmers, spent Hops by themselves, as a manure for Potatoes, are absolutely worthless. *F. H. C.*

Spent Hops for Potato Culture.—Being interested in reading the article by G. A. Dains in the *Gardener's Chronicle* of December 23, 1876, regarding spent Hops, I beg to make a few remarks on the results of a lengthened experience. I live near a farm 2 miles south of Edinburgh, of which my father is land steward, and have been engaged in agriculture as well as horticulture. I will briefly state two different trials I have seen spent Hops undergo. Four years ago, when Hops were first introduced on the farm referred to, it was spread over the ground at the rate of 35 tons per acre, and ploughed in in autumn, and the Potato crop was a failure, owing to frost, when lifted it was found, to the disappointment of all concerned, that the tubers were small in size, deficient in quality, and a remarkably poor crop, while the stalks, when measured, were found to be 4 feet in length. Another trial was made similar to that mentioned by G. A. Dains, was tried the following year: the ground was ploughed in autumn, and in spring, when the drills were made and the Hops spread in them, the sets were placed thereon and covered in; exactly the same result was witnessed when lifted as already alluded to, but ever since it was mixed with other composites it has done very well, so that in my opinion, and that of practical farmers, spent Hops by themselves, as a manure for Potatoes, are absolutely worthless. *F. H. C.*

shoots in their earliest stage of growth. And besides these, the crops of manure were not only good, but in successive years, and as a rule, remarkably free from disease. This is important. Perhaps Dr. Lindley's observation that the neighbourhood of fragrant oils prevents the growth of moulds, may have held good here. Some time ago, the frost of the present year, the Hops may remain after boiling sufficient to repel the attack of the mould. The refuse of distilleries where such plants as Lavender and Peppermint are boiled for the oil they yield, should, as well as spent Hops, be tried by those who have opportunity and the requisite skill. There is no doubt that a crop of hops in this direction, which may encourage further experiments. S. S. Steenoka.

A Vision of Poinsettias.—The practice at Acton certainly seems to be a very simple one. Would Mr. Reeves, or some one else, be kind enough to state the lowest degree of temperature for October, November, December, &c., to which the Poinsettias will thrive so as to come to a tolerable state of perfection? By so doing they would confer a great boon on not a few who are expected to grow the Poinsettias and have not much convenience in the way of heat. *Enquirer.*

The Weather at Ochtertyre, Crieff, in 1876.—The mean temperature during the various months, as computed from daily observations (the thermometer being shaded and 4 feet from the ground) were:—January, 38°·34; February, 35°·45; March, 37°·11; April, 43°·35; May, 51°·26; June, 56°·31; July, 60°·14; August, 58°·24; September, 52°·33; October, 49°·16; November, 38°·28; December, 36°·39. The highest temperatures recorded during each month were:—January, 49°; February, 49°; March, 51°; April, 62°; May, 67°; June, 78°; July, 81°; August, 76°; September, 61°; October, 66°; November, 54°; December, 48°. The lowest temperatures recorded during each month were:—January, 24°; February, 25°; March, 24°; April, 25°; May, 31°; June, 42°; July, 45°; August, 43°; September, 37°; October, 37°; November, 25°; December, 21°. With the thermometer exposed, the highest temperatures in the sun's rays were:—January, 103°; February, 105°; March, 111°; April, 122°; May, 109°; June, 123°; July, 118°; August, 121°; September, 111°; October, 103°; November, 100°; December, 76°. The lowest temperatures with the thermometer exposed on the grass were:—January, 19°; February, 17°; March, 14°; April, 14°; May, 22°; June, 30°; July, 36°; August, 32°; September, 27°; October, 29°; November, 14°; December, 21°. The number of nights on which the thermometer fell below 32° in each month were:—January, 28; February, 23; March, 28; April, 16; May, 13; June, 5; July, 0; August, 1; September, 3; October, 4; November, 10; December, 13. The temperatures at 3 inches below the surface were:—January, 37°; February, 35°·3; March, 37°; April, 44°·4; May, 53°·5; June, 58°·7; July, 63°; August, 61°; September, 54°·2; October, 50°·4; November, 41°·1; December, 38°·6. At 12 inches below the surface:—January, 38°·2; February, 37°·2; March, 38°·1; April, 44°·8; May, 53°·2; June, 58°·5; July, 62°·5; August, 60°·9; September, 56°·1; October, 51°·9; November, 44°; December, 39°·7. At 22 inches below the surface:—January, 39°·1; February, 38°·3; March, 38°·3; April, 43°·5; May, 50°·7; June, 55°·6; July, 60°·3; August, 59°·7; September, 56°·1; October, 52°·5; November, 45°·9; December, 41°·1. The greatest rainfall during the various months was:—January, 3·01 inches; February, 4·57 inches; March, 4·50 inches; April, 3·52 inches; May, 0·19 inch; June, 3·84 inches; July, 5·58 inches; August, 3·32 inches; September, 2·84 inches; October, 2·99 inches; November, 4·51 inches; December, 11·32 inches. The greatest rainfall during twenty-four hours in each month was:—January 20, 0·66 inch; February 27, 0·73 inch; March 4, 0·63 inch; April 26, 1·23 inch; May, 0·09 inch; June 22, 0·09 inch; July 1, 0·53 inch; August 3, 1·00 inch; September 5, 0·87 inch; October 12, 1·14 inch; November 15, 2·63 inches; December 31, 1·53 inch. G. C.

Autumn Planted Potatoes.—Having read Mr. Webster's letter at p. 816, vol. vi., in your number for December 23, I beg to say, with all respect to you, that I have nothing to retract or to withdraw in what I have written on this subject. I think Mr. Webster was easily discouraged from trying more than once, and further that his trying the experiment in a season when the disease was exceptionally bad was all against it, so that I have nothing to retract or to withdraw in respect of soil. Potatoes, and when the disease is very severe good seed is difficult to procure, and as he says his Ashleaf Potatoes produced small tubers without tops, it is to me a proof that diseased Potatoes were planted. Flant potatoes with tubers that were well-drained soil, and the result will satisfy the planter. R. Mather, *The Gardens, Boyne House, Trimbridge Wells.*

The Weather of 1876.—A few notes taken from the records kept here may be of interest to the readers of the *Gardener's Chronicle*. The total rainfall for the year was 32·98 inches, against 37·14 of 1875. The number of days on which 0·1 or more fell during the year was 144; the heaviest rainfall in twenty-four hours occurred on September 28, when 1·26 was taken; the four wettest months were April, 3·71, September, 5·07, November, 3·04, and December, 5·57, rain falling on twenty-three days during this month. The three driest months were May, 0·78, June, 1·04, July, 0·46, while January, February, March, August, and October, gave a steady average of 2·57 inches. The maximum temperature in the shade was reached on August 14, when 89° was registered; the minimum occurred on January 12, registering 17° of frost. The highest reading of the barometer was 30, the lowest 28·3. Two of the most winterly days experienced during the year were the April 13 and 14; the warm sunshine of the preceding week was succeeded by cold east winds and foggy mornings, and one of the heaviest snowstorms ever remembered in this neighbourhood, being 13 inches on the level, and in places drifted to the depth of as many feet. F. Clarke, *Barleythorpe, Oakham.*

Hatching Boxes.—In Christiania and its neighbourhood, and doubtless in other parts of Norway, the gardeners and proprietors fasten (with wire or nails) "Ruge Kasser," or "hatching-boxes," to the upper parts of the trees in their gardens and grounds, to which are regularly resorted to by such birds as build their nests in holes in trees (which are not frequently to be found in the young, healthy, growing trees in a

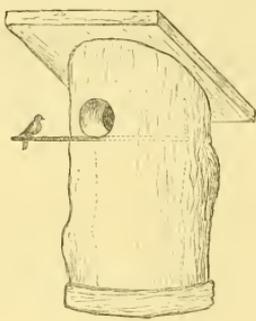

FIG. 9.—HATCHING BOX FOR BIRDS.

garden or plantation near a house), and broods are hatched and reared, safe from the depredations of *Felis domestica*. The presence of such birds in our gardens as the pied and spotted flycatcher, the redstart, timouze, wrenneck, starling, &c. (all of which would, I believe, build in such a "Ruge Kasser"), must be looked upon as an advantage, as they all feed upon insects, and they are pretty and interesting objects in the eyes of young students of ornithology. I send you a rough drawing of a "Ruge Kasser" (fig. 9), and beg to remind your readers that now, in the slack gardening season, is the time to make them, ready to be nailed or wired up in the beginning of February. S. Bryan Crovther, *Emery Down, Lyndhurst, Hants.* [The dimensions are:—Height at back, 16 inches; and of the front, 11 inches. Diameter, outside measure, 8 inches; inside measure, 5 inches. Length of sloping roof, 13 inches. Eds.]

Holly Berries.—It is perfectly true there is a great deficiency of Holly berries this winter, but that is not a very unusual occurrence after a fruitful year. The reason is obvious, that if trees bore largely every season they would soon become bare and worn out. In fact, a rest at times is essentially necessary, in order that the tree may regain its vigour, as an excessive fruiting year is not conducive to strong growth, and *vice versa*. With respect to the scarcity of Holly berries being attributable to the want of bee-fertilizing flowers on the female plant (the Holly being dioecious), I think Mr. Darwin's theory is wrong, as also that the common Holly (*Ilex Aquifolium*) is so very hardy, for I know it will not thrive in Canada, and is only indigenous in most parts of the middle and south of Europe. Although the blossoms in early spring are likely to be, and frequently are destroyed by frosts, which are so apt to occur at that period of the year, and which would account for a partial or total

failure of berries, I believe the present failure has been occasioned by an excess of moisture in the ground, followed by a warm spring temperature, which gave the Hollies an impetus of growth, which they had not had for several preceding years, and thus, instead of producing berries, an unusual growth was made. To prove this, I transplanted many large Hollies the year before last, which at the present time are full of berries, whereas similar plants, not transplanted, have not one; showing that when the redundancy of sap is checked, whether from removal, drought, or disease, fructification ensues without the intervention of bees. Hollies are particularly fine and plentiful in this locality, and so are bees, but still there are no berries. The failure is of too general a character throughout the country to be attributed to the death of bees, which I think must be more imaginary than real. *W. F. G. S.*

In my nursery there was up to Sunday night, December 10, a splendid bed of the common Silver Holly, pyramids, 5 to 6 feet, laden with berries, and joining it on the south side a bed of similar plants of the small-leaved Silver, male. In other parts of the nursery where the common Silver stands alone, there is not a berry, and the same is observable of the Aucuba plants contiguous to the males, being covered with green berries, while distant plants are without fruit. If bees are the chief fertilizers, I have six hives at present, as Mr. Darwin suggests, how comes it that the other beds are without berries, when all stand within an area of 17 acres? On the Sunday night alluded to thieves entered the nursery, and cut down to the stock fifty-nine of the berries, and, as they were all of the same looking as disconsolate as their owner, *George Handcock, Abbey Wood Nursery, Kent.*

The Fungi of "Whales."—In a recent number of the *Gardener's Chronicle* Professor M'Nab communicated an interesting and amusing paragraph, headed the "Flora of the *Sperm Whales* recently discovered by my friend, Mr. Charles B. Plowright, has published in *Grassill's* list of fungi found by himself in the dead carcase of a whale stranded near Kings Lynn. The "whale-fores," says Mr. Plowright, produced an "orange Fusarium" and various moulds, from a crack in the side of the whale's eye (the "Minerva from the brain of Jupiter) an Agaric very near to, if not identical with, *Agaricus bullaceus*—a fungus hitherto supposed to be confined in its ravages to horse-dung. But, strangest of all, "in the very centre of the brain, a curious, shining, yellow, thin stratum" of dry brains, grew, says Mr. Plowright, "a cluster of *Agaricus orestreus*!" (1) Note this disrespectful parasitism of the Oyster Agaric on the collapsed cetaceous brains can only be termed *ostreus* sauce to a whale! *W. F. G. S.*

Vicomtesse Héricart de Thury Strawberry (see p. 21).—The Vicomtesse and its synonyms, namely, *Marquise de la Tour Maubourg* and *Duchesse de Trevisse* or *Trévise*, were all raised by Jamain and Durand; but I do not know the parentage. I believe the "best" know more about hybridization than the guessing hybridizer. I may say in passing, that I believe Mr. Darwin's article on the Holly berries is right, but frost and excessive draughts may have had something to do with it. I saw some few green berries in our church, but not one "Coral Holly" in it. I am a Locke truly said "I saw a little, guess a great deal, and then jump to a conclusion." *W. F. Radcliffe, Jan. 8.*

The Weather at Hutton Hall, Guisborough, in 1876.—The rainfall last year at this place was:—In January, 0·96 inches; February, 2·23; March, 1·67; April, 2·45; May, 4·65; June, 4·25; July, 5·07; August, 2·31; September, 4·33; October, 1·72; November, 3·68; December, 5·15—total inches, 32·93, being in excess of the rainfall of 1873 by 12·05 inches, of 1874 by 7·38 inches, and of 1875 by 2·88 inches. *W. M'Indoe.*

Protection of Bottom Heat for Outside Vine Borders.—In the case of early vineries with outside borders, all growers will admit that the border ought to be protected. Now the common method of doing this is to put any amount of fermenting material on the border six or eight weeks before production commences, and at a time that this takes place, how often do we see the whole covered with snow, which in thawing together with cold rains forms a sad check to the previously, I doubt not, overbested border, and this at a time when fresh material is generally wanted for other purposes. For the sake of argument let us style this bottom-heat, and contrast it with the following plan of protection. Fix a framework to span the width of the border, and sufficiently strong to support shutters (exactly in the same way as lights or sashes in plantations). For the sake of argument should have their outside borders well watered by the end of September, or as soon after that time as a supply can be had. Next by in dry leaves,

as they can be obtained from time to time, till a good covering is on. A shutter or two will have to be removed for that purpose, but care must be taken to replace them again, as the object is to retain the heat by keeping off cold winds, rain, snow, &c. The leaves will check evaporation and the border moist, the latter being obtained soon after the roots pushed into growth, &c., after the first leaves were formed. I will only add that the border remained moist enough throughout the period of forcing, and that the shutters remained on till they were required for the protection of bedding stock, which had been cutting Sweetwaters, the first bunch being cut on May 3. *T. W. Bond, Weybridge.*

Unseasonable Christmas Cards.—Mr. W. G. Smith's "Fungus Card" are evidently quite unexceptional for the time of year, as the fungus is such a late autumn product that it shocks no sensibilities to find it allied to Christmas topics. With a large mass of Christmas cards, however, incongruities are abundant. Warm, sunny landscapes, flowers in the richest and most unatural of hues, Roses, Violets, and numberless unrecognisable kinds decorate these cards to such a large extent that they only serve to show how thoroughly wintery the Christmase is. On the other hand, the stereotyped snow and frost, and the intricate and unmeaning designs, and it seems to be very difficult for the ordinary designer to furnish much that is at once new, yet seasonable. *A. D.*

Florists' Flowers.

In noticing the new Azaleas of 1876, on p. 14, Duke of Edinburgh (Parsons), a finely formed bright coloured variety of good substance, was unfortunately overlooked.

Not only were new DAHLIAS somewhat numerously produced during the past summer, but there was a larger average than usual of thoroughly good flowers. The list of new show varieties obtained by the veteran Mr. John Keynes, of Salisbury, may appropriately lead the way, and perhaps the highest place should be given to Mrs. John Downie, pale ground heavily edged with rosy purple, perfect in form and petal; it is also a flower of great constancy, for it could be seen in fine condition at the Duke's exhibition, and it has failed to obtain a First-class Certificate. Next in order of merit should come Perfection of Primroses, beautiful primrose, slightly edged with rose, fine form and substance; John William Lord, shaded orange-buff, paler on the surface, a novel and pleasing flower of high quality; Minnie Bond, pale cream, charmingly edged with purple, a very taking flower, vivid self bright scarlet, fine petal and outline; John Wyatt, crimson-scarlet, extra fine form and petal; John Fraser, chocolate ground, shaded purple and buff, very novel and distinct; and Dauntless, dark orange shaded with buff. Other decidedly good flowers are Mrs. Drummond, pale lilac; Heron, rich yellow, rich shaded with purple; David Saunders, dark mulberry, fine quality; and Benjamin Crossland, rich dark purple, fine form. Mr. Turner's list, as usual, one calculated to maintain the great reputation of Slough as a Dahlia producing centre. Christopher Ridley, bright glowing crimson-scarlet, fully justifies Mr. Turner's remark that it "is the gem of the season for form," and the fact that it was so often seen testifies to its great constancy; Ariste, yellow, shaded with carmine on the edges of the petals, is a very pleasing flower, of fine form and substance, and is well companioned by Burgundy, rich dark purple, shaded with purple-maroon, a remarkably attractive colour in a show flower. Canary, clear pale yellow, fine form and substance; Drake Lewis, rich bright scarlet, very striking in point of colour, fine form; Figaro, yellow, edged and suffused with bright red; and Black Knight, rich dark maroon, a very near approach to a black Dahlia. The following appropriately bring up the rear:—Elsa, French-white, full-sized and good form; Mr. Urquhart, white, heavily tipped with purple; The Rover, pale buff, a fall flower of excellent form; and Vivian Grey, a quite new and very pleasing shade of colour, best described as a straw-coloured brown, fine form. Mr. Geo. Kewling's Earl of Beauchamp is a noble self of great quality, colour plain, heavily shaded with purple, and probably the best dark Dahlia to be distributed. Mr. Rawlings also has Countess Tasker, white ground, heavily tipped with lilac.

Of Mr. Keynes' new fancy flowers the best are Monsieur Chauvrie, lilac ground, striped and spotted with dark crimson, very fine substance, hold and striking; and Rosetta, a charming flower, white ground, beautifully striped with rosy-purple, most acceptable for exhibition purposes. They are well supported by Hercules, yellow ground, striped and speckled with crimson, a fine hold flower; Tippy Bob, yellow ground, striped with rose and purple, novel and distinct; Lucy Fawcett, straw colour, striped and speckled with rich crimson, and Lady Turner's Mar, salmon, tipped with white. Edith Turner and Mrs. Standish fittingly head Mr. Turner's batch: the former is pure pale yellow, delicately tipped with pure white, a charming flower of fine form—the latter pale amber-yellow suffused with carmine and tipped with white, a very pleasing combination; Mrs. Parris is deep yellow, tipped with white; Gameter, pale buff, striped with maroon; Oracle, deep yellow, heavily striped with bright crimson; and Peacock, dark purple-maroon, distinctly tipped with white. Mr. Rawlings' new Fancy Singularity is something of the character of Mr. Turner's Mar, salmon, but quite distinct from it; the ground colour is amber, edged with red and tipped with white; very novel, fine, and attractive.

So many new varieties of GLADIOLUS are being produced both at home and abroad, and so few are seen at the London exhibitions, that it is only of the latter some estimate can be given. Messrs. Kelway & Son were awarded Certificates for Dr. Hogg, white, suffused with rosy lilac, and feathered with crimson; Lady Aberdare, white, streaked with purple; and the Rev. M. J. Berkeley, salmon-red, the outer petals feathered with scarlet, spike very fine. Marquis of Tara's Mar, salmon, is a fine variety, colour rose, flushed with lilac, the lower segments cream, with crimson flame.

In regard to new HOLLYHOCKS, the paucity of them is explained by Mr. W. Chater, who states that the disease has played such havoc during the past three years that he has been prevented publishing his annual autumn catalogue of Hollyhocks, and so severely did the disease decimate the summer cuttings that up to this time he has not been able to send out a single plant so obtained. His new flowers are Crimson Queen, dark shaded crimson, the darkest flower of this colour yet offered; Her Majesty, bright rosy lilac, in the way of Victor, very large flower, extra fine spike; Le Grand, in the way of Mrs. Chater, but of a deeper salmon, very fine; Achievement, rosy red, flashed with buff in the centre, very pretty and distinct; Virgin Queen, pure white, a large hold flower of fine quality; and Vesuvius, glowing reddish crimson, very bright, and of the finest form. Of the foregoing, Le Grand and Virgin Queen have received First-class Certificates.

Messrs. Veitch & Sons have been remarkably successful in the production of fine new forms of HIPPEASTRUMS, and were awarded First-class Certificates for the following high-coloured flowers:—Agatha, vermilion, striped with scarlet, very fine held petals; Circus, rich blood-crimson, extra fine; Clo, bright scarlet, slightly shaded; Junius, deep crimson flushed with vermilion, bright and striking; Phoebe, glowing vermilion-red, very showy. Rev. T. Stanforth, deep red, striped with crimson; Sultan, deep crimson, very fine; and Thalia, rich blood-crimson. All the foregoing have large open flowers, and generally petals of great breadth and substance.

The new HYACINTHS of the past year were not of a character to excite much enthusiasm among the growers of this fine spring flower. Sultan, single bulb, dark violet-purple, good bells; Golden Lion, single yellow, clear primrose-yellow, large bold spike; and The Shah, single blue, purple, with a peculiar metallic lustre, were shown by Messrs. Veitch & Son, and received Certificates. Messrs. Cutsh & Son had the same award for Princess Louise, double red, bright deep salmon-red, close spike, and well-formed bells.

Mr. Bull's new double bedding *Lobelia coralæa* also macrorata is a double form of *L. speciosa* Paxton; but whether it will be any more effective or useful as a bedder than the first of the type remains to be seen. A deep indigo-blue single variety, named St. Mark's Blue, promises to be a great acquisition among the present selection.

Messrs. Harrison & Son's new *Mimulus moschatus* Harrison is an interesting hybrid, and while the scented character of the Musk is retained the flowers are considerably enlarged and nicely spotted.

The newer Zonal PELARGONIUMS have received so much attention of late in the *Gardener's Chronicle* that it is not necessary to particularise the varieties in this collection. The new flowers raised by the late Mr. J. R. Pearson, Mr. J. George, Mr. F. Miles, and Dr. Denny, among others, have proved to be inclusive of some very fine forms. The trials made at the Chiswick gardens of the Royal Horticultural Society year after year, by Mr. A. F. Barron, afford such valuable opportunities for collecting information and instituting comparisons that the results of these trials may be accepted as reliable. As so many new varieties are constantly being produced, it is well that their claims to value should be investigated and adjudicated on by a competent body like the Floral Committee of the Royal Horticultural Society. I, for one, sincerely hope these functions will not be abdicated in favour of the Pelargonium Society.

The show or large flowered PELARGONIUMS have not been so well represented as in former years; perhaps the new flowers were not in character at the time the meetings of the London horticultural societies were held, and the only ones, only Mr. Foster remains, Black, Foster, and Hoyle, only Mr. Foster remains working in the interests of this fine flower. Of the latter's raising the following Pelargoniums received First-class Certificates:—Bridesmaid, rosy purple lower petals, dark top petals, very fine form and substance; Purity, salmon-red lower petals, dark top petals, large white throat, a fine and striking flower; and Toby, orange-salmon, lower petals heavily veined with black, glossy dark top petals, a fine painted flower; Sappho (Turner), cherry-rose, suffused with purple, dark top petals, is a variety of dwarf growth, and extremel free. Of new varieties of Mr. Foster's raising Mr. Turner is distributing *Edith*, *Edith*, *Heperis*, Lord of the Isles, *Marchioness*, *Princess Donna*, *Rapert*, *Sovereign*, and *Viscount*, several of which received First-class Certificates in former years. The Rev. J. Matthews received the same award for *H. S. Ryder* and *Wallace*, two varieties of considerable promise and good character. The Rev. A. Rawson's striped variety, *Queen of Stripes*, is extremely distinct in character, and will make an invaluable decorative plant, the lower petals bright rose, striped with vermilion lines; the rosy upper petals flaked with glossy dark.

In the way of hardy PERENNIALS a most desirable break has been obtained in the cortoides anemone section by Mr. A. Dean, Belfont, as a result of crossing the forms already in cultivation. About a dozen seedlings have been selected, and two of them have received First-class Certificates, viz., *anæona laciniata*, a deep rose-crimson flower, with handsome lacinated segments, and *grandiflora maxima*, a greatly improved form of *grandiflora*. A fine yellow hose-in-hose Polyanthus, named *Golden Queen*, raised by Mr. J. Miller, Upwey, is a decided acquisition, and will be warmly welcomed by lovers of spring blooming hardy flowers.

Ficotee Princess of Wales is a fine sulphur-coloured self flower, raised by Mr. F. Perkins, Leamington, which is likely to prove very useful for forcing; it is charmingly scented, and supplies quite a new shade of colour.

Messrs. Veitch & Sons' hybrid greenhouse Rhododendrons of the javanicum type will be of great value for house decoration; and the worth of the strain is seen in the fact that not less than seven varieties have received First-class Certificates. A hybrid named *Fisher Holmes*, shown by the well-known Sheffield nursery firm, is remarkable for its large white sweetly perfumed flowers.

Finally, the ROSES claim attention. Lots of new Roses were exhibited during the past year, and Messrs. Paul & Son received certificates for Duke of Cornwall, H.P., deep velvety crimson, flashed with lively red; and *Duchesse de Vallambrosa*, H.P., a Continental variety, colour glossy rose, tinged with lilac; Mr. W. Paul for *Magna Charta*, H.P., a beautiful glow of rose, large and full; Mr. Laxton for Mrs. Laxton, H.P., bright rosy purple; Mr. H. Bennett, for *Comtesse de Séciénye*, H.P., a beautiful flower, delicate rose, tinged with lavender in the centre; and for *Madame François Jamin*, Teas, bright orange-buff, charming in the bud; and Mr. Noble for *Queen of Bees*, Bourton Rose, dwarf in growth, very free, colour bright reddish rose.

Such is the legacy left to floriculture by the year 1876. It is however incomplete without some reference to the interesting trial of bedding Pansies and Violas which took place at Chiswick, under the

aspices of the Royal Horticultural Society, during the past summer. The newer forms cultivated were, Dr. Stuart (Stuart), mauve-purple; Ilcinia (Dean), bluish lilac tinged with red; Peach Blossom (Dickson & Co), reddish or puce lilac, paler at the tips; Princess Teck (Dean), pale bluish lilac; Royal Blue (Dean), deep purplish blue; Sovereign (Dickson & Co), bright deep golden-yellow; White Swan (Dean), pure white; and Williams (Stuart), a greatly improved *Viola cornuta* Perfection. R. D.

MR. DEAN throws out a suggestion for *Auricula* growers in the last number of the *Florist* and *Pomologist*. It is that they should admit a class of SELF ALPINE AURICULAS as an equivalent to the self *Auriculas* admitted as a class amongst the show flowers.

"The first priority," he remarks, "in Alpines is the shaded corolla lobes or petals, *i.e.*, the bases of the marginal or ground-colour must be dark, with a paler edge, the dark hue shading off into the pale. Another important property is that, whether the centre or paste be yellow, or sulphuretyellow, or cream, or even white, it must be free from any trace of that meanness which forms the paste in the true self *Auricula*. But," he argues, "as every correct alpine, according to the Northern estimate, must have shaded petals, it is obvious that some of Mr. TURNER'S flowers, and those produced by other artists, though perfect in the centre, are yet inadmissible, because of their unshaded margins. But why not rather be a class for self alpine, as there is for self *Auriculas* in the show division? Take flowers like Black Prince, Colonel Scott, Diamond, Etna, John Leech, King of Crimson, Mercury, Perceval, and Spangle, out of many others which have been raised at rough, and they prefer in the place among shaded flowers, because almost entirely self-coloured on the margin; and yet, though they have large finely-rounded lips, with golden mealless centres, and brilliant marginal colouring, they are not allowed to start in the competitive race. By all means allow the shaded form to be characteristic of the true alpine, but let there be a class for self, so that they also may have a chance to make a reputation on the exhibition-table."

WE are informed that a most important general meeting of the members of the following FLORIST Societies—namely, the National *Auricula* Society, the Royal National Tulip Society, and the National *Carnation* and *Picotee* Society—will be held at the "Old Bull's Head" (off the Market Place), Manchester, on Wednesday next, January 17, at 2 o'clock P.M., for the purpose of arranging the dates of this year's exhibitions, the schedules of prizes, the plan of judging, and other matters and work connected with the management of the national florist societies.

PROPOSED SHOW OF CARNATIONS AND PICOTEES.—The undersigned get to be allowed to state that, in consequence of the uncertainty as to the action of the Royal Horticultural Society, they intend to promote a show of Carnations and Picotees, to be held in London during the season (July), and they will be glad of the co-operation of their brother florists in the work. A meeting to arrange preliminaries and commence a subscription for the needed prize funds will be held at the rooms of the Horticultural Club, 4, the Terrace, Strand, on Wednesday, Jan. 31, at 1 for 2 o'clock, when the attendance of all interested will be greatly esteemed. *Charles Turner, Royal Nursery, Slough; J. Smith Douglas, Loxford Hill Gardens; E. S. Dowell, Larkhall Rise, Clapham, S.W.*

The Villa Garden.

GENERAL OPERATIONS FOR JANUARY.—The kitchen-garden is practically closed to the Villa gardener. The soil is waterlogged, it is so completely saturated with the rain that falls with such persistence—as if Nature were tremendously in arrears in the matter of moisture, and was making rapid haste to pay off the debt—that to move it with advantage is almost impossible. It cannot be dug except under the most favourable circumstances, if they exist, and therefore it is best not to get on it, for who does so will only tread it into a kind of quagmire, and thus increase the difficulties of getting the soil into workable condition when fine weather comes. If the rain be accumulating on the surface in puddles, and especially near the roots of newly-planted trees, some

effort should be made to draw it off by cutting little channels, and causing it to flow towards some lower spot, where it can pass away altogether.

If he can get at pyramidal and espalier fruit trees from the path, or by laying a short plank on the soil about them, and from such reach the trees, let him prune them by cutting away from the main shoots any small thin growths that are not likely to form blossoms, but being careful not to deprive the tree of any quota of its glory of flower in spring by cutting away blooming buds or fruiting spurs—*i.e.*, short spur-like points that will bear blossom and fruit. They can be readily dealt with by the long tips. Pyramid trees, when planted in a small garden, have to be pretty freely pruned to keep them within bounds; and whether severe pruning be or not a practice to be condemned, space is of first importance, and, if the Villa gardener desires to have several kinds of fruits growing on a given space, he must prune to keep his trees well within their proper dimensions. But there is such a thing as judicious pruning, as opposed to erroneous pruning. The summer pruning of these trees, as recommended by Mr. Rivers and others, practically keeps the trees clear of redundant wood, though it will be necessary to cut back the lateral shoots, thrown out in late summer, but the leading shoots—the tall upright growths which are more or less strong, according to the nature of the soil in which the plants are growing—can be cut back at the end of the summer, as recommended by some, or left on till mid-winter. Our practice is to leave them on Apple, Pear, Plum, and Cherry trees till this time of the year, and then shorten them back to six eyes or so, according to the height required by the tree. This is what we do; and these leading shoots, having become quite hard by Christmas, prove useful as tying sticks to support plants, as Carnations, Pinks, &c. This work can then be proceeded with, even if the soil be wet, so that the plants can be reached from the garden-path on a piece of board laid on the soil as above recommended.

Then wall trees may receive some attention. In many Villa Gardens of oblong shape and restricted dimensions, the garden paths are frequently so arranged as that there is a warm border of 2 feet or so in width, in which the wall trees are planted. These trees can be reached from the path, or at least by placing one foot on the border, keeping the pivot foot on the walk. The weather being so mild, advantage may be taken of it to get all the leading shoots of Peaches, Nectarines, Apricots, and Plums into position, fastening them permanently and securely to the walls by shreds, or to the wires by ties, and by croaking about the joints, as these will have to be shortened back later on. The wet season being so hostile to gardening operations generally, it is well to get such work as the training of fruit trees as farward as possible, so that when the long-hoped-for fine weather comes, the attention of the Villa gardener may be devoted to clearing up arrears of ground-work.

Creepers on walls and on trellises, and also those growing over wire archways and against pillars, should be pruned and trained, and made neat and trim. They are all more or less getting quite active; and how can they be less than active while the weather is so mild as this. In the case of the climbing vegetables, it is his true of Roses and Clematises. The latter are moving forward rapidly, and such strong growing sorts as rubella, Jackmann, tumbidgensis, and others are making a remarkably free growth. It is from the extreme points of the ripened wood of the previous summer that the greatest activity is manifested (shoots that were shortened back to 4 or 5 feet at the end of the summer). If it be requisite to cut back the Clematises close to the ground let it be done at once, and if the wood quickly breaks out again at the points at which it was pruned back, then a few sprigs of evergreens can be placed against them when they are in the flowering state. The Clematis is among the hardiest of hardy plants, but sappy young growths are certain to be injured by frost, and they should be protected accordingly. Roses must be left to the tenderness of Mother Nature. In the case of climbing Roses, thin out the wood rather than cut the leading shoots back hard, unless it is necessary to cut back hard to reelete naked spaces near the ground. Place some manure and leaves about the roots of the creepers after the plants are pruned and trained; it will afford protection in frost, and be an invaluable fertilising agency when, in obedience to the moving

influences of a clear, bright, warm spring, all plants and trees will break forth into a renewed life.

Here, then, are a few of many matters that may fittingly occupy the attention of the Villa gardener during the present rainy season. But the winter is none the less a time for active operations in the garden because it is wintry and dull, and the weather is sunless and the days short. There are many things to be done. All necessary outdoor work should be got forward in suitable weather; and house work, such as cleaning, repairing, &c., can be attended to when rain keeps the gardener within-doors. Care is requisite in affording protection against extremes of heat and cold and sudden changes of temperature, to tender plants in the open air—being very careful not to uncover too soon or too early in the day after severe frost, and never failing to bear in mind that dryness is always an invaluable help in these matters. Another matter of importance is to refrain from potting and repotting plants in a state of rest, except it be those that are being aroused from a dormant state, and when a little heat can be given them. Fuchsias, for instance, are commencing to grow fast, but it is far better to let them alone, and keep them pretty dry at the roots till lengthened days bring more sunlight, and the necessity of repotting cannot be avoided. Their duties will suggest others, for the gardeners' occupation is one requiring a continuous, unceasing, and endless round of attentions, and the more faithfully and intelligently these are rendered, the more are they likely to become so many guarantees for success in the future.

Notices of Books.

AMONG the principal contents of the *Gardener* for the present month are the following:—Forthright Needed by the Gardener. Conservatory Decoration. On Dwarfing Chrysanthemums; Horticultural Boilers; Ornamental Trees and Shrubs—Betulas; Lessons in Drawing, &c.; Market-garden Vegetables; Atmospheric Humidity; The Chrysanthemum and its Culture; Mr. Shirley Hibberd on "Natural Fruit Culture"; Wright's Patent Endless Flame-improving Hot-water Boiler; Flowering Pelargoniums in Winter; White Banksian Rose as a Stock for Maréchal Niel; The Famous Vine Spout; Scorched Leaves.

—Among the principal contents of the *Villa Gardener* for the present month are:—Water Boquets; Embellishing Villa Residences; Gardening for Beginners—Drainage; The *Auricula*; Lilies, Anemones, and Ranunculi; Delphiniums in Pots; Epiphyllums—Leaf-flowering Cactuses for Villa Gardens; The Currant, and its Cultivation; Bush Fruits; Notes on a Few Useful Vegetables of Recent Introduction; Winter and Early Spring Cucumbers; The Treatment of Annuals; The Villa Gardener's Plant Houses; Greenhouse Climbers; Artificial Heat for Small Greenhouses or Plant Stoves; Grafting and Storing Dahlia Root.

PUBLICATIONS RECEIVED.—Journal of Botany.—Journal de la Société Centrale d'Horticulture de France.—The Royal School of Mines Magazine, a new publication, conducted by students of the establishment in Jernyn Street, and largely consisting of the adventures of former geological students in India, Brazil, &c.—Le Moniteur Horticole Belge.—Revue Horticole.—The Gardener.—Villa Gardener.—Westnik.—Belgische Horticole.—Illustration Horticole.—American Agriculturist.—Hamburger Garten Zeitung.—American Agriculturist.—The Horticultural Directory for 1877.

Obituary.

MR. PETER STEWART, gardener at The Glen, Peebleshire, for the last five years, died at Langton, near Dalkeith, on December 22, at the early age of thirty-three, leaving a widow and young family to mourn his untimely loss. He was a native of Dalkeith, and served in the Duke of Buccleuch's Gardens there for about twelve years, afterwards going to the Tweed Vineyard, Clovenfords, with Mr. Thomson, and then to The Glen. His career has been a comparatively short one, but few young gardeners have displayed more energy and ability, or been more successful during the few years he has been at The Glen, and it is pleasant for his friends to know that to the last his services have been most highly appreciated by

Mr. and Mrs. Tennant, his kind and generous employers. Under his able management the gardens at The Glen have become one of the most noteworthy places in the South of Scotland, and during the last three or four years he has been a keen and very successful exhibitor at the "International" and other horticultural shows in Scotland, exhibiting Pines and Grapes in particular in such remarkably fine condition as to have won many of the leading 1st prizes with almost all the best growers in the country. Although cut off so early in life, his fame as an energetic and successful gardener will not soon pass away, nor will he be readily forgotten amongst his acquaintances as a most kind and warm-hearted friend, whose loss they deeply regret.

— We regret to record the death on December 9 last of Mr. F. G. WILKINS, of The Poplars, Leyton. The deceased gentleman had been in ill-health since August last, but as his ultimate recovery was looked forward to, his death at the age of thirty-nine years was rather unexpected. Mr. Wilkins was a great lover of plants, and a warm supporter of flower shows, as his contributions to all the leading metropolitan exhibitions for the last ten years bear witness. Thirteen years ago he began to form the collection of plants which ultimately was destined to become so famous. The first things taken in hand were Pelargoniums, and then, shortly afterwards, Heaths, stone and greenhouse plants, and Orchids were added. Of the manner in which one and all of these subjects were cultivated and exhibited by his gardener, Mr. J. Ward, we were not now easy to speak, so well were his specimens known to most of our readers, and so well did they always stand in the prize lists. We regret to say that the entire collection is to be sold, and that Mr. Ward has to seek a new employer, but we trust, from his abilities as a plant grower, he will not be long in finding a suitable position.

The Weather.

STATE OF THE WEATHER AT BLACKHEATH, LONDON. FOR THE WEEK ENDING WEDNESDAY, JAN. 10, 1877.

Table with columns: MONTH AND DATE, BAROMETRICAL TEMPERATURE OF THE AIR, WIND, RAINFALL. Includes data for Jan. 1-10 and a monthly mean.

- Jan. 4.—Dull and wet till 10 A.M. fine afterwards. Cloudless at night. Very mild.
5.—Fine and bright till 3 P.M.; dull with occasional rain after. Mild.
6.—Dull with occasional rain; fine at intervals. Strong gale in evening. Mild.
7.—Rain till 7 A.M., cloudy after. Frequent rain throughout. Heavy gale in early morning. Mild.
8.—Overcast, dull, and wet throughout. Mild.
9.—One fine day, but occasionally dull and rainy, with slight showers of rain. Cloudless at night. Mild.
10.—Overcast, dull, and foggy day. Heavy rain fell after 4 P.M.

The rainfall of this winter is very remarkable as following the very unusual fall in December. Beginning with December 1, 1876, rain has fallen on every day, with the exception of December 9, 10, 13, 14, 17, 22; and on two days in December, viz. the 24th and 25th, the falls were very heavy, amounting to 6.8 inch, and 1.1 inch respectively. Since the beginning of this year rain has fallen every day; on January 9 and 10 the amount was nearly an inch on each day. The amount of rain from January 1 to the present time is 11.5 inches, the average fall for the whole month of January is 2.9 inch. The amount from December 1 to the present time is 5.02 inches, the average fall for December is 2.2 inches, and I believe that so large a fall at this time of the year is unprecedented.

LONDON: Barometer.—During the week ending January 6, 1877, in the suburbs of London, the reading of the barometer at the level of the sea decreased from 29.50 inches at the beginning of the week to 29.10 inches by the morning of January 1, increased to 29.76 inches by the afternoon of the 2d, decreased to 29.17 inches by the afternoon of the 4th, increased to 29.35 inches by the morning of the 6th, and was 29.08 inches at the end of the week. The mean reading for the week at sea level was 29.29 inches, being 0.43 inch below that of the preceding week, and 0.69 inch below the average.

N.B.—The mean daily readings of the barometer have been all below their averages from Nov. 25, 1876, to Jan. 1, 1877, with the exception of January 4, and 4 days in December, when they were a little above their average values. The mean amount below the average for this period of forty-six days was 0.507 inch.

Temperatures.—The highest temperatures of the air observed by day varied from 50° January 1 to 44° on the 10th; the mean for the week was 52½°. The lowest temperatures of the air observed by night ranged from 33½° on January 2 to 49½° on December 31, 1876; the mean value for the week was 42°. The mean daily range of temperature in the week was 18° on the 1st, 16° on the 2d, 16° on the 3d, 16° on the 4th, 16° on the 5th, 16° on the 6th, 16° on the 7th, 16° on the 8th, 16° on the 9th, and 16° on the 10th. The mean daily range of temperature in the week was 16°.

The mean daily range of temperature in the week was 16°. The mean daily range of temperature in the week was 16°. The mean daily range of temperature in the week was 16°. The mean daily range of temperature in the week was 16°.

Wind.—The direction of the wind was S.W., and its strength strong. The weather during the week was generally dull and wet, and exceedingly mild. The wind was S.W. on Monday, January 1, and also on Saturday, the 6th inst.

Rain was again measured on every day in the week; the amount collected was 1.37 inch.

ENGLAND: Temperature.—The highest temperature of the air was 50° at Blackheath, at Bradford 50½° was the highest temperature; the mean value from all stations was 53½°. The lowest temperature of the air was 26½° at Ecles, 24° at Plymouth, 25° at the lowest temperature; the mean value from all stations was 32½°.

The mean of the seven high day temperatures was the highest at Truro and Plymouth, both 53½°, and the lowest was Bradford, 44°; the general mean from all stations was 48½°. The mean of the seven low night temperatures was the lowest at Manchester, 34°, the highest at Brighton, Plymouth, and Portsmouth, all about 44½°; the mean from all stations was 39½°.

The mean daily range of temperature was the least at Brighton, Portsmouth, Leicester, Norwich, Hull, and Bradford, all about 7½°, and the greatest at Manchester, 15½°. The mean daily range of temperature from all stations was 12½°.

The mean temperature of the air for the week from all stations was 44°, being 7° higher than the value for the corresponding week in 1876. The highest was 49° at Plymouth, and the lowest 39½° at Sunderland. The mean of the 7 days of rain in the week were large everywhere, and varied from 4 inches nearly at Truro, 21 inches at Plymouth, Portsmouth, Birmingham, Sheffield, and Bradford, to 1 inch at Cambridge and Norwich; the average fall over the country was 2½ inches, nearly being 2 inches above the value for the corresponding week in 1876.

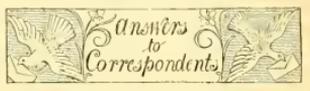

The weather during the week was cloudy and wet and very mild, though fine at intervals. There was still a continuance of floods in the provinces, and in the Thames they have caused great loss of property. The Heavy Gale of Monday, January 1, exceeded any previous for a long time, and was felt all over the country, as well as in Scotland, doing great damage everywhere. Shipwrecks were numerous.

SCOTLAND: Temperature.—The highest temperature of the air ranged from 50° at Leith to 44° at Dundee; the average value from all stations was 47½°. The lowest temperature of the air ranged from 41° at Perth to 25½° at Greenock; the mean value from all stations was 22°. The mean range of temperature from all stations was 25½°.

The mean temperature of the air for the week from all stations was 53½°, being 9½° lower than that of England, and 5½° below the value for the corresponding week in 1876. The highest occurred at Edinburgh, 56°, and the lowest at Perth, 33½°.

Rain.—The amounts of rain measured at the several stations were large, and varied from 31 inches at Edinburgh to 1¼ inch (scarcely) at Aberdeen; the average fall over the country was 2½ inches nearly.

DUBLIN.—The highest temperature of the air was 53½°, the lowest 30½°, the range 23°; the mean for the week was 43°, and the fall of rain was 1.58 inch.

RED SPIDER: LIQUID CARBOLIC SOAP (Pp. 156, p. 25). We have not used the article for the purpose mentioned by Mr. Mark Gardner, but have done so for American Blight on Apple Trees. The article is Liquid Carbolic Soap, and can be obtained of the Cyldestale Patent Company, Three Mill Lane, Bromley-by-Bow, E. P. & M.

ROSE: R. Robinson. The experiment might be worth trying if you first drain the ground. You might also try Osiers.

CHRYSANTHEMUS FRAGRANS: Quenella. This is a sweet scented winter flowering wall plant, common in gardens. You can obtain it from any of the nurseries.

CRANBERRIES: J. V. P. Cranberry Culture, by Joseph Whitwell. Published by Orange Judd & Co., New York.

GRAPE: W. W. We cannot recognise the Grape in the condition in which you sent it. Send again when fresher, and with soil and foliage.

HARDY PLANTS FOR WINDOW CONSERVATORY: J. C. The various forms of Aucuba japonica and himalaica; the variegated varieties of Euonymus japonicus; several of the smaller Retinosporas; Myrtles; Olea fragrans; Osmanthus Aquilifolius; various forms of the Ivy, grown both as creepers and bushes; and the golden forms of Camellias and Thuja.

INSECTS: I. A. Peterborough. The galls on the Swede Turnips are caused by the puncture and deposition of eggs of the wasp, which is the cause of the Curculio pterostigma, the larva of which feeds within the gall, and changes first to a pupa and then to the perfect insect. Marl or chalk has been proposed as the best preventive.

NAMES OF PLANTS: D. M. The fruits of the Gladwyn, or Stinking Iris, I. fetidissima, sometimes called "Wagga-wagga Holly,"—S. P. O. Asplenium bifurcatus (Acrostichum bifurcatum, Sw.); Corallorhiza innata; the mean value from all stations was 32½°. The range of temperature in the week was the largest at Ecles, 25°, and the smallest at Brighton, Plymouth, and Portsmouth, all about 17°; the mean range of temperature from all stations was 26½°.

PLANTING CORNUS ALBA: G. F. M. It depends upon the use it is intended to make of the plantation of Cornus alba, whether it is to be used as a hedge or as a plant. If for cover, 3 feet apart would be a good distance, but if to be grown for its wood to be used in turnery it should be planted from 6 to 10 feet apart. It is propagated from seeds chiefly. Cornus alba produces much better timber wood than C. alba.

TEA PLANTATION: H. M. Write to Mr. Smith, the Royal Botanic Gardens, Kew; or to Dr. Forbes Watson, the Forestry Commission, South Kensington.

TESTING OF NOVELTIES.—A correspondent writes to suggest that the Royal Horticultural Society should undertake this duty, and not only refuse to certificate inferior varieties, but prohibit, by statute for that purpose enacted by Parliament, the sending out of such varieties! Our correspondent overlooks the fact that the best practical work done at Chiswick of late years has been in this direction, though it is pity it could not be greatly extended, and the results made more accessible. As to statutory powers, we are afraid the principles of free trade would prevent any such law being enacted.

••• Correspondents are specially requested to address, post-paid, all communications intended for publication to the "Editors," and not to any member of the staff personally. The Editor would also be glad to be kept by such communications being sent as early in the week as possible. Letters relating to Advertisements, or to the supply of the Paper, should be addressed to the Publisher, and not to the Editors.

FOREIGN SUBSCRIBERS sending Post-office Orders, payable at the post-office, King Street, Covent Garden, London, are requested to be good enough to state in the address the number of the Paper, and the number of the issue, and to send the order to 41, Wellington Street, Covent Garden, at the same time, to inform them of the fact.

DIED, on October 25, at Bankside, Manchester, Charles HUBBARD, 65 years of age, of the firm of Dickson & Robinson, Seed Merchants, Manchester.

—On the 11th, suddenly, at Chappell, Essex, Mr. WILLIAM MORLEY FARROW, aged 38.

Markets.

COVENT GARDEN, January 11.

As American Apples are now nearly off the Market, good table home-grown fruit is realising better prices. Good samples of Grapes are selling well, but inferior ones are very dull. There are very few transactions in Cobs. James Webber, Wholesale Apple Market.

SEEDS.

LONDON: Jan. 10.—A noteworthy feature of the present week is an inquiry from France for Red Clover seed. In addition to the orders sent to this country, the French have during the last few days made extensive purchases by cable on the American markets. From some figures received this day it appears that the shipments from the United States have continued on a most limited scale during the last few days, and that the total exports from New York to London amounted to only 16,186 bags, equal to about 1012 tons. As respects our home-grown Red Clover the supply to hand is good, especially so when we take into consideration the late unfavourable weather. Provincial houses, in despair of buying in their seed stocks on lower terms, are now beginning to operate. The Trade shows some improvement; quotations in France are 3 francs per boll dearer. For Alsike and white Clover the demand is small; currencies unchanged. More attention is now given to spring Tares, without, however, resulting in transactions of any importance. Rape seed sells at stiffening rates in Canary Seed, the movement, for a while, was moderate; terms on which fine samples are now obtainable naturally induce some speculation. *John Shaw & Sons, Seed Merchants, 37, Mark Lane, London, E.C.*

CORN.

At Mark Lane on Monday trade was dull from obvious causes. There was a small supply of English Wheat offering, and not much foreign. Fine dry parcels were firm, while inferior and ill-conditioned produce were cheaper when pressed for sale. The same remarks apply to Barley, the demand being chiefly confined to the better descriptions of grinding. Malt changed hands at about 10s. Canary Seed, Oats, the movement, for a while, was moderate; terms on which fine samples are now obtainable naturally induce some speculation. *John Shaw & Sons, Seed Merchants, 37, Mark Lane, London, E.C.*

CATTLE.

At Copenhagen Fields on Monday the weather operated much against the beast trade; choicest qualities were not much lower, but they were with more difficulty disposed of. There was a large supply of sheep and trade was dull; prices were, however, well maintained. The demand was good for choicest qualities. Calves continued scarce and dear. Quotations: Best, 41s, 6d. to 51s, and 51s, 6d. to 51s, 6d. to 71s, 6d. to 71s, 6d. to 6s., and 6s. 6d. to 7s. 4d., pigs, 41s, 4d. to 51s, 4d.—On Thursday, the few cattle offering being mostly of the rough classes, which were not in request, quotations were lower, and the market of much alteration. Prime calves were scarce and sold at high prices, whilst inferior were very unsaleable.

HAY.

At the Whitechapel market on Tuesday trade was rather quiet. Prices were without change; prime Clover being quoted at 100s. to 144s.; inferior, 85s. to 95s.; prime meadow hay, 95s. to 120s.; inferior, 75s. to 85s., and straw, 60s. to 50s. per load. Thursday's market was scantily furnished with good dry qualities of provender, which were very firm. Quotations: Clover, best, 100s. to 144s.; inferior, 85s. to 95s.; hay, best, 100s. to 135s.; inferior, 65s. to 75s.; add straw, 44s. to 54s. per load.—Cumberland Market quotations: Prime meadow hay, 132s. to 140s.; inferior, 108s. to 120s.; superior Clover, 120s. to 130s.; inferior, 120s. to 132s.; and straw, 58s. to 65s. per load.

POTATOS.

The Borough and Spitalfields reports state that sound Potato continue in request, while a dull trade prevails for others. On previous quotations, the following estimation from a week ago:—Kent Regents, 100s. to 140s. per ton; Essex, doz., 100s. to 120s.; rocks, 60s. to 90s.; Hakes, 150s. to 180s.; and Kidneys, 100s. to 120s.—Last week's imports into London comprised 2972 bags from Hamburg, 3589 bags 131 tons from Brussels, 1349 bags 10 tons from Louvain, 1056 bags 125 packages from Antwerp, 400 barrels 279 bags from Harlingen, and 273 bags from Rotterdam.

COALS.

In the market on Monday the best house coals were unchanged, but seconds advanced 6d. per ton. Wednesday's market was firm, and house coals advanced 6d. per ton on previous quotations. The following are the West Hartley, 16s. 9d.; West Hartley, 16s. 9d.; Walls End—Hetton, 10s.; Hetton Lyons, 16s. 9d.; Lambton, 18s. 6d.; Hartlepool, 18s.; Kilmory, 17s.; East Hartley, pool, 18s. 9d.; Tees, 18s. 9d.; Trindon Grange, 17s. 6d.

To Purchasers of Large Quantities, Market GARDENERS AND OTHERS.

SUTTON AND SONS

Our own stocks of the following Peas at very moderate prices:—

SUTTON'S IMPROVED EARLY CHAMPION, the best and most productive of all cultivations.

Sutton's Kingender Advance
 Daniel O'Rourke Sutton's Racehorse
 Scrimiter Sutton's Choice of England
 Scimitar Yeitch's Perfection,
 and other leading kinds.

SUTTON AND SONS, Seedsmen, Reading.

CHARLES NOBLE, the following, Bagshot, can offer the following:

ROSES, Dwarf, 4s. per dozen, 25s. per 100, 25s. per 100.
 PEACHES and NECTARINES, 25s. per doz., 25s. per 100.
 RHODODENDRONS, Hybrid named, fine, with buds, 6s. forcing or grouping, 1/2s to 1 foot, 21s. per dozen, 25s. per 100.
 do, for immediate effect, 2/2s to 4 feet, and same length, 22s. per dozen, 200s. per 100.
 do, Seeding, 1/2s to 3/2s feet, 14s. per dozen, 200s. per 100.
 do, PONTICUM, 1/2s to 2 feet, bushy, 6s. per dozen, 35s. per 100.
 KALMIA LATIFOLIA, 1 to 1 1/2 foot, buds, for potting, 75s. and 100s. per 100.
 ANDRORHIZA CAROLINA, buds, for potting, 75s. and 100s. per 100.

American Plants Without Fee.

WILLIAM MAULE AND SONS beg to announce that they have received from Continental BIRD DODDENDRONS, with BELGIC and other AZALEAS, at 35s. per dozen, or 410s. per 100.

The above are all grown in stiff loamy soil, on an exposed and elevated situation, and will thrive in almost any soil, free from iron, lime, or chalk.

Having standard RHODODENDRONS, with fine heads, well set with bloom, 2s. 6d. to 2s. 12d. and 4s. 6d. each.

Large bushes of PONTICUM, CATAWBIENSE, and other common varieties, 1/2s. to 1s. 7s. 6d. per 100.

The Nurseries, Bristol.

CHARLES BUTLER, The Nurseries, Wellington, Salop, has to offer the following:—

LARCH, 1 1/2 to 2 feet, 45s. per 100.
 FIR, Spruce, 1 to 2 feet, 45s. per 100.
 Scotch, 1 1/2 to 2 feet, 45s. per 100.
 BEESON, 1 1/2 to 2 feet, 45s. per 100.
 ASH, Mountain, 3 to 6 feet, 45s. per 100.
 SYCAMORE, 3 to 6 feet, 45s. per 100.
 BEECH, 1 1/2 to 2 feet, 45s. per 100.
 PINE, Austrian, 2 to 2 1/2 feet, 45s. per 100; 3 to 4 feet, 45s. per 100.
 Corsican, 12 to 18 inches, 10s. per 100.
 CUPRESSUS LAWSONIANA, 4 to 5 feet, 50s. per 100.
 YEW, 1 1/2 to 2 feet, 45s. per 100.
 YEW, 1 1/2 to 2 feet, well furnished plants, 40s. per 100.
 LAUREL, 1 1/2 to 2 feet, 45s. per 100.
 LARIX, 1 1/2 to 2 feet, good plants, 2 to 2 1/2 feet, 16s. per 100.
 do, bushy plants, 2/2s to 3s. doz., 20s. per 100.

New Cauliflower.

DICKSON, BROWN, and TAIT, SEED MERCHANTS, 43 and 45, Corporation Street, Manchester.

DICKSON, BROWN, and TAIT'S "ECLIPSE" CAULIFLOWERS, which are the best and most productive varieties ever offered, the flutting reports of its usefulness given by many of our customers, &c.

It comes into use about the time of Yeitch's Autumn, but has this advantage over that well-known variety, that it is much more self-protecting, the leaves being white, and stands dry hot weather better than any other Cauliflower.

SHURLEY HIBBERD, Esq., gives the following report in the *Gardener's Magazine*, October 21, 1876:—"Dickson, Brown & Tait's Eclipse Cauliflower.—This is a superb variety for late supply, and is turning in well at the present time. It grows to a large size, and forms a fine close pure heart, being in respect of appearance a first-rate variety for exhibition. It has the merit also of holding its leaves over the crown, so that it is not so much injured either by strong sunshine or sharp frost. The past season's trial Cauliflowers severely, and Eclipse came through the trial so well that cultivators may be properly advised to give this variety a trial. Late Cauliflowers are of immense importance, and those that best bear extremes of weather are the most useful of all."

A CORRESPONDENT in the *Gardener*, October 25, 1876, reports as follows:—"I have tried the 'Eclipse' Cauliflower, and find it to be against all other sorts I find this Cauliflower to be in every way excellent, and a most useful autumn vegetable. The flavor is sweet and delicious, and the plants are perfectly free from any insect pests, and are very large, and very compact. Even averaged heads of it are very large, and its compactness and color are all that can be desired. Its foliage, too, is self-protecting."

Mr. W. UPHORN, The Gardens, Worsley, says:—"Another season's trial has convinced me that Worsley Eclipse Cauliflower is one of the best Cauliflowers I have ever seen. It is so early, and is especially useful in the autumn, coming into use just when the weather is best for planting. It is so early, and is so much appreciated. We are using it, yet, and expect to do so until Christmas."

Our General Descriptive CATALOGUE of Vegetable and Flower Seeds is published, and may be had free on application.

AVENUE TREES.

PLATANUS OCCIDENTALIS (true), 10 to 18 feet high, and girthing 4 to 10 inches at 4 feet from the ground.

LIMES, 12 to 20 feet high, and girthing 6 to 12 inches at 4 feet from the ground.

POPULUS CANADENSIS NOVA, 15 to 16 feet high, and girthing 5 inches at 1 foot from the ground.

ANTHONY WATERER

Has to offer many thousands of the above. They are straight, handsome, and of the best quality. They are also the finest Trees of the kind to be found in any nursery in Europe.

KNEAP HILL NURSERY, WOKING, SURREY.

HARRISON'S NEW DWARF LATE BROCCOLI,

A VALUABLE INTRODUCTION.

We have much pleasure in introducing our NEW DWARF LATE WHITE BROCCOLI, which is undoubtedly the best variety of its class. It is the hardest Late White Broccoli extant. The heads are close, compact, and beautifully white, remaining longer fit for use than any other variety known, coming into use the beginning of May. The footstalk being so remarkably short (the heads almost resting on the ground), affords greater protection from frost, and also enables a much larger quantity to be grown on a given space of ground; thus proving a great acquisition to those possessing small gardens. The quality is excellent, and embraces everything to be desired in a Broccoli, either for a Gentleman's table or for Market purposes. We have received numerous flattering Testimonials from all parts of the kingdom, where it was grown last season, testifying as to its invaluable merits, a few extracts from which we subjoin:—

TESTIMONIALS.

From Mr. T. RABONE, *Gr. to the Earl of Shrewsbury,*
May 10, 1876.

"Broccoli thus far north has not done well this season, but yours has done the best. Nice compact heads, very white and tender, and worthy of a place in every garden, as it takes so little room."

From Mr. G. BRIGHTON, *Gr. to Earl Mount Edgcumbe,*
May 11, 1876.

"I have no hesitation in pronouncing your Dwarf Late Broccoli as being the best late Broccoli I have ever grown. I have had it planted with other late varieties, and it has proved infinitely superior to them all. At the present we have some splendid heads."

From Mr. J. SIMSON, *Gr. to Lord Wharnclyf,*
May 5, 1876.

"We have been cutting your New Broccoli for the last week or ten days, and find it an excellent variety, and one which I shall add to my list in future. There is not a single plant of yours injured; it may, therefore, be put down as the hardest. The heads are good sized, of a clear, creamy white colour, compact, and in flavour excellent."

From Mr. J. RENSHAW, *Gr. to the Marquis of Anglesa,*
May 30, 1876.

"Your New Dwarf Late Broccoli is very good. Dwarf compact habit, with remarkably solid heads of medium size—just the thing for a gentleman's table."

From Mr. GRIMSDALE, *Gr. to the Duke of Somerset,*
May 9, 1876.

"Your New Dwarf Broccoli is the best I ever had. I never saw anything to equal it. It is perfectly hardy, with fine flavour. I cannot speak too highly of it, and am thankful to get it. All that have seen it growing have greatly admired it, with many others."

From Mr. GEO. BRECH, *Gr. to the Marquis of Northampton,*
May 2, 1876.

"I am now cutting your New Broccoli. It is a very late one. I have had it cooked, and pronounce the flavour all that can be desired in a Broccoli. The heads are very firm and of average size, quite hardy, and calculated to stand the winter well. The footstalk of the leaf is very short, it is exceedingly dwarf, and the most compact Broccoli I am acquainted with."

The Stock being limited, we would impress upon our Customers the necessity of sending in their Orders early to ensure a supply for this season.

R. H. HAMPSON, Egerton Mills, Stockport, Manufacturer of **HORTICULTURAL SHADINGS** for protecting Wall Trees from Frost and Insects, &c. 54 and 56 inches wide, any length up to 100 yds. Prices on application.

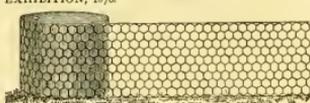

SHAW'S TANNY, ELASTIC NETTING, CANVAS, &c., for Shading, Protecting, and other Horticultural Purposes. For Samples and Prices, apply to **JOHN SHAW AND CO.**, 29, Oxford Street, Manchester.

R. HOLLIDAY, PRACTICAL WIREWORKER, 24, Portobello Terrace, Notting Hill Gate, London, W. begs to call the attention of all Gardeners who are about to have their Garden Walls Wired to his system of Wiring Walls, as being superior to all others for neatness, strength, and durability.

FOR NEATNESS—Because all the Wires are kept perfectly tight, without the use of the Raisidiser.
FOR STRENGTH—Because very strong Wire can be used, therefore not liable to be drawn out of the horizontal line by the branches of trees.
FOR DURABILITY—Because, being able to use the strong Wire, it is not so likely to be eaten through with the galvanism as the thin Wire, as used in the French system.
 The above engraving is an Example of our system of Wiring Garden Walls. We have recently completed the Wiring of the New Garden Walls for the Marquis of Salisbury, Hatfield House. The Walls are 22 feet high and 733 yards long, wired on both sides; making a total length of 1500 yards—our system being chosen in preference to any other.
 Illustrated Catalogues of Garden and Conservatory Wirework, Rabbit-proof Hurdle Fencing, &c., may be had on application as above.

The Sole International Prize Medals for GALVANIZED WIRE NETTING Have been awarded to Messrs. J. E. BROWN AND CO., at the VIENNA EXHIBITION, 1874, and at the PHILADELPHIA CENTENNIAL AND INTERNATIONAL EXHIBITION, 1876.

Oil Paint No Longer Necessary.

HILL and SMITH'S BAC
WARNISH for Preserving Ironwork, Wood, or Stone.
This Varnish is an excellent substitute for oil paint on all outdoor work, while it is fully two-thirds cheaper. It was introduced upwards of thirty years ago by the advertisers, and its genuine good quality, notwithstanding a host of unprincipled imitations, is fully attested by its constantly increasing sale. It may be applied by an ordinary labourer, requires no mixing or thinning, and is used cold. It is used in the grounds at Windsor Castle, Kew Gardens, and at the seats of many hundreds of the Nobility and Gentry, from whom the most flattering testimonials have been received, which HILL & SMITH will forward on application.
Sold in casks of about 30 gallons each, at 12. 6d per gallon, at the Manufactory, or at 8d per gallon carriage paid to any Station in the Kingdom.

UNSOLICITED TESTIMONIAL.
Gleaningly, Llanymyneir, Carmarthen, Nov. 27, 1875.—“Mr. HILL & SMITH encloses cheque for £3 10s., amount due to Messrs. HILL & SMITH, and he considers the Bac Varnish one of the most useful things he ever possessed.”

Apply to HILL and SMITH, Briery Hill Ironworks, near Dudley; or 118, Queen Victoria Street, London, E.C., from whom only it can be obtained.

CAUTION.—It having lately come to the knowledge of HILL & SMITH that spurious imitations of this Varnish are being offered by unprincipled dealers at a slight reduction in price, they would especially draw attention to the fact that every cask of their Varnish is legibly marked with their name and address, without which none is genuine.

LASCELLES' PATENT BENT WOOD CONSERVATORIES and GREENHOUSES.—All Gardeners know that Wood is better than Iron for Glass Growing, and by the above system a handsome curved house can be erected as cheaply as a plain straight one.
The curved house is more durable, stronger, lighter in construction, and no heat glass is required.
W. H. LASCELLES, 121, Bunhill Row, London, E.C., will supply Drawings and Estimates free of charge.

BELGIAN GLASS for GREENHOUSES, &c.,
Can be obtained in all sizes and quantities, of

J. L. HANCOCK, VULCANISERS, INDIA-RUBBER WORKS, 265, GOSWELL ROAD, LONDON, E.C.

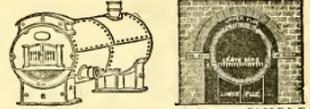

WRIGHT'S PATENT ENDLESS-FLAME IMPACT HOT-WATER BOILER.

Awarded the only English Medal for the best Hot-Water Apparatus at the United States Centennial Exhibition at Philadelphia.
For prices and full particulars please see our pamphlet, entitled “Our Boilers and Heating,” which will be handed post-free on application.

WILLIAM WRIGHT & CO., HOT-WATER ENGINEERS, AIRDRIE, N.B.

STEVENS' TRENTHAM GREENHOUSE BOILER.

After long experience, has proved the most SIMPLE, ECONOMICAL, EFFECTUAL, and LASTING BOILER extant; recently improved. For Illustrations, with full particulars, apply to the Sole Makers.

J. SILVESTER, HOT-WATER ENGINEERS, &c., &c.,
Castle Hill Works, Newcastle, Staffordshire.
Our Boilers are the only ones made with the sanction and under the inspection of the inventor, Mr. STEVENS—all others being base imitations.

AN EXTRAORDINARY BOILER.
During the Great Boiler Contest at Birmingham, in 1872, all Boilers were severely tested to prove their respective merits. One test was, “How long could each Boiler go without Night Attention?” However, one Boiler proved this to a surprising degree, as after being shut up for twelve hours (from 9 P.M. to 9 A.M.), it still retained its heat in 100 feet of 4-inch pipes, and yet had more than a haul of fire drawn from its furnace in the morning—equal, in point of fact, to seventeen hours of continuous firing. What a boon to Gardeners. This was THE CHAMPION, Deard's Patent Close Coil Boiler, for Drawings and Prices of which send two stamps to

Messrs. DEARDS, Boiler Works, Harlow, England who now have their Boilers at work in every country, except three. Amateurs will also find THE WONDER, a smaller kind of Boiler, equally as satisfactory, and certainly “the best thing” out. Awarded five First Prize Silver Medals.

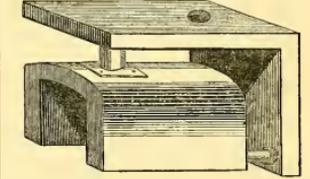

AGRICULTURAL LOCOMOTIVES, STEAM FLOURING MACHINERY, ROAD LOCOMOTIVES, TRAMWAY LOCOMOTIVES, STEAM ROAD ROLLERS.

For Prices, Description, and Reports of Working, apply to the Manufacturers,

AVELING & PORTER, ROCHESTER, KENT; 77, CANNON ST., LONDON, E.C.; and AVENUE MONTAIGNE, PARIS.

AVELING & PORTER'S ENGINES have gained the highest Prizes at every important International Exhibition. The two Medals for Progress and Merit were awarded them at Vienna for their STEAM ROLLERS and ROAD LOCOMOTIVES; and at the last trials of the Royal Agricultural Society of England their AGRICULTURAL LOCOMOTIVES gained the First Prize after exhaustive trials, when one of their 10-horse power Engines, fitted with single slide and ordinary link-motion, indicated 55-horse power, with a consumption of three and one-half pounds of coal per horse-power per hour.

JONES'S PATENT “DOUBLE L SADDLE BOILER.”

These Boilers possess all the advantages of the old Saddle Boiler, with the following improvements—viz, the water-space at back and over top of saddle increases the heating surface on an extent that the PATENT DOUBLE L SADDLE BOILER will do about twice the amount of work with the same quantity of fuel; the cost of setting is also considerably reduced and likewise the cost of running at the same time these Boilers are simple in construction, and being made of wrought iron are not liable to crack. They are made of the following sizes—

Sizes.	To heat of 4-in. Pipe.	Price.
High. Wide. Long.	Feet.	£ s. d.
30 in. 18 in. 18 in.	300	7 0 0

Larger sizes if required.

From MR. CHARLES YOUNG, *Nursery, Baldon Hill, S.W.,*

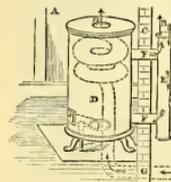

“Having given your Patent ‘Double L’ Boilers a fair trial at my Nurseries, I beg to say that they are most satisfactory. I consider them the best I ever used and without doubt the best economical of all boilers; they will burn the refuse of other tubular boilers I have in work.”

PRICE LISTS OF HOT-WATER PIPES and CONNECTIONS, with Boilers, of all sizes and shapes; or ESTIMATES for HOT-WATER APPARATUS, erected complete, will be sent on application.

J. JONES and SONS, Iron Merchants, 6, Bankside, Southwark, London, S.E.
When ordering Boilers please refer to the above advertisement,

GEORGE'S PATENT CALORIGEN,

FOR
Warming and Ventilating Small
Conservatories.

The only Gas Stove in which the product of combustion is entirely excluded from the Conservatory.
Made in Wrought Iron, £3 3s.
Made in Copper, £5.
Height, 25 inches; diameter, 14 inches.
It will be found very valuable in the Nursery or Sick Room, Damp Buildings, Conservatories, Offices, &c. Exhibited at the Exhibition of 1871 (Department of Scientific Inventions).

Illustrated Prospectuses and Testimonials on application.
J. F. FARWIG and CO., 35, Queen Street, Chelsea, E. C.
This Stove introduces a strong current of warmed (not burnt) fresh air.

LIMEKILN HEATING.

This System of HEATING WINTER GARDENS, CONSERVATORIES, ORANGERIES, FERNERIES, VINERIES, FORCING HOUSES, PINERIES, CUCUMBER, MELON and MUSHROOM HOUSES, STOVES, PITTS, &c.—also for WARMING MANSIONS, PUBLIC BUILDINGS, FACTORIES, &c., is steadily making progress in public estimation, effecting as it does

Great Economy of Fuel and Steadiness of Heating Power,

and rendering the hitherto onerous duties of Stoker comparatively light—no night stoking whatever being necessary.

List of Places where the System is in Operation, with full address in each case, will be sent post-free on application.

Gentlemen and Gardeners wishing to adopt this System will then be enabled to view the Apparatus nearest to their own Establishments, or write to the Gardener, and thus get independent testimony as to the value of this method of Heating.

Estimates will be submitted, on receipt of particulars, free of charge.

FULL PARTICULARS POST-FREE.

W. G. SMITH & CO., HORTICULTURAL ENGINEERS,

Victoria Works,

Bury St. Edmunds.

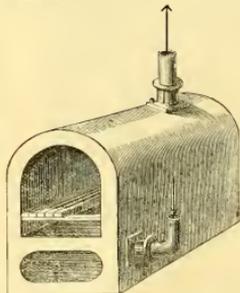

SOLE MANUFACTURERS OF BEARD'S PATENT METALLIC NON-CONDUCTING GLASS-HOUSES.—The Glass is fixed between two layers of prepared foil. The Ventilators are worked by a simple mechanical contrivance, and the whole structure is screwed together so as to render it quite portable. HEATING APPARATUS IN ALL ITS BRANCHES.

ORNAMENTAL CONSERVATORIES and HORTICULTURAL BUILDINGS of EVERY DESCRIPTION.—For lightness, elegance and durability, these Houses cannot be surpassed. The best materials only are used in their construction. Great improvements have recently been made, to obviate the objections to iron houses. Very extensive works on this principle have been satisfactorily executed. An Illustrated Catalogue forwarded post-free on application.

NEW PATENT UNDER-FLUED SADDLE BOILER.

Positively the most Economical Boiler
invented.

NO WASTE HEAT—Furnace and Flues within Boiler.
HEATING SURFACE VERY GREAT—Every part of it exposed to the direct action of the heat.
FLUE LEAVING BOILER NO HOTTER THAN RETURN WATER ENTERING IT—This unattainable with any other Boiler.

ILLUSTRATED PAMPHLET with PRICE LIST on application.

HOT-WATER PIPES, CONNECTIONS and BOILERS —Being manufacturers we can supply these at the lowest possible prices and of guaranteed quality.

HOT-WATER APPARATUS ERECTED COMPLETE in all parts of the country.

E P P S S C O C O A. - GRATEFUL-COMFORTING. - "By a thorough knowledge of the natural laws which govern the operations of digestion and nutrition, and by careful application of the fine properties of well-selected Coons, Mr. Epps has provided our breakfast tables with a delicately-flavoured beverage which may save us many heavy doctors' bills. It is by the judicious use of such articles of diet that a constitution may be gradually built up until strong enough to resist every tendency to disease. Hundreds of subtle maladies are floating around us, ready to attack our unguarded openings, but we may easily ward them off by keeping ourselves well fortified with pure blood and a properly nourished frame." - Civil Service Gazette.

JAMES EPPS AND CO., Homoeopathic Chemists, 48, Treadwell Street, E. C., and 170, Piccadilly, London, S. W.

KINAHAN'S OLD WHISKY. - Kinahan's Old Whisky, through a recommendation of the Medical Profession, the demand for this CELEBRATED OLD LIQUID for purely medicinal purposes is very great, and will increase. - Analyzed by Dr. Hassall. - "I have very carefully and fully analysed samples of this well-known and popular Whisky. The samples were soft and mellow to the taste, aromatic and ethereal to the smell. The Whisky must be pronounced to be pure, well-matured, and of very excellent quality. It is, therefore, well adapted for medicinal purposes in the purity and quality of this Whisky." - Dr. Hassall.

DINNEFORD'S FLUID MAGNESIA. - The best remedy for ACIDITY of the STOMACH, HEARTBURN, HEADACHE, GOUT, and INDIGESTION; and the safest aperient for delicate Constitutions. Ladies, the Elderly, and Infants.

DINNEFORD AND CO. 172, New Bond Street, London, and all Chemists.

HOLLOWAY'S PILLS and OINTMENT. - If the Ointment be rubbed into the throat and chest at the first appearance of hoarseness, and difficulty of breathing, many an attack of diphtheria, bronchitis, and croup would be averted, and many a life saved. - It is also the most efficacious remedy for the most dangerous, frequently fatal, and most distressing of the inflammatory diseases of the throat and air passages are young people, frequently cured, and many others who have behind them often end in pulmonary consumption, that scourge of the Anglo-Saxon race. No matter how severe, but should have these remedies at hand, and in all households Holloway's medicines should be kept as a safeguard and a protection against the countless ills that threaten their door.

THE BEST FLAVOURED WRINKLED PEA.

SUTTON'S DUCHESS of EDINBURGH PEA.

This valuable and distinct Wrinkled Pea was sent out by us, and has been pronounced by several of the most eminent connoisseurs to be the best flavoured variety in cultivation. We cannot recommend it too highly. It is remarkably productive; the pods are long and broad, with a beautiful show of bloom, which renders them exceedingly handsome and suitable for exhibition. They contain from ten to twelve fine peas. The flavour is unequalled, and even when the Peas are quite old they are tender and sweet. It withstands the drought well, and is a continuous bearer, commencing at the end of June, and good Peas can be gathered up to the third week in July. Height 5 feet.

Per Quart, 2s. 6d.

From Mr. WILLIAM PATERSON, *Gardener to Her Majesty the Queen, Balmoral.*

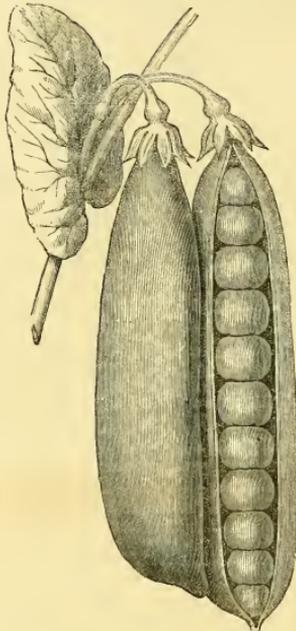

"Your 'Duchess of Edinburgh' is a most splendid Pea, both as a cropper and for cooking."

From Mr. ROBT. COCKS, *Gardener to Lord Auckland.*

"Your 'Duchess of Edinburgh' is without exception the best Pea I have ever seen; it is a wonderful bearer, the pods are all well filled, and the flavour is most delicious. It has been admired by all who have seen it."

From Mr. ALEXANDER LEIGHTON, *Gardener to His Grace the Duke of Somerset, Stover.*

"'Duchess of Edinburgh' is a superior late Pea, both in flavour and bearing."

Sutton's "Duchess of Edinburgh" Pea.

SUTTON'S DUCHESS of EDINBURGH PEA.

From Mr. JOHN H. GOODACKER, *Gardener to the Right Hon. the Earl of Harrington.*

"I sowed the first lot of your 'Duchess of Edinburgh' Pea the end of March; it came fit to use the end of July. It is a good cropper. Pods large, straight, and handsome; eight or nine Peas in each pod, of immense size, and delicious flavour."

From Mr. GEORGE JOHNSTON, *Gardener to the Right Hon. the Earl of Strathmore.*

"'Duchess of Edinburgh' is the best Pea I ever saw, a great improvement on 'British Queen,' or any of its kind. I mean to grow it largely."

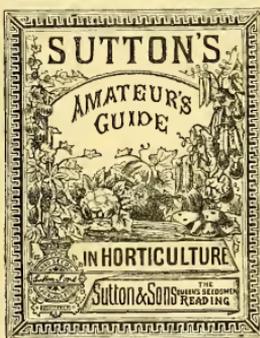

From Mr. GEORGE ABBEY, *Gardener to Sir. C. M. Palmer, Bart.*

"Sutton's 'Duchess of Edinburgh' is a grand Pea, of rather tall habit, having large, well-filled pods, abundantly produced. It is possessed of very excellent qualities, size, productiveness, and exquisite flavour."

From Mr. GEORGE BRIGHTON, *Gardener to the Right Hon. the Earl of Mount-Eden.*

"Your 'Duchess of Edinburgh' Pea is rich in flavour, a great cropper, and should be grown in every garden."

All who have a Garden should read

The most practical work on Vegetable and Flower Gardening yet published, and invaluable alike to the Amateur as well as to the professional Gardener. It is published as a separate work for keeping as a book of reference on all gardening matters, and is beautifully illustrated with nearly 300 coloured and other engravings.

CHARLES TURNER, The Royal Nurseries, Slough.

The Best Medium and Late Kidney Potato in CULTIVATION.
SUTTON'S MAGNUM BONUM.
 A remarkably good cooking Potato.
 An enormous cropper.
 Almost entirely free from disease.
 Indispensable for show purposes.
From Mr. J. P. BELLIS, Gr. to Major Thos. Sutherland, Southampton, 1876.
 "I bought you in March, 1876, a lb. of Magnum Bonum Potatoes, cut them into 20 sets, and planted them 1 foot apart. The hauls covered every foot of ground, and I am convinced that 3 feet square was not more room than was necessary, being a strong growing variety. I lifted the crop in October, and from two to 1 date, it has yielded 270 lbs. of good sound Potatoes."
 50s. per peck, 17s. 6d. per bushel.
SUTTON'S DESCRIPTIVE LIST of choice Seed Potatoes gratis and post free.
SUTTON AND SONS, The Queen's Seedmen, Reading.

WILLIAM CLIBERAN and SON, The Oldfield Nurseries, Atricham.
CHARLES LEE and SON (Successors to Messrs. John & Charles Lee), of the Royal Vineyard Nurseries, Hammersmith, W., beg to announce that in consequence of the Retirement of Mr. John Lee from the business, they have **TAKEN OVER the ENTIRE NURSERY and SEED TRADE**, as successfully carried on for many years by the late Firm, and they trust the same liberal patronage so long given to Messrs. John & Charles Lee will be continued to the New Firm.

Charles Lee & Son pledge themselves to devote all their energy to raising the best Stocks in every department, which the large resources at their command will enable them to supply with considerable advantage to the Public both as regards quantity and price. With a view to a more extensive production of Stone and Greenhouse Plants of the best quality they intend to almost entirely discontinue the raising of Plants in Glass on a new site, a portion of the old Nursery being taken up for building purposes. All orders to be addressed to **CHARLES LEE and SON, Royal Vineyard Nurseries, Hammersmith, W.**, where the general business of the Nursery and Seed Trade will be carried on; or to **Mr. DIGNON, Edinb. Nursery, 11, CANNON, Edinb. Nursery, Mr. WEBB, Arboretum, and Mr. MARSHLEN, Wood Lane, Isleworth.**

NEW SEED CATALOGUE
For SPRING, 1877.

All intending Purchasers of choice Kitchen Garden or Flower Seeds should send for a copy of the **Illustrated Guide for Amateur Gardeners**, which will be found the most complete, useful, and beautiful Seed Catalogue ever published.

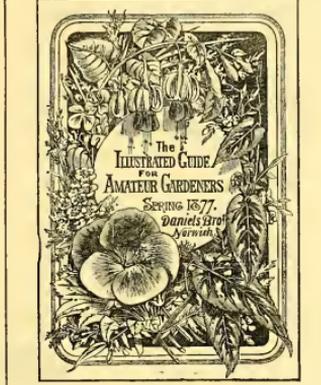

Price 1s., Post-free.

Gratis to Customers or intending Purchasers.

The Illustrated Guide for Amateur Gardeners, Spring, 1877,

Containing 125 pages of beautifully illustrated Letterpress, with two superbly finished Coloured Plates, Original Articles on the Rearing and Cultivation of various Garden Crops and Flowers, and complete Instructions for the successful Management of the Kitchen and Flower Gardens throughout the year, together with a Select List of choice Kitchen Garden and Flower Seeds, Seed Potatoes, &c.

The most practical and comprehensive Guide for the Amateur yet issued, and should be read by every one having a garden.

OPINIONS FROM THE PRESS.

"The inside is quite in character with the beauty of the exterior, and we do not know of a more useful or beautiful garden guide to lie on the drawing-room table."—*Villa Gardener.*
 "This is the most tasteful and best executed thing of the kind that we ever remember having seen, and would be an ornament to any room."—*The Country.*
 "This superbly illuminated and handsomely illustrated annual is something more than a mere catalogue of seeds and plants, inasmuch as it contains the most copious and carefully written instructions for horticulture. The Guide is quite a work of art as well as a compendium of garden work."—*North's News.*
 "The calendar for the kitchen garden will be found most useful. The hints for the raising of crops are at once comprehensive and practical."—*Land and Water.*
 "The most choice and beautiful catalogue we have ever seen."—*Lord's London News.*
 "The flower garden calendar, written especially for this publication, will be especially useful for all lovers of flowers."—*The Record.*
 "Profusely illustrated, and the coloured plates are clearly beyond the average of book illustrations."—*Liverpool Mercury.*

DANIELS BROS.,
 The Royal Norfolk Seed Establishment,
 NORWICH.

ISAAC DANIELS, Nurseryman, Crumkirk.

TO THE TRADE.

HURST & SON,

6, LEADENHALL STREET, LONDON, E.C.,

Beg to announce that they have again secured the ENTIRE STOCK OF SEED OF THE PRIZE QUILLED ASTERS, so successfully exhibited for several years past by Mr. G. WHEELER, Warminster, and now offer the same in Collections of 12, 18, and 24 varieties. For Prices see Addenda to CATALOGUE, which will be forwarded to our Customers. Those whom it may not reach will oblige by applying for a copy.

The Gardener's Chronicle of September 4, 1875, remarking on the Royal Horticultural Society's Exhibition, says:—"Amongst the Asters shown was shown equal to the samples staged by Mr. G. Wheeler, of Warminster, which were grandly finished flowers. He took the First Prize easily in the Classes for 24 French and 24 German or Quilled varieties."

HURST & SON,

6, LEADENHALL STREET, LONDON, E.C.

Complete Liberal Collections of CHOICE VEGETABLE SEEDS,

1875, 21s., 42s., 63s., and 105s. each, carriage paid. As my new and choice seeds are now in large demand, please order early.

CAULIFLOWER, Veitch's Autumn Giant, 12s. 6d. per packet.

LEAF, Alexander Cox, true, 12s. per packet.

ONION, Castello's Prize, true, 12s. per packet.

BROCCOLI, Leanington, finest late, 12s. 6d. per packet.

CABBAGE, Alpha, fine, large, and early, 12s. per packet.

CATALOGUE of New and Choice Seeds on application.

R. M'COMBIE, Grower of Choice Seeds, &c., Christchurch, Hants.

Yewill Nursery.—Late E. Pierce.

B. R. DAVIS, having taken this Nursery, offers the following—Extra fine, well-rooted BEECH, 1 to 4 and 4 to 10 feet; LIME, CHESTNUTS, ELMs, &c., 10 to 12 feet; MAGNOLIA GRANDIFLORA, Exonshire variety; IRON, Minnesota, Tree, and variegated, 3 1/2 to 5 feet; Figs, Spruce, 2 1/2 to 3 1/2 feet. Prices and particulars on application to B. R. DAVIS (late E. Pierce), Yewill Nursery and Seed Warehouse, Yewill.

A. M. C. JONGKINDT CONINCK, Rotterdam Nursery, Defensvaart, near Zwolle, Netherlands, has to offer the following—

YUCCA AUGUSTIFOLIA, large strong, 12s. per doz. per dozen, 12s. 100, per 200. In my nursery this beautiful new Yucca without, without the slightest protection, has the seven winter of 1876.

APPLES, strong 2-yr. Palmettas and Pyramids, 42s. per 100, 10s. 100, per 200.

HARDY AQUATICS at the lowest prices.

MESSRS. JNO. STANDISH AND CO'S CATALOGUE for Autumn, 1876, and Spring, 1877: is now ready, and may be had, post-free, on application.

It contains the following—

Plants of Recent Introduction, Hardy Climbers, Clematis, &c. Stove and Greenhouse Plants, &c. Plants for Winter Forcing, &c. Rhododendrons, Azaleas, &c. Azalea indica and Camellias. Kalmia, &c.

Tree Carnations and Ericas. Roses, Standards and Dwarfs, &c. Ferns and Lycopods. also in pots.

Hardy Trees and Shrubs. Fruit Trees. Transplanted Forest Trees. Grape Vines. Dutch Bulbs, Flower Roots, &c. Royal Nurseries, Ascot, Berks.

Superb Ridge Cucumber.

CUCUMBER, Foster's X.L. Superb Ridge. This variety is a remarkably fine kidney, long, dark green cucumber, and one that can be recommended with the greatest confidence. It is very prolific, and keeps its colour to the last; all who have seen it growing are satisfied that it cannot be surpassed, and those who have tried its flavour are convinced of its excellent quality; length, 2 to 18 inches. Price 6d. and 1s. per packet: prices to the Trade on application.

EDMUND PHILIP DIXON, the Yorkshire Seed Establishment, Hull.

CABBAGE PLANTS, SEEDS, ROOTS, &c. of all kinds, for the Farm or Garden. G. Gee's superior, Bedfordshire-grown Plants and Seeds have attained much celebrity.—Vide Bedford Mercury, July 29, 1876.

The soils of the district offer facilities for growing all the plants for bringing away plants, &c., and under the skill and perseverance of Mr. F. Gee they are turned to good account.—Vide Agricultural Gazette, July 31, 1876. See other opinions of the Press, also a Treatise on the Cabbage. CATALOGUES, howers prices, &c. on application to FREDERICK GEE, Seed and Plant Grower, &c., Biggleswade, Beds.

Public Notice.

For Information upon the Planting, Pruning, and general Managements of Fruit Trees, see

SCOTT'S ORCHARDIST, free, 3s. 6d.

At the Royal Nurseries, Mermaid, Somerset, every description of Nursery Stock is grown ready for sale. Scott's Royal Seed Stocks, Yewill, choice Seeds, Bulbs, and every kind of Garden Requisite may be obtained.

IMPORTANT—Observe the Christian Name,

WM. PAUL & SON, WALTHAM CROSS, N.

SPEED'S VINE AND ROSE MILDEW ANNIHILATOR.

JAMES VEITCH & SONS,

ROYAL EXOTIC NURSERY, KING'S ROAD, CHELSEA, S.W.,

Have much pleasure in offering this excellent preparation for the destruction of Mildew. It proves to be perfectly harmless to the Grape Vine, the Rose, and the Peach when applied to the youngest and most tender foliage, and the fruit itself may be dressed with perfect impunity in any state, even before the thinning period, and there are few things more sensitive than the cuticle of young Grapes in the early stage of their growth.

It kills the Mildew instantaneously, and can be rinsed off within a few minutes of being applied, leaving no smell or sediment, or other traces of its application.

It is not poisonous to Animals, although it is instantly death to all Fungi. Experiments were made on a piece of Mushroom spawn, and one puff of the spray distributor on its little active thread-like mycelium shrivelled it up as if charred. As it kills the fungus in a resting state as well as in an active state, there is every reason to hope that it may be found useful in checking diseases of the Potato, the Hollyhock, &c., that are caused by Fungi.

The following Testimonials have been received:—

From ROBERT HOGG, Esq., LL.D., F.L.S., &c., Pymology Director of the Royal Horticultural Society.

"I have great pleasure in bearing my testimony to the magical effect which your mixture has upon the Mildew of the Vine. When I was at Chatsworth, a few months ago, the application of the mixture, through a spray distributor, on the foliage of the Vine, was so destructive and so instantaneous as to leave no doubt on my mind as to its perfect efficacy in destroying the Mildew. On examining the foliage with a magnifying glass after the application, I could find no trace of the disease."

From Mr. WILLIAM THOMSON, Tweed Vineyard, Cleveford.

"I tested Mr. Speed's remedy for Mildew this last summer, when staying for a few weeks at Chatsworth, and in my life I never saw a more radical remedy for any such pest. One puff of the spray distributor cleared the leaf of a Vine badly affected with Mildew, doing the leaf no harm, and I believe it can be safely applied to the most tender plant, as well as the fruit of the Vine. I believe it will completely supersede the use of sulphur for destroying Mildew on Peaches, Roses, Heath, and all other plants liable to attack by Mildew, and that it will prove a great boon to horticulture."

Sold in Bottles, at 2s., 3s., 6d., 6s., and 10s. each; to make 1 Quart, ½-Gallon, 1 Gallon, or 2 Gallons, ready for use.

Price to the Trade on application to J. VEITCH & SONS, Sole Wholesale Agents.

GARDEN AND FLOWER SEEDS.

THOMAS METHVEN & SONS

REG TO INTIMATE THAT THEIR DESCRIPTIVE PRICED

CATALOGUE OF KITCHEN GARDEN AND FLOWER SEEDS, IMPLEMENTS, &c., for 1877,

Hus to offer many thousands of the above. They may be seen growing at Knapp Hill. They are straight, handsome, and well rooted, and altogether the finest Trees of the kind to be found in any nursery in Europe.

KNAP HILL NURSERY, WOKING, SURREY.

TO THE TRADE.

NEAPOLITAN ONION SEEDS:

**NEW QUEEN,
MARZAJOLA,
GIANT ROCCA,**

**GIANT FLAT RED TRIPOLI,
EARLY WHITE TRIPOLI,
LATE WHITE TRIPOLI.**

G. V. DE LUCA, Nephew of the late Mr. Domenico Piccirillo, begs to inform the Trade that the usual annual consignments of the above selected varieties of these justly celebrated Seeds are now in his possession, and comprise the entire Crop of this Season. Being at present under no engagement with any London Firm, he can deal direct with Buyers for these noted specialities.

The **NEW QUEEN ONION** was first introduced by G. V. DE LUCA, on behalf of the estate of the late Mr. D. Piccirillo (see *Gardeners' Chronicle*, November 21, 1874), since which time he has spared no pains to improve the Stock, with marked success; and he can most confidently recommend these Seeds as being the true varieties.

Prices on application (stating Quantities required) to

SATURDAY, JANUARY 20, 1877.

THE SWILCAR LAWN OAK.

LEAVING the train last autumn at Sudbury, and passing from the fertile valley of the Dove to the high ground of Needwood Forest, we soon observed the towering head of the Swilcar Lawn Oak on some high ground 2 miles distant. This venerable old tree is the patriarch of the forest. Strutt says, in his *Portraits of Forest Trees*, 1824, that this tree measured 19 feet in circumference, at 6 feet from the ground, fifty-four years previously, and that it then measured 21 feet 4 inches at the same height from the ground. It could not now be measured fairly at the same part of the trunk in consequence of an excrescence, which has been many years growing, and has now attained large dimensions; but at 5 feet from the ground it now measures 27 feet. The trunk runs up to a great height, and still carries an imposing top and some widespread lateral limbs.

A lover of trees cannot but feel emotion on finding himself for the first time beneath this towering specimen, the grandest in the forest. Its gigantic size reminds me that some Oaks, as well as some men, be predestined to distinction. You may stumble over a future Lord Chancellor in a village-boy at marbles with his companions, and there are inherent qualities conferring marked individuality on trees as well as men. At first it may seem extravagant to compare even the most wooden men with timber trees, but it will be found on examination that they have much in common. For example, they are both built up by food, and that is a substantial similarity. On the other hand, there are differences. A young fellow hovered about a park-keeper's lodge on an errand connected with a young domestic residing there; the bloodhounds were loosed, and he was brought to bay in a Holly tree. Here is an example of the wear and tear of life in the higher class of animals, and of hereditary tendencies. The Oak is without a nervous system, but it possesses life and hereditary tendencies, and its growth is not purely mechanical. There are both Oaks and men in Needwood Forest possessing unusual vitality, size, and strength of fibre. There was an old deer-stealer, who could throw a fat buck over his shoulders, and who lived to the age of 100. His son mowed the grass around the Swilcar Lawn Oak at eighty-eight, and died at ninety of an epidemic. There is a grandson who closely resembles the portraits of the deer-stealer, and seems likely to live as long. This, then, is a tough and long-lived breed of men. Some Oaks may be constitutionally tough, too, beyond the average. Gardeners have frequent opportunities of observing the individuality of plants under cultivation, whose reproductive organs are subjected to special disturbance owing to the artificial circumstances of their growth. The Oak is not subjected to the same disturbing causes as garden flowers and fruits, yet every acorn buried in the ground has its family disposition planted with it, and it may turn out a Swilcar or prove a pigmy by comparison, even with equal opportunities. There is an old Oak growing near the Swilcar Lawn Oak, on the same yellow clay, and differing from it in size, toughness of fibre, and other respects. Both are English Oaks, and both are of the same variety, with stalked Acorns, their differences being merely individual peculiarities, such as the offspring of two Apple pips might

exhibit if sown side by side. Mr. Jesse mentions the anomaly of an English Oak in Windsor Park producing sweet fruit, closely resembling the acorns of the sweet fruited Oaks of Spain and Arcadia. Climate may have rendered our acorns bitter, but it may be that our Oaks are derived from the same primeval parents as the sweet-fruited species of Spain and Greece, and in Mr. Jesse's specimen we may suspect the reproduction of an ancestral characteristic. The Swilcar Oak has small round acorns, those of its near neighbour are more than an inch long. Not far off, in Bagot's Park, there is a variegated Oak called the White Tree, and producing leaves marked with white and occasionally blotched like those of the Aucuba. The effect of such foliage on a large tree in a park devoted to the growth of the English Oak is very striking. The whiteness of the leaf seems a peculiarity rather than a disease. Perhaps this ornament of the leaf may be another example of a quality latent in the s.c.d.

From our present point of view, it does not appear irrelevant to speak of the inherited tendencies of men in connection with our subject. It has often been remarked that the courage of the Plantagenets has descended to the Queen, and a courtly Dean discovered, by examination of a mural painting in Westminster Abbey, that a singular graciousness of aspect in the handsome face of Richard II. had reappeared in a remarkable degree in one of the Queen's children. Such inherited tendencies certainly exist in royal and other families, and also in Oaks. In many woods *Quercus Robur* exhibits its two varieties with acorns of several shapes and sizes, and with long stalks and short stalks or none, and with leaves whose foot-stalks present similar variations. The fibre, too, differs in texture in the same varieties of the tree. And these differences are inherent, and their causes untraceable; they are individual peculiarities, as size and longevity are to some extent. We are dealing, however, with exceptions, which only prove the rule that "like produces like." Oaks may be improved, no doubt, and rendered more uniform by selection, and therefore Lord Bagot, whose breed of Oaks is a good one, and similar to that of the Swilcar Lawn Oak, is a benefactor in the distribution of good Oak seed from his famous woods amongst his friends.

The Swilcar Lawn Oak was poetically named the "Chief Mourner," on the occasion of the destruction of Needwood Forest. On that occasion it was protected by being enclosed with a pale fence, and a few years since the man who set up the first post of this fence was still living. It is a satire of the small sort on human affairs that this person who assisted in the enclosure of the forest was one of the most notorious deer-stealers who ever walked its paths by moonlight with a flint-and-steel gun. Several acres of Needwood have been preserved around the old tree, and immediately around it is a screen of the greenest Holly, which was encouraged here for the winter feeding of the deer, and kept bushy and vigorous by constant chopping. A poet of Needwood sings pleasantly of a "green robed nymph with a buskined leg and a bosom bare," who was accustomed to linger in this spot. Her name was Zephyr, and she still breathes among the branches of the patriarch, faithful to him as in his youth, and so sweeps the grass-plot on which he stands. So sings the poet in old-fashioned verse, just a little too long, his buskined maiden in the *decoeur* attire still lingering to pause and breathe, and so forth, till you fear a fainting fit or worse. The classical names and notions imported so unnecessarily into English poetry in the last century are not so popular as they were. Fashions alter, ideas only are immortal—*avivata*—Oaks change from day to day, H. Everaugh.

New Garden Plants.

ACER VAN VOLKEMII.*

It is unquestionably a rather unsafe proceeding to establish a new species of Maple with such imperfect material as we have yet been able to obtain. Nevertheless, its discoverer, M. Van Volckem, who knows trees well, assigns its complete description, and we have been quite unable to refer his specimens to any living plant in the nurseries, or in the arboretum at Kew, nor have we been more successful in identifying it with any of the specimens described in books or catalogues of the arboretum at Kew. We are therefore obliged obligingly forwarded for the purpose by M. Boissier. On these grounds, coupled with the fact that whether a seedling variety of the *Sycamore*, *A. Pseudo-Platanus*, or entitled to specific honours, it is simply deserving a separate name for garden purposes, we have named it in honour of its discoverer. It is evidently a handsome quick growing tree, the light green upper surface and silvery under surface of the leaves being very effective. It will be well to give the history of the tree as far as we know it, in M. Van Volckem's words:

"A few years ago I discovered in the Caucasus (and imported) a Maple entirely different from any in the collection of more than eighty species and varieties of hardy Maples in my collection. I think, but am far from sure, I want a plant of it in Kew last year or in 1875 under the name of *Acer* spec. nova (*de Kakhobé* (Georgia, Caucasus)). I found the tree on the southern slope of the Caucasus, in the valley of the Jora, or Yora, a tributary stream of the Kur, about 1000 feet above the level of Lagodechi. It climbs up the slope till the forest ends. It is a very large tree, very distinct from *A. Pseudo-Platanus*, which grows intermixed with it, in its larger and its pale green colour, by which it is recognizable hundreds of yards away. The winged fruits are also smaller. It grows intermixed with *A. Pseudo-Platanus* in the same forests, with no intermediate forms, hence it is not a hybrid form, nor would a mere tree very much distinct in its wild state. It does not grow to so great a height on the slopes of the Caucasus by at least 1000 or 1200 feet, so far as I was able to observe. The form of the tree is more columnar. The light green colour of the leaves makes the difference between the two conspicuous and unmistakable. The colour of the bark and the shape of the buds are different, even in the winter time."

"The country around Lagodechi is very fertile. Near the place is a very large forest of Juglans regia, certainly wild there. Near the river are extensive swamps, and the trees are here growing sometimes as an enormous tree, and sometimes as a large shrubby bush. The two forms are intermixed with each other; so that no condition of soil or exposure can account for their difference. I have seen an intermediate form, and I could not detect any difference between the two forms except as to their habits and size."

So far M. Van Volckem. We find the leaves differ in shape from all the forms of *Acer Pseudo-Platanus* being more oblong, with shallower oblong-lanceolate lobes, and very acute wedge-shaped sinuses between the lobes. The margins are very coarsely toothed, the texture thin, the colour light green above, silvery and quite glabrous beneath. In all the forms of *A. Pseudo-Platanus* the nerves are much more prominent beneath than in this plant, and always more or less hairy towards the base. In this plant the under surface is perfectly glabrous. *Acer* insigne of Boissier, of which, thanks to the courtesy of M. Boissier, we have seen the type specimen, is also quite different. We must await the flowering of M. Van Volckem's tree with much interest, and in the meantime commend it as a distinct and valuable addition to the arboretum. (See fig. 10, p. 73.)

DENDROBIUM (DENDROCYBNE) TIFULIFERUM, n. sp.†

Until now we had only one single truly Pleurothalloid Dendrobium, *Dendrobium longicellum*, Lindl., from Singapore. Our species is much more slender, narrower leaf, on a very long slender, shining stem. The spider-like flower, whose sepals and petals end in long bristles, is purplish in lieu of being straw-coloured, with the points only purplish, as in *D. longicellum*. The lip, too, is much more broken up in long side lacinate. It is nothing to excite the wonder—

* *Acer Van Volckemii*, Mast.—Arbor excolta, foliis (synanthi) palmato 3-5 lobis subnatis argenteo-glaucis omnino glabris nervis parvis prostratis, sinibus inter lobos jorum pte fundis oblongo-lanceolatis ovato-ovatis cuneatis basi acutis; fructibus siccis quadrifloris, lacinis dispositis, albis, multis subvergetibus; foribus adnatis non visis.—Hab. in silvis ad Kakhobé in Georgia Caucasus ubi legit D. Van Volckem. Ab *Acer* spec. insigne differt statu, habitu, nervis, sinibus, glaucis, nervis omnino glabris nec secus nervos albis hirsutis, nervisque minus prominentibus.

† *Dendrobium Tifuliferum*, n. sp.—Aff. *D. longicellum*, Lindl. creule; spathulato tereti caule; basi ovato-oviginato; stemmate tereti, nervibus, sinibus inter lobos jorum pte; vagina lacinate; foribus paucisimis aggregatis virgatis; antibus; meato angustissimo ovato pedicellato quadrifloro; lacinis subvergetibus; lacinis dispositis, albis, multis subvergetibus. Flores purpurei.—Viti, P. Vellozo.

of Orchidists, but botanically speaking it is very curious. It was discovered in the Fiji Islands by their latest explorer, Mr. Peter Veitch, who sent it to Messrs. Veitch, Royal Exotic Nursery, H. G. Rehb. f.

SORBALIA CATLEYANA, n. sp.*

All travellers in tropical America are unanimous in praising the charms of the Sorbalia and the large Eleanthus (Evelynas). I have heard the same glowing description from Humboldt and Pöppig as from Linden, Roez, Warszewicz, Wallis, Wagnier, Bruchmüller, and others. The Sorbalias are accused of being the most beautiful flowers, of the highest value, and best exhibition plants. This may all be true for the species generally grown, but I remember that in 1874, at Florence, an exhibitor, I think Prince Demidoff, sent two or more magnificent masses of Sorbalia macrantha in competition for the highest prize for specimens of flowering Orchids. The buds had not opened at the moment of judgment, owing to the cold and dry air, and the majority of the jurors (who had declared themselves to be able to judge Orchids) did not even take notice of these plants, which were probably untrivial in Europe.

There are, however, Sorbalias with flowers of a firm, fleshy texture, like those of *Cattleya*. I have only met with one species of that kind, the true Sorbalia ligustrum, at the late Mr. Rucker's, at Wandsworth, who was very proud of it. Yet even this is not the firm as one would like it to be, and as they are in strong *Cattleyas* or *Vandas*. The species long known to me, but only now published, has very strong, thick flowers, which ought to last a good while. The stout stem has shining oblong acuminate pointed leaves, and bears several rather slightly flexuose inflorescences with splendid *Cattleya*-like flowers. All my herbarium specimens are described as bearing purplish-brown sepals and petals and a beautifully purplish lip. I have now at hand a sketch of the flowers of the Sorbalia which I have in my plant, which shows the same colours with a white column and three yellow lines over the centre of the lip. No doubt the gold parts are the raised crested keels. The lip appears to form a sharp angle by its lateral lobes overlapping the column, so that it may be compared to a rose. It is represented three times in the same very unusual manner.

It may well be compared to *S. Roezii*, a species I published with some doubt, but which I now regard as a very distinct, beautiful thing, quite worthy to bear Mr. Rucker's name. This species has five to seven fully developed keels over the lip, and no small prickly crests on the sides, such as are to be seen in quantities in *S. Cattleya*. The present plant comes from the revolutionised States of Columbia, and was collected by Mr. Bull, the collector of the living as Mr. Bull, the possessor of the stock, informs me. Now there is an opportunity of trying a species which, in its wild state, bears a profusion of large, nicely coloured, long-lasting flowers. Since its nearest ally has a powerful, agreeable smell of fallflowers, probably the present one will be inodorous.

Good drainage and no end of water during the season of full growth will prove essential conditions to success. H. G. Rehb. f.

THE NEW PLANTS OF 1876.

We resume from p. 43 our brief sketch of the more important of the New Plants which were introduced to the notice of the public during the past year.

ORCHIDS.

Orchids received some good accessions, irrespective of the many interesting forms of *Maxillaria* which have rewarded the search of the collectors, and of which one of the most remarkable is the long-tailed *M. macrantha* described and figured at p. 33, the tails of which are fully 6 inches in length. The species now, however, require to be separated into at least two categories—the ornamental and the curious, and a large proportion of those now known must be relegated to the latter. Amongst *Odontoglossum*, *O. cirrosum*, with its handsome white purple-spotted flowers; *O. Chestertonii*, with its cream-coloured flowers, marked on the sepals and lip with rich brown; and the beautiful yellow-lipped *O. Londeborghianum*, are all charming additions to this deservedly popular genus. *Bollea caesiata*, from tropical South America, with its blue, white-tipped,

* *Sorbalia (Brazilia) Cattleyana*, n. sp.—Pilis oblongo-ligulatis; acuminiatis; rhoribus paucisimis lateralibus; bracteis triangulis parvis; foribus coracatis; sepalis lanceolato-oblongis; petalis subobovatis; ovibus; labellio trilobis, lobis lateralibus oblongatis, medio supra columnam sub angulo erecto; lacinis dispositis, albis, multis subvergetibus; lacinis dispositis, albis, multis subvergetibus. Carinis per medium una supra teres obscuris, antice cristatis, cristulis parvis lateralibus minutis; papulis muricatis circumscriptis; columnis fasciatis; lobis; lobis.—Verae Giesman, H. G. Rehb. f.

yellow-lipped flowers, is said to be very distinct and of considerable beauty; while *Pescatorea Roezlii*, with its large white flowers tipped with blue, affords another distinct and charming type of a meritorious character. Some fine varieties of established species have been added to our lists, as the purple-tipped *Dendrobium Devonianum* var. *Elliottianum*; the thick-stemmed *D. Wardianum* var. *Louii*; a fine form of

having the fronds glaucous beneath; the latter a very distinct bipinnate thick-leaved Fern, with Blechnoid fructification. From New Caledonia M. Linden has introduced *Lomaria gigantea* and *L. neo-caledonica* (two large-growing arborescent forms of the *L. gibba* type), together with *Dicksonia Delplanchei*, *Cyathea nigra*, and *Marattia attenuata*. Mr. B. S. Williams has imported from New Guinea a distinct *Adiantum*

Williams, who both hold stocks of it. An Australasian plant, introduced under the name of *Davallia Youngii*, proves to be a larger growing variety of a well-known species, the *Dennstaedtia davallioides*, *alias* *Dicksonia davallioides*; it is a noble-looking plant for bold rock work in greenhouses, and extremely elegant, though of large growth. As a garden sport, we have had introduced a *Gymnogramma Allstoni*, one of

FIG. 10.—ACER VAN VOLXEMII. (SEE P. 72.)

D. diflorum which M. Linden calls *Gauberti*; and *Phalaenopsis intermedia Brymeriana*. Not the least interesting of these plants are the fine novelties in the shape of hybrids amongst the *Cypripediums* and *Cattleyas*, for which we are chiefly indebted to the Messrs. Veitch & Sons.

FERNS.

Amongst Ferns we have to add the Sandwich Island *Cibotium pruinatum* and *Sadleria cyatheoides*, the former a plant closely allied to *C. Menziesii*, but

of the ethiopicum type, which has been named *A. neoguineense* (see p. 12), and is remarkable for its broadly triangular outline and its roundly-lobed pinnales. The name of *Adiantum palmatum* has also been recently given to the Andean plant associated by some botanists with *A. speciosum*, but which proves to be quite distinct when the two are seen growing together, and also different entirely from the *A. digitatum* of Presl, under which name they had been thrown together. The *A. palmatum* is in the collections of Messrs. Veitch & Sons and Mr. B. S.

the golden-backed series, the peculiarity of which is that the tips of the pinnales are uniformly recurved, so that the gold colour shows on the upper surface. A still more curious sport is the *Pteris serrulata* Leyi, in which the ends of all the segments are converted into elongate leafless tails.

GREENHOUSE PLANTS.

Of greenhouse plants we have usually but a limited number to record, and though the term is expansive enough, our list of subjects still remains small. The

hard-wooded section yields us a beautiful highly-colored species in the Australian Boronia claret brought out by Messrs. Veitch, which has narrow pinnate leaves, and abundant blossoms of a deep purplish rose; it is doubtless a little inclined to grow tall, but our cultivators will know how to grapple with this peculiarity. Then *Grevillea Preissii*, shown by Messrs. Rollison & Sons, another Australian shrub, if not exactly showy, is exceedingly neat and pretty, being of dense bushy habit, with narrowly cut bipinnate leaves, and very abundant racemes of rosy-scarlet flowers. Mr. Bull's double-flowered *Epacris onoseoides* (fore-plant), with its little button-like white flowers growing up the elongated branches, will probably become one of the most useful amongst greenhouse decorative evergreen shrubs of slender habit. *Araucaria Goldiana*, introduced by Mr. B. S. Williams, is likely to prove a fine conservatory plant, and may be described as intermediate between *A. elegans* and *A. Kulei*, the branches being pendulous. *Bananea Canderi* (see p. 793, vol. v.), from Columbia, is a very handsome member of the tuberous-rooted section, from Mr. Bull's collection; its pendulous umbels of numerous bell-shaped rose-colored flowers are very beautiful. We gain a dwarf but exceedingly striking greenhouse perennial in the Peruvian *Begonia Davisii*, which has short-stalked radical leaves of the usual oblique type, and small cymes of brilliant crimson-scarlet flowers on slender scapes taller than the leaves; while in the hybrids of this tuberous-rooted race we have some of the most attractive of summer flowering plants for the greenhouse. Finally, we regain a greenhouse beauty of considerable beauty in the Brazilian *Crinum ornatum rubro-venatum*, the flowers of which are white with a crimson band across each of their six segments.

HARDY PERENNIALS.

Amongst hardy perennials, including with them the hardy bulbous plants, by far the finest object we have seen is the *Lilium auratum cruentum*, a splendid form of that most splendid of all Lilies, in which the golden band is obliterated by a band of crimson extending from the apex to the very base of each segment, and increasing in intensity from the point downwards, the base being a blackish blood-crimson, which suggested to us the name. *Lilium nellhergense* (see p. 332, vol. iv.) is another fine Lily of the longitundum type, and a decided acquisition, which blooms later than most other sorts. The Californian *Fritillaria recurva* is a beautiful dwarfish-growing hardy bulb, with sessile linear leaves, and bell-shaped scarlet flowers, having reflexed segments spotted inside with scarlet, "the red being as bright as that of a Lily." *Fritillaria aurea* from the Cilician Taurus, is another dwarf species, with yellow flowers minutely tessellated with black spots, and is very distinct from anything previously known in gardens. In *Mecopis Wallichii* we have a wonderfully handsome

Poppay, with pure sky-blue flowers—a plant known to botanists, but not previously generally accessible. Mr. Bull has now offered it, however, as *macrantha*, a herbaceous perennial of the labiate order, from California, introduced by Messrs. Veitch, is a charming acquisition, having low tufted stems, with small ovate leaves, and terminating in capitate heads of scarlet tubular flowers—a "very beautiful, and highly aromatic" plant, according to Dr. Hooker, who states that it flowers in October. Another "strikingly beautiful" Californian plant, introduced by Mr. W. Thompson, is the *Mirabilis multiflora*, which has large panicles of flowers, with broad, flat, bright rose-purple corollas, having a darker ring round the throat. The Hawaiian *Amancestrum armentosa* will be a welcome addition to hardy spring flowers, and forms a pretty object with its rosulate tufts of obovate-linear leaves, its red-stalked runners, by which it is freely propagated, and its heads of pale bright rose-colored flowers, which are decorated by a yellow throat surrounded by a deep rose ring. To these as a possibly hardy, possibly half-hardy plant, may be added the beautiful striped-leaved grass which has appeared at some of our shows under the name of *Eulalia japonica variegata*—a plant large enough to be effective, and yet without a touch of coarseness.

ANNALS.

At present there seems to be a dearth of newly-introduced annuals, and we have nothing of very special importance to enter to the credit of the past year. The Chinese *Moriandia sonchifolia*, from its

early flowering habit (March), and its large Stock-like single deep purple cruciferous flowers, something like those of a single Rocket, may be useful for spring gardening; it grows from 1 to 2 feet high, and flowers in racemes. *Helianthus cucumerifolius*, from Texas, is a novelty of some merit; it is of large growth, from 3 to 5 feet high, but freely branched, and altogether devoid of coarseness; the flower-heads are yellow, 3 to 4 inches in diameter, with a black disc. The new seminal form of *Godekia* named *Lily Albomaris* is so exceptionally fine, both in its magenta colour and its stocky floriferous habit, that we cannot refrain from mentioning it in this place; while *Zinnia Darwinii*, a hybrid between *elegans* and *Haageana*, is likely to be a useful decorative plant.

HARDY TREES.

One of the most striking of hardy trees which has lately been made known in Europe is the sapindaceous *Xanthoxerus sibirica*, a faithful representation of which will be found at p. 564 of our vol. v., new series. *Populus canadensis* var. *Van Geertii*, as a robust-growing deciduous tree, and *Weigela amabilis* Loomysianii, as a deciduous shrub, are both remarkable for the pure and bright golden hue of their summer foliage, and will consequently be effective objects in plantations and shrubberies. The *Hydrangea Hortensia* Thomas Hogg (alba), if accurately described, must be a fine hardy shrub, and at the same time invaluable for decorative purposes as a pot plant, since a white *Hydrangea* would afford a fine contrast with the more usual colours, pink and blue. But, far beyond all these points of merit, is Mr. Waterer's *Abies Menziesii* Parryana, mentioned at p. 45, and referred to under this name by Mr. André in the last part of *L'Illustration Horticole*, a Colorado Spruce Fir, of highly character, with the foliage as blue as a thick glaucous covering can make it—as blue as that of the glaucous *Echeveria*, and even of a brighter blue than *Picea magnifica*, and a habit as symmetrical as that of *Picea Pissapo*. T. Moore.

RECENT CONTRIBUTIONS TO THE FLORA OF ICELAND.

By W. LAUDER LINDSAY, M.D., F.R.S.E., F.L.S.

SINCE I visited Iceland (in 1860) and published a *Flora of Iceland** (in 1861), several small collections of flowering plants and Ferns—made mostly in the south-west of that island—have been sent to me from time to time. These collections came directly from Reykjavik, by my worthy friend and correspondent Jon Amason, inspector of the College there.† He called my kind interest to induce attention of the students of the said College to make, during their summer holidays, and in their own districts, botanical collections, in order to their transmission through him to me. The collections that reached me prior to 1870 were placed in the hands of Professor Charles C. Babington, of Cambridge. The names of the plants of which they were made up were no doubt included by him in his *Revision of the Flora of Iceland*‡ (published in 1871), but, other collections have been made and sent since 1870, have been deposited in the national Herbarium at Kew, and have recently been examined by Professor Oliver and J. Baker, F.L.S.

To these gentlemen I am indebted for a list of the aforesaid most recent plant collections made in Iceland by the Icelanders themselves. It appears to me desirable to publish the short list, in order to the encouragement of botanical students in Iceland itself. The fact that their gatherings are duly appreciated and utilised in this country will no doubt stimulate to further gatherings of a more valuable kind. For one of the purposes of this preface is to show (1) that certain Icelandic plants are common and others rare; (2) that certain districts have been sufficiently explored botanically, while others have not; (3) that certain classes of plants have hitherto received all the attention of botanical collectors and botanists, while

* In the *Edinburgh New Philosophical Journal* for July, 1861.

† This gentleman is one of the most distinguished living Icelandic literateurs—an indefatigable collector and transporter of the grand old seeds of his native land, but best known on the Continent of Europe and in England by his two large volumes of *Icelandic Plants*, published in 1859 and 1864. Selections from these tales or traditions were given in an English dress, in two volumes, in 1861 and 1866, under the title of *Icelandic Legends*, collected by Jon Amason, and translated by George E. J. Orwell and Ewiger Magnusson.

‡ In the *Journal of the Linnean Society* (Botany), vol. xi., 1871, pp. 312-316.

others have received little or none; and (4) that, in short, much remains to be done in the collection and study of certain classes of plants from all parts of Iceland, or from particular districts thereof, otherwise that there remains much to deserve and repay special collection and examination.

In the first place, then, the following catalogue may be held to represent simply the commoner flowering plants, Ferns and Horsetails, of the south-western districts of Iceland, within a radius of perhaps fifty miles of Reykjavik, the capital. The list contains no plant not mentioned by Professor Babington in his *Revision*, with three exceptions, that are not given by him as separate species, viz., *Potentilla aurea*, *Plantago maritima*, and *Equisetum pratense*. There are several instances, however, in which, though the plant would appear to be more or less common, Professor Babington has seen it from only one locality, or has found it recorded as having been by others only so found. Moreover, the list now given enumerates only 105 species, while my own *Flora* in 1861 gave 455 of Phænogams, Ferns, Lycopods, and Horsetails; and Professor Babington, in 1871, 467,* so that the present catalogue of recent collections does not represent one fourth of the higher flora of Iceland.

In the second place, while the south-western districts have been pretty well examined as to flowering plants, Ferns, Lycopods, and Horsetails, there are certain other parts of the island of whose flora, whether Phænogamic or Cryptogamic, we know comparatively little. These botanically unexplored districts include especially:—1, the little visited portions of the north-western, northern, eastern, and southern districts; 2, the volcanic deserts of the interior; 3, the southern regions as a whole, and particularly the yet almost unexplored great Jokul deserts.

At present the flora of Iceland may be said to be very much a flora of certain inhabited portions of the coast and its comparatively fertile plains and valleys; of the desert and alpine flora we have yet to learn a great deal.

In the third place, the attention of travellers or collectors, botanical or non-botanical, has been hitherto almost exclusively confined to Phænogams; to these and their allies Professor Babington's *Revision* confines itself; and though in my own *Flora* I have given a list of all the Cryptogams known to occur in Iceland up to 1860, there is avowedly much yet to be accomplished, especially as regards the more minute, mostly microscopic lichens and fungi, as well as algae, particularly freshwater ones, such as the Diatomaceae and Desmidiaceae. In my *Flora* the desmids are represented by a single species, the diatoms not at all, the fungi by thirteen—numbers that serve to show how absurdly meagre is, or at least was in 1860,† our knowledge of the microscopic flora of Iceland.

In the last place, the value of all such collections, made by persons not themselves practised botanists, is seriously detracted from by the failure of the collector to label each plant or group of plants with the name of the exact locality in which it or they were found. Thus, in the *Revision* of 1871, I am enabled to give of my Icelandic plant collection 173 names, because most of the plants were gathered in three localities very different in their character, viz.,—1, very high on Mount Esja; 2, at Thingvall; and 3, in the neighbourhood of Reykjavik. Unfortunately, however, we are left to guess which was found in each locality, and in the case of duplicates the same species may have occurred, so far as we know, in all three localities. In another letter, of date November, 1872, he referred to a collection made "in the small islands of the Breidifjord (broad fiord or bay) in the west." In March, 1871, he mentioned some plants "almost all gathered in the South of Iceland (the

* Dr. Trimen, of the British Museum, informs me (in *lett.*, October, 1876) that the latest best *Flora* of Iceland is Grönholm's, in the *Botanisk Tidsskrift*, of Copenhagen, for 1875, p. 220, 1875-5, noticed in the *Journal of Botany* for 1875, p. 220, 1875-5. He eliminates several of Babington's species, but adds about ten others to the Phænogamic flora as given by Babington; so that the total remains very much the same as given to me in 1861 and Babington in 1871, so far as concerns the mere number.

† I have not myself seen Grönholm's *Flora* of 1875, and am not sure whether it is or others subsequent to 1860 give lists of the lower Cryptogams.

‡ Subsequent to the date of my *Flora* I published certain papers,—"Contributions to the Arctic Flora of Northern Europe," including Iceland—*Journal of the Linnean Society*, vol. ix. (Botany), 1867; 2, "The Arctic Cladonia," including those of Iceland—*Journal of the Linnean Society*, vol. ix. (Botany), 1868; 3, "The Protogaea of Iceland," being remarks on the Icelandic Desmidiaceae, Desmidiaceae, and Algae—*Quarterly Journal of Microscopical Science* for 1867.

Kängvalldisjer), though a very few were from the east (Mílafjallisjer). I had asked the gatherers to take only the most rare plants, but I thought, when I saw them, that some of them were rather common." In August, 1871, he sent a few plants, "all of which were gathered in the district of Borgarfjord, north of Reykjavík; only one, a creeping Ranunculus, was from a hot spring here, not far from Reykjavík." In November of the same year he wrote:—"I fear it will be in vain to promise you some plants from the north, west, and east, and especially from the mountain districts, as few people go there who interest themselves in botany. . . . I think there are very few new plants in this collection, though I know there is one very rare in Iceland, which we call Eyjarós. I have been told that it is found only in two, or, at most, three places, in my country." In our college we have two residents who specially interest themselves in botany. . . . But both of them live here in the south of Iceland, and are not likely to go either to the west, north, or east of their country, and I do not expect them, therefore, to be able to go except those who drive a train of ponies loaded with dried fish, and who will not stop for the gathering of plants."

These explanations were offered in reply to certain suggestions of mine as to the localities most deserving of botanical exploration, and most likely to yield the greatest botanical novelties.

The apparent hopelessness of getting the Icelanders themselves to make a thorough botanical exploration of their own island, and the inaccessibility of its desert, snow, and alpine regions from the difficulties of overland travel, led me to repeat more emphatically a recommendation I made in 1856, that Iceland should be visited by a yacht party of British naturalists for exploratory purposes. The whole summer months might be spent in visiting at least the less known parts of the coasts or fjords that give readiest access to the deserts or alps of the interior. The yacht would always answer as a floating hotel, on the one hand, and as headquarters for natural history apparatus and collections on the other. It could be made to anchor for any length of time at a given spot, and it could be ordered to any point to wait the arrival of a party travelling overland.

KALOSANTHES.

THESE are showy, sweet-scented, succulent-leaved greenhouse plants, which bloom from June to August, just at a time when hard-wooded greenhouse plants, the majority of Pelargoniums, Azaleas, &c., are over—a time when a great and sudden drench of flowering plants for the conservatory is frequently, I had to say, always, felt; they help to fill a gap without their help and sometimes be a gap indeed. In the first place, the soil I have grown them best in has been loam, peat, and cowdung, rotted to mould in equal parts; any well rotted dung will do, but I prefer cowdung if it is to be had. The cuttings should be put singly into 60-pots, and either the few shoots which do not show flower in the spring may be used, or the stems which have flowered may be cut into lengths of about 4 inches, stripped of leaves half their length, and each inserted to the remaining leaves in the compost nard, with a little sharp sand added. They do perfectly well out-of-doors if the winter is not wet; as good a place as any, and in a frame where they may be kept a little for the first week after being put in and kept from heavy rains. The tops of the non-blooming shoots which are used for cuttings should be broken out, in order that the cuttings may break three or four shoots. If the soil is in a moderately moist state when the cuttings are put in they will not need water for a few days, but after they receive water they should be kept fairly moist. They will soon root and throw out three or four shoots each, and on the approach of winter should be put on a shelf where they will just escape frost and be in the light. As early in the spring as the points of the shoots can be fairly got up, so as to

leave the shoots themselves 3 inches long, pinch them out; and as soon as the plants can be trusted without danger in a cold pit shift them into 32-size pots: the soil for this shift will not need sand; they will then start away with from six to ten good shoots. When all danger of morning frosts is past, let them have all the sun and air out-of-doors. See that they stand on a good bottom impervious to worms, for if worms get possession of the pot, they will as usual to expect that it is not so easy to fill up the channels they leave; and it is sometimes troublesome to get a plant which requires keeping dry at any particular season, when worms have invaded the soil, wet again, without soaking the ball in a tub or trough. As the shoots elongate it will be advisable to put four sticks round the edge of the pot, and pass one or two strong strips of matting round to keep the wind from breaking them.

Should a few specimen plants be needed it will be a good plan to select some of the thinnest plants of the batch and cut them down in good time for them to break nicely before winter. The tops taking off them may be used as cuttings, and three or four of them can be put in a pot 6 inches, leaving the top of the shoot intact, and put in a group in the middle of a 48-size pot and looped up to a stick placed in the middle of the group, these will, if put in a semi-shady place, root and make useful stuff for vases and other uses where those in 32's would be too large. They may all be wintered in a similar situation to that recommended for the previous winter, giving them only sufficient water to keep them from shrivelling. As the spring advances nearly every shoot on the plants in the 32-sized pots will set for bloom, when more water and room will be necessary for them. Those which were cut down, should be potted on as soon as they have space can be found for them. If these are required to bloom the next season they must not be stopped after March. Having potted them and got them established, they must have all the sun and air an open situation will afford, and be carefully attended to in the matter of water; they must also be properly secured from breakage by the wind. If larger specimens are required they had better not be allowed to flower, but the tops of the shoots may be put in, in a group as before directed, or potted singly, if small plants with a single truss of flowers are likely to be useful. Those that have been cut down to grow larger will fill 16-inch pots in the spring, and will flower plants as they are manageable, particularly those of *K. coccinea*, which is a large grower. One thing I have tried to inculcate, but which for fear of misapprehension I will put into plain words, is, that to insure a good and regular head of bloom one clear season's growth without stopping is imperative.

There are several kinds of these plants. One small-growing recumbent species has white flowers—I regret I never have been able to get a plant of it when I have been growing them—it is named *K. albiflora*, I believe. The best kinds have grown here, *K. coccinea*, crimson scarlet, with white eye, the largest grower; Madame Celeste Winaas, rose-dink; Madame Traphemus, rosy scarlet; & Phoenix, deep scarlet.

The only insect which troubles the Kalosantes is the aphid or greenfly, which is easily removed by fumigation or syringing. They sometimes are affected with a kind of mildew which takes the form of black spots, generally in the points; it is caused by dampness with cold: a little sulphur dusted on it checks it, but a dryer and warmer atmosphere is the only cure, as far as I know. John Betler.

THE PHYLLOXERA AND INSECTICIDES.

SOME time ago we published in our columns a short account of the results of the investigations of various scientific men in France into the nature of the Phylloxera—a terrible scourge which is committing such wide-spread ravages among the French vineyards. Latterly we have received some reports communicated to the French Academy of Sciences dealing with the attempts which have been made during the last three or four years to arrest the mischief done by the insect, and ultimately to destroy it altogether, by means of some potent drug. It is obvious that the remedy to be employed must possess two qualities at starting, viz., it must destroy the insect, and it must not damage to any great extent the Vine. But, further, it is not sufficient that when put in close contact with the roots of a plant—as in a pot—it should

prove fatal to the insect, it is necessary, if the remedy is to be of real practical value, that it should reach and destroy the Phylloxera on all the parts attacked by it in Vines which are planted out in the open ground. This is a real difficulty to overcome, as the remedy, be it in the form of solution or of vapour, cannot easily permeate the soil, sometimes clayey, sometimes sandy, on which the Vine is growing, so as to reach and act upon the smaller roots and branches whose nutrition the Phylloxera draws into itself.

M. Moullefiere, a Professor at the School of Agriculture at Grignon, was the gentleman delegated by the Academy of Sciences to make the necessary experiments for the purpose of determining what agent was the most practically applicable to the destruction of the Phylloxera, and the account of the numerous substances employed by him with varying results fills no less than 200 pages of a memoir presented to the Academy of Sciences. It is not our intention here to do more than give a brief résumé of the results at which he arrived.

He divides the substances used by him into seven groups, the first of which was composed of manures of various kinds, such as guano, superphosphates, farm-muck, &c.; the second of neutral substances, as water, soot, and sand; the third of alkalis, as ammonia and soda; the fourth of saline products, amongst which were the sulphates of iron, copper, zinc, potassium, and ammonia, alum, and sea-salt; the fifth of vegetable essences and products, as decoctions of hellebore, datura, absinth, valerian, and tobacco; the sixth of empyreumatic products; and the seventh of sulphur compounds. It was only with some of the substances contained in this last group that really satisfactory results were obtained, and it is to M. Dumas, the permanent secretary of the French Academy of Sciences, that the credit is due for suggesting the employment of the alkaline sulpho-carbonates of potassium and sodium and those of barium and calcium. All the other classes of remedies mentioned above were either without effect on the Phylloxera, or, in destroying it, also destroyed or damaged the Vine.

The sulpho-carbonates, which were carefully used by the great Swedish chemist, Berzelius, and also obtained by combining the alkaline mono-sulphides with the bisulphide of carbon, are either liquid or solid, and emit a powerful odour of sulphuretted hydrogen and bisulphide of carbon.

The alkaline sulpho-carbonates in the solid state are of a beautiful reddish yellow colour and deliquescent, but are not easily obtainable in that condition; the sulpho-carbonate of barium can be easily procured, however, in a solid state, and presents the appearance of a yellow powder, but little soluble in water. The sulpho-carbonates decompose under the influence of carbonic acid, forming a carbonate, and evolving sulphuretted hydrogen and bisulphide of carbon. These two latter substances are gradually liberated, and, as they have a very powerful effect on the Phylloxera, one can understand that the sulpho-carbonate, placed in the ground, may prove, by its slow decomposition, a powerful insecticide. In the case of the sulpho-carbonate of potassium, over and above its toxic effect, it has a direct invigorating influence upon the Vine, as the carbonate of potassium is an excellent manure.

The employment of the sulpho-carbonates as a means for the destruction of the Phylloxera was suggested to M. Dumas by the clearly recognized fact that there was of some substance that would evaporate less quickly than the bisulphide of carbon; he saw that it was desirable to apply the insecticides in some combination which would fix them and only allow them to evaporate gradually, so that their action might continue long enough in any one place to infect with their vapours all the surrounding soil.

But the task of eradicating the Phylloxera has by no means been accomplished by the mere discovery of the value for the purpose of these substances; there is the further difficulty of applying them to the Vine in cultivation. One thing seems very certain, that in order to render the sulpho-carbonates practically efficacious in killing the insect, it is necessary to use water as the vehicle by which they may be brought to all the underground parts of the plant, and that the best time of year for their application is the winter or early spring, when the earth is still moist and the quantity of water necessary to be brought on to the ground by artificial means is consequently less. Mixed with lime in the proportion of 2 to 1, these sulpho-carbonates give a powder which can be spread over the ground before the heavy rains, that is, between October and

* I do not find any such name as "Eyjarós" among the native names of Icelandic plants given in my *Flora*. Nor does it appear in the list of plants by way of index to any of the specimens sent to me, so that I have no means of identifying the plant in question.
 † *Journal of a New Field for Tourists*, August, 1856; 2. "Contributions to the Natural History of Volcanic Phenomena, and Products in Iceland"—*Proceedings of the Royal Society of Edinburgh*, 1856.
 ‡ When I visited Iceland there was no such thing as a hotel in the island; but I was most fortunate in procuring quarters at the private residence of one of the leading merchants of Reykjavík.

March, and which will probably prove itself very efficacious.

The conclusion at which M. Mouillefert arrives at the end of his report is that the efficacy of the sulpho-carbonates is proved, and all that is necessary is to bring to perfection their employment in agriculture, which can only be accomplished by the intelligence and practical knowledge of the Vine grower, who is well able to discover the economic processes of culture which are conducive to their successful application.

He ends by saying that "Science has accomplished its mission, and it remains for Agriculture to fulfil it part" in the eradication of the *Phylloxera* from the vineyards of France. *Nature*.

BOTTOM-HEAT: ITS USE AND ABUSE.

I QUITE agree with most of what your correspondent, Mr. D. T. Fish, has so ably said, at p. 11, in favour of bottom-heat, and believe that, when applied at the right time and in moderation, it is one of the most powerful aids to successful cultivation a gardener can make use of. That it is highly injurious to Vines during the early stages of their growth I have long since found from experience, and for years have discontinued it altogether, substituting a thin coating of dry leaves or bracken, covered with shutters or old lights, just to keep out frost and wet from the border. The roots of Vines respond so readily to heat when applied to them that they pump up sap much faster than the slow swelling of the buds require, and the fluid, once started and finding no natural outlet, is forced into other channels, and effects its escape possibly by some of the very roots through which it was taken up, thus keeping up a continuous circulation in that manner till the Vines are exhausted.

Those who have attempted to stop a Vine from bleeding after it has once started to do so, will have some idea of the irrefragable force of sap after it is once fairly set in motion, and with what energy it pursues its course along the various channels allotted. Heat applied to the roots propels it at a quicker rate, and causes it to expand much in the same manner as does water; and I am strongly of opinion that the sap of Vines that set actively moving travels up the stem and returns again to the border, where it is discharged in the soil. If this is the case, as close observation has led me to believe, it is no wonder that Vines subjected to such treatment should start but feebly, and only make progress after they have got fairly into leaf, when any downward current that had previously been set going, would have ceased and taken its proper course. The fact of Vines starting stronger at the extreme end of the border, where they do not feel the influence of heat, shows clearly and unmistakably the evil of piling a mass of fermenting material on their roots, and if those who have been in the habit of so using it will only test the thing for themselves, by covering a portion of their early border, and simply protecting the remainder, I am convinced that they will soon abandon the practice.

It is not many years since that elaborate and costly works were undertaken in several gardens to heat Vine borders by means of hot water, but excepting the fine Muscat Grapes produced under the system by Mr. Drewett many years since, I have not seen anything to warrant the practice being adopted. As to pot Vines doing better with bottom-heat than without it, it should be borne in mind that it is generally applied to them when they are making their growth and have leaves, which is a very different matter to piling it on an outside border or planting the fruit in a mass of fermenting material to start them to do. That some do till this I am well aware, and they will continue to do so till they are convinced of their error; but if I remember rightly, one of our best gardeners (I think Mr. Gilbert, of Barchley) stated some year or two ago that he found they started much stronger and better without it. If pot Vines suffer less than those in a border, it is because the soil is very much drier, in which case the effect of heat would not tell so injuriously on them. I note that Mr. Wildsmith, in his paper relating to the subject of bottom-heat to Vines, says that he lays no claim to originality in discovering that they do not make fresh feeding roots till the buds are expanded. That they do and other deciduous plants do so, is a fact known to most people, or if it were not so what is the use of transplanting such things at the

time of year at which all operations of that kind take place? Vine borders are generally overhauled in the autumn, many of them not being interfered with till after the leaves have fallen; and does Mr. W. suppose that the old mutilated roots remain in that condition till the buds start again in the spring, before forming fresh fibres?

There are few gardeners who have not had something to do with renovating old Vine borders, and in doing so they must have observed numbers of rootlets to all appearance as active as at any time of the year. It is one of Nature's laws that roots are ever elongating and ever at work, although no doubt in a much less degree during the winter than at any other time; but that they are at work then is beyond all question, for if it were not so, how is it possible that any deciduous plants could exist? In the act of transplanting, or during any interference with a Vine border for the purpose of renewing the soil, most of the main roots are broken or damaged; this involves the loss of the principal feeders, but the plant immediately sets to work to repair the loss by forming others, without which it would live but a very short time. There are many who think that because the trees lose their leafless, they are entirely dead, and that there is no movement going on either above or below, but this is one of the most erroneous ideas ever entertained. If the roots were not at work, sending up sap to replace that carried off by drying winds, and to nourish the incipient buds during their slow process of swelling, trees would cease to exist. Nature is never at rest, but goes on unceasingly in all her various departments, and there can be no doubt that as regards root formation she is never at fault, but that the process is ever going on in a greater or less degree so long as there is life in the plant. With Vines I take it that it is not the formation of fresh feeders that does the mischief, as their increase would be highly beneficial, but that the sap is put in rapid circulation, and instead of finding its natural outlet it returns to the soil, thus keeping up simply a flow and return, to the great detriment of the swelling buds, as they would thus be in a measure starved.

With plants in leaf, or with such as have had their feeding-roots disturbed or injured, the effect of bottom-heat would be very different, as it would greatly aid the formation of fresh fibres to take the place of those destroyed, and thus enable them to get quicker to work to repair the injury; indeed, with many plants that have been shaken out and partly disrooted bottom-heat is absolutely necessary. There are many stove subjects that will do in from 10° to 20° less top-heat if they can have their roots in a hot-bed, and although they may not be so serviceable for the decoration of cool houses or exhibition purposes as when grown without it, most of them do best when they have it supplied. What, for instance, should we do without it in the case of Melons and Cucumbers? and do they not always succeed in a more satisfactory manner when the bottom-heat is greatly in excess of the top? And so with many other plants. Mr. Andrew Knight and others tried to do without it for Pine-apples, but the attempt was so much a failure that all who cultivate them now have returned to the old system.

As of all good things, it is an easy matter to have too much of bottom-heat, and to use it for a wrong purpose, as is the case when it is applied to the roots of leafless Vines, where the only effect it has is to cause them to pump themselves dry. *S.W.*

LOCKINGE, WANTAGE.

THIS extremely picturesque domain, the residence of Colonel Loyd-Lindsay, M.P., is situated about 2 miles eastward of Wantage, in the midst of a purely agricultural district. The roadway runs through a village of Lockinge, which is immediately contiguous to the park grounds, and Lockinge Church is almost close to the mansion, the main road being almost within a stone's-throw of it. It is one of those places in which the park grounds melt almost imperceptibly into the fields beyond them, and village and park alike have the appearance of being blended in one community bound together by a common bond of mutual interests. As the visitor drives up to the gardener's residence at the top of the hill, he has the park grounds on the left hand of the village, and on the right a line of semi-detached labourers' cottages, quite picturesque in appearance, in an elevated position, with charming flower-gardens in front and good

vegetable gardens behind; and their appearance testifies to the desire of Colonel Loyd-Lindsay that the abodes of his labourers should be examples of domestic convenience and sanitary arrangements. Prizes are annually offered for the best-kept flower and kitchen gardens, and some of the former, on a gentle slope towards the roadway, are excellent illustrations of taste and skill in the arrangement.

Lockinge is a place of great antiquity. The old Saxon name was "Licing," which, at the Norman Conquest was corrupted into "Lockings." In the ninth century Laking was granted, by charter of Queen Adelstine, to the Abbey of Abingdon, and for some centuries this estate continued vested in the abbey, until its dissolution in 1538, when it was placed at the disposal of the Crown. Clarke's *Parochial Topography of the Hundred of Lockinge* gives full details of the successive holdings of the property until it became the property of Mr. J. P. Bastard, M.P. for Devonshire, and was sold by his successor to its present respected owner.

The mansion occupies a low position, and the manor-house to which it was called was built about the Year 1500. It came into the possession of Colonel Loyd-Lindsay's forefathers, the grounds have been considered improved, and there are constantly being carried out under the superintendance of Mr. James Atkins, the able gardener at Lockinge.

The view of the mansion (fig. 12, p. 81) is taken from the rising ground near to the roadway, and it has been admirably executed by the artist. The church is situated on the right-hand of the mansion, but is hidden from view by the group of trees and shrubs in the foreground. There is a pleasant terrace flower garden along the front and at the sides of the mansion, the principal entrance and carriage drive being on that side of the residence farthest from view. The rising ground and slopes about the residence, and the stretch of park away beyond, are all modern, and there are to be found some splendid examples of Beech, Elm, Sycamore, Limes, &c., also of Yew, Box, Thuja, Wellingtonias, Picea, Finsapo, many kinds of Berberis, Laurustinus, Aucubas, &c. Many choice shrubs are not newly planted, but they are all doing well. Some of the Yews are of handsome pyramid shape, and 18 feet in height.

The grounds are remarkable for the air of repose about them; they seem to be so entirely removed from the busy haunts of man—forming a place in which to seek rest and quiet from the cares of business, the heat of party warfare, and the incessant requirements of modern social life to dwellers in the metropolis. There are extremely pleasant winding walks about the slopes, with here and there artfully constructed pieces of rock-work and waterfalls that look as if they had been fashioned by the hand of Nature; and at the lowest point a winding stream and rustic bridges, the banks clothed with Primroses and other flowers in spring, and in summer with Ferns, Periwinkle, &c. At almost every point some charming feature is introduced, appropriate groups of plants and shrubs, patches of bright flowers, &c. In one spot which the visitor comes upon suddenly—for it is artfully surrounded by a bed of shrubs and trees—there is a small circular flower garden, which at this time of the year is bedded with spring flowers of different kinds, such as Daisies, Arabis, Polyanthus, Aubrietia, Wallflowers, Fansies, Forget-me-nots, &c. In summer-time, the charming display is obtained here by means of ordinary flowering and foliaged plants, admirably arranged, and conspicuous among the subjects were some very charming beds of Lantanas, which were a most pleasing feature.

In addition to the terrace garden, in which the beds are similarly filled as above during spring and summer, there is also what is termed the saloon garden, which is situated in front of the smoking saloon leading to the large conservatory. Here small shrubs are intermingled with Hyacinths and Tulips at this season of the year, and the stone vases, filled with flowering plants in summer, have Yuccas, &c., as their occupants.

There are eight plant and forcing houses in addition to a spacious conservatory, all of which are filled with the usual occupants in excellent condition. Lockinge is not a plant-growing place, but there are many admirably grown specimens of great value for house decoration. A new road, 600 yards in length, leads from the mansion to the new walled-in kitchen garden, which occupies an open, elevated, and somewhat exposed spot. The new kitchen garden was

commenced by Mr. Burr, Mr. Atkins' predecessor in the management of the gardens, in 1871, and was completed under Mr. Atkins. It is about 6 acres in extent, with substantial walls and a range of vinerias and Peach-houses. The kitchen garden is in the chalk, and originally there was not more than 6 inches of natural soil resting on the chalk bed, but it has been made up to the depth of 30 inches by means of soil brought in from the great stretch of downs immediately contiguous, which was mingled with the natural soil. The wall trees are all in a concrete bottom, 5 feet in width. The Peaches that do best outside are Early Grosse Mignonne, Dr. Hogg, Téton de Venus, Early Silver, Noblesse, Royal George, and Princess of Wales. It may be remarked that all the trees are comparatively young and in process of being established, and during last summer bore good crops of fruit. To ensure a due supply, water is laid on to all parts of the kitchen garden by means of eighteen branch pipes from the waterworks on the estate.

The six vinerias are planted as follows—No. 1,

BOURNEMOUTH.

CLOSE to the beautiful estuary known as Poole Harbour, not far from Studland and Swanage, with their fine coast scenery and almost inexhaustible points of interest for the geologist and naturalist, lies the town of Bournemouth. Situated on a sandy coast, and well sheltered by hills thickly clothed with Finasters and other Conifers, this comparatively new town possesses almost unrivalled advantages as a health resort. To its other attractions has lately been added a winter garden and conservatory, a representation of which is given below (fig. 11), and which was opened on Tuesday last.

The winter garden is situated near the centre of Bournemouth, and within easy walking distance of the pier and the public pleasure grounds, and bids fair to become a fashionable and attractive lounge. A quantity of Palms and other ornamental plants has been placed within the wing of the building which has been specially erected for their reception, the corresponding wing being intended for a concert-room.

iron piping being covered with ornamental iron continuous grating. The ventilation is carried out on Taylor's system applied to a portion of the hot-water pipes, the fresh air being conducted by means of zinc piping and covers over the pipe troughs, and communicating with the outer air, thus giving a continuous supply of warmed and vapourised fresh air throughout the building. Additional summer ventilation is provided.

The quadrangle is lighted by a fringe of gas jets round the inner side of the gallery, and the wings, *i.e.*, the concert-room and the tropical department, are lighted by starlights. Water is laid on, and drainage, as well as protection from lightning, is also provided for. The height from the floor to the centre of the roof is about 70 feet, and there is a floor surface of 21,000 square feet. The extreme length of the building is 220 feet, and at its widest part it is 125 feet. The views obtained from the outer balcony, running round the upper structure, are very fine, embracing the Needles and great portions of the Isle of Wight, the Solent, the English Channel, &c.

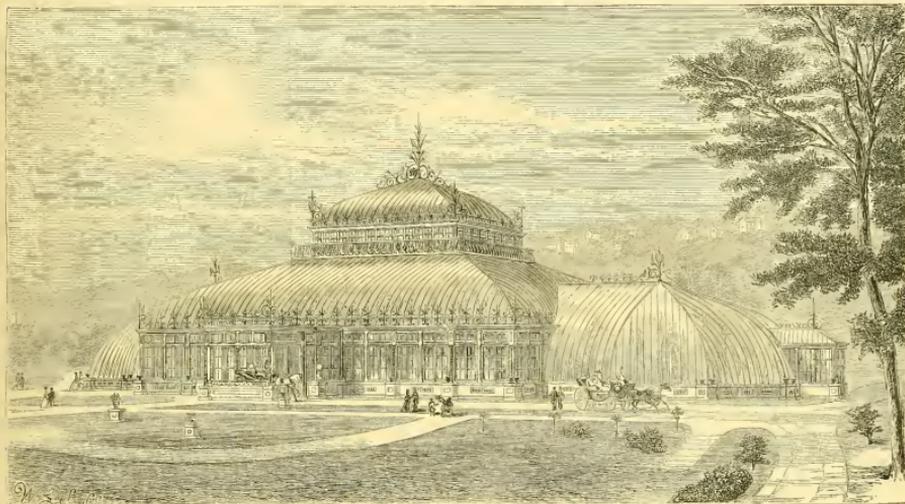

FIG. 11.—THE NEW WINTER GARDEN AT BOURNEMOUTH.

with Madresfield Court and Foster's Seedling; No. 2, with Muscat of Alexandria; No. 3 is a mixed house; No. 4, with Black Hamburg; No. 5, with Alicante and Lady Downe's; No. 6, with Hamburg and Foster's Seedling. Mr. Atkins has been very successful in showing that it is possible to have the Madresfield Court Grape fine in berry, in bunch, and without the trace of a crack, as shown at p. 367 of the last volume of the *Gardeners' Chronicle*. In the two Peach-houses are Noblesse, Royal George, Stirling Castle, Ward's Late, and Barrington; of Nectarines, Albert Victor, very fine, and Elruge; and there is a capital Fig-house also.

The kitchen garden paths are spacious, a central path being 14 feet in width, and all the other paths 10 feet in width, to admit of carts going round with manure, &c.; and on either side of the main path there is a mixed flower border, which admits of many flowers being grown that are invaluable for cut purposes.

Mr. Atkins is well known at various exhibitions as a successful cultivator and exhibitor of fruit and vegetables, and the improvements that are going on at Lockinge, serve to give him a wider scope for the display of his energy and practical skill, R. D.

The building has been designed by the contractors, Messrs. Fletcher, Lowndes & Co., of Great George Street, Westminster, and the erection has been superintended by Messrs. Tuck & Cumber, of Bournemouth. The building consists of the quadrangle, which is 100 feet square, with galleries approached by staircases, and running round three sides; an upper structure, or dome, 42 feet square, with external balcony; a vestibule, within the main entrance; and the two wings, each 50 feet long by 70 feet wide, and 27 feet high. The roofs are curvilinear, and are constructed on Messrs. Fletcher, Lowndes & Co.'s system, with their patent iron tubular ribs, and supported by cast iron columns.

The building is approached from the Exeter road by a carriage drive, and the principal entrance consists of a glazed roof, over the carriage-way, projecting from the vestibule. There are similar entrances at each end and at the back of the building, those at the wings consisting of vestibules projecting 10 feet, and being 10 feet in width. The principal entrances are paved with Carter & Co.'s tiles from the Poole Pottery. The heating apparatus is sufficient to raise the temperature as required from 32° to 65° Fahrenheit, throughout the building, a portion of the cast-

Florists' Flowers.

MESSRS. DOWNIE & LAIR'S NURSERY AT PINKHILL is situated about two miles west of "Auld Reekie," on the Glasgow Road. The Pinkhill Nursery is a branch of the West Coates establishment, where the firm a few years ago built a fine winter garden, now recognised as one of the sights of Edinburgh. Pinkhill has always played the part of a feeder to West Coates, and does so still, but to a greater extent, inasmuch that since Mr. John Downie, the senior partner, has taken up his residence there, Pinkhill has become emphatically the home of the various types of florists' flowers, in the culture of which for so many years the firm has achieved a well-merited success; and now that the crossing and propagation of the various flowers is carried on under the watchful eye of Mr. Downie, one of the keenest of florists and most genial of men, we may expect to see many more fine garden flowers added to the already long list sent out by the firm.

PENTSTEMONS.—At the time of our visit one of the grandest of sights in the floral world was to be seen in

two large beds of Pentstemon, the one composed entirely of named sorts, and the other of seedlings flowering for the first time. Which of the beds pleased us most we were at the time, and still are, unable to say, so abundant were the charms of each. The batch of named sorts included all the varieties catalogued by the firm, while the bed of seedlings contained a great number of their prototypes—in fact, as was remarked by a well-known nurseryman, if all the named Pentstemons were lost they could almost be replaced out of this bed of seedlings. In the improvement of the Pentstemon this firm has taken the lead. Indeed it is to Mr. Downie that the credit is mainly due of bringing the flower to its present high standard of excellence, and as he was kind enough to tell us how in a great measure this was brought about, it may as well be recorded. It seems that, some years ago, a variety named *perfoliatus* was introduced,—by whom we did not learn; but at all events it was a very fine introduction, and distinguished from the ordinary varieties in cultivation in those days by its lengthy spikes and thickly set whorls of short-leaved flowers. Well, this particular variety was planted amongst the other named sorts—and the bees, who are particularly partial to Pentstemons, carried the pollen of *perfoliatus* from flower to flower, and so started the improvement which has resulted in a complete change in the character of the plants, which are distinguished now from the old type of Pentstemon by their much more lengthy spikes and more thickly placed flowers. A batch of seedling Pentstemons has been raised annually at Pinkhills for some years past, and from these have generally been selected about a dozen of the very best to send out in variety. When we saw them last autumn some of the varieties about so selected, and these were named Countess of Tarbat, a very fine variety, with flowers of a deep shade of rose, the throat being white and pencilled with puce; Mrs. Kinghorn, a fine round flower of a rich dark rose, with a white throat, pencilled with rose; John M'Nab, which had a very fine spike of rosy scarlet flowers and a pure white throat; Dr. Masters, a very large flower, crimson scarlet, and pure white throat; Lady Houston Boswell, a large and well-formed flower, in colour a curious combination of white and rose; Octoroon, a dark rosy-crimson flower, with a fine bold throat; Mrs. A. F. Barron, a very early and very distinct flower, light rose, with violet; Lennie Barron, a shaded French-white and crimson pencilled throat; William Fowles, a white crimson shaded flower, of fine size; and Percy Wynne, dark crimson, and white throat veined with rose. Two of these, Mrs. A. F. Barron and Octoroon, were figured in the *Floral Magazine* for December last.

Turning now to the named sorts already distributed we noted as the best of the new varieties sent out last year Mrs. Sutherland Walker, bright scarlet, white throat; David P. Laird, crimson, with a white throat, pencilled with a deeper shade of crimson; Mrs. Wills, pale crimson, with a white throat; pyramidalis, crimson scarlet, with a deep crimson blotched white throat; Lady Dundas, white, shaded with purple; Captain Boyton, purple, crimson, with a white, crimson-striped throat; and Emma Marsh, dark rose, with fine white throat. The whole of these are distinguished for their fine lengthy spikes, and bold even flowers. Out of the dozen sent out in 1875 we noted eight varieties that proved to possess a high degree of merit, viz., Beauty, light purple, with white throat; Duke of Sutherland, bright scarlet, with white throat, very fine; James Watt, rosy crimson, throat blotched and striped with deep claret, the upper lobe white; Mrs. Macfie, purplish crimson, with a white throat; David Thomson, rosy crimson, throat white veined with crimson; Andrew Kemp, ruby-red, white throat heavily veined with crimson; and Dr. Gray, a bluish shade of purple, with a white throat, striped with claret.

The Pentstemon is one of the hardiest of florists' flowers, but in ordinary gardens it is better known as a very showy and useful border plant. Somewhat outside the pale of exhibition flowers in the South, though more favoured in the North, it yet has points of excellence that make it well worthy the attention of the florist, and the many fine named sorts now in cultivation attest that that attention has not been wanting, especially among the Northern growers. Paraking even more largely than the Wallflower or the Antirrhinum of a perennial habit, it is yet best treated as a biennial, or, at the most, as a triennial,

because it is apt to get ragged and shapeless after that period of growth has been passed. Still further, new plants are so easily raised from seed that it is but necessary to sow a pinch of seed each year, in order to secure a constant supply of robust young plants. It is also an excellent characteristic of the Pentstemon, as seen in the Pinkhills seedlings, that it very fairly reproduces by means of seed all the best features of the parent. The better the parents the better will be the stock of seedlings produced, and a selection from the best flowers is a matter of the greatest ease to any grower. Probably a knowledge of this fact accounts for the general non-appearance of named varieties in our gardens, although it by no means accounts for the too common absence of the Pentstemon from garden borders altogether. It may be that the fine qualities of the Pentstemon are not sufficiently understood in the South, and it is less doubtful that if understood they would ensure for the plant a much more general cultivation than it at present enjoys.

Why the Pentstemon should not receive as much encouragement amongst us for exhibition purposes as does the Stock or the Antirrhinum is one of those things that can only be explained by the compilers of floral schedules. Good spikes of flower are more showy than either of these are, quite as easily grown, and admit of the skill of the florist being more fully displayed in adjudging of their merits than do either of the flowers mentioned. Arrangement of flowers on the spike, size and shape of tube, colour, and markings, are alike favorable for accurate judgment, and therefore it is from no intrinsic defects in the Pentstemon that it is, so far, shut out of the pale of exhibition flowers.

An interesting fact in connection with the Pentstemon is the extraordinary fondness of the bees for the flowers. What there is about the flowers that the bees so much appreciate we are unable to say, but the fact remains, that while bees were generally very scarce everywhere last year, as pointed out recently by Mr. Darwin, they might have been counted by hundreds amongst the flowers of the Pentstemons at any time of the day when the weather was fine. We have no recollection of having seen any other plant so much resorted to be grown as a bed flower, but the bees are remarkably fond of the flower there can be doubt, and this furnishes another reason why this beautiful flower should come into greater favour.

ANTIRRHINUMS.—Another interesting feature in the Pinkhills nursery was a fine border of Antirrhinums in full bloom—a brilliant display of richly hued blossoms. A batch of seedling Antirrhinums is also raised here every year, but a greater number have to be grown to secure one good flower distinct enough to name. It is a singular characteristic of this plant that its continued cultivation develops so little improvement in the way of colour. The shape and size of the spikes and flowers have undergone immense improvement; but as regards new shades of colour, such as are so freely produced by the Pentstemon, the advancement of the Antirrhinum may be said to have stood still. There are three or four permanent colours, on which the variations or changes are rung, but from which the flower does not seem to be able to break away.

PHLOXES.—The raising of new varieties of Phloxes of the autumn-flowering section is also being vigorously carried on. The seeds will not ripen out-of-doors so far North, but when grown in pots and flowered under glass they ripen very well. There was a fine batch of seedlings just coming into flower at the time of our visit, and we have heard since that their flowering has given great satisfaction, and several fine varieties have been sent to bloom again this year.

PANSIES.—Next to the Pentstemons, the glories of Pinkhills lay in a large bed of Pansies and Violas planted on a gentle slope facing due south, and which was literally a sight to gladden the heart. The Violas were the Violas with us as were completely burned up, and it was indeed a treat to see such a display at the time. As a bedding plant the Viola stands pre-eminent in Scotland, where the less glaring sunshine and longer dewy nights suit it so much better than in hotter and drier summer weather in the South. Viola has been largely improved by the Northern growers, and so it has in the North, where our familiar names are seldom met with, the Scottish fanciers sticking more to their own productions. Amongst the fine varieties growing in front of Mr. Downie's residence, particularly admired, was the Viola Duchess of Sutherland, of a pale Cambridge-blue shade of colour, free-growing, and very floriferous, an improvement on Dean's Prince

Teck, from which it is a seedling; Mrs. Henry Pease, a pure white flower, dwarf and compact in habit, and very free-flowering; Max Kolb, a fine purple flower; Pinkhills Beauty, a fine shade of purple-pink colour with a dark centre, and fine in form; and King of Bedders, a variety sent out last year, and in the same way as the last-named.

—It will interest lovers of Pelargoniums to know that Dr. Denny's new varieties will be distributed this spring by Messrs Veitch.

Garden Operations.

PLANT HOUSES.

GREENHOUSE HARD-WOODED PLANTS.—The tying and staking of these plants should be pushed on with, so as to finish it as soon as it can conveniently be got through. The bloom-buds of many things will now begin to increase in size, and training is delayed too long when the plants are moved about, knocked off in the operation. Large plants that are only wanted for home decoration will not need as much tying as they would if intended for exhibiting as such. The material that shows the least is black cambric thread, indeed it has to be used so as to be seen; in its use it is necessary to be careful not to tie the shoots too tight, as it will not stretch. Always have new sticks, for even if those used last year seem sound they will before the season is over decay, and then, when the plants are moved about, they are in danger of the collar being injured. Soil of the various descriptions necessary—loam, peat, leaf-mould, and sand—should immediately be got under cover and spread out in open sheds to dry, so as to be in proper condition by the time of potting; and empty flower-pots should be well washed and crocks broken, so that all may be in readiness.

HEATHS.—With these also let the tying be completed as soon after this time as possible, by so doing the plants will when in bloom have a better appearance, as when tying is done a good while before the flowers open the points of the shoots and the leaves have time to assume their proper position. It is well now to make a calculation as to the time it is desirable to have the plants in bloom, and the time to be allowed for home decoration as well as to any that may be wanted for exhibition purposes. As soon as we get any sun they should be put in positions to keep back and push on their flowering according as may be necessary. Any of the plants that are not so retarding house must have a good situation where they will get plenty of light, for Heaths cannot bear being in badly ventilated or dark houses. Putting them at the coolest or warmest end of the house they are grown in will cause two or three weeks' difference in the time of their blooming. Early flowered plants of the *Hymalis* section that have been in conservatories or other places where a higher temperature is kept up, and where they may also not have had enough light and air, should as they go out of bloom be put where they will gradually receive treatment better suited to their wants. Do not let them be exposed to cold draughts of air, but give them abundance of light and the requisite ventilation, and encourage them to begin growing.

SOFT-WOODED GREENHOUSE PLANTS.—Lilies, if wintered under plant stages, or such-like places, must on no account be allowed to suffer for want of water. If from any cause they were not potted at the proper time last year, they should once be attended to, getting the soil in the pots above the bulbs carefully away without disturbing the roots, and replacing it with a good loam, to which has been added rotten dung, a little sand, and some leaf-mould, giving just enough of bloom to put them in a healthy state. Let Primulas have a position as near the glass as possible, and if in a night temperature of 45° they may have plenty of water to their roots, as the light and extra warmth will make them not liable to their greatest enemy, damp. Cuttings of show Pelargoniums struck in the autumn should, when they have filled their little pots with roots, be moved into larger; from a 4 to 6 inches, according to their size and the nature of the variety, will be big enough for them this first season. Give them good light, well enriched soil, and plenty of water, to which add a little sand. Those that have not been stopped should have their points pinched out to cause them to break. Cinerarias that were sown late and are in small pots, if they do not show signs of blooming, will be benefited by being moved into larger pots, and a little water added, and be of service when the earlier blooming plants are over. If they have commenced to push up their flower-stems do not report, as all that can then be done to help them is giving them liquid manure. To manage Primulas, give them a sitting in a hot water bath, treating well, not stinting it for pot-room, and giving it soil consisting of good loam with the addition of a fair sprinkling of sand and a fifth of leaf-mould and rotten

dung in equal proportions. Any plants that need it should now have a liberal shift; they will flower strong and late. Those that are intended to bloom early ought to be well fed with manure-water. Campana pyramidalis, both the white and blue varieties, are very useful decorative subjects, and deserving of being more generally grown than they are; if sown in good time in the spring and well done they make fine blooming plants in about sixteen months. Give plants either grown on from suckers or sown last spring a good position, and never let them get stunted through an insufficiency of pot-room. *T. Entica.*

ORCHIDS.—Advantage should now be taken, whilst there is a comparative slackness of work in the other departments, for cleansing and collecting mosses, and give every plant a thorough cleaning. This matter of sponging will be necessary during almost the whole of the season more or less, for dust will be sure to follow the leaves, and insects to get upon them also; and the more diligent the collector, the more the course be adopted, and the plants carefully gone over. The different forms of scale that attack these plants, whether the soft woolly one that is found chiefly on Cattleyas and *Aerolis*, or those that affect more particularly the *Orchis*, *Vanda*, and *Saccolabium*, or again that small hard one that we meet with chiefly on *Colognea cristata*, are all imported with the plants, and as soon as we have the plants under cultivation the insects appear to thrive and increase immensely. Get a small brush or a pointed stick for the removal of these. In the case of a rise of sponge carefully go over the leaves and bulbs, and thus give a fresh and glossy appearance to the whole. In sponging it is always better to use a little soft soap in the water, and if few drops of turpentine are added to help to kill the smaller scale, whilst it is quite safe and will not hurt the tenderest leaves. Only those should be treated to perform this duty who have previously had experience in the cleaning of plants that are less costly, else if one who is new to the work attempts to kill the smaller scale, he gets the number of cracked and split leaves and scratched bulbs will soon show signs of inexperience and want of care, and in a few hours the results of years of care and toil may be completely spoilt, and thus should give pleasure and satisfaction will then only bring disgust and disappointment. Let a sufficient quantity of sphagnum moss and calcareous peat be got under cover, and on wet days, or when time can be spared, give the moss a good picking over, and take out all green weeds that will be sure to be amongst it, so that when required for potting it will be ready and fit for use. Pots and crocks should also be washed, and placed under cover, and some charcoal obtained, so as to be at hand when needed. The Odontoglossum-house is now being put up to the clerestory aspect, and from the first the flowers of *Alexandria* expand we may look forward to a continuance of bloom. One of the pleasures in connection with this class of plants, more especially those that are purchased as soon as imported, is the fact that it has often happened that when numbers have been obtained for *Alexandria*, and grown on for a year or two under that impression, when the flowers have opened they have proved to be triumphans, and in some cases the even more rare and choice *Andersonianum*; where such is the case a single plant will be worth much more than is often given for the lot. It may be said, however, that sometimes the results are the other way, and that a worse thing turns out amongst what were expected to be all very fine things. It is true, in measure, but the chances now-a-days are much more in favour of the buyer than when this class of plants was first introduced. Again the different, and at the same time, beautiful varieties of *Alexandria* and *Pezomachus* are such, that where convenience can be given them they should be grown by species, and of the hundred, and when established and in flower there are very few signs that can be compared to a stage in the Odontoglossum-house with the spikes of these spreading and drooping over dark green healthy foliage; and when the flowers of *Alexandria* have been seen some twelve years ago, it was directly looked upon as one of the most desirable and useful that had ever been sent over, and each year, though it has been imported by thousands, and gladdened the heart and eye of numbers of eyes, it is now sought for as eagerly as at first, and is in higher estimation than ever. *W. Swan, Wallingford.*

FRUIT HOUSES.

PEACHES AND NECTARINES.—When the time of flowering of these subjects takes place under the variable external aspects which usually prevail during the present month, it may reasonably be considered a somewhat peculiar process, and one that is not the most suitable artificial means should therefore be adopted to effect the object perfectly. At times, however, when this peculiar function fails, the cause is too readily ascribed to it alone, without duly considering the influence of the season, and the inseparably connected therewith; for, for example, as in

would naturally arise from an unmaturred state of the wood by reason of over-exuberant growth being allowed to go unrestricted, or by suffering the borders about the roots to become exceedingly dry before the buds are perfectly developed. To these may be added other matters of detail in management, to which failure in this particular way may therefore with justice be associated and not solely limited to the conditions which are existent in the house at the period in question, for cases occur where excessive frosts are secured, even on the very ordinary circumstances. We invariably pursue a definite course of keeping up a moderate equilibrium of from 50° to 55° at night and from 55° to 60° in the day-time by fire-heat if it be necessary; and under other matters of detail in management, at this time admitting a free course of air through the house; on other occasions ventilating and closing the house at from 57° to 60°; and at times when severe pressure exists externally we are content with 5° less and at times in the day, as on the 10th, we expand, and when the pollen is dry, brush these over with a camel's-hair pencil, or a jar of the trellis by the hand is not amiss; the customary course of sprinkling is likewise adhered to throughout the whole period, and the trees are watered and given evening and early in the afternoon every day, providing the moisture from the former syringing has dispersed. The temperature and treatment in the successional-house, with an increased amount of light, be kept identical with that of the first house, but the same should be lost in completing what-ever remains to be done in this department in the way of pruning, clearing, and training, as the flower-buds are already considerably advanced, and will speedily, with sunshine and favourable conditions, expand, and the operations injurious. *Geo. Thos. Miller, Wycombe Abbey.*

CUCUMBERS.—A very important item in the management of winter Cucumbers is cleanliness. Syringing the plants should be kept sweet and free from decaying matter; free ingress of light should be provided for by frequently washing the glass. If green or black fly put in an appearance dress with Pooley's Black Fly Powder. Destroy red-spider by the removal of old leaves, a few at a time, and careful pruning of the remainder with tepid soapy water—a tedious process many will say, but if taken in time a house of plants may soon be gone over. Smoking at this season, particularly after so much dull weather, is dangerous, the young foliage being so tender and tender. The steaming of pipes or other heated surfaces should also be avoided for the present, as plenty of moisture may be obtained by damping the plants and walls. If severe weather sets in, blinds, mats, or other non-heating material should be used for covering with at night. Maintain a night temperature of 68° to 70°, with a rise of 10° to 15° by day. Pay constant attention to the preparation of materials for frame Cucumbers by frequent turnings and protection from heavy rain. Make further sowings of the most approved kinds for succession, placing single seeds in small pots. Shift on young plants as they require more pot-room, and keep them near the glass.

ORCHARD-HOUSE.—In large places, where an early forcing orchard-house has been provided to save the hard forcing of old-established trees, a selection of the best early kinds should be used for this purpose. One of the very best is Hales' Early, a fine, large, richly-flavoured Peach; Early York, Early Grosse Mignonne, and Abe, equally large and good, although a little later than Beatrice and Louise, are really presentable when well-grown in pots; indeed, these four kinds form the cream of the early forcing peach, and if properly treated these trees should now be going out of bloom, and treated liberally. The fruits will swell rapidly under frequent syringings with tepid water, and a temperature of 50° to 55° at night, with a rise of 10° by day.

In the orchard-house proper—*i.e.*, the cool house—the mild weather is bringing the buds very forward. When fire can be applied in severe or wet weather this is of little consequence, but where the house is unheated every door and window should be thrown open, and the trees kept vegetation in check. All pruning, dressing, and cleaning should be finished, the trees gradually watered, until every particle of soil is brought into a growing state, when the final top-dressing may be applied. Trees established in houses like a hard house to grow in a good turfy loam should be kept light, with a fair sprinkling of old lime rubble, suits them well. The drainage, too, must be good, as size of fruit depends so much upon feeding and the amount of healthy foliage the trees are allowed to carry. Trees intended to be put in late may be prepared for the winter by cutting out a north or west wall until the blossoms begin to show colour, when they must be taken under glass. If well managed through the past summer, but little cutting will be required at this season; but when it is necessary to cut a trunk, explain that the cut is made in front of a triple bud. *W. Coleman, Easton Castle.*

KITCHEN GARDEN.

With the advance of the season rendered vigilance must be exercised in order to keep pace with the different requirements of the day, and in view of the principal of which is to see that a constant succession of *Seakale* is regularly put to work at such intervals as the supply required renders necessary. The ordinary method of covering with pots and fermenting materials is not to be resorted to in any way, but cannot always be thoroughly depended upon for supply; it may with very great advantage be supplemented by taking advantage of the splendid roots for forcing which have been so largely cultivated of late years, and that are so abundant in the country. One or two from seven to nine large roots in 10-inch pots, water them thoroughly, and invert a pot of the same size over them, and place them on the top of the brick-work over a large boiler which heats several houses, covering them with a good thickness of old mats to exclude light. The soil must not be allowed to get dry, and about fourteen days is the average time required to have it ready for table; if pushed faster it comes weak. Another batch of *Asparagus* crowns should be put to work, care being taken to avoid overwatering, of which it is very impatient. A few roots of early sorts of *Khebarb* may have cement barrels, with the heads knocked out, placed over them, and these well covered with stable litter which has not become too much fermented. As a second crop is present when *Asparagus* so scarce, will forced early *Khebarb* cannot fail to be appreciated. Another batch of French Beans should be put to work for succession; where conveniences serve it is better to get in smaller batches at shorter intervals than a great number at all once, and the soil should be kept moist in the way of succession by sowing half the batch of a later sort. Some time in the last week in the month a good bed of prepared fermenting materials should be ready for the sowing of early Carrots the first week in February. This is often done in movable frames with very good success, but it does not economise material. For some years we have devoted a small brick pit a little over 4 feet deep and half sunk in the ground to this especial purpose, and have never failed of a satisfactory result; we usually sow two things, Early French Forcing and the other Early Horn, thus securing a succession to bring in the same two sorts in the open quarter. We take advantage of the heat for a sprinkling of Wood's Early Frame Radish, which is away before it can harm the Carrots. Early Carrots intended for planting in frames next month should be at once laid out on the floor of any erection where there is a constant heat; the advantage to be derived from this practice, both for framework and early planting in the open, is very great, because the plants will set and sprout at all in so late that they would be useless in frames, where every plant is expected to tell; and for the open border it is always a great advantage to be able to select such seeds as will ensure a crop that are ready for planting. If the weather is open at the end of the month, and the ground in such a state that trenching may be carried on, all vacant plots should be attended to at once, and where new plantations of Horse Radish are required now is the best time to plant, or as early after this as the weather will permit; this crop requires deep trenching and plenty of manure.

Now is a good time to decide upon the various plots to be occupied by the forthcoming crops, and proceed with the work of preparation in the order required. One of the first as a general crop will that of Parsnips, which should be sown in the north, the *Hollo*, Crowned and Student are two good sorts; they take to have new seed, as seed even two years old is very uncertain. Look well to the sowing of small salad in heat, and see that Chicory and Witloof are put in heat to be ready for use. The winter stock of the supply of Endive from the winter stores. *John Cox, Redleaf.*

—The Rev. F. Simcox Lea, writing from Worcester to the *Times*, remarks that "Mr. Darwin's statement (quoted in the *Times* of the 11th inst. from our columns) that the Holly is a diocious plant explains a difficulty which the older writers on botany do not solve. Neither Withering nor Sowerby (original editions) gives the Holly as diocious, which in common experience the trees which are fall of flower in the spring, and which never bear berries are familiar. A peculiarity noticed during 1876 in this district was that the abundant berries of the Holly of 1875 remained on the trees all the year, and in my own garden I had the berry of 1875 at the Christmas of 1876. The berry of 1876 was very rare, but the year was remarkable here for a generally deficient fruit crop, the stone fruit and Apples having alike failed. The Portugal Laurel, however, ripened its berries in unusual plenty. This, I believe, is a monocious plant, but the Yew, which is diocious, had also an abundant yield of berry."

THE
Gardeners' Chronicle.

SATURDAY, JANUARY 20, 1877.

APPOINTMENTS FOR THE ENSUING WEEK.

WEDNESDAY, Jan. 18. Sale of Fruit Trees, Roses, Shrubs, &c., at Stevens' Rooms.
THURSDAY, Jan. 19. Sale of Lilies, at Stevens' Rooms.
FRIDAY, Jan. 20. Sale of Hardy Plants and Bulbs, at Stevens' Rooms.

SOMEWHAT to the astonishment we suspect of those who thought they had really seen the last of the ROYAL HORTICULTURAL SOCIETY, a large and interesting display of miscellaneous plants was collected in the Council-room on Wednesday last, thanks to the exertions and good feeling of such exhibitors as Messrs. VEITCH, WILLIAMS, LEE, Sir HENRY PECK, and others. We must refer to another column for the details of what was really a large and interesting meeting, though but thinly attended by the general public.

It was gratifying also to hear a long list of new Fellows proposed. All these signs should encourage the Council. It scarcely admits of doubt that a large accession of new Fellows would accrue if the Society could only get clear of its entanglements to the debenture-holders and the Commissioners. To be saddled with the gardens one day longer than is absolutely necessary will, be believe, be fatal to the rejuvenation of the Society. All that is wanted is an official meeting place for the committees, with space enough for shows, if desired. Any attempt to conciliate the fashion of the town by bands, and such non-horticultural things, will simply be to pursue the same fatal policy which has so well nigh wrecked the Society. Let the Society stick to its own work, and that only. If any considerable section of the Society want bands and promenade-gardens let them pay for them themselves, but let not a penny of money that ought to be spent upon horticultural objects be again frittered away upon unproductive matters of this kind. Every effort should also be made to conciliate and bring in the country Fellows and the real horticulturists of the country. The butterflies will come if the flowers are provided.

AN answer which was given in our columns a week or two ago relating to the COURSE OF THE SAP has elicited a paper from Mr. ANDREW MURRAY, which was read before the Scientific Committee on Wednesday last, and which, at his desire, we reproduce. In our reply, to which Mr. MURRAY takes exception, we gave what we believe to be a substantially correct answer according to the present state of science, but one which it was necessary to compress into as few words as possible. There are three principal theories, which, disregarding modifications, may be thus briefly summarised:—1. The old theory of a regular continuous ascent in the season, and an equally regular descent later on. This seems to be the view of a correspondent at p. 76 of our present issue, but it is one to which we cannot assent. 2. The more modern theory, according to which the descent is not absolutely denied, but whereby it is supposed to be limited by the requirements of the plant at the time; and, lastly, there is the theory broached by Mr. MURRAY himself. There are numerous modifications of these several notions, but it is not our intention to speak of them now. Any text-book may be consulted with reference to them, and hence we prefer to let Mr. MURRAY speak for himself, and to solicit the attention of our readers to the subject, that they may favour us with their views. Only, as the subject is essentially a practical one, we trust they will not rely on their

imagination, but base their statements upon trustworthy facts.

"A great revolution has of late years taken place in the ideas of respectable physiologists regarding the course of the sap; and, what is very unusual, it has taken place silently, and with scarcely any discussion. One regrettable consequence of this has been that those who are out of the current of scientific unwritten opinion remain in ignorance of the change that has been coming over men's minds; and even those who are in the midst of it are at a loss to find what the real verdict of the scientific world is. That this is so will be admitted by those who attended the Botanical Congress at Brussels in May last, where this question formed one of the subjects selected for discussion, and elicited much diversity of opinion; and that a like uncertainty still prevails here may be seen from a reply to a correspondent in the *Gardener's Chronicle*, January 6, 1877—

"It is not affirmed by any one that we know of that the elaborated sap does not descend; the modern notion is simply that it may and does ascend, go horizontally, or in any other direction, as well as descend, according to time, circumstances, and the need of the plant. Suppose, for instance, starch is to be stored in a Potato tuber, or wood to be formed in the root, the matter out of which that starch that wood is formed must in a great measure pass through the leaves, and therefore it must descend to reach its destination. But starch is likewise stored up in the grain of Wheat; in this case, then, it is obvious that the nutrient and store-containing, or storing-up sap, must ascend from the leaves, and the seeds, &c., true of fruits and stones (seeds) placed above the leaves.

"This is not at all what I understand to be the modern view of the subject; neither is it the view which was come to by the Congress at Brussels. It is neither more nor less than the old theory, with scarcely any qualification. That theory was that the sap described two courses, viz., an ascending and a descending course; the ascending course to the leaves, where it was submitted to certain influences which fit it for the nutrition of the plant; the descending one from the leaves, in a condition fitted for that purpose. The modern view, as I understand it, is that the sap describes only one course, viz., that from the root to the leaves, being drawn up by the power of the sun and other concurrent influences. In its course it is like a great river, which steadily flowing to the sea, turns to the right or left, as obstacles present themselves, and opportunities occur, but the delta near the termination of its course, which may be compared to the arrival of the sap at the leaves, it flows in any direction, now dividing to the right and to the left, and again even regurgitating and flowing in a backward direction, but all these anastomoses together, and by simply emptying into the ocean, we may compare is the atmosphere, into which its watery portion is drawn by evaporation from the surface of the leaves.

"It is ten years since Mr. HERBERT SPENCE's paper on circulation and formation of wood in plants (*Linnean Society's Transactions*, vol. xxv.) proved to demonstration that the sap ascended in the branches, and that while of course he could not prove a negative he at least showed that in some of his experiments could he get the sap to descend; he moreover gave a simple explanation of the deposit of wood by the sap oozing through the vessels on its way up and, depositing woody fibre around them. A few years later Professor W. R. M'NAB repeated and extended Mr. HERBERT SPENCE's experiments, with the same results, and, if my memory serves me right (for I have not the paper) showed also that the sap ascended both by the vessels supposed to be appropriated to its ascent and by those appropriated to its descent. I have been under the impression that these experiments, coupled with other facts well known (such as that the bark and wood on the under side of a cut on a tree swells, while that on the upper side does not), had convinced the scientific world that the notion of the descent of the sap was an error. It has never had a particle of proof offered in its support. The only thing I can recollect that I ever heard advanced as such was the experiment of tying a ligature round a branch, when the branch swells above it instead of below it. It is only by a misapprehension of the experiment that this can be likened to a dam keeping back a descending stream. It is the case of a stream expanding itself when it finds space after its passage through a narrow channel. Any stream, after being released from a narrow gully, behaves in this way.

"Seeing, then, that on this important physiological question doubt still exists, I have thought it might be well to give the expression of my opinion to the committee on the subject. I know how difficult it is to submit old opinions, what an exertion of magnanimity is required to acknowledge that we have been in the wrong. I remember, with sympathetic distress, the almost piteous remembrance of a learned Professor at the Congress at Brussels, who, when interrupted in his

argument about the descent of the sap by cries of '*Un'ya pas de vive descendante!*' exclaimed, 'There must be a descent of the sap. I have been teaching it for thirty years. What am I now to say to my students if there is no descent of the sap?' But the greater the difficulty, the more the necessity for consulting such feelings, and putting the question on its right basis.

"I am not at all blind to the consequences of adopting the view that I take. I know that if descent of the sap goes, the elaboration of the sap by the leaves must follow. If it is not to descend of what use to elaborate it in them, and why elaborate it by the leaves rather than by the roots or any other part? The storing-up of liberates will also have to go, both of which are gratuitous assumptions without a particle of proof. The attraction of carnivorous plants will become still more difficult to comprehend, and other more remote corrections or received ideas dependent on them must follow. I do not now concern myself with these; my present subject is the descent of the sap, and it is respectfully suggested to the committee that they could not be more usefully or appropriately employed than in giving an authoritative expression of their opinion upon it. I do not ask, and indeed I would rather deprecate a hasty, offhand judgment on the spur of the moment, which in any view could only be regarded as the expression of individual opinion. What I would like to see published, well considered opinion after mutual consultation by the most eminent physiologists of our body."

— The following is a list of the persons recommended by the Council of the ROYAL HORTICULTURAL SOCIETY to be appointed to the offices of the President, Treasurer, Secretary, committee-men of the Expenses Committee, and Auditors of the Society, at the annual meeting on February 13, 1877:—President, R. HON. LORD ABERDEEN; Treasurer, HENRY WEBB; Secretary, ROBERT HOGG; Expenses Committee-men, F. CAMPION, HENRY WEBB, WILLIAM HAUGHTON; Auditors, JOHN LEE, CHARLES EDMONDS, JAMES F. WEST.

— We have received from a correspondent a piece of the stem of a TOMATO PLANT, which measures 4 inches in circumference. The plant is stated to have produced heavy crops of fruit for over two years, and would have lasted another year, notwithstanding that the stems are beginning to decay in the centre. The plant was raised from a cutting, and planted two years last September in a Pine bed, in the old tan and leaves used for forcing.

— We find that the association of OMPHALODES and DOUTRE WERTZ PEAROSSES, alluded to at p. 59 as a happy but accidental hit in plant grouping, occurred at the Knop Hill Nursery, and not, as there stated, in America.

— According to the *Journal de la Société Royale Agricole de l'est de la Belgique* the loss in the Potato crop from disease has been very heavy in many parts of Belgium. When the crop was dug the tubers were healthy, but during the succeeding fortnight it is estimated that from a quarter to a third became rotten.

— Dr. WITTMACK, of Berlin, has been conducting some comparative experiments to ascertain the DEVELOPMENT OF CEREALS and other plants from NORTHERN SEEDS, by the sowing of home-saved seed in the South. The general result was, notwithstanding some exceptions, that seeds of cereals and other plants from the North develop at first more slowly in Central Europe, but in the end overtake and pass the indigenous seeds.

— Some idea of the extent to which PLANT CULTURE in POTS is carried on in this country may be gleaned from the fact that in one potterry alone—that of Mr. JOHN MATTHEWS, of Weston-super-Mare—1,280,000 pots, varying in size from 1½ to 30 inches in diameter, were manufactured last year.

— The CHAIR OF BOTANY AT ABERDEEN is likely to be vacant shortly. Among the candidates are mentioned the names of Dr. J. E. BALFOUR, Rev. Dr. BROWN, Dr. W. R. M'NAB, and Dr. TRAILL.]

— According to the *Illustration Horticole* an AGRICULTURAL INSTITUTE has been established in PARIS, with M. BOUSSINGAUD as Director, M. FRINGSHEIM as Botanical Professor, and M. DU BRUILL as

Professor of Horticulture, &c. It would have been scarcely possible to select three more appropriate persons.

— In an account of a HAILSTORM AT EMU CREEK, QUEENSLAND, on October 23 and 24 last, given in the *Sydney Morning Herald* just to hand, it is stated that many of the hailstones were as much as 6 inches in circumference, and some that were weighed were over 1 lb. in weight. Holes were knocked through the roofs of houses and barns, and

ANDRÉ'S researches in Columbia. We shall hereafter allude in the ordinary course to M. ANDRÉ'S plants, which, like those of Messrs. WALLIS, CARDEE, SHUTTLEWORTH, BRUCHMÜLLER, and other collectors, will have special interest from the fact that the country is now desolated by civil war, which may prevent further explorations for some time to come. The country is described as so rich in plants that, large as is the number of fine things already received, there are many more yet to be introduced. Considering the melancholy fate of thousands of Orchids

BATA in the same house will shortly be covered with wreaths of golden bloom, forming with the silvery Fern-like foliage a beautiful association. The magnificence of this species is shown only by large specimens of free growth, and this example is one worth inspection.

— Mr. DICK, gardener to Sir IVOR B. GUEST, Bart., Canford Manor, Dorset has been appointed bailiff or manager of Phoenix Park, Dublin, in the place of Mr. C. McDONALD, who retires. This is

FIG. 12.—LOCKINGE, THE RESIDENCE OF COLONEL LOYD LINDSAY, M.P. (SEE P. 76.)

the standing corn was in many places struck down and destroyed.

— Mr. WILLIAM THOMSON, for many years connected with the seed establishment of Messrs. PETER LAWSON & SON, and lately a partner in the firm of PETER ROBERTSON & CO., has commenced business under the style and title of WILLIAM THOMSON & CO., as a seed merchant and nurseryman on his own account, at 16, St. Giles' Street, Edinburgh.

— The current number of the *Illustration Horticole*, which has just reached us, has a special interest from containing the first instalment of M.

torn from the trees to die on the journey to this country, we can but feel that the civil war will have some compensations in affording a fallow time to the Orchids, which otherwise would run a fair chance of extirpation, if there be not some of them extirpated already.

— SERICOGRAPHIS GHIESBREGHTII, an old plant not often seen, is one of the most valuable of the cultivated Acanthaceae. Its scarlet tubular flowers are extremely showy at this season, and occurring in graceful sprays are useful for cut purposes. It is now very ornamental in the temperate-house at Kew. A large specimen of ACACIA DEAL-

one of the best public appointments open to the profession.

— Mr. RUST, of Eridge Castle Gardens, writing in the *Florist and Pomologist* of the NEGRO LARGO FIG, remarks that "Of all the Figs which grow in the garden, this is, to my mind, the most desirable, being fruitful to a degree, and the flavour being the finest I ever tasted. My experience of its good qualities is as grown under glass, and I do verily believe it will yield fruit continuously for eight months out of the twelve. In the early part of December the flavour was as good as it was in June. No fruit trees are more improved by root-pruning than the Fig; they

are thus kept within bounds, and made to produce fruit at an earlier period, while those on the open wall should have a double net over them during April and May, to guard them from the frost."

— Twenty or thirty species of FLOWERING PLANTS were found by the members of the late ARCTIC EXPEDITION between 82° and 85° N., including, says Dr. HOOKER, the beautiful *Hesperis Palasii*, *Saxifraga flagellaris*, and *Vesicaria arctica*.

— At the annual meeting of guarantors and life members of the YORKSHIRE GALA, held recently, Mr. Alderman TERRY presiding, the Lord Mayor (Mr. Alderman MELROSE) was appointed President for the ensuing year, and Mr. Alderman TERRY, who was vice-chairman last year, was elected Chairman in the place of the late Mr. Alderman STEWARD. Mr. Alderman ROOKE was appointed vice-chairman, and the Town Clerk and Mr. J. WILSON were respectively reappointed treasurer and secretary. The following vote of condolence and sympathy with MISS STEWARD and family was unanimously adopted:—

"That this meeting desires to record the great loss the Society has sustained in the death of its deplored Chairman, Mr. Alderman STEWARD, who was connected with it almost from its formation, and whose extensive knowledge of floriculture, and his assiduous attention to the numerous and arduous duties attached to the office, enabled him to render the Yorkshire Gala Society, whilst his genial disposition and adaptability caused its various meetings to be of a most pleasurable character. This meeting also offers its sincere sympathy with MISS STEWARD and the other members of the family in their great and sorrowful bereavement."

Mr. WILSON, the secretary, announced that he had received, in answer to various applications he had made to nurserymen to give special prizes for amateurs and gentlemen's gardeners, which would tend to improve floriculture, benefit the nurserymen indirectly, and also improve the show, promises of donations from the Chairman of £5; Messrs. BACKHOUSE & SON, York, five guineas, for a collection of fruit, to be offered to growers in the six northern counties to be held in 1877; Mr. MAY, of Bedale, £6, for Roses in pots; Messrs. PAUL & SONS, the Old Nurseries, Chesham, £5, for cut Roses; Messrs. CRANSTON & MAYOS, of Hereford, two guineas, for Tea-anted Roses; Messrs. LAZENBY & SONS, York, two guineas; Mr. WILLIAMS, London, one guinea; and Mr. DOUGLAS, York, one guinea.

— The Southampton papers report that the recent high tides have been peculiarly destructive in their effects on the stock in Mr. W. KINGSBURY'S small nursery at Bevois Valley. The nursery is the same as that originated some years since by the elder Mr. WINDERBANK, Mr. KINGSBURY'S former partner, and is so well known in the locality that its desolation, in spite of the occasional danger of inundation, was always regarded as objectionable. It abuts on to the banks of the Itchen River on the one side, and on the other is subject to receive the overflow of storm water from the Bevois Hill when an unusual storm takes place. Some years since, for its last-named cause, the place was flooded and much damage done. On the recent occasion the flood of sea-water broke in and literally flooded all the houses, destroying thousands of seedling plants, and doing mischief to the estimated extent of about £600.

— A very charming effect in spring bedding may be obtained by interspersing strong clumps of the beautiful vermilion-scarlet ANEMONE FULGENS with the charming pale blue MYOSOTIS DESISSERTIOLA. If planted in a sheltered spot this lovely Anemone will flower as early as February, but in the open flower-beds it would produce its blooms at about the same time as does the Myosotis. The latter might be planted up closely to form a carpet, and the Anemone in clumps as pot plants. This Anemone will transplant easily in the autumn, when the clumps should be carefully divided but not be reduced too much. It would be undesirable to divide it in the spring when transplanted back to their summer quarters, as the less disturbed at the growing period the better.

— A correspondent sent us a few weeks ago a double flowered of LAPAGERIA ROSEA, so remarkable in its double condition as to demand notice. Several times it has fallen to our lot to see more or less

double flowers of this beautiful and useful trailing plant, but the one to which we now allude exceeded them all in beauty and the extent of its doubleness, if we may be pardoned the use of such a word. The colour of the outer, or, as we may term them, the guard-petals was rich, and within them was a dense mass of narrow petals as regularly disposed as in the best of the double Paeonies. Our correspondent, who gave no other name than that of a "Constant Reader," informed us that the flower in question was produced as a sport from the ordinary form, and inquired of us as to whether it was likely to be perpetuated. Analogy would lead us to expect that if the sporting branch were propagated by layering or otherwise, that the peculiarity in question would be perpetuated: and for the sake of those to whom double flowers are an attraction it is very desirable that the experiment should be tried, for assuredly this variety is one of the most desirable we have seen. On examining the flower more minutely, we found a calyx of three pieces of the usual form, but rather greener and more leaf-like than usual; within these were three rose-colored petals of the usual form, colour, and size. Within the petals was a row of stamens combined, with a cup below and above bearing imperfect and more or less petal-like anthers. These, which would be a defect from a florist's point of view, were completely concealed by the petals until the flower was pulled to pieces. Within these imperfect stamens came four or five tiers or whorls of petals, one above another, each tier or whorl consisting of brightly coloured petals of the same form and colour, and nearly of the same size as the normal petals. The extreme centre of the flower was occupied by a tuft of small irregularly shaped segments, exhibiting various transitions from the shape of the petals to that of the pistils, many of them showing imperfect ovals on their edges.

— One of the most exquisite plants for wreaths or for adorning dresses is undoubtedly CLEMATIS CALYCINA. Its tufts of bronzy, deeply divided leaves, from the centre of which hang the whitish bell-like flowers, render it one of the most elegant plants we know of. It is not often that we see it "in full bloom," and this winter with us it has been exceptionally full of bloom. Talking of wreaths reminds us of the grotesque abominations which one sees now and then on the heads of ladies or in the show-windows of fashionable milliners and artificial flower-makers. In a window of one of the most celebrated of these establishments at the West-end we lately saw wreaths of Daffodils and of Polyanthus Narcissus, not mixed in with but bearing pinnate leaves like those of Mahonia. After this we were not surprised to see large yellow Calceolarias treated as climbing plants; while Hops of bright gamboge and of clear magenta excited no particular astonishment. In these days, when knowledge and taste are supposed to be so much more widely diffused than heretofore, it seems a pity that artificial florists either do not copy Nature more accurately, or, ceasing to copy servilely, profit by her teachings, and adapt in a suitable and becoming manner the means to the end required. Pure conventionalism is far better than hideous or grotesque caricatures.

— HABROTHAMNUS ELEGANS under certain circumstances is not only valuable for its flowers, but also for the berries, which for a length of time have been very attractive in the temperate-house at Kew. They are purplish-crimson in colour, and some of the clusters may well be compared to bunches of small Grapes. As usually grown this plant does not produce fruit in any quantity, the only requirement, however, seems to be a freedom of growth, such as easily obtained by planting out.

— We learn that Mr. J. F. JOHNSON has resigned the CURATORSHIP OF THE ROYAL BOTANIC GARDEN, BELFAST, with the intention of devoting the whole of his time and energies to the more congenial occupation of a landscape gardener, in which profession he has already a fair share of practice in Ireland, and in other parts of the United Kingdom.

— THE ANNUAL DINNER of the *employés* of MESSRS. DANIELS, nurserymen, of Norwich, took place on the 9th inst., when the community of interest between master and man was pleasantly illustrated.

Home Correspondence.

Dracena indivisa.—Looking over the *Gardener's Chronicle* for Dec. 16, 1876, p. 785, I see what I think an erroneous statement respecting the *D. indivisa*. I have been acquainted with it some ten years. I first saw it at the Abbey Gardens, Trescoe, Isles of Scilly, where I was much struck with it, several being in flower. The gardener gave me some seed, and I was successful in raising several distinct plants. At the Vineage, in Galway, Penzance, there is a splendid plant, about 12 feet high, that has seeded, and plants raised from the same. Large plants flower and seed freely. There is a possibility for small plants to be taken for *D. australis*. I planted some two years since, in a very exposed situation, where they have no protection, and are only about 2 feet high. Your correspondent says that he dug one up after being planted two years, and found that it had multiplied sixfold, forming six handsome pot plants 30 inches high; and again, he says some planted out on the shrubs have reached 6 feet high in the same time. He really must be talking about something else, for with us it does not increase in this way, neither does it grow so fast. *J. G. M., Penzance*.

Lily of the Valley.—Mr. THOMSON, in addressing you on this subject, draws a comparison between *Lily of the Valley* and *Crucifera*, and the *Lily of the Valley* of Belgian origin. Now the two great sources from which our supplies are drawn is Holland and Germany; from the former they are imported in clumps full of flowering crowns, from the latter in single flowering crowns. I wish a number of which go to make up a potful, and it is these which are grown so much for Covent Garden. I have noticed the difference between the two, and an quite sure they are distinct varieties, the German being much superior. Now, without troubling you with my idea of the points of difference, I would say that flowers of each be sent to the *Gardener's Chronicle* office, and, if proved to be distinct, that Mr. W. G. Smith should favour us with an engraving. *F. H.* [Illustrations of the German and Dutch *Lilies of the Valley* will be given in the next issue of the *Chronicle*, and two plants are quite distinct enough for garden purposes. EDS.]

The Supply of a Family.—What extent of kitchen-garden ground and glass would be required to provide a regular supply of forced and choice vegetables, fruits, table plants, and cut flowers the whole of the year for a family of five persons, with two or three attendants and a constant influx of visitors? *B. C., North Durham*. [Your question is a somewhat difficult one to answer, as so much depends upon the special requirements of the family, and various other circumstances, such as situation, climate, soil, &c. However, assuming that "B. C." resides in the country, the extent of ground under cultivation for the supply of such a family should not be less than 4 acres, two of which should be inclosed with walls; the other 2 acres should surround the walls in the form of slips, bounded by an evergreen protecting fence. This quantity of ground, with a judicious system of simultaneous cropping, should produce a large and sufficient supply of hardy fruits and vegetables to meet any reasonable demand. The area and number of the forcing-houses must to a great extent be determined by the actual requirements. The vinery should not be less than three in number, and may average from 40 to 50 feet in length for the production of early, mid-season, and late Grapes. There should also be two Peach-houses of a proportionate size, and Melon, Cucumber, and Mashroom houses respectively. There should also be a house set apart for the forcing of the various products. These houses, with the usual appendage of frames, if judiciously managed, should produce a good supply. In making this calculation an unnecessary house I have omitted such as Pine-houses, Fig and orchard-houses, &c., which may be added at will. With regard to plant-houses for the production of plants for table and cut flowers, &c., it is very desirable to have two or three distinct stores, and to have a great difference in the general treatment necessary for stove plants. A large proportion of the thin, tender foliaged varieties require shade to insure perfect development, while on the other hand there are many flowering and fruiting plants, such as *Campanula*, *Coleus*, &c., which require full exposure to light to ensure anything like real perfection of character; therefore we shall say two stoves, two greenhouses, and two span-roofed pits with a passage down the centre for the production of the bedding-out plants, and also to come in handy for the culturing of soft-wooded plants for table, such as *Carnations*, *Mignonette*, &c. The 20,000 bedding plants required for planting out

will necessarily occupy considerable space, but as I should calculate that at least one-half of this number can be supplied in the shape of hardy plants which will prove far more satisfactory than such a host of gaudily coloured tender things, then the accommodation above indicated will be sufficient in the way of plants. To make anything like a trustworthy calculation of the actual labour required for the working of such a place, it would be necessary to know the nature and extent of the grounds and flower garden, as without this any calculation must be only approximate. Therefore I should say that eight to ten men, including the head gardener, would be ample to keep the whole in perfect order; but much, however, depends upon what the actual labour in the management is constituted. More than one-half of the plants in England are unseasoned, and are consequently badly managed. Large places and inadequate assistance is the order of the day, but such conditions give no real pleasure, profit, or satisfaction to any one. G. W.]

A Quick Method of Forcing Asparagus.—By the same post I have sent you a sample of Asparagus, and as my method of forcing may be different from any other, I beg to send you the details. I have forced two beds this season with great success. My first was taken from the ground on November 14, and from those crowns I cut on November 17, and continued so doing, with a daily yield of 50 bunches. My second bed was also begun taking up my second bed on December 1, and began cutting in six days after planting. At the time of writing I can cut about 150 beautiful heads daily. The plan I adopt is to place the roots in a bed in a tub-like casing of bricks, and to put a piece of glass to plant them on a thin layer of manure and soil, and after placing the roots thickly together I cover all over with a shallow dressing of soil, and then one thing only remains to be done to ensure success, and that is to give plenty of water, either in the form of liquid-manure. This mode of forcing has great advantages, inasmuch that it effects both a saving of time and also of material, and many who have hot-houses but who have not manure for forcing purposes can adopt it. One trial will, I am certain, prove satisfactory. *Clark, The Gardens, Milton Costable, East Dereham, Norfolk.* [We received a very good sample, and are much obliged to our correspondent for the hint. Eds.]

Eucharis amazonica in the Garston Vineyard.—Amongst the many objects of interest to be seen at this famous vineyard in this dull season is a gorgeous display of this beautiful Lily, the culture of which has been ably treated on by several correspondents lately in the pages of the *Gardener's Chronicle*. All or very nearly all agree that to do it well it is necessary, after the winter season's growth, to give it a period of rest, and then plunge in a brisk bottom-heat, when every plant will throw up flower-spikes in accordance with the strength of the bulbs. What prompts me to write of the stock at Garston is not the individual plants, but the manner in which the grower, as our readers must imagine one of those large span-roofed houses, the centre bed of which is filled from end to end with plants in robust health, all about in the same stage of growth, and yielding hundreds upon hundreds of flowers, with far marking purposes must be a very profitable investment. When we bear in mind how simple it is to grow and flower these plants, is it not surprising why any one possessing a hot-house or two should be without them? Taken as a whole, I must confess to never having seen anything to equal this display for uniformity of merit, and upon asking Mr. Cowan how such a result was brought about I was informed that nothing novel in the shape of treatment was tried. The plants had a good season of rest in a cooler temperature than is generally given to them, and that "well-watered" Vine, and that it can be grown to perfection under such circumstances there can be no doubt. The Vine is just breaking, and promises well, and I should say that a visit to the Garston Vineyard next July or August ought to satisfy those who complain of the want of this Vine. It is whether it is worth house-room or not. W. Hinds.

Superheating Vine Borders.—Would it not greatly facilitate the arrival at a correct estimate of the value of superheating Vine borders if it were possible to obtain an exact comparison of the relative temperatures of soil and atmosphere in which trees in a state of Nature first start into growth in the spring? Such an experiment should not be difficult of execution, as a thermometer might be fixed in the head of the tree, and another placed in a hole in the ground at a distance of 8 to 10 feet from the trunk, and the depth at which the roots are found. In this way a fair guide

might be found as to the relative differences of temperature for roots and branches essential for successful Vine culture. It is assumed that with Vine roots inside the temperature of the border there is equal to that of the house, but the probability is that it is considerably lower. This will no doubt be the case with trees growing in the open air. In the case of Vines with the roots outside of the house there can be little doubt that without artificial heat the difference at starting time would be considerable, and that with the application of artificial heat the difference would be extremely unanalogous. The obvious course in such a case would be to bring the temperature of the border somewhat nearer to that of the house by means of leaves, manure, or other heating material, but the danger in this case lies, not so much in exciting the border roots to action as in the soil, which is unduly apportioned, the greatest heat being applied to the surface-roots, whilst those several inches in depth scarcely feel the stimulus. Probably the most natural temperature for outside Vine borders would be found by covering the border during the spring with a temporary glass protection, and this course would doubtless be found safer and more satisfactory in the long run than in applying fermenting material, as the mere exciting unduly of surface-roots is not the best idea of the Vine culture. D.

Veitch's Self-Protecting Broccoli.—In your review of the "Fruits and Vegetables of 1876" I observe you do not notice the above Broccoli. Although situated as this place is, high up among the hills of the North of Wales, I have corresponded with Mr. Johnston, have indeed found it to be the gem of the first water, and I think the following particulars respecting this excellent vegetable cannot fail to be interesting to many of your readers. In June last we planted out which began to be ready for cutting about the middle of November, and from that time up to the present (Jan. 6) we have been cutting from six to ten fine heads almost daily, and when cooked their delicate flavour and tenderness leave nothing to be desired. Where vegetables are wanted in quantity during the winter months every gardener should have a good stock of this choice Broccoli. It only requires to be known to become a garden necessity. *J. Melville, Hutton Hall, Guisborough, Yorkshire.*

The Scarcity of Holly Berries and Bees.—Few but a philosopher like Mr. Darwin would have thought of linking these two facts together as cause and effect. It may, however, be so. Wasps, too, of course, may be held to be bees in this manner, and the scarcity of them may start the spring of the present year was notorious. I have noticed that wasps frequent the Holly a good deal in the spring. Of course, too, the movements of bees and of wind is more important to such plants as the Holly than to most other plants, and the male of the former is not only on the same plant but in the same flower. Neither does the scarcity of bees theory cover such exceptional facts as the one I recorded—one tree among thousands being literally coralled o'er with berries, and the male of the female of the same tree that matter, neither does the severity of the weather nor of drought explain such exceptions; still I am inclined to think the severe cold when the Hollies were in flower had much to do with the destruction of the crop, just as it destroyed Apples, Pears, Plums, Gooseberries, acorns, Beech-mast, and other fruit-bearing flowers by wholesale. No doubt the Holly is a hardy plant—very hardy, in fact; so is the Oak; but, nevertheless, I have seen Oaks killed dead by May frosts; and hence it is reasonable to suppose that Holly may be frost-killed by the same means. The power of bearing berries by frosts biting them hard when in full bloom. No one knows better than Mr. Darwin that the ability of plants to resist cold is a matter of condition rather than of constitution. A plant may pass through zero unscathed when at rest, while all its embryo fruit may be cut off, and even its life be destroyed, by from 10° to 15° of frost out of season. Thus it comes to pass that the cold a plant may safely endure in its own climate is no safe criterion of what it may withstand in another country, inasmuch as in the latter the cold may come upon it in a different stage. Alike in regard to maturity or state of growth, spring frosts, for instance, are not destructive in the ratio of their severity, but rather in the degree of their seasonableness. The plants are allured to abnormal tenderness through far promises of fine weather that are not fulfilled, or unwise cultural devices, and the plants thus taken unawares, and in a tender condition, succumb to the cold. It would, however, be interesting to know the accuracy of bees or wasps was co-extensive with the scarcity of Holly berries, and whether that scarcity was at all affected by the proximity, or otherwise, of hives of honey-bees, which were active last spring in some localities. In regard to this place, for I have not seen a fly or a single berry within more than 500 yards of

them; while the solitary example of a bush laden with berries was nearly double that distance from any honey-bees. Also how far the scarcity of bees would be likely to account for the scarcity of spaw, acorns and Beech-mast, which are almost as rare as Holly-berries in some localities this season. Much Clover seed was also grown in this and other parts of the kingdom; perhaps some of the old agricultural readers of the *Gardener's Chronicle* will say whether the scarcity of Clover seed last year was general. It was a good crop in some localities this season. I have no remark of course, being confined to the honey-bee and its produce, and having no reference to the wild bee or wasp. The latter were very scarce throughout the earlier parts of the season, though they put in a pretty strong appearance here for their share of mallow fruit in the latter part of the season.

— I beg a little space in your journal to confess my error with respect to the cause of the scarcity of Holly berries. I have been convinced of this by the two communications in your last number, by the statement to the *Gardener* by Mr. Fish, and by some private letters which I have received. It appears that several causes in combination have led to this scarcity; but I still think that the rarity of bees of all kinds in this neighbourhood during the spring, of which fact I feel assured, must have played a part, though a quite subordinate one. *Charles Darwin, Down, Beckenham, Jan. 17.*

— There is little doubt that several causes may have made the scarcity of Holly berries last year appear so very general. I have been struck by this. Darwin's hypothesis of bees not fertilising the blossoms is not one of the causes, for bees last year were very plentiful, and the hives stronger than usual. I never before knew such crops of the white Clover as were seen this season. The hives were in the open air, pasture-field and roadside being covered with plants in flower. The bees, therefore, had plenty of food, and an excellent honey harvest was the result. There are immense quantities of Hollies in the hedges and plantations in this district, and in the spring, and the fallures in their berry-bearing are all alike. On the outskirts of Sherwood Forest there are some very long hedges of tall Hollies, and it is only where the bushes have been sheltered with trees that any berries are to be seen on them. The Holly likewise grows and prospers on some magnesian limestone crags near this, where the soil on the surface is very thin, but no berries were produced on the bushes last year, although they usually show more berries than the bushes grown on rich soils. *William Tillyer.*

— I have been struck by a confirmation of Mr. Darwin's theory of insect fertilisation as occurred locally here this year, where our Holly trees are a "glorious sight," as Evelyn well describes them when covered with their coral berries. We have generally myriads of insects in the spring and summer, and also several strong hives of honey-bees quite close to the Hollies. One old bush never fails in any season to have a fine crop of berries ever since it was nearly ringed or barked round by rabbits some severe winter several years ago. *T. R. B.*

The Blackthorn in Bloom on January 9.—It is not nearly three months in advance of its usual period of flowering? I have not been able to go and see the hedge, but I am assured that there are several sprays of white blossom out in full beauty on some Blackthorn near here; so "spring is bidden" as Mr. Howitt termed this flower, has been fulfilled this year. Primroses have been in blossom in the garden for some weeks. *Helen E. Wotney, Linn, Hants.*

Luminous Mycelium.—In the *Gardener's Chronicle* for December 4, 1875, p. 719, will be found an illustration and description of a remarkable case of phosphorescent fungus-spawn found permeating the wood of a rotten stump in the garden of Captain King of Chidbury, Peterfield, who kindly forwarded the original materials to us, has kept the spawn-infested stump in view, and the mycelium has now produced a dense crop of Agaricus fascicularis. Captain King has obligingly sent me another portion of the insect sent by Mr. Mitchell, and he suggests, very apparently spring from the same dense white spawn which was luminous a year ago, but it is not luminous now. *W. G. S.*

The "New Danger for Orchid Growers."—I am obliged to Mr. McLachlan for recalling my attention to the notice of the Embic contained in my friend Lucas' work on the *Insects of Algeria*, in which it is distinctly stated that the young Embic inhabit little silken tunnels, as was also stated to be the case with the insect sent by Mr. Mitchell, and he suggests, in the *Gardener's Chronicle* that the web was probably spun by a species of spider common in Orchid-houses is not supported, although not actually disproved. I have since, however, received a further communication from Mr. Mitchell, and he has forwarded roots and webs, with the statement that he had "seen the insect make its web, apparently for

porposes of concealment, with some organs situate in or near the head; also you will observe the *debris*, i.e., the scales extruded, which resemble wax, and certainly resemble that of some *Vinea larva*, and is certainly not that of a spider. *L. O. Watwood.*

Inside v. Outside Vine Borders.—When such men as Mr. Henderson, who, I believe, has taken more first prizes for Grapes than any other grower, and Mr. Wildsmith, who bids fairly to do as much in the future as Mr. Henderson in this respect, would exclaim, "I may well exclaim, "When doctors differ, who shall decide?" My own experience in Vine culture, as compared with these gardeners, is indeed small; but, nevertheless, I find that white Grapes keep far better and ripen better when planted in inside borders, than the latter give certainly there is trouble in watering. In the case of early Vines, I have always seen inside borders preferable. I am sorry to differ with such champions, but experience alone tells me to plant in inside borders. *R. Gilbert.*

Notes on Grapes.—Observing several inquiries concerning Mrs. Pine's Black Muscat Grape, I am inclined to give you some remarks, and also of my experience with it. I have it worked on Lady Downe's, both sorts bearing; the bunches are very large, with fine berries, but lacking colour, and the bunches partake somewhat of the parent shape, viz., large shoulders and conical bunch, but not so particularly one-shouldered as Lady Downe's. Another, inched on Black Prince, does very well, colouring almost to perfection, with pyramid (inverted) shaped bunches; both these are growing in a late-forced vinery. A third, grafted on Black Hamburgh, both bearing, colours equal to the parent, quite black; this is in a mid-season vinery. I am convinced that Mrs. Pine's requires a longer season, with less fire-heat. Black Alicante does equally well on Lady Downe's and its own roots with me. Even Black Alicante does well on Black Hamburgh, and throws very long bunches, with rounder berries than upon its own roots; upon Black Hamburgh it does well, and the bunches in shape partake of the character of the Black Hamburgh or parent. I don't know better stocks than Foster's Seedling and Black Hamburgh; the former is a remarkably free grower, requires more restraining or pinching than any other I know of. I find stocks influence the style and character of the bunch more than most writers venture to observe or state, and I have tried a good many one time another. With regard to the best place for Black Alicante first, Lady Downe's second, Mrs. Pine's third, West's Saint Peter's fourth, Gros Guillaume fifth, Gros Colman sixth; (the latter requires a long season to grow it to perfection, with plenty of heat, and is the noblest looking Grape grown.) Of white Grapes Muscat of Alexandria and Bowood are best flavoured, but Syrian and Trebbiano for late keeping, also White Lady Downe's. Perhaps I may give you some further remarks about early Grapes on another occasion [viz., do]. For information of other gardeners, and the chief question is, "How do his Grapes look?" and I am sure Dr. Lindley was't far from what he said, "A good supply of Grapes covered a multitude of sins." *A. S. Kemp, Haxton Garden, St. Paul.*

A Holly Tree Fruiting Twice the Same Year.—As there has been a good deal of correspondence lately about Holly berries, I send you the following, *quantum valet*. Some few years ago I had a shooting place in Argylshire, and on one part of the ground was a very fine Holly tree, which had one summer a splendid crop of berries. As the summer passed the berries disappeared, even, I conclude, by birds, or blown down. To my astonishment, a second crop appeared, equally fine, the same winter. The tree was covered from top to bottom both in summer and winter. It strikes me that this is rather a singular circumstance, and I do not think I have had anything to do with the fructification of the berries, as I doubt if there were any near, as it is in a wild part of the county. The tree was on a hillside, facing I should say, about E.S.E., sheltered, and near a salt water spring, and was surrounded by a hedge. It is now still is, a very fine tree. That winter was an exceptionally cold one—snow and frost for three or four weeks continuously, and woodcocks most abundant. *Russell Todd, Jan. 13.*

The Clive House Seedling Grape.—This Grape, for which the Fruit Committee of the Royal Horticultural Society, at their meeting on December 6, 1876, awarded Mr. D. P. Bell, Clive House, Alnwick, a First-class Certificate, was raised twenty years ago in the garden of His Grace the Duke of Northumberland, Alnwick Castle, by William Casley, who was, as most of us are employed in the forcings there. The female parent was Black Morocco, impregnated with the pollen of

White Syrian, for the purpose of causing the former to set its fruit better than it had been in the habit of doing. After being fairly tested, all but the very ripe of the berries were noticed as being of unusual size. From these Mr. Casley saved seeds, which were sown by him, and which produced several plants, the fruit of some being black, and that of others white. After being fairly tested, all but the very ripe were nearly worthless. These two are still in cultivation in the houses there, that for which the certificate was awarded being one of the two. My only motive for interfering in this matter is that honour may be given to whom it is justly due, and that this excellent Grape may be sent out under a false name. I may also state that Mr. D. P. Bell has only had it in his possession for the last few years. *Robert Ewolt, The Gardens, Chillingham Castle.*

Notes on Vine Culture.—I have more than once been struck with the apparent difference in the product of Hamburghs and Muscats upon the same soil. Indeed it may be a question for physiologists to solve whether or not these two kinds of Vines may be termed distinct species. Though I have seen cases where Hamburghs are more at home and succeed better than Muscats, and vice versa, I am inclined to think that the difference in the results of Muscat culture on different soils is even greater than the difference in the Hamburghs, and perhaps more especially in their keeping qualities. To illustrate this point I would refer to the successful case which I think that Mr. Denham, the Duke of Roxburgh's gardener at Broxmouth, used to show at Edinburgh over a dozen years ago. They were large in bunch and berry, and better in that respect than those grown at Floors, but for keeping qualities I am not in a position to judge, they could not be compared. The same thing also, I might say, is the case here after with my experience of Muscat culture at Elvaston. All things being equal, I think finer looking Muscats could be grown at Elvaston than could be grown here, but after being ripe they would not keep nearly so long as at that rate. I should have no difficulty in keeping good Muscats here well into March, whereas at Elvaston they were finished, and I might say in good time to make the most of them by about the new year. A soil that produces good bunches of Muscats is bound to be equally good to be able to sustain their keeping qualities. However, I am inclined to think that inside and outside roots also exert a great influence on the keeping in proper condition of late Grapes. If the roots are wholly inside, and the soil is of a porous nature, they will be inclined to lose the pecuniary life of late Grapes without shrivelling to keep the border without water, which is to be avoided, for the proper atmospheric condition. Outside borders for late Grapes, protected with litter, and a proper atmosphere in the house, would be the best mode of culture in any locality. The Vine is such an accommodating plant that it might be said that only with very early Grapes is so much care required, and these as far as possible, for various reasons, should be substituted with late Grapes or with those of the previous seasons on the early kept, and in the time of ripening. Vines on when the atmospheric conditions tend to give the cultivator more tendrils than bunches, by watering with water of too high a temperature, and when the Vines are in an early stage, causing the shoots to make way without the proper vigour that the cultivator would desire. Circumstances do a great deal in Vine growing. Last autumn in looking at the early Vine border here, which is inside as well as out, I observed that where the front sashes were up (the house being a lean-to), with the sashes being open to the south-west, early bunches were to be found in this very damp part when I could find none elsewhere, the Vines being in a state of rest. Too much moisture in this part caused an untimely root-action. What the general deduction from observations in Vine culture is every cultivator who has followed a reply to me will be the same time from his friends so as to make his practice safe. *R. Mackellar, Ayr, Auld Hall.*

Saponaria acyminodes.—In a recent number of the *Gardener's Chronicle* a correspondent inquires if seed of this plant preserves its vitality for any length of time, or whether it should be sown as soon as gathered. As I have not the value of a reply, I will answer from the result of my experience, and it is to the following effect:—That well-ripened seed of this plant will, in a temperature of 55° to 65°, vegetate freely at any period within a year of its maturity, and in a moderate percentage give an interval of four or five months so that the correspondent has a fair right to conclude that the seed supplied him, and which failed to germinate, was old or defective in quality. *East Anglian.*

Fermenting Materials on Vines.—Borders.—Mr. Hino's theory and my practice differ very much with respect to the value of fermenting materials for horticultural purposes, and I fear his remarks are calculated to mislead, I fail to see how he could

produce ripe Grapes in May, where all the roots are outside, without the aid of the old-fashioned dung-bed. If we start two vineries at the same time and under the same conditions in November and December, using manure on one and not on the other, the benefit arising from the hot dung will soon be very evident, teaching us not to despise the old plans. Whatever differences of opinion may exist with regard to the practice of starting early pot-Vines in bottom-heat, the results are more favourable with it than they are without it; an abundance of roots in a healthy condition is the most essential element in the successful culture of the Vine. It is hardly possible, and quite unnecessary, to start the roots in advance of the top, as they rarely start naturally before the fruit is thinned or sometimes stoned, as may be seen by growing a plant in a glass pot, which is dependent on here a slight time-lapse which is worthy of notice. After planting a Waltham Cross Vine, I noticed a lump of transparent gum exuding from the cut on the main rod; this in a few days became quite hard, and would not dissolve in cold water, but I found it would readily dissolve in warm water. I think this proves beyond a doubt that the hard condensed sap in well ripened Vines requires a moist warmth to set the sap in motion and push the Vines into growth. If we cut a pot Vine off level with the soil, and plunge it in a warm manure-heap outside, where the top remains cold, we find it soon commences to bleed, or as some would say to set the pump going; and it will be found that the roots will not move before the Vine has started at the top again, whereas had it been put on the same temperature in the same nature it might not have moved at all. I once made a plug of Muscat wood to stop a hole in the pipes; this started into growth, and showed a fine bunch of Grapes, whereas had I put it into a hole in the dry hot flue of the same temperature, the pipe would have perished and lost its vitality. It is not an unrefreshing occurrence for Vine eyes when put in to push into growth five or six leaves, and show a bunch of Grapes before making any roots whatever. *J. J. Goodacre, Elvaston.*

Forestry.

As most of the moorland devoted to planting is too wet for the purpose without drainage, underground drains are the best of all other systems designed to be the best for thoroughly drying the ground, but is less adapted for arboricultural purposes than those of agriculture; not that forest trees are less appreciative of well-drained ground than corn or Turnips are, but the comparatively large expense entailed in doing the work being about three times greater, acre for acre, than for open surface drains, and the insurmountable difficulty of preventing the tree roots from penetrating the soil till they reach the tiles and choke them. The soil being rendered loose and open in this way, the drainage drain, becomes on the whole still more attractive to the roots of the trees than the surrounding unbroken ground, hence they soon fill the drains.

Many plans have been proposed for remedying this evil, but none have hitherto proved available or successful. The depth of drain, description of soil, size of tile, &c., severally aid in determining the length of time the drain will act without being choked by the tree roots, but under the most favourable circumstances they will reach them, and render them useless. A modification of the underground tile drain has also been tried, and not without success.

It is constructed in the following manner:—The drain is first cut to the usual depth, 33 to 40 inches, and filled with tiles proportionate to the quantity of water it is to contain, and filled in to about half its depth. It is sloped on the sides, and made in all other respects the same as an ordinary open surface drain. The advantages of this over that of the common tile drain is that the roots are longer in reaching the tile, on account of the sloping exposed surface they must traverse before reaching the loose soil in the bottom of the drain; and often they do reach the tile, and ultimately choke it, so as to force the water to the surface. It then acts as a common surface drain, and in that capacity does its work without entailing any additional expense either by deepening or enlarging the drain in any way.

No part of the surface of a plantation is so completely interwoven with the roots of trees as the margins and bottoms of drains, footpaths, and places rendered bare, whether of herbage or soil; and such being the case it is both expensive and hazardous to deepen existing drains, for the obvious reason that in doing so roots are necessarily cut to such a degree as to cause many trees to be blown down by the first severe gale that occurs.

the island, and with its silvery bark, scanty, light-coloured foliage and dwarfish aspect lends quite a peculiar character to the general herbage of the country. A dwarf Casuarina, generally from 3 to 9 feet in height, and commonly called a Swamp Oak by the Australians resident in the island, occupies irregular patches on the hill-sides near the coast. The wood is tough and the form of the shrub elegant, but in masses the effect is sombre and unpleasing.

In Nouméa itself the usual tropical ornamental shrubs are to be seen, such as Flamboyant (*Poinciana regia*), Oleander, Bougainvilleas, *Bignonia venusta*, Aloes, with young specimens of *Coccoloba* and *Date Palms*. In the neighbouring jungles numbers of *Freyinetia* and *Cordylines*, with a few Ferns, *Blechnums*, *Lygodiums*, *Davallias*, a *Gleichenia*, a *Pteris*, and large masses of *Asplenium Nidus* may be found. Further inland—but it is never possible to get far from the sea, the island being about 230 miles long, and only 40 in width at the broadest part—very irregular and isolated patches of jungle are to be met with, generally, but not always following the course of a stream. Their appearance is very striking. The upper foliage is extremely dense and massive—frequently almost as dark in tint as Ivy, and matted together with heavy-follied creepers. In the midst of this, and in striking contrast with it, may be seen the snow-white foliage of the *Kekane*, or *Candle-nut tree* (*Aleurites triloba*). As a rule, there is very little undergrowth, such as Ferns, mosses, Orchids, &c., in the jungles of the southern part of the island of which we have been speaking. *Cordylines* are quite a feature in these forests, as is in the damper places a certain species of *Araliaceæ* closely resembling *Theophrasta*, and I have come upon splendid white *Lilies* at the edges of the forest at considerable elevations. Sometimes the ground is perfectly bare, scarcely a moss being seen even on the trunks of the trees, and it is possible to move about with the greatest ease and security, except in the neighbourhood of the *Supplejack*. At other times the jungle is a mass of creepers, through which it is extremely difficult to penetrate, but the contrast is always most marked between these and the jungles of South India, Ceylon, or Java.

In all the forests of New Caledonia that I have been in, the shade afforded is most complete, and this may possibly have something to do with the absence of ground vegetation, but I am inclined to think that it is the porous character of the subsoil and the consequent rapid draining away of the moisture that renders the surface so unsuitable for the growth of Ferns and mosses. In the North, where the rainfall is heavier and the geological formation different, consisting chiefly of schists and slates, the forests are both more extensive and really very rich in the undergrowth spoken of—as may be seen by the fact that they contain something like 200 species of Ferns and over 120 mosses. Some of the valleys south of Balade on the north-east coast where Captain Cook first landed, are very steep and densely clothed with forests, suggesting splendid opportunities for the cultivation of Coffee after the Ceylon system; but I was told that the force of the wind is so great during the cyclones which visit the island in the early part of the year that Coffee trees would be torn bodily from the ground and their cultivation under such climatic conditions is, of course, hopeless. At Kanala, about 100 miles to the south-east of this part of the coast, I visited the largest Coffee plantation in the island. This is one of the few spots where any alluvial soil is to be found, and the proprietor of half of it (100 acres) has about fifty planted with Coffee, the rest being under Rice, Maize, Sugar, or Manihot cultivation. Even under such favourable conditions of soil as this, it is found necessary to manure the Coffee trees in order to obtain a satisfactory crop. Several varieties of

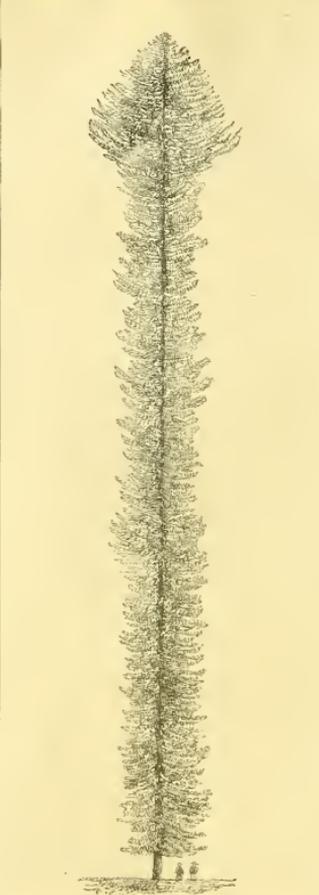

FIG. 13.—ISLET OFF NEW CALEDONIA, WITH *ARAUCARIA COOKII*.

Coffee have been employed, and the trees are planted 8 feet apart and in rows 8 feet wide, so that it is possible to plough up the weeds between them. The plants are topped at 5 or 6 feet and

the primary branches allowed to grow unpruned in any number from the stem, so that the tree presents an extremely bushy appearance totally different from that of the best crop-bearing trees of Ceylon. Even under these conditions individual trees will bear 2 lb. or more of Coffee (prepared), and 7 or 8 cwt. per acre in a favourable year may sometimes be gathered. The injurious prevalence of the black-bug (*Capnodium*) fungus proves that the climate is somewhat too damp and perhaps too cold for the perfect growth of the plant. A white ooccus, too, does a certain amount of injury, but the "leaf disease" of Ceylon, and South India (*Hemicelia vastatrix*) is here, as in Java, totally unknown. The crop-time generally extends over the five months of wet season and considerable difficulty is experienced in drying the parchment coffee for market. At present there are in all about 150 acres of Coffee in the island, planted almost entirely on small alluvial flats, and the annual production, except in a good year, is barely sufficient to supply the wants of the colony; and unless some of the sheltered valleys in the north can be planted up—which as yet has not even been thought of—it seems probable that the importation of this commodity will continue. The only article of consumption that is not imported is sugar. Special efforts have been made and special privileges granted by the Government, in the shape of cheap convict labour and suitable lands in order to make this enterprise successful. The cultivation is chiefly carried on on the west coast from Nouméa northwards, where alluvial flats are more extensive than elsewhere; but these have long ago been all taken up, and the production of sugar has as yet but rarely allowed of much more than a nominal exportation. The fact is that, what with the difficulty of obtaining labour and the natural poverty of the soil, there is little hope that the island will ever yield much more than an ample supply for its own population of 12,000 or 15,000 whites (convicts, Communists, soldiers and settlers), together with its 20,000 or 30,000 Kanaks, in any one of its articles of consumption, unless it be sugar, and even this I think is very doubtful. Several old Bourbon sugar-planters are settled in the colony; one of them, M. de Greslan of Dombes, near Nouméa, kindly showed me all the objects of interest on his estate, which consists partly of alluvial lands suitable for Sugar, Maize, &c., and partly of mountain jungle and grass. From ten to twenty varieties of cane I was informed are cultivated on this estate, the work being chiefly performed by Tamil coolies, formerly imported into Bourbon and exported thence into New Caledonia. Maize, though planted year by year, is frequently a complete failure, on account of the ravages of a brownish-coloured ladybird when the plants are young.

Under the shade of the forest M. De Greslan was planting Coffee trees, those which had been previously planted in the open not having proved a success. He informed me that there were no less than 112 varieties of fruit trees on his estate—Mangoes, Oranges, Rambutans (*Nephelium lappaceum*), Loquats or Japanese Medlar, *Coeur de Boeuf* (*Anona reticulata*), *Soursop* (*Anona muricata*), Pine-apples, Strawberries, *Cerises de Brazil*, *Moreton Bay Chestnut*, *Sapodilla plum*, &c., and that he had been at considerable expense in trying to introduce foreign fruits into the island. He has had to contend with an ineradicable weed called Tea-shrub, which is very disheartening. In the neighbourhood of Nouméa, Potatoes, Cabbages, French Beans, and other European vegetables are cultivated, chiefly by *libérés*, or ticket-of-leave men, in the same gardens with the *Papaya* (*Carica Papaya*) and the *Banana*; but the want of water

for irrigation, as well as for other purposes, is very severely felt, and the vegetables and fruit for the supply of the town are chiefly brought from a distance. The natural grasses of the country are

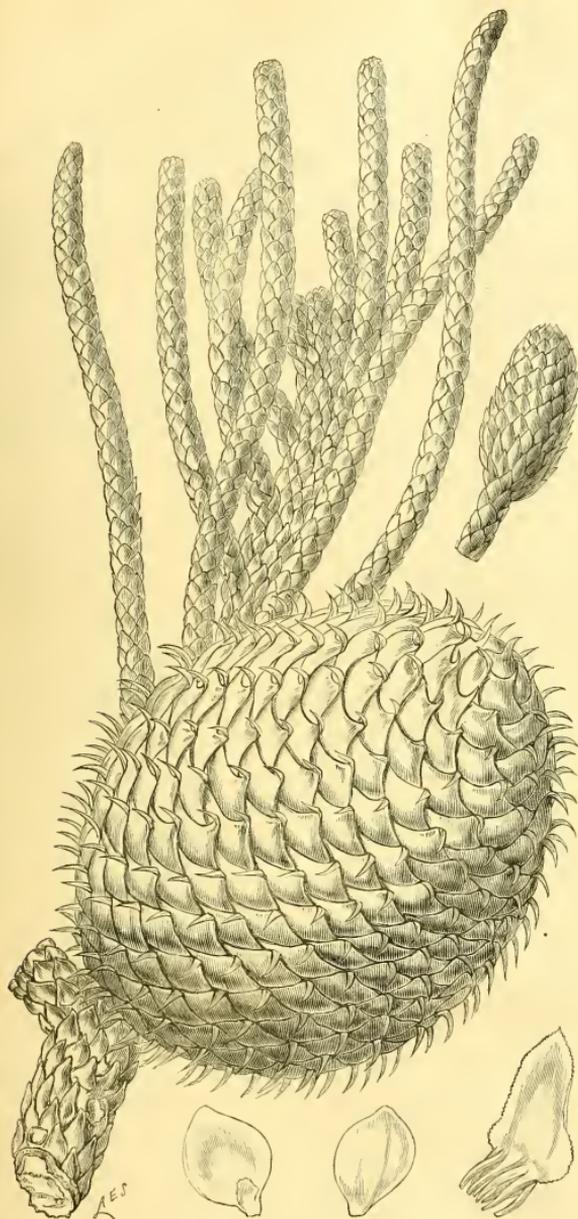

FIG. 14.—ARAUCARIA COOKII. (FROM *Bot. Mag.*)

considered by Australian stockmen to be very poor for the purposes of pasturage, and one of them (*Andropogon austro-caledonicum*, I believe) possesses a spiky seed-case which is said to penetrate

when swallowed by sheep into every part of the body. The land consequently must be eaten bare by cattle before smaller stock are turned on it. Another pest, which threatened at one time to be very injurious, was

Asclepias curassavica, said to have been introduced in soldiers' mattresses from Bourbon or Tahiti. This plant was rapidly overgrowing many of the pastures when a fritillary butterfly appeared in enormous quantities, both in the larva and imago form, and ate it down to the ground. It is perhaps worth suggesting here that this plant may possibly prove of great service to the island, as the *Lantana* promises to be to Ceylon and Southern India, through the renovation of poor or exhausted soils by the deposition of humus.

There are either four or five different species of New Caledonian Pine found in the island, the principal of which is *Araucaria Cookii* or *columnaris*—the one discovered by Captain Cook in the southern parts of the island and on the adjoining Isle of Pines. Some of these trees attain a height of 200 feet, and they appear to thrive best on little rocky islands a few acres in extent or close to the sea. They have a somewhat curious habit, even when growing alone, of shedding their branches for five-sixths or more of their height, and then replacing them by a smaller and more bushy growth, so that the tree at a distance presents a very columnar appearance, the resemblance being increased by the summit being crowned with a mass of foliage somewhat like a capital (fig. 13). The natives do not unfrequently plant these trees in their burial grounds, or rather in the hills of bush where they expose their dead to the birds and the hermit-crabs.

As to the natives themselves, there is very little chance of making them generally useful in the cultivation of the land. Although very muscular they are extremely lazy and independent, and will not submit readily to the necessary discipline of plantation life. Indeed, one can scarcely expect men—many of whom at an earlier period in their lives have been cannibals, and who have indulged themselves with the mad excitement of native warfare—to settle down readily to the humdrum employment of hoeing corn. Other tillers of the soil have consequently to be obtained, by means of labour vessels, from the neighbouring islands, or else by the importation of Tamil coolies from Bourbon. This latter is by far the most successful plan as yet adopted, but it has only been carried out to a very limited extent. The Tamil is exceedingly docile, and though not very muscular, it is surprising how much work he will get through if properly managed. The Kanak, on the other hand, is very difficult to deal with, and the manner in which he has been obtained is not likely to render him cheerfully amenable to the requirements of the planter.

The food which the natives used before the arrival of Europeans was almost exclusively the Taro, I believe of two kinds (*Colocasia esculenta* and *macrorhiza*), which were cultivated in terraces on the hillsides where water was available for the purposes of irrigation. The root of the Fern (*Pteris esculenta*), so universally eaten by the Maories of New Zealand, was scarcely ever used by the Kanaks of New Caledonia. The pith of *Cycas circinalis*, which is common, is often made into a kind of sago and eaten. A few fruits, but none of much importance, are eaten; nor have the natives much animal food except the flesh of pigs that have run wild since their introduction by Europeans. There are no wild animals indigenous to the island—the only ground game ever hunted by the natives being the *Kagou* (*Rhinoceros jubatus*), a member of the same family living in the woods, that has enjoyed security from four-footed enemies so long that it has lost the use of its wings, and can be easily captured by dogs. Young birds, the size of thrushes, I have seen native women transfixing with pieces of stick and roasting alive before the fire. When the locusts make their appearance, as they sometimes do, in enormous swarms, the natives readily procure a meal by setting fire to the grass on a hill-side, and picking up their food ready roasted after the flames have passed.

At the present time it is perhaps somewhat early to form a decided opinion as to the ultimate capabilities of the island when plants from all parts of the tropical and subtropical world shall have been introduced for the purposes of acclimatisation. It is possible that some may be found to overspread the waste places of the island and to impart a fertility to the soil which it does not at present possess, but it may be assumed that as some of the hardiest specimens of tropical vegetation, *etc.*, *Lantana*, *Ageratum*, *Couch-grass*, have failed to make any progress except in very isolated spots, the prospects are not very promising.

It may be mentioned that owing to the absence of

jungle vegetation and lowlands, as well as on account of the narrowness of the island, the climate is extremely healthy, no case of epidemic sickness (unless recently imported) having ever been known in the island, although the fitness of the low-lying parts of Nouméa, owing to the utter absence of any sewage system, is such that it seems little less than a miracle that the town has escaped so long. *R. Abbay.*

Obituary.

It is with the greatest regret that we announce the death, on the 11th inst., of ALFRED SMEE, Esq. An enthusiast in whatever he undertook, he threw himself as warmly into the pursuit of gardening as into the chemical, electrical, surgical, and other subjects in which he attained fame. His garden at Wallington was a perfect epitome of all departments of gardening, useful and ornamental; a keen lover of Nature, he had gathered together a vast variety of interesting plants. Nothing came amiss to his wide sympathies in this way, and if bedding plants were nearly excluded from his garden it was because he liked them less than other plants. His collection of hardy fruit trees was one of the largest of any private collector in this country. The outcome of his garden experience was manifested in his richly illustrated work, *My Garden*—a treasure-house of information for amateur gardeners. Mr. Smee was for some time chairman of the Fruit Committee of the Royal Horticultural Society, and served on its Council. Few men had clearer and juster notions of the duties and objects of the Society, or was more emphatic in giving them utterance. His feelings were always those of a staunch horticulturist, firmly impressed with the conviction that the Royal Horticultural Society, if it were to take its proper position as the national representative and exponent of gardening, should devote all its energies to scientific and practical horticulture. In private life Mr. Smee was beloved for his unvarying kindness and liberality of spirit. As we hope in a short time to publish a portrait of the late Mr. Smee, we defer for the present any further notice of his career.

The Weather.

- Jan. 11.—Overcast, dull, and cold. Strong wind. Occasional rain.
- 12.—A very dull, cold, foggy day. Hoar-frost on ground all day.
- 13.—A fine bright cold day. Fog in morning. A little thin rain about 7 P.M.
- 14.—A dull miserable wet day. Cold and damp.
- 15.—A fine pleasant day. Mild and bright. Shower of rain in early morning.
- 16.—Very fine and bright till 3 P.M.; dull and overcast after. Thin mistral rain in A.M. and P.M.
- 17.—A dull cloudy day. Frequent thin rain. Very mild. Cloudless at night.

LONDON: *Barometer*.—During the week ending Saturday, January 13, in the vicinity of London the reading of the barometer at the level of the sea increased from 29.08 inches at the beginning of the week to 29.55 inches by the morning of the 8th, decreased to 29.48 inches by the afternoon of the same day, increased to 30.05 inches by the morning

of the 10th, decreased to 29.66 inches by the morning of the 11th, increased to 30.07 inches by the morning of the 13th, and was 30.07 inches at the end of the week.

The mean reading for the week at sea level was 29.75 inches, being 0.46 inch above that of the preceding week, and 0.17 inch below the average.

Temperature.—The highest temperatures of the air varied from 55° on the 9th to 35½° on the 12th; the mean value for the week was 46½°. The lowest temperatures of the air ranged from 29½° on the 12th to 44½° on the 8th; the mean for the week was 37½°. The mean daily range of temperature for the week was 9½°; the least range in the day being 5½° on the 11th, and the greatest 13½° both on the 9th and 10th. The mean daily temperatures of the air and the departures from their respective averages are as follows:—7th, 45°, 3, +12°; 8th, 45°, +11°; 9th, 48°, +11°; 10th, 41°, 8, +5°; 11th, 38°, 4, +2°; 12th, 32°, -4°; 13th, 36°, 6, +0°. The mean temperature of the air for the week was 41° 9', being 5° 6' above the average of sixty years' observations.

The highest readings of a thermometer with blackened bulb in vacuo, placed in sun's rays, were 80½° on the 7th, 73½° on the 9th, and 70½° on the 12th; the lowest 28° on the 12th; the highest recorded by this instrument. The lowest readings of a thermometer on grass with its bulb exposed to the sky were 24½° on the 12th, 30½° on the 13th, and 33½° on the 10th; the mean value for the week was 34°.

Wind.—The direction of the wind was S. W. and N. E.; and its strength brisk at times. The latter during the first five days of the week was dull, wet, and very mild; on Friday and Saturday the weather was somewhat finer, cold, but foggy.

Rain fell on five days during the week, the amount collected was 1.88 inch.

ENGLAND: *Temperature*.—The highest temperatures of the air observed by day were 55° at Blackheath and 54° at Truro; at Hull 48° was the highest temperature; the mean value from all stations was 51°. The lowest temperature of the air was 27½° at Nottingham; at Portsmouth and Norwich 32° was the lowest temperature. The mean value from all stations was 39°. The range of temperature in the week was the greatest at Blackheath, 25½°, and the least at Bradford, 18½°. The mean range from all stations was 21½°.

The mean of the seven high day temperatures was the highest at Truro, 50½°, and the lowest at Hull and Sunderland, both 43½°; the general mean from all stations was 46°. The mean of the seven low night temperatures was the lowest at Sunderland, 35½°, and the highest at Plymouth, 41°; the mean from all stations was 38°. The mean daily range of temperature in the week was the least at Norwich and Leicester, 5½°, and the greatest at Truro and Manchester, both 11½°; the mean daily range of temperature from all stations was 8°.

The mean temperature of the air for the week from all stations was 41½°, being 10½° higher than that for the corresponding week in 1876; the highest was 45½°, at Plymouth, and the lowest 39½°, at Sunderland.

Rain.—The amounts of rain measured at the several stations were comparatively small as compared with previous weeks. The heaviest fall, however, was 2½ inches at Brighton, and the least fall was two-tenths of an inch nearly at Leicester, Sheffield, and Liverpool. The average fall over the country was seven-tenths of an inch nearly.

The weather during the week was dull, wet, and very mild till the 11th, and on the 12th and 13th the sky was cloudy, and the weather was frosty and cold, with fog.

SCOTLAND: *Temperature*.—In Scotland the highest temperatures of the air varied from 49½° at Leith to about 45° at Dundee, Aberdeen, Greenock, and Paisley; the mean value from all stations was 48½°. The lowest temperatures of the air ranged from 24° at Paisley to 31° at Edinburgh; the mean from all stations was 27½°. The mean range of temperature from all stations was 21°.

The mean temperature of the air for the week from all stations was 38°, being 5½° higher than the value for the corresponding week in 1876. The highest occurred at Edinburgh, 39½°, and the lowest at Dundee and Perth, both 37½°.

Rain.—The falls of rain varied from 2 inches at Greenock, to half an inch at Dundee and Aberdeen; the average fall over the country was 1 inch.

DUBLIN.—The highest temperature of the air was 56½°, the lowest was 24½°, the range was 31½°, the mean was 41½°, and the fall of rain was 0.17 inch.

JAMES GLAISHER.

Esquiquiers.

He that questeth much shall learn much.—BACON.

158. MAIDENHAIR (BRAZILIAN).—Will you kindly tell me how the fronds are grown or prepared for market so that they may preserve their freshness for so long a time as they are taken to do in Covent Garden. In whatever stage I cut them, whether old, young, or medium, they wither or dry up in a very few hours—before they are in a bouquet an hour they are withered. C. Z. [We believe that only the most dry and best matured fronds are cut and sent by the growers to Covent Garden, and these will only keep fresh for about twenty-four hours. In the florist's shops the fronds are kept in a dark moist place, and when sent any distance are packed in air-tight boxes. They should not be grown too hot or too moist. Eds.]

159. WHITE VARIETIES.—Will any floriculturists kindly inform me if they have noticed whether white or pale varieties of garden plants are relatively more self-fertile than the coloured? Mr. Darwin's white *Mimulus*, pale *Pelargonium*, according to Dr. Denny, and a white *Antirrhinum*, show this peculiarity; but I should be glad to hear of other instances. *George Hamilton, 7, Beestock Terrace, Regent's Park, N. W.*

160. DAMAGE FROM FALLING TREES.—Can you say whether, if a large tree be blown down on a neighbouring land, and fall upon another's, doing great damage, the injured party can claim damages? J. S. [This is a legal question which some of our readers may be able to answer from their own experience. Eds.]

161. ASPHALTE WALKS.—May I inquire of some of your correspondents the best means known of laying down asphaltic walks in gardens; the composition of the materials in parts; whether it should be mixed with hot or cold tar; what thickness is best to withstand the washings of heavy rain; and, if laid now, would frost affect it? To give it a bright glistening surface, would Derbyshire spar, or the chippings of tuffa rock, be most durable and effective? *Cephus*.

Answers to Correspondents.

BOOKS: *Reader*. Yes; at 177, Fleet Street, or through your agent, *Piccadilly*.
GALLS ON VINES: I enclose what seems to be an unusual tufted growth of *Vitis* leaves, in case it may be of any interest to you from a teratological point of view. F. C. [The tufted growth, as shown in the

FIG. 15.—GALL ON VINE.

accompanying illustration (fig. 15), reproduced from our volume for 1873, p. 110, is the work of the gall midge of the *Vitis*, *Cecidomyia* (a.).

DISEASED LEAVES: *Antaeus*. The so-called diseased leaves of *Statice* and others look as if suffering from attack of red-spider. The *Cheriaras* can only be suffering from too much damp either at the root or top, and perhaps also from want of a sufficient circulation of air.

DOUBLE PRIMULA: *E. Hillier*. The flowers are very pleasing—a delicate blush, very full, and nicely fringed. Double varieties are, however, now so plentiful that it needs to be seen growing beside the others to judge if it is superior.

GRASS TREES: *J. Fryer*. We do not understand your question. Do you refer to the Vine pest, *Phylloxera*, to the Vine midew, or what? If you mean the medicinal uses of *Grapes*, apply to Messrs. Churchill, New Bunhill Row.

MISTLETO: *E. F.* The Mistleto will grow on the Thorn, and also on the Apple, Lime, and various other trees. The best plan is to fix the berries on the bark in a sheltered part, and protect them from birds; they will adhere by their own viscosity if crushed on the surface of the bark. The underside of a branch is generally preferred. It may be done now.

Garden Wall Wiring.

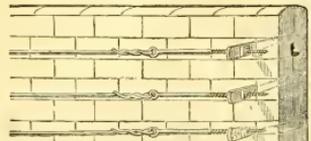

R. HOLLIDAY, PRACTICAL WIREWORKER,
 24, Portobello Terrace, Notting Hill Gate, London, W., begs to call the attention of all Gardeners who are about to have their Garden Walls wired to his system of Wiring Walls, as being superior to all others for neatness, strength, and durability.

FOR NEATNESS—Because all the Wires are kept perfectly tight, without the use of the Raddisseeur.
FOR STRENGTH—Because very much stronger Wire can be used, therefore not liable to be drawn out of the horizontal line by the branches of trees.

FOR DURABILITY—Because, being able to use the strong Wire, it is not so liable to be eaten through with the galvanism as the thin Wire, as used in the French system.

The above engraving is an example of our system of Wiring Garden Walls. We have recently completed the Wiring of the New Garden Walls for the Marquis of Salisbury, Hatfield House. The Walls are 22 feet high and 75 yards long, wired on both sides; making a total length of 1500 yards—our system being chosen in preference to any other.
 Illustrated Catalogues of Gardens and Conservatory Wirework, Rabbit-proof Hard Fencing, &c., may be had on application as above.

THOMAS'S FITTINGS for WIRING WALLS.
 NEW and IMPROVED SYSTEM.

The following prices give the total cost of each line of wire, including holdfast, straining bolt, intermediate guiding eyes, 20 feet apart, and best quality galvanised wire.
 Length of Wall—20 yds. 40 yds. 60 yds. 80 yds. 100 yds.

GALVANIZED IRON RADDISSEURS, for Tightening Wires, one to the centre of each wire, 2s. 6d. per dozen. KEY, for Winding, 4s. each.

SCREWS and NUTS, greater than Raddisseeurs, 3s. 6d. per doz. No. 14 GALVANIZED WIRE, 10 inches apart, 2s. per 100 yds. * * Prices of IRON TRELLIS or ESPALIER for TRAINING FRUIT TREES on the FRENCH SYSTEM, on application.

J. B. BROWN & CO.,
 90, CANNON STREET, LONDON, E.C.

Oil Paint No Longer Necessary.

HILL and SMITH'S BLACK VARNISH for Preserving Ironwork, Wood, or Stone. This Varnish is an excellent substitute for oil paint on all outdoor work, while it is fully two-thirds cheaper. It was introduced upwards of thirty years ago by the advertisers, and its genuine good quality, notwithstanding a host of unprincipled imitations, is fully attested by its constantly increasing sale. It may be applied by an ordinary labourer, requires no mixing or thinning, and is used cold. It is used in the grounds at Windsor Castle, Kew Gardens, and at the seats of many hundreds of the Nobility and Gentry, from whom the most flattering testimonials have been received, which HILL & SMITH will forward on application.

Sold in casks of about 30 gallons each, at 2s. 6d. per gallon, at the Manufacturers, or 2s. 8d. per gallon carriage paid to any Station in the Kingdom.

UNSOLICITED TESTIMONIAL.
Glasgow, Glasgow Herald, Carmarthen, Nov. 27, 1873—
 "Mr. Lloyd Lloyd encloses cheque for £1 5s., amount due to Messrs. HILL & SMITH, and he considers the Black Varnish one of the most useful things he ever possessed."
 Apply to HILL and SMITH, Brompton Hill Ironworks, near Dudley; or 118, Queen Victoria Street, London, E.C., from whom only it can be obtained.

CAUTION—It having lately come to the knowledge of HILL & SMITH that spurious imitations of this Varnish are being offered by unprincipled dealers at a slight reduction in price, they would especially draw attention to the fact that every cask of their Varnish is legibly marked with their name and address, without which no cask is genuine.

W. G. SMITH & CO., HORTICULTURAL ENGINEERS,
 Victoria Works, Bury St. Edmunds.

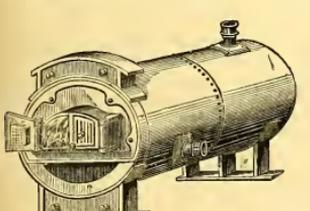

SOLE MANUFACTURERS of BEARD'S PATENT METALLIC NON-CONDUCTING GLASS-HOUSES.—The Glass is fixed between two layers of prepared flint. The Ventilators are worked by a simple mechanical contrivance, and the whole structure is screwed together so as to render it quite portable. HEATING APPARATUS IN ALL ITS BRANCHES. ORNAMENTAL CONSERVATORIES and HORTICULTURAL BUILDINGS of EVERY DESCRIPTION.—Illustrated Catalogues of Gardens and Conservatory Wirework, Rabbit-proof Hard Fencing, &c., may be had on application as above.

An Illustrated Catalogue forwarded post-free on application.

THE THAMES BANK IRON COMPANY,
 Old Barge Wharf, Upper Ground Street, London.

HOT-WATER BOILERS. SURREY SIDE, BLACKFRIARS BRIDGE. PIPES, CONNECTIONS.

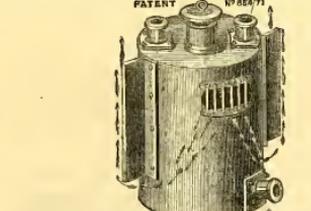

("TRENTHAM IMPROVED" BOILER.)

NEW PATENT "CLIMAX" BOILER (1874). See p. 666, 1874, *Gardeners' Chronicle*.

"GOLD MEDAL" BOILER (Birmingham, 1872).

PATENT "EXCELSIOR" BOILER (1871).

The largest and most complete Stock in the Trade; upwards of Twenty Thousand Pounds' worth to choose from.

("EXCELSIOR BOILER.")

"WITLEY COURT" BOILER (Silver Medal 1872).

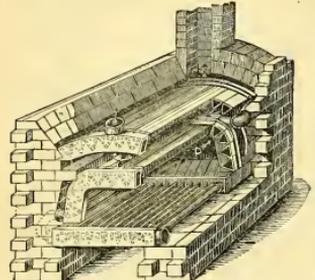

"TRENTHAM IMPROVED" BOILER, with Water-way End and Smoke Consumers.

"TUBULAR," and every other Boiler of known merit or excellence.

Prime Medal Awarded at the National Contest, Birmingham, 1874.

MILL'S PATENT AUXILIARY FUEL ECONOMISER,
 Which can be attached to any ordinary Boiler. These Tables are the greatest Economisers of Fuel and Preservatives of Boilers, Fire-Bars, and Furnace Frocks ever yet introduced to the public.
STAINTON'S NEW PATENT PROFIT DEFENDING LIQUID (see *Gardeners' Chronicle*, AUG. 19, 1876).
HOT-WATER APPARATUS ERECTED COMPLETE.
 PRICE LIST on application; or, Six Stamps for DESCRIPTIVE CATALOGUE, 4th Edition.

MESSENGER AND COMPANY'S
PATENT TUBULAR BOILER.—Nearly 3000 now
in use.

Combines all the advantages of the old Saddle, which is acknowledged to be the most economical, with the Tubular, the most powerful form of boiler. By the use of triangular tubes a larger amount of heating surface is exposed to the direct action of the fire than in any other form of boiler. The water-jacket (B) also receives the most intense heat. The boiler is made of cast-iron, which is admitted to be the best material as regards durability, strength, &c. In consequence of the above advantages we are enabled to supply boilers with a large amount of heating-power at very moderate rates. The power of this boiler can at any future time be increased by adding another row of tubes. Illustrated List free on application to—

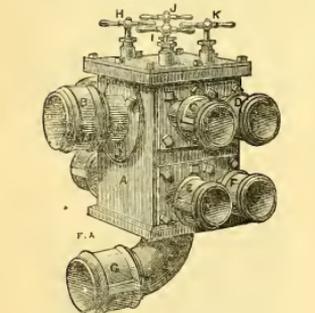

MESSENGER AND COMPANY, Hot-Water Engineers and Horticultural Builders, Loughborough.

FOWLER'S PATENT STEAM PLOUGH
and CULTIVATOR may be SEEN at WORK in every Agricultural County in England.

For particulars apply to **JOHN FOWLER and CO.**, 77, Cornhill, London, E.C., and Steam Plough Works, Leeds.

Hothouses, Hot-water Apparatus, & HALLIDAY and CO., HOTHOUSE BUILDERS and HOT-WATER APPARATUS MANUFACTURERS. Exhibiting the Best Construction! Best materials! Best workmanship! Catalogues free. Offices, 22, BATHON ARCADE, MANCHESTER.

CRITCHLEY'S PATENT HEAT REGULATOR,
AN APPARATUS FOR REGULATING THE HEAT IN HORTICULTURAL BUILDINGS.

A, Iron Box fitted up with water-tight, N, Pipe for Supply of Water from Boiler. C, D, Pipes for Circulating Hot-Water. E, F, Pipes for Return of Water to Iron Box. G, Pipe for Retaining Water to Boiler. H, I, J, K, Piston-Rods for Opening and Closing Valves.

The advantages of this Regulator are that houses may be kept at different degrees of heat, or the circulation of water and heat entirely stopped in one part and not in others. They may be fitted with as many valves as required, and are particularly adapted for forcing houses where top and bottom heat is used. They may be fixed in any part of the apparatus most suitable for working, without regard to the position of the Boiler.

The following Testimonial has been received—
"Berkeley Castle, April 13, 1875.
"Gentlemen,—I am happy to inform you, now that the late severe winter is past, that the Hot Water Apparatus erected by you does its work to my entire satisfaction. As to the two Heat Regulators, which represent thirty valves, I have had ample opportunities of graciously proving them, and unhesitatingly admit they are far superior to any other valve; in fact, I think it is the greatest improvement that has come out for horticultural purposes.
"I am, Gentlemen, yours truly,
"R. H. CROOK,
"Gardener to the Right Hon. Lord Fitzhardinge."

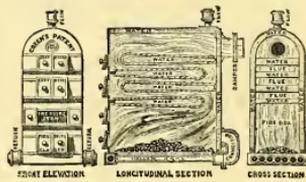

Estimates and Plans furnished for Warming Greenhouses, Mansions and Public Buildings. Orders attended to in any part of the Kingdom, and guaranteed to answer their intended purposes. Prospectus and Price Lists post-free.

Messrs. CRITCHLEY & CO., Horticultural Engineers and Builders, GROSVENOR WORKS, CHELTENHAM.

GREEN'S PATENT
Wrought-iron Hot-water Boilers,
With Shelves and Hollow Grate Bars.

Specialty adapted for heating Greenhouses, Conservatories, Churches, Chapels, Schools, Public Buildings, Entrance Halls, Warehouses, Workshops, &c.

They are the neatest, cheapest, most effective, and durable of any extant.

Descriptive Illustrated Price List may be had free on application to

THOMAS GREEN AND SON, Smithfield Ironworks, Leeds; and 24 and 25, Blackfriars Road, London, S.E.

LIMEKILN HEATING.

This System of HEATING WINTER GARDENS, CONSERVATORIES, ORANGERIES, FERNERIES, VINERIES, FORCING HOUSES, PINERIES, CUMBER, MELON and MUSHROOM HOUSES, STOVES, PITS, &c.—also for WARMING MANSIONS, PUBLIC BUILDINGS, FACTORIES, &c., is steadily making progress in public estimation, effecting as it does

Great Economy of Fuel and Steadiness of Heating Power, and rendering the hitherto onerous duties of Stoker comparatively light—no night stoking whatever being necessary.

List of Places where the System is in Operation, with full address in each case, will be sent post-free on application.

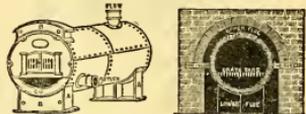

Gentlemen and Gardeners wishing to adopt this System will then be enabled to view the Apparatus nearest to their own Establishments, or write to the Gardener, and thus get independent testimony as to the value of this method of Heating.

Estimates will be submitted, on receipt of particulars, free of charge.

FULL PARTICULARS POST-FREE.

Cowan Patents Company (Limited), 21, WHITEHALL PLACE, LONDON, S.W., and The Vineyard, Garston, near Liverpool.

STEVENS' TRENTHAM GREENHOUSE BOILER.

After long experience, has proved the most SIMPLE, ECONOMICAL, EFFECTUAL, and LASTING BOILER extant; recently improved. For Illustrations, with full particulars, apply to the Sole Makers,

F. & J. SILVESTER, HOT-WATER ENGINEERS, &c., &c., Castle Hill Works, Newcastle, Staffordshire.

Our Boilers are the ONLY ones made with the sanction and under the inspection of the inventor, Mr. STEVENS—all others being base imitations.

ASSISTANT in a Seed Shop.—Age 19; three years' experience. Good references.—W. W., Waverley Nursery, Waverley, near Liverpool.

KINAHAN'S LL WHISKY.
Kinahan & Co. find that, through the recommendation of the Medical Profession, the demand for their CELEBRATED OLD LL WHISKY for purely medicinal purposes is very great, submit with pleasure the following ANALYSIS by Dr. HASSALL, who has very carefully and fully analysed samples of this well-known and popular Whisky. The samples were soft and mellow to the taste, aromatic and ethereal to the smell. The Whisky will have very considerable medicinal value, and of very excellent Quality. The Medical Profession may find full confidence in the Whisky. Sold only in packets, labelled "JAMES EPPS AND CO., HOMEOPATHIC CHEMISTS, 41, Threadneedle Street, and 170, Piccadilly."

DINNFERD'S FLUID MAGNESIA.
The best remedy for ACIDITY of the STOMACH, HEADACHE, INDIGESTION; and the safest aperient for delicate Constitutions, Ladies, Children, and Infants.

EPPS'S C O C C O A.
By a thorough knowledge of the natural laws which govern the operations of digestion and nutrition, and by careful application of the fine properties of well-selected Cocoa, Mr. Epps has produced this pure, well-adjusted, and agreeable beverage which may save us many heavy doctors' bills. It is by the judicious use of such articles of diet that a constitution may be gradually and naturally brought to a state of perfect tone and capacity. Hundreds of subtle maladies are floating around us from time to time, and may escape many a fatal shroud by keeping ourselves well fortified with pure blood and a properly nourished frame.—Civil Service Gazette.

JAMES EPPS AND CO., HOMEOPATHIC CHEMISTS, 41, Threadneedle Street, and 170, Piccadilly.

Cures of Diseases of the Chest by DR. WILLIAMS' PULMONIC WAFERS.
—M. T. WILES, Market Deeping, writes—"My valuable Wafers are very efficient for Chest Diseases. I have tried them myself, and recommended them to several friends, and proved their beneficial effects. In Asthma, Consumption, Bronchitis, Coughs, Colds, Rheumatism, and all Hysterical and Nervous Disorders relief is given. Sold by all Druggists at 1s. 2d. per box."

HOLLOWAY'S PILLS.
This purifying and regulating medicine should occasionally be resorted to during Foggy, or other seasons of the year. It is the best preventive of hoarseness, is useful in throat, diphtheria, pleurisy, asthma, and a sure remedy for congestion, bronchitis, and influenza. Attention to the directions folded round each box will enable invalids to take the Pills in the most advantageous manner; they will be taught the proper doses, and the circumstances under which the Pills are to be used or discontinued. Holloway's Pills act as alteratives, aperients, and cathartics. Weakly persons, who are unable to take any gratifying; even when they fail to cure they always arrest the severity of the symptoms and diminish the danger.

SUTTON'S NEW OR IMPROVED VEGETABLES, ETC.

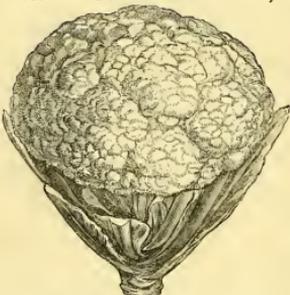

SPECIAL NOTICE TO PURCHASERS.—Sutton & Sons have No Agents, and do not supply the Trade. Every Packet direct from them bears their Registered Trade Mark as above.

THE BEST CAULIFLOWER,

Of rather dwarf and compact growth, with large and beautifully white heads.

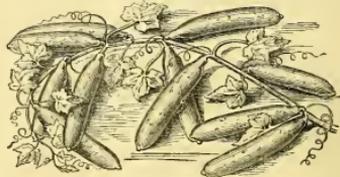

Per Packet, 1s. 6d.

Excellent for early Crop, and useful for a succession through Autumn and Winter.

THE BEST RIDGE CUCUMBER,

Equal to a Frame Cucumber, but can be grown out-of-doors. Per Packet, 1s. 6d.

SHOWING HABIT OF GROWTH.

SHOWING TYPE OF FRUIT.

SUTTON'S KING OF THE CAULIFLOWERS.

From Mr. T. RABONE, Gardener to the Right Hon. the Earl of Shrewsbury and Talbot, Aston Tenny, September 16.

"Your 'King of the Cauliflowers' is the admiration of every one. We have hundreds of the best Cauliflowers I ever saw: they are a marvel, pleasy 12 and 14 inches across, and as close and compact as possibly could be. It is a wonder, certainly."

From Mr. ROBERT COCKS, Gardener to Lord Auckland, September 1.

"Your 'King of the Cauliflowers' is a good variety, with fine compact white heads; stands the drought well."

SUTTON'S KING OF THE RIDGE CUCUMBER,

From 12 to 16 inches in length, very level and uniform, smooth, unribbed, and remarkably productive.

From Mr. WM. WILDSMITH, Gardener to the Right Hon. Viscount Eversley, Auckland.

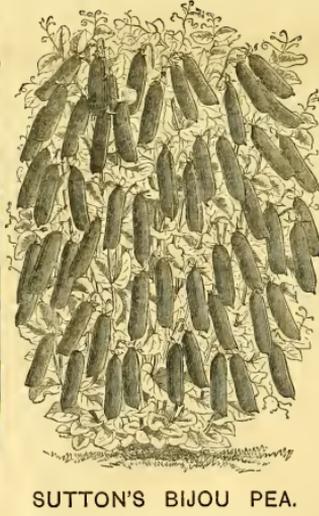

"Your 'King of the Ridge' is the best Ridge Cucumber I have yet seen. It grows as straight as possible, a rare occurrence with this kind of Cucumber."

THE BEST AND MOST DISTINCT EARLY DWARF WRINKLED PEA.

SUTTON'S BIJOU PEA.

This is the very earliest and best type of Dwarf Wrinkled Pea, coming in just before "Little Gem," but is much more prolific, and with larger and better filled pods. In growth it is exceedingly level and uniform, 18 inches high; particularly suitable for Amateurs and small Gardens, as it requires no sticks. It is also valuable for large Gardens, as it forces well. The pods are produced in pairs, very thickly set, extremely large and well filled, often containing from eight to ten fine Peas, which are of most delicious flavour. During the past season this Pea has become a great favourite, and we feel sure it will be universally grown for early use.

Per Quart, 3s. 6d.

SUTTON'S BIJOU PEA.

SUTTON'S BIJOU PEA.

From Mr. ROBERT COCKS, Gardener to Lord Auckland.

"Your 'Bijou' is the best Pea of its height I have seen, and an immense cropper; the flavour is also very good."

From Mr. T. LOCKIE, Gardener to the Right Hon. Lord Otho Fitzgerald.

"Your Dwarf Wrinkled Pea 'Bijou' has proved the earliest and best Marrow Pea of its class I have ever grown."

From Mr. A. HAYTER, Gardener to the Right Hon. the Earl of Shaftesbury.

"I find your 'Bijou' is a good Dwarf Wrinkled Pea, growing about 18 inches high with me; useful for forcing."

From Mr. GEO. BRIGHTON, Gardener to the Right Hon. the Earl of Mount-Edgumbe.

"'Bijou' is a Wrinkled Marrow Pea of excellent quality, and very prolific; the first Wrinkled Pea coming into use; height 12 1/2 ft."

From Mr. R. W. TODD, Gardener to His Grace the Duke of Buckingham.

"Your 'Bijou' is the best Dwarf Wrinkled Pea I ever grew, a good cropper, only 18 inches high. Sowed first week in April, gathered first dish third week in June."

For full particulars of SUTTON'S CHOICE NOVELTIES see SUTTON'S SPECIAL LIST of NEW OR IMPROVED VEGETABLES, Gents and post-free on application.

The following well-known authorities have grown most if not all the varieties offered in Messrs. Sutton's List.

Mr. WM. PATERSON, Gardener to Her Most Gracious Majesty the Queen.

Mr. CHARLES PENNY, Gardener to His Royal Highness the Prince of Wales.

Mr. R. W. TODD, Gardener to His Grace the Duke of Buckingham.

Mr. A. INGRAM, Gardener to His Grace the Duke of Northumberland.

Mr. WM. TILLEY, Gardener to His Grace the Duke of Portland.

Mr. JOHN TOWILL, Gardener to the Right Hon. the Earl of Glasgow.

Mr. JNO. GOODAIRE, Gardener to the Right Hon. the Earl of Harrington.

Mr. T. RABONE, Gardener to the Right Hon. the Earl of Shrewsbury.

Mr. GEO. JOHNSTON, Gardener to the Right Hon. the Earl of Strathmore.

Mr. ROBERT DRAPER, Gardener to the Right Hon. Earl Vane.

Mr. W. WILDSMITH, Gardener to the Right Hon. Viscount Eversley.

Mr. JNO. ALLEN, Gardener to the Right Hon. Viscount Falkland.

Mr. P. FINE, Gardener to the Right Hon. Lord Stanley of Alderley.

Mr. ROBT. COCKS, Gardener to Lord Auckland.

Mr. GEORGE ABBEY, Gardener to Sir C. M. Palmer, Bart.

SUTTON & SONS, The Queen's Seedsmen, READING.

NEW SOBRALIA AND IMPORTED CŒLOGYNES.

MR. J. C. STEVENS will SELL by AUCTION, at his Great Rooms, 38, King Street, Covent Garden, W.C., on THURSDAY, February 1, at half-past 12 o'clock precisely, some fine Plants of the NEW SOBRALIA CATTLEYA, which was fully described by Prof. Reichenbach in the *Gardener's Chronicle* of Jan. 20, 1877, p. 72. Unlike most of the ordinary Sobralias, this species has large thick flowers of a firm fleshy texture, the sepals are purplish brown, with rich rosy-purple lip; instead of the flowers being borne singly, they are produced on stout spikes, each with six or seven flowers, two or three on each spike being expanded at the same time; from which it will be seen what a remarkable Sobralia this is. The plants are good, and just showing strong breaks. Also an importation of the rare CŒLOGYNE GLANDULOSA, C. CORRUGATA, C. ODORATISSIMA, and an unnamed Cœlogyne, probably new; also an importation of the rare DENDROBIUM ALBUM, which Wight, in his *Icones Plantarum Indiæ Orientalis*, describes thus:—"This is one of the handsomest of the genus I have yet met with; large pure white flowers." Also some imported plants of the rare ACANTHOPHIPIUM BICOLOR; this Orchid gives flowers of large size, bright yellow and scarlet. Also some good plants of the exceedingly chaste and beautiful NEW SOBRALIA VIRGINALIS; this has large pure white flowers, with rich golden throat; the plants are showing strong breaks. At the same time will be sold several plants of ODONTOGLOSSUM CRISPIUM (Alexandre), O. VEXILLARIUM, and various other Orchids.

On view the morning of Sale, and Catalogues had.

AUCTION ROOMS AND OFFICES, 38, KING STREET, COVENT GARDEN, LONDON, W.C.

VALUABLE LILIES.

MR. J. C. STEVENS will SELL by AUCTION, at his Great Rooms, 38, King Street, Covent Garden, W.C., on THURSDAY, February 8, at half-past 12 o'clock precisely, an Importation of good Bulbs of the beautiful LILIUM NEILGHERRENSE. The white flowers of this magnificent Lily are deliciously fragrant, and of great substance; it bears several flowers on a stem, each flower nearly a foot long. Also some excellent Bulbs of the following new varieties of Liliium neilgherrense, viz.:-

- LILIUM NEILGHERRENSE ROSEUM—the exterior of the flower tubes of this variety is pink, the interior white.
- LILIUM NEILGHERRENSE FLAVUM—a handsome light yellow-coloured form of this charming Lily.
- LILIUM NEILGHERRENSE TUBIFLORUM—a magnificent pure white Lily, with very long flowers; figured in Wight's *Icones Plantarum Indiæ Orientalis*.
- LILIUM NEILGHERRENSE TUBIFLORUM LUTEUM—a very handsome yellow-flowered variety of tubiflorum. And some

Splendid flowering Bulbs of other choice LILIES, including BLOOMERIANUM OCELLATUM, PURPUREUM, HUMBOLDTII, GIGANTEUM, PARDALINUM, PARVUM, CALIFORNICUM, and WALLICHIANUM; also a quantity of choice Bulbs and Tubers from California, including CALOCHORTUS, CYCLOBOTHRAS, BRODIEÆ, TRITELIAS, CALLIPHORAS, ERYTHRONIUM, BLOOMERIAS, &c.; and some fine blooming Bulbs of the handsome CRINUM BRACHYNEMA, C. AUSTRALE, C. PRATENSE CANALICULATUM, tuberous-rooted BEGONIAS, PANCRATIUM, AMARYLLIS, North American CYPRIPEDIUMS, with a variety of other Bulbs and Tubers.

On view the morning of Sale, and Catalogues had.

GROS GUILLAUME GRAPE

(Roberts' Variety),
THE LARGEST BLACK GRAPE IN CULTIVATION.

W. TAIT & Co.,

SEED MERCHANTS AND NURSERYMEN,
45, CAPEL STREET, DUBLIN.

The entire Stock of this extraordinary Grape has been placed in our hands for distribution. It is a strong growing Vine, good constitution, free from shanking, will keep till spring, and under ordinary management will produce splendidly formed bunches, and well coloured, up to 25 lb. At the winter show of the Royal Horticultural Society of Ireland on November 11, 1875, three bunches of this Grape were exhibited by the introducer, Mr. Roberts, the well-known Grape-grower, of Charleville Forest, Tullamore, which obtained the First Prize, and were awarded the Society's Medal for special and meritorious productions, and it is scarcely necessary to say more than that these bunches, which weighed collectively over 45 lb., were the admiration of everybody who saw them at the Show, and they were seen and admired by many others who saw them growing on the Vine.

This is quite a sensational Vine, distinct from the ordinary kinds of Gros Guillaume and of Barbarossa (with which it is said the latter is identical), inasmuch as it will produce bunches double the weight of those varieties; it is a good bearer, requires no coaxing or high manuring. The Vine which produced those extraordinary and marvellously well finished bunches is growing in nothing but pure loam.

Eyes, or Scions, from fine wood, well ripened, extra size 10s. 6d. each.
Second size do. 7s. 6d. each.

Orders will be executed in strict rotation. To secure strongest Eyes or Scions, early application is necessary.

W. TAIT & CO.,
SEED AND NURSERY ESTABLISHMENT,
45, CAPEL STREET, DUBLIN.

WEBB'S CHOICE VEGETABLE AND FLOWER SEEDS.

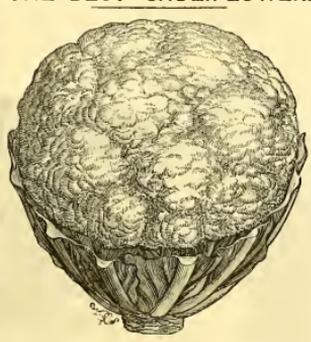

Contains full instructions for the successful cultivation of **THE BEST VEGETABLES AND THE CHOICEST FLOWERS.**

Post-free, 1s. Gratis to Customers.

"A publication of remarkable beauty and interest. The book is one of the best works on Gardening that has yet appeared."—*The Magnet*, January 8, 1877.

THE BEST CAULIFLOWER.

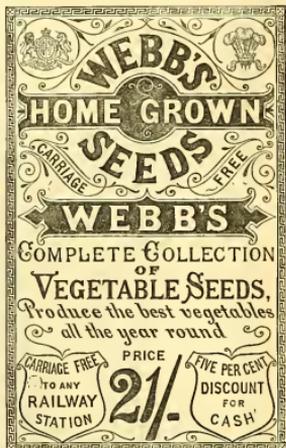

Webb's Early Mammoth Cauliflower.

An excellent compact variety of exceptional merit; stands the drought remarkably well; heads large, firm, and beautifully white; the best for main crop.

Price 1s. 6d. per packet.

Five per Cent. Discount for Cash.

All Goods of 20s. value and upwards Carriage-free to any Railway Station in England or Wales.

WE ALSO SUPPLY COLLECTIONS AT 10s. 6d., 15s., 30s., 42s., 63s., and 105s.

The above contain liberal assortments of the best varieties in cultivation.

WEBB & SONS, The Queen's Seedsmen, WORDSLEY, STOURBRIDGE.

To Purchasers of Large Quantities, Market Gardeners and OTHERS. **SUTTON AND SONS** can offer true stocks of the following Peas at very moderate prices—**SUTTON'S IMPROVED EARLY CHAMPION**, the best and most productive in cultivation. Sutton's King-leader, Sutter's Advance, Daniel O'Rourke, Sutter's Racchose, Fortfydd, Champion of England, Scimitar, and other leading kinds. **SUTTON AND SONS**, Seed Growers, Reading.

Garden Seeds, Gladioli, &c. **IRELAND AND THOMSON** have much pleasure in intimating that their Descriptive Price Catalogue of VEGETABLE and FLOWER SEEDS, GLADIOLI, IMPLEMENTS, &c., is now ready, and will be sent post-free on application. **CESTIA PYRAMIDALIS PLUMOSA, AUREA** and **RUBRA**, per packet, 1s., 2s., 6d. each. **EAST LOTHIAN INTERMEDIATE STOCK**, in three colours, per packet, 1s., 2s., 6d., and 5s. each. **WHITE WALL-LEAVED EAST LOTHIAN INTERMEDIATE STOCK**, per packet, 1s., 2s., 6d., and 5s. each. Seed Warehouse, 20, Waterloo Place, Edinburgh.

SPIREA (HOTELA) JAPONICA, a very strong clump for forcing, equal if not superior to foreign. 20s. per 1000. **SPIREA PALMATA**, fine crosses for forcing, 75c.; smaller, 25s. to 50s. per 1000. **CHARLES NOBLE**, Bagshot.

WEBB'S NEW GIANT POLYANTHUS, Florist Flower, and **GIANT COWSLIP SEEDS**, also Plants of all the varieties, with Double PRIMROSES of different colours; **ADIRICULAS**, both Single and Double, with every sort of Early Spring Flowers. LIST on application, with every sort of Early Spring Flowers. **Mr. WEBB**, Calcutt, Reading.

WEBB'S PRIZE COB FILBERTS, and other PRIZE COB NUTS and FILBERTS. LISTS of these varieties from Mr. WEBB, Calcutt, Reading.

NEW DRACENAS.—Twelve of the finest in cultivation for 1877, well established young plants, growing freely. If potted on now will do for exhibition in the autumn.—D. Bapstist, D. Young, D. Imperialis, &c., included. Packages gratis for cash with order. **JOHN H. LEVY**, Royal Nursery, Croydon.

Superb Ridge Cucumber. **CUCUMBER**, Foster's X.L. Superb Ridge.—"This variety is a remarkably fine hardy, long, dark green cucumber, and one that can be recommended with the greatest confidence. It is very prolific, and keeps its colour to the last; all who have seen it growing are satisfied that it cannot be surpassed, and those who have tried its flavour are convinced of its excellent quality—length, 10 to 18 inches. Price 6d. and 1s. per packet; please refer to the Trade on application. **EDMUND PHILIP DIXON**, The Yorkshire Seed Establishment, Hull.

Shallot Seed. **DAVIS' PRIZE JERSEY**.—A true Shallot, of immense size and exceedingly mild; with ordinary treatment bulbs have been grown to 10 and even 12 inches in circumference—by far the best method of growing the Shallot. Treatment same as Onions. Price 1s. per packet. May be had of all Seedsmen in sealed packets, and Wholesale of Messrs. HURST AND SON, 6, Leadenhall Street, London, E.C., or **E. R. DAVIS**, Nursery and Seed Warehouse, Yeovil.

ROBERT AND GEORGE NEAL, Wandsworth Common, Upper Tooting, and Garrett Nurseries. These Nurseries comprise about 50 Acres of well-grown and a most useful assortment of STANDARD, ORNAMENTAL, FOREST, FRUIT, and ROSES, and SHRUBS, all of which are in a most healthy and fit condition for removal. A personal inspection invited. CATALOGUES free on application. The Nurseries are within a few minutes' walk of the Clapham Junction and Wandsworth Common Railway Stations.

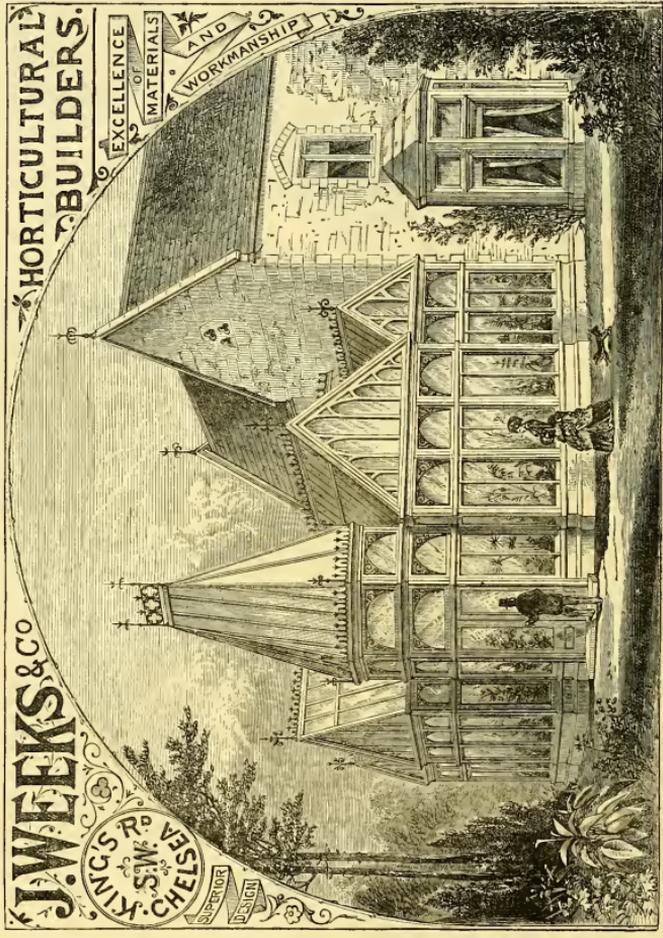

CONIFER AND OTHER SHRUBS, Clean and Healthy. **Laurus**, common, 3 feet, good, 10s. per dozen. **Liquarium sinensis**, 3 to 4 feet, 6s. per dozen. **Japanica, 2 to 2½ feet, 12s. per dozen. **Pinus Cembra**, specimens, 4 to 5 feet, 24s. per dozen. **Picea Finlaysoni**, 3 to 3 feet, 24s. per dozen. **Yew**, English, 3 to 4 feet, 20s. per dozen. **Juniper, 3 to 4 feet, 12s. per dozen. **Acer Negundo**, var. 2, 3 to 4 feet, 9s. per dozen. **Althaea frutex, 2 to 4 feet, 9s. per dozen. **Ribes sanguineum, 2 to 3 feet, 3s. per dozen. **Snowberry, 4 feet, 11s. 6d. per dozen. **Ash, 3 to 4 feet, 10s. per dozen. **Elm**, English, 6 to 8 feet, 20s. per 100. **Wych**, 6 to 8 feet, 15s. per 100. **Fir**, Austrian, 3 to 3½ feet, 12s. per 100. **Oak**, 7 feet, fine, 16s. per 100. **Sycamore**, 6 to 7 feet, 15s. per 100. **Syringae, 5 ft., fine, 6s. per doz. Cash or reference. Catalogues of Trees and Seeds on application to **MARTIN AND SON**, Seed Merchants and Nurserymen, Cottingham, and 64, Market Place, Hull.**************

STEPHANOTIS FLORIBUNDA.—Strong specimen plants of a very free-flowering variety, 10s. 6d. each; smaller, but fine half specimens, which will produce abundance of flower early, the buds just appearing on some, 7s. 6d. each. 60s. per dozen in 20s. (flowered last autumn), 30s. per dozen. This offer is for six weeks only, to make room, the plants being worth double the money. **JOHN H. LEVY**, Royal Nursery, Croydon.

Splendid New Melon 1877. **CHARLES LEE AND SON** (Successors to Messrs J. & C. LEE) have the pleasure to announce that they have purchased the entire Stock of **MANN'S HYBRID GREEN-FLESH MELON**, which they now offer for the first time. It has already earned a high reputation in London and the provinces for its many excellent qualities, among which may be mentioned a remarkably high and exquisite flavour at all seasons of the year—perfection of shape and size for dessert—a thin rind and melting flesh, with an overflow of perfumed juice. It is also a heavy cropper, and forces well. **Ex. Honor.** has spoken of this excellent Melon in the highest terms, and after tasting it pronounced it a fruit of the highest merit.

Mr. CULVERWELL, of Thorpe Perrow, fellow judge with **Mr. FOWLER**, of Harewood House, at the Leeds Horticultural Show, where it awarded a First class Certificate to "Mann's Hybrid Green-flesh Melon," speaks of it as "an exceedingly fine Melon, especially at that early season—the early part of June." **Mr. INGRAM**, of Belvoir Castle, writes, in the third week of October, "that in spite of the disadvantage of a long term of gloomy weather, at that season of the year, 'Mann's Hybrid Green-flesh Melon' was sweet, tender in flesh, very juicy, and distinct in flavor." **Messrs. Charles Lee & Son** are now prepared to offer this very useful and delicious new Melon in sealed packets, at 3s. 6d. per packet.

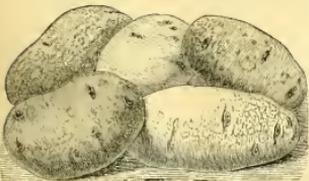

CHARLES LEE AND SON, Hammersmith, W. **Special Offer.** **GEORGE FARNSWORTH** has to offer large quantities of the following—**ASH**, Mountain, 2½ to 3½ feet, 4s.; per 100; 4 to 5 feet, 20s. per 1000. **ALDER**, 20 to 30 inches, 20s. per 1000. **BIRCH**, 15 to 25½ feet, 20s. per 1000. **BERRIS AQUIFOLIA**, bushy, 2 to 3 feet, 40s. per 1000; 2 to 3 feet, 8s. per 100. **CHESTNUT**, Horse, 7 to 9 feet, 10s. per 100. **ELMS**, 3 to 4 feet, 22s. per 1000. **LARCH**, 2 to 3½ feet, 22s. per 1000. **LIMES**, 2 to 3 feet, 3s. per 1000. **PLANK**, 2 to 3½ feet, 20s. per 1000. **LAUREL**, Common, 2 to 3½ feet, 20s. per 1000. **POPLARS**, Balsam, 2 to 3½ feet, 20s. per 1000. **Bloss**, 2 to 3½ feet, 17s. 6d. per 1000; 4 to 5 feet, 20s. per 1000; 5 to 6 feet, 6s. per 100. **RHODODENDRONS**, Hybrid and Ponicus, mixed, 3½s. per 100; 4 to 5 feet, 5s. per 1000; 6 to 8 feet, 12s. per 1000; 9 to 10 feet, 18s. per 1000; 11 to 12 feet, 24s. per 1000; 13 to 14 feet, 30s. per 1000. **STYCAMORE**, 2 to 3 feet, 20s. per 1000; 3½ to 5 feet, 30s. per 1000. Also other Nursery Stock as per LIST. The Nurseries, Malotock.

WEEKS'S IMPROVED CONSERVATORIES IN WOOD AND IRON.

DANIELS' SEED POTATOS.

Our Stocks of POTATOS are warranted True to Name and Free from Disease, all being carefully selected at the time of growth, and afterwards passed through the bands at least three or four times before being sent out, and all inferior, mis-shapen and forked tubers carefully discarded.

To improve the culture and encourage the diffusion of really good varieties, we have determined to offer at the lowest possible rates COLLECTIONS of POTATOS FOR EXHIBITION PURPOSES, and trust our efforts in this direction will meet a want so much felt by our Customers and the gardening community generally. Very carefully in all cases must be left to us; it will be very selection made, and only those of known excellence and superior qualities included.

SATURDAY, JANUARY 27, 1877.

WALKING-STICKS.

IF we were to pick out hap-hazard any one commodity and trace its history from the earliest stage to the condition in which we find it, we should no doubt find that history one of great interest and instruction, for it is a fact that most of us know but little of the manufacture of our principal articles of trade, notwithstanding that many of them are directly derived from sources with which we are specially interested, namely, the vegetable kingdom. This is particularly the case with a dealer in walking-sticks. These articles, with umbrellas, now form a distinct trade, and the wares, as exhibited by the retail dealers, are often most attractive, not only on account of the variety of the sticks themselves, but also on account of their elaborate manipulation, artistic and inartistic. "The Natural History of a Walking-Stick" would form a subject upon which even a book might be written, for we might trace the origin and use of the walking-stick from the very earliest period—how that it was originally a staff, and was used even by the mediæval pilgrims as now by Swiss tourists; how the upper part was often hollow, forming a receptacle for religious relics and snuff or perfume; how the first head of Saffron is said to have been secretly brought from Greece in the hollow head of a pilgrim's staff, and afterwards largely cultivated at Saffron Walden, which place derived its name from the above fact; and further, how that the silkworm was introduced to Europe in a similar manner.

Though the walking-stick of the present day can trace its ancestry to the staff, the bulk of the modern sticks are in no way comparable to their ancestors, inasmuch as in former times they were really of use to relieve the limbs to some extent of the weight of the body, and so were of a tolerable thickness, rigidity, and strength; at the present time they are chiefly carried for ornament, or on account of a prevailing fashion, though indeed the fashion of carrying a stick, whether for use or ornament, has descended through ages, with more or less change. Many old gentlemen still call their walking-stick a staff, and are as particular about its style and mounting as they are about their dress.

Notwithstanding all this a walking-stick, unlike an umbrella, would seem to be an article that would never wear out, and given the chance of accidents by loss or breakage would apparently last a lifetime, or even be passed from one generation to another, which in reality is not an uncommon occurrence. Hence, then, does it come that the manufacture of walking-sticks and umbrella-sticks is one of the great trades of London? Thousands upon thousands and tons upon tons of sticks are cut not only in this country but imported from all parts of the world, simply and solely for use as walking-sticks. From the East and West Indies, China, Java, and Singapore, immense quantities are constantly being brought. From the latter countries come all the varieties of Bamboo known in trade by distinct names, such as the "dog-head" cane, from the fact that a portion of the rhizome is left attached to each stick, which, having two protuberances like ears, gives it a resemblance to a dog's head. These trade names, though ordinarily those under which they are imported, are very often quite unknown to botanists, the names being

evidently more adapted to convey to the popular mind the appearance of the sticks than as indicating their proper scientific classification. Though so many varieties of Bamboo are constantly imported (mostly from China) and very largely used, little or nothing is known as to the species producing them. A few years since a very beautiful stick was introduced from Borneo under the name of Rajah cane; the hardness of this stick, together with its beautiful markings of dark lines, caused it to at once become popular. The name "Rajah" is said to be derived from the fact of the duties paid for its export being claimed by the Rajah of Borneo. Though enormous quantities of this stick were, and, indeed, are still, being imported, nothing is known as to its botanical origin further than that it is the stem of a Palm.

Another favourite stick is that of the Pimento, or Allspice (*Pimenta vulgaris*). This is more particularly adapted for umbrella-sticks, owing to its extreme rigidity and strength and its non-liability to warp. These sticks are imported from the West Indies, often in tolerably thick billets, and with a crook or bend, from which a knob or hook may be formed. From the West Indies also come many of the Orange and Lemon sticks, perhaps the most highly prized of all natural sticks, that is, of sticks with the bark on. These are valued on account of the fine white lines abundantly seen on the bark, especially after being polished; they are, moreover, suitable both for walking-sticks and umbrellas, the bark being removed and the stick smoothed for the latter purpose. Though there is something in common between the Orange and Lemon sticks, the first may easily be known by its beautiful green bark, with fine white longitudinal markings, while the Lemon can be detected by its symmetrical proportions and the regularity and prominence of its knots. In these, as in all other sticks, the quality varies very considerably; though they can be procured at almost any stick-dealer's, choice specimens are rare, and realise large prices.

The well-known Malacca cane is also a very choice stick; it is the produce of *Calamus scipionum*, and does not come from Malacca, but is imported from Siak, on the opposite coast of Sumatra. These canes are valued according to the length of their internodes; a perfect stick of the required length taken from between the nodes fetching a very high price, sometimes, indeed, as much as ten guineas, but this, of course, depends a great deal on the style of mounting. A genuine or perfect Malacca cane should be the natural stick, properly tapering, and simply cleaned and polished; quantities of those, however, seen in the shops have had their nodes rubbed down to make them appear continuous, after which they are stained or painted, and finally polished, and when so finished they are extremely difficult, except to a practised eye, to detect from a natural Malacca cane.

Of late years an immense number and variety of sticks have been imported into this country from Algeria, where many kinds are systematically cultivated for commercial purposes. From this country are chiefly imported the sticks of the Pomegranate (*Punica granatum*), Olive (*Olea europæa*) Myrtle (*Myrtus communis*); the petioles of the Date Palm (*Phoenix dactylifera*), and latterly the small branches of a species of Eucalyptus, probably *E. globulus*. All these, more especially the Olive and the Myrtle, have been and are still in great request.

Such, then, are some of the sticks of foreign produce which constantly and in large numbers find their way into the English market. Besides these we have many kinds of British-grown sticks, the principal of which are Ash, Oak, Holly, Blackthorn, Cherry, Maple, Hazel, Crab, and, last but not least, the Box and common Furze, added to which the Channel Islands supply us with the well-known Cabbage-stalks. *J. R. Jackson, Kew.*

(To be continued.)

WINTER DECORATIVE PLANTS.

In addition to the many flowering plants grown for decorative purposes at mid-winter, Ferns play an important part, and especially the Maidenhair Fern, *A. cuneatum*, and the elegant *A. gracillimum*. At the Royal Nursery, Ascot, Messrs. Standish & Co. grow these two in immense quantities, and at Christmas there could be seen two long span-roofed houses quite filled with some thousand plants of *A. cuneatum*, the great majority in 32-pots, with larger examples in pots an increased size. Every plant was a perfect specimen in itself, so admirably was it grown. The ferns are not marketed, but simply grown for the florists, and they are constantly being sent to London. The ripened developed fronds are those gathered, as they stand much better and last longer than the young ones. They are gathered and carefully laid in baskets, and reach their destination without taking harm. *A. gracillimum* is wonderfully well grown at Ascot. There are those who term it a "miffy grower," and say they cannot do anything with it, but at Ascot it is the very perfection of vigour, and if anything more robust than *A. cuneatum*. It is a very fast grower.

A large number of plants had been raised from seed, and it is curious to note that a few of the very young stage the pinnae were as large as those of *A. cuneatum*; but when it gets into size, the young fronds take on that small elegant form peculiar to it. So rapidly do the plants come on from seedlings, that there were admirable specimens in 48 pots that were in the seed-pans a year ago. Some extra large specimens showed off the character of the species to the very best advantage. It may be that failures with this charming Fern arise from the use of too much peat in the soil: at Ascot no peat whatever is used. The soil is a sandy, turfy loam, and a little horse-manure, and strong plants have a little weak manure-water once a week, and rather more in summer-time. The experience gained at Ascot teaches that *A. gracillimum* will not grow in peat. The cuneatum is increased by dividing the plants when they break into growth after being cut over for the London season. The plants, as soon as they begin to be active, are cut to pieces, and potted in 32-pots.

Asparagus decumbens is much grown for table decoration at Ascot; its long handsome shoots are very acceptable for clothing the stems of tall eperges. This species was growing in 48-pots, and a line of plants along the front of a stage of Camellias, &c., hung down like a fringe. The plant puts forth pseudobulbs like an Orchid, and is nearly deciduous in summer, but most ornamental in winter.

GREENHOUSE PLANTS.

THEIR CULTURE AND MANAGEMENT.

BIGNONIAS.—The different species here treated of are climbing or twining plants, and are suitable for greenhouse or conservatory decoration as roof climbers, covering back walls, or growing round pillars. So managed their natural habit is seen to advantage, as a portion of their shoots can be allowed to hang in graceful festoons, and even when not in flower, grow in this way they are very effective. They can be so arranged as to drape the wood or ironwork of the building in a manner to take off the objectionable straight lines without shutting out too much light from the general occupants of the house. This is a matter that cannot be too forcibly impressed upon those who have the charge of plant structures of this description—that where roof-climbers are allowed to form a complete thicket up to the glass, as a consequence they exclude the light from the plants that occupy the lower stages in a way that precludes the possibility of the latter doing more than drag out a miserable existence.

Roof-climbers have an elegance that cannot be imparted to ordinary trained pot specimens; but to allow the comparatively few plants that can be accommodated on a roof to monopolise the whole house, so as to render the cultivation of everything else attempted to be grown an impossibility is as great a mistake as can well be committed. In this as in most other things a medium course is the best; the roof of a conservatory can be sufficiently draped with climbers as to answer the purposes required, without making the body of the house a mere living sepulchre for the unfortunate plants placed therein. Subjects for furnishing the roof in this way can either have their roots kept confined in

pots proportionately large to the size of the plant, or, as is more usual, be planted out; the latter system has many advantages, not the least of which is that the plants will last much longer so treated, but the space thus apportioned to the roots should always be sufficiently confined to prevent the plants getting too rampant. Neither should plants intended for growing in this way ever be turned out in these prepared beds whilst they are very small, or in many cases unless naturally strong growers they do not do well, for the reason previously explained in connection with the management of conservatory cypresses, that the roots will not firmly take they cannot lay hold of the soil before it gets sour, in which case they rarely afterwards do satisfactorily; therefore if the plants are small it is generally better to grow them on in pots for a year, and afterwards to put them out.

Climbers are often grown for sale and kept with their roots confined in small pots until they get so stunted as to prevent their growing freely, consequently it is much the best to select such as are young and free in growth in preference to those that may be larger yet not in as good a condition. If of the usual size, in 6-inch pots, they should be repotted in April, giving them a 3-inch shift. All the kinds here treated of will succeed in a mixture of turfy loam, and fibrous peat in equal proportions, to which should be added enough sand to keep the whole porous; do not make the soil too fine, and pot moderately firm. In most cases it will be better to confine these Bignonias to a single stem until they have attained a considerable height, consequently they will not require the leading shoot stopping, but should be encouraged to extend in length, and for this purpose three or four long sticks should be inserted in each pot, round which the plants ought to be kept regularly trained, not allowing the shoots to twine about them in a way that they will be difficult to undo. Through the spring and summer encourage growth by syringing overhead, and every afternoon, and keeping the atmosphere moistened in very bright weather, during which a thin shade will assist them. When the roots get well hold of the soil give them plenty of water, and admit air freely, to keep the growth strong; towards the close of summer disperse with shade and the use of the syringe, so as to harden them up. Keep during the autumn and winter in an ordinary greenhouse temperature, with just enough water at the roots to maintain the soil in a medium state of moisture.

Before growth commences in the spring they should be turned out into the border wherein they are to be grown; this ought to be well drained with 5 or 6 inches of broken crocks or porous bricks, over which some fibrous material from the soil should be placed, so as to keep the latter from being washed down into the drainage; in this put 10 or 12 inches of good soil, consisting of a mixture of peat, loam, and sand similar to that already advised in planting a portion of the roots. Such as are at the outside of the ball should be loosened and spread out in the border; in this way they will soon begin to grow and occupy it. Syringe them regularly overhead every day all through the growing season; on a free use of the syringe in this way a good deal of success depends, as by so doing insects are kept down. All the after-treatment required to be kept the shoots trained to the wires that are to support them, and the space between them intended to fill is covered, regularly use the knife, so as to keep them in due bounds. In time the soil becomes exhausted; to remedy this, a couple of inches should be taken off the surface each spring without injuring the roots, and its place supplied by new soil, to farther assist which, liberal applications of manure-water may be given them during the growing season.

The following varieties are deserving of cultivation:—

B. capensis (*syn.* with *Tecoma capensis*) has orange-coloured flowers, produced in summer. It is a native of the Cape of Good Hope.

B. capreolata: flowers scarlet, blooms in June and following months. It comes from North America.

B. grandiflora: flowers from July to September. This fine variety comes from Caracas.

B. speciosa: a pink-flowered plant from Uruguay, blooms in the spring.

B. Tweediana: a yellow-bloomed kind, that flowers in the summer. It is from Buenos Ayres.

B. venusta: a once-colored variety, blooms in the autumn. A native of South America.

B. (Tecoma) jasminoides: a handsome pink-flowered species, from Moreton Bay.

Insects.—Red-spider will live upon them, but must be kept under by a free use of the syringe. Should be kept under by a free use of the syringe. Should be kept under by a free use of sponge and brush. *T. Barnes.*

GARRYA ELLIPTICA.

AMONG HARDY ornamental shrubs few surpass the *Garrya elliptica*, which is just now clothed with its long pendulous racemes of flowers, that hang from the tips of the branches in the greatest profusion. In form and appearance these greatly resemble the catkins of the Hazel or Filbert, but they are considerably larger and much heavier, and being looked up as they are by such dark rich foliage, and flowering at this season, when all else is bare and desolate, they produce a striking effect, and command admiration. In habit and growth the plant is much like the evergreen Oak, except that it is more free and open, and has leaves considerably larger and more elliptic in shape. Considering its great beauty and the length of time it has been introduced, it is very remarkable that it appears so little known, for it is a plant one seldom meets with except in very extensive collections. This is much to be regretted, as it is well adapted for any of the many uses to which shrubs are generally put. It, however, sheds off to the greatest advantage when trained up tiers or buttresses to walls, or when planted at equal distances on the latter to form panels to be filled in with other plants of distinct character. In positions of this kind they are singularly attractive, as the whole of their flowers are thrown out clear of the foliage, where they are moved by every passing breeze, and exhibit themselves in the most graceful manner possible.

It is a shrub that will bear the knife well, and may be pruned hard in every season, but this should be done directly the bloom fades, or the plant will not have time to break again and ripen the young growth, without which it would not flower again the following winter. Those we have are spurred close back any time in April, so as to confine them to their present size, and when so treated they never fail to produce an abundance of bloom from the top to the bottom, in which condition it is impossible to imagine anything more ornamental in the plant way at this season of the year. The female variety appears to be even more scarce than the male, as I note in a recent issue of the *Gardener's Chronicle* an inquiry from a correspondent as to whether it is likely the plant can be obtained, and as it is said to fruit freely, it would form a most suitable companion to the other, and be an object of much interest, as well as furnishing a supply of seed from which to raise others.

Their propagation is, however, by no means difficult, as I have raised many from layers, and I have no doubt but they would strike readily from cuttings if put in at the proper season, which for most evergreens is about the middle of September—a time when they soon form a callus, and emit roots the following spring. If propagated in this way, it is necessary to put them in a sheltered situation, where they would be safe from cold cutting winds, and not exposed to the fall effects of severe frosts, as they are not so hardy as Laurel or Aucuba, and being of a more firm woody nature, have less sap to keep them alive. Layers may be put in at any time, and all that is requisite with these is to select the best of the lower branches, and bury them under some sharp sandy soil, of from 4 to 6 inches in depth, leaving out all the ends of the shoots, which in the course of a year or so will form so many plants. I have just been pleasuring to myself what exquisite looking evergreen edgings *Garrya elliptica* would form, and how beautiful it would almost every twig laden with the pendulous inflorescence with which they are clothed nearly the whole of the winter.

As it is a plant that stands cutting so well and may therefore be kept at any form or shape, no living screen could be all compare with it when used for such a purpose. Pruned and trained as a pyramid, to plant in conspicuous places on lawns or other positions, they have a most graceful effect, or left pretty much to themselves in the shrubbery they are sure to attract notice, and, in the rich garb they assume, assert their superiority over most of their competitors as decorative plants. The wet mild winter has suited them admirably, and I have never seen them in finer condition or better clothed with flowers—the result, no doubt, of the fine dry autumn we had, which was so favourable for ripening the wood of all our trees and shrubs—a blessing that will be shared in by all during the ensuing summer should we but get a favourable spring to set the blossoms, with the buds for producing which all kinds of trees are now bristling, but fear to rush forward a state of escape unless we see a check by a change in the weather. J. S.

BOTTOM HEAT WITHOUT COST.

THIS will no doubt be welcomed as a boon by many cultivators. For there can hardly be a doubt that one chief reason why bottom-heat has often been disparaged or derided arises from its cost. Whether generated from below or sent down from above, bottom-heat costs much in labour and material. The few examples examined of borders heated by something like a forest of hot-water pipes, however successful, assuredly presented a vivid illustration of the expensiveness of the heat thus provided; and banks of fermenting material also cost a good deal to move to and fro, and be kept warm enough for service when used as a source of bottom-heat. It must also be admitted that there is difficulty as well as danger in depending on the erratic irregularity of fermenting materials as a source of bottom-heat. The heat rises and falls at times in the most irregular and unexpected manner: when most is needed there is least—when least, most. Even the most skillful in these matters, cannot regulate a hotbed as they best stoke a fire. Only a short time ago, one of the worst gardeners told me of mishaps of this kind that lost him a crop of Grapes, and impaired the health of fine young Vines for a year or two. A bed of spent-looking material was renewed with a truckload of London dung: the latter went off almost like a charge of gunpowder, and before the violent character of the decomposition was discovered every root within a foot of the surface was destroyed. The mass when moved was so hot that the men could not stand upon it, and it smelt as if the dung had been saturated with some mineral oils. So offensive as well as hot was the whole mass, that it was burned up, as it was considered unfit for manure. No doubt this was an exceptional case, but it illustrates in a striking manner the danger (similar in kind, though less in degree) to which cultivators dependent on fermenting materials for bottom-heat are daily exposed.

No doubt hot water, judiciously arranged and wisely used, reduces the danger of bottom-heat to a minimum, and regulates its amount with almost mathematical precision. But every real advance in safety and exactness enhances the cost, and it would be quite impossible to produce bottom-heat without cost for horticultural purposes by means of hot water either in pipes, tanks, open gutters, or by any other manner or mode of distribution. Neither do I promise this boon by means of limekiln-heat. That system has done all I stated I saw it do, and probably more, and "I bate not a jot of heat or hope" of its past and present doings and future achievements. But I am not about to advocate the warming of Vine borders with limekilns, nor the vineries or Pine stoves themselves with hot-water boilers set astride their top or sunk into their hot, dusty throats. All that may be practicable enough, but my object now is quite different. In promising bottom-heat without cost, it may be wise to pause and inquire how comes it that bottom-heat is wanted. Nature's law is that terrestrial and celestial temperatures should run a sort of neck-and-neck race for supremacy or equality. As a matter of fact the two often run a dead heat: at other times and seasons the one may be slightly in advance of the other, but these two are ever struggling for an equilibrium of temperature. The earth and air exchange solar heat, and divide it between them; to do so, however, with effect and on anything like fair principles of reciprocity, the one must have free access to the other. Nature never attempts to shut out atmospheric heat from the earth, nor terrestrial heat from the air. The wisdom of cultivators, in devising means by which to place the roots of such plants as Vines, for instance, in a colder medium than their tops, would seem perfect and unique folly to Nature. That folly would seem to Nature to blossom into fatuity, if after doing so efforts were made to warm cold borders outside, when they might have been kept sufficiently warm without cost by simply making them inside. Hence our simple recipe for bottom-heat without cost is to place the roots of all plants in the same structures in which they are grown. The roots will be kept about the same average temperature as the tops, and this will be found sufficient bottom-heat for Vines and nearly all other plants.

On this point I am glad to endorse the views of such a distinguished Grape and Melon grower as Mr.

Widmirth. I also agree with his condemnation of half-and-half borders. It is difficult to conceive how this great source of bottom-heat, the ground-floor of vineries and other houses, has so seldom been utilised. Anywhere, almost anywhere, outside has been preferred to the inside. And yet the floors of vineries afford ample space for borders. No doubt they are often washed into mud or sodden into sores, but all that is readily altered, and no one can contend that as good borders may not be as easily formed and kept rich and good inside as out. They are also far more under control. Heat is provided for them by the operation of natural laws, that cost nothing to enforce. The supply of water may be adjusted at pleasure, food may be given or withheld as wanted, drainage and aeration are more easily managed on inside borders than out. More, inside borders are helpful to the tops; their surfaces are better evaporators of moisture and gaseous food than shelves, pipes, floors, or walls. Nothing seems so grateful or helpful to leaf and stem as the raw loose surface of freshly moved rich soil, such as good Vine borders are made of.

Vines ought to have bottom-heat, in fact they will not thrive without it. Late Vines planted outside have their roots sufficiently warmed by the direct solar rays, and the contact of warm air. Early Vines—that is, all that are expected to ripen their fruit before May or June, or early in July—may have sufficient bottom-heat without cost by simply growing them wholly in borders inside the houses in which the tops are grown. If any Vine-grower, in any way valid reason, or just cause or impediment, why Vines will not do as well or better in inside borders than out, perhaps he will now be good enough to declare it, or for ever after held his peace, and grow his early Vines in inside borders from this time forth, and thus obtain his bottom-heat for nothing. D. T. Fish.

P.S.—Since writing the above I observe that Mr. Henderson, one of the oldest and best Grape growers, objects to inside borders, on the ground that they are mostly faulty, as is proved by the fact that the roots are always trying to get outside. But such objections are readily answered. To contend that outside borders are *per se* better than inside, is really to assert that the climate of England is more suitable for Vine roots than the artificial climate of our vineries. All beyond this is matter of making and management; and if inside borders fall from faults of either, the fault is wholly the cultivator's, for the borders are wholly under his control. As to the roots trying to get out, that is a matter of solar attraction, as Mr. Henderson will find if he makes an outside Vine border on the north side of the vinery—the outside roots will show an equally strong tendency to come in. Besides, roots will generally find and hug walls very closely, and hence their proximity to them is no sure proof that they are trying to get either out or in, but rather that they find it good to be there.

New Garden Plants.

DENDROBIUM PETRI, n. sp.*

This is a rather promising, neat Dendrocarye. Imagine a reduced D. Farmeri, with one or two upright racemes of white flowers and very small bracts. It grows to the height of more than a foot, and its shining stems, as well as the small leaves and racemes, would make a good effect in a dense mass in the eyes of those Orchidists of a refined taste who think white an elegant colour, and preferable to the bright colours of the Poppy or Sunflower. It may be compared with the Dendrobium Moorei of Darwin von Müller, which has much smaller flowers, and in which the lip, in lieu of being rhombiform, is ligulate-acute, with two angulate teeth before the base. There is a peculiar, nearly square callus between the teeth, described as "raised lines." Our species is probably a Polynesian discovery of the zealous traveller, Mr. Peter Veitch, to whom it is dedicated, and who has sent it to the Chelsea nursery. H. G. Rehb, J.

* *Dendrobium (Dendrocarye) Petri*, n. sp. — Caulibus acutis superne viximatis, internodiis, trifloris, liliaceis, oblongis acutis, imbricatis; racemo solitario tunc racemis brevibus erectis glaberrimis; bracteis ovatis, mucronatis, mucronibus perianthii feracibus, quatuordecim partem, acutis; sepalis ligulatis, acutis, sepalo medio oblongo acuto; lobis perianthii; labello caudato rhombico utraque dimiduatione, collo ligulato a basi in ducibus, his retibus, semine basilico, utraque angulo; columna truncata. Flores albi. Polynesia (see Anahy). Petrus Veitch, qui locum nunciat. H. G. Rehb, J.

CURMERIA WALLISII, Mast.*

This is a new and beautiful stove foliage plant of the Aroid family, of tufted habit, with somewhat spreading stalked leaves of an ovate-oblong slightly oblique form, rounded at the base, acute at the apex, where they are somewhat abruptly prolonged into a short acumens. The margin of the leaf is entire and bordered throughout with a narrow band of white. The midrib is depressed upon the upper, prominent on the lower surface, and from both sides of it proceed in an arching manner to the margin a series of secondary nerves at short intervals, the intervals being filled with smaller nerves closely crowded together.

yellow blotches, the under surface is glaucous, pinkish beneath the green upper surface, paler beneath the yellow spots, the whole sprinkled with minute white dots.

The largest leaf seen by us measured about 6 inches in length (not including the stalk), by 3 in breadth, but we have little doubt that these dimensions will be exceeded as the plants increase in vigour. The leaf-stalks are channelled on the upper surface, and measure from 1-2 inches in length, half of that length being occupied by a sheathing base. We refer to the foot-note for the strictly technical characters of the inflorescence, but we may say that they are such as to induce us to place the present plant in the genus *Curmeria*, a genus founded in the *Illustration*

to *Curmeria picturata*. The three species may thus briefly be distinguished:—

C. picturata, Lind. et André, *Ill. Hort.* 1873, p. 45, t. 121.—Leaves on short stalks, cordate, with two rounded basal lobes, ovate, or ovate-oblong, pointed, marked along the midrib with a narrow silvery white band.

C. Roezlii, Mast. in *Gard. Chron.* 1874, p. 804, figs. 159, 160.—Leaves on long stalks, ovate-oblong, rounded or slightly tapering at the base, not cordate, tapering gradually at the apex, and with a few pale yellow scattered blotches on the upper surface.

C. Wallisii, Mast. *infra*.—Leaves on short stalks, slightly oblique, ovate-oblong, rounded and slightly tapering at the base, abruptly acuminate at

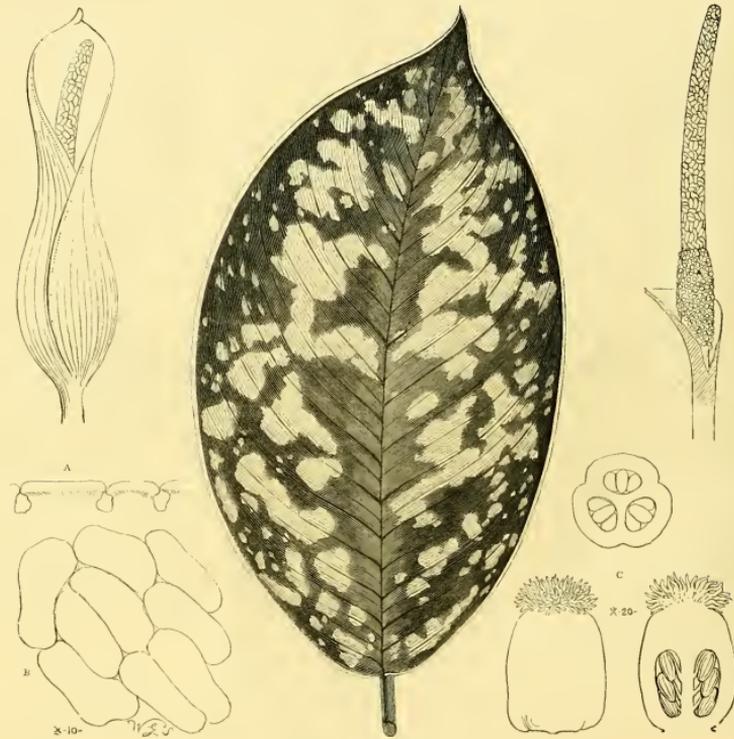

FIG. 16.—CURMERIA WALLISII. (SPATHE, SPADIX, AND LEAF, NAT. SIZE.)

A, B, Side and face of stamens, enlarged to diameters. C, Elevation and sections of ovary and stigma, enlarged 20 diameters.

The ground colour of the upper surface is of a rich velvety green, broken up by irregularly maplike

* *Curmeria Wallisii*, Mast., sp. nov.—Acaulis rhizomate perennante aromatica; foliis patensibus fasciculatis et nitris, petiolatis, petiolis 1-2 poll. long. maximo pro parte vaginatum, superne antequam canaliculis a latere compressis, lamina glabra superne intense viridibus irregulariter aureo-maculatis subtus pallidioribus glaucescentibus ovato vel obovato-oblongis basi rotundatis apice breviter subitotque detulde-acuminatis, albo-marginatis; spatia brevi pedunculata 3-3½ poll. long. basi convoluta ventricosa, medio contracta supra medium porum aperta, apice brevis-acuminatis pallide puncta maculis albidis minutis conspersa, intus nitida; spadice tereti spatia vix breviter nudique floribus obtecta.—Flores terre cunio et in conspectibus.

Hujus generis species tres sunt descripte nempe—1. *Curmeria picturata*, Lind. et André, *Ill. Hort.* 1873, t. 121. Foliis patentibus ovato-oblongis basi cordatis medio-argenteo-fasciatis. 2. *C. Roezlii*, Mast. in *Gard. Chron.* 1874, p. 804, figs. 159, 160. Foliis erecto-patensibus longe petiolatis oblongo-acuminatis basi rotundatis. 3. *C. Wallisii*, Mast. ut supra. Foliis patentibus brevi-petiolatis ovato-oblongis oblique detulde-acuminatis basi angustatis insigniter aureo-maculatis.

Horticult. 1873, p. 45, t. 121, by MM. Linden and André, on the plant known as *C. picturata*, and to which we were enabled to add a second species, *C. Roezlii*, in these columns—1874, p. 804, figs. 159, 160. The present plant, like the last mentioned, is a native of Colombia, whence it was introduced by Mr. Wallis, as the *C. Roezlii* was by the collector whose name it bears. All three species were introduced to commerce by Mr. W. Bull.

C. Wallisii has at first sight much resemblance to *C. Roezlii*, but is very superior to it as a garden plant, from the brightness and elegance of its variegation. It differs also in its relatively broader, more ovate, more abruptly pointed leaves, and especially in its shorter leaf-stalk, the relative shortness being especially observable in the petiole proper, or that portion which intervenes between the sheathing portion of the leaf (the latter not shown in the illustration, fig. 16) and the blade, in this respect approaching

the apex, bordered with a white edge, sprinkled above with bright golden blotches.

All the species are from Colombia, and have a more or less aromatic perfume when bruised. *M. T. M.*

ALFRED SMEE.

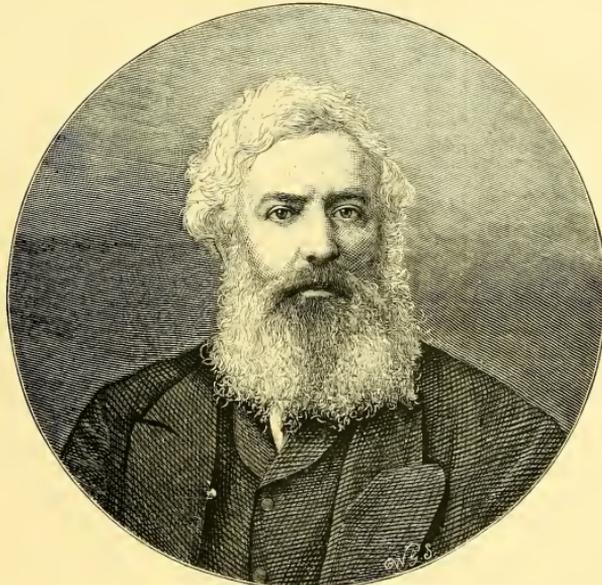

We avail ourselves of the opportunity afforded us by the publication of a portrait of the late Mr. Alfred Smea to give a few additional particulars of his career. Educated at St. Paul's School and King's College, London, he pursued his medical studies at St. Bartholomew's Hospital. This is not the place to dilate upon his strictly professional labours; it must suffice to say that he early attained eminence as a lecturer and teacher in surgery, and held many appointments in connection with medical institutions,

To the last he retained his position as surgeon to the Bank of England, where his father had been Accountant-General. Mr. Smece himself, in conjunction with the engineer, Mr. Hensman, and the printer, Mr. Coe, devised and brought out the present form of the Bank of England notes and cheques; while his professional knowledge made him a valuable coadjutor in various life insurance offices and similar institutions. Of one of these, the Gresham, which has attained a foremost position, he was one of the original founders. The bent of his mind was early turned to chemical and electrical studies, on which he published various memoirs, but in connection with which subject he will probably be longest remembered by the form of battery known as Smece's battery. His scientific attainments were speedily recognised, for he was elected a Fellow of the Royal Society at the unusually early age of 23, while the Society of Arts awarded him a gold medal in recognition of his in-

all plans for the increase and dissemination of knowledge was manifested in many ways, among others in the establishment of educational lectures at the London Institution, of which he was a Vice-President. In conjunction with Sir James Hannen, Mr. Justice Pollock, and other old Paulines, he succeeded, moreover, in modifying the scheme of the Educational Commissioners for the reorganisation of St. Paul's School. His love for Nature was a veritable passion. Many years ago the Fern-cases in his dwelling-house in Finsbury Circus were as remarkable, and attracted almost as much attention, as those of the late N. R. Ward. The writer of these lines well remembers the time when he was in the habit of passing and re-passing the windows in Finsbury Circus, with the sole object of ascertaining what were the species that thrived under such disadvantageous circumstances. In later years Mr. Smece became possessor of an extensive garden at Wallington, near Croydon, and here, having wider

luxuries of a greenhouse, a fernery, a stove, or a vinery. Mr. Smece's "poor man's houses" exactly realise this ideal. They are sufficient to give profit, pleasure, may, luxury to the mere labourer. Of course it is not to be expected that the keeping or the condition of the houses, or of the plants in them, would satisfy a head gardener on a ducal estate, but from the point of view of the proprietor they are all that could be desired or expected, and relatively to the outlay we should not be surprised if the produce were larger, as the pleasure to the proprietor was certainly greater, than in establishments of greater pretensions.

Insects, fishes, birds, fossils, nothing came amiss to the hospitable proprietor of this garden. How keen his interest, how great his delight in these matters, is evidenced in his work, *My Garden*, reviewed in these pages at the time of publication. This work is illustrated with a profusion of excellent woodcuts, and in its wide extent of knowledge and genuine sympathy

THE LATE ALFRED SMECE, F.R.S.

vention of Smece's battery, and of his metallurgical researches. His publications were indeed numerous and varied, displaying great industry, unvarying energy, a wide general knowledge of many subjects, an intimate acquaintance with a few, and a vivid imagination, which led sometimes to hasty inferences and fallacious analogies. Of this his papers on the Potato murrain, and the aphides which accompany or are consequent upon it, afford notable proof. It is, however, certain that, however much mistaken he might have been in this matter, full justice was never done to the acuteness of his observations, and even now the important though subsidiary part that aphides play in the destruction of the Potato, and which was first published by him, is hardly sufficiently recognised.

Alfred Smece was, indeed, a genuine enthusiast, actuated by the highest principle and deepest sympathy for science, but so hurried on by the fervour of his disposition that the careful and patient spirit which characterises the highest type of the man of science was overpowered by the rapid insight which characterises the man of genius. His sympathy with

scope, he devoted himself with characteristic zeal to the formation of a garden, which, if such an expression may be used, is encyclopedic. It contains something of everything. Though the surface is flat, landscape effects and artistic surprises are numerous. The visitor passes in a moment from a bold bit of lake scenery to a tiny Fern-clad ravine, through which meanders a crystal stream laving as it goes a host of lovely bog-plants; a turn, and the visitor is in a Rose garden, or admiring a choice collection of alpine. Now long shady walks invite attention, now the treasures of the herbaceous border attract notice. Nor is the more utilitarian part of gardening omitted—on the contrary, it is in places somewhat too obtrusively prominent. Be this as it may, the collection of vegetables, and specially of fruit trees, is very remarkable. No mere amateur's collection within our experience rivalled this one in extent and variety. As to the houses and garden structures they are numerous and efficient. They have no architectural pretensions, indeed one object of the proprietor was to show how at a comparatively very slight expense men of very moderate means might enjoy the pleasures and

for all natural objects is a worthy exponent of the author's character. Its range is wide rather than deep, but it is impossible not to catch from its pages some of the enthusiasm of the writer. As an encyclopedic treatise for the amateur as distinguished from the professional gardener, we know of none to approach this.

At the Royal Horticultural Society, of which Mr. Smece was for a time member of Council, President of the Fruit, and member of the Scientific Committee, Mr. Smece's sympathies were always strongly and unmistakably on the side of pure horticulture. Though his schemes and proposals were, we believe, not always sufficiently practical to commend themselves to his associates in the Council, yet no man had a sounder, juster notion of what the proper functions of a horticultural society should be. His public addresses on the scope and duties of the Royal Horticultural Society, and on the paramount necessity of making it a scientific and not a merely fashionable Society—of fostering its powers for the public good rather than for the frivolous pleasure of the few—were always no less sound and sensible than they were energetic. III

liberty of spirit and genial hospitality were marked characteristics, so much so, that few men had a larger circle of friends, or was more beloved by them than he. It may perhaps be allowable to allude to his garden parties, and to the much-appreciated hospitality he showed to his English fellow-jurors in Florence at the time of the Botanical Congress in that city.

Alfred Smeed died on January 11, and was buried on January 16 at Deddington, within sight of the garden of which he has given a history, which may fairly compare with that which White gave of his parish at Selborne.

Mr. Smeed leaves a widow, a daughter married to Professor Odling, the eminent chemist, and a son who follows with no uncertain step in his father's footsteps.

Foreign Correspondence.

BOTANIC GARDEN, GRAHAMSTOWN, SOUTH AFRICA: *Dec. 13, 1876.*—In an article on *Encephalartos Altensteinii*, which appeared in the *Gardener's Chronicle* of September 23, 1876, it is stated that the trunks are "quite glabrous, and marked with three- or somewhat four-lobed scars, indicating the place from whence former leaves have fallen away." Now, I must beg to say that the words in italics are incorrect, as not more than a fourth part of the scars to be found on the trunks of the species in question ever bore perfect leaves. Quite half of the whole length of the trunks of those species of *Encephalartos* with which I am acquainted were found in advance of the leaves; and in the case of *E. Altensteinii*, spaces of from 4 to 6 inches in length are to be found, at more or less regular intervals, the whole length of the trunk, which spaces were formed as stated.

It is pretty well known that the *Encephalartos* have periods of partial rest after the production of a set of fronds, but the resting is more apparent than real. Close inspection will show that active work is going on the whole time. It will be seen that the bases of the last-formed leaves are receding from the apex of the trunk, and that a cone, clothed with woolly scales, is taking the place of the leaves.

At length the period for the production of new fronds again comes round, and one result of the growth of leaves will be, to force out into line with the older portion of the trunk the said cone of scales, thereby adding some 4 or 6 inches to the height of the plant.

It is obvious that the above facts have some bearing on the question of the great length of time that some newly-imported trunks of *Encephalartos* are before producing fresh leaves, and an importer may, from the position of the last set of fronds, and the width of the cone of scales from the base of the fronds to the apex of the cone, form some idea as to when new fronds may be expected to appear. *E. Tidmarshii*, *Curtator*.

Florists' Flowers.

CYCLAMEN PERISCIUM.—Do we fully realise the fact that the Persian Cyclamen is really and truly an autumn and winter flowering plant? Years ago, when the old system of drying-off in summer and almost roasting the bulbs to death in hot weather, in order, as it was supposed, to drive them into bloom in spring, it was thought to be a floral feat to have the flowers as early as February and March! A more judicious treatment has happily superseded, though it is as yet only imperfectly understood, for not long since a journal accustomed to include horticultural matters among its contents was found gravely asserting that the bulbs must be well dried off in summer if a quantity of flowers were looked for in spring. The roasting process is still followed in some gardening establishments.

In order to thoroughly appreciate the glorious decorative value of *Cyclamen periscium* it should be seen in quantity, as one can see it at Mr. H. B. Smith's, Ealing Dean Nursery, where, at the beginning of the month, some 10,000 plants were gathered together, a large majority of them for market purposes. These are peculiar in the long, low, span-roofed manner, presenting an unbroken surface of varied colour, not in monotonous patches of white, purple, pink, &c., but mingled together, and presenting a

most charming floral aspect. The greater number of the plants were in 48-pots, and they were blooming with great freedom; the number of flowers on some of them was perfectly astounding, plants sixteen months from the seed-beds were producing something like 200 blossoms. They were carefully counted, so that no error of calculation might occur. And not only does the Cyclamen remain a long time in flower, but it is also invaluable for furnishing cut blooms, and they last a considerable time in water.

As far as the improvement of the cyclamen is concerned in the direction of form and colour, Mr. H. B. Smith is doing good service to floriculture. He has originated some purple and crimson flowers of great richness of colours, the petals large, broad, and stout, some exceedingly pretty pink and pale rose shades, and some pure white flowers of high-class quality.

The culture of the Cyclamen, as followed at Ealing Dean, appears to be of a simple character. The seed ripened in June and July is sown in August, in pans of light rich sandy soil, plunged in bottom-heat, and by the end of November the seedlings are pricked off into 60-pots, about fifteen plants in a pot, and still kept in a warm moist temperature. In February they are potted singly into small "Long Toms," and still kept close under glass; the next shift is into 60-pots, and finally into 48's in the month of May. They then go out-of-doors into cold frames, where they are kept growing, being freely watered, shaded from hot sun, and sprinkled overhead. There is no resting space, and the plant does not require any. It was stated by Mr. Smith that he had this season raised 11,000 seedlings, and they abounded on every hand.

The soil used for the Cyclamen is a light loam and leaf-mould, and a little sand. If the loam be at all heavy, a little peat should be mixed with it to keep it open. Good drainage is indispensable. The first batch of plants is sent to market in November, and the supply is continued as long as there are plants to send. *R. D.*

The Villa Garden.

ORCHARD HOUSE.—There is no reason why an orchard-house should not form a part of the gardening arrangements of a Villa residence; and we make this statement while fully aware that the system of orchard-houses has not made the headway that it was at one time confidently expected it would. Orchard-houses, like almost every other horticultural venture, have found their advocates and their opponents; the *pro* and *con* have been put with singular vigour, and they have been as vehemently supported as they have been contemptuously denounced, and probably, after all, the truth has lain somewhat midway between the two. It is very often the case in disputed matters that the happy medium is frequently the best point of advantage.

We are always contending that, the Villa Garden being generally restricted in extent, should yet be made as full of interest as possible. Thus it is we are found advocating the Villa orchard-house. High authorities have frequently been found writing and speaking against small orchard-houses, but in apparent defiance of these—high authorities are oftentimes not a whit more infallible than little ones—we yet advocate a small orchard-house.

What shall be the form of the orchard-house? It can be either span-shaped—that is, with an ordinary ridge roof sloping on either side from the middle of the west—or it may be a lean-to against a north, east, or side wall. The span-roofed house is perhaps to be preferred, but a very useful orchard-house can be had in the form of a lean-to. We do not decry large orchard-houses, but consider small ones the best for an ordinary Villa residence, where space is somewhat restricted.

The orchard-house need not be lofty. In a small house the trees would be in pots, as there would scarcely be accommodation for standard trees planted out, and as the pot trees should be as near the glass as possible, the roof should be low, for the fruit must not be too far from the glass, if we would have it finely flavoured and highly coloured. A certain height must be had, and the breadth of the house must be regulated as much by the necessities of free circulation within as by the strength of the house to bear gales of wind, if the house occupies an open and

exposed position, or is subject to a weight of snow on the roof.

Whether the house have a framework of brick, or is wholly of wood, revolving wooden shutters should be fixed in the walls to admit of plenty of ventilation when it is desirable to give it. Whether it be a span-roofed or a lean-to house, let there be some 4 feet of supporting wall of brick or woodwork, and on the top of this a foot or 18 inches of a strong glass frame, from the top of which the roof should spring. Top ventilation, *i.e.*, means of ventilating in the ridge of the roof when required, must be provided. Such a house—of which this is but a bare outline—is simple in construction and efficacious when properly managed. It would not possess the architectural elegance found in a greenhouse or conservatory, but if kept clean and painted would never be an unightly object from the dwelling-house.

In the case of a lean-to house the wall at the back might be utilised for cordons Peaches and Nectarines, Vines, &c., planted out at the proper time in a well-prepared border, but the Vines must not be allowed to cover too much of the roof to the exclusion of the sun from the plants beneath.

Supposing a house such as we have sketched be built, the next thing is the matter of furnishing it. Nurserymen invariably keep a collection of orchard-house trees in pots—for we are proceeding on the principle that the plants will be in pots—and the following varieties of Peaches are well suited for orchard-houses, viz., Earl of York, Grand Magnonne, and Royal George; Nectarines—Pitman's Orange and Hunt's Tawny; Pears—Jefferson, Green Gage, McLaughlin's Gage, and Standard of England; and the Moorpark Apricot. This selection can be added to with desirable varieties, and also with suitable selections of Apples and Pears, if it should be desired to include these in the collection. The trees should (when purchased) be fairly well set with fruit-buds, and re-potted in a suitable compost in October or November last.

At this time of the year the pots should be well bedded in leaves, as a protection from frost. We are dealing with a cold orchard-house; hence the necessity for keeping frost from the pots. The leaves may come just above the rim of the pots, and when it is desirable to examine the plants in case any require water, the leaves can be drawn on one side, and replaced when the task is finished.

Nothing has yet been said as to pruning the trees, and excepting that two or three of the early Peaches are put into a gentle heat of say 45°, to get them a little forward—in which case the necessary pruning must be done before the plants are removed there—the general pruning need not be done till the end of January. It should not be delayed later, for it is a law in practical horticulture "the sooner a shoot is pruned the stronger will it break." If any delay be made in the pruning, it should be in the case of plants that have put forth a gross growth; delay in this case has been found to impose a slight check on the plants, and, further, a well-known cultivator of orchard-house trees has remarked that "as a rule too much wood is left on orchard-house trees, and they produce too many flowers. Cultivators are far too anxious to secure a fine and plentiful show of bloom, forgetting that, the greater the quantity of bloom, the more trying it is for the plant, and the less likely are the flowers to set. A Peach tree in a 12-inch pot, for instance, with fifty or 100 flowers upon it, is just as good (if not better), and will produce as good a crop, as one with ten times the amount. In pruning, therefore, it is well to bear this in mind—that every flower-bud, if properly developed, will produce a fruit, and that only a few (if Peaches, one on each shoot) are required. Excepting where it is needed for the formation of the tree, the shoots of Peaches, &c., in pots, or all bush and pyramid specimens, should not be left more than 2 or 3 inches in length. Where the trees were closely pinched during the past year, the twiggly ends only require to be cut off. Care must be taken at all times to prune direct to a wood-bud, which may be known by being much more slender and pointed than the flower-buds. Where no wood-buds are to be found, the shoots must be kept at full length if they cannot be dispensed with."

And lastly, while the weather is so mild, and there is such a tendency on the part of plants of all kinds to come forward quickly, the house should be kept open night and day, so as to retard the trees as much as possible.

THE

Gardeners' Chronicle.

SATURDAY, JANUARY 27, 1877.

APPOINTMENT FOR THE ENSUING WEEK.
THURSDAY, Feb. 1—Meeting of the Linnean Society, at 8 P.M.

THE subject of the desirability of a more extended CULTURE OF HARDY FRUITS is one of those questions which, like the condition of Kensington Gardens, crops up at tolerably regular intervals to disappear in due time and to be no more heard of till the swing of the pendulum once more brings it under notice. It may be because the statements made are usually obvious and do not admit of argument that nothing comes of them. If they roused opposition or antagonism people would be stimulated to do something, whereas now they hear or read and nothing comes of it all.

Many years ago MR. ROACH SMITH took up the question, not being by any means the first to do so, but we do not know that anything more cogent has been since urged. Now, again, the question has been ventilated at the all-embracing Society of Arts, where Mr. G. C. T. BARTLEY has been illustrating his favorite topic of thrift by pointing out how much is lost to the country by allowing pieces of waste ground, railway embankments, and the like, to remain unused. MR. BARTLEY'S propositions, like those of his predecessors, will be unanimously assented to—viz., that the supply of fruit is less than it ought to be, and that it would be advantageous to increase it. How is this to be done? MR. BARTLEY advocates, amongst other things, the reclamation of waste pieces of ground and of railway embankments. Why not cultivate these, and make them productive? We believe the reason is that, under most circumstances, fruit culture would not be remunerative in such places. If they could be thrown into the allotment-gardens of the poor well and good, but in most instances they are detached pieces removed from habitations or ready means of access, and naturally ill adapted by site or soil for fruit-cultivation.

It will not pay to stick in a fruit tree in any description of soil, as if one were merely sticking a stake into the ground. To be made profitable the ground must be trenched and manured, and fruit trees of a kind suitable for the locality planted. This being so, there can be no doubt that, on the small disjointed scale we are now alluding to, fruit culture would not be profitable. Where fruit is grown for culture as a commercial investment it requires an outlay of capital and labour. If that capital and labour are to return a fair interest they must be intelligently directed and used under certain conditions, but if these conditions be unattainable, then fruit culture will involve a serious loss. Now we cannot help thinking, looking at the matter from a practical point of view, that such would be the result if MR. BARTLEY'S plan of utilising waste scraps of land were adopted. Add them to the adjoining fields, grow Jerusalem Artichokes on which require no special preparation or care—though like everything else, much improved by care, or let them remain as common pasturage for village cows and geese. The question of railway banks is different. There are doubtless miles of embankment which might be profitably used, as one sees them on the Continent, for growing Osiers, or for coppice-wood. Filberts and nuts might be used for this purpose, and in some places Strawberries might, as has often been pointed out in these columns, be most advantageously grown, their runners serving to keep up the banks, while their fruit would be sure to find a market.

The culture of fibre plants, such as the common Nettle and other fibrous "weeds," might be profitably undertaken in the neighbourhood of paper mills. Indeed, there are various means of utilising railway banks which might be adopted, and, as we believe, with generally better results than fruit-growing. The experiment of growing fruit trees on either side of the line, has been tried in Belgium, and we gave an illustration of the plan adopted in that country in our volume for 1869, p. 277. Subsequent enquiries made by ourselves in Belgium from competent authorities, have, however, led us to doubt whether the experiment is worth repeating in this particular direction.

For the domestic supply of fruit or for culture on the small scale, infinitely more might be done in our cottage gardens and on our cottage walls. We have often urged this subject on the attention of country gentlemen, and of the local horticultural societies. The cottagers want the instruction, which any good gardener could give them, as to what to plant and how to plant it. The Grantham Horticultural Society, at the instigation of Mr. W. INGRAM, if we mistake not, offers to successful cottagers competing for prizes at the show approved kinds of fruit trees for the situation and aspect on which their gardens and houses are placed. This is an example worthy to be followed, as there is no reason why the great majority of our cottages might not be clothed with Apricots or Pears, and why Apples and Gooseberries should not be found in every cottage garden.

If the Society of Arts can bring about so desirable a result, it will add to the obligations it has already conferred on the country, and it will perhaps shame the Horticultural Societies of the kingdom into a wider sense of the duties they owe to the community.

We have on more than one occasion called attention to the recent appointment by Her Majesty's Office of Works of an ex-military gentleman as Bailiff, or Chief Superintendent, of the Royal parks, and we are constrained to do so again through an article which appeared in our admirably conducted contemporary, the *Builder*, on the 13th inst. The *Builder* is usually so averse to jobbery, so anxious to uphold the dignity of art and the rights of the workman, that it is a little surprising to see it sanctioning an article so contrary to its usual high sense of what is fit and becoming. The writer of this article, which seems to have been officially inspired, first makes certain insinuations of a grave character against the present Superintendents as a justification for the appointment, and then offers an apology for the selection of an ex-officer of Engineers instead of a practical man.

We would remark that if the office of Park Bailiff is a good or necessary one—which is open to doubt—it cannot require the casting of aspersions on the character and efficiency of faithful public servants, who have no means of defending themselves before the public. Such insinuations are unwarrantable and unjust. The present Superintendents are men of ability and integrity, and were appointed to their respective positions as being the best qualified, and we maintain they have executed their trust well. It is a distinct breaking of faith with them, therefore, to suddenly usurp their powers and reduce their status, which the appointment of this new office and the new regulations do.

We join issue with our contemporary as to the wisdom of appointing a military gentleman to the office. The new Bailiff may be, for aught we know, a gentleman of very correct taste, and he is reputed to be a good maker of roads, but we never heard of him as a horticulturist or a landscape gardener, or a forster, or, indeed, as possessed of any knowledge fitting him for such an office. How,

then, is he to superintend or satisfactorily control the actions of the Superintendents under him who are possessed of that knowledge?

According to the *Builder*, such knowledge is not requisite "when it is considered that each of the Royal parks has Superintendents who are practical gardeners, &c. . . . It may be urged that special horticultural knowledge was not particularly requisite in the holder of the new appointment." This is strange doctrine, not likely to be accepted. What, then, we would ask, are the new Bailiff's qualifications, or what the duties that he can perform that could not be done quite as well without him? He cannot direct the actions of the Superintendents, in practical matters, but he can thwart and impede them. What service is the new official likely to render, from a gardening point of view, to MR. ROGER, of Battersea, who, treading in the steps of JOHN GIBSON, has made Battersea Park a model, to which, year after year, the horticultural critics point with just pride and admiration? Of what advantage will it be to Victoria Park, so ably managed by MR. MCINTYRE, to receive instructions as to matters of gardening details from an ex-officer of Engineers? How is such an officer to set about regenerating the plantations in Kensington Gardens? If this style of appointment is to prevail, we may expect to see the Royal Gardens at Kew, Edinburgh, and Glasnevin superintended by a nominee of the Government with no special knowledge of the work of his department. The Superintendents will now, instead of consulting with the Secretary or First Commissioner direct, have, we believe, to receive the sanction and approval of this new official even to the merest trifle. More red-tape! more economy!

The cost of this new office, including clerks and assistants, cannot be reckoned at less than £1000 per annum, so this is what the country will have to pay for this new deputy official. Will the "Office" be able to show any return for this great expenditure? We doubt it, but we again quote the *Builder*—

"It is reported that the holders of the larger privileges in connection with the Royal parks, such as the ownership of boats let out for hire for rowing or pleasure parties, at so much an hour, and those other privileges, as in the East-end parks, in the matter of swings and merry-go-rounds, will be subject to a change. In the Crystal Palace grounds, and other public places of entertainment, large sums are paid yearly by owners of like appliances to those seen in the Royal parks."

So here we have shadowed forth, not very lucidly, some of the duties which it is considered desirable for a military gentleman to accomplish. Seeing that this department has always been under the direct control of the Office itself, we fail to see why the Park Superintendents should be made the scapegoats for such an appointment.

The solution of the whole case seems to be, that the appointment of a practical man as Chief Superintendent of the Royal parks, which was first proposed by MR. AYRTON, and lately sanctioned by the Treasury, has been so arranged by the present Office of Works as to secure a mere official deputy, instead of a general surveyor of parks, as was originally intended. We doubt if the public will be satisfied with the change.

—We are glad of the opportunity of figuring the magnificent Australian *DEUTERIUM SPECIOSUM* VAR. *HILLII* (fig. 15), for its merits are less known than they deserve to be. Few more glorious sights have met our eyes than that which greeted us on opening a package lately from the Hon. and Rev. J. T. BOSCAWEN. Our page will only allow us to give a portion of one spike, but it may suffice to give an idea of its massiveness and beauty. The variety *Hillii*, figured in the *Botanical Magazine*, 5261, differs from the old specimen in its narrower and longer sepals and petals, as pointed out by Baron VON MÜLLER. The stems also are more elongated. The plant is a native of tropical Australia, Queensland, but the species extends into the cooler southern latitudes of New South Wales and Victoria. The flowers are of a creamy white colour, and have a pleasant fragrance.

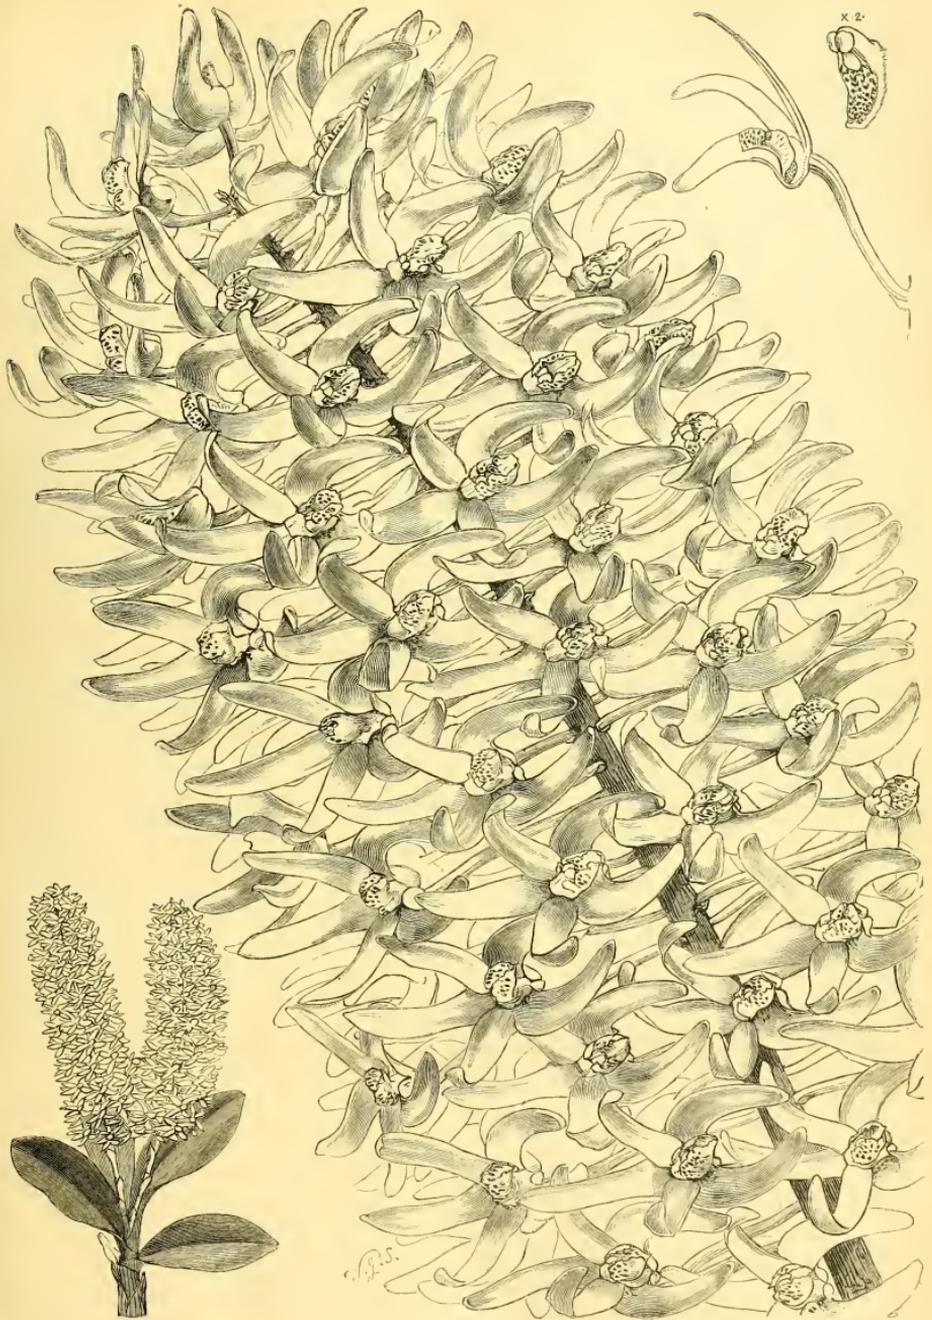

FIG. 18.—*DENDROBIUM SPECIOSUM* VAR. *HILLII*.

Compared with its Indian allies the present plant freely but little heat, and it usually flowers freely every year from the same bulb. Sometimes it flowers twice in the year, and last year Mr. BOSCAWEN'S plant flowered a third time from the same pseudobulb—a very unusual occurrence. Nothing could be finer and more healthy than the foliage which accompanied these magnificent spikes. Mr. BOSCAWEN'S plan of culture, however, is very simple. After flowering the plant is allowed to rest for a month or six weeks; it is then placed in an intermediate house and copiously watered every day till the pseudobulbs are formed, when it is placed out-of-doors or in an orchard-house in the sun.

— The proposed SOUTHERN SHOW OF AFRICULAS is, we are glad to say, likely to be successfully carried out. A meeting of the committee is to be held on January 31, to approve the prize schedule, which has been drawn up by MESSRS. TURNER, DOUGLAS, and DODWELL. We understand that upwards of £60 will be offered as prizes, and that some £120 more of subscriptions are necessary to meet this outlay and the necessary expenses, so that any supporter of florists' flowers or patron of horticulture who has not subscribed may yet have an opportunity of doing so. Subscriptions should be sent direct to the Hon. Secretary, Mr. E. S. DODWELL, 11, Chatham Terrace, Larkhall Rise, Clapham, S.W.

— The successful candidates at the recent election of pensioners in connection with the GARDENERS' ROYAL BENEVOLENT INSTITUTION were Mr. JAMES GOSLING, Mrs. W. P. AYRES, and Mrs. MARY ANN ADDISCOTT.

— MILLA LEICHTLINII, a new and quite distinct species, is flowering in the Royal Gardens, Kew, both under glass and in the open ground. It was sent hither by Herr MAX LEICHTLIN, who received it from the Chilean Andes. In structure it approaches *M. porrifolia*, but agrees in habit only with *M. sessiliflora*, another Chilean species, not yet introduced. The peduncles and pedicels are so extremely short that the flowers appear low down among the leaves, and just above the ground. The leaves are about six to a corn, erect, bright green, 3–4 inches long, and $\frac{1}{4}$ inch broad. The flowers are fragrant, pure white, each segment with a greenish keel, and rather more than 1 inch in diameter. Two or three tubels are produced to a corn, and each umbel has two or three flowers. This interesting plant we know of now only in the Kew collection. It is quite hardy, and will doubtless be as easily grown as the other species. A figure was published in the *Botanical Magazine* of June last, and in our volume for 1875, p. 234, will be found the original description by Mr. BAKER.

— The next meeting of the INSTITUTION OF SURVEYORS will be held on Monday evening, Jan. 29, when the adjourned discussion on the paper read by Mr. W. T. MARKIOTT at the last meeting, entitled "Riparian Rights," will be resumed.

— A winter made up of mild muggy weather and an excess of rainfall is certain to prove one of unusual difficulty to the Potato grower. The present season has proved to be one of remarkable difficulty in STORING POTATOS in such a way as shall check that premature growth invariably so detrimental to the future crop. The great heat and drought of the past summer ripened off the Potato crop prematurely, and left the tubers in a most excitable condition. These causes, combined with the mildness of the winter, have tended to generate an early starting of shoots, especially where the tubers are stored in bulk, or influenced by the prevailing moisture. The most effective remedies are found in storing thinly on airy shelves, where on dry days an abundance of air can be admitted, and where also there is sufficient space to admit of a frequent overhauling of the stocks to pick out all diseased or decayed tubers. Seed Potatoes cannot have too much light and air during the resting season consistent with the exclusion of moisture and frost, and, if shoots are induced, these will never become attenuated or be otherwise than stout and healthy as long as there is an abundance of light and the small roots emitted at the base of each shoot are unable to find moisture. We recently saw at the

Aston Lower Grounds, Birmingham, an admirable arrangement for storing a large quantity of seed tubers in a most effective way, and yet in a small compass. Mr. SPINKS had imported the idea from France, and put it into successful operation. A series of shallow wooden trays, all of the same size, each one having legs at each corner about 3 inches in length was provided. As these were filled with a single layer of tubers closely set together they stood one on the other, and thus air was enabled to freely circulate amongst them. It is a capital arrangement for the storing of many kinds in small quantities.

— We understand that Mr. J. H. BURTON has been appointed successor to the late Mr. P. STEWART as gardener to CHARLES TENNANT, Esq., The Glen, Peebleshire.

— At a meeting of the Metropolitan Board of Works held on the 12th inst. Mr. LAMMIN introduced a deputation from the parish of FULHAM, who presented a memorial on the subject of the recent INUNDATIONS in their parish. The memorial was stated to emanate from certain proprietors who had received great damage to their stock and property by the recent high tides. They were last year subject to a similar calamity, since which time they had raised a portion of their banks at their own cost; but, although anxious to do all in their power, they found the work of greater dimensions than they could attempt, and concluded by asking the immediate assistance of the Board. Mr. HARRY VEITCH, in support of the memorialists, said he represented the most immediate sufferers, amongst whom the principal were the class of market gardeners of London, raising the more delicate descriptions of vegetables, acres of which crops had been destroyed. His (the speaker's) own firm last year estimated their losses at £2000, and had to burn 12,000 young trees from their plantations. At a meeting of the Fulham Board of Works held subsequently, Mr. VEITCH, together with Mr. WALDEN, an owner of Osier beds, and several other occupiers of land adjacent to the Thames subject to inundations, made a statement of the grievous losses to which they have been subjected, and to which they are still liable by the rising of the water. Mr. VEITCH said the destruction to his property and consequent loss in business would amount to £2000; Mr. WALDEN, a grower of Osiers, would lose £3000; Mr. MATHER, who had been drawing £20 a week for Mushrooms, has had all his stock and plant washed away; Mr. WALDEN has had all his cut Osiers washed away. There were altogether 180 acres of land under water.

— The spring, summer, and autumn flower shows of the ROYAL CALEDONIAN HORTICULTURAL SOCIETY will be held on the following dates:—March 28, July 11, and September 12.

— Some of the WINTER FLOWERING SUCCULENTS are extremely showy, and seem too little appreciated for floral decoration. In the succulent-house at Kew *Crasula lactea* was prominent in flower a short time since. *Echeveria fulgens* is just now very attractive, and likely to be so for some time. *Kalanchoe laciniata* has been very ornamental for several weeks. The bright yellow flowers remind one of *Chlora perfoliata*, and these, with the peculiarly cut leaves, form a novel and striking specimen. *Senecio macroglossus* is much to be valued among succulents as a winter-flowering climber. The flower-heads are bright yellow, and in point of size perhaps second only to *S. pulcher*. The leaves so closely resemble Ivy as to afford much interest from that circumstance.

— The HOLLYHOCK DISEASE has proved so destructive to the stock of Hollyhock plants at the Saffron Walden Nurseries, that Mr. CHATER has been driven to adopt means to mitigate as far as possible the severity of its attacks. Last season Mr. CHATER adopted a plan which, he reports, has answered admirably; and indeed the results far exceeded his most sanguine expectations. In the early autumn of 1875 large trenches were dug, similar to Celery trenches. The bottom was forked up, and a good dressing of decomposed manure was worked in, and the soil laid up rough, to be pulverised and rendered workable by the winter frosts. In these trenches the Hollyhock plants, to stand the summer,

were planted out, but previous to doing so the soil in the trenches was again forked over, mixing in with it the sides of the trenches also. Here the plants grew rapidly, and with great freedom, and, as Mr. CHATER remarks, "I obtained from them some of my finest flowers, which quite reminded me of past seasons, before the fungus made its appearance. Several of my new varieties came from these rows." The growth of the plants during the season was worth seeing." These plants were free from the disease, and at taking-up time they were quite healthy, have kept so all the winter, and they are furnishing a supply of young plants for sale in the spring, and Mr. CHATER is depending on these for material on which to found a spring catalogue. By some special perseverance, by thinly planting the Hollyhocks, by putting the plants in exposed situations, and mulching them during summer, Mr. CHATER hopes to be able to overcome the disease eventually. It does appear true that the moisture the season the less marked is the disease, and the more vigorous the growth of the plant the greater is the resistance to its advance. This system of growing the plants in highly manured trenches supplies an invigorating soil, coolness and moisture at the roots, and the mulching maintains a surface assistance which must exercise a beneficial influence.

— The question of the EFFECT OF COLD SPRING WATER ON PLANTS growing in a high temperature has again been raised by a correspondent of the *Revue Horticole*, whose experiments convinced him that plants thrive equally well under cold-water treatment, as when water at the temperature of the atmosphere of the house is given to them. He conducted his experiments during the months of January and February last year. Two pans each of the seeds of a variety of plants, ranging from hardy indigenous species to tropical ones, were sown at the same time and subjected to exactly the same conditions with the exception of the difference in the temperature of the water. In the one case it was taken from the tubs exposed to the outside temperature, and in the other it was applied at the same temperature as the atmosphere of the house. The writer adds that his experience leads him to prefer spring water to water taken from the river Seine, for syringing, especially for sown-wooded plants. How far this treatment will answer, practical experience alone can prove, but there is no doubt that plants will flourish under widely different conditions in respect of the temperature of the soil. We have seen, for example, on growth of a large Grape Vine, whose roots were all outside, in a house where it was usually started into growth at the beginning of the year, and the other part outside on a raised trellis on a slate roof, each bearing a good crop of fruit in its season. Another remarkable fact is the very high temperature some plants will bear without injury. The *Botanische Zeitung* lately called attention to the almost forgotten observations bearing upon this subject recorded by HUMBOLDT in his *Reise in die Aequinotiale-gegend des Neuen Continents*. Carefully read, the temperature of the water of a hot spring in Caracas was 90° of the Centigrade scale, or above 194° Fahrenheit, and the travellers were not a little surprised at the luxuriant vegetation immediately around and overhanging this almost boiling cauldron. Fig trees, delicate feather-leaved Mimosa, and a variety of other plants continually exposed to the vapour, and whose roots extended into mud at a temperature of 185° Fahrenheit, exhibited the most beautiful verdure. An arborescent *Aloué* was actually growing in the centre of a pool of slush which gave a temperature of 158°. We might add that some individuals of the human family swallow, with apparent impunity, beverages at almost any temperature between the freezing and scalding points.

— At a recent meeting of the Horticultural Society of Berlin a report was read on the results of the deliberations of a committee previously appointed to consider the means of providing YOUNG GARDENERS with a more complete EDUCATION than is at present within their reach. The report includes a scheme of a course of practical and theoretical instruction, which if carried out must prove a great boon to the gardening community. Even now probably no country can produce a better educated set of gardeners than Germany, and there is no doubt that there are fewer quite illiterate men among her good practical gardeners than would be found in this and some other countries. The

committee, consisting chiefly of some of the foremost shapblers in the vicinity of Berlin, was unanimously adopted, recommended the Society to petition the Minister for Agricultural Affairs to assist them in founding a high school for gardeners. It is unnecessary to say more than that the course of instruction proposed should confer a very liberal education. Candidates must have previously worked at least twelve months in some garden or nursery, and, after three years' instruction at the high school, undergo an examination—those who pass the examination to have the preference in filling up vacancies in all state appointments. Another subject before the Society was the formation of an arboretum and a nursery in the vicinity of Berlin, with a special view to the instruction of the public in the selection of trees and shrubs suitable to the climate and other conditions. This is real horticultural work, and of more service than an extravagant number of expensive shows. Reading the history of our own Society, we are struck with the fact that too much wealth has been the cause of most of its disasters, as well as the neglect of the more modest yet more useful duties of such a society.

— The WEST OF ENGLAND ROSE SHOW is fixed to take place at Hereford on Thursday, July 6.

— We hear that the NATIONAL ROSE SOCIETY is making good progress, and there is no doubt that after the next meeting, when the schedule for the show is arranged, and a fuller programme of its intended operations is circulated, it will have a large accession of members. Several well-known rosarians in different parts of the country have consented to act as local secretaries, and to advance the interests of the Society in their neighbourhoods.

— An excellent example of a highly successful MUSHROOM BED can now be seen at The Elms, Acton, the residence of C. O. Ledward, Esq. Mr. J. HEPFER, the gardener at The Elms, is a well-known exhibitor at the meetings of the Royal Horticultural Society, and at the one held on the 17th inst. he sent some baskets of Mushrooms of fine quality. They were grown in an ordinary Mushroom-house, the bed having been spawned on November 23, and the first crop of Mushrooms was gathered the week after Christmas. The bed presented an extraordinary sight a few days ago, for the Mushrooms were produced all over it in dense clusters. It is said that the mild, close weather has been eminently favourable to the production of heavy crops of Mushrooms; still there were evidences that the bed had been skilfully managed, and the large crop was owing to its excellent construction. Mr. HEPFER's method may be summarily stated, and that of other growers, but it may perhaps be useful to some to set it forth. The manure from the stable is mixed with three or four barrowful of road scrapings, and then shaken up well three or four times till thoroughly heated; it is then taken into the garden, placed in the wooden bed, and well rammed down into it. This occupies one day. The next day the bed is spawned by placing the pieces of spawn in the hot dung to the depth of 3 or 4 inches, and then the usual covering of soil is spread over it. A good loam is used, not sifted as is recommended by some, but simply crumbled small. Daily the bed is examined, and the temperature kept up to 90° for three weeks, and then altered to 65° or 70°, and ultimately reduced to 55°. This bed affords a constant supply, for two months at least, of such Mushrooms as a gardener may be proud to place on his employer's table.

— The annual exhibition of the RICHMOND (Surrey) HORTICULTURAL SOCIETY is announced to be held in the Old Deer Park on Thursday, June 28.

— We hear that Mr. WILLS has retired from his post as Floral Director of the WESTMINSTER AQUARIUM. The permanently planted specimens have had to suffer about as great hardships and torture as ever fell to the lot of plants, and the destruction from the effects of gas and a dry dusty atmosphere on the costly Tree Ferns, Palms, and other plants, is lamentable to witness. In spite of these disadvantages Mr. WILLS has contrived to the last to make a bright display of flowering plants, and in a few days since the display, with Hyacinths and other spring flowers. About 40,000 flowering plants have been used during

the season. Certainly the Aquarium is not the place to grow plants in, and it is no better adapted to show them in.

— There was again a very full attendance at the monthly dinner of the HORTICULTURAL CLUB, at 4, Adelphi Terrace, on Wednesday last. Subjects of interest were discussed, and the following members elected—George P. Hawtree, Lanley Place, Slough; James Boyd, Paisley, N.B.; and E. Dixon, Covent Garden.

— We learn from M. LINDEN, of Brussels, that the ADIANTUM SPECIOSUM noticed and figured by us at p. 41, and described as having been sent out by Messrs. VEITCH & SONS, was introduced by him. It came from the neighbourhood of Haancabamba, in Peru, and the stock was disposed of to Messrs. VEITCH & SONS, by whom it was distributed. M. LINDEN also informs us that another fine species of *Adiantum*, *Fern*, *A. peltatum*, imported by him from Moyobamba, was disposed of in a similar way to the Messrs. VEITCH. We are glad to be able, in making this rectification, to give more definitely the habitats of the plants, which are two of the finest species of *Adiantum* in cultivation.

Home Correspondence.

The Royal Horticultural Society.—Since I was illegally deprived by the Society of a Life Fellowship granted for horticultural services, I have seldom adverted to its doings, or those of its supporters. It seemed more consistent with one's sense of self-respect to retire into the background and attempt to distinguish in renovating the Society or launching a new one. However, your oft-repeated remarks upon the devotion of horticulturists to the old Society as assumed to be proved by the good display at the little or great shows at South Kensington, suggests the utterance of some serious thoughts that have often occurred to me. You have been strong in the condemnation of the policy of the old Society. Even its last advance of policy—the admission of guinea Fellows denuded of all powers or honour but that of nomination to see the welfare of the Society to its present disreputable condition shall in their superior wisdom provide for them—has met from you the condemnation which it deserves; and yet, running parallel with this, every show or other attempt to assist the Society in its present state receives the fellest, some call it fulsome, praise. How is this? Can a wrong be righted by supporting the wrong and praising all who support me or societies in wrong-being or wrong-doing? Is it or is it not true that the Royal Horticultural Society has sacrificed the credit or the interests of horticulture to gratify a faction or conciliate fashion? If not this, where is the justice or the wisdom of the charges that are being constantly made against it by yourselves and others? And if these charges are true, why should the wisdom or public spirit of all those who support the Society in its said courses be held up to admiration or imitation? All such praise and such support seem to many of us to render reform more difficult, and reconstruction almost impossible. It seems quite a new doctrine virtually to advocate that the best way to remedy an evil is to support it to the utmost of your ability. This is what all those who are making efforts to uphold the Society as it is seem to say to me, and I do not think it true. In this matter, who stand aloof from the shows are probably better friends to horticulture than the horticulturists who, no doubt with the best intentions, hasten to make the exhibitions successful. There can hardly be a doubt that, as long as these and other courses of revenue are available, the Society will adhere to its present policy. Now that all other legitimate means of reforming have been tried to little purpose, the time seems opportune and ripe for a new policy on the part of horticulturists, and the wonderful reform thus—Either make the Society in fact as in name, horticultural in government, fellowship, policy, or no more horticultural products shall be forthcoming to support it this would quickly starve the Society into submission or ruin. We have heard about the old ship *de navigation*: if she will consent to be overhauled, and if need be new manned, and above all will take a new tack, well; but if not, the sooner she founders the better. A larger vessel, with sounder timbers, and better rigging, and a better crew, is needed, as is needed to do justice to the horticultural wants and capacities of the present day. Adaptation, enlargement, or reconstruction, these call for the earnest consideration of every true horticulturist. In all such matters, the horticulturists of the Society simply because it is so, and that wholly by its own faults—which it still per-

sists in—got into bad repute, is a policy wholly unworthy of the commanding genius and wonderful business and common-sense capacities of horticulturists. D. T. Fish.

“Oh, most lame and impotent conclusion!”—after all this has been thrown back into the arms of the South Kensington ensnarer, and the Society to continue its existence as a parasite on a rich London district. Is it not about time to form a new Society—a national society of horticulture—which will be maintained by the now great and every-day-increasing body of horticulturists of the country? I have too many ties to the old Society, and too many friends among those who work it, to make me like to take an active part in raising a new one; but if any competent, energetic man will come forward, who, partly for the love of the cause, and partly for the promotion and a post, is disposed to work the matter, I will show him that there is abundance of power and will through the country, which only wants being brought together and organised to make a great Society; and meanwhile, as there may be another turn of the wheel, and the Council may be driven to seek their main support from the more earnest horticulturists, let me beg those who are collector names of would-be guinea Fellows of the Society when free, to increase rather than relax their exertions. George E. Wilson.

I have noticed a few remarks from the pen of Dr. Hogg in the *Standard* of January 20, and presume they may be taken as the official utterances of the Council, and there are one or two points in them that appear to be of very considerable interest at this moment. I will assume that the statement respecting the debentures being a charge against the surplus income after payment of its expenses only is a satisfactory one. I presume, therefore, that the same our Councils in times past been doing? Should not the first moneys they had have been placed to the credit of their rent account? I know my landlords have always given me pretty clearly to understand that the first duty of the tenant is to provide for their calls to the moment, but here, according to the Secretary's own words, the Council have been guilty, to say the very least, of a great piece of folly in paying the interest of the debentures on some occasions, which he says are only an after-charge, and leaving the whole of the Society's property at South Kensington at the mercy of our landlords, whom he sees reason to think will assert their authority, and bid us depart bag and baggage. Viewed in the mildest light, it is about as unbusiness-like a way of acting as could be devised. I am sure our tenants must have great doubts as to the real status of the debenture-holders to have acted in this way; for if not, they would seem to have acted disloyally in paying an after-charge, and leaving a debt unpaid on which, it might be said, the interest was due. The Society seems to depend. The Secretary further states that the Council, in total opposition to the vehement and oft-expressed opinion of the great body of the horticultural Fellows, are again coquetting with the South Kensington trustees, and are more to have been kept in their dreary splendour—we are to have pensions, hands, &c. All this has been tried before, and did not pay. Why, then, will they try to exist on the traditions of the past? Why do not they recognise the necessity of moving with the times? It is useless to go over again all the old sores, heartburnings, and discontents without a satisfactory issue from them seeming possible. I sincerely hope in Mr. Wilson's scheme of reconstruction he will not forget to make some proper provision for the nomination, as well as the election of members of the Council, &c. Our present form of receiving a printed notice of the names whom the Council recommend to fill the vacancies has long been a source of irritation and discontent to a large body of horticulturists, and has been the cause of more than the proper power of resistance. A day for nomination prior to the election would change all this, and give some real life and vitality to the impulses of the Society's affairs. *Robert Ernie Glouin*. [The remarks of the Secretary above alluded to have struck consternation into the breasts of the well-wishers to the old Society. We know not what to think, but we trust some explanation may be forthcoming. If not, the labour of the past few years has been indeed labour in vain. Eds.]

Double White Hepatica.—In the *Gardener's Chronicle*, Oct. 11, 1876, p. 494, reference is made to the double white Hepatica. It has been for many years renowned amongst growers of herbaceous plants that such a variety existed, but scarcely any one ever saw it. The late Mr. Donaldson frequently mentioned it if he met any one, and I think I can clear away the mystery respecting it. Some years since, when in the employment of Messrs. Hugh Low & Co., the late Mr. Hugh Low requested me to put a quantity of double white Hepatica just to do it. I did so, and the plants were sown in a row on the north side of a wall; most of them flowered, showing they were the right variety. Some time in

June or July following many of them threw up a second lot of flowers, every one of which were pure white and double. I remember showing some of them at Mr. Low's. They think do not vary with the double white Hepatica as a distinct variety, as all the plants that were not sold produced double blue flowers the next spring at their natural season of flowering. *William Hodge.*

The Rainfall at Dynevor Castle, Llandilo.—It may interest some of your readers to see the amount of rain we have had in the west part of Carmarthenshire:—January, 3.83 inches; February, 5.84; March, 3.12; April, 3.12; May, 0.60; June, 2.10; July, 2.43; August, 6.35; September, 6.40; October, 7.65; November, 5.96; December, 10.69—total number of inches, 59.62. The number of days on which 0.1 inch or more fell was 201, the greatest fall was on August 2, when 2.48 inches fell; 2.28 inches also fell on October 8; and over 1 inch fell respectively on eight other days in the year. *J. Ticehurst, Llandilo.*

Blackberries.—I think I before have recommended your readers to set up a Blackberry bed. The last year I had such a splendid crop, and so much enjoyed them, that I again most warmly recommend all who have not yet done so to once get a stock from Fisher, Holmes & Co., Handsworth, Sheffield, from whom I had mine, with directions for their growth. With the addition of one-third Berries, or a Lemon or two, they make a delicious tart; and for a month or six weeks the beds here are always occupied by youngsters (and oldsters also) picking the fruit at a time when there is not much to be had in the garden. In your columns of September 4, 1875, Blackberries were so much commended, and again in number for November 6 ("J. J.") gives such excellent recipes for jelly, &c., that I feel sure many would much enjoy a row or two of them right sort in their gardens. Fisher & Co. call them "Parsley-leaved," and their leaves are so prettily cut that they are almost worth growing as an ornament, independent of their fruit. The last summer and autumn were with us so dry and burnt up that all our bush fruits failed except the Blackberry bed. I should be glad if any of your readers would give their experience of the American kinds, and where they were procured from. *W. D. F.*

Fruiting of *Trachelospermum jasminoides*.—I have sent to you a few pods of seed of this plant, best known as *Rhynchospermum jasminoides* (fig. 19). We have several large plants on balloon trellises, they bloomed profusely last April and May, and as the flowers went off large numbers of these pods remained on all the plants. I have grown and flowered these same specimens for some years, and have not noticed their fruiting before, nor do I recollect having seen them in fruit elsewhere; but for all that the occurrence may not be singular. When the pods are first seen, and for some time after, the tip ends of each pair are united, as in the specimens you will see marked; after a time they disunite and grow apart. *John Wallis, The Gardens, Orwell Park, near Ipswich.*

How to Preserve Seeds.—Nearly every one knows to his cost the sad havoc made amongst early sown Peas and Broad Beans by rats and mice; but, perhaps, all do not know that these pests will not touch any seeds that have been mixed with a little red lead and water before sowing. I have never known this treatment fail to protect Peas, Beans, Radishes, Broccoli, Lettuce, Mustard and Cress, &c., from the ravages of rats, mice, as well as of all kinds of birds. No nets are required for seeds of any kind where red lead is used, and it does not affect the germinating power of the seed in the least. It may be powdered lead that is used, and the cost is about 4d. per lb., but the cheapest way of purchasing it is to get a small barrel, and a propagating glass is a handy thing to mix it in. Just enough water should be used to make the lead stick to the seeds; stir it round until it dries on and sow at once. *Robert Coock, Edinborough.*

Fair Dealing in the Seed Trade.—The conduct of one of our old customers, who succeeded his father, an equally good man, has been so exceptional in a matter of business, and so thoroughly what an Englishman's dealings in business ought always to be, that I consider it is quite worthy of a place in your columns. Your readers may be aware that it has of late years, through absurd competition, been customary for the seed trade, long before they can possibly know what the harvest may produce, to sell their Peas, Beans, and all kinds of seed at a speculative price, by which the seed is almost certainly damaged, and, as in this year of a generally deficient harvest, seeds have been sold in the summer at prices considerably less than their real value. The seed has, however, to be delivered at the price sold, while the seasons are less than usual, but the seeds have been sold at a higher price than they can be bought at after an abundant har-

vest, the seedman is expected to reduce his price, so that he has to suffer in either case. And now for the case of our old customer. He had bought very cheaply and fairly in the autumn at a given price, the harvest has been short and the Peas he bought are worth double the price they were sold to him at. In settling his quarterly account he writes thus:—"January 10, 1877.—As your imperfect knowledge of the value of the Peas in the autumn caused you to put too low a price on them, I see no reason why I should derive an advantage from the circumstance, and therefore I request to be allowed to pay the worth of them. I have added £— to your account." If every man in

The Rainfall at Alnwick Castle in 1876.—As the fall of rain during the last year has been in this part much above the average of former years, it may be interesting to some of your readers to know the quantity fallen during the various months, as recorded in the gardens here:—January, 0.88 inch; February, 4.23; March, 3.13; April, 4.40; May, 1.35; June, 3.42; July, 1.44; August, 2.60; September, 3.74; October, 1.06; November, 3.99; December, 8.38; total rainfall in the year, 39.52 inches. The rain gauge stands 178 feet above the level of the sea, and 4 inches above the ground; the funnel is 5 inches diameter. The rain is measured always at 9 A.M. *Alnwick Ingram, The Gardens, Alnwick Castle, Jan. 15.*

FIG. 19.—TRACHELOSPERMUM JASMINOIDES.

A, B, Fruit with plumose silky hygroscopic pappus. A, Pappus in moist air. B, Pappus in dry air.

business would treat his fellow with the same upright, generous, honourable spirit, that our old friend (who has little idea that we are writing of him) has done us, trade would be far more honest, and peaceable, and profitable, and the knaveries and trickeries of business would be unknown. *A Seed Merchant.* [Surely the names of those who act thus honourably should be made known. EDS.]

The Rainfall at Dale Park, Arundel.—The rainfall here for the past year was as follows:—January, 0.60 inch; February, 2.73; March, 3.85; April, 2.20; May, 1.12; June, 1.28; July, 0.86; August, 3.28; September, 6.04; October, 1.77; November, 3.47; December, 8.76—total, 35.06; being an excess of 4.38 inches on the previous year. *E. Sandford.*

The Best Late Grapes.—Herewith I send you a bunch of each of the three sorts of late Grapes that, in my opinion and experience, have proved to be best—Muscat of Alexandria, Lady Downe's, and Gros Colman. You will observe that Gros Colman is extraordinarily thin-skinned for a late Grape, and that the flavour is by no means second-rate. *W. H. Williams.* [The sample of Lady Downe's was first-rate. Gros Colman was tender and agreeable, but not equal to it in flavour. As always, Muscat of Alexandria comes first. EDS.]

Dracæna indivisa.—"J. G. M., Penzance," has mistaken what I wrote respecting this fine plant. I did not say that a specimen 9 feet high was only two years old, but that it was "about as many (*i.e.*, nine seasons) old." Nor was that other plant which stood

two winters out on an exposed cliff only two years old, for it was previously a well-established pot-plant, five or six years old, which, as the winds prevented its increasing in height, naturally subdivided into half-a-dozen easily detached portions. We have, in the garden, a very lovely *D. australis* which has twelve stems, all about equally tall, and spreading outwards. Such a plant as this would be much remarked anywhere. But I am pleased to hear that *Dracena indivisa* reaches to 12 feet high in Cornwall, for, if so, then here in the Channel Islands we may also look to see it quite as lofty. As yet it is, comparatively, unknown in the

November 9 last, Mr. Roberts, gr. to the Countess of Charleville, exhibited some very fine examples of this Grape, three bunches of which weighed 45 lb. 6oz. Mr. Roberts has kindly favoured us with a photograph of the heaviest of the three bunches, which weighed 16 lb. 6 oz., and the form and massive character of this excellent example of Mr. Roberts' skill as a Grape grower is well portrayed in the accompanying illustration (fig. 20). Mr. Roberts considers his true variety of Gros Guillaume, which is different to the ordinary forms in cultivation. At the same exhibition Mr. Roberts staged three bunches of Chald of Hale, weighing 18 lb., and also a fine sample of Gros

capital position. Care should be taken not to let them get too wet until growth commences, which will be in about three weeks. When fairly rooted they should be removed to a cold frame, always kept close to the glass, and never be overcropped. They may be potted in July into 4 or 5 inch pots, and should be watered with a little well-rotted manure and sand, again placing them in a cold frame close to the glass, and exposed to the light and air till the end of September, when they should be hoisted and receive a little fire-heat on cold nights. The temperature should never fall below 55°. A little weak guano-water may be given weekly when the pots become filled with roots. Plants grown in this way are stout and very short-jointed, retain their leaves to the pot's edge, and rarely exceed 12 inches in height, with scarlet heads 8 to 12 inches in diameter. If very dwarf plants are required they may be had by later propagation. *J. H. Goodacre, Elvaston.*

A Question for Vine Growers.—I should feel very much obliged to any of your correspondents who occasionally favour us with their useful and practical remarks on Vine culture in your columns, if they would give me their advice in the following case. I have some very long ranges of Vines, Black Hamburgs and Muscats, which have been forced for early work for twenty-five years past and have borne good crops during that time. They have received good treatment and have not been over-cropped, but the last few years they have shown signs of getting tired of the forcing, breaking weaker and with less fruit, this being more especially the case with the Hamburgs, the Muscats producing much stronger wood. The borders are outside and on the side of a hill, with porous rocky bottom. They are mulched each year with stable-manure, and now and then the surface-earth is peeled off and replaced with fresh, but the main roots have gone deep, so that this only seems to affect the surface ones. Would there be a chance of bringing them once more into bearing if the old rods were cut down so as to allow a young cane to take their place, or will it be necessary to root out the worn-out Vines and plant young canes? The latter course would be expensive, on account of the loss of crop. I feel sure there must be many whose houses are in a somewhat similar state to mine, and I shall be grateful to any one who will give me a practical hint as to the best course to pursue. *E. L., Jersey.*

Luminous Mycelium.—With reference to the letter of "W. G. S." in your last number, I had hoped to have sent him a piece of the luminous mycelium with the fungus upon it. Unfortunately the recent rains have caused a landslide, which brought the whole stump down and covered it with earth; there were some fragments of luminous wood, but only a small piece of fungus could be recovered. *H. King, Chit-hurst, Jan. 22.*

Euonymus japonicus.—I herewith send you two small branches of fruit of the *Euonymus japonicus* or Japanese Spindle Tree. The plant from which I gathered them is 10 feet high and nearly as much through. It is covered with the berries, which have proved useful during the past festive season in the absence of Holly berries. My attention was called during the past summer to a plant growing at Havre des Pas, near the sea, which was then covered with clusters of small greenish white flowers. I have watched that and other plants, all growing in very sheltered situations, and seeing the pretty fruit in such abundance on this particular plant this morning I sent it to you. Although I have known this plant more than forty years I never recollect to have seen it in flower or fruit before. It, as well as the golden-leaved variety, is used extensively here for planting hedges with, and answers the purpose admirably where no particular power of resistance is required. *Charles B. Saunders, Jersey.*

Cedars of Lebanon.—In Mr. Evershed's interesting article on the Cedar of Lebanon he observes, at p. 40 of the *Gardeners' Chronicle*.—"In Evelyn's *Silva* of 1664 he does not mention the Cedar of Lebanon, and we may, therefore, be sure that it had not then descended from its Syrian mountain to the congenial level of the banks of the Thames," but though Evelyn in the pages which he devotes to the tree he loves so well by reputation, points to his knowledge of it as not growing then in England, it seems due to his great desire to introduce it to note his endeavours towards its growth. In the opening sentence of vol. ii. of the same work he mentions the cedar of Lebanon, and in no way backwards in his own exertions, for at p. 9, after a description of the trees on "Mount Lebanon," he observes relatively to the

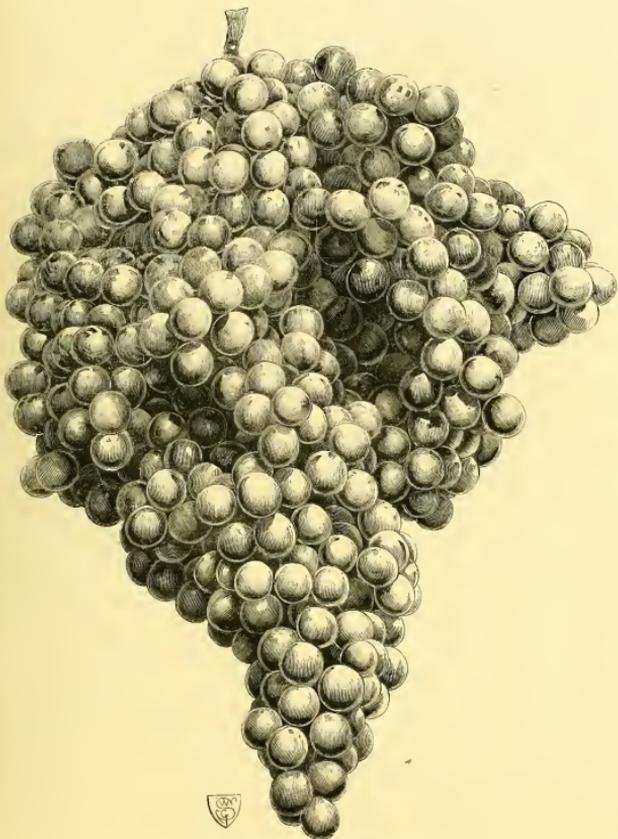

FIG. 20.—GROS GUILLAUME GRAPE GROWN BY MR. ROBERTS.

islands. Attention has been lately drawn to the beauty of this plant in a contemporary, and young specimens are now being offered for sale at very high prices, so that, considering how readily some parts of the Scilly Isles could be made into nurseries of it, there may be persons willing to do so. But the particular reason of my mentioning the fact of its doing fairly well on the seashore was to show how much less delicate its habit is than is supposed, while on lawns its peculiarly striking appearance would be a desirable feature, even if a little protection were given during the severest weather only. *Thos. C. Erbsaht.*

The Gros Guillaume Grape.—At the autumn fruit show of the Royal Horticultural Society of Ireland, held in the Exhibition Palace, Dublin, on

Colman. For these highly meritorious productions the Council of the Society subsequently awarded Mr. Roberts a silver medal. Eds.

Poinsettia Culture.—A simple and successful mode of Poinsettia cultivation that may suit "Enquirer's" convenience came under my notice about twelve years ago, and up to the present time I have not seen a better. Commenting with the ripened plant, which generally swells up its buds about April and May, let these buds be taken off with an inch of the old wood attached and put into 3-inch pots horizontally, in a similar manner to Vine eyes, with the point of the bud just level with the surface of the soil. Then plunge into a bottom-heat of about 75° or 80°; round the sides of a Cucumber or Melon frame is a

culture:—"The seeds drop out of the cones as the Fir and Pine kernels do when the air, sun, or moisture open and unglue the scales, which naturally it else does not in those of the Cedar till the second year, but which after all the preparations of burying in holes in the earth and sand in which they are after to rot, may more safely be done by exposing the clogs discreetly to the sun, or before a soft and gentle fire, or, I think best of all, by soaking them in warm water." Hence, according to the author, the seeds are not so delicately to the Cedar, and in his letter on the "damage" to his trees by frost of the preceding winter, written April, 1684 (see *Philosophical Transactions*, 1684), and printed in the collection of his miscellaneous writings, he remarks, when speaking of his "Exotics"—"The Cedars, I think, are lost," may refer to other species. Still whether or not Evelyn was as Loudon thinks probable, the introducer of the Cedar into England, there is much of interest in the certainty of his having himself imported the cones from Lebanon, and experimented on their treatment. O.

—We have here an old Cedar of Lebanon, variously estimated at from 200 to 260 years old, and which at 4 feet is 19 feet 9 inches in circumference. It is in the neighbourhood of the base of the spread of the two longest lateral branches is 92 feet. *C. v. Crousthorst, Gr. to A. Duncan, Esq., Holbrooke, Chiltolhurst.*

Weather Folk-lore.—It is an old saying with the people round here (Atherstone), "When the wind is on Martinmas Eve (November 11), there it will be the wind of the winter. It is pointed out so far—it was south on the Eve, and it has been there most of the time ever since. Another saying is, "When there are two full moons in one month there are sure to be large floods." This also has proved true—there were two full moons in December, and disastrous floods. *W. Brown, Merle.*

Condition of Vine Roots.—I am glad to be able to send you some information respecting the condition in which I found the roots of some Vines that I uprooted here in June, immediately after the fruit was cleared off, in order to replant with young Vines the same season. These Vines were started at the end of November, and were planted in an inside border with apertures in the front wall to enable the roots to ramble outside at pleasure. When clearing out the old border we found very few living roots inside the wall, the greater part, and by far the healthiest, were outside—the roots were only just starting, and were outside in both inside and out at the same time. The outside border had been covered with a slight botch to protect it from severe weather. The Vines were tolerably healthy, and produced a moderate crop of fruit. Had I the opportunity to bury the roots as I pleased, experience teaches me to have inside borders for (very) early and (very) late Grapes only, for Vines planted in small inside borders flourish only for a short time. Ordinary season Grapes, say from July till November, may be made to flourish with a good longer duration, especially where there is good drainage. The finest house of Black Hamburgs I ever saw was where all the roots were outside, and the best finished Muscats were all inside. As a constant reader of the *Gardener's Chronicle*, I can answer for myself that I do not wish in any way to discourage Mr. Wildsmith from putting his views before the gardening world, but shall be ever ready to accept them at their worth. It would be well, however, for him to remember that Heckfield is very favourably situated in many things, and that Vines flourish there, while in other places things very hardy will only just live. *J. H. Goodrich, Elyston.*

Reports of Societies.

Botanical, of Edinburgh: Feb. 11.—Dr. Cleghorn in the chair. The following communications were read—

1. **Obituary Notices of Members Deceased during 1875-76.** By Professor Balfour and Mr. F. M. Webb. *N. Veridicus*, a new species of *Neris*, in Invernesshire, in July last, by the Scottish Alpine Botanical Club. By Mr. John Sadler, Secretary to the Club. [This paper we shall publish shortly.]

3. **Notice of some British Plants in the University Herbarium, at the Royal Botanical Garden, part 3.** By Mr. F. M. Webb.

4. Of Elodea (the American Water-weed) Mr. Webb mentioned that the earliest specimens contained in the collection were from Dr. Johnston, 1848. He also sent a series of the Irish plant sent by Professor Oliver, in 1874; and of the Scotch plant the original specimens picked August 13, 1875, by Messrs. Robb and Sturrock, with Mr. Robb's letter asking identification. The collection of Potamogetons he stated to be very good, including many from Mr. Kirk, and their value increased by the

whole having passed through the hands of Dr. Boswell in the preparation of *English Botany*. Of Salix he stated the Herbarium contained a very fine series, including the original and recent specimens of Rev. J. E. Lee, in his collection of alpine plants, and of the plants therein described, besides representing the determinations of Mr. Crowe and Sir J. E. Smith. In speaking of S. Grahami, he quoted Mr. Watson's statement, that Dr. Graham assured him the plant was brought from Sutherlandshire only herbaric, and stated that if the plant now labelled S. Grahami in the Edinburgh Botanic Garden was the same, it had certainly again reverted to S. hercatica, for it undoubtedly was nothing more. Perhaps, however, the original had been introduced from the West Indies to the genus Willows, viz., S. Sadleri, Mr. Sadler had given his original specimens to the collection. Of the Oaks, Mr. Webb said the collection could fairly challenge competition, it numbered some eighty sets of specimens, including the material Dr. Johnston had collected as the basis of his paper read to the Society, March 11, 1841, in which he showed that the book botanical characters by which *Quercus pedunculata*, *intermedia*, and *sessiliflora* are distinguished pass insensibly and completely into each other. Referring to the genus *Ranunculus*, he showed specimens, and gave a list of localities in the three Lothians, Fife, and Roxburgh, for *R. pratensis*, which is not mentioned in the *Flora of Edinburgh*; he also spoke of *R. conspersus* as likely to be found where *R. domesticus* (aquaticus) prevailed, and pointed out the occurrence in large quantity, by Tweed above Kelso, along with that species; and of *R. rupestris*, only recently brought into the British list, but found in Jersey, and distinguished as a distinct plant by the Rev. W. W. Newbould in 1841. Mr. Webb also mentioned the interest of specimens of *Erica vagans* Professor Balfour at Babbicombe in 1839, which, with queries and interrogations, had lain undetermined from that time in the Ramex folios of the Herbarium.

4. **Notes on the Localities for Erica vagans in Scotland.** By Professor Balfour.

Dr. Balfour stated that he had lately received a letter from Mr. James Gilmour, Birmingham, informing him that a gentleman (Mr. John Douca) had gathered in September last specimens of *Erica vagans* growing on the hillside within half-a-mile of the inn at Stronachlach near the head of Loch Katrine, Fifehire. Dr. Balfour was at first doubtful of the genuineness of which was exhibited) and the locality, but the question was as to its being in a wild state and a native in the locality. This has not been proved, and Dr. Balfour looked upon it as an accidental escape from some garden. *Erica vagans* seems in Britain to be introduced from Perthshire in 1830, and has never been reported from other counties, but the localities are all very doubtful. The English counties mentioned are Devon, Gloucester, Worcester, Glamorgan and Derby, and the Scotch counties Argyll and Inverclyde, and Perthshire. Dr. Balfour was informed by the late Mr. Robert Traill, of Aberlady, that the plant grew on the hills near Lochliphead, and accordingly visited the district in September in 1868, but failed in finding it. After visiting the hills he went to Sir John Orle's house at Kilmory, which is in the district, where he saw abundance of the *Erica vagans* both in the garden and outside of it. The plant seeds well, and is scattered far and wide.

In 1836 Mr. George Dodds, then a student of Cornwall, sent me some specimens of the Heath from the neighbourhood of Inverness. *Proceedings of the Botanical Society for 1837*, the following statement occurs—"Mr. W. H. Campbell read a letter from Mr. Robert Ball, of Dublin, to Sir W. Hooker, mentioning that *Erica vagans* had been discovered by Dr. Barlow on an inlet on the coast of Waterford, near Tramore, in Ireland." In Baker and Tate's *Flora of Northumberland* it is stated that there are fine specimens of the plant in Robertson's collection in the Newcastle Museum, labelled *N. Veridicus*, and now Perthshire, 1841. *Cyclops vol. iii. p. 150.* Mr. H. C. Watson says that *Erica vagans* is only known with certainty, in a few localities in Cornwall, chiefly on the Lizard. In his *Topographical Botany of 1873* he mentions only Cornwall, as a plant, and refers to the other stations as misreported or planted.

5. **Holly in Flower at Christmas.** By Mr. M'Nab. At the last meeting of the Botanical Society I called attention to the great scarcity of Holly berries on the trees and bushes round Edinburgh. Since that time I have received a number of letters from my correspondents in various parts of the kingdom. From these I learn that the scarcity has been very general, and different causes are assigned for it. The only places where an abundant supply of berries was noticed were in some of our Highland districts, such as at the Trochais and Loch Katrine, also at Loch-

ard in Aberfoyle. One correspondent, at Knaclagh, near Dublin, informs me that, on sending into the garden before Christmas to collect what sprigs of Holly could be got with berries, instead of berries, he got only a few twigs, and he accordingly found that several of the trees were covered with clusters of white and cream-coloured flowers. I immediately wrote for specimens, which I now place before the Society, on which all the flowers, both open and closed, are preserved. The cones assigned for this early blooming was, that the blossoms must have been destroyed by snow and frost on April 14 last year. During the past summer many of the plants had nothing to do in the way of maturing fruit, so flower-buds had been formed and the blooms opened before their time. What the result of this early blooming will ultimately have on the Holly, another year will tell. On looking over the Holly bushes now in the garden young buds are observed to be very abundant, but so backward that flowers cannot be expanded for months to come. There is a fair appearance of fruit for next Christmas, if no untimely frost should occur. Some correspondents allege that the late wet autumn had much to do in causing the berries to fall off white in a green condition. This I do not believe, as the berries were not there when they were not in such quantities as to fall. The few which did ripen are those which must have been in the best condition, and perhaps partially sheltered at the time the general blooming was destroyed.

6. **Effects of the Late Moist Autumn on Certain Plants.** By Mr. M'Nab.

The autumn of 1876 has been particularly unsuitable for ripening the flower-buds of many of those plants which are generally lifted from the open air during the months of August, September, and December, for the purpose of subjecting them to artificial heat, and thus bringing them into flower during the winter season, both for conservatory and table decoration. Rhododendrons, particularly the late-flowering varieties, known and cultivated as the *R. nobilissimum* &c., are exceedingly useful for this purpose. They are lifted in flower-bud, and forced almost every year. Although many of those lifted last autumn were apparently well-budded, very few of them seem to have been properly ripened, and the flowers have developed in a state of scarcity of Rhododendron flowers at this season seems very general, particularly in the gardens and nursery establishments round Edinburgh, and I am inclined to think, from the high price of flowers quoted in Covent Garden, that the scarcity is not at all confined to this district. Judging from the unripened state of those Rhododendrons already experimented on, I have no hesitation in saying that the number of imperfect blooms has in a measure been caused by the unusually great deficiency of sun during the autumn and winter months, and the incessant rains experienced during that time. At this period the effect is well marked on all the early flowering Rhododendrons, but what it will be on the late-flowering varieties, as well as on the blossom of other plants, I do not know, and it is difficult as yet to say. Rhododendrons, as a rule, particularly if the buds are well ripened in autumn, and even under an ordinary clear sky, are generally much more easily forced into bloom than those specimens put into heat, and which have not been subjected first to a certain amount of autumn or winter frost. Even the frost of last November has had no effect on those already tried, the buds not being sufficiently matured beforehand for this purpose. The early ripening of Hyacinths, Tulips, and Narcissus, as well as many other plants, and the almost universal frost, strongly owing to the late sunless weather experienced since they were subjected to heat.

Dr. Paterson mentioned that at Airthry Castle the Peach blossoms this season were all white instead of pink, which was probably for want of sun.—Mr. Dunn stated that in some of the cases and in some of the peach-houses at Dalkeith, and moreover the flowers were small and thin in the petals, nevertheless they were setting well.

Miscellaneous Notices.—1. A letter was read from Mrs. Dalziel stating that the Holly bushes in the neighbourhood of Loch Katrine had the second year's crop of berries. Specimens of fruiting branches were exhibited. Mr. Dunn stated that at Drumlanrig, in Dumfriesshire, the Hollies had fruited abundantly this season.

2. Mr. John M'Credden presented specimens of *Cyclopteris fibellata*, *Utricularia*, and *Leprodendron* growing from Wigan coal-field.

3. Dr. Paterson, Bridge of Allan, exhibited a large growing plant of *Lycaste Skinneri* with monstrous flowers.

4. Dr. Cleghorn presented dried specimens of *Eriostachys purpurata*, the stems and leaves of which, when pounded up are used for poisoning fish in some parts of India. Also specimens of *Reptonia buxifolia* from Peshawar Valley. The tree, which grows from 6 to 12 feet in height, yields a small edible berry. It is called Gurghrah.

The Weather.

STATE OF THE WEATHER AT BLACKHEATH, LONDON, FOR THE WEEK ENDING WEDNESDAY, JAN. 24, 1877.

Table with columns: MONTH AND DAY, BAROMETER, TEMPERATURE OF THE AIR, Hygrometric observations, WIND, RAINFALL. Rows for Jan 18-24 and a Mean row.

- Jan. 18.—A dull overcast day. Occasional rain. Mild.
19.—A very gloomy day. Rain fell in morning. Strong wind. Very mild.
20.—A dull gloomy foggy day. Mild.
21.—A fine, cold day. Bright and clear. Fog in morning.
22.—A very fine clear day. Cool. Hoar-frost and fog in morning.
23.—A very fine bright day. Hoar-frost and slight fog in morning.
24.—A fine day, light clouds. Cool. Rain fell in early morning.

LONDON: Barometer.—During the week ended Saturday, January 20, in the vicinity of the metropolis the reading of the barometer at the level of the sea decreased from 30.07 inches at the beginning of the week to 29.56 inches by the morning of the 14th, increased to 30.14 inches by the evening of the 15th; decreased to 29.8 inches by the evening of the 18th, and increased to 30.55 inches by the end of the week. The mean reading for the week at sea level was 29.97 inches, being 0.22 inch above that of the preceding week, and 0.06 inch above the average.

Temperature.—The highest temperatures of the air observed by day ranged from 58° on the 19th to 45° on the 15th; the mean for the week was 51°. The lowest temperatures of the air observed by night varied from 33° on the 15th to 47° on the 19th; the mean value for the week was 35°. The mean daily range of temperature for the week was 12°, the greatest range of the day being 14° on the 20th, and the least 9° on the 17th. The mean daily temperatures of the air were as follows:—14th, 43°; 15th, 38°; 16th, 46°; 17th, 45°; 18th, 44°; 19th, 53°; 20th, 43°; 21st, and the departures in excess of their respective averages were:—7, 4, 2°, 3, 9, 5, 11°, 5°, 7°, 0, and 6°. The mean temperature of the air for the week was 45°; 5, being 8.7° above the average of sixty years' observations.

The highest reading of a thermometer with blacked bulb in vacuo placed in sun's rays, was 81° on the 16th, 77° on the 15th, and 65° on the 19th; on the 14th 51° was the highest reading. The lowest readings of a thermometer on grass, with its bulb exposed to the sky, were 30° both on the 15th and 19th, and 24° on the 16th; the mean reading for the week was 33°.

Wind.—The direction of the wind was S.W., and its strength brisk at times. The weather during the week was generally dull, cloudy, and showery, but still very mild. Fog prevailed on Saturday the 20th.

Rain fell on five days during the week; the amount collected was 0.45 inch.

ENGLAND: Temperature.—The highest temperatures of the air observed by day were 58° at Blackheath and 57° at Cambridge; at Plymouth 54° was the highest temperature. The mean value from all stations was 55°. The lowest temperature of the air observed by night was 31° at Manchester; at Portsmouth and Liverpool 36° was the lowest temperature. The mean from all stations was 34°. The range of temperature in the week was the least at Brighton and Portsmouth, both about 19°, and the greatest at Manchester, 26°. The mean range of temperature in the week from all stations was 22°.

The mean of the seven high day temperatures was the highest at Truro, 57°, and the lowest at Hull, 48°; the general mean from all stations was 50°. The mean of the seven low night temperatures was the lowest at Wolverhampton, 34°, and the highest at Portsmouth, 43°; the mean value from all stations was 39°. The mean daily range of temperature in the

week was the greatest at Birmingham, 14°, and the least at Bradford, 8°; the mean daily range from all stations was 11°. The mean temperature of the air for the week from all stations was 44½°, being 5½° higher than the value for the corresponding week in 1876. The highest was 47½°, at Portsmouth, and the lowest 41°, at Wolverhampton.

Rain fell on every day in the week at Plymouth, Nottingham, and Exeter, and on five or six days at most other stations. The amounts measured during the week varied from an inch and six-tenths at Plymouth, an inch and four-tenths at Truro, and an inch at Liverpool, to three-tenths of an inch at Cambridge and Norwich; the average fall over the country was seven-tenths of an inch.

The weather during the week was cloudy and dull, showery, but very mild. At Brighton on January 19 the highest temperature was 54 7/8°, and is the highest temperature in January during thirty-seven years; and Saturday, January 20, was the first day without rain since December 24, 1876, at Brighton.

SCOTLAND: Temperature.—The highest temperatures of the air varied from 53° at Leith to 48° at Dundee; the mean from all stations was 50°. The lowest temperatures of the air varied from 27° at Perth to 34° at Dundee; the mean value from all stations was 32°. The mean range of temperature from all stations was 18°.

The mean temperature of the air for the week from all stations was 40°, being 4° lower than that of England, and 1° higher than the value for the corresponding week in 1876. The highest occurred at Paisley and Leith, both 42°, and the lowest at Perth, 38°.

Rain.—The amounts of rain measured during the week varied from 2 1/2 inches at Greenock and 2 1/4 inches at Paisley to rather more than three-quarters of an inch at Aberdeen and Leith; the average fall over the country was 1 1/2 inch nearly.

DUBLIN.—The highest temperature of the air was 54°, the lowest 29½°, the range 25°, the mean 43½°, and the fall of rain 1.05 inch.

JAMES GLAISHER.

Obituary.

It is our sorrowful duty to announce the death of Mr. ALEXANDER CAMPBELL, which took place at his residence, 11, Thyssa Street, Chorlton Road, Manchester, at the advanced age of four score and two years. Mr. Campbell, who some fifty years since was gardener to the Comte de Vandes at Bayswater, left that situation in December, 1857, to take charge of the Botanical Gardens, Manchester, and rich faithfully did he discharge his trust for nearly thirty years; for not only was there a rich collection of flowering plants, Palms, &c., got together, but at one time there was also a fruit department in the gardens, and Pine-apples, Grapes, and Peaches "claimed kindred there;" and as the "olive branches" of our merchant princes were constant visitors to the gardens, and childlike craving information, the curator was always a centre figure in the group,—"A man he was to all the country dear."

How many grown-up amateurs have dated their first knowledge of plants from Mr. Campbell may never be known, but the seeds were sown, and we are happy to say the crop is heavy, for the gardens within thirty miles of Manchester are at this day rich in floral wealth, as the grand annual exhibitions amply testify. Mr. Campbell, by his extensive acquaintance with the great growers of new and rare plants in London and in the provinces, collected a mass of choice specimens with which the gardens were enriched. Mr. Campbell's kindly welcome to strangers visiting the gardens may have had much to do with their making him presents of plants and seeds in return, for friendship's sake, for he was passionately fond of plants, and seemed always thankful for any addition to his collection, which he had loved so long and so well; and now that he has gone to his last resting-place in the Salford Cemetery (Mrs. Campbell had gone before him some years since), loving hands placed a wreath of flowers upon his coffin.

Mr. Campbell, who by his name, as so many suspect, was a native of Scotland, having been born in the parish of Contin, Ross-shire, never wholly discontinued the northern form of speech. His name may yet be found in the Gaelic Family Bible, as is the customary register of that time and place. His long and extensive experience made him like a book of reference to those who sought information on a plant. He was a corresponding member of the Horti-

cultural Society in its palmy days; and the late Mr. J. C. Loudon constantly consulted him when he was his neighbour at Bayswater. He has left a valuable library of books on botany, natural history, &c., to his son and heir, who has seen the press to his honoured parent in his declining years. Mr. Campbell was able to walk until within a few months of his decease; he had no particular ailment, and died from decay of Nature. The writer saw him only one day before he died, in his last peaceful sleep, breathing calmly as a child. A. F.

Enquiries.

Has that gentleman much shall learn much.—BACON. 162. CHARCOAL FOR VINE BORDERS.—Which is the best way of putting charcoal in vine borders for assisting Grapes to colour? Is it any one putting charcoal into old borders for that purpose? If so, what quantity is required for a border 15 feet by 20 feet? E. B. [See Mr. Wildsmith's communication at p. 718, vol. v. Eds.]

163. RAISING STOCKS IN SCOTLAND.—What month do they use for raising stocks in Appie and Peat pips, for stocks in Scotland? W. H.

164. ROMAN HYACINTHS.—M. M. asks if any one can tell him the origin of the early-flowering white Roman Hyacinths, which have been largely cultivated for many years during the past few years. They seem quite constant to the diminished growth and loose spikes of smaller flowers which have characterised them from the first, and their odour is different—sweeter than that of the common Hyacinth, and suggestive of specific difference. The flower, too, is different in form and shorter and broader in the tube than the blue specific types of Hyacinth grown in botanic gardens. They have been sometimes referred in gardens to Bellisaria romana, but have nothing to do with that plant, being true Hyacinths. Do they come from any distinct wild stock or are they selections selected and perpetuated by the Dutch florists?

165. DIGGING MACHINE.—Has such an implement as a digging machine, capable of being worked by a small steam engine, or, in fact, any other form of digging machine, ever been invented and brought into practical use? [Mr. J. H. Knight, Weybame House, Farnham, is the inventor of a digging machine, which we understand, and we believe, to be actually, in one of the Kentish Hop-gardens, last autumn. Eds.]

Answers to Correspondents.

BONE DUST: North Lincoln. 8 to 10 cwt. per acre of bone-dust is a common dressing in Cheshire. It would probably be a more economical, and equally permanent, dressing during the past few years, to get a growth of grass by applying a cwt. per acre of nitrate of soda at two dressings, in March and April respectively, and then feed off the growth with sheep and cattle, giving them decorticated cotton-cake on the land all the summer.

CINERARIA LEAVES: Cor. The markings are the work of a grub which tunnels through the substance of the leaf. Watch in the evenings, and pick off and burn every affected leaf.

CHIMONANTHUS FRAGRANS: J. M. Hardly against a wall, and will grow well under ordinary treatment.

CORNUS ALBA, &c.: G. P. M. The red stems of this shrub are more ornamental than those of Cornus mas, which are green. C. alba should not be planted under trees. It will keep rain from falling on a wall, and will so far tend to dry it; but if the damp arises from an imperfectly built foundation it will not stop the damp from rising, nor will any other plant.

CREEPERS: North Lincoln. Cratogeomys pyramidalis, Heclera Regeneriana, Smilax rotundifolia, Lonicera brachyopoda (near evergreen), Bridesia spicata.

DARLINGTONIA: F. M. Dublin. The Darlingtonia of De Cadeville, in the collection of the late Duke of Devonshire, is a name to be abandoned, as it is a mere synonym of Desmanthus, Darlingtonia of Torrey, nat. ord. Sarraceniacus, is to be retained as correct, and superior to the latest views.

GARDEN ENGINE: B. B. The engine now inquired about is sold by Messrs. Barnard, Bishop or Barnard, Norwich. See our last vol. p. 175.

LOVE IN A MIST: J. P. The popular name of Nigella damascena.

MILDEW: P. B., Sunk Island. A low temperature in conjunction with a moisture-saturated atmosphere will produce mildew on Vines, and it is to be avoided by keeping the air in the house brisker and drier, and in dusting the affected parts with flowers of sulphur.

MONASTERS MUSHROOM: J. Hopkins. A not very unusual occurrence.

MOSES: J. B. Try Berkeley's Handbook (Reeve & Co.).

NAMES OF FRUITS: J. G. The name of Black Gillyflower is quite correct. See American fruit lists.

NAMES OF PLANTS: W. D. 1. Lobelia floribunda; 2. Justicia spicata; 3. Nephrodium molle. Of the others, send better specimens.

* Numerous communications are unavoidably postponed.

ERRATA.—At p. 80, col. c, for "M. Pringsheim," read "M. Prillieux." At p. 89, col. a, for "Thunja Cavendishii," read "Musa Cavendishii."

PUBLICATIONS RECEIVED.—The Various Contrivances by which Orchids are Fertilised by Insects, by Charles Darwin, M.A., F.R.S., &c., 2d edition, revised. Murray, W. & A., 10, Abchurch Lane, London. Paris, the following new publications and reprints:—Les Aliments; Guide Pratique pour Constatier les Falsifications des Farines, Féculés, Cafés, Chocolats, Thés, Epices, Aromates, &c. Markets.

COVENT GARDEN, January 25.
The supply of Apples is now confined to Golden Knobs, Blenheim Orange, and Wellingtons, with moderate consignments from America, all of which are now making good prices. Early forced vegetables are arriving in fair quantities; culivars of the season are in the market. Cucumbers are in good demand. Kent Cobs scarcely asked for. James Webber, Wholesale Apple Market.

VEGETABLES.

Artichokes, per bush	4 0-0	Leeks, per bunch	5 0-0
Asparagus, per doz.	1 0-0	Lettuces, per doz.	1 0-0
Beet, per doz.	1 0-0	Onions, per bush	1 0-0
Brussels Sprouts, per bush	7 0-0	Peas, per bush	1 0-0
Carrots, per bush	0 6-0	Potatoes, per bush	1 0-0
Celery, per bundle	1 2-0	Rhubarb, per bundle	1 0-0
Chilis, green, per 100	3 0-0	Spinach, per doz.	1 0-0
Cucumbers, each	2 0-0	Tomatoes, per doz.	1 0-0
Endive, per doz.	1 0-0	Turnips, per bush	4 0-0
Herbs, per bunch	0 2-0	Peas, per doz.	1 0-0
Radish, per bush	4 0-0	Peas, per doz.	1 0-0
Potatoes—Kent Regents	4 0-0	Potatoes—Kent Regents	4 0-0

to 4 5; Kidneys, 4 0 per ton.

FRUIT.

Apples, per 1/2 sieve	1 6-0	Oranges, per 100	5 0-0
Cobs, per 100	1 0-0	Peaches, per doz.	6 0-0
Grapes, per lb.	3 0-0	Pears, per doz.	1 0-0
Lemons, per 100	1 0-0	Pine-apples, per lb.	2 6-0
Melons, each	1 6-0

Tropaeolum, 12 buds. 0 10-0
Violets, 12 buds. 1 6-0

Stephanotis and Gardenias blooms are very scarce.

SEEDS.

LONDON, Jan. 24.—Our seed market this week has been fairly attended, and more disposition to operate has been shown by country buyers. From America (in which country this season the chief interest is centered) the arrivals of red Clover seed continue on a most limited scale, and values in consequence, both here and there, exhibit remarkable steadiness; indeed, the firmness which characterises this leading article imparts a strong healthy tone to the whole trade. A good quantity of the Clover seed shipments from New York finds its way to our market in consequence. Of home-grown samples of red Clover seed there is a fair number offering, but they mostly represent exceedingly small quantities. There has been more business doing in Alsike at increased rates. White Clovers will sustain the late advance. Trefoil is quiet. The bulk of red Trefoil sold this week for export consumption, is held in London; and the unprecedented rise last autumn, and the tempting profits consequently offered, induced country houses to let go their seed holdings, at a considerable price, and to come upwards. Renal grasses, although not at present much dealt in, are quietly hardening in value. For Sainfoin and Lucerne occasional buyers are found at full rates. Rape seed must be noted 25. to 27. per cwt. dearer. There is more enquiry for spring Tares, and quotations in Kongberg are a good shilling higher. Canary seed is unchanged, and Hemp is still cheap and neglected. Blue boiling Grass, owing to the colder weather, are in somewhat improved request. Linseed is without alteration.—John Shaw & Sons, Seed Merchants, 37, Mark Lane, London, E.C.

CORN.

At Mark Lane on Monday millers operated very cautiously in Wheat, and quotations were much the same as on Monday last. Fine dry samples of English Wheat, however, were held for rather more money, owing to the smallness of the stock, but steady prices of sale, and prices were unchanged. In Mail, superior qualities were decidedly firm. Oats changed hands quietly, on former terms. The bulk of red Potatoes available here for Malin, Penza, and Pesa. Flour was quite as dear, but not freely dealt in.—On Wednesday there was no new feature in the trade. Fine dry parcels of Wheat were firm, with a slight advance in quotations, and ill-conditioned samples were dull. The same remarks apply to Barley and other classes of spring corn. In flour there was a tendency towards further improvement.—Average price of corn for the week ending January 20.—Wheat, 52s. 11d.; barley, 30s. 7d.; oats, 24s. 11d. For the corresponding week last year—Wheat, 44s. 9d.; barley, 24s. 2d.; oats, 23s. 10d.

CATTLE.

At Copenhagen Fields on Monday prices for beasts advanced a little, although trade was not very brisk. The number of sheep was much smaller, and prices rather quiet. Choice calves made a high price. Quotations—Beasts, 4s. 6d. to 5s. 6d., and 5s. 6d. to 6s. 6d.; calves, 5s. 6d. to 5s. 10d.; sheep, 5s. 6d. to 6s. 4d., and 6s. 4d. to 7s. 4d.; pigs, 4s. to 5s.—Thursday's market was moderately supplied, and a quiet one, prices of all the more important classes for beef, but steady prices for sheep. Prime calves continued to bring high prices.

HAY.

At Whitehall market on Thursday there was a steady demand for fodder, and with only a moderate extent of previous quotations was the week ending in Prime Clover, 100s. to 142s.; inferior, 85s. to 95s.; prime meadow hay, 50s. to 120s.; inferior, 70s. to 85s.; and straw, 20s. to 26s. per load. There were fair supplies of Corn Threshed, but a dull trade, the weather being against demand. Quotations.—Clover, best, 100s. to 142s.; inferior, 85s. to 95s.; hay, best, 100s. to 125s.; inferior, 60s. to 145s.; and straw, 20s. to 26s. per load. Prime Clover, 100s. to 142s.; inferior, 85s. to 95s.; meadow hay, 130s. to 142s.; inferior, 110s. to 118s.; superior Clover, 125s. to 142s.; inferior, 115s. to 130s.; and straw, 50s. to 55s. per load.

POTATOS.

The Borough and Spinfields markets reports state that the quotations for Potatoes are not so good as of the better class there was only a moderate supply. A fair demand prevailed. Kent Regents, 100s. to 160s. per ton; Essex do., 100s. to 140s.; Scotch do., 95s. to 100s.; and 100s. to 120s.; Dutch do., 100s. to 120s.; Victoria 100s. to 150s.—Last week's imports into London comprised 21,457 bags 280 tons 55 casks and 25 casks from Antwerp, 26,508 bags Hamburg, 4617 bags 455 casks from Rotterdam, 294 casks Rotterdam, 126 bags 100 casks Boulogne, 136 bags 12 barrels and 100 bags Rouen.

To the Trade.
W. P. LAIRD AND SIBTHORP, NURSERY.
3729, Dundas, N. B., have to offer:—
"TRANSLATED"—Larch, 2 to 3 feet; Scots Fir, 4s. 1/2; Silver Birch, 2s. 1/2; Norway Spruce, 2s. 1/2; Fir, 2s. 1/2; Limes, 3 to 4 feet; Walnuts, 4 to 6 and 6 to 8 feet; Hollies, 4 to 6, 12 to 18, and 18 to 24 inches; Irish Junipers, 4 to 6 feet; Yew, 12 to 18 inches; Irish Yews, 4 to 5 feet.
SEEDLINGS.—Larch, 1 yr. and 2 yr.; Scots Fir, 1 yr.; Silver Birch, 1 yr. and 2 yr.; Norway Spruce, 1 yr.; Fir, 2 yr.; Beech, 1 yr.; Spanish Chestnut, 2 yr.; Hazel, 1 yr.; English Elm, 1 yr.; Turkey Elm, 1 yr.; Sycamore, 2 yr.; RHUBARB.—Johnson's St. Albans.
SEED POTATOS.—Garden sorts.
Special offer of above may be had on application.

MANURE.—Composed of the blood, bone, &c., of animals, which are boiled down and carefully manufactured into a powdered manure on the premises of a large slaughterer. This now famous manure, possessing as it undoubtedly does, the greatest amount of phosphoric acid, has been used with the greatest success by upwards of 500 Farmers, Nurseriesmen, Market Gardeners, and Farmers. Many testimonials. Sent in stone free to rail or wharf, 11s. per cwt., 4s. per ton. Samples free.
M. H. BENTOTE, Lausanne Road, Nunhead (near Junction).

ODAMS' MANURES.
FOR ALL CROPS.
Manufactured by the NITRO-PHOSPHATE and ODAMS' CHEMICAL MANURE COMPANY (Limited), consisting of London and Glasgow, and having Messrs. J. M. G. & Co., Chairmen.—ROBERT LEEDS, Keewick Old Hall, Norwich. Managing Director.—JAMES ODAMS, Secretary.
Sole Office, 100, Fenchurch Street, LONDON, E.C.
WESTERN COUNTIES BRANCH—Crown Street, Exeter. Particulars of all the above may be had of the Secretary, or may be had of the Local Agents.

COCOA-NUT FIBRE REFUSE,
newly made.—Reduced price, 20 bushels, 6s. 3d.; 100, 200, or on Truck-load, &c. Delivered free to any rail in London. See full particulars of all the above in our Catalogue, Batterssea, S.W.

HORTICULTURAL BUILDER and HOT-WATER APPARATUS ENGINEER,
STANLEY BRIDGE, KING'S ROAD, CHELSEA, LONDON, S.W.

HARRISON'S NEW DWARF LATE BROCCOLI.

A VALUABLE INTRODUCTION.

We have much pleasure in introducing our NEW DWARF LATE WHITE BROCCOLI, which is undoubtedly the best variety of its class. It is the hardest Late White Broccoli extant. The heads are close, compact, and beautifully white, remaining longer fit for use than any other variety known, coming into use the beginning of May. The footstalk being so remarkably short (the heads almost resting on the ground), affords greater protection from frost, and also enables a much larger quantity to be grown on a given space of ground; thus proving a great acquisition to those possessing small gardens. The quality is excellent, and embraces everything to be desired in a Broccoli, either for a Gentleman's table or for Market purposes. We have received numerous flattering Testimonials from all parts of the kingdom, where it was grown last season, testifying as to its invaluable merits, a few extracts from which we subjoin:—

TESTIMONIALS.

From Mr. T. RABONE, *Gr. to the Earl of Shrewsbury,*
May 30, 1876.

"Broccoli thus far north has not done well this season, but yours has done the best. Nice compact heads, very white and tender, and worthy of a place in every garden, as it takes so little room."

From Mr. G. BRIGHTON, *Gr. to Earl Mount Edgcombe,*
May 31, 1876.

"I have no hesitation in pronouncing your Dwarf Late Broccoli as being the best late Broccoli I have ever grown. I have had it planted with other late varieties, and it has proved infinitely superior to them all. At the present we have some splendid heads."

From Mr. J. SIMPSON, *Gr. to Lord Wharffinch,*
May 5, 1876.

"We have been cutting your New Broccoli for the last week or ten days, and find it an excellent variety, and one which I shall add to my list in future. There is not a single plant of yours injured; it may, therefore, be put down as the hardest. The heads are good sized, of a clear, creamy white colour, compact, and in flavour excellent."

From Mr. J. RENSRAW, *Gr. to the Marquis of Anglesa,*
May 30, 1876.

"Your New Dwarf Late Broccoli is very good. Dwarf compact habit, with remarkably solid heads of medium size—just the thing for a gentleman's table."

From Mr. GRINDDALE, *Gr. to the Duke of Somerset,*
May 9, 1876.

"Your New Dwarf Broccoli is the best I ever had. I never saw anything to equal it. It is perfectly hardy, with fine flavour. I cannot speak too highly of it, and am thankful to get it. All that have seen it growing have greatly admired it, with many others."

From Mr. GEO. BENCH, *Gr. to the Marquis of Northampton,*
May 5, 1876.

"I am now cutting your New Broccoli. It is a very late one. I have had it cooked, and pronounce the flavour all that can be desired in a Broccoli. The heads are very firm and of average size, quite hardy, and calculated to stand the winter well. The footstalk of the test is very short, it is exceedingly dwarf, and the most compact Broccoli I am acquainted with."

The Stock being limited, we would impress upon our Customers the necessity of sending in their Orders early to ensure a supply for this season.

Price, Retail, 1s. 6d. per Packet,
or may be had of HURST AND SON, 6, Leadenhall Street, E.C.

HARRISON & SONS, Seed Growers, LEICESTER.

Is now ready, and will be forwarded free on application.

THE NURSERY AND SEED BUSINESS

So successfully conducted for a number of years by the late Mr. JOHN INGRAM, will be continued to be carried on in its various branches, as heretofore, by his Widow and Two Sons, in the name of **WOOD AND INGRAM**, who respectfully solicit a continuance of the kind and liberal patronage which has been given for a lengthened period to their Establishment.

THE NURSERIES, HUNTINGDON.—January, 1877.

JEFFERIES' LITTLE QUEEN COS LETTUCE,

Per Packet, 1s. 6d.,

Is the Earliest, Best Flavoured and Best Coloured Lettuce in cultivation.

MR. EARLEY, The Gardens, Valentines, says:—
"Your Little Queen Lettuce proved a good selection, although the weather was very adverse to the trial."
MR. MEADES, Gr. to the Rt. Hon. Viscount Barrington, Becket Park, says:—
"Your Little Queen Lettuce is a capital variety, as hard as a stone, and has kept well from running to seed this dry summer."

MR. FARR, Gr. to Sir R. Knightley, Bart., Pawley Park, says:—
"Your little Lettuce has proved a very useful one, although the season has been very trying for that class of stuff; its early bearing and crisp sweet flavour are sufficient to recommend it to all who are desirous of a small but good Lettuce."

A Packet of this excellent Lettuce will be included in all our Collections of Vegetable Seeds.

JEFFERIES' HALF GUINEA COLLECTION OF VEGETABLE SEEDS,
JEFFERIES' GUINEA COLLECTION OF VEGETABLE SEEDS,
JEFFERIES' TWO GUINEA COLLECTION OF VEGETABLE SEEDS,

MESSENGER & COMPANY,
CONTRACTORS, MIDLAND HORTICULTURAL BUILDING AND HOT-WATER
ENGINEERING WORKS, LOUGHBOROUGH,

Beg to call attention to the above illustration, which shows a very advantageous arrangement of Glasshouses which has been adopted for several important Works on M. & Co.'s recommendation.

Only thoroughly well-seasoned timber used. Glasshouses erected on Messenger's patent principles are, owing to mechanical arrangements, very strong, most durable, light, elegant; perfect efficiency for purpose intended is guaranteed; are economical in cost and maintenance. Messenger's Patent Boilers, Flexible Jointed Hot-water Pipes and Valves, are now in use in many thousands of instances, with the greatest success. Particulars on application.

Plans and Estimates forwarded. Ladies and Gentlemen waited upon. The Plans of Architects and others carried out. Illustrated Circular Free.

ART-WITH-ECONOMY-APPLIED-TO-CONSERVATORIES

In consequence of the increasing demand for Conservatories, in which pure art is combined with moderate cost, T. H. P. DENNIS & Co. have been led to introduce designs of a character hitherto unknown. One of these designs, showing a house 22 feet 6 inches x 13 feet 6 inches, is annexed, and the result, as regards the extremely low price (which includes fixing, glazing, painting, carriage, &c.), has been attained only by special machinery and a system of interchangeable parts.

T. H. P. DENNIS & Co. are also prepared to provide and fix Hot-water Heating Apparatus and Horticultural Buildings of any dimension or description.

Full-sized specimen of Greenhouses, &c., and Hot-water Apparatus in work, can be inspected at Mansion House Buildings, London, E.C.

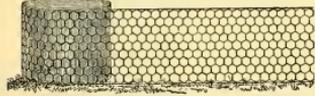

Gentlemen waited upon at their residences by experienced designers.

Estimates and Plans free.

SHAW'S TIFFANY ELASTIC NETTING, CANVAS, POULTRY FENCING, and other Horticultural Purposes. For Samples and Prices apply to JOHN SHAW and CO., 29, Oxford Street, Manchester.

J. B. BROWN & CO.,
90, CANNON STREET, LONDON, E.C.

R. HOLLIDAY, PRACTICAL WIREWORKER, 22, 24, Fotherby Terrace, Notting Hill Gate, London, W. He can call the attention of all Gardeners who are absent to have their Garden Walls Wired to his system of Wiring Walls, as being superior to all others for neatness, strength, and durability.

FOR NEATNESS—Because all the Wires are kept perfectly tight, without the use of the Radisiseur.

FOR STRENGTH—Because every wire stronger Wire can be used, therefore no stable tie is drawn out of the horizontal line by the branches of trees.

FOR DURABILITY—Because, being able to use the strong Wire, it is not so likely to be eaten through with the galvanism as the thin Wire, as used in the French system.

The above engraving is an Example of our system of Wiring Garden Walls. We have recently completed the Wiring of the New Garden Walls for the Marquis of Salisbury, Hatfield House. The Walls are 12 feet high and 2 1/2 yards long, wired on both sides, making a total length of 1500 yards—our system being chosen in preference to any other.

Illustrated Catalogues of Garden and Conservatory Wirework, Rabbit-proof Hurdle Fencing, &c., may be had on application as above.

R. H. HAMPSON, Egerton Mills, Stockport, R. H. Manufacturer of HORTICULTURAL SHADINGS for protecting Wall Trees from Frost and Insects, &c. 54 and 60 inches wide, any length up to 100 yds. Prices on application.

Established over a Quarter of a Century.

Is in use over many thousand miles, And has been awarded the Medals and Highest Commendation of all the leading Agricultural Societies.

It is constructed with POWERFUL WINDING STRAINING PILLARS, RIGID INTERMEDIATE IRON POSTS, STRONG and DURABLE WIRE CABLE STRANDS, Forming the most efficient Strained Iron Fencing known for agricultural and general purposes.

Continuous Bar Iron Fencing.

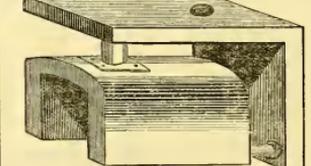

With bars secured by F. M. & Co.'s Patent Self-locking Joints, which effectually prevent the uprights being pushed aside, and are independent of loose pins, wedges, or staples.

IRON ENTRANCE and FIELD GATES, IN WROUGHT and CAST IRON, Designed for the Mansion, Villa, or Farm, WICKET and GARDEN GATES, In Great Variety of Patterns.

Iron Hurdles, Railing, Tree Guards, FRUIT ESPALIERS, WALL FRUIT TRAINERS, &c. Illustrated and Described in F. M. & Co.'s New Catalogue, sent on application.

LONDON BRANCH:
1, DELAHAY ST., WESTMINSTER, S.W.

JONES' PATENT "DOUBLE L" SADDLE BOILER.

These Boilers possess all the advantages of the old Saddle Boiler, with the following improvement—viz, the water-space at back and over top of saddle increases the heating surface to such an extent that a "PATENT DOUBLE L SADDLE BOILER" will do about twice the amount of work with the same quantity of fuel; the cost of setting is also considerably reduced, and likewise the space occupied; at the same time these Boilers are simple in construction, and being made of wrought iron are not liable to crack. They are made of the following sizes:

Sizes.		To heat of 4-in. Pipe.		Price.	
High.	Wide.	Long.	Feet.	£ s. d.	£ s. d.
20 1/2	18 1/2	18	300	7	0 0

24 1/2	24 1/2	60 1/2	1,800	25	0 0

Larger sizes if required.

From Mr. CHARLES YOUNG, Nurseries, Balham Hill, S.W., May 29, 1873.

"Having given your Patent 'Double L' Boilers a fair trial at my Nurseries, I beg to say that they are most satisfactory. I consider them the best in use, and without a doubt the most economical of all boilers; they will burn the refuse of other tubular boilers I have in work."

PRICE LISTS OF HOT-WATER PIPES and CONNECTIONS, with drawings, of all sizes and shapes; or ESTIMATES for HOT-WATER APPARATUS, erected complete, will be sent on application.

J. JONES and SONS, Iron Merchants, 6, Bankside, Southward, London, S.E. When ordering Boilers please refer to the above advertisement.

THE PATENT "EXCELSIOR" LAWN MOWER,

The simplest and best ever introduced.

Waite, Burnell, Huggins & Co., 228, UPPER THAMES STREET, LONDON, E.C., Sole Consignees for Great Britain, Ireland and France, have pleasure in submitting the "Excelsior" as possessing the following advantages over other Mowers:—

- It cuts longer grass. It needs less repairs.
- Its adjustments are more correct. Its adjustments are more correct.
- It rolls the ground. It cuts the borders.
- It cannot clog. It cuts the borders.
- Its draft is lightest. It is a perfect mower.

Has never been beaten in Competitive Trials.

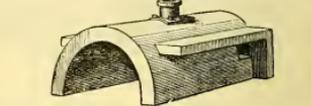

PRICES: (Including Collecting Boxes)

Silver Medal 1874. **THE TERMINAL SADDLE BOILER.**—First-class Certificate, 1873; Highly Commended, 1873; and First-class Certificate, 1875.

"This Boiler possesses the rare merit of sucking all the heat from the fire."—Gardener's Magazine, p. 256. "It has never been severely tested and it never burns any kind of fuel in the Terminal Saddle."—Journal of Horticulture, p. 37. "For moderate cost and real efficiency the Terminal Saddle is one of the very best."—The Gardener, p. 95.

Prospectus sent free. T. JONES, Temple Street, Manchester.

AN EXTRAORDINARY BOILER.

During the Great Boiler Contest at Birmingham, in 1875, all Boilers were severely tested and the victor, in respect of merit, One test was, "How long can each Boiler go without Night Attention?" However, one Boiler proved to a surprising degree, as after being shut up for twelve hours (from 9 P.M. to 9 A.M.), it still retained its heat in 1000 feet of 4-inch pipes, and yet had more than a basket of fire drawn from its furnace in the morning—equal in point of fact, to seventeen hours of continuous firing. What a boon to Gardeners. This was THE CHAMPION of the Patent Close Coil Boiler, for Drawings and Prices of which send two stamps to

Messrs. DEARDS, Boiler Works, Harlow, who now have their Boilers at work in every county of England, a smaller kind of Boiler, equally as satisfactory, and certainly "the best thing" out. Awarded five First Prize Silver Medals.

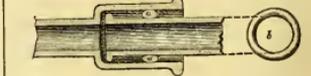

AGRICULTURAL LOCOMOTIVES, STEAM PLOUGHING MACHINERY, ROAD LOCOMOTIVES, TRAMWAY LOCOMOTIVES, STEAM ROAD ROLLERS.

For Prices, Description, and Reports of Working, apply to the Manufacturers,

AYLING & PORTER, ROCHESTER, KENT; 75, CANNON ST., LONDON, E.C.; and 0, AVENUE MONTAIGNE, PARIS.

AYLING & PORTER'S ENGINES have gained the highest Prizes at every important International Exhibition. The two Medals for Progress and Merit were awarded them at Vienna for their STEAM ROLLERS and ROAD LOCOMOTIVES; and at the last trials of the Royal Agricultural Society of England their AGRICULTURAL LOCOMOTIVES gained the First Prize after exhaustive trials, when one of their 10-horse power Engines, fitted with single slide and ordinary link-motion, indicated 35-horse power, with a consumption of three and one-fifth bushels of coal per horse-power per hour.

F. & J. SILVESTER,
 HOT-WATER ENGINEERS, &c., &c.,
 Castle Hill Works, Newcastle, Staffordshire.
 Their Boilers are the only ones made with the sanction and under the inspection of the inventor, Mr. Stevens—all others being mere imitations.

LIMEKILN HEATING.

This System of HEATING WINTER GARDENS, CONSERVATORIES, ORANGERIES, FERNERIES, VINERIES, FORCING HOUSES, PINERIES, CUCUMBER, MELON and MUSHROOM HOUSES, STOVES, PITS, &c.—also for WARMING MANSIONS, PUBLIC BUILDINGS, FACTORIES, &c., is steadily making progress in public estimation, effecting as it does

Great Economy of Fuel and Steadiness of Heating Power,

and rendering the hitherto onerous duties of Stoker comparatively light—no night stoking whatever being necessary.

List of Places where the System is in Operation, with full address in each case, will be sent post-free on application.

Gentlemen and Gardeners wishing to adopt this System will then be enabled to view the Apparatus nearest to their own Establishments, or write to the Gardener, and thus get independent testimony as to the value of this method of Heating.

Estimates will be submitted, on receipt of particulars, free of charge.

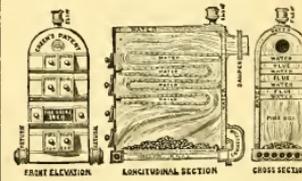

FULL PARTICULARS POST-FREE.

W. C. SMITH & CO., HORTICULTURAL ENGINEERS,
 Victoria Works, Bury St. Edmunds.

SOLE MANUFACTURERS OF BEARD'S PATENT METALLIC NON-CONDUCTING GLASS-HOUSES.—The Glass is fixed between two layers of prepared felt. The Ventilators are worked by a simple mechanical contrivance, and the whole structure is screwed together so as to render it quite portable. HEATING APPARATUS IN ALL ITS BRANCHES. ORNAMENTAL CONSERVATORIES and HORTICULTURAL BUILDINGS of EVERY DESCRIPTION.—For lightness, elegance and durability, these Houses cannot be surpassed. The best materials only are used in their construction. Great improvements have recently been made to obviate the objections to iron houses. Very extensive works on this principle have been satisfactorily executed. An Illustrated Catalogue forwarded post-free on application.

To the Seed Trade.

WANTED, as SHOPMAN, a thoroughly experienced man for the Seed Trade. Unexceptional references required as to ability, &c. Apply, stating age, salary required, and to all other particulars, to A. Z. Gardner, Clerkenwell Office, W.C.

WANTED, a young MAN, with a fair knowledge of the Seed Trade. Apply, with full particulars, to Mr. J. ROY, & SONS, Market Place, Birmingham.

WANTED, a thoroughly competent BOOK-KEEPER, with a knowledge of the principles of book-keeping, &c. Apply, by letter, X. Y. Z., Mr. R. Cooper, 152, Fleet Street, London, E.C.

Steward and Bailiff.

WANTED, an intelligent, well educated, energetic Man, to fill the above situation, and to act as Manager of a large Farm, and Superintend the keeping up of an extensive Domain and Estate, under a non-Resident Agent. He must be a first-rate Practical Agriculturist, and have a thorough knowledge of the principles of Accountancy, mathematical and experienced. He will have the care of a valuable Herd of Fines Cattle and Flocks of Game and Sheep, and must be well up in all Estate Matters, Draining, Building, Repairs, Saw Mills, and Steam Machinery, and the Supervision and direction of a Staff of Workmen in different departments. He will have the assistance of a Clerk in his official work and correspondence, and the use of a horse and vehicle for his use. Large Salary. A Gentleman's Family, and has an undeniable character. The Wife must be a good Dairy and Poultry Manager. Apply, by letter, X. L., Buckhurst Park, Sunninghill, Berks.

WANTED, as FARM BAILIFF, a married Man, without encumbrance, who thoroughly understands the duties of a Gentleman's Farm, and has an undeniable character. The Wife must be a good Dairy and Poultry Manager. Apply, by letter, X. L., Buckhurst Park, Sunninghill, Berks.

WANT PLACES.

F. G. HENDERSON AND SON have many excellent GARDENERS of approved testimonials for ability now waiting in their Nurseries for employment.

E. G. H. & Son will be pleased to answer any enquiries from Noblemen and Gentlemen requiring such.—Pinneapple Nursery, Maida Vale, London, W.

Head Gardeners.

JOHN LAING can at present recommend with every confidence several energetic and practical Men, of great ability and firm character. Lays, and Gentlemen in WANT of GARDENERS and BAILIFFS, or GARDENERS for First-rate Establishments or Single-plants, &c. will be glad to have any assistance by applying at Stansfield Park and Rutland Park Nurseries, Forest Hill, London, S.E.

B. S. WILLIAMS, having at the present time several very excellent GARDENERS upon his Register, is desirous of placing them in Situations where great experience and trust are required. B. S. W. would at the same time beg to intimate that when a Gardener is applied for that the filling of the situation should be left with him, as that would prevent unnecessary correspondence and delay.—Victoria and Paradise Nurseries, Upper Holloway, London, N.

GARDENER (HEAD).—WILLIAM SIMPSON is in want of a situation as above; is at present Foreman in the Gardens at Berkeley Castle, Gloucestershire, where all enquiries respecting character, &c., will be answered.

GARDENER (SECOND, OR FOREMAN) in the Houses in a good Establishment.—Age 25, married, no children; thoroughly understands the profession. Good character and references.—H. H., The Graces, Potence Park, Exeter.

GARDENER (UNDER), in a good Establishment, under Glass.—Age 30; six years' experience. Good character.—G. TAYLOR, Essex Park Gardens, York.

GARDENER (UNDER).—Age 20; has been accustomed to Vinery, Orchard-house, and Conservatory. References.—HORTUS, Fentonville, West Canford, Cornwall.

GARDENER (UNDER), or IMPROVER, in a good Establishment, where several are kept.—Age 20; good reference.—C. R., Longspire House, Whitechurch, Hants.

JOURNEYMAN, in the Houses; age 22.—Will be pleased to be disengaged to return to work, and would be pleased to meet with a situation as above; where Pines and Orchids are grown preferred. Can be highly recommended. Most useful when he has been in the last two years. A weekly Premium not objected to.—The Gardens, St. Vincent's, Grantham.

JOURNEYMAN, in the Houses.—Five years' experience with Plants and Fruit. Good reference.—Address, asking terms, to H. GRAVES, The Gardens, Edenthorpe, Doncaster, Yorkshire.

FOREMAN (SINGLE), in a good Establishment.—Has a knowledge of Pines, Orchids, Stove and Greenhouse Plants, and Gardening in general. Good personal character.—F. G., 25, Grange Road, Camden Town, N.W.

FOREMAN, in a good Gardening Establishment.—Age 24; has filled similar situations, and can be highly recommended (as a good practical Man who is interested in his profession). Formerly employed by—A. B., Post-office, Moulton, Northampton.

FOREMAN, in the Houses, or General.—Married; has a good knowledge of the work in each Department, and would be willing to carry out the Gardener's instructions.—R. 124, Robinson's Park Road, S.W.

IMPROVER, in a Nobleman's Establishment, where Forcing is done.—Age 20; has had twelve months' good character.—R. BOOKER, King's Arms, Hampton Court, Middlesex.

IMPROVER, in a Nursery, or in a Gentleman's Garden. Good reference.—J. READ, Brookman's Park, Hants.

SUPERINTENDENT of Estate Works, in Public Parks, and Gardens.—CHARLES McDONALD has resigned the Management of the Phoenix Park, Dublin, having resided his services as above; has had great experience in the direction of building, Road-making, &c., in carrying out Forest Work, and Gardening in all its branches, and thoroughly understands the Management of all kinds of Stock. Highest testimonials.—CHARLES McDONALD, Holton, Wotton, Yorkshire.

M. R. TOWERS, having resigned his situation as GENERAL MANAGER for the Messrs. OSBORN, OSBORN, & CO., in the City of London, & in appointment, or for an engagement as Manager of a Department, &c., and he ventures to believe that his thorough knowledge of all the various branches of Horticulture, and his experience also as a LANDSCAPE GARDENER, THELWELL FRANK, & CO., will enable him to place at the disposal of an employer all the most important advantages. Communications addressed to The Cottage, Osborn's Nursery, Fulham, S.W., will be duly attended to.

ENGINE DRIVER and CARPENTER (ROUGH) or PAINTING and GLAZING, &c.—Respectable twelve years' good character.—F. G., Strawberry Vale, Teddington, S.W.

EPSS'S COCOA: "BY A THOROUGHLY GRATEFUL-COMFORTING. By a thorough analysis of the analysis of the best which governs the operations of digestion and nutrition, and by careful application of the fine properties of well-selected Cocoa, Mr. Epss has provided our breakfast tables with a delicately-flavored beverage which may save as many heavy doctors' bills. It is by the judicious use of such articles of diet that a constitution may be gradually built up, until strong enough to resist every tendency to disease. Hundreds of subtle maladies are floating around us ready to attack wherever there is a weak point. We may escape many a fatal shaft by keeping ourselves well fortified with pure blood and a properly nourished frame."—Civil Service Gazette.

JAMES EPSS AND CO., HOMOEPATHIC CHEMISTS, 48, Threadneedle Street, and 120, Piccadilly.

KINAHAN'S L.L.L. WHISKY. Kinahan & Co. find that, through the recommendation of the Medical Faculty of the Faculty of Physicians, GREAT OLD L.L.L. WHISKY for purely medicinal purposes is very great, submit with pleasure the following Analysis by Dr. Hussell:—It is composed of the purest and finest samples of this well-known and popular Whisky. The samples were analyzed and analyzed, and found to be pure, and of the highest quality. The Whisky must be pure, aromatic and ethereal to the smell, and of the highest quality to be pronounced to be of the highest and of very excellent quality. The Medical Profession may feel full confidence in the purity and efficacy of this Whisky, and of its good Titchfield Street, Oxford Street, London, W.

DINNEFORD'S FLUID MAGNESIA. The best remedy for ACIDITY of the STOMACH, HEADACHE, &c. It is the safest and most agreeable for DELICATE DIGESTION; and the safest aperient for delicate Constitutions, Ladies, Children, and Infants.

DINNEFORD'S FLUID MAGNESIA, 175, New Bond Street, London, and all Chemists.

HOLLOWAY'S OINTMENT and PILLS.—Have the Remedy within your reach.—Nothing has yet equalled the efficacy of Holloway's Balsamic Pills in checking disease, and restoring the system to its natural state. They not only all impurities from the blood, and regulate and invigorate every organ. Immense care is taken to ensure the genuine preparation, and to prevent any cheap imitations which may be caused to invade seeking health by Holloway's Medicine. Their composition is of the most careful study, and the impurities of your virtues by time, sea voyage, or climate. They over-urge or cause incumbrance. In disturbances of the system, disordered bowels, and in all the various affections of the bowels, these Pills exercise an almost magical power, which cures disease mildly, quickly, conveniently, and cheaply.

THE BEST MEDIUM & LATE KIDNEY POTATO IN CULTIVATION.

SUTTON'S MAGNUM BONUM.

A REMARKABLY GOOD COOKING POTATO. | ALMOST ENTIRELY FREE FROM DISEASE.
AN ENORMOUS CROPPER. | INDISPENSABLE FOR SHOW PURPOSES.

SUTTON'S
MAGNUM BONUM
POTATO.

We had the pleasure of introducing this splendid new and distinct Kidney Potato last season, but as our supply was limited only very early orders could be executed, and many customers were disappointed. We grew it largely last year, and have a good stock now ready for delivery, for which early orders are solicited. It is, without exception, the finest medium and late Kidney Potato in cultivation, and is highly recommended by all the principal Potato Growers in the country. The tubers are large and oblong in shape; the skin is russeted; flesh perfectly white and mealy, and of exceptionally fine flavour. It is a remarkable cropper, far exceeding any other English variety. We have received many letters from customers stating that this Potato is free from disease.

CHEAPER BY THE SACK OR TON.

SUTTON'S
MAGNUM BONUM
POTATO.

From SHIRLEY HIBBERD, Esq., *Stoke Newington, November 8, 1875.*
"Your new 'Magnum Bonum' Potato singularly combines beauty of appearance with high quality, and I believe it will prove the most generally useful variety ever put into commerce. It is a first-rate sort for the table; the flesh white, dry, and mealy; the flavour all that can be desired. When grown here for trial in 1874 the stools averaged 2 lb. to 7 lb. each of handsome roots. In 1875 the stools averaged 6 lb. to 9 lb. each, grown in ridges on my undrained clay."

From Mr. W. WILDSMITH, *Gardener to the Right Hon. Viscount Eversley, October 13, 1876.*
"I had one gallon of 'Magnum Bonum' Potatoes from you, the yield from which was 45 bushels, four-fifths of them being as fine as those I showed in my collection at the Alexandra Palace. As to quality I cannot speak too highly, the flesh being perfectly white and mealy, and of a real Potato flavour. I have noted it for one of my main crop Potatoes next year, and I do not but, when sufficiently known, many will follow my example."

From Mr. J. P. BELLIS, *Gardener to Major Thoyts, Sullingtonstead, November 15, 1876.*
"I bought of you in March, 1876, 1 lb. of 'Magnum Bonum' Potatoes, cut them into fifty sets, and planted them 3 feet apart. The hauls covered every foot of ground, and I am convinced that 3 feet square was not more room than was necessary, being a strong growing variety. I lifted the crop in October, and from two sets I dug 21 lb., and altogether 275 lb. of good sound Potatoes."

SALES BY AUCTION.

Otontoglossum crispum (Alexandri) (Blunt), OTONTOGLOSSUM CRISPUM (Blunt) ... MR. J. C. STEVENS will sell by AUCTION, at his Great Rooms, 38, King Street, Covent Garden, W.C., on WEDNESDAY, February 7, at half-past 12 o'clock precisely, a fine collection of Otontoglossum crispum (Alexandri) (Blunt), Otontoglossum glaucum; also established plants, mostly with flower-pikes, of Phloxes, Schillars, P. amabilis, Loddonians, P. rosea, and P. grandiflora; good plants of Lydia Dyeria, Otontoglossum crispum, O. hastatum, O. glaucum, Saccolabium, Dendrobium, &c.; an importation of Dendrobium speciosum, comprising the whole stock at present received from this nursery; also a quantity of the following Hallii, Oncidium Kogerii, Cattleya superba, &c.; a fine Orchid from Messrs. J. Backhouse and Son, including three plants of the rare and beautiful O. Loddoniana; Lodeborghianum; also many other rare Orchids rather in the flowering period; also an importation of a rare hardy Tree Fern from Belgium.

On view the morning of Sale, and Catalogues had.

Valuable Lilies. MR. J. C. STEVENS will sell by AUCTION, at his Great Rooms, 38, King Street, Covent Garden, W.C., on THURSDAY, February 8, at half-past 12 o'clock precisely, a fine importation of good BULBS of the beautiful LILUM NEILGHERENSE. The white flowers of this magnificent Lily are deliciously fragrant, and of great substance. It bears several flowers on a stem, each flower nearly a foot long. Also some excellent bulbs of the following new varieties of Lilium neilgherense, viz. LILUM NEILGHERENSE ROSAEUM—the exterior of the flower-tubes of this variety is pink, the interior white. LILUM NEILGHERENSE FLAVUM—a handsome yellow-colored form of this charming Lily. LILUM NEILGHERENSE TIBIFLORUM—a magnificent pure white Lily, with very long flowers; figured in Wight's Icones Plantarum Indiar Orientalium.

LILUM NEILGHERENSE TIBIFLORUM LUTULUM, a very handsome yellow-flowered variety tubiflorum. And some splendid flowering bulbs of other CHOICE Lilies, including Bloomerian, Cypripedium, porphyrocephalum, Hamulidula, glaucopetalum, parvum, multiflorum, and Wallchianum. Also a quantity of CHOICE BULBS and young plants from California, viz. Platium autumnum, Brodiaea, Tritelia, Calliparis, Erythronium, Bionera, &c.; and some fine BLOOMING BULBS of the handsome Garden-hyacinths, C. australe, C. parviflorum, and C. tuberosum-rooted Begonias, Pansies, Anemones, Amaryllis, North American Cypripediums, with a variety of other Bulbs and plants, and a large quantity of fine Platium autumnum.

On view the morning of Sale, and Catalogues had.

Plants and Bulbs. MR. J. C. STEVENS will sell by AUCTION, at his Great Rooms, 38, King Street, Covent Garden, W.C., on SATURDAY, February 10, at half-past 12 o'clock precisely, a fine selection of the following FRUIT TREES, HARDY ORNAMENTAL TREES and SHRUBS, LILiums, GLADIOLI, RANUNCULI, &c., and some choice plants of the following description: On view the morning of Sale, and Catalogues had.

Established Orchids. MR. J. C. STEVENS will sell by AUCTION, at his Great Rooms, 38, King Street, Covent Garden, W.C., on THURSDAY, February 15, at half-past 12 o'clock precisely, part of the Collection of ESTABLISHED ORCHIDS, in the possession of the late Mr. G. and sold in consequence of removing. Amongst them will be found many rare and choice varieties. On view the morning of Sale, and Catalogues had.

Auction Mart, Tokenhouse Yard, London, E.C. SALE of 6000 LILUM AURATUM, just arrived in splendid condition from Japan; an unusually fine importation of Garden-hyacinths, in the possession of the late Mr. G. and some which are starting into growth, including magnificent trunks of Cyathus dealbatus, Dianthus, aquarum, and Scabellum, together with a quantity of GLADIOLI and other Hardy Bulbs.

Messrs. PROTHEROE and MORRIS will sell the above by AUCTION, at the Mart, London, E.C., on MONDAY, February 12, at 12 o'clock precisely. On view the morning of Sale. Catalogues may be had at the Mart, and of the Auctioneers, 98, Cracechurch Street, E.C., and Leytonstone, E.

Edgware, N.W. IMPORTANT CLEARANCE SALE OF VALUABLE NURSERY STOCK, comprising a great variety of Lawn Trees, including the following: Water and Gas had on 1000 specimens, Lonicera, magnifica, Douglasii, 4 to 10 feet high; a valuable collection of choice and rare Green shrubs, including the following: Edgware and Ornamental Planting; also a fine collection of Orchids, in all choice varieties, and a number of Camellias and other Greenhouse Plants.

Messrs. PROTHEROE and MORRIS will sell the above by AUCTION, on the Premises, on the View Road, Edgware, N.W., on SATURDAY, February 17, at 12 o'clock precisely. On view the morning of Sale, and Catalogues had at the Premises, and of the Auctioneers as above.

Noting, S.W. PRELIMINARY NOTICE. MESSRS. FLETCHER and MORRIS are instructed to sell by AUCTION, on the Premises, the Exotic Nursery, Sitting, S.W., on THURSDAY, February 22, at 12 o'clock precisely, a fine and thriving young NURSERY STOCK. May be viewed prior to the Sale, and Catalogues may be had on the Premises, and of the Auctioneers as above.

TO BE LET, a NURSERY, with Immediate Possession, seven miles from London, containing a seven-acre Dwelling-house in good repair. Water and Gas had on four newly-erected Greenhouses. Heated with Hot-water, with Range of Pits, situated in a healthy position, and well supplied with water, with or without the Nursery. Lease of years term (unexpired); all at the low rental of £25 per annum. The above to be disposed of, on account of ill health, on moderate and liberal terms. Apply personally, on the Premises, to W. HOWITT, Hford, Kent.

Productive Fruit and Vegetable Gardens. TO BE LET, with possession, the WALLEDEN GARDENS of a MANSION, distant about 7 miles from Reading, comprising Gardeners' Cottages, Vineries, Forcing Pits, Potting Sheds, Fursure-and Premises, embracing an area of nearly 2 acres, and well adapted for producing early Fruit and Vegetables for London, Reading, or other markets. The Garden is well-stocked with all varieties of Fruit and Vegetables. The tenant will be required to pay the valuation of the outgoing tenant. For further particulars, apply to Messrs. RAWLANCE and SOUTAREY, Salisbury; and 29, St. George Street, Westminster, W.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—At a General Meeting of the Members of this Institution, held on January 19, for the purpose of ELECTING PENSIIONERS, £1000 was on the Funds, the following was the result of the Ballot:—

CATALOGUES free on application. JAMES TYNAN, Seed Warehouse, 63, Great George Street, Liverpool.

To the Trade.

W. P. LAIRD and SINCLAIR, NURSERYMEN, Dundee, N.B., have to offer:—

TRANSPLANTED.—Larch, 2 to 10 feet; Scots Fir, 2 1/2, 1 1/2, and 1; Silver Fir, 9 to 10 inches; P. Laricio, 2 1/2, 1 1/2, 1 1/2, 1 1/2, 1 1/2; Walnut, 4 to 6 and 6 to 8 feet; Green Holler, 6 to 12 and 12 to 24 inches; Irish Juniper, 4 to 6 feet; Laurustinus, 12 to 18 inches; Irish Yew, 4 to 5 feet.

SEEDLINGS.—Larch, 1 1/2, and 2 1/2; Scots Fir, 1 1/2; Silver Fir, 2 1/2, and 3 1/2; Pinus austriaca, 2 1/2; P. Strobus, 2 1/2; Beech, 1 1/2; Chestnut, 2 1/2; Hazel, 2 1/2; English Oak, 1 1/2; Turkey Oak, 2 1/2; Sycamore, 2 1/2.

RHUBARB.—Johnstone's St. Martin's. BIRD POTATO.—Special offer of above may be had on application.

ISAAC DAVIES, NURSERYMAN, Ormskirk, has to offer the following:—

RHODODENDRUM PRINCE.—Raised by me and sent out eighteen years ago, is still a great favourite with all lovers of early-blooming plants. I can now supply good bushy plants, covered with flower buds, at 15s. per dozen.

SWEET-SCENTED RHODODENDRONS.—Also raised and sent out by me, and which I find constant that they will be highly esteemed for many years, being of a bushy habit, early, and very free-blooming, the flowers large, white, and most deliciously fragrant.

I am happy to state that these plants have been found to withstand the winter in the open ground without the least injury. In respect of the undoubted value of these novelties, I should be glad to refer to the Curator of the Botanic Gardens, Manchester.

Prices and full descriptions of these and other novelties post-free to any address on application.

The Best Scarlet-fleshed Melon.

SUTTON'S SEED OF BATH.—From Mr. W. Widdis, Gr. to the Right Hon. Viscount Eversley.—"I consider your Hero of Bath the best scarlet-fleshed Melon yet in commerce, being of a quality, appearance, and productiveness. His Lordship, who previously had a prejudice against scarlet-fleshed Melons, pronounces this variety superior."

From Mr. Thomas Lockie, Gr. to the Right Hon. Lord Otha Fitzgerald, at Great House, County of Wick, Ireland.—"The best I have ever grown of the scarlet-fleshed class. It is very handsome, of good constitution, and excellent in flavour." Price 3s. 6d. per packet.

SUTTON AND SONS, The Queen's Seedsmen, Reading.

Special Offer.

Also other Nursery Stock as per LIST. The Nurseries, Malton.

The Best Medium and Late Kidney Potato in

SUTTON'S MAGNUM BONUM. A remarkably good cooking Potato. An enormous cropper. Almost entirely free from disease. Indispensable for show purposes.

From Mr. J. P. BELLIS, Cr. to Major Thoys, Sulhamstead, Nov. 25, 1876. "I bought of you in March 49 lbs. 1 lb. of Magnum Bonum Potatoes, cut them up 50 sets, and planted them 3 feet apart. The hauls covered every foot of ground, and I am convinced that 3 feet square was not more room than was necessary, being a strong growing variety. I lifted the crop in October, and from two sets I dug 23 lb. and altogether 297 lb. of good sound Potatoes."

Price 2s. per bush, 12s. 6d. per bush. SUTTON'S DESCRIPTIVE LIST of choice Seed Potatoes gratis and post-free.

SUTTON AND SONS, The Queen's Seedsmen, Reading.

Centauria canadensis (Wholesale Price). WOOD AND INGRAM offer for summer-sown-plants, of the above, thoroughly established in thumb-pots, at 20s. per 100. Package 3s. per 100, or 12. 6d. for 50, not less than 2s. 6d. and all the price.

The Nurseries, Huntingdon.

The Royal Norfolk Nurseries, Eaton, near Norwich.

VALUABLE LILIES.

MR. J. C. STEVENS will SELL by AUCTION, at his Great Rooms, 38, King Street, Covent Garden, W.C., on THURSDAY, February 8, at half-past 12 o'clock precisely, an Importation of good Bulbs of the beautiful LILIUM NEILGHERRENSE. The white flowers of this magnificent Lily are deliciously fragrant, and of great substance; it bears several flowers on a stem, each flower nearly a foot long. Also some excellent Bulbs of the following new varieties of Liliun neilgherrense, viz.:-

LILIUM NEILGHERRENSE ROSEUM—the exterior of the flower tubes of this variety is pink, the interior white.

LILIUM NEILGHERRENSE FLAVUM—a handsome light yellow-coloured form of this charming Lily.

LILIUM NEILGHERRENSE TUBIFLORUM—a magnificent pure white Lily, with very long flowers; figured in Wight's Icones Plantarum Indice Orientalis.

LILIUM NEILGHERRENSE TUBIFLORUM LUTEUM—a very handsome yellow-flowered variety of tubiflorum. And some

Splendid flowering Bulbs of other choice LILIES, including BLOOMERIANUM OCELLATUM, PURPUREUM, HUMBOLDTII, GIGANTEUM, PARDALINUM, PARVUM, CALIFORNICUM, and WALLICHIANUM; also a quantity of choice Bulbs and Tubers from California, including CALOCHORTUS, CYCLOBOTHRA, BRODIAEA, ARITHELEIAS, CALLIPORAS, ERYTHRONIUM, BLOOMERIAS, &c.; and some fine blooming Bulbs of the handsome CRINUM BRACHYNEMA, C. AUSTRALE, C. PRATENSE CANALICULATUM, tuberous-rooted BEGONIAS, PANCRATIUM, AMARYLLIS, North American CYPRIPEDIUM, with a variety of other Bulbs and Tubers.

On view the morning of Sale, and Catalogues had.

AUCTION ROOMS AND OFFICES, 38, KING STREET, COVENT GARDEN, LONDON, W.C.

SPLENDID NEW MELON, 1877.

CHARLES LEE & SON

(Successors to Messrs. J. & C. LEE)

Have the pleasure to announce that they have purchased the entire Stock of

MANN'S HYBRID GREEN-FLESH MELON,

Which they now offer for the first time.

It has already earned a high reputation in London and the provinces for its many excellent qualities, among which may be mentioned a remarkably high and exquisite flavour at all seasons of the year—perfection of shape and size for dessert—a thin rind and melting flesh, with an overflow of perfumed juice. It is also a heavy cropper, and forces well.

Dr. HOGG has spoken of this excellent Melon in the highest terms, and after tasting it pronounced it a fruit of the highest merit.

Mr. CULVERWELL, of Thorpe Perrow, feld judge with Mr. FOWLER, of Harewood House, at the Leeds Horticultural Show, where they awarded a First-class Certificate to "Mann's Hybrid Green-flesh Melon," speaks of it as "an exceedingly fine Melon, especially at that early season—the early part of June."

Mr. INGRAM, of Belvoir Castle, writes, in the third week of October, "that in spite of the disadvantage of a long term of gloomy weather, at that season of the year, 'Mann's Hybrid Green-flesh Melon' was sweet, tender in flesh, very juicy, and distinct in character."

Messrs. Charles Lee & Son are now prepared to offer this very useful and delicious new Melon

In Sealed Packets, at 3s. 6d. per Packet.

CHARLES LEE AND SON, HAMMERSMITH, W.

LARGE ESPALIER APPLES.—Very fine French Trees, full of fruit-buds, measuring 6 to 10 feet and a 6 to 6 feet high. Names and price on application to FREDERICK PERKINS, Nurseryman, Regent Street, Southampton.

BOULTON & PAUL,

HORTICULTURAL BUILDERS AND HOT-WATER APPARATUS MAKERS,
ROSE LANE WORKS, NORWICH.

Having rebuilt our Works, that were destroyed by the Fire on the 11th of August, 1876, we are now prepared, with the aid of new and commodious workshops, and the most complete plant of wood-working machinery and tools for working in Iron in the trade, together with an efficient staff of designers and workmen, to undertake any kind of Horticultural Buildings and Hot-water Work. The floor space in our workshops now covers upwards of $2\frac{1}{2}$ acres. Our present timber stock, of first quality, dry and seasoned wood, amounts to upwards of 36,000 cubic feet—this being stored at our wharf was not injured by the fire. We are, therefore, with these facilities, in a position to execute all orders with dispatch, and at the lowest cost for the best work and materials.

Surveys made in any part of the Kingdom. Ladies and Gentlemen waited upon at the shortest notice.

The Ninth Edition of our CATALOGUE, illustrated with upwards of eighty designs, may be had, post-free, for twenty-four penny stamps.

The following Price Lists sent Post-free on application, viz. :—

- LIST OF PATENT GREENHOUSES—TENANT'S FIXTURES.

SATURDAY, FEBRUARY 3, 1877.

WALKING-STICKS.

(Continued from p. 105.)

IT will readily be conjectured that a large stock of these roughly cut sticks, both of British and foreign produce, would appear when stacked together like so much firewood, and this is the impression one has on passing through the several floors of the store-house for raw material belonging to Mr. Henry Howell, of 150, Old Street, City Road, London, the largest manufacturer of naturally grown walking and umbrella sticks in England. This building, which is nearly 100 feet long and about 60 feet high, has four separate floors, in which are classified the various English and foreign sticks; and although each one of the hundreds of thousands of sticks thus stored has been carefully selected for the purposes of the trade, to the uninitiated they all appear like so many stacks of faggots; but if we pass on to the factory (an immense building of several storeys, which, together with the warehouse, covers a space of some thousands of square feet), we shall see the various processes through which each stick passes till it is finally ready for the retail market.

In a great many sticks, whether of British or foreign growth, much labour and discrimination are needed to reduce and form them to the necessary shape. In the Ash or Holly, for example, the naturally grown branches are mostly too thick to allow of them to be simply straightened, polished, and sent into the market; they have, therefore, to be reduced by a process of planing and rasping, by which the required taper is given and the knob or hook formed, after which it is smoothed and polished, or perhaps before polishing it is artificially coloured in imitation of other sticks, or carved and figured according to the fancy of the manipulator or the demands of fashion. The young saplings of the Ash, however, prepared with their bark on, require but little treatment at the hands of the workmen besides forming the heads, cleaning and polishing, and when finished they make excellent sticks. Very few, indeed, of British-grown sticks are in their natural condition sufficiently straight for use as walking-sticks, and indeed some of the foreign produce are even more crooked; for instance, the Carob (*Ceratonia siliqua*), quantities of which are imported from Algeria—these have all to be straightened by mechanical means. They are buried in hot sand over a stove till they become quite pliable. In front of the heap of sand is a stout board, 5 or 6 feet long, fixed at an angle inclined from the workman; in the edge of this board are square notches. When the stick has become sufficiently pliable by being buried in the hot sand, the workman places it in one of the notches, and strains and bends it till he has succeeded in producing a perfectly straight stick. In this way the most crooked, and, to all appearance, worthless sticks, are made so straight that the result appears almost impossible, more especially when it is borne in mind that the workman has no other guide but his well-trained eye to help him. When straightened to his satisfaction the sticks are placed on one side, and as they cool they become perfectly rigid.

Efficiency in this branch of walking-stick making is only attained after many years of training and practical experience on the part of

the workman, and this can be easily imagined when we remember the different effects produced by heat on the various kinds of wood—the degree of heat necessary to straighten one kind of stick being often sufficient, if applied to one of a different kind, to completely spoil it. The application of heat in various forms, as will readily be supposed from the above illustration, is an important element in the operations of the stick-maker. The same power which makes a crooked stick straight can be applied to make a straight one crooked, and so we find that the hard and brittle stems of the Bamboo, the partridge and the Rajah canes, as well as the various kinds of English sticks where Nature has not provided any kind of knob or crook, are by the application of heat curled into the necessary shape to form a handle. Most of our readers will, however, be aware that the naturally-formed knob or hook is more highly valued by connoisseurs of walking-sticks.

Of the final processes of cleaning, polishing, and ornamenting we need say nothing, it will suffice to show the enormous extent of the trade when we say that in the establishment above referred to nearly 200 skilled workmen are constantly employed in the preparation of naturally grown walking-sticks and umbrella-handles.

This trade is essentially a British industry, but large quantities of sticks are also made in France and other parts of the Continent. Though we import so many in their rough state from all parts of the world, the imports of manufactured sticks are comparatively few. From France we get some tastefully mounted canes, and from Hamburg we import the cheaper kinds of painted canes; but for substantial and well-got-up sticks, more especially for natural sticks, the British manufacture is noted, not only at home, but in the foreign markets, large quantities being exported to North and South America, as well as to other parts of the world.

I am indebted to Mr. Howell for many of the particulars contained in this article, as well as for the following list of sticks known in commerce, the botanical origin of many of which is quite unknown. Perhaps some of the readers of the *Gardeners' Chronicle* may be able to throw light upon those to which the scientific names are not attached.

Sticks from Algeria.

Olive— <i>Olea europæa</i>	Chestnut— <i>Castanea vulgaris</i>
Myrtle— <i>Myrica communis</i> ?	Cork— <i>Quercus suber</i>
Pomegranate— <i>Punica granatum</i>	Bastard
Carrot— <i>Cerastium cilicium</i>	Bay-tree
Orange and Lemon— <i>Citrus sp.</i>	Dwarf fig—petioles— <i>Phoenix</i>
Eucalyptus— <i>E. globulus</i>	Dactylifera
	Wild Bamboo

West Indies.

Pimento— <i>Pimenta vulgaris</i>	Supple Jack— <i>Foullonia sp.</i>
Coffee— <i>Coffea arabica</i>	Orange and Lemon— <i>Citrus sp.</i>
Flowered Ebony— <i>Erya Ebecum</i>	Myrtle
Souppwood— <i>Spandium saponaria</i>	Black Torch
Birao— <i>Xanthoxylon Clava</i>	Grass— <i>Acrosmia sclerostachya</i>
Herculia	Wild Bamboo

English.

Blackthorn	Ground Ash
Osier	Holly
Crab	Rowan
Warded Crab	Birch
Whitehorn	Mountain Ash
Hazel	Cherry
Maple	Dogwood
Furze	Chubbe (Jersey)

Bamboo, chiefly from China.

Ordinary yellow-rood Bam-	Doghead Cane
boo and black do.	Beeble Cane
Mountain Reed	Whangce— <i>Phyllanthus?</i>
Carolina Reed	Whangoo Bamboo

Australian.

Milken (perhaps a species of <i>Drosera</i>)	Loya
Cardwell	Bramble

Other Varieties from the East.

Partridge cane (a Palm)	China
Pennang Lawyer (Licuala)	Borneo
Calamus (Calamus stipitatus)	Penang
Rajah	Java
Red Rutan (Calamus)	Singapore
Black (a Palm)	Java
Jungle (a Palm)	Java
Zeppoy	East Indies
Chi-Chi	Java
Tea tree (not Thee)	China

Miscellaneous.

Assyrian Thistle	Smyrna
Marcor	France
Black Jacks	South Carolina

—and a fine knotted stick recently imported in considerable quantities under the name of Ceylon Vine, the native country, however, of which is doubtful, and it may prove to belong to the order Sapindaceæ. *John R. Jackson, Museum, Kew.*

PLANT PORTRAITS.

ARIES FIELDINGI, Orchidaceæ (*Belgique Horticole*, 1876, t. 18, 19).—The well-known Fox-brush *Aries*, referred as a variety to *A. multiflorum*, Roxb. With this plant is given a list of the cultivated species, with comments thereon.

BILBERGIA HORRIDA, Regel, Bromeliaceæ (*Belgique Horticole*, 1876, t. 22).—A species with strongly toothed, white-handled leaves, and erect racemes of white flowers, the tips of whose petals are tipped with blue. It is a native of Brazil.

BILBERGIA SPECIOSA, Bromeliaceæ (*Revue Horticole*, 1877, p. 10).—A Brazilian species, supposed to be a variety of *B. Crociana*. The leaves are tufted, strap-shaped, obtuse, serrated, highly covered with bran-like scales. The flowers crowded in spikes or racemes, with numerous rosy red bracts; the calyx of carmine-red, the petals violet, shaded with red. The plant is of vigorous habit, and flowers several times in a year.

BILBERGIA VIRIDIFLORA, H. Wendland, Bromeliaceæ (*Belgique Horticole*, 1876, t. 20 and 21).—A species with long loose panicles of greenish flowers. It is supposed to have been procured from Brazil.

COLOMBIER PEACHI, *Revue Horticole*, 1876, p. 30.—Of this a coloured figure is given. It is said to be of merit *tout à fait hors ligne*, and was raised by M. Leprieux, jun., of Montreuil. The glands of the leaves are globular, the flowers of medium size. The fruit is a freestone of medium size, perfectly spherical, downy, richly coloured, and finely speckled on the sunny side. The flesh is melting, of exquisite flavour. The kernel oval, deeply furrowed. The fruit ripens in the first fortnight of September. M. Carrière, a good judge, speaks of it in the highest terms. It is in the hands of M. Jamin, of Bouris-la-Reine, and M. Colomlier, of Vitry-sur-Seine.

DENDROBIUM GIBERTI, *Illustration Horticole*, t. 258.—A species with a dense panicle of pale yellow flowers, the lip being of a darker orange colour. It is nearly allied to *D. densiflorum*.

DIMORPHIS KIRKII, *Potanical Magazine*, t. 6276.—A pretty bulbous plant, with spotted leaves, like those of a *Lachenalia*, and a spike of small white bell-shaped flowers. The figure was taken from a plant which flowered at Kew in July, 1873. The plant is a native of Zanzibar.

LIVISTONIA AUSTRALIS, *Potanical Magazine*, t. 6274.—A noble Australian Fan Palm, for many years one of the choicest ornaments of the Palm-house at Kew, where it flowered every year, but at last lost owing to its accommodation. The figure gives but a poor notion of the beauty of this fine species.

MADREVALLIA ATTENUATA, *Potanical Magazine*, t. 6273.—One of the more inconspicuous white-flowered species, with long-spreading tails to the flowers. It was described in our columns by Professor Reichenbach in 1871, p. 834, and was introduced into commerce by Messrs. Veitch. It flowers at Kew in December.

× **NEGELIA**, *HYACINTHINA* *Revue Horticole*, woodcut, p. 29.—A dwarf-growing hybrid *Negelia*, producing a profusion of pale blue-coloured pendulous flowers in a dense spike. It appears to be a desirable variety, and is to be sent out by M. Jules Vallrand, of Bois de Colombe, France.

NEPENTHES VERTICILLATA, *Illustration Horticole*, t. 261.—A Bornean species, known in gardens as *N. lanata*, or *N. villosa*. See Dr. Moore in *Gardeners' Chronicle*, 1873, p. 542.

PHILODENDRON GLORIOSUM, *Illustration Horticole*, t. 262.—Described as a truly glorious plant. According to the figure it is a scandent plant, with large bold cordate ovate-acute leaves of a deep rich green colour, the midrib and secondary nerves being of a snow-white colour, and the margins of the leaves bordered with a thin edging of a pink colour. M. André met with it in a virgin forest on the borders of the River Gustavina, in Colombia, and was, as he says, struck with admiration at its beauty. It has been successfully introduced into the establishment of M. Linden, of Ghent.

SONERILA MADAME VICTOR ALESCHI, *Illustration Horticole*, t. 259.—A hybrid raised by M. Linden,

with leaves of a bronzy green, marked and spotted with white, and resembling those of *Tydea anabilis*.

TELEPACHIA OCCIDENTALIS, *Potanical Magazine*, t. 6272.—A *Cacumbia*, of singular and striking appearance, of climbing habit, pedate 5-foliolate leaves, tendrils and white bell-shaped flowers $\frac{1}{2}$ inch to 2 inches in diameter, with a purple centre, and five deeply fringed segments. The Gourd is 2 feet long, ovoid-oblong, with ten prominent winged ribs, and the cells filled with golden-yellow pulp. The seeds are numerous. The plant is a native of West Tropical Africa, where the seeds are eaten by the natives, and used for extracting oil. It flowered at Kew in September, 1876.

TILLANDSIA FRUINOSA, Swartz, Bromeliaceæ (*Belgique Horticole*, 1876, t. 16 and 17).—A rootless plant, with a thick, rather elongated, bulbous stock, from which proceed numerous long, linear, ciliated leaves with sheathing bases. From the centre of these rises the inflorescence, consisting of a spike of rose-coloured bracts enclosing purplish flowers. The plant may be grown suspended from the rafters of a greenhouse. It is a native of the West Indies.

TYDEA CECILIE, *Illustration Horticole*, t. 260.—One of M. André's discoveries in the mountains of New Grenada, between 2000 and 3000 feet above the sea, in a temperature of +30° C. at noon. The plant was growing amid the fissures of the rocks. The leaves are a velvety violet colour, with white markings. The flowers are pink, with the limb spotted with darker spots of the same colour.

XANTHISMA TEXANUM, *Potanical Magazine*, t. 6275.—A hardy annual Composite, with sessile, linear, dentate leaves, and heads of yellow flowers like a *Crocopsis*. The plant, which is a native of Texas, flowered at Kew in November last.

ASPECTS FOR PLANT HOUSES.

It is so universally recommended for span-roofed plant-houses to be built with the ends facing north and south, so that the sides face east and west, that it will doubtless be considered an act of temerity to dispute the soundness of the advice, yet I do dispute it, at least so far as to say it is not the best position—that an aspect for the sides south and north, with ends east and west, is quite as good, and I think a great deal better.

The greatest drawbacks to the perfection of the first position, viz., ends north and south, are, first, that during the winter when the sun has but little power except when within a few degrees on either side of the south the bars and framework of the house, be they ever so slight, cast a shade over its interior which is of great disadvantage to the plants, and on a frosty morning in midwinter the ice on the glass will remain unmelted a good hour longer than upon a house facing south.

In the second place, when the sun rises early in summer the east face of the house receives the full glare immediately it is above the horizon, which endangers tender foliage. Houses in this position are often hotter at 5 o'clock on a summer's morning than they are at 10 o'clock, owing to the interposition of the bars and rafters as the sun works round.

And in the third place, in the fall the afternoon of a summer's day, pouring as it is, its full force direct upon the west face, renders it almost impossible to close the house till late in the day unless a heavy shading is left on after closing; and unless your house is a stove for foliage plants only, this is a great drawback.

Now the position I advocate—viz., ends east and west, with broadside north and south—has none of these disadvantages, for in the first place it receives the full force of the little sun we have in winter, which shines right through the house, reaching the back stage as well as the front most cheerfully.

In the second place, the hot summer sun rises upon the face of the house gradually, giving time for the drying up of condensed moisture, and the danger of scorching is less than where the glare is sudden.

And in the third place, as the sun approaches the west in the early summer, the house may be closed, the blinds raised, the plants well syringed, and the atmosphere and temperature of the tropics maintained for hours in broad daylight without danger of scorching, giving the foliage of your flowering plants time to dry before night comes on, the advantage of which will be appreciated by all cultivators.

All the great plant-growers with whom I am or have been acquainted have had greater difficulties to contend with in the structures they have had at command than are here enumerated, yet, as far as my experience goes, building houses facing east and west, where the ground allows of the north and south aspects being used, is a great mistake. *John Bester.*

FERTILISATION OF PLANTS.*

(Continued from p. 48.)

The first series of experiments was made on the so-called *Convolvulus major* (*Ipomoea purpurea*), which, having conspicuous corollas, is greatly interested by humble-bees, but is also highly self-fertile, so that the number of seeds produced by intercrossing and self-fertilisation differed very slightly. Mr. Darwin experimented on this plant for ten years, planting seedlings of exactly the same growth on opposite sides of pots, and the general results were that the excess in height per cent. of the former over the latter varied from 14 to 46; or, taking the intercrossed plants as 100, the mean height of the self-fertilised was 77. The intercrossed plants showed greater vigour and weight. A chief difference was in the number of capsules produced, although the seeds per capsule differed but slightly, so that the actual fertility of the intercrossed as compared with that of the self-fertilised was as (from 100) 35 to 100 : 64.

Mr. Darwin next fertilised flowers of the ninth intercrossed generation with pollen from a new stock, while other flowers were again intercrossed. The results were greatly in favour of the new cross in height, as 100 : 78, *i.e.*, almost the same ratio as that of the mean of the intercrossed for ten years to the self-fertilised, or as 100 : 77. In weight the ratio was 100 : 51. An exceptional plant appeared in the sixth generation, which Mr. Darwin called Hero, as being remarkable for its strong self-fertilising powers, and for showing no benefit when its children and grandchildren were not merely intercrossed, but crossed even by a new stock.

Mimulus luteus afforded quite analogous results. For three years the intercrossed exceeded the self-fertilised in height as 100 : 65. In the fourth generation a new variety appeared, which grew taller, had whiter and larger flowers, and transmitted these characters with great fidelity, so that all the plants in the later self-fertilised generations belonged to it. These frequently exceeded the intercrossed in height, even in the ratio of 137 : 100, and in fertility as 147 : 100. As with Hero so with this pale variety of *Mimulus*, intercrossing did no good. But it differed from Hero when crossed by a new stock, for the heights of the eighth self-fertilised generation thus crossed were to that of the ninth self-fertilised generation as 100 : 52, and in fertility as 100 : 3.

"Better evidence," says Mr. Darwin, "could hardly be desired of the potent influence of a cross with a fresh stock on plants which had been self-fertilised for eight generations, and had been cultivated all the time under nearly uniform conditions."

Here, then, is a most important fact for horticulturists, and it is associated with another of equal value, that greater variety of colours are produced in proportion to the crossing; while on the other hand perpetual self-fertilisation seems invariably to reduce them to a uniform tint. Mr. Darwin first noticed this in the seventh generation of *Ipomoea*, of which all the flowers were of a uniform remarkably rich dark purple tint, which remained constant up to the tenth and last generation raised. Likewise had he repeatedly intercrossed flowers a much more uniform colour than those originally raised from purchased seed. Similarly with *Mimulus*, the original plants varied greatly in the colour of their flowers, so that hardly two individuals were quite alike, the corolla being of all shades of yellow, with the most diversified blotches of purple, crimson, orange and coppery brown, probably the result of much intercrossing. On the other hand, the form which appeared having great self-fertility was not only tall, but its flowers were large, nearly white, and blotched with crimson, and retained a surprising uniformity throughout later generations.

Brassica alpestris.—This, like other cruciferous plants, is adapted for crossing with its two shorter stamens, and self-fertilisation by its four longer ones ;

and, if varieties are grown together, it is consequently very difficult, as Mr. Darwin proved, to raise pure kinds. Height in this case proved quite fallacious, but weight showed the vast superiority of intercrossing by the ratio 100 : 37, while the fertility was as 20 : 25. Finally, crossing with a new stock increased the weight of the cross to the ratio of 100 : 22. Mr. Darwin tested the statement that a cat-leaved curled and variegated white-green Cabbage would not cross with a similar crimson-green Cabbage. This was an error, but the former was partially sterile, which may possibly account for the statement. The latter crossed by the former afforded curious results. A few reverted to a pure green, and became very vigorous, but many more of the self-fertilised seedlings of crimson-green thus reverted, and grew taller by 2.5 inches than the crossed plants. Hence reversion to a more natural condition acted more powerfully on their growth than the influence of crossing with a semisterile variety.

It would have been interesting for gardeners had Mr. Darwin experimented on the effects of crossing upon "root" plants. He only remarks that the effects of Kohl Rabi were particularly plain in the enlarged stems of the mongrel seedlings of varieties of Cabbages grown together.

Pisum sativum is fully self-fertile in England, and is rarely intercrossed, as no British insects are usually strong enough to effect it. Hero varieties grown under the same main plan, Knight's, produced by artificial crossing, lasted over sixty years, and were always self-fertilised. Owing to the varieties being self-fertilised for many years, a cross brought no benefit at all, or rather had a deteriorating effect; for the heights were as 100 : 115; but Mr. Knight proved that a short variety crossed by a tall one gave rise to offspring twice its height. Mr. Laxton also proved that crossed varieties gave rise to prolific offspring. From this species we learn that when a plant has after many generations become, as it were, habituated to self-fertilisation, then intercrossing does no good.

This we have seen is paralleled by Hero in *Ipomoea*, and probably by *Lathyrus odoratus*, though Mr. Darwin did not test this species; though he crossed different varieties varying in colour, and obtained a new sub-variety, and in the next generation the offspring varied still more—proving the good effect of crossing varieties if colour-variations are required. On the other hand a spontaneous variety may appear, and then this may prove true to its kind.

Phaseolus multiflorus, or Scarlet Runner, is very sterile in the absence of fertilising insects, but self-fertile if the petals be only mechanically moved. The cause of the great variability in the colouring of the seed-skins is disputed, but seems most likely to be due to intercrossing. The crossed and self-fertilised plants differed but little, if anything, in height and fertility. *P. vulgaris*, though closely allied to the preceding, differs from it in being highly self-fertile, yet varieties cross freely if planted together.

Plataginum zonale.—This genus is strongly proterandrous and almost self-sterile, but in pale-coloured varieties the pistil matures early and the plants then become "great seeders." The physiological importance of this fact will be alluded to hereafter. In Mr. Darwin's first experiments he crossed plants raised by having for the same stock, and no benefit accrued—a result similar to one obtained by crossing plants of *Origanum* propagated by stolons. A cross with the pollen from a different plant gave offspring, compared in height with one from a flower fertilised by pollen from another flower on the same plant, in proportion of 100 : 74. It possessed also greater vigour. It would have been a desideratum to know what, if any, effect was produced by crossing on the "zones." For Mr. Grieve found the pollen of *Zonal Plataginum* to affect *Geranium pratense*, both in the colour of the flowers as well as in the variegation of the leaves. *Chromola*, July 8, 1876, but nothing is said about it.

Dianthus Caryophyllus.—This plant is also strongly proterandrous, and great care must be taken to prevent varieties crossing if pure strains are required. The number of seeds from crossed and self-fertilised parent plants (as was not unfrequently the case at first) differed but little, the ratio being as 100 : 92. That of the heights of the second generation were about as 100 : 86 when both were grown in the open ground, but when crowded in pots, the result of struggling for existence, which self-fertilised plants usually manifest, was very apparent, the relative heights being as 100 : 58. In the third generation,

however, the heights, though grown in pots, were as 100 : 99. They were, however, "drawn," being "light and weak," but, as ascertained by weight the latter showed the ratio of 100 : 49—a fact which well illustrated the danger of estimating solely by heights. Another curious fact happened in the third generation. The self-fertilised became much more fertile than the intercrossed, the number of seeds being as 125 : 100. This was probably due to the sexual organs maturing more nearly together, and so being less dichogamous. This is similar to *Pelargonium* and *Primula*, which may also become self-fertilising from a like cause. A fresh cross from a new stock was now introduced. The first effect appeared to indicate a decrease of fertility, but the offspring, compared with the self-fertilised, were in weight as 100 : 33, and their relative heights as 100 : 81. Lastly, the pale pink or rose colour of the fourth self-fertilised generation were "as uniform in tint as those of a wild species." The flowers of the fourth intercrossed generation were likewise nearly uniform; but the newly-crossed plants varied extremely in colour. *George Henslow.*

(To be continued.)

New Garden Plants.

DENDROBIUM (PELIDIONUM) MOHLIANUM, Rehb. f.*

When the late Dr. B. Seemann came home from the Fiji Islands he spoke in rather high praise of a *Dendrobium* he had found on Buku Leva and Voma peaks, at an altitude of 4000 feet. It is a *Pelidionum*, somewhat comparable to *Dendrobium thyrsoides* from the Fiji Islands, as it was in weight as 100 : 33, and their relative heights as 100 : 81. It has, however, a quite new and most striking character. The lip is inflexed at its end into a shoe, in the way of that of a *Cypripedium*, and it was these nice cilia which were later observed in *D. trichostema* of New Guinea. *Rehb. f., Bot. Bez. 1847, tab. 47, not Bl.* It has, however, a quite new and most striking character. The lip is inflexed at its end into a shoe, in the way of that of a *Cypripedium*, and it was these nice cilia which were later observed in *D. trichostema* of New Guinea. *Rehb. f., Bot. Bez. 1847, tab. 47, not Bl.* It has, however

Anthurium Patini I received through the kindness of Dr. Maxwell Masters, and I can decidedly affirm that the plant is allied to the genus *Spathiphyllum*. It agrees with *Spathiphyllum* in the trinervous flowers (petals 6, stamens 6, 3 locular ovarium), but differs in the ovarium having uniovulate cells. *Anthurium floribundum*, Linden et André (*Ill. Hort.* 1877, p. 22, t. 159), the flowers of which I received by the kindness of Mr. Veitch, belongs also to the genus *Amomophyllum*; but the cells of the ovary are very often 2-ovulate, therefore this species, *Amomophyllum floribundum* (Linden et André), Engler, resembles the genus *Spathiphyllum* in the structure of ovary, in which the cells of the ovary are 8-2-ovulate, but the form of the ovary is quite different. Possibly species will hereafter be found with characters forming a transition between *Spathiphyllum* and *Amomophyllum*. A. Engler, *Botanic Garden, Munich*.

STAPELIA PAENTISTROIS, N. E. Br. (Fig. 21.)

Stems erect, branching at base, 3-5 inches high, $\frac{3}{4}$ inch thick, puberulous, four-angled, sides very concave, angles obtuse, toothed, teeth erect. Flowers 1-3, erect from the base of the young stems, not very forked. Pedicels $1\frac{1}{2}$ inch long, puberulous. Calyx lobes narrow linear-lanceolate acute, 5 lines long, 1 line broad, puberulous. Corolla 2-3 inches in diameter, the back minutely puberulous, pale green tinged with reddish brown towards the tips, the face rugose, the centre densely villose, with long, soft, rich purple-red hairs, which extend a short way up the base of the lobes; the latter are 1-1 $\frac{1}{2}$ inch long, 7-8 lines broad, lanceolate-acuminate, spreading or reflexed, glabrous except just at the base, and fringed with long, simple, purplish hairs, dark red or purple-brown, the basal part marked with numerous slender, transverse, undulated yellow lines; ligulae erectly spreading, linear, concave, apex recurved, truncate, with a central projecting tooth, or truncate-emarginate with the tooth from the base of the notch, or very rarely entire and acute (as in the figure), the base and the margins of the apex dull greenish; rostra very suddenly recurved at the base, and horizontally spreading almost to the sinuses of the corolla, subulate-triquetrous, blackish purple; also the flat, wing-like dorsal appendages of the rostra free to the base, horizontally spreading, shorter than the rostra, straight or curved, linear, obtuse, entire, blackish purple.

This very pretty species may at once be distinguished from all yet described by the horizontally spreading processes of the inner corona. The above description and figure was made from the same plant that was figured in the *Botanical Magazine*, t. 5963, as *S. sororia* of Masson, from which species it differs in its much more slender stems, (only half as thick), smaller flowers, and different corona; it is also alluded under the name of *S. Conreilli*. The ligulae are usually truncate-emarginate with a projecting middle tooth, the side lobes being very short and rounded, as figured in the *Botanical Magazine*, but in one flower examined by me some of them were quite entire and simply acute, as here represented. N. E. Brown, *Aca.*

BOTTOM-HEAT WITHOUT COST.

On reading the above heading in the *Gardeners' Chronicle*, p. 107, many gardeners must have been on the tenterhooks of expectation that some great discovery in bottom-heating was about to be divulged. Mr. Fish is, however, such a master in surprises in horticultural matters that we must rather regret that this, his last essay on heating, has nothing sensational about it. There cannot be the least doubt but that placing the roots of all plants in the same temperature as their tops are grown in is the natural way to success in their cultivation, especially in the winter months. In growing early Grapes—that is, where they are expected to ripen from April till June—if the roots of the Vines are all confined inside the house the gardener can then attend to their wants in every detail of cultivation, and, therefore, no one can gainsay but that the system is sound in practice. I have, however, grown good crops of early Grapes in vineries where the Vines were planted inside and the roots could get to the outside borders, which were protected by Oak leaves mixed with litter, and the surface covered with wooden shutters. The varieties of Vines grown were principally of the Frontignan section, which are well known to delight in heat, and they produced more vigorous wood and bunches than those in the vineries where the roots of the Vines were confined inside. Where, however, labour and materials are scarce, and readiness is desirable on the outside borders, I am of Mr. Fish's opinion that the growing of very early Grapes in structures where the borders are inside is the safest and best system.

In growing the main crops of summer, autumn,

and late-keeping Grapes, I have found, after a long experience, that the best results have been from vineries where the Vines were planted inside but the roots were left to ramble in properly prepared outside borders at their "own sweet will." There is something more in solar attraction, and its atmospheric effects in making Vine roots always try to reach the outside border when they can, than Mr. Fish gives credit for. The late Mr. John Wilson, when gardener at Worktop Manor, once told me that the original Black Danascus Vine planted there, and which grew in the corner of a vinery where its roots were confined inside, had managed to get through the rotten brick-work into an ashheap and luxuriated there. On making some alterations here this year near the outside borders in the main range of vineries, the Vine roots were found running into the burnt clay that had been filled into a drain, and this was 4 or 5 feet from the made borders. I believe, therefore, that for Vines, where they are expected to grow to a good old age and permanently

warm, dry summers. This vinery has now been planted fourteen years, and never misses bearing good crops of Grapes, with bunches and berries of good size, and their colour that of rich golden hue which the Muscat shows when in perfection. There is no extra expense in heating the air-drains in this house, for the same boilers heating the atmosphere of it heats the piping in the outside where the drains are placed.

I have now given as above my experience in Grape growing, but with fear and trembling, for hath not Mr. Fish recorded his "anathemas"—that if no one can convince him that outside borders are better than inside ones then they are for ever after "to hold their peace"? I hope, therefore, that other extensive Grape growers will support me, and advance the cause of practical horticulture by giving their opinions on the subject, so that it may be impartially ventilated in the columns of the *Gardeners' Chronicle*, William Tillery.

to bear good crops, that the system of planting them inside the house, allowing the roots to get to the outside border, is better than wholly confining the roots inside, unless it is in the case of very early Grapes.

As to the artificial heating of Vine borders, if Mr. Fish saw how the system is pursued here I am sure he would be quite delighted with it, and praise it above limekiln heating. A large vinery, 106 feet in length and 18 feet in breadth, is planted principally with Muscats, and its borders inside and outside have heated air drains every 4 feet. This is effected by having two rows of 4-inch piping placed at the level of the drains, and the heated air in the drains communicates with the large channel inside the house where the flow and return pipes are placed. The cutting where the two rows of piping is placed on the outside of the border is flagged over the brickwork, with ventilators on the top to regulate the supply of air from the outside to the drains. Plenty of drainage is laid on the surface of the drains, and the roots of the Vines are quite safe from any undue heat or too much drying if plenty of water is given to the borders in

SCHLIMIA TRIFIDA.

This interesting plant, described by Professor Reichenbach at p. 708 of our last volume, was exhibited at the meeting of the Royal Horticultural Society on January 17, by Sir Trevor Lawrence, Bart., and attracted a good deal of notice from the visitors on account of its remarkable appearance, so unusual in texture as to have been apparently modelled out of thick wax, and so peculiar in form that the individual blossoms were compared to ancient Grecian helmets. To this remarkable appearance of the flowers, so unlike any other familiar flower, is to be added the fragrance which it would seem is characteristic of the genus, inasmuch as the original species is called *jasminodora*, and the fragrance of the present is described by Sir Trevor Lawrence as being between that of *Jasmine* and bergamot.

The general aspect of the plant is very much that of a small *Stanhopea*, the foliage and pseudobulbs being very similar in character. The drooping racemes are one-sided and few-flowered, the blunt sac of the two connate sepals (not cuneate as planted by

oversight (at p. 708) giving the individual blossoms when reversed the helmet-shaped figure above referred to, while the third sepal is ligulate and projected forward. The general colour of the flower is a waxy white.

The plant is, it appears, New Grenadan, and was sold as *S. jasminodora* at one of Stevens' sales in May, 1874. The Floral Committee gave it a Botanical Certificate.

area in 1876 was 47,393,000 acres, exclusive of heath and mountain pasture land and of woods and plantations. This total exceeds that of 1875 by 80,000 acres, and between the years 1869 and 1876, 1,293,000 additional acres were returned as under cultivation in the United Kingdom. This increase is mainly in Great Britain, and the respective proportions in each division are 824,000 acres for England, 181,000 for Wales, and 200,000 for Scotland.

of 1875, but Oats were grown in Great Britain on 125,000 acres more than in the previous year, a larger acreage than in any year since the agricultural returns were collected. This may be accounted for by the relatively high price of Oats during the past year, and also by their being sown on a large area of land intended for Wheat for which the seed time was unfavourable.

The fifth table gives the acreage under orchards, market gardens, nursery grounds, and woods, in each county in England, Wales, and Scotland, from which we extract the following:—

FIG. 22.—SCHLIIMIA TRIFIDA (FLOWERS WHITE, FRAGRANT).

AGRICULTURAL STATISTICS.

We quote the following from the Agricultural Returns for Great Britain just issued by the Statistical and Commercial Department of the Board of Trade:—

The total quantity of land returned in 1876 as under all kinds of crops, bare fallow, and grass, amounted for Great Britain to 31,544,000 acres. For Ireland the returns obtained by the Registrar-General show a total of 15,725,000 acres, and for the Isle of Man and Channel Islands the totals are respectively 93,000 acres and 31,000 acres. Thus for the whole of the United Kingdom the cultivated

area under Wheat in the United Kingdom in 1876 was 3,124,000, being 11 per cent. less than in 1875, and 22 per cent. less than in 1869, when the area under that crop was greater than in any other year from 1868 to 1876. In Great Britain alone the decrease from 1875 was 10 per cent., and from 1869 19 per cent. An unfavourable seed time is stated to be the principal reason for so large a falling off this year, but the cause alluded to as accounting for decreased arable land may be held to apply more particularly to Wheat.

The acreage under Barley in 1876 both in Great Britain and Ireland corresponds pretty closely to that

Note.—The greater part of the acreage of orchards and some part of the acreage of market gardens are included in the general returns under separate crops of grass.

The decrease under green crops, as compared with 1875, is considerable in Great Britain, amounting to 90,000 acres, or 2½ per cent., while in Ireland there is little change, the larger extent of Turnips and Mangel almost making up for the diminished acreage of Potatoes. It is noticeable that the acreage under the latter crop in the United Kingdom is now considerably less than at any time in the past decade. The fear of disease is alleged by some of the collectors as a reason for so steady a falling off. Of the other green crops in Great Britain, Turnips show a small increase, Mangel a decrease of about 4 per cent., Cabbage, &c., about 5 per cent., and Vetches, Lucerne, &c., about 12 per cent.

The land under Flax increased largely in Ireland in the present year, but is still little more than half what it was in 1867, when more than a quarter of a million acres were sown with that crop. In Great Britain its acreage is still insignificant, being confined to only a few counties.

The acreage under Hops shows a further increase in Great Britain, and may now be reckoned at 70,000 acres, being an increase of 4000 acres since 1874.

Bare fallow was much larger in 1876 than in the previous year, much land being left uncropped owing to the wet and unfavourable seed time.

There was an increase of more than 4 per cent. in the acreage under artificial grasses in Great Britain, and the total of 4,540,000 acres is the largest yet recorded.

Permanent grass for hay shows little variation from 1875, but the figures for that year were exceptionally large. In permanent grass, not for hay, there is an addition of 193,000 since the previous year.

The following is a summary of total acreage under each principal crop in Great Britain in 1876:—

Principal Crops.	Acres.
England	9,809,342

Natural History.

THE SPORTS OF WILD BIRDS.—Anything relating to the garden is always acceptable to those who admire the works of Nature, and what subject more innocent and enjoyable than noticing the unaccountable sports of wild birds. A blackbird in a pretty country parterre is now hopping among pigeons, doves, ducks, chickens, dogs, and cats, feeding at stated hours of the day, and answering to the name of Dick. Until a few weeks ago, and all through the last summer, he would come to a cage at sunset, which was placed on a garden-seat for him to roost in, nor was the cage-door fastened after he had settled on his perch; but now, and thus far in winter, he prefers open air, and sleeps on an old tree near. Early in the morning he takes strolls along the paths, and goes regularly at the hour for feeding the poultry, after which he finds his way among the shrubs searching for worms. Occasionally a wild blackbird visits him, until the approach of some one of the family, when the wild bird flies away, leaving Dick to himself.

Sparrows and other small birds are fed daily from the dining-room window, when our tame blackbird, which is sure to be there too, will display his dexterity and authority by driving the smaller birds away, and usurping more than his share of the crimals. His movements altogether are most interesting, especially when titbits are scattered for a scramble.

Many years since a robin became most familiar with the ladies of the same place. Bobby would come at their call all across the garden, hop about them, perch upon the dress of either, sing his plaintive melody upon the finger of one, take a bit from her mouth, displaying signs of joy at seeing his two favourite friends, and, after all, quietly retire, as recorded at the time in your journal; but the sender of this account never before heard of a blackbird becoming so tame as the one now described to be seen at the Laurels, Clever Hill, Windsor.

WASPS.—This is a bad time of year to write upon wasps, when there are none; but seeing how many of your correspondents were tormented with these twohose pests last year, I send my experience of the last two years. I cannot explain the facts; I only state what I saw and afterwards tried. The same remedies may not suit other places, and are probably well known to many.

In 1875 I saw a large house of ripe Grapes in great perfection at Beechwood, in Cheshire, with all its windows open, the fruit fully exposed. I saw four large plants of Tomatoes in pots standing on a border, looking very much out of place amidst such fine Grapes. This made me ask the gardener why he kept them there, when he told me "it was to keep out the wasps." I then observed that not a single wasp was in the house, while at a small vineyard within a quarter of a mile they swarmed. This year I grew a good many Tomatoes in a viney, for the double purpose of use and to keep off wasps from the Grapes, and I never saw one in the house; there were plenty about the garden.

Last year I had a good crop of Peaches, which were sadly tormented by wasps and flies. Seeing Mr. Scott's advertisement, I wrote for a bottle of his wasp destroyer, and, following his directions, put a few drops on branches, which at that time were alive with wasps and flies in the full sunshine. I felt very incredulous as to what Mr. Scott says on the subject, but on going to the trees an hour or two after not one wasp was there, and the fruit was saved from them for some days.

Now Dr. Slade's spiritualistic performances seem nothing to what these few drops per tree effected. I could not see that a wasp touched the poison, nor did I find a dead wasp, but all disappeared. I often seem as if bluebottle flies send scouts to look out for dead and dying, as if you notice in any sick chamber, whether of man or beast, there is always one very knowing-looking bluebottle, who sits quiet taking observations, and as soon as death comes off goes the fly and brings all his relatives. Now whether the wasps keep an ambassador to notify to headquarters how wasp politics go on I know not, but I am certain of the fact I mention, that every wasp departed and I ate my Peaches in peace. As I before stated I only mention facts, and I find Tomatoes and Scott's wasp destroyer both effective.

I may perhaps trouble you with a little more upon the natural history of wasps and hornets, I hope some gardeners will try these two simple remedies next year. *W. D. F.*

THE GOATSUCKER.—I quite agree with your correspondent, Mr. Wilson, that "the hurring" sound proceeds from the bird at rest. In all opportunities I have had of watching them, their flight in hawking after food has been as noiseless as that of the owl, but when resting after a flight they have commenced "hurring" almost immediately.

Barrett White in his *Natural History of Solborne* says: "There is no bird, I believe, whose manners I have studied more than the Caprimulgus (goatsucker) . . . but I have always found that though sometimes it may chatter as it flies, as I know it does, yet in general it utters its jarring note sitting on a bough." Again I agree with Mr. Wilson, the goatsucker is by no means a shy bird; so long as the observer remains stationary they continue their flight after food, frequently passing within a few yards. A relative of mine has in his possession a specimen that was shot in consequence of its persistently settling on the roof of a cottage and "jarring" to the annoyance of the inmates, who regarded it as a bird of ill-omen. With us the favourite resorts of the goatsucker are Fir plantations adjoining heath or open ground. *Fisher, Ainstill, Esfordshire.*

I am glad to see that a correspondent has noticed "R.'s" communication about the nightjar or

Fern owl. "R." was wrong in nearly everything he wrote on the subject, radically so with regard to the "hurring" sound the bird makes, which, so far as my experience goes, is invariably made when it is settled on a bough. Directly it takes wing it ceases the "hurring," although in its owl-like flight it occasionally utters a short cry or screech. I have never seen it, except in woods or plantations, and have certainly thought it was far from a timid bird. *John W. Downing.*

Having been very busy and much away from home, I have been prevented replying to Mr. Wilson's note upon this bird (*vide p. 14*). My short observations were made last season in the North of England; I noticed the birds were more plentiful than I ever remembered, this perhaps caused me to observe them more closely. I have no doubt Mr. Wilson is quite correct, for White seems to be of the same opinion. In this locality they are only to be met with on a wide heath, skirted on one part by a young plantation, where the birds were flitting from the roadway to the branches; they appeared then to produce the hurring sound, as well as when going from branch to branch. Probably Mr. Wilson, from closely watching their habits, has come to a different conclusion. Again, I generally look upon it as a shy, timid bird; but what may arise from the fact that it is hunted by the boys when they have opportunity, as it is to be seen in a park, where it feels safe, and is never allowed to be molested, it may then become trustful; but it should have every protection extended to it, if it is only as a garden or farm friend. Very few of the denizens of our woods and heaths do more good. *R.*

Garden Operations.

PLANT HOUSES.

GREENHOUSE HARD-WOODED PLANTS.—Any one who ever intends to succeed in plant-growing, either large or small specimens, will find it imperative to be continually on the look-out for the insects that wage an unceasing war upon the subjects they cultivate. Hard-wooded greenhouse plants, taking them collectively, are much less liable to the attacks of aphids than softer, more succulent things, the juices of which afford more suitable food for these parasites; yet experience with these plants, on Aphelicia in particular, often happens that a few aphides during the autumn and winter months infest the hard-wooded plants, and go on slowly increasing through the winter on *Pleromas*, *Boronia*s of different species, but more especially *B. pinnata* and *Drummondii*, *Adenandra*s, *Compholobium*s, and *Aphelicia*s. In the case of almost all these plants the insects are so different in appearance, and have such a puny, ill-fated character as to be scarcely recognisable, and in some not very easily seen, and they rarely increase to an extent so as to be readily detected by their numbers, yet they frequently do an immense deal of harm before they are noticed by those who have not had much experience with these plants. On *Aphelicia* in particular they attain such a diminutive size, and are so nearly the colour of the leaves, that it requires a quick eye to detect them; but if the points of the flowering shoots for the season, on which they principally congregate, are closely examined, the excrement will be seen, which is changed by their feeding on *Aphelicia* so as to have the appearance of minute white crystals. Where they exist on these plants, unless speedily destroyed, they will have the effect of killing every flowering shoot, and generally succeed as turning them blind. I have seen many fine specimens so affected, the owners of which have not been able to detect the cause. On *Gompholobium*s the insects find a little more genial feeding-ground, but on them are small, congregating on the underside of the leaves, and if not noticed will be very soon seen on the foliage. On *Boronia*s, the dirty deposit they make soon becomes mouldy, to the destruction of the leaves, which will fall off in quantity with little perceptible cause. Contrary to what might be supposed, having apparently so little vitality when living on these plants, they are immeasurably more difficult to kill than when in the plump, fat condition they are found in on many soft-wooded subjects; so much so, that tobacco-smoke can scarcely be applied strong enough to kill them, for which reason washing with tobacco-water is the best remedy, and it should be used tolerably strong. One or two washings with the syringe, the applications being such as to reach every part of the plants, leaving it to dry on, will generally be found effectual. *Salosonates* at this time of the year are frequently affected in like manner, the insects getting into the points of the shoots, and to be seen need to be looked for; on these plants they do not absolutely destroy the flowers

but they cause all the leaves that surround the heads of bloom to turn quite yellow, which gives the plants when they ought to be at their best a very unsightly appearance. Here again washing with tobacco-water is the best remedy. As the tying is completed, every plant should be washed with a fine spray of glass and kept clear of its neighbours; yet so elevated, especially in good light houses, they will bear being much nearer together than when placed where there is comparatively less light. Such an arrangement is especially desirable for the glass, or flower-beds, that from this time forward will bear a little shade, being stood underneath them; which is not only an advantage in economising space, but gives to the hard-wooded plants an improved appearance, going away with the objectionably flowered look that these structures too often have at this season. Those useful winter forcing plants, *Genistas* and *Acacias Drummondii* and *armata*, especially where brought into flower so early as the commencement of the year, *Taxus* and, after a few seasons, allowed to get into an unsightly straggling condition, by letting them after blooming go on growing without a sufficient use of the knife; they are much the most serviceable when freely cut in the summer after the flowering is over, and to keep them in a close compact form and limited size. After being cut in they should be kept in a genial atmosphere and care taken to see that they are completely free from red-spider, to which the *Genistas* especially are very subject.

SOFT-WOODED GREENHOUSE PLANTS.—In *Floribacous* *Calceolarias*, where required early in flower, should now be kept a little warmer than ordinary plants, and get the plants in the pots, so that they have a light situation, and if possible a little moister atmosphere than most things require. *Fuchsias* struck last summer must have careful attention, to see that they do not want for pot-room, for if they are not got in the pots, they will not grow so freely afterwards. Keep the main shoot trained to a single stick, stopping it and the side branches proportionately with the habit of growth of each individual variety, so as to lay the foundation for dense bushy specimens; 15° to the night will be a good temperature, syringe overhead daily to keep down red-spider. So treated they will bloom early, and make much handsomer plants than the old stools. Where the latter are to be again used they should now be started in the same manner, and should be kept in the pots as they have made an inch of growth. Give more air to the general stock on calm sunny days, but be careful of cold draughts, for the weather at this early season is so changeable that in one hour we may have a frost as April, and the next cold and cutting. *T. Baiusa*.

ORCHIDS.—The vesica section of the *Calanthes* which we have done mention of, and that the bulbs may have a period of rest before starting them in March, as well as also for utilising the year they have taken up, it is preferable that they be shaken out of their pots, the greater part of the old dead roots cut away, and the plants set on some airy compost, in a warm pot, pan, and a stool on a warm shelf or stage; here they will keep plump and hard, and in the course of a few weeks will push out the breaks from the base of the bulbs. As *C. Veitchii* goes out of flower, it may be treated in a similar manner; the bulbs of this, however, are generally enclosed, and since it is one of the most useful of winter-blooming Orchids, and it is desirable that a number of it should be obtained, it may be easily increased by breaking or cutting the bulb through the middle, so that the top and bottom halves may be kept in separate pots. The broken ends, however, should have a little sulphur rubbed on them to dry up the sap that exudes, and thus prevent them from being lost by damp or rot. *C. Turneri* and *nivalis*, that always bloom later, may be started in the first week in March, in the same manner to perfection. The compact form of the first-flowered, with the pure white colour of the sepals and petals and rosy purple eye, makes this a very desirable addition to this section, and that the two varieties are both desirable for culture. *Mascua* and *Dominians* will now be growing fast, and must be well attended to as regards water; *C. veratrifolia* will also be growing freely, and with the advanced growth the flower-spikes will be pushing up, and both may be growing at the same time; if there is any yellow-fly, it should be got rid of by sponging or smoking. This is a regular time in flower, and if it is wanted for exhibition purposes, unless it is very forward, it had better remain in the warm division and come gradually on, otherwise the stock in a cool house the flowers will apt to damp and open very badly and irregularly. Such of the *Deudrobiums* as are still in a dormant state, and among these may be named *litiflorum*, *Bensoniæ*, *crystallinum*, *Parishii*, *replicatum*, *Devoniensis*, &c., may be fully revived, and as soon as any of the first symptoms of returning activity and growth such a course of treatment must be adopted as they will require for their full development. One of the first will be *C. Devoniensis*, and unless looked well to, the

young breaks as soon as they push up are liable to be eaten through by the small shell-ani, which is likely to be hidden among the moss. Trap these with pieces of Potato hollowed out in the middle, and placed about on the plants. Look to *D. Falconeri* in the cool division, and see that it does not suffer with its cool treatment above what may consistently be considered sufficient for the forming and setting of the flower-buds, which latter will be looked for some two months hence. *D. Cambridgeanum* and *chrysanthum* will now be growing fast, and must be attended to with care. Carefully regulate the temperatures of the divisions, avoid and guard against a hot and dry state of the atmosphere, at the same time be careful that an excess of moisture is not permitted to remain in any of the pots, and do not suffer the plants to get close to the lower ventilators of the *Orchidoglossum*-house, and occasionally on the other divisions also, but be careful that they are closed in good time, otherwise the houses may fall much lower than is desirable. *W. Swan, Fallowfield.*

FRUIT HOUSES.

PINES.—At about the commencement of March we make it a practice to go through that section of the plants which has been wintered in pots of from 5 to 8 inches, and shift into fruiting pots a number equal to the requirements for next winter and spring. Only such plants as are in a highly selected condition should be selected, and those of the *Queen* and similar tender-rooting kinds are placed in 10-inch pots, and such as the *Smooth Cayenne* and other strong rooters have 12-inch ones afforded them. After these plants are potted, the growing pots should be kept at a temperature of 50°, but not much surface growth should be permitted until more propitious circumstances exist outside; a mean of 55° at night and 65° in the daytime will therefore be ample for some time afterwards. At the same time the plants are to be supplied with suckers, which form an immediate assistance to the preceding. The requirements to carry these operations into effect should have attention, and the loam, which is the chief component, should be seen to at once, as it should be in a moderately dry state when used, or otherwise in embedding it firmly round the balls of the plants it may be rendered impervious—a condition which would speedily indicate its results, and effect the same. The temperature of the water used in watering, also be necessary for the suckers, in order to have the bed in a proper state at the time. If space will admit, all those suckers which are on fruiting plants, or stools from which fruit has recently been cut, should be kept in the same way until they are ready to be started. Carry out former directions with respect to all young stock, see that these do not suffer from the lack of water, and especially those which are shortly to be shifted. The temperature of the soil should be kept at this year about 55°, of reducing the amount of fire-heat to its minimum state and of materially assisting the maintenance of a higher standard inside, which is very beneficial to fruiting plants, and which are coming up, which will now be the case with the most standard kinds of plants, so that the fruit may be fit for summer use. *George Thomas Males, Wycombe Abbey.*

ORCHARD HOUSE.—Many sanguine pomologists admit that the pot culture of fruit trees has not made the progress they anticipated, simply because the system, comparatively new, has not been properly understood, and many failures may be traced to the practice of keeping excitable trees in pots, and to the use of the Chamberlain glass all the year round, instead of removing them to an airy place out-of-doors as soon as the wood is ripe, where, with the pots well protected from frost by means of leaves or Fern, the trees can have the benefit of autumn rains, and the danger of the winter of frost dropping in the spring through being kept too dry at the roots when at rest or premature excitement is done away with. Assuming that the general stock of trees is now in position under glass, and the soil in a medium growing state, all the ventilators and doors must be kept open to retard the opening of the blossoms, as we may yet experience severe frost, and even then during bright sunshine, which we frequently have in frosty weather, the ventilators should be kept open to retard the temperature. For the mid-season house I would recommend *Royal George*, *Royal Kensington*, *Bellegarde*, *Nobilisæ*, and *Dymond Peaches*; *Elrage*, *Pimston Orange*, *Pine-apple*, *Albert Victor* and *Napier Nectarines*; *Moopack* and large early *Apricots*; *Bigreague Nappels*, *Governor Wood*, and *Black Crispstraw Cherries*. *W. Coleman.*

CUCUMBERS.—With increased light and an improved state of the weather, winter Cucumbers are now making good growth, and assuming better colour and texture of foliage. Plants that have been some time in bearing, and are now showing signs of exhaustion, will make a fresh start and produce a quantity of useful fruit at a time when fruit is most in

demand if a portion of the old soil which has become sour is removed from the roots and replaced with good turfy loam and lime rubble, previously warmed to the temperature of the house. The turf should be broken up with the hands, and firmly packed over the surface of the bed, so that the roots may be at the same time removed to make room for the young growths, which may be trained over all vacant spaces, and stopped at the first joint beyond the fruit, when the roots have taken to the top-surface, care being taken that the trellis does not become crowded with useless spray, which is always detrimental to successful cultivation. The night temperature may now be raised to 70°, with a rise of 10° to 15° by day from sun-heat; close at 80°, and springing a little, care being taken that the trellis and trellises are used they may now be lowered a little to prevent the leaves from touching the glass, which must be kept clean. Keep the first set of young seedlings near the glass until they are about 12 inches high, and then they have filled the pots with roots they may be transferred to the hills, fruiting-pots or boxes, in hot-water pits. If the latter are used, they should be filled to within 6 inches of the rim, to leave room for earthing-up as the roots appear on the surface. Care should be taken that the trellis and trellis, but do not stop them until they have filled two-thirds of the allotted space. *W. Coleman.*

KITCHEN GARDEN.

The recent changes from long-continued drenching rains to weather which is more favourable to garden operations will cause this to be a very busy department, and it would be as well if a little extra labour could be bestowed on the necessary operations connected with the preparation of the soil, and the trellis. Very much of the success which will attend the produce of the kitchen garden through the whole year depends upon the amount of labour which is expended upon it during the next three months. In most seasons we may safely calculate on being able to trench up roughly vacant plots at ground level during the two preceding months, and, by seizing the opportunity afforded by dry frosty mornings of forcing the ground over, to bring the soil into a condition favourable for the reception of the crops, but in a season like the present all these operations are in arrears, and hence the necessity for extra strength being put on, and likewise for taking every opportunity, when weather and conditions of soil will serve, to commit to the earth such crops as are required early, amongst which a good sowing of *Early Peas*, such as *Advancer*, should not be forgotten. Another sowing of some of the varieties of *Early Long Beans* should be got in for succession; the supply required should always regulate the quantity sown, but as a rule succession is shorter in seasons sowing a lesser quantity at shorter intervals. It is quite safe now to make the principal sowing of *Celery* for the market, and to plant a few plants in the brick heat of a dung-bed in a frame, so as to give them more room, which is preferable to sowing in pans or boxes, which, from their confined space, and the necessity for sowing thickly, is apt to draw them up weakly, and they receive a check when pricked out. The same dung-bed and frame may be made available for the first sowing of *Snow's Superb Winter Broccoli*, also *Veitch's Autumn Giant Cauliflower*, *Veitch's Self-protecting Autumn Broccoli*, which will be ready to set out for the first time, and *Walcheren Cauliflower* will also be useful, as will also some *Lettuces* for succession. A good-sized frame of early *Potatoes* should be planted at once, and some *Radish* seed scattered over the surface; and if the early sowing of *Potatoes* is not done, it should be no time should be lost. When started air should be constantly supplied, to prevent drawing up weak. A good bed of *Cabbages* from the late sown plants last year should now be planted, to succeed those planted in the autumn, and to be used as seed. It also be sown in a warm corner for successions. It is now time to plant out *Garlic* and *Shallots*. These flourish best in a stiff soil and plenty of manure; plant in rows about 6 inches apart. *Large Onions* may be sown in rows 12 inches apart, and very small ones from the stores (if no larger *Peas* so much the better), if planted out now, will be highly appreciated for kitchen purposes by-and-by, when the winter stores are exhausted. Give to *Cauliflowers* in frames and under handlights plenty of air in suitable weather; remove all decayed foliage, air the soil, and dust over with dry soil and ashes now and then. When there is no *Cucumber*-house the supply will mainly depend upon the produce from dung-beds in frames, and these should be sown in rows 12 inches in the briskest heat at command, so as to have the plants ready to ridge out by the end of this month. A good supply of fermenting materials should be kept in a course of preparation by frequent turnings, to sweeten and render it suitable as soon as it is used as soon as thrown into a bed. *John Cox, Rolford.*

THE
Gardeners' Chronicle.

SATURDAY, FEBRUARY 3, 1877.

APPOINTMENTS FOR THE ENSUING WEEK.

WEDNESDAY, Feb. 7.—Sale of Orchids at Stevens' Rooms.
THURSDAY, Feb. 8.—Sale of Orchids at Stevens' Rooms.
FRIDAY, Feb. 9.—(Sale of Hardy Plants and Bulbs, at Stevens' Rooms.)

THE Bill affecting the future management of our great arterial HIGHWAYS, brought into the House of Commons last year only to be scotched almost before it had seen the light, is promised as a pressing measure for the ensuing session, and in the interests of thousands of hardly pressed ratepayers it is to be hoped that it will, if carried, be found effectual in giving the desired relief. Although not technically a horticultural topic, our highways and roads are intimately associated with it in relation to their construction and maintenance, but in the neighbourhood of large towns, and especially around the metropolis, the condition of our highways is a matter that very largely affects the market gardener, as his draught both ways is exceedingly heavy, and the stern necessities involved in the housing of an immense population have driven him farther and farther out into the country, so that now teams of heavily laden garden produce have to travel distances varying from 10 miles to 20 miles ere they can reach that great central depot which has such a world-wide reputation as the garden-market of London.

Whilst the tollbars stood the highways were fairly well maintained, but just as these tolls offered a decided bar to locomotion and internal communion between localities, so also did they violate those principles of progress and free trade upon which our political economy is now based. Under the laws that established highway trusts and tollbars, all kinds of agricultural or garden produce, and manures for the improvement of the land, received a degree of immunity from tolls that spoke well for the sagacity of the landowning legislators of those days in looking after their own interests. With the abolition of tollbars go these special privileges, and as the cost of maintenance is now thrown on the parishes through which the respective highways pass, farmers and market gardeners alike have to bear the burden of cost, and this has proved in numerous cases to be so heavy as to be a veritable millstone round the necks of the unfortunate ratepayers. Ordinary parish roads are chiefly intersecting means of communication between one great highway and another, and, therefore, the maintenance of these has never proved to be a heavy burden to any parish, but the traffic on the arterial highways is immense, and is gradually growing; further, it would appear to become of a heavier and consequently more grinding nature as years go on, and thus the wear and tear on any important highway is so great as to thrust upon poor parishes a burden they are unable to bear.

The provisions of the Government Highway Bill are not widely known, and, as far as the coming one is concerned, are simply conjectured, but it is understood that the Bill proposes to establish County Boards having power to take charge of all arterial highways within the county, and to make rates for their maintenance over the entire area. It is difficult to believe that this will prove to be the most satisfactory method of solving a somewhat pressing difficulty. In populous urban parishes, such as those which immediately surround London and other large towns, the evil does not forcibly present itself. A wider area of municipal government thus absorbing into some dozen or more of parochial vestry executives would be an undoubted boon, and

where Government is hardly called upon to intervene, but in more rural districts the burthen is singularly heavy, and if relieved, as thus proposed by the Bill, no doubt the ratepayers would be satisfied so far without taking much thought as to the statesmanlike character of the proposal, or whether it was likely to prove in the end at once the cheapest and most efficient that could be devised. Unfortunately in relation to our highway management a much more drastic measure is required to put it on a sound and sensible basis, and make highways and public footpaths everywhere more adapted for the wants of modern civilisation than they now are. To touch the urban vestry system of government will require a strong hand, and any measure proposing to alter and amend parochial administration in rural parishes can only be made effective by grave determination.

The present system of managing the parish roads by local and untrained surveyors is as rotten as are the roads they profess to keep in repair. In nine cases out of ten the appointments are almost permanent, and open the door to much rank jobbery; and, worst of all, whilst the parochial surveyor is endowed with large powers to make rates and expend them, he has no professional auditing of his accounts to submit to, the members of the vestry only going over the accounts; and nothing is easier than to throw dust in the eyes of the few assembled ratepayers, who have to take all submitted to them for granted. It is one of not the least of the evils incidental to this form of parochial highway administration that the men selected as surveyors rarely have any practical knowledge of road making or road repairing; and farther, having their own business matters to attend to, naturally give those a preference over the highway management. They are also, from a fellow feeling, naturally very lax in insisting upon the trimming of roadside hedges and the cleansing of watercourses, and permit the cutting of turf and various other trespasses and nuisances in the shape of huge heaps of manure on the roadsides, such as would not be allowed if a professional man held the position of surveyor. The real remedy for these defects in our highway management will be found in making the Union, and not the parish, the limit for highway administration.

The Board of Guardians is gradually becoming enlarged from a body merely having powers in Poor Law Administration to a board having the management of all public matters within their Union area. It is now the sanitary authority; it has recently had large powers given it under the Education Act of last year, and it can hardly be out of character to make it the Highway Board for the whole Union. Ere these enlarged powers be granted, however, it will be necessary to reconstitute it on a more popular basis, as probably the Board of Guardians at present presents one of the most unrepresentative of public elective bodies in the kingdom. It will be but necessary to abolish voting-papers, and make the present ratepayer parish constituency the electoral body for, say, the triennial election of the members of the Board, and its popularity becomes at once assured. With its new duties it may be necessary to increase its members, and then it can divide itself into poor-law, sanitary, educational, and highway committees, performing, through efficient officers, its work thoroughly and well within the radius of its operations. Here, then, is offered a solution of both the arterial and parochial highway difficulties. The County Board and its widespread costly administration over, after all, only a few highways, becomes needless,—the Union becomes the equal area for rating and maintenance of all highways within its bounds. The highway committee appoint a professional surveyor, whose time is entirely occupied in looking after

the highways within his charge; he has his own gangs of men throughout the district under his daily supervision, his own horses and carts and all necessary repairing implements. The committee buy and sell, keep a rigid supervision of accounts, all roads and footways are kept in an even state of repair, and the end of parochial highway jobbery is brought about. These ideas are commended to the attention of Mr. SLATER BOOTH.

— AT one of the recent meetings of the Royal Horticultural Society, Mr. MOSELEY, one of the naturalists attached to the late Challenger Expedition, showed a series of Japanese illustrated works on horticulure and agriculture, which were of great interest and no slight artistic merit. One of the volumes, beautifully printed on Daphne paper, was devoted to illustrations of the process of CULTIVATING RICE, from the sowing of the seed to the harvest thanksgiving at the ingathering of the crop. One of these illustrations has, by permission of Mr. MOSELEY, been engraved by Mr. WORTHINGTON SMITH, who has very accurately copied a scene representing the thinning out and transplantation of the Rice plants in the flooded fields wherein it is cultivated (fig. 23). The whole work gave a vivid idea of the industry and skill of the Japanese.

— The *Bulletin de la Société d'Acclimatation* for November, which we have lately seen, contains a catalogue of all the plants at present growing in the Society's garden at Hyères. This catalogue consists mainly of plants hardy in the open air at Hyères, and includes the collections of Grape Vines, Oranges, subtropical fruit trees, &c., and will be found very useful by those interested in forming collections in the South of Europe.

In a recent number of *Der Gartenfreund*, an Austrian contemporary, and the organ of the Horticultural Society of Vienna, there is an admirable article, by LOFTHAR ABEL, landscape and architectural gardener, on the SOCIAL STANDING OF GARDENERS IN AUSTRIA. It is headed by LINDLEY's gardener's watchword, and the whole argument resolves itself into this, that as soon as gardeners generally have attained that degree of culture and refinement which will qualify them for intercourse with the members of other professions, then they will certainly rise in the social scale. The leading gardeners of this country are highly complimented, as are also the possessors of large gardens, who extend some consideration to their gardeners. Otherwise the article in the main might be addressed to the young gardeners of this country, who, collectively, are responsible for the social standing of the profession in the immediate future. The majority of our best practical gardeners will agree with us, we believe, that very much remains to be done before the general run of English gardeners will be raised to the level of their occupation. Of course there will always be a large number of people who mistake their calling, just as in every other walk of life; but these may be left out of consideration.

— In a report on the condition and progress of the gardens of the Society of Acclimatization at Hyères, the *Bulletin* for November gives the RATE OF GROWTH OF VARIOUS SPECIES OF EUCALYPTUS and other Australian trees. The Eucalypti rapidly form very straight, slender trunks of very durable wood. *E. globulus*, sown in March, 1873, and planted in a row, are now from 20 to 35 feet high, the greater part being over 25 feet. Seedlings of the same species planted out in 1870 are now from 48 to 65 feet high, and some of them are 40 inches in girth. Another species, probably *E. maculata*, planted at the same time, is now about 32 feet high, the trunk being about 10 inches in diameter a yard from the ground. Some experiments with seedlings gave a rate of growth exceeding an inch in the twenty-four hours.

— As an illustration of the IMPORTANCE OF THE CAROB TREE (*Ceratonia Siliqua*) IN PORTUGAL, we may point to a recent report on the trade and commerce of Lisbon, where we are told that the Ceratonia is one of the principal resources of the province of Algarve, and that a severe drought that visited

the province in the year 1875 had begun to cause the death of the trees. The general failure of these trees is described as being equivalent to the utter ruin of the largest and best part of the inhabitants of the province.

— At the annual meeting of the HIGHLAND AND AGRICULTURAL SOCIETY, held on Jan. 17, Professor BALFOUR reported that the following premiums had

mannana, and its suitability for the climate of Britain. 4. The medium gold medal, or £5, to Mr. THOMAS WILKIE, forester, Invergarry, N.B., for a report on the management of plantations.

— We have received from the agent of the Canadian Government in London a pamphlet containing some interesting facts connected with STOCK RAISING and the BREEDING OF PEDIGREE CATTLE

G. F. WILSON, F.R.S., was unanimously elected President, and Mr. E. S. DODWELL Secretary. About £25 was subscribed at the meeting in aid of the funds for the necessary prizes. It was thought that, if possible, the show should be held at South Kensington, provided satisfactory arrangements could be made.

— The rashness exhibited on the part of those who declare certain varieties of POTATOSTO to be "disease

been awarded in the Forestry Department:—1. The gold medal, or £10, to Mr. WILLIAM GORRIE, consulting landscape gardener, Rait Lodge, Trinity, Edinburgh, for a report on the Tree Mallow (*Lavatera arborea*) as a new agricultural plant for cattle-feeding, paper-making, and other purposes. 2. The medium gold medal, or £5, to Mr. ROBERT HUTCHISON, of Carlowie, for a report on the *Taxodium sempervirens*, or Red-wood, for timber purposes. 3. The medium gold medal, or £5, to Mr. ROBERT HUTCHISON, of Carlowie, for a report on the *Picea Nord-*

in the Dominion of Canada. Those of our readers who may be interested in this subject should apply for a copy at the Canada Government Office, 31, Queen Victoria Street, E.C.

— At a meeting held as announced on the 31st ult., in reference to the organisation of an EXHIBITION OF CAPRATIONS and PICOTEES during the approaching summer, the projected show was approved, and a committee, with power to add to their number, was appointed to make the necessary arrangements. Mr.

resisting" is constantly being illustrated in various ways, and the experience of those who make a speciality of the Potato goes to prove that, if an average of three years be taken, no variety is altogether exempt from the ravages of the disease. An amateur cultivator of our acquaintance grew the American variety Eureka in 1874 and 1875, and finding it, notwithstanding statements to the contrary, of good cooking quality, and entirely free from disease during the time he had grown it, strongly recommended it to his neighbours and friends. But mark the result of the season 1876.

He writes:—"This season Eureka all rotted down, other varieties stored round them remaining very good." But while making this statement, the writer reiterates the favourable opinion he had already expressed as to the culinary value of Eureka:—"I find it cooks extremely well, very white and mealy, from my sandy red land, in fact most of the American varieties are of good quality from this soil, whilst in the clay lands herabouts they are simply worthless." This is an invariable experience with the American Potato. The writer makes another statement in regard to American Potatoes worthy of being recorded:—"On some light sandy land a short distance from here" (he is writing from the southern part of the county of Warwick) "all the red American Potatoes turn white after being grown in it about three years, at the same time yielding enormously." The land is chiefly let out as allotment gardens to labourers, and this season the Early American Rose was quite white in the skin. Did what is known as the White American Rose originate in this manner?

—In wintering stock plants of the useful *MESSEMBRYANTHEM CORDIIFOLIUM VARIEGATUM* it is expedient to keep the plants so dry at the roots as generally done? The condition of some plants in 48-pots seen a few days ago in a cold greenhouse, which has no apparatus for heating by artificial means, seemed to raise the question as to whether it is conducive to its well-being to keep the plants dry at the roots. They were occupying a sunny shelf, and on all occasions when dry the plants were freely watered. The growth was almost as luxuriant as at mid-summer. The plants were cuttings struck last spring, and were well established in their pots, and a good supply of cuttings could be obtained from them. True, the season has been an exceptionally mild one, but then it has been very damp and cold. It may be that drought at the roots during winter is more injurious than moisture, supposing the plants be well established in pots and there be sufficient drainage. This hint is thrown out for the consideration of those who have to winter in quantity the choicer bedding plants.

—Major HALLETT has been lecturing before the Tunbridge Wells Farmers' Club on SEED SELECTION, and his lecture is so interesting that it is a matter of regret to us that the crowded state of our columns forbids us from extracting the greater part of his observations. For the present we must confine ourselves to the following extract, in the hope of subsequently returning to the subject. The full text of the lecture is given in the *Brighton and Sussex Daily Post* of the 27th inst.

"Very close observation during many years has led me to the discovery that the variation in the cereals which Nature presents to us are not only hereditary, but that they proceed upon a fixed principle, and from them I have deduced the following law of development of cereals:—1. Every fully-developed plant, whether of Wheat, Oats, or Barley, presents an ear superior in productive power to any of the rest on that plant. 2. Every such plant contains one grain, which, upon trial, grows more productive than any other. 3. The best grain in a given plant is found in its best ear. 4. The superior vigour of this grain is transmissible in different degrees to its progeny. 5. By repeated careful selection, the superiority is accumulated. 6. The improvement, which is at first rapid, gradually, after a long series of years, is diminished in amount, and eventually so far arrested that, practically speaking, a limit to improvement in the desired quality is reached. 7. By still continuing to select, the improvement is maintained, and practically a fixed type is the result."

—The large ORCHID-HOUSE at GUNNESBURY PARK, Acton, the residence of Baron LIGNÉ DE ROTHSCHILD, is just now remarkable for the fine display of Phalænopsis in flower. Altogether there are about fifty plants growing in baskets suspended from the roof at the front of the house, a considerable majority being of *P. Schilleriana*. About forty plants are now in bloom; and, while the spikes are of good size, regard being had to the dimensions of the plants, the flowers are large and finely coloured. *P. amabilis* is very beautiful, and *P. grandiflora*, being a little later, is not yet in bloom. Mr. RICHARDS grows all his Phalænopsis in these suspended baskets, with but little soil in them, and the leaves they put forth are large and finely marked. The floral spectacle presented by the line of so many plants in bloom is of an

imposing character. Other Orchids in bloom are *Laelia anceps* Dawson, with three very fine flowers of most delicate beauty, the interior of the crest being richly striped with rosy crimson; *Masdevalla Veitchii*, with twelve large and brilliantly coloured blossoms; several fine varieties of *Odontoglossum Alexandrine*, one pure white being remarkable for its chaste beauty. This beautiful Orchid is largely grown at Gunnesbury, and Mr. RICHARDS states he is scarcely without flowers all the year round. A plant of *O. Andersonianum* has thrown a five-branched spike having quite sixty buds on it, and this will be in bloom a week or ten days hence. *Odontoglossum bichonense* has six large spikes of blossoms; and *Sophranites grandiflora* is particularly effective. The whole collection of Orchids, which are grown mainly for cutting from, are in fine condition, the result of high-class culture.

—Mr. VAN TIEGHEM has been elected a member of the Academy of Sciences, Paris, Botanical Section, in the place of the late Professor DEJONGHIAERT.

—At the meeting of naturalists in Hamburg last year, Professor J. BOHM read a paper on the RELATIONSHIP BETWEEN ROOT DEVELOPMENT AND THE SIZE OF THE LEAVES. In some experiments on the influence of various saline solutions on germinating plants of the Scarlet Runner Bean, growing in a sandy soil impregnated with salt, he found that the effect usually showed itself in the very slow development of the stem, and the extraordinarily small size of the leaves. Analyses of the ashes proved that these conditions were not brought about by an undue absorption of salts. No other explanation could be found but that the solutions acted injuriously upon the roots of the plants under experiment, and this view was confirmed by direct experiment. It was also proved that the solutions acted injuriously upon the development of the stem and leaves independently of the root. The main result of the experiments was simply a confirmation of the generally accepted theory that there is an intimate relationship between root development and growth above ground.

—At the same meeting, Dr. REICHENBACH, the President, described a very REMARKABLE CAMPANULACEOUS PLANT, which he believed to be a hybrid between *Campanula barbata* and *Phyteuma hibernicum*. Only a solitary plant of it was found, and of this only a dried specimen now remains. It was discovered by Baron VON HAGENMANN, in the Scier Alps. Dr. REICHENBACH calls it *Campanula Hausmanni*, and says that it may most aptly be designated as a *Campanula* with the flowers of a *Michauxia*. Respecting the transformation of Ferns, Dr. REICHENBACH mentioned a case of reversion of an abnormal form to the normal state, and another case in which the normal form had begun to vary. The first was the well-known variety of *Asplenium Filix femina*, called *Fritzelle*. This, planted out in a shady place in the Hamburg Botanic Garden, suddenly changed into the common typical form, not only in the cutting of the fronds but also in their size. The other was the ordinary *Scopolandium* with narrow acute fronds, which were succeeded by others forked at the tip.

—Dr. REILEY has published, under the title of "POTATO PESTS," an illustrated account of the Colorado Potato beetle and other insect foes of the Potato, with suggestions for their repression, and methods for their destruction. It will be our duty to notice this publication more at length on another occasion, but the matter is so important that we lose no time in saying that the pamphlet can be obtained of Messrs. TROBNER & Co.

—We understand that Mr. E. BENNETT, of the Rabley Nurseries, Shenley, Herts, formerly gardener to the Marquis of SALISBURY, has been appointed Floral Director of the Royal Aquarium, Westminster.

—Our contemporary, *Nature*, has published Mr. J. S. GARDNER'S lecture on the TROPICAL FORESTS of HAMBURGH, given at South Kensington in connection with the Loan Collection of Scientific Apparatus. The lecture was illustrated by a rich collection of fossils, chiefly from the valley of the Bourne,

and by an imaginary landscape representing the vegetation of the Bourne valley during the eocene period. This lecture was an extremely interesting one, not alone to geologists, but also to botanists, great care having been exercised in the determination of the fossil remains of the plants. We have some experience of the difficulties attending the determination even of fresh leaves of not uncommon plants, for many of our correspondents seem to think we ought to be able to recognise the smallest scrap of any plant they may send to be named. If it is so difficult to recognise living plants, what must it be with the imperfect, petrified remains the geologist has to deal with? Nevertheless, the fossils from the Bourne valley (and other parts, of course) represent plants so different from the existing vegetation that every one must realise the fact that our flora has undergone an entire change since the comparatively recent eocene period. Mr. GARDNER exhibited many fossils undoubtedly belonging to families not represented in the present flora. Respecting the genera, and still more the species, there can be little certainty in the majority of instances. Among Mr. GARDNER'S numerous specimens were several Proteaceæ, referred to *Dryandra* and *Stenocarpus*, fan-leaved and feather-leaved Palms, large Aroids, and, what was more interesting than all the others, remains of a gigantic member of the Cactus family. Associated with these were Oaks, Elms, Beeches, Maples, and other equally familiar types, with a crowd of others now strangers to our soil. Still we cannot accept Mr. GARDNER'S inference that the climate of that period may be spoken of as actually tropical. At the present time there are temperate representatives of the Palms, Aroids, Cactæ, and other families, and it is quite possible that the temperate types were formerly more numerous.

—Professor BOHM, of Vienna, has been repeating some of SAUSSURE'S experiments relating to the ABSORPTION OF CARBONIC ACID BY PLANTS. If green leafy twigs of *Ligustrum vulgare*, or any other plant, are placed in an absorbing tube, containing atmospheric air, and excluded from the light, the volume of gas is considerably reduced whilst there is at the same time a generation of carbonic acid. Taken into broad daylight the original volume of gas is reinstated, but this phenomenon is wholly due to the absorption of carbonic acid by the cell contents, but more especially to the storing up this gas in the cell-wall. At a temperature of 212° dry branches appear to absorb even more carbonic acid than fresh ones; but whereas, in the latter, it is comparatively quickly expelled by the hydrogen, oxygen, and nitrogen, in the former it is given off only very slowly, probably as in coal.

—How much the aspect of the VEGETATION OF THE SOUTH OF FRANCE AND ALGERIA will eventually be modified may be gathered from the large scale on which the Acclimatization Society is raising various subtropical plants hardy in that region. Although many of them are likely to possess nothing beyond their ornamental value, others have been selected for their economic products. Among plants raised for sale they have in the gardens at Hyères about 50,000 plants of the following species:—*Chamærops humilis*, *C. exelca*, *Corypha australis*, *C. Gébanga*, *Phoenix dactylifera*, *P. ionensis*, *P. pumila*, *Sabal*, various species; *Jubæa spectabilis*, *Dracæna indivisa*, *Phormium tenax*, *Dasylium*, various species; *Hakea Victorice*, *Araïa Sieboldii*, &c. This does not include a large stock of *Eucalyptus*, *Casuarina* and *Acacia*. The Society also possesses a large collection of Bamboos, and it is one of the special features of their labours to try the hardiness of the various kinds and get a stock of those likely to prove commercially useful in the Mediterranean region. *B. aurea*, *nigra*, *mitis*, *flexuosa*, *violascens*, and *Quiloi* are the hardest. A species, most likely Himalayan, received under the name of *Bambusa Thonarsii*, exhibited a most remarkable luxuriance. In October last a single plant had produced during the summer fourteen stems upwards of 16 feet high. In size this exceeds all others in the climate of Hyères.

—Dr. SOBERER, the author of a handbook on plant diseases, read a paper at the meeting of naturalists in Hamburg last year on the NATURE AND CAUSES OF CANKER IN APPLE-TREES, illustrated by

an estate not far from here, where Holly trees abound, one in the vicinity of a beehive was covered with berries, while others not far off had scarcely a berry upon them. I think this fully supports Mr. Darwin's suggestion that the scarcity of bees during the early part of the season may account for the small allowance of berries at Christmas. *William Elliott, Crofton House, Stroud, January 14.*

In Mr. Darwin's recent letter to your journal on Holly berries he states that the Holly is a

thesis, "the ovary is often abortive and four-lobed without stigmas." He thus not only classes it with perfect plants, but also notices an exceptional difference. Will you therefore allow me to ask whether all our long-venerated botanical authorities were mistaken, or whether the marvellous transformation of trees with perfect flowers into dioecious trees has really taken place, and that, too, in the short space of about sixteen years? If the trees observed by Lindley were becoming monoecious, it would be a wonderful

of Old England for more than twenty years. I believe they originated with John Percival and John Lewis, and were made under the latter's superintendance at Aston, near Northwich, Cheshire, in the year 1847. They are very much used in this neighbourhood, as Potatoes are extensively grown for market, and hardly a farmer or cottager but has them in quantities. The boxes are also very useful for storing the finer sorts of Apples and Pears, as they can be taken to the trees and the fruit placed in them as gathered, so preventing any moving or bruising in transit to the seed, and they are easily looked over when there. *Wm. Cruickshank, The Gardens, Arley, Northwich, Jan. 30.*

Vegetable Shows.—I am not in a position to say whether or not the Royal Horticultural Society intends this year to give the Cabbage growers an opportunity to show the most useful occupants of the garden; but as it cannot be expected that the large seed firms will be so liberal every year, if the Society will do nothing we must take the field to ourselves. I am perfectly willing to subscribe my mite, and I should like the opinion of others on the subject. *R. Gilbert.*

The Royal Horticultural Society.—It has been eloquently said of a certain place that in the lowest depth a lower deep still opens in a deep descending series of woes. Substitute the word degradation for woes, and the sentence correctly describes the present state of the Society. How art thou fallen, beautiful Flora and luscious Pomona! was the thought that brought a blush to my cheeks as I read the Secretary's begging appeal to the rich Kensingtonians in the *Daily News*. That such a letter should ever have been written is degradation enough, but that it should have been penned by a distinguished horticulturist who has taken sweet counsel with his brethren at the Horticultural Club and other places, concerning the best means of reconstituting the Society on a horticultural basis, makes degradation wear the semblance of insult. You suggest the probability of some explanation being forthcoming: I hope it may; but it is difficult to see how any explanation can alter the fact that any horticultural secretary, of his own option—for his letters to all the daily papers are extra-official, and are not sent by order of the Council—has thrown the horticulturists wholly overboard, and has appealed, hat in hand as it were, to the South Kensingtonians to subscribe the funds to uphold the gardens, engage the bands, start the promenades, restore an entrance, &c., on the ground that the said gardens are a great advantage to the residents and owners of property in the neighbourhood. What, in the name of common sense, has a Royal Horticultural Society to do with such paltry pettifoggish objects as these? What has South Kensington or its resident owners or occupiers done for horticulture that the secretary of a Royal Society should become a beggar, as it were from door to door, on their behalf? Are such narrow policies and mean practices in accordance with the cheer, of which we hear at times so much? And if they are, perish a thousand charters rather than that they should be continued. A good deal is also heard at times of the *prestige* of the Society; ut upon such *prestige* as can be acquired by begging for such unworthy objects, with a threat—for the threat is, if the money be not forthcoming the property may probably be built over. Well, as far as horticultural *prestige* goes, probably the sooner the better; but it ought to have been added that the property belongs to the nation, and cannot be built over unless for national advantage. The time has surely come for action among horticulturists. I am glad to see Mr. Wilson has arrived at that point, and now that he has I will gladly give my name to his guinea scheme as the basis of an entirely new policy, or new Society—I care not which. I would also remind him that the horticultural public cannot live long on the mere promise of guinea Fellowships, equal in elective and executive functions to any other. It seems to many of us full time that the promises were consolidated into facts. I do not believe in the turning of any wheel to horticultural advantage unless the willing, skilful hands of horticulturists put their own shoulders to it in earnest. The mere waiters upon Providence seldom find many prizes turn up for trees. To idly wait when stirring work lies before us to do is proof positive either of incompetence, indifference, or indolence. Horticulturists have counted the many kicks the Society has given them. The worse the usage any of their number have received the more they have rallied round the Society, and the more they have been praised for doing so. Let the fat go forth—no more plants, flowers, fruit, vegetables to the society—no more notices from the horticultural press—until your policy is the only one for which you exist as a Society—the advancement of horticulture; and then, before another month, we should either have a new policy or a useless encumbrance swept out of the way. Perhaps the last would be best. What should we lose by the de-

FIG. 25.—ADVENTITIOUS BUDS ON THE ROOT OF BRASSICA RAPA.

"dioecious plant," and that during forty years he has looked at many flowers in different districts, but has never found an hermaphrodite. In subsequent letters to the *Times* (January 17 and 19), the names of Withering, Sowerby, Smith, and Hooker, are quoted as authorities for regarding the Holly as a plant bearing perfect flowers. To these names those of other celebrated botanists might easily be added. I will, however, only refer to Professor Lindley. So late as 1860, in his *Descriptive Botany*, a manual for students, specially urging the importance of "correct, scientific descriptions," he, after particularising each part of the Holly in the usual way, remarks in paren-

proof of "development," but for Holly trees in general to have become dioecious would be so marvellous that students cannot help being anxious for authoritative opinion on the matter. *E. A. Malminger, 281, High Street, Chatham.* [We believe the common Holly to be polygamous. In the nurseries the best of the cultivated varieties are strictly dioecious. Eds.]

Potato Spritting Boxes.—I can fully endorse your remarks regarding Potato spritting (p. 114), and can strongly recommend the "spritting boxes," but think Mr. Spinks need not have gone to France for the idea, as they have been in general use in this part

struction of the Royal Horticultural Society's South Kensington Gardens? Perhaps, and perhaps not, the property is bound to be used for the advancement of science, the culture of the taste and the promotion of the happiness of the people. The Lindley Library? This by no means follows. It would probably be gladly handed over to a new society, and if not, Her Majesty's Commissioners would doubtless gladly afford facilities equal to those enjoyed at present to all comers. There would be little risk of losing the use of the Lindley Library; that secured, its ownership is a matter of little moment. But we should not lose sight of the gain much by the loss of a little less or more than a mere deed of partnership between two bodies that have shown their inability to act together for the good of horticulture. It has been broken and set aside again and again, and its main purpose, the elevation and advancement of the science and practice of horticulture as a cultural and enabling power on national life, has been sacrificed for the most paltry objects. But we might lose the Chiswick Gardens, and we might not; and if we did, they could be replaced. A general month's offer offered to be one of twenty to subscribe £1000 each for the establishment of new gardens in a new locality. What should we gain by the establishment of a new Horticultural Society? First, freedom of action; secondly, freedom from interferences; thirdly, freedom to initiate a purely horticultural policy, untrammelled by red-tape and vicious traditions; and, finally, freedom to select the best men for all offices, unbiased by personal considerations. It is only needful to grasp the bearings of the subject, to have the liberty, and to set it on fire with the enthusiasm for horticulture that abounds throughout the country, and much of which is now running to waste for lack of an outlet to give it proper expression—to see that a true national Society might easily be formed, and that we need never move aside prospects and power. *D. T. Fish.* [Without by any means endorsing all our correspondents' views, we may yet express our unqualified regret and dismay at the recent action of the Secretary to the Society. Probably an explanation will be forthcoming at the annual meeting. Ed.]

The Golden Champion Grape.—I have forwarded for your inspection a cut from a Golden Champion Vine of one year's growth. I do not grow it on its own roots, as I find the wood is much firmer when worked on the Muscat, and its propensity to rot in the berries is less in instances; it yields a colour, when ripe, much improved. The specimen I have sent you is from a bud worked on Black Hamburgh, which is the first I have tried on that variety, and I should like to know if a similar growth at the Hamburgh is also to be expected. I shall be glad to see any notices. You will see the cane is perfectly ripe, and the pith quite in proportion. I am a little sanguine as to its further results in the approaching season, as it is a variety especially esteemed at Raby. *Richard White.* [A sample of extraordinary vigour, exactly one inch in diameter, well ripened, and with a very moderate development of pith. Ed.]

Poinsettias in a Low Temperature.—At p. 52 "Inquirer" asks the lowest degree of temperature that Poinsettias can be grown in to a tolerable state of perfection. Having myself rather limited in the way of heated structures I adopted the following mode of treatment, which I found answered well. Cuttings were put in singly in thumb pots in the second week in June, and plunged in bottom-heat in a Melon frame. In about three weeks they were rooted, and I then removed to a cucumber frame near at hand, where they remained standing on the surface of the bed for about three weeks, when they received the final and only shift into 48-pots, and were gradually hardened off to a cold frame, where they remained until the end of August, when they were removed to a cold house under an east wall with no heating apparatus to it at all, in a temperature ranging between 50° and 55° till the end of October. From here they were removed to their flowering quarters, in a house of extraordinary vigour, where they were frequently under 90°. The plants in question were from 2 to 24 feet in height, and the head of bracted leaves 12 to 16 inches across, and of a brilliant colour. The soil I used was good yellow loam, with a little rotted cow-dung. The plants should never be allowed to grow dry, as they will be sure to lose their leaves, and plants of that description look miserable. I do not mean to say that Poinsettias may not be grown finer in places where they have every convenience in the way of glass, but that they need not be so, or any other way to grow them to a tolerable state of perfection if they grow Cucumbers in a common garden frame, and have a house of 60° of heat to flower them in in autumn. *W. The Gardens, High Green House, Sheffield.*

Premature Growth of Vine Roots, &c.—Farson me for again troubling you in this matter just to pay

how deeply I am interested in the discussion, and also to offer a word of reply. First, to the veteran Mr. Henderson (p. 151), who I am sorry does not approve of inside borders—well, we'll agree to differ. I have not the honour of his personal acquaintance, but I know him sufficiently by repute to believe that he practices what he preaches, and this matters little to me, for the lateinery here, which is a span-roofed house, 52 feet by 25 feet, has the border entirely inside; and though there are several hundred bunches of fruit still hanging, I can conscientiously affirm that not one berry per bunch has cracked or fogged off, notwithstanding the excessive wet period we have had, which certainly would not have been the case had the borders been unprotected. The border is concreted and walled round, and the roots cannot get out, but (this is one to Mr. Henderson) as soon as the Grapes are cut, and the little light taken off from the border it is as it were, turned out to the atmosphere. We have another viney with borders entirely inside, but the lights being fixtures the border cannot be exposed to the atmosphere, yet I can perceive no ill effects on that account, and the Vines flourish equally well as the others. I also wish to offer a word of explanation to "S. W." (p. 76). I am quite ready to admit what he advocates, viz., that no plant is ever entirely at rest; and when I wrote of the Vines being at rest, I meant that they should till the buds were expanded or were in full leaf. I did not for a moment think that my meaning would be so construed, though perhaps it would have been better had I written (which was really my meaning) that they remain in a comparatively inactive state up to the end of the season, and the period of the growth of roots—was made till then. At p. 118, Mr. Goodacre, after virtually endorsing my views as to inside borders, tenders me some advice, and, though it has nothing whatever to do with the subject, yet being entitled to reply, I will do so. I have to thank him for his kind writing about, and leisure to write it, I shall do it, and court honest criticism, but despise personalities. I am proof against any discouragement he or any one else has to offer, so he need not be alarmed on that score; and, according to Mr. Goodacre, I live in the land of Gothen, you may shortly expect to have some celestial effusion from *W. Wilmshurst*.

Brussels Sprouts.—This vegetable, on which much dependence is placed, has with many signally failed to afford the usual supply. This has been caused by their growth having been checked during the dry summer and autumn. Here they have been in the greatest abundance, as the plants were raised under glass, and got out early in May. Those who do not make a practice of sowing their Brussels Sprouts in the open air, but who have a hot bed, or a cold frame, will find it will pay well to do so now if a few old lights can be spared for the purpose, and a trifling bottom-heat afforded, to get them to germinate freely. The raising of Brussels Sprouts in this way may appear a useless expenditure of labour and means, but adverse seasons have so baffled with, and gardeners are expected to meet all difficulties of that kind, and not to fail in producing everything in the vegetable line when wanted. To grow Brussels Sprouts in the style they should be they must be got established before hot, dry weather sets in, when they will continue to push on daily increasing in size and strength till they are capable of bearing at least double the ordinary, and of much superior quality to any that can be raised in the open air, and those sown and treated in the ordinary way. *F. S.*

Gros Colman Grape.—Mr. Goodacre asks (p. 51) "What has become of Gros Colman, so highly spoken of last season?" I have not had much experience with this fine Grape, but favouring it last season I have formed a very favourable opinion of it, and sowed 274 plants in a cold frame. Last year one of them bore five and the other six bunches, which coloured and ripened off well. Had I known at the time they were thinned that the berries would have got to the size, and the bunches to the weight they did, I should probably have lessened the number of bunches. Not only is it a fine-looking Grape, but the flavour of those grown here was also good. In this regard I consider it one of the best late Grapes. I exhibited it at two of our local shows, and on each occasion it was highly praised for its beauty and flavour was awarded to it. The bunches were left on one of the Vines until about the middle of December; the berries were then in excellent condition, as fresh-looking and plump as in August, and appeared likely to bear a heavy crop. Should you have any more to bear I have no doubt it will be extensively cultivated, particularly for late use. *M. Sant, Stourton.*

Hardenbergia bimaculata and Chorozema cordatum splendens.—I was much struck the other day when visiting Lockinge Park, Colonel Loyd Lindsay's seat, illustrated in your columns at p. 81, with the beauty of the above as winter flowering

plants for the decoration of the greenhouse and conservatory. They are most valuable plants, and the specimens were about 24 feet, grown and trained upon trellises, and were one mass of flowers, the beautiful orange and scarlet of the *Chorozema* forming a grand contrast with the deep blue of the *Hardenbergia*, and certainly they are worthy of a place in every collection. Mr. Atkins, the gardener, informed me they had been in flower fully a month. *A. Outram, Victoria and Paradise Nurseries, Upper Holloway, London, N.*

Why are Inside Borders Rootless?—Will you allow me to inform Mr. Henderson that the reason why Vines root "struggle to get out" (see p. 51) is because inside borders are kept too dry. About five years ago I planted a range of vineeries with inside borders, taking care at the time to place all the roots pointing in an inward direction, thinking that by so doing they would feel from the inside before going out. The Vines made rapid progress, and it was thought such excellent top-growth must have a corresponding root-growth, which undoubtedly they had, but not inside, for it was found, on examining the border, that the roots had all been trained to the drainage, and then outdoors to the outside borders. As the inside borders were prepared at great expense, the thought of their being useless was anything but pleasant. I was told by those qualified to give an opinion, that the soil was so dry, and the outside border were evidently more suited for them." On one occasion, being caught in a sharp shower, I ran for the nearest shelter—the vineery; and the question suggested to my mind while listening to the rain beating on the roof was—Do we give water to these inside borders in sufficient quantity to compensate for the amount kept off by the roof? If not, why not? Surely, from their position, if they don't get more, they certainly ought not to have less. Fortunately at this time we had a water supply laid on, and I was enabled to give the inside borders a soaking. The result of such soakings being that the roots are now to be found turning their attention inside. Another mode of utilising rootless inside borders will, I think, recommend itself; that is, to plant young Vines, or, what I prefer better, insert an eye at the back wall of the vineery immediately under each Vine on the roof, train the young Vines up the wall and inarch them with the Vines on the roof. Suppose, for instance, that variety you mention, say, of *Muscat Alexandria*, I would plant the wall with such a cane, not only because it is a strong roofer, but if inarched on the Vines sufficiently low on the roof, say from 9 inches to 1 foot, the result will be that two or three bunches at the top of each Vine will be Muscat, while the Vines on the wall will not fail to set; this not only gives an extra variety, but greatly assists from the hanging properties of the latter in connecting the link between early and later varieties, besides supplying each Vine with a double portion of root. *T. W. Bond, Webridge.*

Cedars of Lebanon.—Your correspondent "O." corrects an error in my article on the Cedar of Lebanon. In fixing the date of its introduction I intended to say, "In Evelyn's *Silva* of 1664 he does not mention the Cedar of Lebanon" as having been at that time introduced into this country. I have always understood that he planted the tree at his residence at Wotton. It would be interesting to know if any of his specimens remain. Mr. Crowhurst describes a large tree—10 feet 9 inches at the feet. The picture would have been better with the addition of the height to the crown. *H. Evershad.*

Vine Borders.—Some time ago it was said that the son of Hardwick had set, and really it appears to have left Mr. Fish in darkness, and prevented him from seeing clearly what direction Vine roots take. If they did, as he says, take a southerly direction, they might answer the purpose of the compass to travellers; but these notions are wrong, as every practical gardener must know that a Vine in a healthy state pushes out roots in every direction. Mr. Fish must have enjoyed a happy state of things if he has not had some such a little manure without well turning and sowing it is every vintage he has seen. If the soil's sweetening it is every vintage he has seen. The soil's sweetening, this bitten, would do well to spend a time in some of the London market gardens, where he could learn the use of stable manure for bottom-heat, early forcing, &c. *F. H. Goodacre, Ebbwton.*

Fish asks to be shown why Vines will not do as well with their roots confined in inside borders alone. This needs no showing; I never yet saw an instance where the Vines did not show it themselves, and that unmistakably when they have been planted seven or eight

years, by evincing weakness in the canes not thickening more than half so fast as if the roots had access to a good outside border as well, and by the time they were a dozen years old they generally increase in girth almost imperceptibly, and are seldom more than half the strength that those are which have more room, and the same is well made harder all the way round attention in the shape of plenty of water, sufficient solid and liquid manure, and the surface renewing with new soil, so far as the non-interference with the roots will permit. The fact is, if Vines are intended to bear so costly double or triple the space which an inside border alone affords, *T. Baines*.

Guinea Fellowship.—The proposal of the Royal Horticultural Society to admit guinea Fellows without a vote is by no means satisfactory. Those who have given their names to me as guinea Fellows have done so only on condition of incurring no further liability, and on condition that the Society is relieved from its present incumbrances. The Society is not free; therefore, had the Council offered a full guinea Fellowship instead of proposing it in the circumscribed form in which the guinea Fellows would probably not have come in. Now, as to the future, I trust in the proverb "who waits wins;" and I believe that those who have given their names as would-be guinea Fellows in the Society when free, will be content to wait till the Society is relieved from its liability, and be asked for their subscriptions till the time of freedom has come. I should very much prefer to see the old Society take its proper position as representative of the horticulture of the country, but if it does not see its way to do so, and prefers to continue as an appendage to South Kensington, I think it certain that some qualified man will see the strength of the position, and will raise up a Society which will become the strongest and most prosperous of societies, with here-quoted in London, including the most divided and least prosperous, as the Royal Horticultural Society has been for at least the twelve years I have known it, and for long before. The great body of horticulturists of this country has always held aloof from the Royal Horticultural Society, and I believe will continue to do so, long as it continues under the shade of South Kensington. *George F. Wilson*.

Breeding Lobelias.—Will any of your readers kindly give a short account of their experience with the dwarf Lobelias in various localities, and in particular best in their respective localities? I have used *L. Lastrous* very extensively during the two past summers, and find it a regular gem, being very dwarf and dense flowering of a very deep blue, with a rather large white eye, and the eye is my only objection to it as in my opinion there is rather too much white. *Bluestone* I find very useful, but not quite so dwarf as *Lastrous*, neither is it so compact in its habit. *W. Shivers, Royal Pavilion, Brighton*.

Platycodon grande.—In the gardens of S. Stearn, near a fine plant of *Platycodon grande*, and was informed by Mr. Ireland, the head gardener, that it was purchased a little over two years ago, quite a small plant in a 32-pot. It now measures 5 feet 6 inches in diameter. I think so grand and perfect a specimen, grown to the above dimensions in so short a time, highly worthy of notice. *S. Johnson, Royal Nurseries, Ascot*.

Hubbets on Vine Borders, &c.—I hope the subject of the premature rooting of Vines will not be allowed to drop until it has been fully discussed, as it is rather best to be profitable to a large number of your readers. I think it well put by Mr. Baines, when he says we "have much to unlearn as well as to learn," notwithstanding all that has been written on Vine culture. This reminds me, too, in the same paper on winter raising as applied to stove plants are to my mind well worth thinking over. In your last issue, p. 84, Mr. Goodacre says he fails to see—the roots being outside—how ripe Grapes are to be had in May for one an fully persuaded that this is possible—and that for a number of years in succession—by simply adopting a similar method of early protection that mentioned by Mr. Wildsmith (see p. 20), especially if means are provided for throwing out the water, and rain, as I have done for the early Vines here for the last six or seven years, and have often regretted not having the means of warming the border, which has a north-west aspect, and only gets a thin covering to keep out frost, but experience teaches me that a hotbed is not absolutely necessary. I must here admit that I have a 4-feet border inside, which I think helps us a little, the front wall of the house being arched in the usual manner. We start steadily with the new year, and commence in June, and I have the pleasure of the editorial query at the end of the communication by Mr. Wildsmith above alluded to. This I also

hope to see satisfactorily answered. I am under the impression that where the outside border is but slightly protected, as the one just described, and having an inside border as well, the roots inside are the first to move, being in a higher temperature. I have never had ocular demonstration that it is so, but it seems reasonable to me to think that such has been the case. I remember once seeing a rod from an old Vine in a late house that had been taken through the partition into an early house adjoining, and whose shoots must have been well-nigh half-matured before any growth was visible on the other parts of the Vine. Now, supposing it had been possible to have increased the temperature of a portion of the border (which was an outside one), would it be unreasonable to expect to find the roots in the warmest part the most active? I should like to say whether or not having two sets of roots has any injurious effect upon the constitution of the Vine. *Thomas J. Crane, Gr., Logkirk, Chichester, Kent, Jan. 22*.

Orobanchae minor.—We have had quite a curiosity in our nursery here, namely, the flowering of a quantity of *Orobanchae minor*, a specimen of which I send you in this post; you will have seen it upon your Bourbadia pots, the seeds no doubt having been brought in with the loam. *William Rollison & Sons*.

Notices of Books.

M. ROTHSCHILD has lately issued a fourth edition of M. Cordier's work entitled *Les Champignons*. Those who read French will find a popular account of the organisation, physiology, reproduction and other generalities of hymenomyces fungi, together with detailed descriptions and synonyms of all those species native to France and which are of interest by reason of their useful or noxious properties. A most complete list of all the species of the genera mentioned is also given, together with excellent indices, for which the reader will be thankful. The system followed is that of Persoon. But the point of most importance to our readers in the volume before us consists in the coloured plates, chromatolithographs, sixty in number, and representing a considerable number of species, and which will be found very serviceable to amateurs. The whole forms a handsome volume, attractive and useful to beginners, for whom it is principally intended, but not complete enough in its indications and literary references for more advanced students.

— Under the title of *Forage Plants*, Mr. Thomas Christy (155, Fenchurch Street) gives an account of *Symphitum asperillum*, a well-known herbaceous plant closely allied to our wild *S. officinale*, and which is highly recommended as a forage plant by Professor Duckman and other agricultural authorities. We have no personal acquaintance with the plant as a forage plant, but if hardiness, rapid growth, abundant foliage, and facility of propagation are requisites, then this plant is likely to be very useful. We suppose the plant would do best on heavy wet soils and temperate climates. Whether it will be so suitable for hot beds, in this matter, is open to doubt, though its fleshy root-stocks will enable it to withstand the ill effects of drought. The same pamphlet contains a number of miscellaneous trade notices, amongst others of a plant-case lined with felt, and intended for the transmission of fruit and other trees to India and the colonies; and an illustration of a Chilean plant, *Cesalpinia brevifolia*, the pods of which furnish a gum used in tanning operations under the name of *Balsamocarpon*, and known also as *Algorbaba* and *Algoravilla*—names of vague and uncertain application. The gum is said to yield 80 per cent. of tannic acid, if the pods are picked before the rainy season; if allowed to remain till the rainy season the value of the gum is much impaired.

— M. Rothschild has lately published a second edition of M. Dupuis's *Les Papillons*, or Natural History of the Butterflies of Europe, a quarto volume richly illustrated with excellent woodcuts, and with fifty hand-coloured plates representing a very large quantity of species. The book is well adapted for young entomologists, and forms a handsome volume for the drawing-room table.

Reports of Societies.

Meteorological.—The annual general meeting of this Society was held on Wednesday, the 17th ult., at the Institution of Civil Engineers, Mr. H. S. Eaton, M.A., President, in the chair. The Council in their report to the Fellows expressed their satisfaction at the progress that had been made by the Society during the year. The first point on which they thought there was reason for congratulation was the publication in their *Journal* of the daily observations taken at Hawes and Stairfield Turgis, and of the monthly abstracts of the observations at thirteen other stations. The increase in the number of Fellows was considered worthy of special reference, as it is an indication not only of the vitality of the Society, but also of the advance which meteorology is now making amongst the professional and general public. They also referred with much satisfaction to the enlargement of the quarterly *Journal*, as well as to the printing of the catalogue of the library and of the list of Fellows, which have both been issued during the year. They drew special attention to the report of Mr. Symonds on the new stations which had been inspected and brought into relation with the Society. The financial position, notwithstanding the large outlays during the year, was very good. The report also contained the very interesting discussion by the Rev. T. A. Preston, M.A., of the observations on natural periodical phenomena.

The Weather.

STATE OF THE WEATHER AT BLACKHEATH, LONDON FOR THE WEEK ENDING WEDNESDAY, JAN. 31, 1877.

Jan. 25.—Overcast, fall, with occasional rain till 7 P.M.
 26.—A fine bright day. Cold. Slight fog and hoar-frost in morning.
 27.—A dull day, cool, with frequent thin rain.
 28.—Fine and cloudy, occasionally dull, with showers of rain.
 29.—Fine and clear till 2 P.M., cloudy after. A little rain fell between 2 and 4 P.M.
 30.—Overcast, with frequent heavy rain till 12 A.M. at 11 P.M. at 11 P.M. A fine and bright after. Strong gale.
 31.—Fine, but cloudy till 6 P.M. Overcast and wet after. Cool. Solar halo in morning.

LONDON: Barometer.—During the week ending Saturday, January 27, in the suburbs of London, the reading of the barometer at the Jersey sea gauge increased from 30.22 inches at the beginning of the week to 30.66 inches by the morning of the 21st, decreased to 30.13 inches by the morning of the 24th, increased to 30.19 inches by the afternoon of the same day, decreased to 30.61 inches, by the afternoon of the 25th, increased to 30.22 inches by the evening of the 26th, decreased to 30.13 inches by the afternoon of the 27th, and was 30.24 inches at the end of the week. The mean reading for the week at sea level was 30.26 inches, being 0.28 inch above that of the preceding week, and 0.21 inch above the average.
Temperature.—The highest temperatures of the air varied from 53° on the 25th to 43° on the 26th; the mean value for the week was 48°. The lowest temperatures of the air ranged from 28½° on the 27th, to 34½° on the 24th, the mean for the week was 34½°. The mean daily temperature of the water of the week was 16½°, the greatest range in the day being 20° on the 23d, 25th, and 27th, and the least 11½° on the 26th. The mean daily temperatures of the air, and the departures from their respective averages are as follows:—21st, 49°-3; 22d, 47°-1; 23d, 41°-7; 24th, 35°-8; 25th, 43°-2; 26th, 41°-4; 27th, 42°-9; 28th, 42°-9; 29th, 38°-8; 30th, 38°-8; 31st, 38°-8; 0.7° The mean temperature of the air for the week was

39°.4, being 1.7 above the average of sixty years' observations.

The highest readings of a thermometer, with blackened bulb in vacuo, placed in sun's rays, were 105° on the 23rd, and 91½° on the 21st and 24th; on the 21st was the highest reading. The lowest readings of a thermometer on the grass, with its bulb exposed to the sky, were 23° on the 27th and 23½° on the 23d; the mean value for the week was 26°.

Wind.—The direction of the wind was mostly S.W. and S., and its strength moderate. The weather during the week was somewhat fine, and frequently foggy. Lunar halos were seen on the 21st and 24th.

Rain fell on three days; the amount collected was 0.39 inch.

ENGLAND: *Temperature.*—The highest temperatures of the air observed by day were 54° at Truro and 53½° at Blackheath; at Hall 47° was the highest temperature. The mean value from all stations was 50½°. The lowest temperatures of the air observed at Liverpool were 28° at Hull and 28½° at Blackheath; at Liverpool 36½° was the lowest temperature. The general mean from all stations was 31½°. The range of temperature in the week was the greatest at Blackheath, 25½°; and the least at Liverpool, 13½°. The mean range of temperature from all stations was 17°. The mean of the seven highest day temperatures was the highest at Truro, 51½°, and the lowest at Leicester, Norwich, and Hull, all about 44½°. The mean from all stations was 47°. The mean of the seven low night temperatures was the lowest at Blackheath and Wolverhampton, both 31½°, and the highest at Truro, 41°. The mean value from all stations was 35°. The mean daily range of temperature in the week was the greatest at Blackheath, 16½°, and the least at Bradford, 7½°. The mean daily range from all stations was 11½°.

The mean temperature of the air for the week from all stations was 40½°, being the same as the value for the corresponding week in 1876. The highest was 46°, at Truro, and the lowest 38°, at both Wolverhampton and Hull.

Rains.—The fall of rain varied from three-quarters of an inch at Truro, Bristol, and Sheffield, to a quarter of an inch at both Nottingham and Sunderland. The average fall over the country was half an inch nearly.

The weather during the week was somewhat fine, but not at some places. Lunar halos were seen on four days in the week at Bristol.

SCOTLAND: *Temperature.*—The highest temperatures of the air varied from 51° at Paisley to 47½° at Edinburgh; the mean value from all stations was 48½°. The lowest temperatures of the air ranged from 31° at both Dundee and Paisley to 33° at Greenock; the general mean from all stations was 32°. The mean range of temperature from all stations was 16½°.

The mean temperature of the air for the week from all stations was 40½°, being 4° lower than the value for the corresponding week in 1876. The highest happened at Paisley, 41½°, and the lowest at Dundee, 28½°.

Rains.—The fall of rain varied from 3 inches at both Greenock and Paisley to half an inch at Leith. The average fall over the country was 1½ inch.

DUBLIN.—The highest temperature of the air was 53°, the lowest 30½°, the range 22½°, the mean 43½°, and the fall of rain 0.36 inch.

JAMES GLAISHER.

Law Notes.

IMPORTANT TO SEED MERCHANTS.—*Cross & Donaldson v. Fleming & Co.*—This case, which was heard at the Ballymena Quarter Sessions, stood over for judgment, and a few days since the Chairman (J. H. Orway, Esq., & C.), before whom the case was heard at Ballymena, delivered his judgment in the Sessions Court. The facts transpire in the Chairman's remarks below. The Chairman said this was an action for not delivering goods according to contract. The contract was by parole only. The defendant seemed cautious not to have the terms of the agreement reduced to writing. Some telegrams passed, but the Statute of Frauds was not satisfied so far as a note or memorandum was concerned. The facts were shortly these: The plaintiffs agreed to buy from the defendant 15 tons of Italian Rye-grass, upon a sample shown to them, for £150, 10s. per ton. The plaintiffs then received a bulk sample—namely, a sample taken from the bulk that they were to get. This was sent. The defendant, in his evidence before me, used the following words:—"They (the plaintiffs) bought all I had, 15 tons more or less; out of what they were to take I sent the

bulk sample." That bulk sample, which weighed 4 lb., the plaintiffs received and kept, and sent to the defendant a letter, in which they said, "The bulk sample compared, and we regret to find it hardly up to sale sample. You must see and keep up the quality in your first transaction." I consider, then, that they took and accepted the bulk sample, hoping that the large quantity, when delivered, would be perfectly equal to it. The defendant then delivered to the plaintiffs 6 tons of the article sold, which, as they swore, and by independent witnesses was proved to be inferior (for the benefit of £1 5s. a ton) to the bulk sample. After forwarding the 6 tons the defendant went to Belfast and saw the plaintiffs, who complained of the quality of the 6 tons they had received, but said they would keep them if the remaining 9 tons were, in the judgment of men most experienced and respectable in the trade, equal to the sample. The defendant said he would not accede to this, and would not leave those 6 tons he had delivered, and insisted on taking them back, which he did, notwithstanding the remonstrances of the plaintiffs, paying them £2 11s. 9d. for the carriage, which, had the contract been carried out, they would not have declined. On the same day the defendant sold the selfsame seed to a Mr. Lytle, of Belfast, at £18 a ton, there having been a very considerable rise in the market since the sale to plaintiffs, of which rise the defendant, as it seems to me, was anxious to have the benefit. The action was for the non-delivery of the goods according to the original contract. The defendant, through his counsel, relied on the Statute of Frauds—the goods being over the value of £10—and contended that, as there was no note or memorandum in writing, the action should fail. But a note or memorandum in writing is not the only mode of taking a contract out of the operation of the statute—the acceptance and receipt of part of the goods will have the same effect. By the common law, a parole sale of goods might have been in every instance effected by an agreement, coupled with a tender of payment or a delivery of part of the goods by way of earnest. And if A had agreed to pay to B, the owner, a certain sum for goods, and B had agreed to take it; if B had tendered the goods, or A the price, or B had received any part of the price, though but a penny, or A any portion, even the smallest, of the goods, both would have been bound by the bargain. Such was the law before the Statute of Frauds, and so it is still where the value of the goods is under £10, but where the value is over £10, then if there be no part payment by the vendor, or no receipt or acceptance by him of a part of the subject-matter of the sale, or no memorandum or note in writing of the terms of the sale signed by the parties or their agents, the contract is invalid. Thus the old law as to part payment by the buyer, or receipt of part of the goods by him, is retained; and if neither of those elements exist, there must be a note in writing; but if either do exist, a writing is unnecessary. Here there was no writing, no part payment, and the question is, was there a delivery and acceptance of a part? In *Hinde v. Whitehouse*, 7 East, 558, it was held, and it has never, as far as I know, been questioned, that acceptance of a sample which is to be accounted as part of the commodity sold, is sufficient to bind the parties. And on this matter I refer again to the testimony of the defendant, according to which he said, "out of what they were to take I sent the bulk sample." Now, generally speaking, the cases in which a question arises as to the effect of a delivery of goods or part of them, is where the vendor sues. If he contends that goods were received and accepted by the buyer, actually or constructively, he sues for goods sold and delivered; if he cannot sustain a case upon actual receipt and acceptance of all the goods, he sues for goods bargained and sold, and the question is, whether, upon the facts, the Statute of Frauds is satisfied. But I take it that if there was an acceptance of part of the goods sold, the statute would be satisfied. And as I think the sample in this case was part of the goods sold and, according to *Hinde v. Whitehouse*, bound the bargain, I am of opinion that if the parties were reversed, and if Messrs. Cross & Donaldson found the market had fallen, and wished to have escaped from their contract, Mr. Fleming could not have successfully set them. If that be so, there should be reciprocity, and what would bind Messrs. Cross & Donaldson to a bargain should also give them the advantage of it, and what would justify their being sued as defendants would justify their suing as plaintiffs. I confess, however, I am not aware

of an action under a similar state of facts being brought by a purchaser for the fulfilment of a contract, but my ignorance does not show that many such cases may not have existed. It is plain that if there had been a contract in writing the plaintiffs here could have sued, and the Statute of Frauds makes the delivery and acceptance of part equivalent to a writing. Upon principle, then, I think the action can be maintained. It was once thought, and many cases seem to support the opinion, that there can be no acceptance within the Statute of Frauds unless the buyer is proved from objecting that the vendor has not fully performed the contract on his part. But the very well considered case of *Morton v. Turbit*, 152 B. & 423 and 14 J. 669, has dissipated that doctrine and established that there may be an acceptance of goods sufficient to make a contract valid within the meaning of the Statute of Frauds without the buyer having precluded himself from contending that they did not correspond with the sample, and the same doctrine it recognised and adopted, especially in the very recent case of *Mr. Justice Brett* in the judgment case of *Grinoldy v. Wells*, 9th Rep. law report of Common Pleas. In the case of *Morton v. Turbit*, before Lord Campbell in the Common Pleas, after mentioning the sufficiency of part payment to bind the vendee, his Lordship said—"The same effect is given to the corresponding act by the vendor if he shall deliver part of the goods sold to the buyer, and if the buyer shall accept such part and actually receive the same. As part payment," he continued, "however minute the sum may be, is sufficient, so part delivery, however minute the portion may be, is sufficient." I am (for the reason I have given) therefore of opinion that the plaintiffs are entitled to recover, and I shall give a decree in their favour, as it is accorded with the truth and honour of the case. As I said before, the very same seed was sold at the rate of £18 per ton (making a difference of £2 10s. a ton) on the day the plaintiffs objected to the 6 tons delivered to them. The plaintiffs would then have to pay for seed inferior to the sample they purchased by £37 10s., and the difference in value between the sample and seed delivered by the defendant was proved to be £1 5s. a ton, which, if added to the £37 10s., would greatly exceed my jurisdiction. I decree for £40. *Northern Whig.*

Enquiries.

Has that questionist much shall learn much.—BACON.

166. ORCHARD GRAPE GRASS.—Will any of your readers say if they know the "Orchard Grape Grass" of America? We generally understand, when our correspondents mention "Orchard Grass," they mean "Cocksfoot," or *Dactylis glomerata*. K. O. F.

Answers to Correspondents.

BOX HEDGE: C. D. Your Box hedge, 3 feet high, should transpire readily enough, if done with proper care. The Box is a free-rooting species, preferring a calcareous soil. If done in dry weather the plants should be well watered.

DENDROBATHY SIMPSONIUM: T. C. Your plant is *Dendrobathrum Simpsonii*, but not so fine a variety as that figured last week.

FICUS COOPERI: *Constant Reader*. The plant was introduced by Mr. W. Swinney, and was understood to be from the South Sea Islands. It fruits occasionally when grown under glass. It was named after Sir Daniel Cooper, who brought it home.

GOOYEYER DISCOLORE: J. H. Pot in chopped sphagnum and broken lumps of light peat earth, with good drainage below.

GRAPEF FOR INARCHING: A. B. P. Black Hamburg and Royal Muscadine.

MANETTI ROSES: H. E. We presume you mean to inquire how low these should be worked. Certainly close to the ground.

NAMES OF BURLAP: E. Hall. Your Grape is the same as a variety grown in the Royal Horticultural Gardens, Chiswick, under the name of Large Black Fernal. It seldom becomes black, however, in this country, and is not of much value.

NAMES OF PLANTS: *John Illman*. The spotted variety of *Trifolium repens*, or some closely allied species.—*L. E. C.* *Cenothus nuceus*, is *Garrya elliptica*.—*Mrs. C. M.* We do not recognise the Acorn, nor do we believe you will succeed in getting them to grow, as Acorns do not long retain their vitality.—*Mrs. W. C.* *Thysanotus rutillaris*; *s.* *Asplenium obtusatum*.—*A. B.* *Aster carneus* var.—*Hoyer*. *Statice fruticosa* probably, but the specimen was too poor to determine it exactly.—*W. B.* *Griselinia littoralis*.

POPLAR SCREEN; *Subscriber*. As a screen 12 feet high, quickly formed, to hide some cottages, you can

Roshers Garden Edging Tiles.

THE ABOVE and many other PATTERNS are made in materials of great durability. The plainest sorts are especially suited for KITCHEN GARDENS, as they harbour no Slugs or Insects, take up little room, and, once put down, incur no further labour or expense, as do "grown" Edgings, consequently being much cheaper. GARDEN VASES, FOUNTAINS, &c., in Artificial Stone, very durable and of superior finish, and in great variety of design. F. ROSHER AND CO., Manufacturers, Upper Ground Street, Blackfriars, S.E.; King's Road, Chelsea, S.W.; Kingsland Road, E.

Agents for LOOKER'S PATENT "ACME FRAMES" PLANT COVERS and PROPAGATING BOXES; also for FOXLEY'S PATENT BEADED GARDEN WALL BRICKS.

Illustrated Price Lists free by post. The Trade supplied.

ORNAMENTAL PAVING TILES, for Conservatories, Halls, Corridors, Balconies, &c., from 3s. per square yard upwards. Pattern Sheets, of plain or more elaborate designs, with prices, sent for selection.

WHITE GLAZED TILES, for Lining Walls of Dairies, Larders, Kitchen Ranges, Baths, &c. Grooved and other Suitable Paving of great durability, Wall Copings, Drain Pipes and Tiles of all kinds. Roofing Tiles in great variety. Slates, Cement, &c. F. ROSHER AND CO., Brick and Tile Merchants. See addresses above.

SILVERSAND, fine or coarse grass as desired. Prices by Post per ton or truck-load, on Wharf in London, or delivered direct from Pits to any Railway Station. Samples of Sand free by post.

FILTS and BRICK BURKS for Root-crocks or Ferneries. **KENT PEATS or LOAM** supplied at lowest rates in any quantities.

F. ROSHER AND CO.—Addresses see above. N.B.—Orders promptly executed by Rail or to Wharves. A liberal Discount to the Trade.

SHAW'S TIFFANY, ELASTIC NETTING, CANVAS, &c., for Shading, Protecting, and other Horticultural Purposes. For Samples and Prices apply to JOHN SHAW AND CO., 20, Oxford Street, Manchester.

Metallic Hothouse Builder to Her Majesty. HENRY HOPE (late Clark & Hope, formerly Clark).

HOTHOUSE BUILDER and HOT-WATER APPARATUS ENGINEER. 55, Lionel Street, Birmingham. Established A.D. 1818. BOOKS of DESIGNS, 2s. each.

For the Extensive Ranges of Metallic Hoouses in the Royal Gardens, Windsor and Osborne, were executed at this Establishment.

Indestructible Terra-Cotta Plant Markers.

MAW AND CO'S PATENT.—Prices, in Printed Patterns, and Specimens, sent post-free on application; also Patterns of Ornamental Tile Pavements for Conservatories, Entrance Halls, &c. MAW AND CO., Benthall Works, Broseley.

RUSSIA MATS, for Covering Garden Frames—ANDERSON'S TAGANROG MATS are the cheapest and most durable. Price List, which gives the size of every class of Mat, forwarded post-free on application. JAS. T. ANDERSON, 7, Commercial Street, Shoreditch, London, E.C.

RUSSIA MATS.—A large stock of Archangel and Petersburg, for Covering and Packing (price on application for Archangel)—Petersburg, 60s. to 100s. per 100; superior close-wove, 40s., 50s. and 55s. per 100; Packing Mats at 30s., 30s., and 35s. per 100; and all other descriptions of Mats at equally low rates, at J. BLACKBURN AND SONS, 4 and 5, Wortwood Street, London, E.C.

RUSSIA MATS, for Covering from Frost, from 30s. to 70s. per 100; packing from 30s. GUNNY BAGS, from 3d. each, delivered free to any Station in London. SUTHERLAND, SON AND CO., 11, Fenchurch Buildings, Fenchurch Street, London, E.

RUSSIA MAT MERCHANTS.—Seedsmen, Growers and other Buyers, can have the Wholesale sale Prices for ARCHANGEL and all kinds of PETERSBURG MATS, RAFFIA MATS, &c., on application to MARENDAZ AND FISHER, James Street, Covent Garden, London, W.C.

MATS.—Archangel, Petersburg, Packing RAFFIA for tying. TRAINING STICKS, BAMBOO CANES, &c. Before purchasing send for prices to C. J. BLACKBURN & CO., Cox's Quay, Lower Thames Street, London, E.

Oil Paint No Longer Necessary.

HILL AND SMITH'S BLACK VARNISH for Preserving Ironwork, Wood, or Stone. This Varnish is an excellent substitute for oil paints on all outdoor work, while it is fully two-thirds cheaper. It was introduced upwards of thirty years ago by the advertiser, and its genuine good quality, notwithstanding a host of unprincipled imitators, is fully attested by its constantly increasing sale. It may be applied by an ordinary labourer, requires no mixing or thinning, and is used cold. It is used in the grounds at Windsor Castle, Kew Gardens, and at the seats of many hundreds of the Nobility and Gentry, from whom the most flattering testimonials have been received, which HILL & SMITH will forward on application.

Sold in casks of about 30 gallons each, at 2s. 6d. per gallon, at the Manufactory, or 1s. 8d. per gallon carriage paid to any Station in the Kingdom.

UNSOLICITED TESTIMONIAL.

Glanville, Llanwunwan, Carmarthen, Nov. 27, 1873.—"Mr. Lloyd Lloyd, encloses cheque for £1 5s., amount due to Messrs. Hill & Smith, and he considers the Black Varnish one of the most useful things he ever possessed."

Apply to HILL and SMITH, Brerly Hill Ironworks, near Dudley, and 116, Queen Victoria Street, London, E.C., from whom only it can be obtained.

CAUTION.—It having lately come to the knowledge of HILL & SMITH that spurious imitations of this Varnish are being offered by unprincipled dealers at a slight reduction in price, they would especially draw attention to the fact that every cask of their Varnish is legibly marked with their name and address, without which none is genuine.

PATENT "EXCELSIOR" BOILER (1871).

("WITLEY COURT" BOILER.)
"WITLEY COURT" BOILER (Silver Medal 1872).
"TRENTHAM IMPROVED" BOILER, with Water-way End and Smoke Consumer.
"TUBULAR," and every other Boiler of known merit or excellence.
Prize Medal Awarded at the National Contest, Birmingham, 1874.

The largest and most complete Stock in the Trade; upwards of Twenty Thousand Pounds worth to choose from.
MILL'S PATENT AUXILIARY FUEL ECONOMISER, Which can be attached to any ordinary Boiler. These Tubes are the greatest Economisers of Fuel and Preservatives of Boilers, Fire-Brass, and Furnace Fronts ever yet introduced to the public.
STAINTON'S NEW PATENT FROST DEIVING LIQUID (see "*Gardener's Chronicle*," Aug. 19, 1876).
HOT-WATER APPARATUS ERECTED COMPLETE.
PRICE LIST on application; or, Six Stamps for DESCRIPTIVE CATALOGUE, 4th Edition.

CRITCHLEY'S PATENT HEAT REGULATOR,
AN APPARATUS FOR REGULATING THE HEAT IN HORTICULTURAL BUILDINGS.

A, Iron Box fitted up water-tight. B, Pipe for Supply of Water from Boiler. C, D, Pipes for Circulating Hot-Water. E, F, Pipes for Return of Water to Iron Box. G, Pipe for Returning Water to Boiler. H, I, J, K, Piston-Rods for Opening and Closing Valves.

The advantages of these Regulators are that houses may be kept at different degrees of heat, or the circulation of water and heat entirely stopped in one part and not in others. They may be fitted with as many valves as required, and are particularly adapted for forcing houses where top and bottom heat is used. They may be fixed in any part of the apparatus most suitable for working, without regard to the position of the boiler.

The following Testimonial has been received:—

"Berkeley Castle, April 13, 1875.
"Gentlemen,—I am happy to inform you, now that the late severe winter is past, that the Hot-Water Apparatus erected by you is doing its work to my entire satisfaction. As to the two Heat Regulators, which represent thirty valves, I have had ample opportunities of practically proving them, and unhesitatingly admit they are far superior to any other valve; in fact, I think it the greatest improvement that has come out for horticultural purposes."
"I am, Gentlemen, yours truly,
"R. H. CROOK,
"Gardener to the Right Hon. Lord Fitzhardinge."

Estimates and Plans furnished for Warming Gentlemen's Mansions and Public Buildings. Orders attended to in any part of the kingdom, and guaranteed to answer their intended purposes. Prospectus and Price Lists post-free.

ELISHA T. ARCHER, only Maker of "Frige Domo," Brockley Road, Forest Hill, London, S. E., and of all Florists and Seedsmen. All goods carriage paid to London.

NOTICE—REMOVED FROM 3, CANNON STREET, CITY.

R. HOLLIDAY, PRACTICAL WIREWORKER,
24, Portobello Terrace, Notting Hill Gate, London, W., begs to call the attention of all Gardeners who are about to have their Garden Walls wired to his system of Wiring Walls, as being superior to all others for neatness, strength, and durability.

FOR NEATNESS—Because all the Wires are kept perfectly tight, without the use of the Raddisair.

FOR STRENGTH—Because very much stronger Wire can be used, therefore not liable to be drawn out of the horizontal line by the branches of trees.

FOR DURABILITY—Because, being able to use the strong Wire, it is not so likely to be eaten through with the galvanism as the thin Wire, as used in the French system.

The above engraving is an Example of our system of Wiring Garden Walls. We have recently completed the Wiring of the New Garden Walls for the Marquis of Salisbury, Hatfield House. The Walls are 12 feet high and 750 yards long, wired on both sides; making a total length of 1500 yards—our system being chosen in preference to any other.

Illustrated Catalogues of Garden and Conservatory Wirework, Rabbit-proof Hurdle Fencing, &c., may be had on application as above.

HORTICULTURAL WINDOW GLASS.

A large variety of sizes, 15 0/2, 12 0/2, 6 1/2, 21 0/2, 16 0/2, 6d. per 100 feet. Large sizes, in Cases, for Cutting up, 15 0/2, 4ths, 3/6; 3/4, 4/6; per 100 feet. 2 1/2, 0/2, 4ths, 3/6; 3/6, 6d. per 100 feet. Prices forwarded for large and special quantities.

J. SMITH, The Royal Label Factory, Stratford-on-Avon.

LONDON and COUNTY BANKING COMPANY.

Established in 1836, and incorporated in 1874 under "The Companies' Act, 1862."

Subscribed Capital—£5,750,000, in 75,000 Shares of £50 each.

REPORT ADOPTED at the ANNUAL GENERAL MEETING, February 4, 1877.

ABRAHAM HUGHES PHILLIPOTS, Esq., in the Chair.

The Directors, in submitting to the Proprietors the Balance Sheet of the Bank for the Half-year ended December 31 last, have to report that after paying interest to Customers and all charges, allowing for rebate and making provision for Bad and Doubtful Debts, the Net Profits amount to £105,447 6s.

This sum, added to £25,770 2s. 3d., brought forward from the last account, produces a total of £131,217 8s. 3d.

The recommended dividend of a Dividend of 8 Per cent. on the half-year, which will absorb £15,000, leaving a balance of £116,217 8s. 3d. to be carried forward to Profit and Loss New Account.

The present Dividend added that paid to June 30 makes 16 per cent. for the year 1876.

The Directors retiring by rotation are James Carter, Esq., Edward Leachford Lambington, Esq., and William Henry Smea, Esq., who, being eligible, offer themselves for re-election.

By the retirement of Stephen Symonds, Esq., on account of ill-health, there is a vacancy in the Auditorship, which it is in the power of the meeting to fill up.

The Dividend, £1 12s. per Share, free of Income Tax, will be payable at the Head Office, or at any of the Branches, on or after Monday, 17th instant.

BALANCE SHEET OF THE LONDON AND COUNTY BANKING COMPANY, DECEMBER 31, 1876.

Table with 5 columns: Description, £, s., d., £, s., d. Includes Capital paid up, Reserve Fund, Customers' Balances, Profit and Loss Balance, Cash on hand, Investments, Government and Municipal Stocks, Colonial Government and other Stocks, Discounted Bills, Liabilities to Customers, and Profit and Loss Account.

CA. PROFIT AND LOSS ACCOUNT.

Table with 5 columns: Description, £, s., d., £, s., d. Includes Interest paid to Customers, Dividend of 8 per cent, Balance carried forward.

Dr. Balance brought forward from Last Account, Gross Profit for the Half-year, after making provision for Bad and Doubtful Debts.

Table with 5 columns: Description, £, s., d., £, s., d. Includes Gross Profit, Balance carried forward.

We, the undersigned, have examined the foregoing Balance Sheet, and have found the same to be correct.

(Signed) WILLIAM NORMAN, RICHARD H. SWAINE, Auditors.

By Order, GEO. GOUGH, Secretary, London and County Bank, January 25, 1877.

London and County Banking Company.

NOTICE IS HEREBY GIVEN that a DIVIDEND on the CAPITAL of the COMPANY, at the rate of 8 per cent. on the Half-year ended December 31, 1876, will be PAYABLE to the Proprietors, either at the Head Office, 21, Lombard Street, or at any of the Company's Branches, on or after Monday, 17th instant.

By order of the Board, W. McKEWEN, General Manager, 21, Lombard Street, February 3, 1877.

BEG TO ANNOUNCE THAT, IN CONSEQUENCE OF THE

RETIREMENT OF MR. JOHN LEE

from the Business, they have taken over the entire NURSERY and SEED TRADE so successfully carried on for many years by the late Firm, and they trust the same liberal patronage so long given to Messrs. JOHN & CHARLES LEE will be continued to the New Firm.

CHARLES LEE & SON

pledge themselves to devote all their energy to Raising First-class Stock in every Department, which the large resources at their command will enable them to supply with considerable advantage to the Public both as regards quality and price.

With a view to a more extensive production of STOVE and GREENHOUSE PLANTS of the best quality they intend to almost entirely rebuild their extensive ranges of glass on a new site, a portion of the old Nursery being taken up for building purposes.

All Orders to be addressed to

CHARLES LEE & SON,

ROYAL VINEYARD NURSERY, HAMMERSMITH, W.,

where the general business of the Nursery and Seed Trade will be carried on; or to

Mr. DIXON, Feltham Nursery,

Mr. CANNON, Ealing Nursery,

Mr. WEBB, Arboretum,

Mr. MARSLÉN, Wood Lane,

} Isleworth.

Messrs. W. TAIT & Co., Seed and Nursery Establishment, 45, Chapel Street, Dublin.

Roses, Fruit Trees, Evergreens, &c. WILLIAM FLETCHER'S CATALOGUE is now ready, and may be had post-free on application. The Nursery Stock generally is very fine, healthy, and well-rooted. Early orders are respectfully solicited. Ottershaw Nurseries, Chertsey, Surrey.

Special Culture of Fruit Trees and Roses. THE DESCRIPTIVE and ILLUSTRATED CATALOGUE of FRUITS (by THOMAS RIVERS) is now ready; also CATALOGUE of SELECT ROSES. Post-free on application. THOMAS RIVERS and SON, Sawbridgeworth, Herts.

Beautiful Lilies. MR. WILLIAM BULL has received an importation of the following choice Indian Lilies:— LILIU M NEILGHERRENSE.—The white flowers of this magnificent Lily are deliciously fragrant, and of great substance. It bears several flowers on a stem, each flower nearly a foot long. 7s. 6d. and 10s. 6d. each. LILIU M NEILGHERRENSE ROSA.—The exterior of the flower-tubes of this variety is pink, the interior white. 2s. and 3s. 6d. each. LILIU M NEILGHERRENSE FLAVUM.—A handsome light yellow-coloured form of this charming Lily. 10s. 6d. and 15s. each. LILIU M NEILGHERRENSE TUBIFLORUM.—A magnificent pure white Lily, with very long flowers, figured in Wight's Icones Plantarum India Orientalis. 10s. 6d. and 15s. each. LILIU M NEILGHERRENSE TUBIFLORUM LUTEUM.—A very handsome yellow-flowered variety of tubiflorum. 10s. 6d. and 15s. each. And from California splendid flowering bulbs of various choice LILIES, including Glorionium, ocellatum, parviflorum, Humboldtii, pardalium, parvum, and californicum. Also a quantity of CHOICE BULBS of the BECKERS of Calochortis, Lycobotrys, Arabidopsis, Tricorys, Calliparas, Erythronium, Bloomeria, &c.; and some fine flowering Bulbs of the handsome Chinese Iris, including C. australis, L. pretense, caucasicum, tuberosum-rooted Begonias, Fancitium, Amyallus, North American Cyperidium, with a variety of other Bulbs and Tubers. Establishment for New and Rare Plants, King's Road, Chelsea, London, S.W.

VEITCH'S SELF-PROTECTING AUTUMN BROCCOLI.

JAMES VEITCH & SONS HAVE MUCH PLEASURE IN DIRECTING ATTENTION TO THIS VERY VALUABLE BROCCOLI FOR AUTUMN AND EARLY WINTER USE. This Plant is of robust but upright growth, and the heads, which are beautifully white, firm, and compact, are thoroughly protected by the foliage, and remain a long time fit for use. It will be found extremely valuable as a succession to our Autumn Giant Cauliflower, which has met with so much approval, and is now an established favourite in all gardens.

The Plant is of robust but upright growth, and the heads, which are beautifully white, firm, and compact, are thoroughly protected by the foliage, and remain a long time fit for use. It will be found extremely valuable as a succession to our Autumn Giant Cauliflower, which has met with so much approval, and is now an established favourite in all gardens.

Mr. WESTCOTT, Gr., Raby Castle, writing Nov. 21, says:—"I am now commencing to cut some splendid heads of the new Broccoli you sent me for trial. It is evidently a variety distinct from any one I am acquainted with, and from its splendid protecting habit, short and immensely hard woody stem, I am under the impression it will stand unharmed many degrees warmer water. The plants are of immense strength, and the heads, both in size, texture, and odour, all that can be desired."

Mr. PERKINS, Gr. to Lord Heniker, Thorsham Hall, says:—"It comes in just as the Autumn Giant, and other Cauliflowers are going out, and is, therefore, most invaluable. It is quite distinct, and also wonderfully self-protecting; some rows of it at this place withstood 13° of frost last night, November 21, 1876. Wherever a long succession of Cauliflower is required this must be the one for late use."

Mr. JAMES ADAMSON, Brynkinnell, writing in the "Journal of Horticulture" of January 4, says:—"This variety of Broccoli seems to me to be quite distinct from any other I know, and, like the Autumn Giant Cauliflower, is a grand acquisition to our list of autumn and early winter vegetables. The stem is short and stout, the head well protected, close, and compact, and of excellent size for table use. I cut the first early in November, and am still cutting."

(December 22). We had no frost in November, and while numbers of Autumn Giant Cauliflowers were destroyed, this Broccoli was unharmed. To those who have not grown it this past season I would say—do so next, and you will not be disappointed."

Mr. MCINDOR, The Gardens, Hexton Hall, Gainsborough, December 29, 1876.—"I beg to take this opportunity of congratulating you upon sending out such a splendid acquisition as your Self-protecting Autumn Broccoli, which I am sure to be, for many years. In June last we planted-out 300, which began to be ready for cutting about the middle of November, and from that date until now we have been cutting from six to ten heads daily. Where vegetables are wanted in quantity during November and December, no grower will be safe without this choice Broccoli."

Mr. W. JOHNSON, Bayham Abbey, writing to the "Gardener's Chronicle" of December 20, 1876.—"At this season of the year Cauliflowers are in constant demand, and to find a reliable variety that will fall-in from the middle of November onwards is a great boon to gardeners. In this matter we have Veitch's Self-protecting Autumn Broccoli, a gem of the first water, and I think it requires nothing further from me than to say it is simply unique."

Price 1s. 6d. per Packet.

SEED CATALOGUE now ready, and will be forwarded post-free on application. ROYAL EXOTIC NURSERY, KING'S ROAD, CHELSEA, LONDON, S.W.

JEFFERIES' LITTLE QUEEN COS LETTUCE,

Per Packet, 1s. 6d., Is the Earliest, Best Flavouring and Best Coloured Lettuce in cultivation.

MR. FARLEY, The Gardens, Valentines, says:—"Your Little Queen Lettuce proved a good selection, although the weather was very adverse to the trial." MR. MEADES, Gr. to the Rt. Hon. Viscount Barrington, Becket Park, says:—"Your Little Queen Lettuce is a capital variety, as hard as a stone, and has kept well from running to seed this dry summer."

MR. FARR, Gr. to Sir R. Knightley, Bart, Fawley Park, says:—"Your little Lettuce has proved a very useful one, although the season has been very trying for that class of stuff; its early hearting and crisp sweet flavour are sufficiently recommended to all who are desirous of a small but good Lettuce."

A Packet of this excellent Lettuce will be included in all our Collections of Vegetable Seeds.

JEFFERIES' HALF GUINEA COLLECTION OF VEGETABLE SEEDS, JEFFERIES' GUINEA COLLECTION OF VEGETABLE SEEDS, JEFFERIES' TWO GUINEA COLLECTION OF VEGETABLE SEEDS, JEFFERIES' THREE GUINEA COLLECTION OF VEGETABLE SEEDS, Are the best obtainable. For particulars, obtain our "Illustrated Garden Guide."

APPLES, strong 3-yr. Palmettes and Pyramids, 42s. per 100, 60s. per 200.
HARDY PALMS at the lowest prices.

Presented (by post) on application,
NEW CATALOGUE for 1877.

MESSRS. CLIBRAN AND SON will have great pleasure in sending their PRICED DESCRIPTIVE LIST for this Spring, free by post on application. Their stock of Flower Flowers, Fencing and Saw-wooded Plants generally, are surpassed by few, if any, either in extent or quality, all the newest and best varieties being constantly on hand, and the most correct care is taken to keep the varieties true to name. Another great advantage is, that none of the plants offered are taken directly from a warm springhouse, but are all carefully hardened and most of them potted off singly, and either fitted to travel by rail or post without the slightest injury. A great proportion are autumn-stock plants, and many of the undermentioned can be sent by post—

- Abutilons, in variety, 3s. 6d. per dozen.
- Adonis, in variety, 3s. 6d. per dozen.
- Ageratum, in variety, 8s. 6d. per dozen.
- Agrostis, in variety, 3s. 6d. per dozen.
- Camellias, 30s. and 42s. per dozen.

- HYDRANGEA**, from named collection, 1s. and 2s. 6d.
- FRIMROSE**, POLYANTHUS, and ONLIP, best quality, 1s. 6d. per dozen.
- WALLFLOWER**, double German, mixed colors, 6d. and 1s.

NOVELTIES IN FLOWER SEEDS.

- ALONSO ALEIFLORA**.—New distinct species from Mexico, introduced by Mr. Roel, the distinguished collector, flowering freely, from 12 inches up to 2 feet in height, producing long terminal spikes of pure white flowers with yellow eye. It is recommended for pot-culture, as it will continue to flower a long time after the first flowers through the autumn and winter when most acceptable for bouquets and table-decoration, producing its bloom in terminal spikes. It will be found a desirable and useful substitute for Lily of the Valley, as used in our bouquets with so charming an effect when arranged as to overtop the other flowers by 1 or 2 feet.
- BROWALLIA ROEHLII**, 1s. COBEA HIRSUATA, 2s. 6d.
- HUMEA ELZEANS ALEA**, 1s. AGERATUM SNOW-FLAKE, 1s.
- MIMULUS BRILLANTISSIMA**, seedling, 1s.
- PELVIA OKANA**, fine plant (see description in Catalogue), 1s.
- TORENIA POUKIERI**, new annual form of this beautiful collection of colours, 1s.
- ERYNGIUM LEAVENWORTHII**, ornamental plant, 1s.
- PERYETHEM ACRUM LACINIATUM**, fringed-leaved Feather, 2s.
- ASTER**, Firelight, most beautiful and brilliant new quilled variety, 2s.
- SAXIFERA NEPALENSIS**, fine ornamental species for pot culture, 1s.
- PAPAVER UMBROSA**, show flowers, 2s.
- LAIATRIS PICOINACHYA**, 2s.
- CANTERBURY BELLS**, double frilled flowers, beautiful variety of colors, 1s.
- CUPHEA ROEHLII**, 1s. **BAMBUSIA GRACILIS**, 2s.

PINE-APPLE NURSERY, MAIDA VALE, LONDON, W.

New and Choice Seeds for 1877.

J. SCOTT'S Priced Descriptive ILLUSTRATED CATALOGUE of 55 pages will be forwarded to all applicants. It contains much useful and reliable information to Amateurs.

JOHN SCOTT,
 The Royal Seed Stores, Yeovil.

GROS GUILLAUME GRAPE
 (Roberts' Variety).

The largest Grape in Cultivation.
 Eyes or Scions from fine, strong, well-ripened wood, 20s. 6d. each
 Ditto ditto ditto second size 7s. 6d. 1/2

For particulars of this remarkable New Grape see *Gardener's Chronicle* of January 29, pages 102 and 119, or apply to

Messrs. W. TAIT & CO.,
 SEED AND NURSERY ESTABLISHMENT,
 45, CAPEL STREET, DUBLIN.

CHARLES LEE AND SON (Successors to Messrs. John & Charles Lee), of the Royal Vineyard Nursery, Hammersmith, W., beg to announce that in consequence of the Retirement of Mr. John Lee from the business, they have TAKEN OVER the ENTIRE NURSERY and SEED TRADE, so successfully carried on for many years by the late Firm, and they trust the same liberal patronage so long given to Messrs. John & Charles Lee will be continued to the New Firm.

Charles Lee & Son pledge themselves to devote all their energy to raising First-class Stock in every department, which will be large raised with the most careful and able hands, to supply with considerable advantage to the Public both as regards quality and price. With a view to a more extensive production of Stove and Greenhouse Plants of the best quality they intend to almost entirely rebuild their extensive ranges of glass on the site, a portion of the old buildings to be taken up for building purposes. All orders to be addressed to

CHARLES LEE AND SON, Royal Vineyard Nursery, Hammersmith, W. All orders to be sent to Charles Lee and Son will be carried on; or to Mr. DIXON, Feltham Nursery, Mr. M. CANNON, Ealing Nursery, Mr. W. E. BOREHAM, Weymouth Nursery, Wood Lane, Islington.

Special Offer to Builders and Others.

JAMES GRANT, Bridge Nursery, Barnes, S.W.—LURELS, common, 1s. to 1s. 6d. PRITTS, broad-leaved, 3s. to 5s.; sempervirens, 3s. to 4s. LILACS, common, 4s. to 6s.; grandiflora, 4s. to 6s.; white, 4s. to 6s. FRUITS, 1s. to 1s. 6d. CURRANTS, Red Grape, per 100. JHYME, common, per 100; Lemon, per 100. For prices apply above.

RALPH ROBSON, NURSERYMAN, Hexham.

Has to offer the following—
LARCH, Native, 1-yr. seedling, fine.
ASH, 2-yr., 27s. 1/2 to 18s. 6d. fine.
POPLAR, British, 12 to 15 feet, fine.
GOOSEBERRY BUSHES, Lancashire varieties, FRUIT, 10s. to 15s. per dozen, standard.
 All the above are fine bush stuff, and well grown. Prices on application.

G. DOWNS, Bagshot, Surrey, can supply,

- PINUS LARICIO**, 3-yr. seedling, 10s. per 1000.
- FIR**, Spruce, 6 to 10 inches, bedded, 1s. 6d. per 1000.
- PINE-APPLES**, 12 to 15 inches, bedded, 12s. 6d. per 1000.
- HOLLIES**, Green, 2 feet, 15s. per 1000.
- SHEDDING**, 6d. 10s. per dozen.
- RHODODENDRUM**, 1 foot, 2s. 6d. per dozen.
- AZALEA PONTICA**, 1 to 1½ feet, 3s. 6d. per dozen.
- ABIES ORIENTALIS**, 1 to 1½ feet, 2s. per dozen.
- GOOSEBERRIES**, of sorts, 2s. per dozen.
- CURRANTS**, of sorts, 2s. per dozen.
- PEARS**, Pyramid, in seedling state, 9s. per dozen.

No charge for packing.

HENDER AND SONS, Bedford Nursery,

Plymouth, beg to offer Seed of their strain of Large-flowering PETUNIAS, which is the finest in the world. Size, 1s. to 2s. per packet. 1s. per packet. None genuine unless bearing our seal, "Hender & Sons."

By Mr. W. PATTERSON, *Gardener to Her Majesty the Queen, Balmore, Perthshire*, *Journal of Horticulture*, says: "Your Petunias are very fine; indeed they are the finest strain of seedlings I have ever seen, and if the merits were fully known to the public you would be the first to take for sale for ever."
 "I never saw a finer strain of Petunias in all my experience."
 —J. KEWES, *Secretary*.

"The Petunias I had for you were splendid, and greatly admired by thousands who visited Kensington Park." —J. Knowles, *Acting House*.

"Your Petunias are quite as new, many blooms measuring 4½ inches across, of the most brilliant colors imaginable; the markings are endless, and each plant is a distinct variety, and of very high percentage of double flowers." —G. JARLEY, *Florist, Newmarket, Berks*.

"Colors beautifully blended, a peach or rose color, with white lines spotted with red, &c., &c., reminding one of a leuciscolous." —J. BURY, *Examiner*.

"A very superior strain of striped and blotched varieties, in every way the finest we have seen." —*Gardener's Chronicle*.

"The flowers are of fine form, good substance, various and pure in their colours." —*Gardener's Magazine*.

"Fine Bold flowers, with white ground, striped and flaked with purple and crimson." —*The Garden*.

"We have fifty flowers of Hender's seedling Petunias, each a distinct variety, large, each strikingly and beautifully coloured." —*Journal*.

"The extraordinary size and exquisite blending of colour is truly astonishing." —Rev. H. A. Cressy, *Marchant, Tiverton*

Super Stock—all Transplanted.

- R. W. PROCTOR** has to offer the following—
 FIR, Spruce, 6 to 10 inches, bedded, 2s. per 1000.
 CHESTNUTS, Spanish, 1 foot, 20s. per 1000.
 PINUS LARICIO, 3-yr. seedling, 10s. per 1000.
 ABIES ORIENTALIS, 1 foot, 20s. per 1000.
 HOLLIES, Green, 1 foot, 20s. per 1000.
 BERRIES, 15s. per 1000, 20s. per 1000.
- Super Stock—all Transplanted.**
 R. W. PROCTOR has to offer the following—
 ASH, Weeping, 2 to 3 feet, 20s. per dozen.
 BERRBERIS DULCIS, 2½ to 3½ feet, 7s. 6d. per 100.
 CHESTNUT, Horse, 1 to 1½ feet, 20s. per 1000.
 HOLLY, Common, bushy and well rooted, 1½ to 2 feet, 2s. per 100; 2 to 2½ feet, 3s. per 100.
 LAUREL, Common, 2 to 3 feet, 15s. to 1s. 6d. per 100.
 LAUREL, Common, 3 to 4 feet, 20s. per 100.
 LAUREL, 1 to 2 feet, 20s. per 100.
 MYRTLE, 1 to 2 feet, 20s. per 100.
 POPLAR, Balsam, 1 to 1½ feet, 9s. per dozen.
 SYCAMORE, 1 to 1½ feet, 20s. per 1000.
 WEEPING WILLOW (American), Standards, 12s. per dozen.
 FIKVET, Box-leaved, very stiff and bushy, 2 to 2½ feet, 20s. per 1000.
 Evergreen, 2 to 3 feet, 20s. per 1000.
 OVALIFOLIUM, very bushy, 2½ to 3½ feet, 3s. 6d. per 1000.
 PINUS STROBUS, 9s. Weymouth, well furnished plants, 7 to 8 feet, 20s. per 1000.
 The Nurseries, Ashgate Road, Chertsefield.

THE BEST BUILT HOTHOUSES, CONSERVATORIES, &c., AT THE LOWEST PRICES.

Plans and Estimates given for Horticultural Buildings of every description, either in Wood or Iron.
H. Ormson's Work, on an extensive scale, both Building and Heating, may be seen at the Royal Gardens, Kew,
and at many of the Seats of the Nobility and Gentry throughout the Country.

CAST-IRON AND SLATE FOUNDATIONS, IF PREFERRED TO BRICKWORK.

PLAIN AND INEXPENSIVE HOTHOUSES

Designed and Built with a strict regard to Economy in Price, the best of Materials and Workmanship, and Practical Adaptation.

ORMSON'S PATENT TUBULAR CORNISH BOILER and Ormson's Patent Divisional Hot-water Apparatus
SURPASS ALL OTHER SYSTEMS OF HEATING BY HOT-WATER.

HOT-WATER PIPES, BOILERS, &c., AT WHOLESALE PRICES.

Surveys made and Gentlemen waited on in any part of the Country. Plans and Estimates on application. Tenders from Drawings prepared by Architects.

HENRY ORMSON,
HORTICULTURAL BUILDER and HOT-WATER APPARATUS ENGINEER,
STANLEY BRIDGE, KING'S ROAD, CHELSEA, LONDON, S.W.

T. H. P. DENNIS & COMPANY.

Motto, "Art with Economy" as applied to Conservatories.

HORTICULTURAL BUILDINGS OF ALL DESCRIPTIONS & HOT-WATER HEATING APPARATUS
ERECTED AND FITTED IN ALL PARTS OF THE KINGDOM. ESTIMATES GRATIS.

Show Rooms: MANSION HOUSE BUILDINGS, LONDON, E.C.,
where full-sized Specimens of Greenhouses, &c., and Hot-water Apparatus at work can be inspected.

Works: CHELMSFORD.

ESTABLISHED

A CENTURY.

NOW READY,

WM. ROLLISSON & SONS'

NEW AND GENUINE

Flower Seeds, Vegetable Seeds, Farm Seeds,

CAREFULLY SELECTED FROM

THE BEST ENGLISH AND FOREIGN STOCKS.

SEED CATALOGUE FOR 1877

GRATIS AND POST FREE ON APPLICATION.

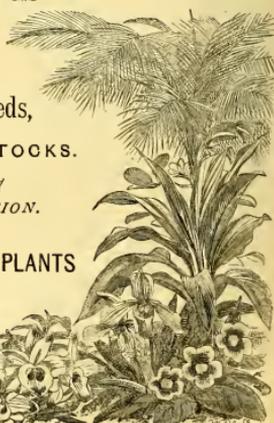

Also TENS of THOUSANDS of

WELL GROWN STOVE, GREENHOUSE and HARDY PLANTS

OF EVERY DESCRIPTION ARE ALWAYS TO BE SEEN AT

THE NURSERIES, TOOTING,

LONDON, S.W.

benefit of the community those physiological principles which he had laboured through life to establish."

Mr. Knight's first paper to the Royal Society was that famous one in which he maintained *inter alia* that the life of a graft or of a cutting was limited like that of the stock from which it was taken, and in that way he accounted for the decay and degeneration of many old varieties. Though this opinion was stated with great ingenuity, and backed up by many facts, yet the balance of evidence has shown that in this particular Knight was in error. Of more practical importance were his researches on crossing fruit trees for the purpose of obtaining new and improved varieties. To Knight has sometimes been attributed the first practice of hybridisation, but this is an error. Camerarius a century and a half a century before Knight had suggested it not practised it, while Kölreuter, forty years before Knight, actually put it into practice. To Knight's labours in 1798 must, however, be attributed the practical realisation of the idea so far as fruit trees are concerned.

Among his other papers, to which we can only cursorily allude, are those curious ones, wherein by sowing seeds on wheels revolving vertically and horizontally, he was enabled to determine that the descent of the radicle into the ground was due to gravity, and to demonstrate the effect of centrifugal force upon seedlings. The rise of the sap, the channels through which it passes, its change in the leaves, the consequent formation of wood, bark, and buds; the growth of roots according to the nature of the soil, and the fact that fibrous roots are not always, as Mirbel and others thought, annual, but only in certain plants—these were among the points which occupied Knight's attention. Knight was no microscopist, indeed in his day the microscope was a rare instrument, and it had not attained to the perfection it now has. Hence it is that many of his notions are no longer tenable, being contradicted by the minute structure of plants, of which he knew comparatively little. Knight's papers on physiological horticulture are, for the most part, based on his scientific investigations, and are indeed the application to practical ends of those researches. His paper before the Horticultural Society in 1804, on the means of producing new and early fruits, is a case in point.

These practical papers are very numerous. They form the mine from which Lindley and other writers on scientific horticulture have borrowed largely, and furnish excellent examples of the kind of research which a horticultural society should promote. We do not cite more of these papers because they are probably well known to many of our readers, and much that Knight taught is now interwoven into the daily practice of horticulture. It may, however, be of interest to add a list of the varieties of the best fruits raised by him.

Apples.—Spring Grove Codling, Downton Lemon Pippin, Herefordshire Gillyflower, Grange Apple, &c.

Pears.—Elton Water, and Black Eggle.

Strawberries.—Elton and Downton.

A large and long-keeping red Currant.

Plants.—Ickworth Impatiens, a large purple Plum not named, and two improved Damsons.

Nectarines.—Impatiens, Ickworth, Downton, and Althrop.

Vegetables.—Monarch, Althrop Crassane, Rouse Level, Winter Crassane, Belmont, and many others.

Many excellent and productive varieties of Potatoes, of which the only one named is the Downton Yam.

The Knight Pea, and improved varieties of Cabbage.

MIMICRY IN FUNGI.

For many years past I have observed a phenomenon in connection with the higher fungi, which had it been observed in the case of animals, would, I have little doubt, been put down under the head of "Protective Resemblance." Quite recently a case was published in the columns of the *Gardeners' Chronicle*, wherein Agaricus fastidiosus, a poisonous fungus (greatly resembling the common Mushroom, but widely separ-

ated by anatomical characters), grew upon a Mushroom bed. During the past week a correspondence of the *Gardeners' Chronicle* has sent a dense mass of fungi from a Mushroom bed to be named. At first sight the plants of which the mass consisted had apparently all the characters of the subgenus Clitocybe, and I was inclined to refer them without doubt to Agaricus dealbatus, because this white-spored plant (which generally grows in Fir plantations) is in the habit of occasionally forsaking its normal place of growth and appearing on Mushroom beds. The Mushroom-bed variety of Agaricus dealbatus is well known, as (when in this position) it always grows in groups, and the caps of the fungi are much lobed and undulated. My surprise, therefore, was great, on examining the spores of the plants, to find them not white but pink; the fungus was not *A. dealbatus*, but *A. oreella*. Both species have exactly the same white, lobed and undulated tops, the same anatomical characters, and the same strong fungoid odour; moreover, both are edible.

In the *Gardeners' Chronicle* for November 16, 1872, p. 1258, I published several instances of a similar mimetic habit in fungi, as—1. Cantharellus carbonarius and Agaricus atratus, two totally different fungi, with strong external resemblances; these commonly grow in company on wood ashes. 2. Agaricus fascicularis, *A. albicola*, and *A. conissans*, diverse fungi, with almost exactly the same coloration and habit, which grow in company on stumps. 3. Agaricus carbonarius and *A. sponmosus*, found on wood ashes, &c.

Every fungologist is acquainted with Agaricus cucumis. It is known in an instant by its strong odour of stinking fish; it grows upon the ground and upon fragments of dead wood, and has red-brown spores. Now I have found a plant with every anatomical character of *A. cucumis*, in exactly the same habit, with the same abortive odour, but with white spores. According to Fries, this colour of the spores makes the plant another species belonging to a different section of Agaricus. Is it so, or is it possible for a brown-spored Agaricus to have a white-spored variety? There are white varieties of several of the larger fungi, and every mycologist will remember the case of *A. cretaceus* which has been placed at various times by different authors in the white, the pink, and the purple-brown spored sections.

Agaricus parilis, a white-spored Agaricus, and *A. popinalis*, a pink-spored species, are distinct, but they have strong external resemblances, and I have frequently found them growing together. I have seen the white-spored Agaricus ostreatus and the pink-spored *A. euosmus* so much alike in general aspect that it was simply impossible to distinguish one from the other without reference to the spore-colour, and the odour has been the same in both. With me they grow on the same trees, and at the same season of the year.

Had I time to refer to my drawings and notes, I could give many other instances of "mimicry" (or what might pass as "mimicry" in fungi, *W. G. Smith*).

NITROGEN AND VEGETATION.

In a lecture by Dr. J. H. Gilbert, delivered at South Kensington, which has recently appeared in these columns, the subject of the agricultural statistics of nitrogen has been very fully treated. The lecturer showed, from the Rothamsted experiments, what quantity of nitrogen is actually found in various agricultural crops grown for many years without any supply of nitrogen in the manure; he discussed the various natural sources of nitrogen which are available to plants; and, finally, he considered the losses of nitrogen which the soil suffers by drainage, and possibly in other ways. It is clear that if our knowledge of the subject were complete, we should be able to account for the increase of nitrogen in a soil and crop at harvest by merely summarising all the gains and losses of nitrogen which had taken place throughout the year. At present, however, so much information is still needed as to the supply and the loss of nitrogen, both in the case of soils and plants, that no such account can be attempted, even in the most favourable circumstances, and therefore especially welcome. We propose to give in the present paper a short account of some recent French investigations of peculiar interest: they were published for the most part after the delivery of the Kensington lecture.

It is a well-known fact that ammonia is one of the

substances which are capable of supplying nitrogen to plants; any farmer is indeed familiar with the potency of ammoniacal manures. It has also been long known that air contains an exceedingly small quantity of ammonia, and that this substance is also found in rain, dew, and all terrestrial waters, including the ocean. Soils also contain very small quantities of ammonia. This wide distribution of ammonia is due to the fact, that both free ammonia, and its carbonate, are gases which diffuse rapidly in the atmosphere, and are thus carried to every part of the globe.

With these general facts chemists have long been acquainted, but the laws which regulate on the one hand the volatilisation of ammonia from water or soil into the air, and on the other its absorption from the air by water and soil, have scarcely been made the subject of study. M. Th. Schönlöb has quite lately treated this subject in a masterly manner in a series of papers read before the French Academy of Sciences. By logical deductions from known facts, and by an extended series of new and ingenious experiments, he has indicated the laws under which the transference of ammonia takes place. The following is an outline of his general conclusions.

When air containing ammonia (or carbonate of ammonia) comes in contact with pure water, the ammonia is absorbed by the water till a point is reached at which the ammonia in the water and air are at the same tension. At this point the ammonia is probably no longer in contact with the water, but the two, both the air and water are then in equilibrium. Did the water contain more ammonia it would yield it to the air; did the air contain more ammonia it would yield it to the water. This equilibrium is at once disturbed by a rise or fall of temperature. If the temperature rises, the tension of the ammonia in the water is increased, and ammonia passes into the air until a new equilibrium is established. If the temperature falls, the contrary takes place, and ammonia is transferred from the air to the water.

M. Schönlöb has constructed an apparatus in which air containing a known proportion of ammonia can be passed through water, and the quantity of ammonia taken up by the water ascertained. He has experimented with pure water and with sea water, using air containing those proportions of ammonia which are actually present in the atmosphere. He has also varied the temperature from near the freezing-point to the highest heat attained by a tropical ocean. By such experiments he has succeeded in reducing to a mathematical expression the laws which regulate the interchange of ammonia between air and water.

These fundamental laws being known, it is now possible to calculate the percentage of ammonia in the rain formed by the cooling of any warm wind of known composition, and to solve by calculation all questions as to the distribution of ammonia between air and water of known temperature. One result of these calculations is to show the impossibility of rain ever completely washing out the gaseous ammonia from the air through which it falls. The whole of the nitrate of ammonium in the air may indeed be removed by rain, as this salt must be assumed to exist as floating particles of dust, but the gaseous ammonia can never be thus abstracted. Indeed rain falling from a colder to a warmer region of the atmosphere must frequently give up ammonia on entering the warmer stratum. Schönlöb has, in fact, observed that the rain is sometimes richer in ammonia after rain. Calculation also shows that the rain successively formed during the cooling of a warm wind will become richer in ammonia as the cooling progresses. This is again consistent with the fact that the rains of winter are sometimes richer in ammonia than those of summer, although in winter the air contains less ammonia than in summer time.

Some of the most important of Schönlöb's conclusions are those drawn from experiments on sea-water. The ammonia in sea-water exists in a diffusible form, and not in the state of fixed salts as supposed by some chemists; sea-water, therefore, readily parts with its ammonia to air when the tension of ammonia in the water is greater than that in the atmosphere. In the tropics, where the surface water is raised to a high temperature, the conditions are most favourable for a transference of ammonia from the ocean to the atmosphere. Schönlöb believes that the principal source of the ammonia of the atmosphere is to be found in tropical regions; here the tension of the ammonia held by water or soil is so much

increased by the high temperature that a far larger proportion of the ammonia must pass into the atmosphere than in colder regions. Once in the atmosphere the ammonia is immediately diffused in all directions, and is carried by winds to all quarters of the globe. In Schöning's determinations of the ammonia present in air, he found much more in southerly winds than in northerly, especially in winter time.

The ammonia of the atmosphere Schöling regards as of primary importance in the nutrition of natural vegetation. That plants are capable of assimilating gaseous ammonia Schöling himself has shown, in confirmation of the earlier results of Sachs and Meyer. The absorption of gaseous ammonia by the leaves of plants is, however, not the only mode in which the ammonia of the atmosphere becomes available for nutrition—ammonia is also absorbed from the atmosphere by soil. The action of the soil is probably more important than that of the living plant. *A. Warrington.*

(To be continued.)

THE GENUS AGAVE.

The illustrations which will accompany the present series of papers are selected from photographs which were made three or four years ago of the principal specimens in the collection of Mr. Wilson Saunders. In selecting these, as well as in planning the *Revisions*, the principal idea of Mr. Saunders was to place on record plates of those plants of which it was not possible to preserve satisfactory specimens in a herbarium. In Agave and its allies this seemed particularly desirable, because there are a very large number of closely-allied forms, of very few of which figures have been published. Accordingly, Mr. Saunders had photographed all the different forms in his collection which were in a sufficiently mature condition to make it worth while to do so. Altogether about sixty forms were thus recorded, and at the same time I made notes upon the specimens. Mr. Saunders has presented to the Kew Herbarium a complete set of the photographs, and it has been thought that many readers of the *Gardener's Chronicle* would feel an interest in having an illustrated account of the genus to refer to. My original idea was simply to print with the figures the descriptions of the plants to which they refer. But now that we have lost General Von Jacobi, who devoted himself to the group with so much enthusiasm and perseverance for a long course of years, it seemed desirable to attempt something more than this, little as I feel myself competent for the task. The naming of these plants has for so long rested in General Jacobi's hands that, as so often happens in similar cases, others have neglected them, and now that it is gone we are in great danger of drifting into a state of utter confusion.

Any one accustomed to determine plants knows how difficult it is to work from descriptions alone, and here we have a very large number of described species, of which there are neither figures nor herbarium specimens to fall back upon. It is greatly to be wished that some one who has the necessary time and opportunity would step forward and take up the matter. In the meantime, while waiting for the appearance of this coming monographer, having, after studying the collection of Mr. Saunders, gone through our own collection at Kew with Jacobi's book in hand, and having studied the very rich series belonging to Mr. T. Peacock at Hammersmith, I propose to take advantage of this opportunity to give a summary descriptive enumeration of all the species with which I am acquainted, treating the matter from the point of view of a general botanist.

For a non-specialist to have his say about them is, perhaps, in the present state of things, the best thing that could happen, for there cannot be any doubt that a large proportion of the so-called species to which names have been given cannot be considered as established on safe grounds. Many rest solely upon notes taken upon one or a very small number of flowerless individuals, and no doubt when they are fully studied in a more or less flowering condition a great many of the 155 named that stand in General Jacobi's list will have to be placed as varieties or mere synonyms. Besides the writings of Professor Karl Koch and General Jacobi—the latter contained in his well-known monograph that came out in the *Hamburg Gartenerziehung* from 1864 to 1867, and two supplements which appeared in the *Abhandlungen der Schlesischen Gesellschaft*—

there is an excellent recent paper on the Agaves found within the limits of the United States by Dr. G. Engelmann in the third volume of the *Transactions of the Academy of Science of St. Louis*. Jacobi's latest catalogue will be found in Regel's *Gartenflora* for the year 1868, at p. 346.

Key to the Genera.—Agave and its three American allies may be distinguished from one another by the following characters, the only other genus that approximates to them being the Australian *Doryanthes* :—

- Perianth forming a distinct tube above the
 - Segments of the perianth oblong-lanceolate, as long as or longer than the lobes or funnel-shaped tubes, becoming much exerted. } AGAVE.
 - Segments of the perianth minute, oblong-lanceolate, persistent, cylindrical. } BRAVIA.
 - Perianth given to the ovary, or very nearly so.
 - Segments of the perianth broad oblong, spreading horizontally. Filaments much swollen and trigonous at the base. } FOURCROIA.
 - Segments of the perianth linear-lanceolate, persistent, entire, or filaments fusiform in the lower half. } BESCHOMBERIA.

Subgenera of Agave, founded on Inflorescence.—The best primary subdivision of the genus Agave is furnished by the inflorescence, in which we have the three following well-marked types, which were defined long ago by Salisbury (*Genera of Plants*, edit. Dr. J. E. Gray, p. 78) as three distinct genera.

Subgenus I. EUAGAVE (Agave, Salisb.).—Flowers in clusters, crowded at the end of branches, which form a broad deltoid candelabrum-like panicle. Examples—*A. americana*, *A. Scolymus*.

Subgenus II. LITTEA.—Flowers in pairs (rarely in threes), arranged in a dense simple cylindrical sub-paniculate panicle. Examples—*A. geminiflora*, *A. filifera*.

Subgenus III. MANFREDA.—Flowers solitary, arranged in a lax simple spike. Examples—*A. virginica*, *A. maculata*.

These correspond to the three sections of Dr. Engelmann, who calls them *Paniculata*, *Geminiflora*, and *Singuliflora*, and as the structure of the perianth is quite uniform in general character in all the three, we certainly cannot properly regard them as divisions of a higher than sectional value. Although I would not rather see these as my primary subdivisions, if it were possible, yet the inflorescence of a large number of the species is not known I shall be obliged to follow Jacobi's plan of adopting a sequence founded upon leaf character. Where I give between the generic and specific name of the plant the word *Euagave*, *Littea*, or *Manfreda* in brackets, it implies, therefore, that the inflorescence is known, and that it conforms to the character of the type as just defined; and where no subgenus is mentioned, it implies that I am not aware that the inflorescence has been noted. The Manfreda inflorescence is restricted to one peculiar type of leaf, but *Littea* cannot be known from *Euagave* by any foliage characters, and both as regards the leaves run through a wide range of variation.

Groups of Agave founded on Leaf-character.—The best groups founded upon leaf-character, which I am able to construct, run as follows, viz. :—

Series I. CORIACEO-CARNOSE.—Texture of the leaf rigid, not fleshy nor yielding to the touch when mature. End spine large, hard and pungent. Teeth usually large and very horny, rarely small, or the edge minutely denticulate or filiferous.

I. Group Filifera.—Edge of the leaf splitting off into distinct threads. Examples—*A. filifera*, *A. schidgeri*.

II. Group Marginalis.—Edge of the leaf furnished all the way down from the top to the bottom with a distinct horny border, of the same texture as the teeth. Examples—*A. lophanta*, *A. univittata*.

III. Group Submarginata.—Edge of the leaf with a distinct horny border as in the last group, but beginning at the top and failing to reach the bottom. Examples—*A. applanata*, *A. Hookeri*.

IV. Group Americana.—Edge of the leaf without any distinct horny border; teeth large. Examples—*A. americana*, *A. potatorum*.

V. Group Rigida.—Edge of the leaf without any distinct horny border; teeth small, but distinct, deltoid. Examples—*A. rigida*, *A. xalapensis*.

VI. Group Striata.—Edge of the leaf without any distinct horny border, and only minutely serrulate. Examples—*A. striata*, *A. dasylirioides*.

Series 2.—CARNOSO-GORICEAE.—Texture of the leaf thick, fleshy, and yielding to the touch when mature. End spine small, scarcely at all pungent. Teeth never large, as is commonly the case in the first series, small but distinct, deltoid, horny at the tip, the edge sometimes filiferous, minutely serrulate or subentire.

VII. Group Geminiflora.—Edge of the leaf splitting off into distinct threads. Example—*A. geminiflora*.

VIII. Group Albidus.—Edge of the leaf furnished with distinct deltoid teeth 1-1/2 inch long. Examples—*A. Celsiana*, *A. Sartorii*.

IX. Group Gasteroides.—Edge of small ensiform leaf minutely serrulate. Examples—*A. virginica*, *A. variegata*. (This is the group with the Manfreda inflorescence.)

X. Group Subtrigifolia.—Edge of the large oblong-spathulate leaf minutely serrulate or subentire. Examples—*A. attenuata*, *A. Elaeagnina*.

Series III. FLEXILES, or YUCODDEAE.—Texture of the leaf thin, firm, flexible, like that of a Yucca. End spine small, slightly pungent. Teeth always distinct, small or moderately large. Only a single group, XI. Examples—*A. vivipara*, *A. yuccifolia*.

Most of these eleven groups contain only few species, the large ones being the second, fourth, and eighth. *J. G. Baker.*

PLEASANCE SMITH.

This lady, who died on the 3d inst., in her tenth year, has claims upon the special memory of our readers. Apart from her great age—which is in this case sufficiently authenticated—Lady Smith, for her own sake and that of her husband, deserves a tribute of respect from all interested in natural history. We call some particulars of her life from the *Times* of the 5th inst., and to them we are enabled, through the kindness of Mr. Kippist, to add some few details :—

"She was born in 1773, two years before the outbreak of the American War, sixteen years before the fall of the Bastille. At the age of twenty-three (1796) she was married to Sir James Edward Smith, who was then a young physician of limited means, but had the courage to purchase on his own responsibility the collections and library of Linnaeus, and thus became the founder and first President of the Linnaean Society. Sir James found in his young wife a helpmate who took the deepest interest in his pursuits, and their house at Norwich became the centre of the literary and scientific society which then distinguished that ancient city. He died in 1828, so that Lady Smith, after thirty-two years of wedlock, lived in widowhood for nearly half a century; for twenty-eight of those years she resided in the house built by her father in the High Street of Lowestoft. She had a constitution without a blemish; she hardly knew what illness was till within the last two or three years; she had preserved almost all her teeth, and her eyesight was good enough to enable her to read reports of speeches in the *Times*; her hearing remained almost unimpaired to the very end. To the time when her eyesight began to fail her handwriting was of that clear and beautiful kind which in these days is seldom seen. Even when her eyes grew dim she continued to write letters to those she loved, and though the lines disclosed the difficulty she had in carrying her pen evenly along the paper, the thoughts and language showed no decay of vigor in her mind. In youth she was extremely handsome, as may be seen from a picture of her as a girl, painted by Opie, soon after her marriage. She preserved many traces of this beauty, and at the age of 100 her animated eyes and fresh colour never failed to call forth the admiration of those who saw her. But what still more caused admiration was the unabated freshness and youthfulness of her sympathies and affections."

The history of Sir James Smith's purchase of the books and collections of Linnaeus, of the chase of the treasure by a Swedish vessel sent to recover it for the Swedish nation, which had allowed so great a prize to become the property of a foreigner—all this is well known to naturalists. What follows is not so well known outside the Linnaean Society, and therefore it is worthy of mention here. Sir James Smith was the founder (1788) and first President of the Society, and the latter at his death became the possessors by purchase of the library and collections of the great Swede. Lady Smith kept up to the last an unabated interest in the prosperity of the Society, and from

time to time corresponded with its officers, and contributed memorials and relics of Linnaeus, as well as of her husband.

Amongst other donations to the Society may be mentioned the correspondence of Sir James Edward Smith, beautifully mounted and arranged, and occupying nineteen quarto volumes, with occasional explanatory notes written in that neat roundhand writing which was characteristic of her even to the last. From these notes and letters in great measure were compiled the published memoirs of Sir James Smith. In order to make the gift the more complete, the officers of the Society requested Lady Smith to favour them with a portrait of herself, to be inserted among these letters; and in complying with this

its surface are representations of the flower and seed-vessels of the plant as well as of the Litchi, the Mangosteen, and other fruits. On another occasion she presented to the Society Toland's *Life of Milton*, which had formerly been the property of Linnaeus, accompanied by a letter which showed, as almost all her letters do, how she retained a cheerful even playfully happy tone of thought and expression into extreme old age. Alluding to the *Life of Milton*, just referred to, she says she gives the book to the Society without apprehension, inasmuch as it is "too small to be an incumbrance, and too valuable not to be welcome."

In May, 1873, Mr. Bentham being then President of the Society, a congratulatory address on the part

are indebted for the privilege of illustrating the species. Dr. Engelmann, the learned monographer of the Cactaceae of the Mexican boundary, has also kindly identified the plant for us so far as the materials before him would allow. The plants are usually simple, but when injured by fire "they branch from the base, and form a pile of prickly balls."² The flowers are greenish, the fruit nearly an inch long, blueish, and of the shape and taste of a Gooseberry. *E. viridescens* is described in the latest revision of the Californian flora (*Botany of California*, vol. i.; *Polypetalae*, by W. H. Brewer and Sereno Watson; *Gamopetalae*, by Asa Gray, 1876, p. 245) quoted below.

TELIPOGON CRESCUS, Robb. f.*

The Telipogons form a wonderfully ethereal genus. They have narrow thin stems with distichous

FIG. 26.—ECHINOCACTUS VIRIDESCENS.

request Lady Smith, in September, 1872, forwarded a photographic copy of the portrait by Opie above alluded to, and which does indeed represent a lady of singular beauty. On the back of this photograph is written by Lady Smith herself this inscription—which is the more interesting as she was then in her hundredth year—"PLEASANCE SMITH, Lowestoff, b. 11 May, 1773, copied from Opie's portrait 1798."

In May, 1869, she presented to the Society a curved rhinoceros horn, accompanied by a note, mentioning the fact that the horn had been sent to Linnaeus from China, and had been described by Sir James E. Smith in his *Exotic Botany*, and which is figured in Lady Smith's *Memoir* of her husband, vol. ii, p. 230. The hollow base of the horn is carved to represent a Lotus (*Nelumbium*) leaf, and on

of the Fellows was sent to Lady Smith on the completion of her hundredth year, and a characteristic letter was received in reply.

It is quite clear, from the statements of those who had the privilege of knowing her personally, as well as from her letters, that the grave has closed over one not more remarkable physically than for the virtues, the graces, and the charms of her mind.

New Garden Plants.

ECHINOCACTUS VIRIDESCENS.*

Some plants of this striking Cactus have lately been introduced by Mr. J. T. Peacock, to whose courtesy we

* *Echinocactus viridescens*, Nut.—Heads solitary (4–7 in diam., 2–3 feet high), globose or depressed, with about thirteen obtuse tuberculated ribs, and a woolly depressed summit; spines

leaves, now crowded together, now distant. The generally ancapitous racemes bear very conspicuous bracts with dorsal keels; and the flowers are

stout, reddish, straight, or recurved, all annulated, about twelve, radiating, and four to six stouter central ones; flowers greenish, 1½ inch long, with numerous (twenty-five or more) rounded, denticulate, imbricated sepals on the ovary, as many on the tube, and about the same number of oblong, obtuse, denticulate petals; stigmas twelve to fifteen, linear; berry pulpy, green, scaly, with numerous small pitted seeds.—For. and Gray, p. 351; Eng. Cact. Mex. Bound, 94, t. 20. The plant is said to be cultivated in Europe as *E. californicus*. Botany of California, p. 245.

Telipogon Crescus.—Ait. T. Hausmanniano, Robb. f.: sepalis triangulis acuminate aristatis intermixtis supra nervium medium extus carinatis; tepalibus cuneato rhomboidis obtusisunguibus dimidio antico basi brevioribus, latis quinque-nerviis; nervis emiliibus nerviulis ascendensibus rete effluensibus; nervis lateraliibus ramulosis; lobello valde transverso, fimbriato antice retusato vix apiculato; nervis tredecim rete nervulorum excepto imagine demumino hinc retusato, columna calva.—Nov. Grammat. det. C. Bruchschiller (deff. amic. Low). Corder and Shuttleworth.—*Telipogon Crescus*, Robb. f. in *Linnaea*, xli, p. 20.

usually very striking. The narrow triangular sepals are totally hidden by the thin, very broad, grand petals, and the lip. Originally two species were discovered by Humboldt and Bonpland; by-and-bye, after a long interval, a few more came. Lately, however, it became necessary to publish no less than twenty-seven species at once. My collection at the present time contains more than half a hundred species, many of them due to Messrs. Wallis, Roehl, Klaboch, Krause, Bruchmüller, and Patin.

These beautiful butterfly-like things—provided we had such creatures with three wings!—have yellow flowers and a short column, now full of violet hairs, now with a fabulous crown of striking forked hairs, now with white sentile hairs, seldom quite naked. The variation of the petals and lip, too, is very great; a considerable number have those organs equal, others unequal; some

from the revolutionary States of Colombia. Amidst these is, I am glad to say, *Telipogon Croesus*, the first flowers of which Mr. Low gave me many years ago. It is one of the best species of the genus, well covered with its flowers a modern German five-shilling piece, yellow, with a dark network. It would be a great success to secure the *Telipogons* in Europe, since they afford some new types. Their cousins, the *Trichoceras*, are rather pretty, and much easier to introduce for their more plump bulbous growth, but their flowers are too small; while the majority of *Telipogons* have much larger flowers. There is no doubt that they would prefer a very cool treatment. Director Linden, who was the first modern traveller who met with *Telipogon*, indicated them as growing in their native country at an elevation of 10,500 and 7840 feet (see Lindley, *Orchidæ Lindeniæ*, p. 23). *H. G. Rehb. f.*

of bright colour. There are scarcely any flowers in the garden, and yet nothing can be more pleasant to the eye than the arrangement, by judicious forethought, of scarcely half-a-dozen species of common trees.

The gardens bear a matured aspect of antiquity, and are of great age. They were planned in 1550, by II. Tribolo, under Cosimo I., and carried out, in the latter half of the sixteenth century, by Baccioanti. Many of the statues are restored antiques, and include four unfinished works by Michael Angelo, said to have been intended for the tomb of Pope Julius II.

Another magnificent garden, or rather park, is in course of completion on the heights of San Miniato, from which a fine view of the city and its surround-

FIG. 27.—VIEW IN THE MAIN ENTRANCE OF THE BOBOLI GARDENS, FLORENCE.

are as thin as the thinnest tracing paper, others have a stronger texture; some have few, others numerous nerves, and these are either quite simple or connected by transverse bars. There are some with many projecting small dots on the side of the nerves.

At present the writer of these lines only knows of a single case of a *Telipogon* having flowered in Europe. It was in 1847, when Messrs. Veitch flowered *Telipogon obovatum*, Lindl. The late A. Bruchmüller, who discovered several new species on the old hunting-grounds of collectors at Ocaña (*Croesus*, *hastatus*, *auratus*, *Alberti*, *Bruchmüller*), made it a point to try to bring the *Telipogons* alive. Sitting on muleback, he had his small cases with his pets before him, but they died when he came to the hot regions. I have now a reasonable hope of our at length seeing the plants alive, since Mr. W. Bull sends me specimens to name, of *Orchids* brought home by Messrs. Carder and Shuttleworth

FLORENTINE GARDENS.

At the back of the Pitti Palace, and immediately adjacent to the botanical garden, are situated the famous Boboli Gardens. From the higher part of them a fine panorama of the city is obtained, enriched by the pleasant foreground of the garden. Grand specimens of *Cupressus pyramidalis* break the beautiful distance and rise out of a charming labyrinth of terraces, pools, fountains, sculpture, and noble walks deeply sheltered by avenues of Oriental Plane, *Quercus Ilex*, and *Laurus nobilis*. The evergreen Oak is the *pivot de résistance* of the garden, here trimmed into wall-like masses enclosing long vistas, again trained overhead into a complete arched shelter from the summer sun, and occasionally rising up as separate individuals above the general level of the sea of leafy verdure. One notable feature is the absence

ings is obtained. It is on a much larger scale than the Cascine or Boboli, though it cannot, for many years, compare with either in their wellworn richness of the planting which age alone can give.

From the limited time at my disposal, I had but little opportunity of examining the indigenous flora of the neighbourhood, so rich in bulbous plants; but through the kindness of my friend, Mr. S. Sommier, I was enabled to obtain several species from their native habitats. Our first visit was to a meadow between the Cascine and railway station, in which on March 2 two forms of *Crocus biflorus*, nearly out of flower, were most abundant in some places, almost wholly replacing the turf. The commonest form was the little striped variety, *Crocus pusillus* of Tenore, intermixed with *estriatus*, a pale lilac unstriped variety with a bright yellow throat. Compared with the "Scotch

Crocus" of British gardens, which Dean Herbert supposed was derived from it, is a woody little plant, and on looking through Gussone's herbarium at Naples I was fortunate in finding a specimen from a native habitat on the road between Ariano and Monte Calvello, near Salerno, labelled *pasillus* var. b. Tenore, precisely identical with our garden plant; so that there is little doubt that the Scotch Crocus was derived from South Italy. Interminably with the Crocuses at the Casine was *Colchicum Leveii*, apparently of smaller habit than C. autumnale, but its flower is unknown to me.

On March 3 Mr. Sommer accompanied me on a pleasant excursion to the north-west of the city. Passing out of Florence by the Via Bolonnesa we visited the Villa Herzen, the grounds surrounding which are interesting to the botanist as the habitat of various bulbous plants. In the terraced Olive gardens and vineyards both the white and blue varieties of *Hyacinthus orientalis* occur in great profusion. There are also five or six species of Narcissi, including Bertolonii, Tazetta, odorus, italicus, papyraceus, and a species allied to *papyraceus* of shorter and more robust habit and rather larger flowers, bulbs of which I obtained through the courtesy of Dr. Herzen. *Gagea arvensis* is an abundant and attractive little plant in the fields surrounding Florence; and *Narcissus crassus*, a species separated by Professor Parlatores from N. Tazetta, occurs on the south side of the city.

From the Villa Herzen we ascended to the village of Pratolino, passing en route the grounds of Prince Demidoff, who is one of the most successful cultivators of stove plants in Italy.

In a wood about half a mile beyond the village of Pratolino the lowland form of *Crocus vernas* occurs in the greatest profusion, including an endless series of varieties from pure white to deep purple, corresponding with nearly every variety produced by the Dutch cultivators. Scarcely two individuals were precisely alike, and seminal variation must be a constant character of the species. The ground was covered with dead matting of dead thick leaves, and through seven or eight thick masses the flowers had penetrated without the slightest displacement or deviation. The leaves of the late winter's fall were tough, and as yet undecayed, and it seems difficult to believe that the penetrating force of the delicate flowers is merely mechanical. Mr. Sommer informs me that a much larger form of *Crocus vernas* is found at higher elevations about Florence, and specimens sent me by Mr. Groves of Florence, from Monte Marone, in the Abruzzo, obtained at an elevation of 6000 feet, are larger than the Pratolino form. A parallel variation in size occurs in the case of *Crocus minimus* in Corsica, the typical small form being restricted to low elevations, whilst on the mountain tops, from 2500 feet up to 6000 feet, it attains the size of *Crocus versicolor*. *Geo. Murray, F. L. S.*

Florists' Flowers.

"THE AUBICULAS are delightfully on the move," wrote a well-known cultivator a few days ago. This was the experience of a northern locality; here in the South they also commenced to move days ago. A revived root-action is taking place, and the manifests itself in an awakening of the growth. It is the occasion when the Auricula cultivator braces himself to action, when for his plants now need all his care and attention. One important duty required at his hands is that of top-dressing the plants. This is of great value to them, for during the autumn and winter the roots fill up the body and bottom of the pot. When they commence to root in spring they are put forth from the stem of the plant just beneath the soil, and they are at work near the surface; hence the necessity, therefore, for a supply of good rich soil for these roots to feed upon, for they are the main feeders during spring. Without good roots actively at work among the soil, it is useless to look for finely marked pips of excellent quality. Some cultivators do something else than top-dress their plants: they also make a point of giving them freshly cleaned quarters. The plants are taken out of the frame on a fine day, and carried into a summer-house or any place of temporary security; and then the interior of the frame is carefully cleaned and brushed. In the case of an old-fashioned garden frame, in which the plants are stood on an ash or gravelled bottom, it is customary to stir

up the surface and take some of it away, and add a fresh covering of sand, coal-ashes, &c. Mr. John Hepworth, of Haddersfield, a well-known amateur cultivator of the Auricula, prefers to make his bottom of clean washed sand from the road, with which is mixed a quantity of fresh slaked quicklime. Next comes the cleansing of the plants. The process can scarcely be better expressed than in Mr. Hepworth's own words, as given in the *Florist and Poinsettist*. "After clearing the frames," he states, "I commence to clean the plants. Having first obtained a small threepeny painter's brush, I take the pots one by one, give the plants a good brushing all over the leaves, also underneath, and round the bole of the plant." This is very necessary, for during the prevailing mild weather green-fly congregates quickly about the hearts of the plants, especially on plants kept in rather close quarters. This done, then follows the process of top-dressing. Mr. Hepworth well describes this act in plain and simple terms. "I take a wooden skewer, run it round inside the rim of the pot to the depth of an inch or so, then turn the pot on one side, just giving it a slight tip, so that the water hanging on the inside has fallen off, and having at my hand some fresh well-sweetened mould, not over old, as some folks mention, I fill up the pot with a small tin scoop to its usual depth of about half an inch from the rim—not too full up to the leaves of the plants, but leaving the bole of the plants slightly visible. This done, the pots are placed in their usual place in the frame, laying a mat or two temporarily over the lights at night till I have gone through the entire collection. Then, having got them in the frames, I put on the lights, and keep them on for a fortnight or so, tilting them slightly at the back, but allowing the plants no rains or artificial watering during the fortnight." The soil used for top-dressing is generally one with some unctuous food in it for the young rootlets. That generally employed is one part good heavy loam, one of leaf-mould, and the remaining two parts well-decomposed cow or sheep manure. The application of water carries the fertilizing properties on the surface soil down to the large root-feeders below, and they do derive benefit from the dressing. *R. D.*

Forestry.

THE difficulties of growing GAME COVERT are in most districts very considerable, owing to the circumstance that what should constitute shelter, protection, and food for one class of game, is eaten, destroyed, and rejected by others. The rearing of covert for pheasants alone, for example, is cheaply and easily accomplished; but when the threefold object of growing plants productive of food for birds, and shelter and protection for winged and ground game is to be attained, the work is difficult, and often impossible, not to speak of the expense and tediousness of the operation. When to the ordinary difficulties and obstacles of growing game covert in inland and favourable districts we add those arising from a maritime severe exposure, it taxes the most experienced and skilful forester severely to know how best to attain it. After many abortive efforts under the latter adverse circumstances I have at last partially succeeded under the following practice.

Thorough drainage, by whatever means, is an essential condition; for although we hear much about certain trees and shrubs that luxuriate on wet soils, observation and experience very clearly demonstrate that no arborescences will succeed, and endure for any length of time, in soils other than dry. The numerous kinds of Willow, the Alder, American hazel, or Bield, Cherry Spirea, with wild Briar, and common Bramble, all grow more or less successfully upon comparatively wet ground, but it must not on that account be concluded that they either prefer such, or that they will not thrive better upon good dry soil. Willow and Alder are frequently consigned to cold wet bogs and marshes, but that is simply because in such situations most other trees refuse to grow at all, and the former at best, under such circumstances, are but short-lived and unsightly, unmistakably indicating that they also prefer dry to wet soils.

In planting game covert within the influence of the sea, other matters than those for inland planting have to be considered, which the following examples will illustrate. On a bank sloping towards the open

German Ocean, soil dry and of good quality, well adapted for the growth of most hardy evergreens commonly planted for game covert, and which was desired to be grown on the site for that purpose, especially to afford protection during winter, it was evident that no evergreen would stand the winter in such an exposure, and it was chiefly winter covert that was required. What was to be done? Deciduous plants would grow, but they would not produce winter covert. Evergreens would grow to some extent in summer, but they would not stand the winter. On seeing a young Beech tree with its scathed leaves adhering tenaciously, I concluded such might, in some measure at least, meet the requirements of the case, and I forthwith proceeded to plant it closely and extensively, and with very satisfactory results. The Beech, as is generally known, retains its leaves throughout the winter, so long at least as it is low and bushy, as in hedges clipped or pruned; and in this state the leaves, though dry and withered, afford comparatively good protection to game, the best at least that can be produced under such a combination of adverse circumstances.

The scrubbe Oak, and the common Oak, when the latter is of low height, like the Beech, retain their leaves during winter, and only defoliate when the buds begin to expand in spring. Unlike the Beech, however, the former is expensive, and the latter more choice of soil, while neither of them branch and spread out so well as the Beech. The common Bramble to some extent fulfils the requirements of such situations by partially retaining its foliage, but it requires better soil than the Beech to grow luxuriantly.

The Dahpne and Berberis make excellent under-covert, as they both spread and rise to a fair height. They also produce berries which pheasants are very partial to.

The common Privet is again a well-known favourite covert for game, and will succeed upon any dry soil, even under the shade of deciduous trees. Neither of the three latter, however, will endure severe maritime exposure, and hence should not be relied upon for that purpose.

The Sea Buckthorn is an excellent plant for seaside planting, and none endures the salt spray better. As it defoliates in winter, however, it is on that account less suitable than Beech.

The common Elder, where the soil is good, grows well at the very margin of the sea, and though rendered leafless several times during the summer months, will yet shoot forth anew, and overcome its privations. *C. Y. Michx, Callen Itous, Callen, Farnham 30.*

Garden Operations.

PLANT HOUSES.

PLANT STOVE.—Allamandas not yet started into growth should be got to work at once, cutting them well back, soaking their balls, getting away half of the old soil, and re-potting in new, which make quite soil, and at the same time putting them on their heels, by doing which now before they begin to grow the danger of breaking the young shoots in the operation is done away with. *Clerodendron Thompsoni* and *Balfourianum*, that are still at rest, ought to be started now, and at the same time put on their heels, and train them on the trellises they are to bloom upon. *Caladiums*, too, should be started: the amount of pot-room given them will of course be regulated by the size the plants are intended to grow to. If desired big they must not be staked in the size of their pots; whereas if they are wanted small, say, in 6 or 8-inch pots, the bulbs can be divided, not having the pieces too big in this case. As a decorative plant for conservatory use the small-leaved *C. argyrites* is very serviceable; for this purpose it should not be grown too hot, and if they are wanted small, say, in 6 or 8-inch pots, the bulbs can be divided, not having the pieces too big in this case. As a decorative plant for conservatory use the small-leaved *C. argyrites* is very serviceable; for this purpose it should not be grown too hot, and if they are wanted small, say, in 6 or 8-inch pots, the bulbs can be divided, not having the pieces too big in this case. THE
Gardeners' Chronicle.

SATURDAY, FEBRUARY 10, 1877.

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY, Feb. 12	12	Sale of Lilium auratum from Japan at Stevens' Rooms.
TUESDAY, Feb. 13	13	Royal Horticultural Society: Annual General Meeting, at 2 P.M. ; Royal Agricultural Society: Meeting of Field and Rural Committees, at 11 A.M. ; Scientific Committee, at 4 P.M. ; Sale of Orchids, Fowers, Bulbs, &c., at Stevens' Rooms. Meeting at 8 P.M.
WEDNESDAY, Feb. 14	14	Liverpool Horticultural Society: Meeting at 8 P.M. ; Sale of Orchids at Stevens' Rooms.
THURSDAY, Feb. 15	15	Sale of Conifers, Fruit Trees, Roses, &c., at Stevens' Rooms.

THE apprehensions felt by many at the recent utterances of the Council of the ROYAL HORTICULTURAL SOCIETY in the *Times* will, it is to be hoped, be allayed at the forthcoming ANNUAL MEETING. If not, we can but look upon the change of policy hinted at as altogether retrograde—nay, absolutely suicidal, and almost a justification of those who would seek to found a new Society. What has been the general outcome of all the meetings, stormy and peaceable, the discussions, the letters, the varied expression of opinions during the last few years? What but this, that the Royal Horticultural Society must revert to first principles, be a horticultural society in fullest reality, not half real, half sham, as now? We are weary of reiterating the proper scope and duties of a horticultural society. The right key-note has been struck again and again, in the Council-room, and out of it, by some whose voices are now quiet in the grave, as by others happily still among us, even by members of the existing Council.

But, we are told that the debenture-holders and the Commissioners between them play the part of PHARAOH, and refuse to let the horticulturists go, and that, under these circumstances, we are to make the best of a bad bargain—grin and bear it—eat our Leck, and do other unpalatable things. What the best of a bad bargain in the opinion of the Council is, is shown in the following extract sent us some time since for publication; this we had not the heart to print then, but now, in view of the approaching annual meeting, we must do, though with bitter humiliation:—

"4. The Council have determined to continue the South Kensington Gardens on their former footing, and to make them as attractive to the residents in their neighbourhood and of London generally as the means and nature of the Society will permit.

"5. If the subscription income of the Society for next year be raised to £10,000, the South Kensington Gardens will be secured to it certainly until 1892, to the great advantage of the residents and owners of property in their neighbourhood. If such income be not raised, these gardens will pass into the possession of the lessors, and probably be built over.

"6. To place the Society in a more prosperous and secure position than it has ever occupied nothing more is wanting than, for the present year, a renewal of a part only of the subscriptions which have recently been discontinued, and for the coming year an effort which wealthy South Kensington would scarcely fad, and which will raise the £20,000 above referred to.

"7. The Council are trying, so far as their funds will allow them, to meet the wishes of their London Fellows. The principal western entrance has been reopened; the gardens, which have suffered nothing that a few days' labour will not repair, are being put in order; and the bands and promenades in the conservatory will be resumed on an early date."

The horticultural expenses have been reduced to a minimum. Such men as BERKELEY, DYER, HEMSLEY, and others have been with scant ceremony dismissed from their offices, on account of insufficient funds; even the salary of the librarian has been cut off. The work at Chiswick has been reduced to a point lower than which it can hardly go. We have

acquiesced in all this because we were told it was essential; we assented to it because we saw the Council bravely struggling to pay its debts; nay, we are told, and no doubt truly, that there are now no obligations whatever save the lien of the debenture-holders, and that is looked on as a debt and not a debt! We witnessed with the greatest pleasure the paying up of prize-money, and the distribution of the long-overdue medals. We saw a general desire to conciliate the horticulturists, and to do, so far as extremely crippled means would permit, good horticultural work. On these grounds we assented to the economising policy of the Council, though it was often painful and grieved to us to have to do it. But now what reward are the horticulturists—those self-sacrificing horticulturists who have kept what little life there has been in the Society for the last few years—to have for all this? Doubtless an extension of true horticultural work—something towards the reorganisation and reconstruction of the Society on a proper footing. But no; will it be believed that the "gardens are to be continued on their former footing"? Bands and promenades, and all the worn-out machinery that have proved the downfall of the Society, are to be restored. Does not every one know that it is the South Kensington Garden upon which the Society has absolutely thrown away £73,000, which has been the main cause, if not the only one, of all the Society's troubles?—and yet it is to be reinstated as before, if means permit. If this were only intended as a temporary measure, no objection could be made to it, but the gardens are to be kept till 1892 if—oh, the force of that little if!—if the income can be raised to £10,000. Most earnestly do we wish it may not be, if such is to be the result.

At any rate, in place of expanding the basis of the Society, making it national and popular, searching the gardens of the country for new Fellows at a low subscription, instituting local committees and local secretaries all over the country, encouraging local societies, teaching gardeners of all degrees by precept and example, striving to create a general interest in gardening, and to do good to peer and peasant in every accessible corner where a flower can blossom, a fruit tree grow—in place of all this, we are to go on piping and fiddling to the South Kensington audience, who neither understand our work, nor care for our play. It may be said, and with truth, that hitherto the horticulturists have not of themselves been able to maintain their own society. But why? Mainly because the Society has neglected its proper work to provide a recreation ground for the inhabitants of wealthy Kensington, and has taken no pains to do good to the people and the country at large. And, on the other hand, what have the South Kensington residents done for the Society? Have they enabled the Society to pay its way, to keep up the gardens? Have they done the horticultural work of the Society, made its exhibitions, served on its committees? Have they even had the grace to come and look on with a smile of approval? Not a bit of it. They have not done any one of these things. Had it been otherwise it might have been prudent, nay just, to consider their interests, but, like rats, they have left what they thought a sinking ship. If they come back they will be as useless to a horticultural society as before, for it has been proved that they will not come in numbers sufficient to make the gardens pay their own expenses. They have no sympathy with the objects of the Society, so that even if they did come forward in their thousands we should still cry, warned by past experience, *non tali auxilio nec defensoribus istis*.

But it may be this is all a jest on the part of

the Council, to be explained on Tuesday next—that their utterances are meant to be taken in a non-natural sense, as some persons are said to interpret the Thirty-nine Articles; or in a Pickwickian sense—any sense but what seems to be the right one. If this be the real interpretation we may perhaps admit that "It was right to dissemble your love," but ask, "Why did you kick us downstairs?"

— THE judges in the Horticultural Department of the Philadelphia International Exhibition, 1876, recommended to the United States Centennial Commission for awards a "very choice collection of new and rare plants, well grown and in excellent condition after transportation of such delicate articles—an exceedingly creditable display," exhibited by Mr. B. S. WILLIAMS; also "a small collection of Filmy and other Ferns," exhibited by the same gentleman; "a very rare collection of Rhododendrons, Hollies, new and rare Conifers, broad-leaved evergreens of the best kinds for lawn decoration," exhibited by Messrs. JAS. VEITCH & SONS, Chelsea; also "an exhibit of evergreen plants, consisting of the best varieties of Rhododendrons, Hollier, Aucubas, &c., for fine growth and careful training, and unique in new kinds," shown by the same firm. A medal was also awarded to Mr. W. BULL for "coloured plates of flowers." The judges were:—DR. GEORGE THURBER, Messrs. W. D. BRACKENRIDGE, F. PENTLAND, and W. SAUNDERS.

— We are requested to state that the SCHEDULE OF PRIZES FOR THE AURICULA SHOW to be held on April 24, at the Crystal Palace, as a Southern offshoot of the National Auricula Society, will be ready for issue in the course of a few days, and may be obtained from Mr. E. S. DODWELL, 11, Chatham Terrace, Larkhall Rise, Clapham, S.W. The subscriptions, which amount to nearly £70, will be nearly sufficient to admit of a liberal prize list being issued, and to meet the incidental expenses. The classes seem to be framed to suit growers of every grade, so that if the competition is at all what may be expected the show will be a most interesting one for the lovers of the Auricula, much more so than any which has taken place in the South of England during the present generation at least. It has been decided to adopt as few restrictions and limitations as possible, in order to secure greater breadth of and variety in the several classes. The chief of these adopted are:—To require *disjunct* varieties in classes containing two or more plants; to permit only one truss in Auriculas, but not to limit the trusses in the classes of alpinas; to admit shaded and unshaded varieties amongst these latter; and not to confine Polyanthes to the gold-laced types. In every class it is desired that the best should win, and so that the leading properties are not violated no rigid or fast rules beyond those indicated above will be observed. The premier class will be that for twelve *disjunct* varieties—and here it may be pointed out, for the consolation of our Northern friends, who generally adopt very rigid rules in these matters, that although the committee does not in this case limit the exhibitors to show an equal number of the four usual types—green, grey, and white-edged and self—or even representatives of each, yet those who best illustrate these several types will assuredly come nearest to the only essential limitation, that of *disjunct* varieties. The success of this attempt to organise an Auricula show in London shows that the taste has not altogether died out, and that it is possible, if set about in a right manner, and by the right men, to obtain the support of the growers and admirers of a particular flower, in an honest attempt made to advance the interests of floriculture through any of its many channels.

— The whole of Mr. LANTON's valuable stock of seedling and other Pelargoniums, including Vesta and Mrs. Trevor Clarke, which have been awarded First-class Certificates by the Floral Committee of the Royal Horticultural Society, has passed into the hands of Mr. R. GILBERT, of Burghley. The stock of named and unnamed seedling Roses, grown by Mr. LANTON, has been acquired by Mr. TURNER, of Slough; and Messrs. VEITCH & SONS have secured all his seedling Peas, including five Certificated varieties, and all the seedling Strawberries, including Pioneer.

— The continuous rainfall has so saddened the ground that those among *GLADIOLUS* cultivators who are in the habit of planting in February will, unless a quick drying time soon happens, have to postpone the operation beyond the usual time. The bulbs will remain plump and fresh till April if properly preserved during winter. They require to be kept dry and cool—dry enough to keep them from being affected with mildew and rot, and cool enough to prevent a premature growth and shrivelling up. In the warmer and milder districts of England planting may be safely commenced in February in well prepared ground, but in the North, where it is bleak and cold, it is

dener and an enthusiastic total abstainer of a special prize in cash, conditionally that the beer special prizes were refused, has been accepted, and this year at least the society's schedule will be purged of any association with the beer-barrel.

— The unusual mildness of the winter has already made *TURNIP TOPS* almost a drug in the market, the general abundance of this homely vegetable having been added to by the drought last summer, in consequence of which comparatively few of the summer sowings came up sufficiently early to produce good market roots. There has indeed been an abundance

experience is that a large number of plants, whose ordinary flowering season is in March or April, are already in flower, though, it should be stated, in many cases imperfectly. During the whole of December, and the greater part of November, the mean temperature was considerably above the average; and although we have experienced a few sharp frosts, they have only exercised a retarding influence. During the first week in January the mean temperature was (at Blackheath) 10° above the average for the last six years, namely, $46^{\circ}.8$; during the second week, $41^{\circ}.9$, or $5^{\circ}.6$ above the average; during the third week, $45^{\circ}.5$, or $8^{\circ}.7$ above the average; and during the

THOMAS ANDREW KNIGHT. (SEE P. 169.)

best to defer the operation till the end of March or beginning of April. In the latter case the bulbs cannot be too carefully preserved. In the case of extra choice varieties, it would be a wise precaution to pot the bulbs now, and transplant them to the open ground in April. A good many cultivators in the North make an annual practice of this, and find they gain considerably in doing so.

— Some time since a correspondent criticised the conduct of the committee of a large horticultural society in the South of England because *SPECIAL PRIZES* in the shape of casks of beer were admitted into the society's schedule. The expression of opinion brought to bear on the committee would seem to have borne good fruit, as the offer by a well-known gar-

den of green stuff of all kinds available for the season, Spinach also having been very abundant, not the least check so far having been given to its growth. The pinch for green stuff will probably come presently, for the Broccolis, whether purple or white, are neither large nor plentiful, drought and chub having proved enemies of potent strength at and after planting. If the open mild weather should long continue, all kinds of green tops will soon be running off to flower, thus considerably shortening the green crop season.

— The accounts from different parts respecting the *EFFECTS OF THE MILD WEATHER*—disregarding the rainfall—on vegetation vary very widely. Some correspondents assert that they find very few things in advance of their usual state at this period; our

fourth week, $39^{\circ}.4$, or $1^{\circ}.7$ above the average. With the exception of the last week the mean temperature was as high as the average mean temperature for the same weeks at Nice, Toulon, and Marseilles. To the absence of sun-light may be ascribed the relatively slight stimulation plants have received. But a couple of hours in Kew Gardens on the 5th of the present month gave us some insight into the number of hardy things in advance of their normal season. The following, among others, were noted, and doubtless many others escaped notice. Of course, a certain proportion of them are flowering at the usual period. Several common things are omitted. First among trees and shrubs there were in flower, or bursting into flower, *Amygdalus communis*, *Berberis nepalensis*, *japonica*, *Darwinia*, and *fasciculata*; *Cor-*

cus paniculata and *Mos. Chimonanthus fragrans*, *Noyalus* (4 flowers), *Coronilla glaucan*, *Erica codonodes* and *carnea*, *Kerria japonica* (single-flowered), *Lonicera Standishii* and *fragrantissima*, *Nuttallia cerasiformis*, *Oreodaphne californica*, *Prunus cerasifera*, *Pyrus japonica*, *Shepherdia argentea*, and *Yucca gloriosa*, the spikes of many of which were injured beyond recovery. Among herbaceous subjects the most noteworthy were *Iris stylosa*, *Saxifraga ligulata*, *Iberis Garreuxiana* and *semperflorens*, *Alyssum saxatile*, various species of *Crocus* and *Helleborus*, *Eranthis byemalis*, *Viola fibroides* alba, *Viola*, *Daisies*, *Wall-flowers*, &c. A few of the foregoing plants deserve a word of commendation, whilst others are so commonly seen and known that they recommend themselves. *Berberis nepalensis* is a grand subject in light soils and sheltered situations, as also its close ally, *B. japonica*; *Erica codonodes* is a fine hardy Heath, normally in bloom this month and last. The single-flowered *Kerria* against an east wall is a mass of blossom, finely shown off by the beautiful green of its foliage. Must people would prefer it to the double-flowered variety. *Nuttallia cerasiformis* is a roseaceous shrub or small tree with the aspect of a white-flowered *Ribes*, and equally as profuse a bloomer as *R. californicum*. *Oreodaphne californica* is a handsome evergreen Lauraceous tree, which has frequently been mentioned in the columns of this journal. Of the less familiar herbaceous plants noted above, *Iris stylosa* and *Helleborus caucasicus* are specially worthy of consideration. Finally, the old *Saxifraga ligulata* is a fine sturdy plant, very ornamental both in foliage and flowers. Another thing that attracted our attention was the bed in the herbaceous ground containing some nine or ten species of *Ferula*, the leaves of which were already in an advanced stage of development, and among the most beautiful objects to be found in leaf early in the year.

— The annual GRAND FLORAL FÊTE AT YORK is announced to be held on June 13, 14, and 15.

— A correspondent informs us that he has received from a publisher in Belgium a copy of a small book (which he had given no order for), accompanied by a post-card requesting that thirty stamps might be sent in return for it. Our correspondent thinks this is a good plan to adopt to sell works which are not in demand, but as he objects to being victimised himself, he would equally reject to hear of others being so treated, and recommends his *confères* in the trade not to pay.

— The next INTERNATIONAL POTATO SHOW will be held in the gardens of the Royal Horticultural Society, and probably the Council will add to the prize list a set of medals. The date is not yet fixed, but we understand the promoters contemplate holding the show somewhat earlier than hitherto.

— In large ORCHID HOUSES great difficulty is frequently experienced in keeping up a sufficient supply of ATMOSPHERIC MOISTURE during the growing season, and especially in this case in those established in which it is necessary to keep the paths sufficiently dry to be walked on with comfort. In some houses the paths are covered down the centre with ornamental iron gratings, and we have seen them covered with cocoa-nut matting, but both of these plans are somewhat expensive, and we do not think either so effective as a plan adopted by Mr. J. T. PEACOCK in one of his structures at Sudbury House, Hammersmith, and which simply consists in paving the floors with the small, square, bevel-edged blue bricks used in stables, which floors, while containing an innumerable number of channels for the holding of water, are still sufficiently dry to be walked upon with comfort by any lady or gentleman.

— M. CH. JOLY, of Paris, has issued a pamphlet on the Sewage Question—*La Question des Eaux usées*—in which he adopts for the most part the conclusions which have been arrived at by the Rivers Pollution Commissioners of this country.

— The explanation of the fall of the leaf in autumn is found in most text-books, and has frequently formed the subject of comment in these pages. But the converse question, WHY THE LEAVES OF SO-CALLED EVERGREENS DO NOT FALL, is one not so often

asked. M. MER, who has lately been investigating the matter, reports in a recent number of the *Bulletin de la Société Botanique de France*, that the reason for their retention may be found in the absence or imperfect development of the dividing layer, as in some bulbous plants, and which is one cause of the fall of deciduous leaves, and in the large number of fibrovascular bundles, which serve to tie the leaf to the branch.

— MM. DETHÉRAIN and VESQUE have been experimenting on the RESTRACTION OF ROOTS, with the general results that root-adsorb oxygen gas and emit carbonic acid gas (true respiration); and that oxygen is necessary to the roots, which must have access to that element or the plant will suffer even if the leaves be exposed to the air. A small quantity of carbonic acid is given off by the roots.

— A report and balance-sheet of the HAILSTORM RELIEF FUND have been published, from which it appears that the total amount raised for the relief of the sufferers in the neighbourhood of Tottenham was £779 18s. 7d., of which £699 15s. 8d. was distributed among forty-one persons in sums varying from £111 4s. 10d., the highest, to £1 7s. 8d., the lowest. The total amount asked for by those who suffered damage was upwards of £2000, but the assessment committee carefully investigated each case, and acted accordingly.

— As a mark of respect and friendship for Mr. JOHN LEE, who has lately retired from business, several of his friends have invited him to a complimentary dinner at the Horticultural Club, on Thursday, February 15 next.

— The next meeting of the INSTITUTION OF SURVEYORS will be held on Monday evening, February 12, when a paper will be read by Mr. G. J. SYMONS, entitled "Rainfall, and its Relation to Civilised Life." The chair to be taken at 8 o'clock.

— The January number of the *Nuovo Giornale Botanico Italiano* contains, among other articles, one on a variety of *Calystegia sylvatica*, with a deeply five-lobed corolla; another on galls produced on the leaves of Vines by a species of *Phytomyza*; another on a similar subject, but wherein the malady is caused by a fungus, *Antroscium*. Signor BECCARI contributes two interesting papers on the development of *Gnetum*, and on the structure of that very curious plant *Cardiopteris*, which he refers to the neighbourhood of *Convolvulaceæ*.

— What effect have the FROSTS OF WINTER ON EVERGREEN LEAVES? This is the question which M. MER has been striving to answer, and from his paper in the *Bulletin de la Société Botanique de France* we gather that in some cases, as in Ivy, the leaves may rely on the reserve stores accumulated in the stem without themselves assimilating any food from the air. In other cases they form starch in their tissues, and if this be not always readily found the explanation is to be sought in the circumstance that it is transferred to the store cells in the stem as soon as formed. M. MER'S paper must be read in detail. We can merely add that he divides the tissues of the leaf into two groups, the office of the one being to assimilate, that of the other to store the food formed by the former.

— Mr. R. SPINKS, late foreman to Mr. DICK, at Canford Manor, Dorset, has been appointed head gardener to W. F. CHILDE, Esq., Kinlet Hall, Shropshire.

— A very useful illustration of the ease with which it is possible to decorate the FORECOURT GARDENS OF COTTAGES by means of a few simple, unpretentious flowers, recently came under our notice. The cottage was one of a row, and of the humblest kind, and was tenanted by a labouring man. There was no attempt at arrangement or the production of effect, the whole was merely kept neat, and nothing more. There was, however, in bloom a fine plant of the Christmas Rose, a few bunches of the winter Aconite, several single Primrose of various hues of colour, double white and red Daisies, some common Pansies, bunches of Snowdrops just peeping up, and patches of *Myosotis disitillator* bursting into bloom. In addition were *Polyanthus*, *Arabis*, yellow *Aly-*

sum, *Daffodils*, and several other kinds of early spring flowers—enough during their season to make this little garden look very gay and pleasing. Had not this little floral display been somewhat singular, it would scarcely have been so suggestive, but the common culture of early hardy flowers in cottage gardens does not appear to be by any means so frequent as could be desired. Perhaps some of this negligence on the part of the cottager is due to the comparative discouragement given of late years to the cultivation of hardy plants by the gardens of the rich, the more showy but hardly more beautiful summer bedding stuff having considerably elbowed the hardy plants out of favour. Societies established to promote a love for horticulture amongst cottagers might do much practical good by distributing amongst them large quantities of the simpler hardy spring flowers.

— Mr. W. B. FREEMAN, of the Model Farm, Shilling (Assam), has published a brief manual on Potato cultivation. The pamphlet is intended for translation for the benefit of the natives, and is, therefore, as clear and simple as possible. The Potato disease proper does not appear to be troublesome in the Khasia hills, in spite of the large rainfall to which they are subjected.

— From a note in the last monthly Report of the American Department of Agriculture we gather that in 1876 the RAISIN GROWERS OF CALIFORNIA about trebled their product of the previous year, the receipts at San Francisco by the close of the year would probably reach 60,000 boxes, against 18,000 or 20,000 last year. It is stated that one vineyard dried 240 tons of Grapes, producing 80 tons of raisins. The dry summers of California, and the regular and limited period of her annual rainfall, give special facilities for drying in the sun. Grapes dried in this way produce much finer raisins than those dried by artificial heat. The Grape growers of California also exhibit great ingenuity in shielding their Grapes against occasional and unexpected showers; frames are provided for the spreading of the fruit, and are arranged for convenient handling and packing, so that all the grapes may be successively exposed to the sun. On the approach of rain the frames are specially placed under cover, and when dry weather reappears are again spread out.

— THE WEST OF ENGLAND ROSE SHOW will take place at Hereford on Friday, July 6, not Thursday, as recently announced in our advertising columns.

— Professor M'NAB has contributed a valuable paper to the Royal Irish Academy on the anatomical characters serving to distinguish the species of *ABELIS*. The paper is the result of the microscopical examination of many thousands of sections of the leaves. For the most part, Dr. M'NAB'S conclusions agree with those of M. BERTRAND, though there are occasional discrepancies. Throughout Dr. M'NAB has profited by the experience and practical knowledge of his father. The characters of the shoots, buds, and foliage are given, together with the anatomical characters presented by the latter. The confusion in the nomenclature of some of these plants is so great, that cultivators would gladly avail themselves of any ready means to distinguish the several forms.

— Towards the close of last year a DIGGING MACHINE, patented by Mr. KNIGHT two or three years ago, was tried on Mr. CHAMBERS' farm at Langley, Kent. The work was thought by several practical farmers present to be fairly well done, and what disapprobation was expressed referred principally to the amount of tackle required, and to minor details, which in all probability will be altered. Another digging machine was patented last August, and at the annual meeting of the Maidstone Farmers' Club, held on January 25, Mr. W. H. SAMSON, the inventor, who is a resident in Maidstone, exhibited a model of it. According to the *South Eastern Gazette*, his explanation of it was attentively listened to, and several members expressed themselves in favour of its general principles, but for the most part they wished "to see the thing at work" before giving an opinion upon its merits. "Of course," says our contemporary, "whether the machine will bear out the promises of the inventor is a mere matter of conjecture, but after a careful examination of the model we are

him. It would be a terrible tax on them. What would the richer classes say if they were asked to subscribe 1 per cent. of their income to a horticultural list? The list of young Fellows, now in the printer's hands, contains the names of many of the ablest and best known gardeners in the kingdom, who have thus shown their sympathy with the movement and greatly strengthened the list; but I think it would be Utopian to the last degree to trust to the hardy-earned wages of gardeners to furnish means of support for a great society. Professional gardeners can be excellent and most useful friends in many ways to a society without becoming Fellows, and many of them have considerable influence with their employers. In the report will be seen two instances where employers, in acknowledgment of long valuable services, have given in their gardeners names as would-be Fellows. The Rev. E. R. Benyon, of Culford, named Mr. Griese as a Patron four-guineas Fellow, as was also his friend Mr. Robert Gibson, of the Poles, gave Mr. Hill's name as a Hanbury. I believe these will not be solitary instances. It has been suggested that country societies should subscribe and nominate some of their body, and that those of them should be gardeners. I hope, somehow, we shall continue to have a fair sprinkling of them, and most of the country nurseries; but the main support of a strong society must come from owners of gardens. In the test experiment made in this neighbourhood, out of some fifty who had been asked to give their names as owners of gardens, and there was only one professional gardener, and he in a very good position. At p. 149 Mr. Fish—who I am glad to see will give his name to our list—reminds me that "the horticultural public cannot live long on the mere promise of gardeners' Fellowships." The only promise I have made is that when 500 suitable names are forthcoming all the rest will follow. It is for the "horticultural public" now to work, not for me. I will gladly furnish circulars, &c., to assist the canvass, but horticulturists must work out suitable lists in their own way, which they have influence. *George F. Wilson, Heathbank, Weybridge, Hants.*

Temperature of Outside Vine Borders.—Perhaps it may be servicable in the present discussion about heat for outside Vine borders during the period of forcing for Grapes, to have the average temperature of the soil at 1 foot below the surface as supplied by Nature to a house started April 7, compared with the underground temperature at the same depth enjoyed by Vines started December 1, supposing in each case that the house is made up with sun-heat in the afternoon, and occasionally syringed for a fortnight previous. From the daily record of the underground temperature kept here with tested thermometers for the Scottish Meteorological Society, at depths of 3, 12, and 22 inches, I have taken the mean temperature for each month at 12 inches for the years 1874 and 1875. In order to avoid any local peculiarity, and to widen the average, I have taken the means for each month over the same period as registered at Thirlestane Castle, Berwickshire, obtained from the Meteorological Office (*Journal*), and by taking the mean of the Sutherland and Berwickshire averages for each month, I think it will give a fair average for Scotland:—

Natural Mean Temperature at 1 foot Underground.

January	..	35.1	July	..	59.4
February	..	35.8	August	..	59.2
March	..	36.7	September	..	58.4
April	..	45.3	October	..	47.9
May	..	50.9	November	..	42.6
June	..	58.5	December	..	38.2

Natural Mean Temperature at 1 foot Underground for House Started Dec. 1.	Natural Mean Temperature at 1 foot Underground for House Started Dec. 1.	Natural Mean Temperature at 1 foot Underground for House Started Dec. 1.
First month, December	34.6	10.5
Second	January, 35.7	15.1
Third	February, 36.6	20.6
Fourth	March, 38.7	30.7
Fifth	April, 45.4	42.9
Sixth	May, 50.9	54.0

From these figures it will be seen that Nature supplies a considerable mean monthly increase of temperature in the soil during the first four months of growth in spring—beginning at March with 35.7; April, mean in July, at 59.4, after which commences a steady decline. It has been proposed to cover early Vine-borders early in autumn, and to depend upon Fern or thatch and covers to supply the necessary root temperature for forcing during the winter months. I have never would be considered for its attending this method, where the roots are all outside, as though no doubt a few degrees more than the natural underground temperature would be secured, yet I doubt if more than the natural increase of temperature in the soil could be looked for; indeed, from December to February there would probably be a

steady fall, as the heat retained in the border in autumn would be gradually given out and lost, thus giving a falling instead of a rising underground temperature during the first three months of growth, and reversing Nature's method. Even assuming that these coverings furnished an increase of temperature corresponding to the ordinary underground increase, that would only give a rise of 4.1 from December to March, the natural temperature at 1 foot underground being, December, 34.6; January, 35.1; February, 35.2; March, 38.7. Too much artificial heat is no doubt injurious to early Vine borders. If we go to the other extreme, and give none at all, I believe that will be found equally so. Experience and observation of Nature's teachings would seem to indicate that the road to success lies between the two extremes. *D. Melville, Dunrobin.*

Poinsettias.—In many places the conservatory is attached to the mansion or villa, the stove being some distance away, as in the case with me. The lilies go into the conservatory a hundred times where they would only go into the stove once. Therefore, to enjoy them as much as possible, Poinsettias should be moved to the conservatory as soon as they have tolerably good-sized bracts. On December 18 I took my plants into the conservatory, and to-day, February 5, they are still quite fresh. The temperature ranges between 48° and 55°, but never above the latter. I keep them on as dry a bottom as possible. They require much less water when removed to a colder house. *G. P., Holland House, Weston-super-Mare.*

Three-quarter Span-roof Garden Frame.—Messrs Boulton & Paul, Rose Lane Works, Norwich, have favoured us with the accompanying illustration, fig. 29, of a new frame made by them for growing Cucumbers, Melons, &c., and for storing fruit. It is made to give greater height and more convenience

FIG. 29.—CUCUMBER AND MELON FRAME.

than other frames made by the same firm. The front is 11 inches high without the light, 32 inches high at the ridge, and 22 inches high at the back. The front lights can be turned back on to the lights behind, and the back lights be turned on those in front, giving access to all the plants inside. They are made of red deal, and glazed with 21-oz. glass. The illustration shows the lights to open with gearing, any of the lights can be lifted up when required without altering the other lights. The back and front gearing work separately.

Large Garden Pots.—Having seen at pp. 80 and 147 notices of the different sizes of lower-pots in use, I thought it might be interesting to some of your readers to know that galvanized iron pans serve the same purpose, where a size of pot larger than is made at the potteries is wanted. Wooden tubs are generally used for plants requiring a shift at this stage, but these are not very durable, though made of the best material, when used for planting growing. We don't know how long galvanised iron pails will last, but should expect them to last much longer than wood. Some may have doubts about using iron for planting growing, but iron being considered to be injurious to plants; but such does not appear to be the case with galvanised iron, as we have had them in use for the past twelve months for different sorts of plants, which are in the best of health. The pans are full of roots, and the roots in contact with the iron are as fresh and healthy as those grown in the common earthenware pot. I may say that they are painted outside the same colour, and made the same shape as the common flower-pot, and at a little distance the one would not be known from the other; also that the first cost of them is little more than the price of the largest-sized pot made in this locality. *P. G., Leywood, Sussex.*

The Buckley Fund.—In the interest of those for whom the above fund has been subscribed, I, as hon. treasurer, beg to announce, that at a meeting of

the committee held on Monday evening the 5th inst. at the City Criterion, a sub-committee was appointed to enquire, and accordingly arrived at some decision with respect to the manner in which the balance of the fund shall be applied. Any gentleman wishing to subscribe will please do so at or before that meeting, when it is hoped as many subscribers as possible will make it convenient to attend. *George Deal, 13, Carlyle-square, Chelsea, Feb. 7.*

Bottom-heat Without Cost.—I was tickled with an article at p. 107 on "Bottom-heat Without Cost." I read it carefully, and found that it was Knight's theory revived—namely, that the earth was heated by the air, and not the air by the earth, and, *et cetera*, no plant could have any power to combat the air, but that a stage of wood, since the red brick pot and the soil therein had the same warming apparatus as that which warmed the foliage of the plant. The reasoning was faultless, but, alas! the theory could not be reduced to practice. The Pice-apple grown upon shelves were shabby and withered, and the system has been a laughing stock from that day to this by practical men. The Pice-apple has peculiarities that are not always taken into account. The plant is a regular pincer-plant, carrying in its capacity a large amount of water. At the end of the day, and of its channelled leaves are formed by Nature to keep up the supply by every watering, sprinkling, condensing, &c. By whatever means it quenches its thirst, one thing is certain, that it will endure great bottom-heat, and that, in order to get a good account of the plant is a surface feeder, and never travels far unless it gets planted out on a bed of decayed leaves, and like half the plants known riots in leaf-mould. The difficulty in getting bottom-heat for the Vine is great, on account of the rambling character of the plant, for it will travel in good pasture 30 or 40 feet from the place where it was planted. Its rambling shoots are notorious runners, but not more so than its feeders, but as the one works in the dark, and the other in the day, vague notions are entertained of the nature of the rambling eye, however, will recognise a healthy feeder, and read its history; its size, its colour, its plump appearance, are all marks of excellence regarding the medium in which it has lived. An eminent Grape grower in the North has given me the most beautiful and manufactured the finest samples of Grapes that up to that time had ever been seen, and they certainly got bottom-heat, and perhaps three times as much water as we were wont to give to growing Vines; but let any one examine a Vine branch, and see the sec loc of the one-year's wood, which is open like a wine stew, that when a Vine bleeds from mismanagement it runs like "a sma' still." Much judgment is needed to hold the candle to the Vine, for the wet and warm time is only to be tolerated when the plant is making wood, for the extraordinary size and quality of Grapes exhibited as grown by heated bottom-heat; and from Mr. Knight down to this time nothing marvellous has ever come of inside borders, simply because the heat of the earth is unable to warm the soil beyond the depth of a few inches. Cuttings not only strike best in a good bottom-heat, but much time is gained thereby, showing that a temperature much above what a cold frame yields is the best artificial medium for the most valuable and useful of our fruit ever sown, which is open like a wine stew, that when a Peach-house well managed, for when watered at random by the boy in charge it is well wetted on the surface but not so lower down, and when the fruit has hung long on the trees the earth will be dry enough, if it is to guarantee its sufficiency of water, for the earth must not be forked beyond a few inches lest the roots should suffer? At Clun, in Aberdeenshire, the fruit-houses were kept in the nearest order I have ever seen, for the surface soil wore holiday attire, and consisted of finely sifted very black peat or bog earth, and tickled into the corners with a very small birch broom. Now the state of the inside border, thus disguised and painted black, as they are galled; and the soil, being at a low level, certainly got bottom-heat as much as it could be for nothing; and I went to Leck, in Staffordshire, once to see two tanks containing gold fish, and was surprised to find what a temperature the fish could bear, for they thronged the place where the warm water came in from the engine, and had fresh water, as they were, where the condensed water from a paper-mill entered the river, the place was thronged with small fish, who evidently

ingly practise when they want bottom-wood. Mr. Murray's paper implies a general or all downward growth. He Dr. Darwin's experiment, recorded in books, by which he traced the ascent of a coloured infusion, in a species of Euphorbia, to the extremities of the leaf, and the descent of a milky juice in another set of vessels from thence into the petiole, on its way to the stem. But those who have practised ringing, or watched its effects, need not look further for evidence of a downward growth. To mention one among many cases. A thriving young Scotch Fir in my shrubbery, about a feet high, was completely killed by the weight of a snow which 2 inches by the friction of a ligature. This happened in winter. The following year it grew but little, but threw out an abundant foliage of a lighter colour than before, and the next year, in addition, a numerous crop of small cones. At this time, and during the next season, the whole stem above the standard part increased in girth, while below it remained as before the accident. Ultimately the wound grew up by an advance of the upper lip, and the tree, but with a spindle shank, resumed its ordinary growth. Such are the ordinary effects of ringing, and the effects of the upper branch at the expense of the lower stem and the roots; a shorter growth of wood, a disposition to form flower-buds, and, in the case of fruit trees, earlier, larger, and more highly coloured fruit. In this case, however, the weight of the wood, and an unusual supply of the proper juice is stored in the ringed branch, and that it is full fed, while the stem and roots are deprived of their usual share, and so perhaps checked in their action. Mr. Murray's theory does not guide us to an answer—it seems to be useless. S. S., *Sevenshoes*.

Mildness of the Season.—This place is situated about 500 feet above sea level, which no doubt has much to do with our singular exemption from frost. We have, however, the disadvantage of lying on the north side of an extensive ridge running eastward from Tunbridge Wells, and so steep, indeed, is the incline northwards that the sun does not shine on any part of the ground in the kitchen garden before 9.30 A.M. at this season of the year. Our altitude and position does not altogether account for the condition of things at the present time. In the rockwork round my house scarlet Pelargoniums of years are still alive, the lemon tree is in flower, and the plants are very comfortable, and putting out new leaves. Petonias and Maurandya Barclayana against a wall continue to grow, and Verbenas are growing almost as well as they did in the summer, but do not flower. I do not cuttings, but I see to-day (February 1) that they are making fresh leaves. Notwithstanding the mildness, the want of sun has prevented wall trees from making that progress which they often do during sharp frost when there is sunshine with it. They look much more promising, however, than they did at this time last year. D. Buchanan, *Sherrwood Park, Tunbridge Wells*.

High-class Potatoes.—Charles Mackay in one of his fine songs makes a clown to exclaim:—

"The King can drink the best of wine,
So can I, so can I;
And has enough when he would dine,
So have I, so have I;
And cannot order nor in shine,
Nor can I, nor can I;
Then where's the difference let me see
Betwixt my lord and me."

I often have this stanza brought to mind when I sit down to partake of a dish of Potatoes as good and as delicious as can be had in all the wide world, and know that even the Queen, with all her gardens and power, cannot have at her table a more acceptable dish of Potatoes than I can. Those who cultivate only coarse growing kinds, and are thoughtless how speedily to fill the bushel as a matter of preference to quality, must remain ignorant of the delicacy found in a well cooked dish of high-class Potatoes. It is a noble peculiarity of this excellent, that if intrinsically good it needs only the addition of a pinch of salt to render it perfect. All other condiments or additions serve only to spoil, and if he has but the best sorts [and somebody to cook them], the humblest cottager may have his Potatoes served up in all respects equal to those served to the table of a King. I allude to whom I see some of the Rector of Woodstock, said, "they are so delicious that I keep them expressly for my Sunday dinner," probably intending

to pay tribute to the quality of the Potato, and to the high quality of his potato. Similarly, when I can sit at my table with more than usual abundance, the mid-day meal, I have a dish of either Lapstone, the Rector, President, Scotch Lute, Onwards, Bountiful, King of Potatoes, or some similar garden variety, in none of which are found the popular Artichoke texture and earthy flavour so prominent in the coarse American kinds. On the 4th of this month I partook of a dish of President that had been lifted with others from the field only the day previous, having been almost flooded during the greater portion of the month in which it had been growing five months after ripening, and yet were as white, clean, and delicious as it was possible for a Potato to be. The prevailing rage for "bulk" is driving these more refined garden kinds out of the field, and yet there are none more fit for eating. A small Potato, the size of a hen's egg, if of the best quality, is worth one twice the size for eating, if the latter has only size to recommend it; for, after all, though the market-grower is only concerned to fill the bushel, the private gardener has his employers' table to cater for, and no gardener will be content to dine off Artichoke Potatoes when he knows he can have those of the highest quality. Those who cultivate the little Golden Pippin Apple or Winter Neis Pear tell us that they prefer flavour to mere size, and their taste is to be commended. In so many instances, the Potato less size, but of more delicate flavour than big coarse ones, should be grown by all who prefer quality to mere size and bulk. A. D.

Cauliflowers.—It is much to be feared that most plants of these raised from autumn-sown seed will play tricks this year and "bolt" for, to use a familiar agricultural term often applied to Wheat when too forward, they already look "weather-proud." This weather-proud appearance results from an unusually mild winter, accompanied by one of the most excessive rainfalls on record, and the two combined have done much to hasten on the growth of the plants. Plants are now as forward as they ought to be in April. Whether under glass or entirely in the open air, the case is just the same, and it will therefore be unwise to trust entirely to either, for the chances are that those who do so will find themselves worst supplied just at a time when they are the most needed. In view of this it is well, I think, to sound a warning note, that timely preparations may be made to avert a scarcity of a vegetable held in such universal estimation as the Cauliflower very deservingly is. The best plan to adopt, in the open air, is to place, in light rich soil in pans or boxes, and place the same in heat, so as to get it up as quickly as possible, after which it should be nursed on close up to the glass, where it can get both warmth and air, to keep the plants on drawing so soon as large enough to handle they should be pricked out at about 3 inches apart, on a gently fermenting hotbed, where they may be allowed to remain till they are of proper size, and the weather is sufficiently favourable for planting them out. Treated in this manner the plants will almost certainly do well, as those sown in August, which in even ordinary seasons are very disappointing from the premature way they turn-in, while those raised now never fail to give satisfaction, and produce full-sized heads if properly cared for as to soil and situation. The great point with spring-sown Cauliflowers is not to coddle them unnecessarily, but to keep them up close to the glass, where they can have plenty of light and air to induce a strong, sturdy habit, in which state they are most preferable to the plants that have been brought. As to the plants that are now sown, it is well to remember that there are none better for spring work than the old Early London—a variety that is in much esteem with market gardeners, who, as a rule, are pretty good judges of what is best to grow, and if with this popular variety some Walcheren are sown at the same time, they will do well, and will certainly do well in well to succeed them. As to autumn-sown plants, where they are not in too forward a condition to destroy all hope, the only thing that can be done for them now is to expose them to all the air possible by lifting the glass, and handling them as they should be, and while we get a continuance of the present mild weather; and should sharp frost occur, even then they should be tilted, as Cauliflowers will stand a good deal if they are thoroughly dry, although it should be borne in mind that they are just now more tender than usual from the free soft growth they have made. 7. 5.

The Weather of 1876 in West Herts.—The rainfall of the first four months in this year, calculating from the middle to the end of April, was very heavy, amounting to 10.7 inches, and the total for the same months of 1875 the fall of that year to the end of April amounts to a little over 6 inches. It will be seen that last year the rainfall thus far was very copious; but it is of the next three months that I can say the most remarkable contrast. In the latter part of the whole month of May was a little over half an inch. The same amount would fall quite

freely in two showery days, but in this month it took eight damp days to obtain so much, the showers being very slight. The amount of rain for the year 1876 was registered. The month of June was a little better—1.26 inch, or about equal to four showery days, though in this month it took eleven slight showery days, the heaviest fall happening on the 15th, when 0.54 inch was recorded, and the next day 0.22 inch, but no better registered. The month of June was a little better—1.26 inch, or about equal to four showery days, though in this month it took eleven slight showery days, the heaviest fall happening on the 15th, when 0.54 inch was recorded, and the next day 0.22 inch, but no better registered. The month of June was a little better—1.26 inch, or about equal to four showery days, though in this month it took eleven slight showery days, the heaviest fall happening on the 15th, when 0.54 inch was recorded, and the next day 0.22 inch, but no better registered. The month of June was a little better—1.26 inch, or about equal to four showery days, though in this month it took eleven slight showery days, the heaviest fall happening on the 15th, when 0.54 inch was recorded, and the next day 0.22 inch, but no better registered. The month of June was a little better—1.26 inch, or about equal to four showery days, though in this month it took eleven slight showery days, the heaviest fall happening on the 15th, when 0.54 inch was recorded, and the next day 0.22 inch, but no better registered. The month of June was a little better—1.26 inch, or about equal to four showery days, though in this month it took eleven slight showery days, the heaviest fall happening on the 15th, when 0.54 inch was recorded, and the next day 0.22 inch, but no better registered. The month of June was a little better—1.26 inch, or about equal to four showery days, though in this month it took eleven slight showery days, the heaviest fall happening on the 15th, when 0.54 inch was recorded, and the next day 0.22 inch, but no better registered. large Planes, and one of the most prized trees on the estate, the Catalpa syringifolia, shared the same fate, lying prostrate on the lawn. In the extensive pleasure-grounds huge limbs of hard-wooded trees bestrew the great walks, leaving unobstructed proofs of the violence of the storm in all directions. Adjoining the end of the pleasure-grounds is a grove, consisting chiefly of Beech trees, from which it derives its name (Beech Grove), which presents a spectacle seldom or never witnessed in this locality: scores of trees, mostly Beech, but here and there a Silver Fir or a Cedar of Lebanon, have been swept down. Several Scotch Firs and Austrian Pines, apparently having too firm a hold of the ground, were snapped asunder as if swept off, and hurled yards away from their stump. In the belts and coverts the boundaries of this and adjoining estates the trees were swept down by hundreds, and houses were partially destroyed, in some instances by chimneys falling in, and tiles and slates were blown about in all directions. Altogether this was one of the most disastrous and distressing storms experienced of late years in this locality. *Spectator.*

The Villa Garden.

WHEN will the fine weather come?—weather so brisk and drying as that "rain which raineth every day," or almost every day, may subside below the surface, and enable the gardener to get on to the soil, and resume his long suspended operations? We are among those found regretting that they dug any portion of their spare soil in autumn; but then who could have foreseen the persistent rainfall that has happened, and which will make the winter through which we are passing famous in the annals of time? Soil of any kind, of retentive character that was dug in autumn is now of a very sticky character, and moves far worse than that which has been left untouched. And yet if we had experienced instead of the rain a period of sharp frost and drying winds, the soil moved with the spade in autumn would have been benefited by it. We must, like sensible persons, take things as they are, and make the best of them.

KITCHEN GARDEN CROPS.—Early Peas sown in November are now coming through the soil; and, the rain notwithstanding, the bright sunny periods that do manifest themselves to our great gratification show us the rows of Peas making a surprising progress. If the soil is too wet to hoe it by the sides of the rows, a gentle stirring process among the Peas will greatly assist them. The genial quickening influences of the warm sun and the halmy air favourably incites the crop to active growth when they can penetrate the soil. The birds are finding these Peas out, and their depredations must be checked. A young cat hanging after its first taste of bird-life, is an excellent protector as long as the fit of enthusiasm lasts. Slugs are troublesome also, but a little dry lime or soot sprinkled along the sides of the rows generally answers the purpose of an effectual barrier. This sprinkling needs pretty constant repetition for a time.

Slugs are very troublesome just now to the winter Lettuces. They are patting forth a delicious young growth, and slugs are as much gourmands in their way as the representatives of the higher orders in the animal kingdom. Here also a sprinkling of lime is of great service, and also stirrings of the surface soil. If frost and snow should come, a few branches of Spruce Fir stretched about among the young Lettuces will prove a great protection. The cold draughts of such wintry influences coming among us with a sudden rush, and we must not presume on the tractable character of the season.

The Early Longpod Beans, planted at the same time as the Peas, are moving on with great rapidity; when sown on a slightly sloping south border, with a wall, hedge-row, or belt of trees at the back, they are in a very favourable position. In a neighbour's garden we saw a few days ago, a piece of Seville Longpod Beans fully 9 inches above the soil, and growing very strongly. They are now earthed up to within 3 or 4 inches of the tops, and the soil between the roots has been well stirred. Nothing in the garden is so promising, and if only the spring will be merciful a good crop may be anticipated. Potato planting will shortly claim attention, that is, as soon as the soil is at all workable. Seed Potatoes are giving some trouble this season, especially the early sorts, for they, owing to the mild, moist weather

are growing very fast. The best thing to be done is to get the seed spread out as thinly as possible in a cool airy place, so that they can sprout into growth. It is a good plan to have the seed in shallow boxes, so that they can be carried to the ground where they are to be planted without the necessity for meddling with or moving them. We have recommended in previous papers the ridging up for the winter of ground intended for early Potatoes. Supposing this was done last autumn, and the weather becomes dry enough to move the soil, planting can be proceeded with, and when the planting commences the rubbish-heap that we have so frequently recommended comes into play. A rubbish-heap to be in the highest degree serviceable should be occasionally fired, or at least all the coarser woody portions of it should be burned. This gives a valuable lot of ashes, and these ashes, when mingled with leaves, refuse soil from the potting-bench, clippings of turf edges and flower beds, the sweepings from walks, &c., forms an excellent material to put in with the seed Potatoes. The valleys between the ridges should be first forked up lightly, and the soil beaten to pieces as much as possible, then some of the material just referred to spread in the trench, the seed placed on it, and some more added (in quantity sufficient to cover the tubers), and then sowed (from the ridges crumbled in over them. By-and-by, when the plants grow, and earthing-up becomes necessary, the soil of the ridges can be used for the purpose, and, finally, the soil on which they rested forked over, so as to supply material for the final earthing-up.

Remembering that Onions form a leading crop in the kitchen-garden, it is time attention be turned to sowing some seed. As a general rule, Onions are not sown early enough, and the consequence is they get arrested in their growth by dry weather in spring, and seldom make up for the check after. We can here learn a lesson from the Banbury Onion-growers—the men who grow such splendid Onions for exhibiting in August; their time for sowing is the first and second weeks in February. They manure their ground well in October and November, and then throw it up rough for the winter. In January, as soon as dry weather permits of its being done, they fork it over, break it well to pieces, and then, taking advantage of a drying frost, tread it down firmly. A few days after, and when the weather is fine, drills are drawn a foot apart, and the seed thinly sown in them, some wood ashes covered over it, and then the soil is raked on to the seed, and beaten down with the back of a rake.

It may be asked, Whence the necessity for digging the ground so deeply for the Onion, seeing that it roots so sparingly? But the fact is the Onion roots much more deeply into the soil than is generally imagined, and the richer the soil is in vegetable food the quicker is the growth. The great thing with Onions is to get the roots well down into the soil before dry weather sets in, and then the bulbs swell out finely. The Banbury growers water freely in dry weather; they also (after they have thinned out the bulbs to the proper distance) keep the soil well stirred about the plants, and top-dress with wood-ashes and manure; and later on, when the bulbs are swelling, dress with bonedust and guano. All these attentions are not necessary in the case of a general crop of Onions for culinary use, but they serve to show how the crop may be augmented. The earlier Onions are ripened off, the more matured do they become for keeping, supposing it be a variety which keeps well.

Notices of Books.

Potato Pests; being an Illustrated Account of the Colorado Potato Beetle and the other Insect Enemies of the Potato in North America, with Suggestions for their Repression, and Methods for their Destruction. By Charles V. Riley, State Entomologist of Missouri. New York: Orange Judd Company; London: Trubner & Co.

Mr. Riley is well known for his able reports as State Entomologist of Missouri, and for the care and skill with which he has conducted observations into the life economy of various insect pests, from which North America has of late years suffered, or by which she has been threatened. Among those which he has so studied with much credit to himself and advantage to the public, the Colorado beetle of course occupies a prominent place; and now that that pest has spread over three-fourths of the cultivated area of the United

States east of the Rocky Mountains, it is unnecessary to say that an authoritative work regarding it, giving full information as to its habits and life, with directions as to the best means of encountering it and destroying it, must be most useful.

To us and our readers it is not, indeed, new. Most of the information contained in it has already appeared in Mr. Riley's annual reports, which have been noticed by us as they appeared, but State reports, extending over a series of years, and containing a multitude of subjects, are not the kind of work that will be sought for by the general public wanting only information on one particular subject. Mr. Riley and his publishers, in producing a small cheap work confined to this subject have, therefore, supplied an important want peculiarly felt at the present juncture. The work is in duodecimo form, and is liberally illustrated by woodcuts from Mr. Riley's own pencil, for to his other accomplishments he adds that of being an admirable artist.

The subject, not being a new one to our readers, we shall not trouble them with any extracts relating to the appearance and life of the beetle. The part that will have most interest for them will be Mr. Riley's opinion as to the chances that we have of escaping an invasion from it in this country. On that point he says:—

"In 1874 the Governments of Belgium, France, Switzerland, and Germany prohibited the importation of American Potatoes, and Italy, the Netherlands, and Great Britain, which had been urgently solicited to follow their example, began seriously inquiring into the necessities of the case.

The British Government was naturally slow to take such stringent steps, which would more deeply affect it than the other nations named, for there is no one man does the larger trade in American Potatoes. In reply to Mr. Herbert, M.P. for Kerry, who asked the Chief Secretary for Ireland whether Her Majesty's Government had taken any steps to prevent the introduction of the insect, Sir M. H. Beach sought to abate fear, rather than to encourage it, and wisely concluded that any interference with the trade should first have the most careful consideration. Those who had watched the insect's gradual spread during the past seventeen or eighteen years, from its native Rocky Mountain home to the Atlantic, and had seen how the lakes, instead of hindering its march into Canada, really accelerated that march by floating it on vessels, rafts, and other floating objects, could have no doubt that the same cause for the alarm felt by our Transatlantic friends.

"Yet the opinion had been repeatedly expressed by the writer—and very generally coincided in by all who had any familiarity with the insect's economy—that when it made its descent into Europe it would most likely be carried in the perfect beetle state on some vessel plying between the two continents. For while the beetle, especially in the non-growing season, will live for months without food, the larva would perish in a few days without fresh Potato tops, and would, I believe, starve to death in the midst of a barrel of Potatoes, even if it could get there without being embedded; for while it so voraciously devours the leaves it will not touch the tubers. The eggs, which are quite soft and easily crushed, could, of course, only be carried over on the haulm or on the living plant; and while there is a bare possibility of the insect's transmission in this way, there is little probability of it, since the plants are not objects of commercial export, and the haulm, on account of its liability to rot, is not, so far as I can learn, used to any extent in packing. Besides, Potatoes are most exported during that part of the year when there are neither eggs, larvae, nor Potato vines in existence, in the United States."

"While some Europeans have thus been induly alarmed, and inclined to take prohibitive measures to prevent the insect's introduction, others have ridiculed the idea that the insect could get to Europe, one of them declaring that there is no more danger of the insect's chance transportation than of that of our rattlesnake. Considering that half the weeds of American agriculture, and a large proportion of our hardy insect pests, find their way to beetles, viz., the Asparagus beetle (*Crioceris asparagi*), and the Elm leaf beetle (*Galeruca calmarianis*), in the very same family as our Doryphora, have been imported among us from Europe, there would seem poor foundation for such argument. Indeed, the reported occurrence has summed up in living Doryphora in the French docks, in a cargo just coming from London, is the best evidence; it effectually sets at rest the several allusions to, and bears out the views I have on former occasions expressed as to the possibility of the beetles being carried over in vessels."

"It is argued by others that on the continent of Europe our Doryphora will be more effective in England, but, on a sufficiently long residence in England, France, and Germany I am decidedly of the opinion that they delude

themselves who suppose that Doryphora could not thrive to the greater part of Europe, and that to abandon all precautionary measures against its introduction on such grounds would be the height of folly. An insect which has spread from the high table-lands of the Rocky Mountains across the Mississippi valley to the Atlantic, and that flourishes alike in the States of Minnesota, Wisconsin, Upper Canada and Maine, and in Maryland, Virginia, and Texas—in fact, wherever the Potato succeeds—will not likely be discomfited in the Potato-growing districts of Europe."

We must refrain from entering into the contrary arguments of those who maintain that its invasion is a purely imaginary danger; but we may say that our own opinion coincides with that of Mr. Riley. We have no expectation that we shall be able to keep the beetle from coming into Britain. It will come, we do not doubt, again and again. Nor do we think that if it were allowed to settle it would have any difficulty in establishing itself permanently. The wideness of its range in America shows that it possesses a degree of adaptability various conditions that must dispel any hope of that kind. But we have no fear on that account that the Potato crop will be destroyed, or that we shall have to pay \$1. a bushel for them, like the inhabitants of St. Louis in 1873. We cannot keep it from coming over, but it will be our own fault if we allow it to gain a footing. It will be an easy job to stamp out the first broods. It is a very different thing clearing them off a single Potato field or two compared with resisting a solid invading army of them extending over 15° of latitude, as in America. Of course, if we act like ostriches, and think that by shutting our eyes to the danger we shall escape it, then we should soon find how helpless we are in contending against it; but we have no fear on that account, and whatever the *laissez faire* gentlemen may say we do not intend to be, nor do we think that there is any danger of, our being caught napping.

We have not left ourselves space to say anything about the proper precautionary and remedial measures, but as in no view could these be required before the month of June, we have plenty of time to return to the subject. *A. M.*

Among publications on our table we may mention a new edition of *Stornom's Etymological and Pronouncing Dictionary* of the English language (Blackwood & Sons), which in small compass contains a very large amount of information relating to the significance and varied adaptation of words. The grouping of compound words appears to us very serviceable. Many of the more modern scientific terms are included, so that the volume is likely to be very useful for those who require a compact and useful dictionary.

The last number of the *Bulletin d'Agriculture* contains a coloured plate of the striped variety of the Duchesse d'Angoulême Pear. The following varieties are mentioned as having striped forms:—Alexandre Lambre, Bergamote Crassane, De Hollande, d'Été, Beurré blanc, Beurré d'Amalins, Beurré Gris, Beurré d'Hardenpont, Beurré Crassane, Élé de Chaumont, Williams' Bon Chretien, Bon Chretien d'Hyver, Citron des Carnes, Doyenné du Comier, Duchesse d'Angoulême, Longue verte, Louise Bonne d'Avanches, Messire Jean, Fasse Colmar, Roussellet de Reims, St. Germain.

PUBLICATIONS RECEIVED.—Synopsis Cedeomyiadarum, by J. E. von Bergenstamm and Paul Low, a very complete synoptical résumé of the literature, the classification, and the plants affected by the gall midges.

Natural History.

THE FIRST BUTTERFLY was captured here on the 6th. Having had sufficient conversation with him, I send him on, that you may for yourself judge how wonderful are the products of our delectable mountains. He is a fine specimen of the small Tortoiseshell, Vanessa urticae, of which thousands are annually produced here, on a fringe of Nettles I allow to root on the margin of a grass field. The small copper, common blue, large and small meadow-brown, orange-tipped, and brimstone are also common, the last-named being usually the first butterfly of the season. In 1874 the brimstone was captured here on March 23, and in 1875 on April 17. The rare Death-head, *Acherontia atropos*, bred so freely here last summer

that we found about thirty of the handsome caterpillars well fed and ready to hibernize when the Potatoes were lifted. *Shirley Hibberd, Stoke Newington, Feb. 7.*

THE GOATSUCKER.—Professor Rymer Jones, in his *Animal Catalogue*, gives the following description of this bird:—"Their eyes are large, their beak, furnished with strong moustaches, and more deeply cleft than in swallows, is capable of receiving the largest insects, which it retains by means of a viscid saliva. The nostrils are in the form of small tubes near its base. Their wings are long, their legs short and feathered, and the thumb can be directed forwards. These birds live solitary, and only fly during the twilight or on fine nights. They pursue moths and other nocturnal insects, and lay a small number of eggs. When they fly the rushing of the air into their wide mouths produces a peculiar humming noise. They have been accused of sucking goats, whence their name; but this is an unfounded calumny that, perhaps, had its origin from the circumstance of their frequenting fields where goats and sheep are herded, in pursuit of the insects that are attracted by their presence." *R.*

Law Notes.

IMPORTANT TO IMPORTERS OF FRUIT FROM BELGIUM.—*Scorrier v. The Great Eastern Railway Company*.—At the Westminster County Court on Tuesday last, before Mr. Judge Bayley, the plaintiff, proprietor of the Coburg Hotel, Charles Street, Grosvenor Square, and the defendant to recover the sum of 30s. for loss of fruit in transit from Belgium by the company's line.

The plaintiff said that on November 11, 1876, he ordered from a grower at Lessing in Belgium 6 cwt. of Apples at the rate of 30s. per cwt., but on the delivery of the hamper at his residence in London it was weighed, and found that 1 cwt. of the fruit had been abstracted. He had made several applications to the company, who denied their liability, hence the present action.

In reply to the learned Judge, the plaintiff said the goods were in the first place delivered at the station of the Belgian State Railway Company, at Lessing in that country, upon which his Honour remarked that he was of opinion he had used the wrong company.

In this view of the case the Company's solicitor coincided, remarking that in doing so he could prove, if necessary, that the contract was originally made with the Belgian State Company, they having the usual running powers over the Great Eastern line; still that did not render the Great Eastern Company liable for any contract entered into with the Belgian State Company, and that if the goods had been either stolen or lost the Belgian Company were alone liable, and that the plaintiff's remedy was against them, and not against the defendants.

Judgment was accordingly entered for the defendants, who did not apply for costs.

RAILWAY LIABILITY AGAIN.—*Iretton v. The Great Northern Railway Company*.—At the Westminster County Court, on January 10, the case was heard before Mr. Judge Bayley, in which Mr. H. T. Roberts appeared as solicitor for the plaintiff, and Mr. Harnsworth as standing Counsel for the Company.

Mr. Roberts, in opening his client's case, said he was a fruiterer carrying on business in Covent Garden and at Leeds, and urged that the goods in question were not delivered within reasonable time, as the Leeds market opens at 6 and closes at 11. The goods—several baskets of Strawberries and Grapes—were sent on July 3, and not arriving in time the Strawberries, which were worth 8s. per basket, had to be sold for 4s. per basket; and the Grapes, originally worth 2s. 6d. per pound, were sold, in consequence of loss of market, at 1s. 6d. per pound, and that the loss the plaintiff had sustained was £6 5s.

Arthur John Iretton, salesman in Covent Garden, stated that on July 3 he consigned fifteen dozen baskets of Strawberries and 65½ lb. of Grapes to Leeds, where he had an establishment. They were delivered to the defendant's carman and marked "Fruit: perishable," with orders to forward them at once, without delay, and received the signature of Sinnet, the defendant's carman, for their receipt on account of John Ashley, the goods traffic manager, of

King's Cross. The plaintiff said he had applied to the Company for indemnification, but they declined to come to any compromise, and would not even answer his letters.—In cross-examination he stated that he was also a wholesale salesman at Leeds, and knew the Leeds market well, and all business there was over by about 8 o'clock in the morning. Mr. Bailey, to whom the goods were consigned, was his commission salesman there. The loss on the goods was £6 5s., as customers would not wait, and the goods did not arrive till 11 o'clock in the forenoon.—Re-examined: There was no doubt as to when the goods were delivered to Sinnet, the carman.

William Bayley said he came from the Leeds market; he received the consignment in question, but not till after the market had closed, which it usually does at 11 o'clock. The Strawberries deteriorated from 8s. to 4s. a dozen baskets, and the Grapes from 2s. to 1s. 6d. per pound, as he had to sell them to retail dealers, they being of no good to his usual customers.—Cross-examined: There is a second market, but not of a wholesale nature. It is not always the custom to send perishable goods by passenger train, but such a course is sometimes adopted.—The Grapes were to be sent to Harrogate, and were too late to be of any avail.

This being the plaintiff's case, Mr. Harnsworth urged that there was a discrepancy in the dates, as there was no evidence that the goods were delivered on July 3, as the 11th was on the particulars. The learned Judge said that appeared to be so, and offered to adjourn the case, but Mr. Harnsworth elected to go on with it.

Sinnet, the defendant's carman, was called, and deposed to receiving the goods between 4 and 6 o'clock on July 2, which ought to have been at the Great Northern Station at King's Cross about 7 P.M.

After this evidence, Mr. Harnsworth addressed the Court at considerable length, and called several witnesses on behalf of the Company, whose evidence went to prove that the Company were not liable; but the learned Judge, after reviewing the whole facts of the case, ruled in favour of plaintiff for the amount claimed, with costs.

- Feb. 1.—Dull, very cloudy. Rain fell in morning, and at 10 P.M. Mild.
- 2.—A dull cloudy day. Mild. Rain in morning and evening. Cloudless at night.
- 3.—A fine bright day. Rain fell in early morning, and again at 7 P.M.
- 4.—A fine bright day. Cloudless at night.
- 5.—Fine but cloudy. Dull, with thin rain at times.
- 6.—A fine cloudy day. Occasional thin rain till evening. Mild.
- 7.—Fine, but cloudy and dull at times. Smart shower of rain at 8 P.M. Temperature unusually high for the season.

LONDON: *Barometer*.—During the week ending Saturday, February 3, in the suburbs of London the reading of the barometer at the level of the sea decreased from 30.24 inches at the beginning of the

FRUIT.

Table listing various fruits and their prices per bushel or dozen, including Apples, Peaches, Pears, Lemons, and Melons.

VEGETABLES.

Table listing various vegetables and their prices per bushel or dozen, including Artichokes, Asparagus, Beans, Carrots, Cabbages, and others.

SEEDS.

LONDON: Feb. 7.—Messrs. John Shaw & Sons, of Mark Lane, write that the seed markets have this week exhibited no special feature of interest...

CORN.

At Mark Lane on Monday trade was very dull for Wheat, and quotations were fully 2s. per quarter lower than on Monday se'night.

POTATOS.

The reports from the Borough and Spitalfields markets state that Regents were dull at a reduction, but otherwise the trade maintained a moderately firm appearance.

COALS.

There was a large supply of house coals at market on Monday, and prices fell 1s. The top price was 17s. per ton.

Special Offer.—150,000 Vesuvius. WILLIAM BADMAN offers strong autumn-struck VESUVIUS, from single pots, 10s. per 1000; or from store-pots, 8s. per 1000, 75s. per 1000, package included.

DANSY BLUE KING.—The finest hardy Blue Plant in cultivation; strong flowering plants, 10s. per 1000, 75s. per 1000, 2s. 6d. per dozen.

PALMS for TABLE DECORATION.—Twelve distinct choice sorts, ready to pot in 5-inch pots, 10s. per 1000, 75s. per 1000, 2s. 6d. per dozen.

JOHN L. COUPLAND, FLORIST, HESSLE. Double FLORIGONIUM.—Beauty of Osebo, Queen Victoria, Prince of Novelties, Captain Raltes, Marcellino Florenpe, King Albert—15s. per 1000.

EARLY FLOWERING PELAGONIUMS.—Dignity Charlie, Alma, Kingston Beauty, Madam Gewinckel, James O'Neil, &c. 15s. per 1000.

Special Offer of FOREST and ORNAMENTAL TREES. PINE AUSTRIACA, well furnished, 3 to 4 feet, 15s. per 1000; 4 to 6 feet, 20s. per 1000.

Messrs. HALL and CO., having large quantities of the above plants, offer them at special prices; the whole are clean and well grown, and are confidently recommended to intending planters.

Patented Peat for Orchids, &c. BROWN HICK CO. PATENT. Best quality for Orchids, Stone Plants, &c., 26s. 6d. per truck.

MANURE, first-class, made from Blood, Bone, &c., of animals, 12s. per cwt., 40s. per 1000.

COCA-NUT FIBRE REFUSE, FOR POTTING and PROPAGATING. Cheapest and best advertised. Before purchasing elsewhere write for Sample and Prices, &c.

M. H. BENTOTE, FIBRE MAKER, LAUSANNE ROAD, NUNHEAD, SE. COCA-NUT FIBRE REFUSE, newly made.—Reduced price, 30 bushels, 6s. 8d.; 100, 20s.; 250, 45s.; 500, 85s.; 1000, 150s.

COCA-NUT FIBRE REFUSE, invaluable for Gardening purposes. One thousand tons of refuse, 10s. per 1000, 75s. per 1000, 2s. 6d. per dozen.

ODAMS' MANURES, FOR ALL CROPS. Manufactured by NITRO-PHOSPHATE and ODAMS' CHEMICAL MANURE COMPANY (LIMITED), consisting of Tenant-Farmers occupying upwards of 150,000 acres of Land.

SHURSTON'S COMPOUND.—Used by many of the leading Gardeners since 1859, against Rust, Mildew, Fire, Greenfly, and other Blight, in solutions of from 1 to 2 ounces to the gallon of soft water, and also as a winter dressing for the roots of Fruit Trees.

SIMPSON'S RED SPIDER, THRIPS, &c. ANTIDOTE. Testimonials of the highest order on application. Per quart, condensed, 6s.; per pint, 3s. 6d.

RUSSIA MATS, for Covering from Frost. From 30s. to 70s. per 1000; packing from 20s. GUNNY BAGS, from 2s. to 4s. per 1000, according to quality.

RUSSIA MATS.—A large stock of Archedal and Petersburg, for Covering and Packing (price on application for Archedal)—Petersburg, 60s. to 100s. per 1000.

RUSSIA MATS.—A large stock of Archedal and Petersburg, for Covering and Packing (price on application for Archedal)—Petersburg, 60s. to 100s. per 1000.

RUSSIA MATS.—A large stock of Archedal and Petersburg, for Covering and Packing (price on application for Archedal)—Petersburg, 60s. to 100s. per 1000.

BEST & CHEAPEST INSECTICIDES

Duty Free, under permission of the Hon. Board of Customs.

THE "LONDON" TOBACCO POWDER, "Horticultural" Tobacco Juice, also TOBACCO PAPER, CLOTH and CORD.

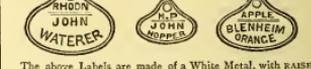

Particulars on application, GORRY & SOPER, BONDED TOBACCO STORES, SHAD THAMES, LONDON, S.E.

Important Notice. GENUINE ROLL TOBACCO PAPER, in packets; also CLOTH of best quality. Trade price very low.

TOBACCO CLOTH and PAPER.—The cheapest and best article for Smoking Greenhouses and Destroying Fly. Price 21s. per lb. or 10c. per lb., 12s. Tobacco Paper, 10s. per 1000, 4s. per cwt. P.O. payable at 16, Blackfriars Road, S.E.

GENUINE TOBACCO PAPER of best quality, price 10s. per lb., or 4s. per cwt. W.M. KENYON, Tobaccoist, 4, Pollard Street, New Town, London, E.C.

Under the Patronage of the Queen. J. SMITH'S IMPERISHABLE STRATFORD LABELS.

The above Labels are made of a White Metal, with RAISED BLACK-FACE LETTERS. The Gardener's Magazine says:—"We must give these the palm before all other plant labels; as the very first in merit."

Metallic Hothouse Builder to Her Majesty.

HENRY HOPE (late Clark & Hope, formerly Clark), HOTHOUSE BUILDER and HOT-WATER APPARATUS ENGINEER, 55, Lionel Street, Birmingham. Established A.D. 1817. BOOKS OF DESIGNS, 5s. each.

THE Extensive Ranges of Metallic Hothouses in the Royal Gardens, Windsor and Osborne, were executed at this Establishment.

Oil Paint No Longer Necessary.

HILL and SMITH'S BLACK VARNISH for Preserving Ironwork, Wood, or Stone. This Varnish is an excellent substitute for oil paint on all occasions, while it is fully two-thirds cheaper. It was introduced upwards of thirty years ago by the advertisers, and its general good quality, its penetrating power, its unparalysed durability, is fully attested by its constantly increasing sale. It may be applied by an ordinary labourer, requires no mixing or thinning, and is used cold. It is used in the grounds of Windsor Castle, Kent Gardens, and at the seats of many hundreds of the Nobility and Gentry, from the fact of its finishing materials have been received, which HILL & SMITH will test on application.

Sold in casks of about 30 gallons each, at 1s. 6d. per gallon, at the Manufactory, or 2s. 6d. per gallon carriage paid to any Station in the Kingdom.

UNREGISTERED TESTIMONIAL.

Clarendon, Elmington, Cornwall, Nov. 27, 1873.—
"Mr. Lloyd Lloyd encloses cheque for £3 5s. amount due to Messrs. HILL & SMITH, and he considers the Black Varnish one of the most useful things he ever possessed."
Apply to HILL and SMITH, Brierly Hill Ironworks, near Dudley; and 148, Queen Victoria Street, London, E.C., from whom only it can be obtained.

CAUTION—It having lately come to the knowledge of HILL & SMITH that spurious imitations of this Varnish are being offered by unscrupulous dealers at a slight reduction in price, they would especially draw attention to the fact that every cask of their Varnish is legibly marked with their name and address, without which none is genuine.

WILLIAM S. BURTON, GENERAL FURNISHING IRONMONGER, by appointment to H.R.H. the Prince of Wales, sends a Catalogue gratis and post-paid. It contains upwards of 800 Illustrations of his unrivalled Stock, with Lists of Prices and Plans of the Thirty Large Show-rooms, at 23, Oxford Street, W.; 1, 1A, 3, 1 and 4, Newman Street; 1, 5, and 6, Perry's Place; and 1, Newman Yard, Manufacturers, 84, Newman Street, and Newman Mews, London, W.

Garden Wall Wiring.

R. HOLLIDAY, PRACTICAL WIREWORKER, No. 24, Portobello Terrace, Notting Hill Gate, London, W., begs to call the attention of all Gardeners who are about to have their Garden Walls Wired to his system of Wire Walls, Garden Water Ferneries, &c., for neatness, strength, and durability.

FOR NEATNESS—Because all the Wires are kept perfectly tight without the use of the Raktidiser.

FOR STRENGTH—Because every wire is made of the best material, and is not liable to be drawn out of the horizontal line by the branches of Trees.

FOR DURABILITY—Because, being able to use the strong Wire, it is not so likely to be eaten through by the galvanism as the thin Wire, as used in the French system.

The above engraving is an example of our system of Wiring Garden Walls. We have recently completed the Wiring of the New Garden Walls for the Marquis of Salisbury, Hatfield House. The Walls are 4 feet high and 7 1/2 yards long, wired on both sides; making a total length of 1200 yards—our system being chosen in preference to any other.

Illustrated Catalogues of Garden and Conservatory Wirework, Rabbit-proof Hurdle Fencing, &c., may be had on application as above.

J. J. THOMAS & CO., PAIDINGTON WIREWORKS, 285 and 326, EDGWARE ROAD, LONDON, W.

Post-office Orders to be made payable at 310, Edgware Road.

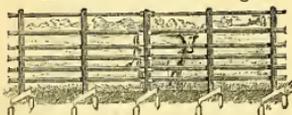

R. H. HAMPSON, Egerton Mills, Stockport, M. Manufacturer of HORTICULTURAL SHADINGS for protecting Wall Trees from Frost and Insects, &c. 4 and 6 inches wide, any length up to 100 yds. Prices on application. Established over a Quarter of a Century.

Is in use over many thousand miles, and has been awarded the Medals and Highest Commendation of all the leading Agricultural Societies.

It is constructed with POWERFUL WINDING STRAINING PILLARS, RIGID INTERMEDIATE IRON POSTS, STRONG AND DURABLE WIRE CABLE STRANDS, Forming the most efficient Strained Iron Fencing known for agricultural and general purposes.

Continuous Bar Iron Fencing.

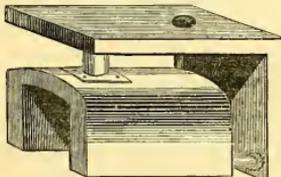

With bars secured by F. M. & Co's Patent Self-locking Joints, which effectually prevent the uprights being pushed aside, and are independent of loose pins, wedges, or staples.

IRON ENTRANCE and FIELD GATES, IN WROUGHT and CAST IRON, Designed for the Mansion, Villa, or Farm, WICKET and GARDEN GATES, In Great Variety of Patterns.

Iron Hurdles, Bailing, Tree Guards, FRUIT ESPALERS, WALL FRUIT TRAINERS, &c. Fully Illustrated and Described in F. M. & Co's New Catalogue, sent on application.

LONDON BRANCH: I, DELAHAY ST., WESTMINSTER, S.W. JONES'S PATENT "DOUBLE L" SADDLE BOILER.

These Boilers possess all the advantages of the old Saddle Boiler, with the following improvements—viz. the water-space at back and over top of saddle increases the heating surface to such an extent that a "PATENT DOUBLE L SADDLE BOILER" will do about twice the amount of work with the same quantity of fuel; the cost of setting is also considerably reduced, and likewise the space occupied; at the same time these Boilers are simple in construction, and being made of wrought iron are not liable to crack. They are made of the following sizes—

Sizes.	To heat of 4-in. Pipe.	Price.
High. Wide. Long.	Feet.	£ s. d.
20 in. 18 in. 18 in.	300	7 0 0
20 " 18 " 24 "	400	8 0 0
20 " 18 " 30 "	500	9 0 0
24 " 24 " 18 "	700	11 0 0
24 " 24 " 24 "	850	14 0 0
24 " 24 " 30 "	1,000	16 0 0
24 " 24 " 36 "	1,200	20 0 0
28 " 28 " 60 "	1,800	25 0 0

Larger sizes if required.

From Mr. CHARLES YOUNG, Nursery, Balham Hill, S.W., May 29, 1873.

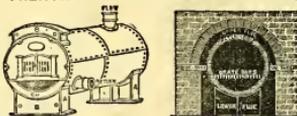

"Having given your Patent 'Double L' Boilers a full trial at my Nurseries, I beg to say that they are most satisfactory. I consider them the best in use, and without doubt the most economical of all boilers; they will burn the refuse of other tubular boilers I have in work."

PRICE LISTS OF HOT-WATER PIPES and CONNECTIONS, with Boilers, of all sizes and shapes; or ESTIMATES for HOT-WATER APPARATUS, erected complete, will be sent on application.

J. JONES and SONS, Iron Merchants, 6, Bankside, Southwark, London, S.E.

When ordering Boilers please refer to the above advertisement.

STEVENS' TRENTHAM GREENHOUSE BOILER.

After long experience, has proved the most SIMPLE, ECONOMICAL, EFFICIENT, and LASTING BOILER extant; recently improved. For Illustrations, with full particulars, apply to the Sole Makers,

F. & J. SILVESTER,

HOT-WATER ENGINEERS, &c., &c., Castle Hill Works, Newcastle, Staffordshire.

Our Boilers are the only ones made with the sanction and under the inspection of the inventor, Mr. Stevens—all others being base imitations.

COWAN'S PATENT COMPENSATING SYSTEM OF HEATING, FOR HORTICULTURAL, PUBLIC, and OTHER BUILDINGS.

The most important discovery for saving the cost of fuel, for steadiness in heating power, and dispensing with night stoking. One Apparatus will do the work of several Boilers, and in some cases produce a profit.

Heating by the Ordinary Systems.

Hothouses, Mansions, Churches, and other Buildings efficiently heated by other approved methods, where the Patent Apparatus cannot be adopted.

A large Stock of the most improved forms of Boilers to select from.

HEAT and LIGHT.

COWAN'S PATENT COMBINED GAS-MAKING and HEATING APPARATUS, By which Country Mansions and Public Institutions may be heated and lighted, in most cases free of cost.

HORTICULTURAL BUILDING.

All structures specially adapted to the purposes for which they are required, built of the best materials and workmanship, at moderate prices.

Plans and Estimates free. An Illustrated Pamphlet free.

All work done by the Company is guaranteed.

THE Cowan Patents Company (Limited), 21, WHITEHALL PLACE, LONDON, S.W., and The Vineyard, Garston, near Liverpool.

GREEN'S PATENT Wrought-iron Hot-water Boilers, With Shelves and Hollow Grate Bars.

Specially adapted for heating Greenhouses, Conservatories, Churches, Chapels, Schools, Public Buildings, Entrance Halls, Warehouses, Workshops, &c.

They are the neatest, cheapest, most effective, and durable of any extant.

Descriptive Illustrated Priced LIST may be had free on application to THOMAS GREEN and SON, Smithfield Ironworks, Leeds; and 54 and 55, Blackfriars Road, London, S.E.

AGRICULTURAL LOCOMOTIVES,

STEAM PLOUGHING MACHINERY, ROAD LOCOMOTIVES, TRAMWAY LOCOMOTIVES, STEAM ROAD ROLLERS.

For Prices, Description, and Reports of Working, apply to the Manufacturers,

AVELING & PORTER,

ROCHESTER, KENT; or GANNON ST., LONDON, E.C.; and 9, AVENUE MONTAIGNE, PARIS.

AVELING & PORTER'S ENGINES have gained the highest Prizes at every important International Exhibition. The two Medals for Progress and Merit were awarded them at Vienna for their STEAM ROLLERS and ROAD LOCOMOTIVES; and at the last trials of the Royal Agricultural Society of England their AGRICULTURAL LOCOMOTIVES gained the First Prize after exhaustive trials, when one of their 20-horse power Engines, fitted with single slide and ordinary link-motion, indicated 35-horse power, with a consumption of three and one-fifth pounds of coal per horse-power per hour.

AN EXTRAORDINARY BOILER.

During the Great Boiler Contest at Birmingham, in 1872, all Boilers were severely tested to prove their respective merits. One test was, "How long can each Boiler go without Night Attention?" However, one Boiler proved this to a surprising degree, as after being shut up for twelve hours (from 9 P.M. to 9 A.M.), it still retained its heat in 100 feet of 4-inch pipes, and yet had more than a bushel of fire drawn from its furnace in the morning equal, in point of fact, to seventeen hours of continuous firing. What a boon to Gardeners. This was THE CHAMPION, Deards' Patent Close Coil Boiler, for Drawings and Prices of which send two stamps to Messrs. DEARDS, Boiler Works, Harlow, who now have their Boilers at work in every county of England except three. Amateurs will also find THE WONDER, a smaller kind of Boiler, equally as satisfactory, and certainly "the best thing" out. Awarded five First Silver Medals.

JAMES LYNE HANCOCK'S Improved India-rubber Socket-rings FOR THE JOINTS OF HOT-WATER PIPES.

Description of Sketch—

A. The Rubber Ring as rolled into the Socket.

B. The Ring being inserted in the Pipe.

The best MONDAY Agricultural Journal.
The only Illustrated Agricultural Journal.

THE
AGRICULTURAL GAZETTE
(ESTABLISHED 1844),

FOR LANDOWNERS & TENANT FARMERS.
Every Monday, price 4d.; post free, 4 1/2d.

The AGRICULTURAL GAZETTE gives full Market Reports, both Metropolitan and Provincial; accurate Accounts of Prices and Sales, Proceedings of Agricultural Societies, Farmers Clubs, and Chambers of Agriculture—their Meetings, Exhibitions, and Discussions are Reported fully, and with promptitude.

EVERY DEPARTMENT OF THE ESTATE or FARM receives attention—Land Agency, Estate Equipment, Forestry, Farm Buildings, Roads, Fences, Cottages—Live Stock, Plants, and Implements of the Farm—Drainage, Tillage, and Manuring of the Soil.

The VETERINARY DEPARTMENT of the paper is under Professional Editorship.

Departments relating to the POULTRY YARD, the APIARY, and the GARDEN of the Farm are also under separate Professional direction.

REVIEWS are published of all Books claiming a place in the Library of the Farmer.

REPORTS of Noteworthy Estates, Farms, Herds, Flocks, and Factories, are given from week to week.

Teachers and Students of the several sciences in which the Agriculturist is interested—BOTANY, CHEMISTRY, PHYSIOLOGY, ENTOMOLOGY, NATURAL HISTORY—are constant contributors.

Special attention is given to AGRICULTURAL IMPLEMENT manufacture. Improvements in Machines are reported—New Inventions made known—Patents discussed—and the Implement Factories of the Country described. Engravings, always necessary in such cases for intelligible description, are given without stint.

No expense is spared in ILLUSTRATIONS.

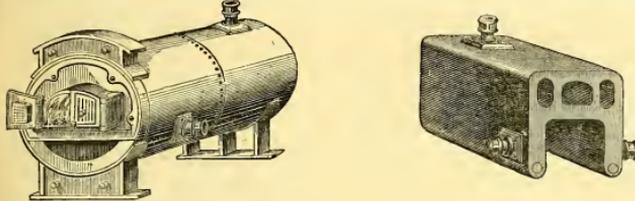

Not only Implements, but Plants, Weeds, varieties of Cultivated Crops, &c.; and Animals—Breeds of Horses, Cattle, Sheep, and Pigs; also Poultry, Insects, General Natural History; and Buildings—Farmhouses, Homesteads, Cottages; Photographs illustrative of Country Life and Occupations, whether at home or abroad—all these provide subjects for the Engraver. Portraits and Memoirs of Noteworthy Agriculturists are also occasionally given.

GARDENER (HEAD).—Married; twenty-five years' experience; good at Grapes, Stove and Greenhouse Plants. Well finished in Landscaping. Leaving through death of employer.—J. H., Garden Lodge, Wallington, near Carlsham.

GARDENER (HEAD).—Age 38, married, no family; thoroughly understands Vines, Melons, Cucumbers, Stoves and general Horticulture. Kitchen Address: Gardening; a good Redder, also good knowledge of Annuals. Ten years in present situation.—T. PUGH, The Quines, Colchester.

GARDENER (HEAD).—Age 40, married, one daughter; thoroughly practical in all branches of the profession, including Laying-out New Grounds; can Manage and teach the use of the Diagonal March. Excellent character and references.—GARDNER, Craigercock Castle, Murrayfield, Edinburgh.

GARDENER (HEAD), to any Nobleman or Gentleman requiring the services of a thoroughly practical Man in all branches of Horticulture.—Age 40, married, no family; well versed in the general routine of Gardening to any extent.—References.—R., 4, High Street, Highbury, London, N.

GARDENER (HEAD), to any Lady or Gentleman requiring the services of a strictly sober, honest, and industrious Man.—Age 38, married, one child; five years' experience in the profession of a Gardener as above; thoroughly understands the general routine of Gardening in all its branches.—Address as above.

GARDENER (HEAD), to any Lady, Nobleman, or Gentleman requiring a first-class Gardener; married, one boy (age 17).—ROBERT FLEMING for ten years gardener to the late R. Houghton, Esq., J. F., Sandeys, near Stone Liverpool. Very highly recommended. Excellent character from present employer (J. G. Houghton, Esq.), who is leaving Sandeys.—Address as above.

GARDENER (HEAD).—JOHN JOHNSTON, Gardener, has had thirteen years in the Marquess of Londonderry, Fitz Mchynilleth, North Wales, has now resigned his situation, and wishes to offer his services to any Lady or Gentleman requiring the services of a good practical Gardener. Excellent character from present employer.—Address as above.

GARDENER (HEAD), to any Lady or Gentleman requiring the services of a thoroughly practical Man; age 28.—JAMES ALEXANDER, the Gardens, Woolsey Park, Wakefield, will be pleased to treat as above; has been Foreman for the last two years, and is well recommended. Mr. Hudson, the Gardener, will kindly answer any enquiries.

GARDENER (HEAD), where one or more are kept.—Age 17, married; practically experienced in Early and Late Forcing, Fruits, Flowers, and general Horticulture. Growth of Stove and Greenhouse Plants, for Exhibition or otherwise. References and testimonials of the highest order.—R. J. K., Beadway, Greenhill, S.E. field.

GARDENER (HEAD), to any Lady, Nobleman, or Gentlemen requiring a thoroughly practical Man, where one or more are kept.—Age 38, married, one child; has had twenty years' experience in First-class Establishments—the Management of Stoves, Vines, Cucumbers, and Vegetables. References will bear the strictest investigation.—P. I., Read Hall Lodge, Whalley, Lancashire.

GARDENER (HEAD), age 29, married, two children.—GEORGE TAYLOR, over three and a half years Gardener to the late Mrs. Cowlish, in the neighbourhood of the late principal Foreman under Mr. Gilbert, Burghley, seeks an engagement as above; well acquainted with all matters relating to Horticulture. Highest character and testimonials. Wages expected, £30 to £35. Disengaged early in March. Brackles Castle, Poole, Dorset.

GARDENER (HEAD), age 31.—DAVID LONG offers his services to any Nobleman, Lady, or Gentleman requiring a thoroughly practical Gardener; well up in Early and Late Forcing, Vines, Peaches, Melons, Stove and Greenhouse Plants, and Kitchen and Flower Gardening. Has been in some of the best places in England and Scotland. Excellent references.—DAVID LONG, The Longhills, Branton, Lincoln.

GARDENER (HEAD, OR WORKING), where two or three are kept.—Age 31, married, one child; can be well recommended in any situation.—W. H. PICKLETT, agent, Kent.

GARDENER (HEAD, WORKING), where from three to six Men are kept.—Three years' character.—L. W., 36, Seaton Street, King's Road, Chelsea, S.W.

GARDENER (HEAD, WORKING), where several are kept.—Age 42, one son (age 17); thoroughly acquainted in every branch of Gardening, and is well up in Fruit Growing, and Out. First-class reference.—D. S., Mr. Setts, Baker, High Street, Dartford, Kent.

GARDENER (HEAD, WORKING), where another is kept.—Age 38, married, no family; twenty-five years' experience in Vines, Cucumbers, Peaches, and Kitchen Gardening. Excellent character.—R. P. COCKO, Windford Row, Bracknell, Berks.

GARDENER (HEAD, WORKING).—Age 38, married, no children; thoroughly competent in all branches of Gardening, Stove and Greenhouse Plants. Excellent character from present employer.—W. R., Haverstock Hill, Kenilworth Town, London, N.W.

GARDENER (HEAD, WORKING), where more are kept.—Married, no family; understands Gardening in all its branches. Good character and testimonials. Well known of Fowley.—R. TALKING, Calverton Hill, Nottingham.

GARDENER (HEAD, WORKING), where four or more are kept.—Age 40, married, no encumbrance; thorough knowledge of Gardening, understands Vines, Vines, Peaches, and Stoves, Greenhouse Plants, also Flower and Kitchen Gardening. Highly recommended.—A. F., Grazebrook, Leamington, Warwick.

GARDENER (HEAD, WORKING).—Age 36, married; thoroughly practical in Stoves and Greenhouse Plants, the Cultivation of choice Fruits, Flowers, and Vegetables, and thorough in all Gardening operations. Highly recommended.—FRANK CROSS, Garden, Millfield, Warwick.

GARDENER (HEAD, WORKING), age 39, married.—G. SMITH, Gardener to E. Marriot, Esq., can with confidence recommend his present and former employers or Gentleman requiring a good practical man in all branches of the profession. Good personal character if required, and testimonials from employers.—EVANS, Thurstoft Hall, Malty, Rothham, Yorkshire.

GARDENER (HEAD, WORKING).—Age 36, married, one child (aged 12); thoroughly competent and practical, with over twenty years' experience in the Culture and forcing of Plants, Stoves, and Flowers, and general management of Good Gardens. Highest references.—eight years of experience in last situation.—References.—JAMES, 49, Stanford Road, Fulham, S.W.

GARDENER.—J. SIMPSON, Head Gardener to the Right Hon. the Earl of Wardecliffe, Wortley Hall, Sheffield, would be glad to recommend his present Employer and Great to D. W. Herford, Esq., Fench House, Ragnatstown, Ireland, is now disengaged, and would be glad to offer services as above. Has had very extensive experience in the Management of New Grounds and Plantations, both in England and Ireland, and is thoroughly conversant with the duties of a Gardener, and would be pleased to answer any enquiries as to his abilities and general character.—WILLIAM TANTUM, Messrs. J. Dickson & Co., Stationers, 10, Abchurch Lane, London, E.C.

GARDENER, OR GARDENER AND FORESTER, to any Nobleman or Gentleman requiring a thoroughly practical Man.—WILLIAM TANTUM, for the past eight years Gardener and Great to D. W. Herford, Esq., Fench House, Ragnatstown, Ireland, is now disengaged, and would be glad to offer services as above. Has had very extensive experience in the Management of New Grounds and Plantations, both in England and Ireland, and is thoroughly conversant with the duties of a Gardener, and would be pleased to answer any enquiries as to his abilities and general character.—WILLIAM TANTUM, Messrs. J. Dickson & Co., Stationers, 10, Abchurch Lane, London, E.C.

GARDENER (SINGLE-HANDED).—Age 27, married; understands Flower and Kitchen Gardening, Vines, &c. State wages.—S. A., No. 2, Seabro Villas, Southampton, Hants.

GARDENER (SECOND), in a Gentleman's Garden, where seven are kept.—Age 35; ten years' experience.—I. E., Castle Place, Worcester.

GARDENER (SECOND), under Glass or otherwise.—Single. Good character from last situation.—G. G., Court, Salop.

GARDENER (SECOND), in a Gentleman's place.—Age 21, single, well experienced. Good references.—C. C., 10, Abchurch Lane, London, E.C.

GARDENER (SECOND), in a good Establishment, where several are kept.—Age 24; thoroughly interested in the profession. Excellent reference as to character.—J. L., 1, Postion, Stourton, Stourbridge.

GARDENER (SECOND).—Age 24; well accustomed to forcing in general, and has had knowledge of Stove and Greenhouse Plants. Two years' experience. Can be well recommended.—T. S., 3, Rose Cottage, Railway Road, Fellingdon, W.

GARDENER (SECOND, OR SINGLE-HANDED).—Age 58, married, no family. Good references from last and previous situations.—Y. H., 35, High Street, Camden Town, N.

GARDENER (SECOND), or FOREMAN in the House.—Age 46. Can be highly recommended.—A. B., Stanley Bridge Post-office, Fulham, London, S.W.

GARDENER (UNDER).—Age 22. Eight years' experience. Can be highly recommended.—A. B., Paul's Nurseians, Walkham Cross, N.

GARDENER (UNDER).—Age 19; two years' experience in a good character. A. B., Northend, Henley-on-Thames, Oxon.

GARDENER (UNDER), in a Gentleman's Garden (good), where he can improve himself in the House.—Age 19; highly preferred. Five years in present situation.—J. H., Hasted, Herts.

GARDENER (UNDER), in a good Garden.—Age 22; has had the opportunity of acquiring a general knowledge of Gardening, both Outdoor and Under Glass, in various situations, which he has acquired during three years. Reference can be made to the Gardener under whom he is at present serving.—R. GRANT, The Gardens, Chiswick, near Uxbridge, Hampshire, W.

GARDENER (UNDER), or IMPROVER for a few months.—Low wages to commence.—A. W., 43, Shakespear Lane, Stoke Newington, N.

GARDENER (UNDER), or IMPROVER, together or separate, in a Gentleman's Establishment.—Age 24; has had several years' experience in the management of Stating wages and all particulars, to Mr. W. FLITTOF, Wetfah, Middex.

GARDENER (UNDER), as IMPROVER in the House.—Age 19. Two years' good character from last place.—G. D., Mount House, Fenny Stratford, Bucks.

FOREMAN in a Nobleman's or Gentleman's Establishment.—Age 24; has had five years' experience in the profession. Two years' good character from last place.—G. D., 47, Peple Street, Bishopshildes, Chester.

FOREMAN, in a Nobleman's or Gentleman's Garden.—Age 24; has a thorough knowledge of Fruit Forcing, and general Horticulture. Good reference.—E. R., The Gardens, Switshild, Loughborough.

FOREMAN, OR SECOND, in a Nobleman's or Gentleman's Garden.—Young; understands Early and Late Forcing, Fruits, Flowers, and general Horticulture. Well placed. State wages given and all particulars.—W. C., Post-office, Slough, Bucks.

FOREMAN, OR JOURNEYMAN.—Wm. LLOYD, could recommend a young Man who has had a thorough education, and who has been employed as above to any Gardener requiring a steady, honest, sober, and industrious Man.—Broughton Hall Gardens, Sligo, Yorkshire.

PROPAGATOR (GENERAL, INDOOR).—First-class. Well used in the profession. Near London preferred.—M. F., Post-office, Hampstead Road, London, N.W.

JOURNEYMAN, in the Houses.—Age 22; had seven years' experience in large Establishments. Good references.—GEORGE MITCHELL, 144, Southam Street, Cambridge, London, S.E.

JOURNEYMAN, or IMPROVER, in a thorough good Establishment.—Age 21. Three years' good character from present situation.—A. B., Postoffice, Hatfield, Ashford, Kent.

IMPROVER, in a Nobleman's or Gentleman's Garden.—Age 18; fifteen months' good character.—A. B., Post-office, Shrewham, Kent.

SUPERINTENDENT of Estate Works, Parks, Parks, and Gardens.—CHARLES McDONALD, having resigned the Management of the Phoenix Park, Dublin, offers his services as above; has had great experience in the Erection of Buildings, Drainage, Fencing, Forest Work, and Gardening in all its branches, and thoroughly understands the Management of Parks and Gardens. References.—CHARLES McDONALD, Hetton, Skipton, Yorkshire.

TO BOTANISTS.—The Advertiser is anxious to obtain an appointment as ASSISTANT to any Gentleman holding a License to sell.—ALFRED GARDNER'S Chronicle Office, W.C.

TO THE WHOLESALE SEED TRADE.—An Advertiser, age 35, having a connection and thorough knowledge of the trade, and a good House on the Irish Ground, either on salary or commission; he has already an Agency, apart from the Seed Trade, which does not fully occupy his time. References.—ALFRED GARDNER'S SEED TRADE, Abbey Hotel, Dublin.

Seed Trade.
SHOPMAN (RETAIL).—Age 21, First-class references.—BETA, G. Young, 8, Scotia Street, Glasgow.

SHOPMAN.—Fifteen years' experience in all branches of Seed and Nursery Trade. First-class references from leading London Houses.—N. B., Gardner's Chronicle Office, W.C.

GRATEFUL-COMFORTING.

"By a thorough knowledge of the natural laws which govern the operations of digestion and nutrition, and by careful application of the fine properties of well-selected Cocoa, Mr. EGGS has provided our breakfast tables with a delicately-flavoured beverage which may save us many heavy doctors' bills. It is by the judicious use of such articles of diet that a constitution may be gradually built up until strong enough to resist every tendency to disease. Hundreds of subtle maladies are floating around us ready to attack wherever there is a weak point. We may escape many a fatal fault by keeping ourselves well fortified with pure and healthful Food, and sound sleep."
—*Chill's Service Gazette.*
Sold only in packets, labelled
JAMES EGGS AND CO., HOMEOPATHIC CHEMISTS, 45, Theobald's Road, London, E.C.

K I N A H A N S' L L W H I S K Y
Kinahan's L.L. Whisky is the result of the production of the Medical Profession, the demand for their CELEBRATED OLD LL WHISKY for purely medicinal purposes is very great, and the following are the names of the samples of it which are well known and popularly acknowledged to be of the best and most aromatic and ethereal to the smell. The Whisky may be pronounced to be pure, well-matured, and of very excellent quality. The Medical Profession may feel full confidence in the purity and quality of this Whisky."

D I N N F O R D S' F L U I D M A G N E S I A.
The best remedy for ACIDITY of the STOMACH, HEARTBURN, HEADACHE, COLIC, and INDIGESTION. Sold only in packets for delicate Constitutions, Ladies, Children, and Infants.

D I N N F O R D S' P I L L S.
HOLLAND'S WATER. While the weather remains changeable, and the cold still preattending to the very sources of life, the skin will become inactive, and the digestion impaired, unless counteracted by means of a medicine which is universally acknowledged to be the safest, speediest, and best corrective of indigestion. Loss of appetite, acidity, and flatulency, are some of the most distressing ailments which are remedied with ease by these purifying Pills. They strike at the root of all ailments, and restore to the stomach its natural secretory action of gastric juice, and regulate the action of the liver, promoting in that organ a copious supply of pure wholesome bile also necessary for digestion. These Pills remove all indigestion and obstruction.

THE BEST KIDNEY POTATO FOR MEDIUM AND LATE CROPS,

SUTTON'S MAGNUM BONUM.

We introduced this splendid new and distinct Kidney Potato last season, and it gave unqualified satisfaction. It is, without exception, the finest medium and late Kidney Potato in cultivation, and is highly recommended by all the principal Potato Growers in the country. The tubers are large and oblong in shape; the skin is russetted; flesh perfectly white and mealy, and of exceptionally fine flavour.

From Mr. W. WILDSMITH, Gardener to the Right Hon. Viscount Eversley, October 21, 1876.

"I had one gallon of 'Magnum Bonum' Potatoes from you, the yield from which was 45 bushels, four-fifths of them being as fine as those I showed in my collection at the Alexandra Palace. As to quality I cannot speak too lightly, the flesh being perfectly white and mealy, and of a real Potato flavour. I have noted it for one of my main crop Potatoes next year, and I doubt not but, when sufficiently known, many will follow my example."

THE BEST SCARLET-FLESHED MELON,

Sutton's Hero of Bath.

This superb Melon was introduced by us, and is acknowledged by some of the most eminent fruit growers to be the best scarlet-fleshed variety ever brought out.

From Mr. W. WILDSMITH, Gardener to the Right Hon. Viscount Eversley.

"I consider your Hero of Bath the best scarlet-fleshed Melon yet in commerce, being A 1 in quality, appearance, and productiveness. His Lordship, who previously had a prejudice against scarlet-fleshed Melons, pronounces this variety superb."

From Mr. THOMAS LOCKER, Gov. to the Right Hon. Lord Okefalgarah, August 27.

"I consider your Hero of Bath Melon the best I have ever grown of the scarlet-fleshed class. It is very handsome, of good constitution, and excellent in flavour."

Price 2s. 6d. per packet.

THE BEST CAULIFLOWER,

Sutton's King of the Cauliflowers

From Mr. T. RABONE, Gardener to the Right Hon. the Earl of Shrewsbury and Talbot, September 16.

"Your 'King of the Cauliflowers' is the admiration of every one. We have hundreds of the best Cauliflowers I ever saw; they are a marvel, plenty 12 and 14 inches across, and as close and compact as possibly could be. It is a wonder, certainly."

From Mr. ROBERT COCKS, Gardener to Lord Auckland, September 1.

"Your 'King of the Cauliflowers' is a good variety, with fine compact white heads, stands the drought well.

Price 1s. 6d. per packet.

CATALOGUES of all other Nursery Stock free on application. **Large Flowering Potatoes.**

HENDER and SONS'S Brains in the Field at the Worcester Show. We beg to offer seed of the above strain, which is brought to its present perfection by over twenty years' hybridisation and selection. Each year we selected the best varieties for seed out of a large number of seedlings, for many years past numbering 20,000 per year.

MR. BRADY of Hereford Road Nursery, Baywater, writing in *Gardener's Magazine*, says:—"This firm has done more to improve the plant than any one else; flowers measuring 4 1/2 inches across, colors beautifully blended together, habits as short-jointed as Heaths, and as showy as scarlet Geraniums."

"Your strain of *Petunias* is splendid." **J. BRADY,** *Gardener to Lord Roberts, Landwyck.*

"I have great pleasure in bearing testimony to the superiority of your *Petunias*." **J. BRADY,** *Gardener to Earl of Morley, Saltram.*

"The *Petunias* raised from your seed gave us the greatest satisfaction, and admired by every one. They were the best we ever saw." **BRYANT and HOOKER,** *Nurserymen, Bristol.*

"From the above I have selected 1100 single plants from the seed-pans, grew them on, and with six obtained the 1st prize against eight competitors at the Royal Western Horticultural Society's Exhibition, 1876. I have carried similarly." **J. RELLAND,** *Gardener to W. Radford, Esq., Plymouth.*

Single, 2s. per packet; 10s. per dozen; 100s. per 1000. All packets sealed "HENDER and SON."

We can supply a dozen Plants, named, which would include the above, for ever raised, for 75s. post-free, in May. **OUR AMARANTHUSES,** *Hendri*, 6d. per packet, and *Princes* of Wales, 2s. per packet, are the finest in cultivation for decorative purposes. **HENDER and SONS,** Nurserymen, Plymouth.

 203, Upper Street, Islington, N.

Splendid New Melon, 1877.
CHARLES LEE & SON (Successors to Messrs J. & C. Lee) have the pleasure to announce that they have purchased the entire Stock of MANN'S HYBRID GREEN 'LISIE' MELON, which they now offer for sale at a low price. It has already earned a high reputation in London and the provinces for its many excellent qualities, among which may be mentioned a remarkable high and equable flavour at all seasons of the year—perfection of shape and size for dessert—a thin rind and melting flesh, with an overflow of perfumed juice. It is also a heavy cropper, and forces well.
 Dr. Hogg has spoken of this excellent Melon in the highest terms, and after tasting it pronounced it a fruit of the highest merit.
 Mr. CULVEWELL, of Therpe, Perrow, fellow judge with Mr. Foulard, of Haverley Wood, at the Leeds Horticultural Show, where they awarded a First-class Certificate to "Mann's Hybrid Green-flesh Melon," speaks of it as "an exceedingly fine Melon, especially at that early season—the 24th of August."
 Messrs. Charles Lee & Son are now prepared to offer this very useful and delicious new Melon in sealed packets, at 3s. 6d. per packet.
CHARLES LEE AND SON, Hammesmills, W.

From Paris—Roses, Peonies, Camellias.
LÉVEQUE AND SON, NURSERYMEN,

BOULTON & PAUL, NORWICH,

HORTICULTURAL BUILDERS AND HOT-WATER APPARATUS MAKERS.

No. 60.—PATENT PORTABLE UNIVERSAL PLANT PRESERVER.

These excellent span-roof frames are made with wood sides, to which are bolted iron girders to carry the lights. These lights will turn completely over and lie on the other side while attending to the plants inside. They are very portable; a man can easily remove the small size, two men can carry any size up to 12 feet by 4 feet. The use to which they may be applied is unlimited, as almost any class of plants can be grown in them.

Carriage paid on any Railway Station in England, also to Dublin, Edinburgh, and Glasgow.

No. 64.—PATENT PLANT PRESERVERS, ARRANGED TO BUILD ON BRICK WALLS.

This is the Practical Gardener's and Nurseryman's favourite frame, now largely used for storing the great quantities of bedding plants in winter, and is much used for growing Melons, &c. This is suitable for building on brickwork, as shown by section of No. 64.

Section No. 64 shows the frame built on brick-work, with a pit sunk low enough for making a dung bed for growing Cucumbers, Melons, &c. This form can be made up to any length required.

Carriage paid on any Railway Station in England, also to Dublin, Edinburgh, and Glasgow.

"Gentlemen,—The frames arrived safely, and give satisfaction. I would not have thought they could have been packed to have come in such good order, the paint on the lights was not even scratched.

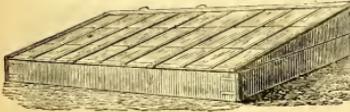

Carriage paid on any Railway Station in England, also to Dublin, Edinburgh, and Glasgow. Packing Cases are charged, and half of the cost allowed if they are returned in good order, carriage paid, to our Works, within a month of delivery of the frame. New Illustrated CATALOGUE of Conservatories, Greenhouses, Peach Houses, Forcing Houses, &c., post-free, on receipt of 24 penny stamps, the cost of which will be deducted from the amount of first order.

PARHAM'S PATENT SYSTEM OF GLAZING (without Putty) on CHANNELLED WROUGHT-IRON RAFTERS

secures almost entire immunity from Breakage of Glass, extreme facility for Repairs, and absolute freedom from Drip. It is most extensively adopted, and meets with unqualified approval.

No. 62.—PLANT CASES.

These neat and ornamental frames will be found useful to place on a Lawn or Terrace, or may be used for a Fern Case indoors. The larger sizes make excellent Vineries; in No. 6 size 12 to 15 lbs of Grapes may be grown. Made of the best material, painted four coats, glazed with best 21-oz. sheet glass. Any size can be put together in a few minutes, and is then ready for use. All sizes are 2 feet high at the sides.

For larger sizes see Special List.

No. 74.—NEW THREE-QUARTER SPAN-ROOF GARDEN FRAME.

Our illustration shows a New Frame for growing Cucumbers, Melons, &c., and for storing plants. It is made to give greater light and more convenience than the Melon frame, No. 72. The front is 21 in. high, without the light, 24 in. high at the ridge, and 22 in. high at the back. The front lights can be turned back on the lights behind, and back lights turned on to the front lights, giving access to all the plants inside. They are made of the best red deal, sides and ends 1 1/2 in. thick, 2 1/2 in. light; all are painted four times, and glazed with 21-oz. sheet glass, nailed and putted in, same as the Melon Frames, No. 72. The illustration shows the lights to open with gearing; any of the lights can be lifted up when required without altering the other lights. Back and front gearing work separately.

CHOICE

FLOWER AND VEGETABLE SEEDS FOR 1877.

DALSAM, Williams' Superb Strain	Per packet	1s. 6d.
BEGONIA FRIEDELII	.. 2s. 6d.	1 6
BEGONIA SEDENI SEMI-PLENA	2 6
BEGONIA, Hybrid, finest mixed	2 6
CYCLAMEN PERSICUM GIGANTEUM.—This is a great improvement on the old type, the flowers being thrown well above the foliage, each flower measuring from 2 to 2 1/4 inches in length; pure white, with a fine bold vivid-purple eye	.. 5s. and 2 6	2 6
CYCLAMEN PERSICUM, Williams' Superb Strain, .. 3s. 6d., 2s. 6d., and 1 6		1 6
CELOSIA PYRAMIDALIS PLUMOSA	1 0
CALCEOLARIA, Williams' Superb Strain, .. 2s. 6d. and 1 6		1 6
CINERARIA, Williams' Extra Choice Strain, .. 1 6		1 6
.. Finest Erect Varieties	.. 3s. 6d., 2s. 6d., and 1 6	1 6
.. Finest Drooping Varieties	1 6
PRIMULA, Williams' Superb Strain, Red, White, or Mixed	1 6
PRIMULA SINENSIS FIMBRIATA COCCINEA (New), colour brilliant scarlet with bright sulphur eye, exquisitely fringed and of great substance	1 0
PRYTHALUM GOLDEN GEM	1 0
SOLANUM, Williams' Improved Hybrids	1 6
STOCK, Williams' Improved Giant Scarlet Brompton	1 6
WALLFLOWER, Harbinger, Autumn and Winter flowering	1 0

Packets of Flower Seeds, excepting heavy kinds, Free by Post.

SPRING 1877

VEGETABLE SEEDS.

BEANS, Williams' Early Prolific Dwarf French—per qt.	3 0
BRUSSELS SPROUTS, Welch's Giant, one of the finest in cultivation	per packet 1 0
CUCUMBER, Walker's Hero (New) 2 6
.. Ormsdon Major 2 6
ENFIVE, Williams' Gloria Mundi 1 0
MELON, Ormsdon Major Hybrid 2 6
.. Laura's Beauty (New) 2 6
.. Surprise (New) 2 6
ONION, Williams' Magnum Bonum 1 6
PEA, Williams' Emperor of the Marrows	.. per quart 2 6
TOMATO, The 100 Days per packet 1 6

All seeds amounting to 20s. will be delivered free of carriage to any Railway Station in England.

SCHOOL GARDENS IN SWEDEN.

GOTHENBURG in Sweden has been lately boasting in the full sunshine of celebrity on account of its experimental attempt to diminish intemperance by establishing municipal public-houses. From the last accounts there seems some reason to doubt whether the experiment has been attended with all the success claimed for it, but no one will dispute the town's claim (if it care to make it) to originality and independent thought. The matter recalls to our mind another instance of a similar character emanating from that quarter, and relating to our own special subject.

A few years ago an attempt was made in Sweden to teach gardening at country schools, of which a full description was given at the time by Von Huttig of Gothenburg; which, however, attracted no attention in this country. As, however, some features of the plan may possibly be of use as hints for ourselves, we think we may occupy the attention of the reader to more purposes than by giving a summary of the information communicated by Von Huttig.

By the term school garden is meant a garden granted by the Town Council or others in authority, to the public school of a district, in which the pupils shall receive instruction in horticulture.

In Germany they are almost unknown, and in Sweden they are still rare; and even at the present day they there receive much opposition from the prejudiced ideas of the people, who are of opinion that every minute not occupied in reading is so much time lost.

For more than ten years an eminent Swedish author and pomologist, Dr. O. Eneroth, sought to awaken public interest to the importance of introducing horticulture as a subject of instruction into our public schools. His efforts have not been wholly fruitless; all the authorities, including the Ministry, desire the introduction, but as yet it is not the law of the land. A new school statute indeed has lately been promulgated, but sufficient provision has not been made for securing competent teachers. The teachers have to be taught before they can teach. Various other difficulties were encountered, in the way of inducement, inspection, time, interference with other studies, and the ambulatory character of many of the schools in Sweden, arising from the sparse population and the want of school houses. Where these do not exist, the master collects some of the scholars together in one peasant's house, then passes on to another in three months' time, when he gets some more—and so on. The teacher has often to go miles to his scholars—and it is not surprising that under such untoward circumstances the teaching of horticulture has not made the desired or expected progress.

Some progress, however, has been made. The establishment of regular schools, with judiciously contrived school-houses built by the pecuniary assistance granted by the State, the provincial representatives, and the agricultural society of the province, as well as by private individuals, is going on. Every community requires, according to its extent of from 1 to 4 and more square miles, a greater or less number of school-houses, with a corresponding number of teachers; and when any new school building is now erected, at the representation of the school inspector, a possible garden at some later period is borne in mind, and the inspector usually does not rest

by whom it will be distributed. In habit and general character it is said to resemble the well-known popular variety called Vesuvius, differing only in having the blooms invariably striped. Mr. Cannell in his characteristic style remarks that "its sale and propagation will never cease until it is seen in every window." A cutting, it appears, has been stolen, and a reward is offered for its discovery.

FLORENTINE GARDENS.

FLORENCE: *March 2, 1876.*—Situated at a low level, and completely sheltered by hills, Florence in the advance of vegetation presented a greater contrast to the North Lombardy plain than two degrees of lower latitude would represent, for spring was here at least a month earlier than at Trieste and the northern Italian cities; and the *fortis*, or flower-women, both in the flower-markets and streets, were already well supplied with the early produce of the delicious

duction of feathery masses of *Ferala* and *Araucaria excelsa* as central features.

Our English climate would of course limit the available selection, but with *Yucca*, *Thuja*, *Araucaria imbricata*, *Retinosporas*, and other *Conifera*, associated with *Ferala*, *Gunnera scabra*, and the common *Rhubarb*, just such effects could be obtained as are so pleasant to the eye in the Florentine squares.

Florence is rich in public gardens. The Cascine, a continuation of the Lang Arno, is a noble promenade, well-kept, and perfect as regards planting and simple dignity of effect, though there is nothing special to note in a purely horticultural sense. The establishment, including the *Muses de Storia Naturale* and the Botanical Garden, is the central point of attraction to the naturalist visiting Florence, and for its size is one of the most complete and best ordered in Europe. It has been of gradual growth by additions made to the *giardin*, or observatory, founded under the Medicis. The botanical collections include a fine series of wax models prepared by MM. Calamai and Tortari, under

species under the names of *lageniformis striatus* and *aureus striatus*, to which I must draw the attention of Crocologists, as it accords with nothing that has hitherto been described, with a bright orange limb, the three outer divisions suffused externally with bronze. It somewhat resembles the plants in cultivation under the names of *stellaris* and *sulphureus striatus*, but the almost entirely indented scarlet stigma separates it from the aureus and musicus group, and seems to connect it with *susianus* and *reticulatus*, between one of which and *aureus* it may possibly be a hybrid: there were a few patches of it grown for ornament in the King's garden, but I could ascertain nothing about its history or origin.

The botanic garden is too limited for an extensive collection of trees, but in a small open quadrangle fenced in by high walls under the Pitti Palace is an interesting collection of Chinese and Japanese species, including a grand specimen of *Sophora japonica*, various species of *Camellia*, *Saliburgia adiantifolia*, *Magnolia fuscata*, M. Yulan, M. obovata, M. anoneflora, *Cunninghamia sinensis*, *Daphne variegata*, *Chamaecyparis excelsa*, *Leucis Camphora*, *Hydrangea quercifolia*, *Thea viridis*, &c.

There are also a few good *Conifera* scattered about the garden, but the general collection of trees is meagre, and might be augmented with advantage. *Geo. Hays, F.L.S.*

THE PHYLLOXERA.

A GENTLEMAN the other day called my attention to a long article on the subject of the invasion of France by the Phylloxera, from the pen of Professor Planchon, of Montpellier, in the *Revue des Deux Mondes* for January 15 of the present year. From what this writer indicates, there is an opinion prevalent, which, however, he does not seem to vouch for, that some of the American foxy Vines resist the attacks of the insect. [See our issues for August 21, 1875, and June 3, 1876. Eds.] If this could be verified, say by the Scientific Committee of the Royal Horticultural Society, it would be worth while to grow such Vines as *V. Labrusca*, *V. rotundifolia*, or any other that might be found to be proof against the attacks of the pest, and inarch our own Vines on them, as Plums, Pears, Peaches, and other fruit trees are inarched or grafted. Some say that all the foxy flavoured Vines of America are exempt from attack.

It is not for me to say how the committee should proceed in the matter, but one certain way of getting at the truth would be to plant a Vine infested with the insect in a box, or pot, with one or other of these American Vines, and in the course of one season the proof either way would be absolute. If this question could be set at rest, and the fact certified, that such Vines as I have alluded to really resisted the insect, a boon of immense value would be conferred, not only on this country, but on Europe.

To practical men it is perfectly clear that though the sulphocarbonates, and other remedies proclaimed by Mr. Phylloxera, may kill the Phylloxera, it is not possible to get it applied so as to secure this result. Any one who has seen and examined the vineyards of the Rhine, must know that the roots of the Vines extend into fissures of the rocks, where no insecticide can get near them. If a remedy of universal application is ever discovered, it must be in the use of a stock that the insect won't feed upon; and whoever makes this discovery will immortalise his name. From what Mr. Tiley writes the other day, I observe that he is making experiments with some infested Vines: let me call his attention to the subject in hand.

While on this matter it may not be out of place to remark that smaller matters than the ravages of Phylloxera have attracted the attention of Government, and that it might be well if by an Order in Council, or in some other way, it was made compulsory on any one having the pest to report it at once, and to destroy the Vines within a given time. In this way it might be stamped out of the country, and kept out, if the importation of Vines was forbidden under severe penalty. *W. Thomson, Tuxed Vineyard, February, 1877.*

FERTILISATION OF PLANTS.

(Continued from p. 139.)

Petunia violacea.—A dingy purple variety was cultivated for five generations. The ratio of the average heights of the intercrossed to the self-fertilised was 100 : 71; but in the third generation the difference was reversed, for the heights were then as 100 : 131. Mr. Darwin's explanation (p. 275) is, that the seeds from which the self-fertilised plants of the third generation were raised, were not well ripened, which fact,

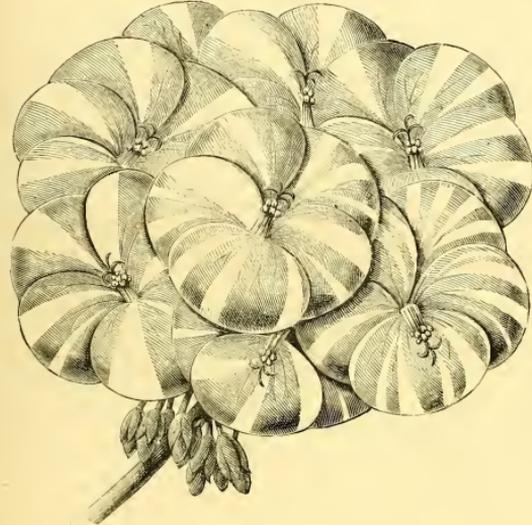

FIG. 32.—PELARGONIUM (ZONAL) NEW LIFE.

climate. Seen from the surrounding heights, the huge dome of the cathedral, with its many-coloured campanile, and the towers of the churches rise out of the dense variegated mass of the mediæval city, which dies away into the surrounding grey hills through a bright halo of white villages and villas spreading up on all sides amidst Olive gardens, sombre groups of Cypress, and light fleecy patches of Almond trees in full flower. One of the most striking features to the new-comer is the laying out of the squares or piazzas, in which the horticultural features harmonise so thoroughly with the surroundings, as to put to shame our own efforts at city gardening, which in our West Central squares goes little beyond the fencing-in of an unhealthy deciduous thicket by a forbidding iron railing.

In the Florentine squares the development of distinct features is aimed at. Crowding is always avoided, and the symmetrical disposition of a few trees and plants, generally in association with sculpture and fountains, brings all into pleasant harmony with the architectural surroundings. *Chamærops Fortunei*, C. humilis, and tall *Yucca* are contrasted with *Thuja* area and other *Conifera* of massive form; and a farther contrast to the whole is obtained by the intro-

duction of Professor Amici, also a good collection of wood sections, fossil plants, &c. The first nucleus of the natural history collection was formed by Pietro Leopoldo and Targioni, by the former of whom the garden was founded a few years after the museum. The formation of the splendid main herbarium (L'Herbier Central) is due to Professor Parlatore, the present director, who commenced it about the year 1844, and to this has recently been added, in a separate adjacent gallery, the fine private herbarium of the late Philip Barker Webb.

The botanical garden, immediately adjacent to the museum, though well-ordered, bears evidence of intermittent growth, and consists of semi-isolated patches and terraces rising up to and intermixed with the Boboli Gardens. The glass-houses, as in most Italian gardens, are defective in structure, and the cultural details are, in consequence, scarcely equal to those in English establishments of the kind.

In the cultivation of bulbous plants in pots and cold frames the garden greatly excels, and there is perhaps no other botanical garden in Europe that could exhibit so complete a collection of European bulbs in a thoroughly healthy condition. Amongst the *Croc*, of which there is a fine series, there is a

he says, gave them an advantage (?), and refers to a similar case in Iberis, but in p. 192 he attributes the inferiority of the very same crossed plants of this third generation of *Petunia* to their not having been sufficiently ripened, and thus producing weakly plants compared with the self-fertilised, as (he again says) also occurred with Iberis; but on p. 103 we read:—"I record in my notes that the self-fertilised seeds [of Iberis] from which the self-fertilised plants were raised [and which were 5 or 6 inches taller than the crossed], were not so well ripened as the crossed." Hence, there are two errors of statement as well as adverse reasonings from the data! Mr. Darwin also accounts for the greater growth of the eighth generation of *Ipomoea* from their having been raised from unhealthy parents (pp. 38, 39). Surely, if it be beneficial to have unripened seeds and unhealthy parents, at least as far as height is concerned—and Mr. Darwin has selected that as his standard of superiority—natural selection ought to have prevented seeds from maturing, and encouraged the visits of aphides! But I think we may find another explanation. On p. 274, Mr. Darwin says, "very significant sentence." It is a remarkable fact that in one pot in which the plants of both lots grew extremely crowded, the intercrossed were thrice as tall as the self-fertilised." This implies that in the other pots they were not so crowded. Now, there is abundant evidence throughout the book that intercrossed and perhaps especially crossed plants, *i.e.*, with new stocks, show, as a rule, a very great superiority over self-fertilised plants when struggling in competition; but, when not crowded, or when grown in open ground, then the difference between their heights and weights is greatly reduced, and may be actually reversed. Indeed Mr. Darwin had already stated this fact in his *Animals and Plants under Domestication*, vol. II., p. 128, in alluding to his method of culture. It is of importance that the two lots of seed should be sown or planted on opposite sides of the same pot, so that the seedlings may struggle against each other, for if sown separately in ample and good soil, there is often but little difference in their growth." I will return to this fact hereafter. Hence I would attribute the vigour shown by the self-fertilised plants of the third generation of *Petunia* to less crowding. And here I will venture to remark that Mr. Darwin's plan of sowing both intercrossed and self-fertilised seedlings in the same pot—though with the express object of imitating Nature, and thereby revealing the superiority of the former—would have been readily met by also growing similar pairs in separate pots. Then, there is reason to know that the relative heights would have been much nearer uniformity. As it is, the absolute vigour of neither can be estimated, though the relative vigour is clearly in favour of the intercrossed. Mr. Darwin, indeed, himself elsewhere recognises the great importance of freedom of growth for self-fertilisation to be successful; for in speaking of an experiment with an equal-styled "very self-fertilising red-flowered variety of *Primula veris*," he says:—"Judging from the previous generations, the extreme unproductiveness of the self-fertilised plants in this experiment was wholly due to their having been subjected to unfavorable conditions, and to severe competition with crossed plants; for had they grown up in good soil, it is almost certain that they would have produced a large number of capsules."

Canna Warvicevicum affords another case resembling *Pisum sativum*, for this species is highly self-fertile, and "as plants are cultivated in pots, and are not exposed to competition, they have been long subjected to uniform conditions;" and Mr. Darwin adds, "we have no right to expect much or any good from intercrossing plants thus descended and thus treated." And no good did follow, except that the intercrossed plants yielded rather more seeds, viz., as 100:85. But the self-fertilised plants mostly flowered before the intercrossed.

There are two more plants, *Eschscholzia californica* and *Reseda odorata*, I will remark upon, for I think Mr. Darwin has drawn erroneous conclusions from them.

In the reader will carefully peruse the first paragraph of chap. xii., pp. 436-7, I think he would be led to suppose that *Reseda* and *Eschscholzia* were good examples to illustrate the "injurious effects of self-fertilisation, for as [some individuals of] these are sterile with their own pollen, they have been long naturally crossed, and the artificial crosses in my experiments,"

says Mr. Darwin, "cannot have increased the vigour of the offspring beyond that of their progenitors. Therefore the difference between the self-fertilised and crossed plants raised by me cannot be attributed to the superiority of the crossed, but to the inferiority of the self-fertilised seedlings, due to the injurious effects of self-fertilisation."

The last sentence, which I have italicised, is very misleading.

In the introductory remarks on *Eschscholzia* (p. 109), the second sentence directly contradicts the above; for it runs as follows:—"A cross greatly increases the procreancy of the flowers of the parent plant." This is repeated on p. 275, in the words, "A cross does some good."

Mr. Darwin received seed from Brazil, where *Eschscholzia* is "absolutely self-sterile," and, therefore, unlike English-grown plants, which are more or less self-fertile. It proved, however, to be not so sterile in this country; hence he was able to raise self-fertilised plants; the relative fertility of the intercrossed to the self-fertilised being as 100:15, where the "15" represents so much absolute gain, and considerable for a single generation; but in the next generation the relative fertility appears now as 100:86.7! Turning next to the comparative results between the heights of the first generations—*i.e.*, grandchildren of those grown in Brazil—the heights are as 100:101, and in the second generation as 100:116! Mr. Darwin observes on this:—"As the grand-parents absolutely required cross-fertilisation, I expected that self-fertilisation would have proved very injurious to these seedlings. . . . But the result showed that my anticipation was erroneous."

He next crossed the Brazilian plant with an English stock, and it would be inferred by analogy that great benefit should accrue; but the self-fertilised actually beat the crossed in height, 100:109, and in weight as 118:100; and Mr. Darwin further remarks that the self-fertilised were also apparently superior in hardiness. The only point, then, where the crossed were superior to the self-fertilised was in fertility; but when we remember that *Eschscholzia* is absolutely self-sterile in Brazil, it is more surprising to find the ratio so near equality in two generations.

Surely, then, it is unfortunate that Mr. Darwin should have specially alluded to this plant as proving the "injuriousness" of self-fertilisation, for his own data not only fail to support his conclusion, but maintain exactly the reverse, for the acquirement of self-fertilisation is, *per se*, so much actual gain to the plant of a new and benefited means of propagation, and, as he has already ascertained that, such plants, by gaining new constitutional elements by transportation to this country, became more vigorous than the normally intercrossed, or even than plants crossed with a new stock.

Eschscholzia is not a unique case, for *Reseda*, likewise mentioned as supporting the idea of the injuriousness of self-fertilisation, also tells against such being the case.

Reseda lutea is sometimes absolutely self-sterile. Some plants, however, produced a few spontaneously self-fertilised capsules; propagating from these latter in pots, the results gave the mean ratio of heights as 100:85, and in open ground as 100:82. And Mr. Darwin adds, "It is a singular fact that the tallest plant in the two rows was one of the self-fertilised." The ratio of their weights was still more striking—*viz.*, of those in pots 100:21, but in open ground as 100:40.

Reseda odorata.—This species shows degrees of fertility from absolute self-sterility to full self-fertility. Arranging Mr. Darwin's results as follows:—I. Intercrossed plants from the highly self-fertile parents, compared with self-fertilised. *a* (in pots), heights were as 100:82, weights as 100:67; *b* (in open ground), height as 100:105 (weights not given). II. Intercrossed plants raised from a semi-self-sterile parent, and compared with self-fertilised plants, raised from the same parent. Mr. Darwin here makes a remark similar to that upon *Eschscholzia*:—"I expected that the seedlings from this semi-self-sterile plant would have profited in a higher degree from a cross than did the seedlings from the fully self-fertile plant, but my anticipation was quite wrong." *a*, height as 100:192, weight as 100:99; *b*, height as 100:90 (weights not given).

Now, comparing these two sets of results, a remarkable fact is seen, that in the first generation the plants from fully self-fertile and self-fertilised parents grown in pots (*a*) do not give such high results as the self-fertilised plants raised from semi-sterile parents under

the same circumstances. But while the former show a vast improvement when grown in the open ground (I., *b*), the latter show none!

Now it is a general rule, as already stated, that self-fertilised plants cannot stand competition at all equal to intercrossed plants; but when planted in the open ground the contrast is greatly lessened, *i.e.*, the ratio becomes more nearly one of equality, in other words the self-fertilised recover vigour in a higher ratio than the intercrossed are improved by freedom of growth. So here, from I. (*b*) it is to be inferred that the self-fertilised have a greater "elasticity" of growth, so to say, than the intercrossed. This was likewise the case with the weights of *Reseda* lutea. II. (*a*) would seem to show that the vigour of the offspring from parents semi-sterile is relatively greater than that of the offspring from fully fertile parents when compared with the intercrossed plants of each kind; and had not *Eschscholzia* showed a similar fact these results of *Reseda* could scarcely have been considered trustworthy.

Hence it is very unfortunate for Mr. Darwin's argument to have especially selected *Reseda* and *Eschscholzia*, for these certainly do not prove any "injurious" effects to arise from self-fertilisation, but just the reverse!

The fact appears to me to be this:—The word "injurious" is a purely relative term. If a plant is so highly differentiated that it has not only become adapted to insect agency but also to be self-sterile, then, of course, to put its own pollen upon the stigma of a flower, rather than that of another plant, may be said to be, relatively to the latter process, at least useless if not injurious. But when we see a plant thus usually self-sterile becoming, under changed circumstances, self-fertile, this power of self-fertilisation is actually so much positive gain, as Mr. Darwin admits "the obvious fact, that the production of seed is the chief end of the act of fertilisation, and that this end can be gained by hermaphroditic plants with incomparably greater certainty by self-fertilisation." Now it is clear that many plants have become highly differentiated by adaptation to insects, and in becoming so, the pollen has physiologically changed correlatively to such a degree as to be useless on the flower's own stigma. This therefore is so much absolute loss to the plant, as it now has to depend, with less certainty, upon the chance visit of insects; but when the plant can recover its lost power, and especially when it can acquire fresh and new constitutional elements, then, as we see in *Reseda* and *Eschscholzia*, the first result is the absolute re-gain of self-fertilisation, which may be accompanied by an equality with, or even a superiority in vigour to, the intercrossed.

In a later communication I propose continuing the subject of self-fertilisation. *George Henslow.*

ASPECTS FOR PLANT-HOUSES.

MR. BESTER'S arguments in favour of altering the aspect of span-roof plant-houses, from east and west, to north and south, strike me as being a little one-sided, and I fear the plants would think so too, if only the effect of the east-bars was opposed to the sun. It appears to me that a lean-to house placed against a wall would suit the plant nearly as well, and be much warmer. As regards the shading of the house in winter by the framework, I should think that the sun about noon-dawning comparatively perpendicularly, first on the east side, then passing over the ridge to the west side, would meet very little obstruction, and I do not think the sun would melt ice on the north side of a span-roof at all. Secondly, the fact of a house being warmer at 5 o'clock than at 10 on a summer morning may be due to the ventilation being closed at 5 o'clock and open at 10, rather than to the effect of the east-bars shading the interior. Thirdly, as to the impossibility of closing span-roof houses facing east and west till late on a summer evening, owing to the sun shining full on the west side till late at night—that is a question between the sun and the advocates of the early-closing movement; and as the sun is rather behind the times in the matter of shortening its working hours, the only thing to be done is to leave down the blinds on the west side, till Old Sol retires for the night. This is surely better than in a roof facing south, where the sun only gets shining into the interior for a few hours near noonday, owing to the east-bars acting as a shade as soon as it gets a few degrees on either side of the

meridian—at least, if they shade it in one case they will in another also.

Now, let us look for a little at the position Mr. Bester advocates—viz, sides facing north and south. He says it receives the full force of the sun, and it shines right through the house. I say the sun can shine on the south side only, and if there are tall plants in the centre of the house, as is generally the case in span-roofed buildings, they will keep the sun from shining past them, and a lean-to would suit the same purpose, and be warm too.

I believe there is more scorching due to the thin 16 oz. glass so extensively used now-a-days, than to the sun's glare on the moisture.

All great cultivators will have great difficulties to contend with, in this world, so long as the sun goes its daily rounds in the hot-headed, independent way it has done hitherto; and I would respectfully advise your readers to consider the other (or north) side of the question before they alter the position of span-roof houses.

While an article like Mr. Bester's is very good as affording an opportunity of discussing the question in the pages of the *Gardener's Chronicle*, still, as a friend of mine, a horticultural builder, said to me the other day, "You have no idea, Mr. C., what trouble such articles give us builders; for instance, when a gentleman getting up a span-roof house sees an article like this, he makes me put it up according to the directions given in the article; and then other people seeing the house, blame the builder for placing it with a bad aspect; and make up their mind that they will not employ me to do their work, if I do not know how to place it properly." But that is a mild case. Why, it is only a month or two since one of the garden papers had an article copied from another paper giving full instructions to those about to erect glass, with a specification, specifying among other things that the boiler is to be capable of heating the whole up to a temperature of 180° in the coldest weather, and the wood to be sent to the job without being painted or primed, so that people may see if the timber is good or not. Fine work it would be, especially in wet weather like this, and you know no person will take a builder's word against such an article.

"It is the same in the heating, too. There is that new endless something boiler that burns dirt; in fact I expect to hear every day that they are burning bricks in it, without fuel; then we shall have a brick-kin as well as a jimekin heating apparatus. In fact, I am thinking of bringing out a new boiler myself; it is to be heated with turpentine flannels wrapped all round the boiler. You know there is an awful heat in a piece of flannel wetted with turpentine. I use it on my breast when I have a cold, so I can speak from experience, and remember, Mr. C., I shall expect a first-class testimonial from you when you see it." *Aqua-Calida.*

NOTES ON OPEN-AIR VEGETATION.*

THE winter, so far as it has gone, has been rather remarkable, wind and rain in excess, with comparatively little snow and frost, particularly in this district of Scotland. The first snow which fell, and perhaps the heaviest, was on the 8th and 9th of November, doing a vast amount of injury at the time by breaking down the branches, and damaging the bark of many deciduous and evergreen trees throughout Scotland, such as Oaks, Beches, Elms, Silver Firs, and Spruce. This, with subsequent falls, rapidly disappeared. Although snow up to this time in this locality has been less in comparison to many winters, rain has, however, fallen in greater abundance during the last five months than has been known in this district during the same period for many years. So much has this been the case that all low and level grounds are saturated with water, and all therefore very much against the flowering of many of the hardy spring bulbs. The Snowdrop, for instance, at this particular time (January 31) used to be abundantly in bloom, not only on the elevated grounds, but all over the level garden lawns; now they are only to be seen partially in flower on raised and sloping banks where the ground is somewhat dry, while those on flat lawns and in low, damp situations are scarcely appearing above the surface of the soil. This dampness may

also account for the backwardness apparent in the flowers of the Crimean Snowdrops (*Galanthus plicatus*), *Leucojum vernum*, *Crocus susianus*, and even the varieties of *Crocus vernus*, all of which were recorded in flower during the month of January last year, when the weather was colder. I am not prepared to say how long it is since we had such an amount of moisture during any one winter; this, however, I do know, that for the last fifty years we have never been troubled with water in some of our garden stakesholes till the last month, necessitating pits to be sunk in them, and a daily baling out of a quantity of clear water. What effect this excess of moisture will ultimately have on the roots of many shrubby and herbaceous plants growing near the surface it is difficult to say.

Owing to the comparative mildness of the winter, so far as it has gone, many of the autumn plants carried more or less in flower throughout it, not, however, in very good condition—kinds in all probability which would not have been in flower during an ordinary severe one, such as *Primroses*, *Polyanthus*, *Gentiana acialis*, *Veronica repastris*, *Lithospermum fruticosum*, *Potentilla alba*, *Iberis*, *Aubrietia*, *Wallflower*, &c., while the various species of *Helioleba* have been remarkably fine, as well as *Tussilago fragrans*, *Sternbergia lutea*, and *Crocus Imperati* (both the latter growing on high parts of the rock garden), *Erica carnea alba*, *Jasminum nudiflorum*, *Garrya elliptica*, and *Viburnum Tinus*. The flowers of the common *Cardus* have been particularly abundant throughout the month, and if no frost should occur a full crop of *Hazel-nuts* may be looked for in autumn.

From the selected list of forty-two plants whose flowering has been annually recorded during the last twenty-seven years four species only flowered during January, while eleven species of this number were noted during the same month last year.

<i>Caryoph. Avellana</i> ..	January 14, 1876.	January 1, 1877.
<i>Tussilago fragrans</i> ..	" 12 "	" 3 "
<i>Helioleba tripartita</i> ..	" 12 "	" 8 "
<i>Colchid. nivale</i> ..	" 16 "	" 15 "

Besides herbaceous plants, there are also several other shrubby species which are usually noted as being in bloom in the open air at this particular time, but which are still considerably behind. Of these may be mentioned, *Rosa*, *Myrica*, *Menyanthes*, *Rhododendron*, *Myrtillus*, *R. Nobleanum*, and *Cornus mascula*; but whether this arises from the sunless, wet autumn, or the want of the necessary amount of frost to mature them for early blooming, it is difficult to say, probably both combined.

In order to continue the meteorological tables which I have carried on during the last twenty-two years, showing the amount of frost during each month from October till April inclusive, I have to add the following observations. During October, 1876, we did not record a single degree of frost, notwithstanding that 35° were registered during the united October months for the last twenty-two years. The lowest markings were during 1856, 1857, and 1862, when 3° only were indicated during each October month; while the highest was during 1859, when 56° of frost were registered. The lowest markings during the month of October, 1876, were on the 2d, 23d, 25th, 26th, 27th, and 31st, when 37°, 37°, 36°, 37°, 33°, and 35° were indicated, while the highest morning temperatures were on the 7th, 8th, 9th, 17th, 18th, and 19th, indicating respectively 55°, 53°, 50°, 50°, and 50°.

During the month of November, 1876, the thermometer was the same time as at below the freezing point, indicating collectively 82°, being two more than was noticed the previous year—the lowest markings being on the mornings of the 7th, 8th, 10th, 11th, 20th, and 30th, indicating 26°, 26°, 20°, 22°, 23°, and 25°, while the highest morning temperatures were on the 3d, 4th, 5th, 17th, 18th, and 19th, indicating 45°, 45°, 46°, 45°, 43°, and 43°.

During the month of December, 1876, the thermometer was twelve times at or below the freezing-point, indicating collectively 43°, while the corresponding month last year indicated 84°. The lowest temperatures were on the mornings of the 1st, 3th, 23d, 24th, 26th, and 27th, indicating 29°, 25°, 24°, 16°, 27°, and 27°, while the highest morning readings were on the 2d, 5th, 6th, 7th, 10th, and 11th, indicating respectively 42°, 43°, 44°, 45°, 43°, and 43°.

This last January the thermometer was sixteen times at or below the freezing-point, indicating collectively 73°, while 103° were registered during the same month last year. The lowest markings during

January were on the mornings of the 2d, 3d, 12th, 15th, 22d, and 23d, indicating 20°, 18°, 25°, 27°, 26°, and 28°, while the highest morning temperatures were on the 8th, 9th, 11th, 19th, 20th, and 28th, indicating 40°, 37°, 37°, 38°, 39°, and 37°.

NITROGEN AND VEGETATION.

(Concluded from p. 175.)

THE absorption of ammonia by soil is controlled by a number of conditions; the physical and chemical characters of the soil, its condition as to moisture, and its being covered or not by vegetable growth, all largely influence the extent of the absorption. Schlösing made experiments on two soils. The ammonia in these soils was determined, and they were then freely exposed to air, but sheltered from rain. Dry soil was found to absorb ammonia to a considerable extent; a limit must, however, be reached as soon as the tension of ammonia in the soil equals that in the atmosphere. With moist soil the case is different; here the ammonia absorbed is quickly oxidized to nitric acid, and the soil is consequently capable of continuing the absorption of ammonia for a far longer time, and of taking up a much greater quantity.

In the appropriation of atmospheric ammonia by plants and by soil, but especially by the latter, we appear to have an important supply of nitrogen to vegetation. The amount of combined nitrogen sufficient to account for the amount found in the vegetable growth annually produced; the supply furnished by the rain is, however, supplemented by this direct absorption from the atmosphere both by soil and plant. Schlösing has repeated with great care the experiments of Debrünn, but can find no evidence that the decayed vegetable matter of soils has the power (as was asserted) to produce ammonia from the free nitrogen of the atmosphere. He believes that there is at present no evidence that the free nitrogen of the atmosphere becomes available to plants, except to the small extent in which it is converted into nitrous acid by electrical discharges in the atmosphere. This nitrous acid is oxidized and carried to the soil by rain in the form of nitrate of ammonium.

While this action of electricity is, in Schlösing's judgment, the only original source of combined nitrogen on the surface of our globe, there are several actions by which combined nitrogen is lost. It is absolutely lost to some extent during the decay of nitrogenous organic matter (as farmyard manure), when an insufficient quantity of oxygen is present, a portion of the nitrogen reverting under these conditions to the free state. It is lost to our soils to a large extent by the removal of nitrates in the drainage water in the form of *Urea*, which has already been discussed by Dr. Gilbert in the lecture previously referred to. The loss to the soil from this cause must in many cases exceed the whole amount of nitrogen supplied by rain. The nitrates thus lost by drainage pass into the rivers, and finally into the sea. Here they serve as food for marine plants, which in their turn become the nutriment of marine animals. The plants and animals on their decay furnish ammonia; but the ammonia contents of the ocean cannot exceed a certain point without interchange taking place with the air resting on its surface. The atmosphere is thus continually enriched with ammonia, which is immediately dried, and carried by winds over the surface of the land. From the atmosphere the soil finally takes up as ammonia the nitrogen it had previously lost as nitric acid. Continents, with their porous soils, and shallow waters, are, in fact, an oxidising medium; continental nitrogen tends to resolve itself into nitric acid, which finds its way to the sea. The deep waters of the ocean present no such facilities for oxidation; here nitrogen finally takes the form of ammonia, and entering the atmosphere recommends its circulation in Nature.

Such is the simple and beautiful conception of Schlösing. The ocean is the vast storehouse of combined nitrogen for the whole world; ammonia is the carrier by which this nitrogen is gradually conveyed to every part of the globe, which supplies nitrogenous food to the whole vegetable kingdom, and balances the gains and losses of land and sea. If we believe with Boussingault that the production of nitrous acid by electric discharges takes place to a very considerable extent in tropical regions, far exceeding the amount annually brought down in rain in these higher latitudes, we have also in the am-

* Read at the February meeting of the Edinburgh Botanical Society, by Mr. M. Nabu.

moma of the atmosphere the vehicle by which this great original source of combined nitrogen is made available for the whole globe; for as the nitrates produced by electrical discharges in the tropics run their course, they must sooner or later take the form of ammonia, and entering the atmosphere become subject to the laws of diffusion.

We must, in conclusion, say a few words respecting the recent investigations of another French chemist, M. Berthelot. We have spoken already of the fact that an electric discharge through the atmosphere causes a small quantity of the nitrogen and oxygen in the air to combine and form nitrous acid. M. Berthelot has made the results produced by an electric discharge through gases a special subject of study; he finds that many combinations and transformations can be effected by this means, and that a silent discharge of electricity produces a greater chemical effect than a visible spark. In the course of his experiments he observed that moist cellulose (filter-paper), or a solution of dextrin, absorbed nitrogen from ordinary air when placed in a vessel through which an electric discharge was maintained; this nitrogen he states entered into non-volatile combinations, and was evolved as ammonia only when the paper or dextrin was heated with alkalis at a high temperature. In the earlier experiments Berthelot employed a powerful induction coil as the source of electricity; in his last published paper he gives the results obtained when employing only the ordinary electrical tension of the atmosphere. The moist paper, or dextrin, was placed in a sealed glass tube filled with air; the outside of the tube was coated with tinfoil, and connected with the earth. Inside the glass tube was another tube, insulated from the outer one; this was coated with silver foil, and connected, by a platinum wire, passing through the outer glass, with the atmosphere at a height of about 2 yards from the ground. The construction was such that the outer tube had the electric tension of the earth, and the inner tube the tension of a layer of air 2 yards above the earth's surface. The experiments continued two months. On opening the tube, and analysing the paper or dextrin, nitrogen was found in every case to have been fixed in appreciable quantity.

These results obtained by M. Berthelot are certainly startling, and will require thorough confirmation before they can be received as established facts. In M. Berthelot's opinion they point to a hitherto unrecognised source of combined nitrogen to vegetation. Plants, on his view, acquire nitrogen from the atmosphere through the medium of electric action. The question will doubtless before long be submitted to investigation by other chemists.

Before closing these notes of recent investigations we may remark how little either of them touch the great practical questions brought out by the Rothamsted field experiments, and dwelt on by Dr. Gilbert in his lecture. The action of atmospheric ammonia, and of atmospheric electricity, however important we may suppose them to be, must have their action on the fields at Rothamsted as well as on other parts of the globe; it is clear, therefore, that their united efforts are incapable of sustaining the small and gradually diminishing cereal crops which are grown at Rothamsted without nitrogenous manure. On the other hand, it requires a distinct kind of facts from those yet assumed to explain the widely different relations to nitrogen of graminaceous and leguminous crops, which is taught so prominently by the Rothamsted results, and is supported by universal agricultural experience. *A. Warrington.*

SPECIMEN FUCHSIAS.

THE county of Wilts is famous for its splendid exhibition Fuchsias. A batch of growers living in the districts of Trowbridge and Devizes have for some years past vied with each other as to who should produce the finest examples of cultural skill at the exhibitions of the Trowbridge and Keovil district horticultural societies, the Bath floral *fiête*, and other places, during the months of August and September, and the invariable result is such an exhibition of specimen Fuchsias as is perhaps scarcely equalled in any other part of the United Kingdom. The leading growers are Mr. J. Lye, gr. to the Hon. Mrs. Hay, Clyffe Hall, Devizes; Mr. Thomas King, gr. to R. V. Leach, Esq., Devizes Castle; Mr. J. Doel, gr. to J. E. Hayward, Esq., Trowbridge; Mr. J. Hobbs, gr. to J. Gayton, Esq., Trowbridge; Mr. J. F.

Mould, nurseryman, Pewsey, and Mr. J. Matthews, Trowbridge.

The illustration on p. 211 (fig. 35) represents an example of the well-known variety *Arabella*, one of a group of six varieties exhibited by Mr. J. Lye, Clyffe Hall Gardens, at the meeting of the Trowbridge Horticultural Society on August 25 last. On this occasion Mr. Lye was placed first with six and four varieties, Mr. J. Hobbs being 2d in each class. Mr. Lye's plants averaged 6 to 7 feet in height, and from 3 to 4 feet in diameter at the base, most symmetrical in shape, and with the lowermost branches completely draping the pots. Cleanliness, freshness, and a general style showing high-class culture, were the characteristics of all the plants in the leading groups in these two classes. Mr. Lye is now the champion grower of the district, and every year he has to run the gauntlet of a severe competition. His

bited these plants 8 feet in height and 4 feet through, well covered with flowers.

Mr. Lye does not confine his exhibiting to plants eighteen months old; as his best specimens vary in age from one and a-half to five years, according to the duration of the varieties, as some last longer than others. After the plants are five years of age they are discarded, and replaced by young plants raised in the manner above described.

But to continue the method of treatment followed by Mr. Lye. About the end of October, when the plants have done flowering, they are pruned back to two or three joints beyond where they were cut back the previous year, placed in their winter quarters to rest, and kept moderately dry. The last week in January or the first week in February, the roots of the plants are thoroughly shaken clear of the old soil, and repotted. The young

FIG. 33.—DWARF JAPANESE PINE TREE.

plants excite the highest admiration of all who see them, and could they be exhibited in London in the style in which they are shown at Trowbridge they would be looked upon as illustrating a veritable floral-censational sensation.

The cultural process adopted by Mr. Lye can be set forth in a few words. Cuttings are taken at the end of March or the beginning of April, the most vigorous growths being selected for the purpose; they are placed singly in thumb-pots, and put into a Cucumber or Melon frame having a suitable moist bottom-heat. As soon as the roots reach the side of the pots the plants are repotted, and this is repeated as required up to the first or second week in July; at the same time stopping and pinching back the shoots, in order to get the plants to the proper shape required.

The plants are then allowed to flower during the autumn, and thus is laid the foundation, so to speak, of the plants that will be exhibited a twelvemonth after. At eighteen months of age Mr. Lye has exhibi-

plants struck the previous spring are placed in 14-inch pots; the older ones into 16-inch pots, and the compost used is made up of equal parts of good fibry loam and leaf-mould, a little peat, and silver or sea sand, and some good rotten cow-dung, all of which is well mixed together before using. The plants are placed after repotting in a cold greenhouse, and kept under glass till the first week in June, then they are placed out-of-doors, and are well sprinkled during hot weather to keep down red-spider, &c., and occasional doses of manure-water are given. The best kind of liquid-manure for the Fuchsia, Mr. Lye finds to be horse-dung or soot, put into a tub to soak for a week or ten days before using, and a good soaking is given to the plant about once a week. With plants cultivated in this way Mr. Lye has taken twenty-nine first prizes with Fuchsias since 1866, and that in the face of severe competition.

Mr. Lye is also a raiser as well as a cultivator of Fuchsias, and has produced some fine exhibition forms, found in the following list of the varieties he culti-

vates for show purposes. Light varieties : Mrs. J. Lye, white tube and sepals, dark red corolla shaded with purple—remarkably free, and possessing an excellent pyramidal growth; Arabella, a good old variety; Miss Lye (Lye), in the way of Arabella, but having a darker corolla; Marginata, a charming variety, the pretty pink corolla being distinctly margined with carmine on the edges; Schiller, a good old variety; Rose of Castile, remarkably free and effective; Delicata (Lye), white tube and sepals, light rose corolla, good free habit of growth; Arabella Improved (Lye), a marked improvement on the old form; Beauty of Swanley (Lye), an extremely pretty light Fuchsia, pure waxy white tube and sepals, the latter most elegantly reflexed; corolla bright pink, of

and sepals, purple corolla, excellent habit, and a good grower: a specimen of this shown by Mr. Lye at the Bath exhibition held in September last was acknowledged by all the leading growers present to be the best flowered specimen they had ever seen; Elegance (Lye), scarlet tube and sepals, with light blue corolla, drooping graceful habit; Puritani, a fine old variety; Improvement, glossy red-carmine tube and vermilion sepals, deep violet-blue corolla tinged with carmine; Swanley Gem, tube and sepals coral-scarlet, the corolla rose-coloured and prettily frilled, a distinct and showy variety; and the Hon. Mrs. Hay (Lye), a very free blooming and showy dark variety, but rather coarse. Of double varieties the two following are grown by Mr. Lye:—Marksman, tube and sepals

Hall Gardens ever since he was a lad, and gradually worked his way up to be head gardener. Mr. Lye's father had the management of the farm lands under Admiral Bouverie, and the Hon. Mrs. Hay, his daughter, for the space of forty years; and when he became disabled he was pensioned for life, and Mr. Lye succeeded to the management both of the farm and garden. One of the principal features of the estate is the fine examples of Scotch Fir, which are much admired for their magnificent proportions.

Mr. Lye is also the raiser of one of the most promising of the new Potatoes of last year, viz., Lye's Favourite. It is a seedling from the Red Emperor, very distinct in character, and of excellent quality. R. D.

FIG. 34.—A JAPANESE HOUSE GARDEN.

good shape; habit free and most graceful; white Souvenir de Chiswick (Lye), a showy white variety, resembling in general habit the dark variety known by this name—white tube and sepals, the latter long and beautifully reflexed, corolla bright rose-pink; Queen Victoria (Doel), white tube and sepals, with dark red corolla, very good for exhibition; and Covent Garden White (Doel), an excellent market and decorative variety.

Of dark varieties the following are grown:—Favourite (Doel), scarlet tube and sepals, very free blooming—a capital show variety; Pauline, dark red tube and sepals, and purple corolla, a good old exhibition variety; Gazelle, scarlet tube and sepals, and purple-blue corolla, one of the very best of the section, and having a good habit; Constellation, much in the way of Gazelle; Charming (Lye), scarlet tube

bright carmine, purple corolla, a good grower, and one of the very best doubles; and La Neige, a variety resembling Madame Cornellissen, but much larger, tube and sepals carmine-red, and snow-white corolla.

One great feature in Mr. Lye's specimen plants is the entire absence of the appearance of anything like artificial supports, except in the case of the central stake to maintain the plant in an erect position. There is a complete covering of leaves and blossoms, even the pots in which the plants are growing are almost, if not quite, hidden from view.

Mr. Lye's professional triumphs are not confined alone to Fuchsias. For fourteen years past he has been an exhibitor of fruit, flowers, and vegetables, and has taken over 400 prizes, the greater portion having been 1st prizes. He has been in the Clyffe

JAPANESE GARDENS.

SOME time since we were enabled to lay before our readers some account of the process by which the Japanese gardeners succeed in dwarfing trees of various kinds, and growing them in vases of porcelain of relatively small dimensions. The illustration we gave on that occasion (fig. 33 p. 206) was copied from one which appeared in the *Revue Horticole*. The present one (fig. 34) is taken from a treatise on Japanese gardening, brought home in the *Challenger* by Mr. Moseley, and represents a miniature mountain, with toy-houses amid trees and woods, and laved at the base by a tiny lake. The "trees" most frequently used are species of *Retinospora* and other dwarf Conifers, and frequently dwarfed species of *Pyrus*, the flowers of which have a pretty effect.

Notices of Books.

Thomé's Text-Book of Botany.*

Mr. A. W. Bennett has issued a translation of "the recognised text-book of botany in use in the technical schools of Germany, which (first published in 1869) is now in a fourth edition" and he recommends it on the score that it is believed "that no work of the same scope is yet to be found in the English language embracing the whole range of elementary botany, of a size and price (for the student within the reach of all) nearly as good of natural science."

The first three out of (in all) eight chapters deal with anatomy. Whether Germans begin with anatomy in teaching botany we know not, but we unhesitatingly say that the arrangement is unphilosophical. A young pupil must follow in his individual case the methods by which the science itself has been elaborated, *i.e.*, analytically and not synthetically. He must begin with morphology. Lindley, Henty, and Oliver rightly follow this plan; and to try to teach the pupil to reconstruct the plant out of its elements is a method only to be regarded as a pernicious survival. The algebraic figures before us do not constitute for this purpose principles, although in the matter appears to be brought down to the latest knowledge.

Mr. Bennett's object (he says) was to adapt the work to the use of candidates for the South Kensington, and for seven of the London University examinations; but we doubt whether he has entirely succeeded. Chapter 4, on morphology, has hardly a page of letterpress on roots, and involves one, if not more errors, *e.g.*, *Plantago major* (and Mr. Bennett gratuitously adds *Scabiosa succisa*) is given as an example of a præmorse root, both being rootstocks. "Phylloclasis," "stipulation," and "metamorphosis" are requirements in the London University scheme. The first is most meagrely treated; the two-fifth and three-eighth "divergences" being alone alluded to; the spines of *Gossypium* are called stipules, and the bladders of *Urticaria* are described as "floats," and figured; but not a word is added as to their true carnivorous nature, and Mr. Bennett adds in a note that the pitcher of *Nepenthes* is regarded as an "expansion of the lamina" instead of a gland.

Another error of importance is the retention of the old theory of a calyx-tube, no mention whatever being made of the receptacular tube. It is not only thus in the text, but supported by the translator in a note. This is the more remarkable, as he translated Sachs' *Zeichn.*, where the development is fully described (p. 200).

Of all the requirements of a candidate for the London University examinations, that upon which the examiners lay most stress is the "demonstrations of the botanical characters of plants," and no work professing to be a guide for their examinations is complete without some instructions as to how to describe plants. Lindley, Henty's *Text-Book* (edited by Masters), and Oliver alike insist upon this, and the total absence is a serious blot in Mr. Bennett's adaptation of Thomé's work.

The systematic portion, which is equally divided between Cryptogam and flowering plants, is adapted to the *Genera Plantarum*, and describes the cohorts, together with such orders as are required for the above-mentioned examinations. X.

— Messrs. Cassell, Petter & Galpin announce the early publication, in monthly parts, of a new work, with paintings from Nature of the wild flowers and plants of Great Britain, under the title of *Familiar Wild Flowers*, by F. E. Hulme, F.L.S., F.S.A., Art Master at Marlborough College.

— Among the articles in the February number of the *Gardener* are the following:—Bottom-heat, &c.; Manures and Manuring; Lessons in Drawing; the Apple—Cultural Suggestions; Dissemination of Seeds; Gardeners' Mutual Improvement Societies; Flowering Pelargoniums in Winter; A Seventh Year of Rest for Vines—Would it be Gain? Sympathy Between Head and Under Gardeners; Double Chinese Primulas; Notes on Alchemists; Forcing in Darkness to get the Common Lilac White, &c.

— The principal contents of the *Villa Gardener* for February are articles on How to Reduce your

Coal Bills; Embellishing Villa Residences; the Economy of the Rubbish Heap; Gardening for Beginners; *Coccyzium discolor*; Stocks in Pots; Hedge Rose Budding, and the Budding of Wild Rose Stocks in Shrubberies or Woods; Winter Dressing Fruit Trees for Insects.

Natural History.

STOCK Doves.—I enclose the contents of the crows of two doves shot here this day, numbered 1 and 2. Packet No. 1 contains the leaves of *Taraxis* (I imagine), and a few grains of Wheat, and other seeds. I have never before found this mixture of food in the craw of the stock dove. The contents of No. 2 are the same that I have often found in them. I hope to learn that these latter are the seeds of some noxious weeds; for if so, these beautiful birds must be doing incalculable good at this time of year, and ought not to be condemned (as they frequently are, I fear) to wholesale destruction by their really mischievous brethren of the Columba family—the wood-pigeons. *H. F. V.* [Seeds found in No. 1 were *Cerastium arvense*, *Chenopodium*, *Polygonum*, probably avicular; few *Taraxacum* or *Charlock* seeds, Wheat grains (decayed), and possibly *Taraxacum*. In No. 2, almost entirely *Chenopodium*; the remainder, *Polygonum avicularis*.]

Obituary.

WE have the painful duty of recording the demise of Mr. JOHN HARRISON, of The Nuth of England Rose Nurseries, Darlington. Mr. Harrison a few months ago removed from the establishment at Darlington, to a comfortable residence in his nursery at Catterick Bridge. On Sunday afternoon, the 4th inst., whilst on his way to chapel, he fell down suddenly as if in a fit; he was removed home as speedily as possible, and soon afterwards died. The deceased had been in the nursery trade upwards of fifty years, and died at the advanced age of seventy-six. The event will create a void in the horticultural world, and many will have to deplore the loss of a valued and sincere friend. As a Rose grower he stood deservedly high, and was an efficient supporter of most of the principal exhibitions in Yorkshire and Northumberland, besides other parts of England.

He had been a successful exhibitor of the Rose for a number of years, taking prizes at all the leading exhibitions. If there is a consolation for his loss, or if there is a mitigation for our grief, surely it will be found in the good name he has left behind; high and low, rich and poor, everybody speaks well of him. His innate goodness of heart, his genial happy disposition, his ready disposition, his only straightforward bearing, his noble nature, and the proud position he had attained for himself, all combine to make us feel the loss we have sustained. Mr. Harrison leaves behind him a sorrowing wife, and several children. Two of his sons, aged from thirty to forty, have been brought up to the nursery business.

Mr. Harrison's remains were removed from his residence at Catterick Bridge, near Richmond, to Darlington, on Wednesday, the 7th inst., and interred in the family burial ground.

— We also record with regret the death of Mr. WILLIAM MELVILLE, of the Tyneville Vineeries, Jersey, which sad event took place on January 27, in the sixty-sixth year of his age. Mr. Melville was for thirty years gardener at Dalmeny Park, near Edinburgh, and retired about eight years ago on a handsome annuity from the Earl of Rosebery. He was an enthusiastic cross-breeder of plants, particularly of the Brassica tribe, and sent out amongst others the Albert and Rosebery Sprouts and the Variegated Kale. He was also the raiser of the Muscat Champion Grape, and was one of the first in early life to improve the Pansy. He brought up a family of fifteen children, to all of whom he gave a good education, and six of them were brought up as

gardeners. Mr. Melville had a happy and pleasing disposition, and was fond of talking about, and communicating his ideas upon, his favourite hobby—the cross-breeding of plants.

— Died, at Croydon, on February 8, JOHN SAMUEL GLENDINNING, aged 33 years.

Garden Operations.

PLANT HOUSES.

GREENHOUSE HARD-WOODED PLANTS.—Any additions that have to be made to the hard-wooded stock in the shape of young plants to be obtained from the nurseries, should at once be attended to, as when this got before has commenced, they are much better than when subjected to packing and transit with fresh soft shoots upon them. In all cases give the preference to young healthy plants, however small, over such as have suffered the slightest through being kept too long in the pots they occupy. The larger plants may tempt the eye, but little ones in a free condition always outgrow them, and rarely fail to outlive them. *Erythrina cristata-galli* (the Coral plant) is a very useful subject for conservatory decoration; if it is kept in a greenhouse temperature it will bloom about the end of July, but by treating as hereafter described for an induced to flower twice. Plants shook out now, potted in good loam, to which is added a sixth of well-rotten manure and a fair amount of sand, and put in a house where there is a nice growing temperature, will bloom during the spring. After they have had a rest, shake them out, cut back, re-pot, and start again. They will flower in the autumn—a time when there are not so many indoor blooming things. Plants of *Aralia Sieboldii*, raised from seed last year, if now put into from 10 to 12-inch pots, will, before the time comes to plunge them outdoors, get nicely established. Potting soils that were advised a few weeks ago to be got under cover should be frequently looked to and turned over, so as to bring them from the saturated condition which everything exposed has been in to a fit state for use, and to see that there is a sufficient quantity of peat, loam, and leaf-mould for all purposes that may be required during the spring months. They should occupy, if possible, an open shed where the wind will have full access to them. If however they are to be kept in a greenhouse, an account attempt to carry out the work until the soil is in a fit state to dryness, as even the strongest growing plants in existence will not succeed if potted in material that is too wet, however porous it may be rendered by the use of sand. Begonias in permanent culture are frequently too much inclined to this matter. One means that I have used to test the state of the soil as to moisture is to take a bit between the finger and thumb, just a small pinch, when prepared with the sand in it, and if any perceptible water can be squeezed out, it is too wet.

Heaths.—Many of these, if in a healthy satisfactory state, will be growing actively, and pushing up their blooming shoots, the roots, too, being correspondingly at work. Plants that need it should have a shift now. If this is done carefully, they will not be checked at all, and will bloom better than if left in a cramped state; there is also one great additional advantage, that there is not near so much danger of their dying when the potting operation is performed early, as when it is deferred until later on. It is a matter of course, that if they have been of a harder description, and they must not have so much root-room as sorts that are free growers, which latter ought never to be allowed to get into a condition anything like pot-bound. If this ever occurs, they are a deal more likely to suffer from it, by more root-room given them; these do not need so much sand in the soils as the others. Pot all hard, and do not for a few weeks admit any side air near the plants. A day or two previous to potting go over them very carefully, and see that they are all well. Camellias.—Plants that bloomed in the autumn will now be commencing to grow; they ought to be encouraged by putting them where they will have a temperature of 55° by night, and 10° or 15° more in the day, with plenty of moisture in the atmosphere and also at the roots. As they go out of flower they should be cleaned well with sponge and brush; this ought to be done before they begin to grow, as the young tender leaves are soon injured.

CONSERVATORY.—The climbers here should be regulated, cutting-in those that need it closer now than at any other time in the year. Give as good and thorough a cleaning as possible if mealy-bug or scale exists. All subjects that are permanently planted out will be benefited as well as those that are not infested with either of the insects mentioned above, by being well cleaned to remove the dirt that gets on the leaves during the winter season when the syringe is not much used.

* Thomé's *Structural and Physiological Botany*. Translated and edited by A. W. Bennett. (Longmans.)

SOFT-WOODED GREENHOUSE PLANTS.—There is no time in the year when *Chicorarias* are more useful for cutting than just about Christmas, as they give us the scarce, indispensable colour—blue, at a season when there is little else of it but early forced Hyacinths and Violets, and however acceptable both these are, they look dull by the side of a bright *Chicoraria*. To have them at this time they should be sown at once as an attempt at forcing them, and the season stages is sure to end in weak, poor heads of flower. Such kinds of Lilies as commence growing early, as, for instance, eximium, or longiflorum as known by some, will by this time have appeared above-ground, and should be sown in pots, and either in a cold frame where they can be protected from frost, otherwise, if they are allowed to become drawn now, no after treatment can remedy the mischief. *T. Britton.*

ORCHIDS.—It will now be necessary to go through the collection, and top-dress or pot many of the plants, according to their several requirements. If there are a number that will need potting, whether to give them a larger shift or on account of the soil having got into a sour and soddened condition, it should be borne in mind that only such sized pots should be used as the plant can reasonably be expected to fill in one, or at the most two seasons. Orchids invariably delight in having their roots in a similar sized pot, and the roots may sprout freely some soon after they start away from the base of the bulb or young growths; and if this is the inside of the pot, or crocks, or charcoal, the roots will keep longer in a healthy and growing state than if large plants are put in a smaller sized shifted, and if the crocks or crocks used among the soil. Bearing this in mind, see that in potting the pots are well crocked, the pot-sheds being fixed in the pots in an upright position, and taking care to put them in so that they will be as open as it is possible to get them. On these plants some sphagnum moss, and in making the plant up use some small crocks or pieces of charcoal in the soil, as well as fixing some larger pieces with the soil as the operation progresses. A little sharp silver-sand mixed with the soil will be very beneficial in keeping the soil open and sweet. Many of the plants, however, will not require fresh potting this season, and where such is the case they should be top-dressed as far as it can be done without injury to the roots and young breaks. The surface, too, of some of the plants should be covered with some of the best fern or with the green conifers that so quickly spreads upon plants that for a lengthened period during the season are kept continually moist. Pick this all carefully out, and then work some moss, or manure, or other such matter, amongst the plants, and press the whole well together, that the plant may stand firm, and with a few stakes make the whole secure and steady. Where, as recommended last season, any bulbs of *Dendrobiums* were pegged down on the pots of the *Ardisias*, *Yandias*, and a little more moss given dried, and fastened on blocks, or put into small baskets, where they will get a little more careful attendance than if left to push up long shoots among the other plants. They should, however, be taken away, and should be beneath the roof of the house, and the pots in the pots they were pegged down in, would make it in some cases a difficult matter to get them out, at the same time endangering the plant from whence they are taken. The *East India* plants and the *Dendrobiums* should be taken in hand first. Before the houses are rearranged, sponge all the glass inside, and scrub the woodwork, rafters, &c., and arrange them all so that each may have the advantage of the direct rays of sunlight so far as it can be managed. An advance must now be made in the temperature of the houses, and a little more moisture given during the daytime. Morning readings:—*East India* plants, 60° to 65°; *Dendrobium-house*, 55° to 60°; *Cattleya-house*, 55° to 58°; *Odontoglossum-house*, 50° to 53°. Raise the temperature 5° by fire-heat, and if the sun should break through, another 5° by hot air, and it may be permitted and gladly accepted. When the air outside is favourable—and this winter at present it has been so in an unusual manner—advantage must be taken of the opportunity, and air given to all the houses, and the bottom ventilators of the *East India* plants will now be gay with bloom; see that they are kept free from damp, otherwise they soon become spotted. Another of this genus that will now be showing signs of growth is *C. pandurata*; it will grow very freely in moss and peat, and should be kept in a cold *East India* house: as the young growths advance the flower-spikes push up in the centre of the new leaves, and as its peculiar green and black flowers expand it forms an object at once attractive and fantastic. When growing it must have a good supply of water, and as its large leaves are liable to be attacked by red-spider, it will continually need looking over and sponging. *W. Swan, Fallowfield.*

FRUIT HOUSES.

PEACHES AND NECTARINES.—In early started houses by this time the trees will have reached that

stage of growth when disbudbing is usually effected. Although this practice is necessary at times, without doubt it is, in the case of early forcing trees, especially those to be applied, so much as to be even more detrimental than beneficial. Instead of divesting the trees of so much foliage at the present period, we nip out the points of the shoots, leaving from four to six leaves below, and thin out the foliage and fruit as follows:—In the case of the male and fruit are somewhat more developed, letting all the terminals run which are not over-exuberant, and otherwise checking those which are likely to absorb more than their share of sap. Continue to liberally apply the syringe over the trees twice every day, and especially to the portions which are placed near the heating medium, whereabout that invincible enemy, red-spider, often first appears. Every means which is calculated to produce a stimulating effect in the house should now be used, in the way of stimulating the soil, and light sowing about once a week of guano on the mulching material will also be productive of good; artificially, 55° to 60° at night, and 60° to 65° in the day should still rule, and 70° to 85° by solar means; ventilate at 70° and close at 75°. Be cautious in airing at the front of the house when cold drying winds prevail, unless, as it should be, a heated pipe is so fixed as to moderate its effects. Take advantage of suitable occasions for impregnating the flowers as they open with insecticides, and give a similar course of treatment here to that already indicated for the early house. In later houses the mildness of the season has brought out the flowers considerably before the usual time. A free course of ventilation is indispensable here, and either inside or outside, otherwise, should severe winter weather, much harm may happen in those houses without means of resistance. *G. T. Miles, Wycombe Abbey.*

CUCUMBERS.—Since my last paper was written we have experienced a few bright sunny days, a condition under which forcing has made satisfactory progress, and as few plants more speedily show the beneficial effects of sun-heat than Cucumbers, the occupants of this department have made considerable improvement in growth, vigour, and quality of the fruit. Unfortunately, a return to wet weather will necessitate increased firing to keep up the top and bottom heat, and the cultivators must be content with the watch for red-spider, which invariably follows, and if not at once checked will soon work serious mischief among plants which have been some time in bearing. If taken in time, the best remedy for its destruction is careful sponging of the leaves; but when it has become very rampant, occasional sowings with a weak solution of Gishurst or mildewers when hard firing can be dispensed with will be found the means of keeping the *Cucumber* grower's worst enemy in check. In middle, the result of this course of treatment is to be seen in the low straggling plants. Use, itself, apply the usual remedy and resort to conditions the reverse of those which have caused it. Remove male blossoms. Avoid overcrowding of young growths and foliage; impregnate the most promising fruit with a little saltpetre. Keep up a good supply of fermenting stable dung and Oak leaves for use as required, and see that the stock of loam under cover does not fall short. If through the past winter it has been out in the wet, a few days' exposure to the atmosphere in a dry airy place will be necessary before it is taken in to use. *W. Coleman.*

ORCHARD HOUSE.—Although the temperature has ranged high, fruit trees in cold houses, particularly when ventilation is given, will be found to be little and far forward than those on open walls. This undoubtedly is due to the absence of sun, but with a change to bright weather trees under glass will make rapid progress, and many of the early flowering kinds will soon begin to develop their blossoms—more the most delightful. It is the anxious time for the owner of the unheated orchard-house, who will of course have canvas, tiffany, or other protecting material ready for use in the event of a change to frosty weather. When the pot culture of fruit trees was in its infancy the idea of warming an orchard-house was looked upon as an unnecessary extravagance, but experience proves the contrary—the cost of many of the small slow-combustion boilers is so trifling, they require no brickwork for setting, and the pipes can be fixed by the bank labourer, and that is required in the way of fuel is a moderate supply of small coal or coke for producing sufficient heat to counteract the injurious effects of frost or damp where the trees are in bloom. Trees which have been some time under glass must have sufficient water to keep the soil in a healthy growing state, but those which have recently been taken in will hardly require it before the end of the month. The modern mode of preparing trees for

pot-work by annual lifting, root-pruning, and replanting in the open ground until well furnished with fibrous roots is more economical than the old system of potting up maidens to fill up space in the orchard-house which might otherwise be occupied by fruit-bearing trees. *W. Coleman.*

KITCHEN GARDEN.

Some few rows will require particular attention in sowing about this time, and although a very much of its utility will depend upon the state of the soil, for it is not in a good state to receive seed, it is better to wait a week or so rather than risk the crop; but Parsnips, if required fine and in quantity, should be sown the first favourable chance. These are not all that are sown at this time, and well manured the previous year. And at the time of sowing, if the soil is not in a well-pulverised condition on its surface, and tolerably dry, draw out the drills, and sow the seeds (which should always be new), and fill up the drills with fine dry sand sifted through a sieve. If slugs attack the young plants when up, put some quicklime in a serim canvas bag, and shake it over the beds on mild evenings. Peas will again require attention in sowing about the end of the month, and one long row of an early sort and one of a good second early will suffice for succession at present. The advancing crops will require to have the earth drawn up to the rows, and the earliest will require some shelter against cutting winds. Small branches of Spruce Fir are well adapted for the purpose; we have also used with great advantage the stumps of young Birch besoms, which, stuck in thickly on each side of the rows, are excellent protectors. The earliest sown Beans will also be advancing, and should be sown in proportion to the rows, and some dry leaf-mould inserted along the rows among the plants, which, owing to the mild winter, are rather drawn. Look over *Cashiflow* plants in frames and under handlights, and remove all decaying foliage, stir the surface of the soil, and once more dust the surface with dry soot, lime, and sharp cal-cabes, mixed together. Lettuce plants in frames or under south walls will also be benefited by surface stirring and dressing. Some Myatt's or Veitch's Ash-leaved Potatoes planted now at the foot of south walls will come in very useful for succession after brasses and ridges, which, when there is a sufficient supply of fermenting materials, may be made up at the end of the month similar to *Cucumber* and *Vegetable Marrow* ridges, by marking a bed in the open quarters, 6 feet in width, and of such length in proportion to the material available. Throw out the soil right and left to the depth of 18 inches or 2 feet, fill up the trench with from 2 to 3 feet of prepared dung, let it stand a few days for the violent heat to pass off, then cover the surface with 4 inches of soil, and 5 inches of manure row from row, and 6 inches in the row, and let it all up about 5 inches; the middle will sink considerably, so that by the time the tops appear through poles may be laid from side to side, and mats spread over on cold nights. Here, again, some Wood's Early Frame Lettuch is sure to come in useful, and if a pinch or two of Lettuce seed also thinly scattered over the surface will do no harm, and often proves very valuable for maintaining a succession. Some Brussels Sprouts should be got in at once for the earliest planting; a warm south border is best, and if possible place some handlights over the bed for a time, but avoid drawing the plants up weakly. The first opportunity should be taken, when the soil is sufficiently dry, to stir the surface well amongst growing crops of Cabbage and Lettuce, also to remove all dead and decaying leaves from the beds of winter greens of all sorts as well as from the Broccoli beds. Looking forward a little to the requirements of next month beds should be at once put through the process of deep trenching and manure mixing, and the main range of open plantations of Globe Artichokes and Sea-kale at the proper time. Jerusalem Artichokes should now be planted; these are generally banished to the out-kirts, but if much in request they will pay for good ground and extra attention. A busy time is presented in the way of cutting up of trenching, manuring, and preparation of the soil should be pushed forward at every opportunity. *John Cox, Redfern.*

THE JAPANESE PERSIMMON (*Diospyros Kaki*) fruited with Mr. G. F. Wilson. It was tried by the members of the Royal Horticultural Society—result, a general outcry—only the account put it “very faces.” Such an ignominy must have beenfalling on the name of the fruit. Over two per cent of tannic acid found. Now we know what was the matter. Any Southern darkey would have said, “Dem ‘Simmins wasn’t ripe.” It must have been a very funny thing to have seen that august body with its mouth full of a fruit in a winter position. We doubt if this fruit will completely ripen in England. We tasted of the first fruit that matured here, and there was no trace of astringency. *American Agriculturist.*

THE

Gardeners' Chronicle.

SATURDAY, FEBRUARY 17, 1877.

THE annual meeting of the ROYAL HORTICULTURAL SOCIETY passed off in the quietest and tamest of manners, reflecting, perhaps, the paralysis which seems to have temporarily affected the Council. The official report was taken as read, although it was only put into the hands of the Fellows as they entered the room, together with a very imperfect balance-sheet. We must refer to the full reports on another page for the details. It must suffice here to make a few general remarks. In the first place, in spite of the disappointment that will be felt at the absence of any scheme of reorganisation and reconstruction, there is much to support the opinion that the existing Council is the best and most honest that the Society has had for some years. It is satisfactory, too, to note that the utterances of the President are decidedly more horticultural than on a former occasion. Though himself one of Her Majesty's Commissioners, and having local interests of his own in South Kensington, the President fully admits the disastrous nature of the alliance between a horticultural society consisting of a small number who care for practical and scientific horticulture, and (at one time) a large number who had no special taste for gardening, but who were willing to pay to be amused, and to subscribe towards maintaining a private recreation ground for their families.

The President told the Society that if between Christmas next and the Christmas following £10,000 be not raised, Her Majesty's Commissioners will be in a position to "extinguish the Society," a phrase that we presume is not to be interpreted literally.

With reference to the debenture-holders (whose only claim we are told is upon *surplus* income), the Council, like honest men, but not uninfluenced by the fear of personal liability we imagine, express their sense of the obligation under which the Society rests to the holders of those documents, and their desire to meet those obligations honourably.

What, then, is the outlook? Suppose—and it is not impossible that, at the last moment, some of the residents, awakening from their present indifference, and fearful of losing a convenient airing-place, will render it more than a supposition—suppose the £10,000 is raised, what will be the result? Why, that the Kensington Garden, with all its burdens, would be retained till the expiration of the lease, unless, indeed, Parliament, urged on by the general Press, should interfere to prevent the appropriation to a class of what should be free to the public. Surely this is not a pleasant prospect to look forward to, for it has been all but universally admitted as most desirable that the connection between the two discordant interests—the horticultural and the residential—should be put an end to as soon as possible. Each might work in harmony with the other if desired, but practical independence is the best for both parties. This has been affirmed at a general meeting, and, as we have seen, the Council admit its desirability. But, say they, they have tried in vain to effect this separation in various ways. They find that the Society is so tied and fettered this way and that, that it is impossible to obtain that freedom and liberty that all desire so strongly. We give the Council credit for what they have done in this matter, and if they have failed, their failure is not greater than that of their predecessors, while it is partly redeemed by excellent work of a horticultural kind for which all horticulturists are

grateful. But their failure to accomplish their purpose surely does not justify them in hugging their chains and making them girt more tightly. If they cannot rid themselves of their fetters all at once, a persistent application of the file will ultimately accomplish the desired end. "We have done all we can: what more remains to be done that we have not done?" is in effect the cry of the Council. And as they have not been able to decide upon any satisfactory answer to this question they have decided to go on in the old rut—to spend a thousand a year (see the report) at Chiswick, for the purpose of growing decorative plants for Kensington, and thus waste a large portion of what little substance they have, in the interests of the resident Fellows, in the hope, unquenched by experience, that they will be repaid by an increased subscription list.

It is this tendency to move in one groove only that has aroused the alarm, we might even say the indignation, of many of the staunchest horticulturists. Let the Council take example by a beast that is tethered. He does not—albeit tied and restricted in his range—move backwards and forwards in the same directions only, like a sentry, but he radiates in all directions, and he goes round from one point to another to an extent limited by the length of his tether. He does indeed make the best of his situation. The Council is tied—we all want to loosen the tie. We can't do it at present, but surely our choice of work is not limited to one direction only, and that direction one which has been proved to be woefully unprofitable. Granted that for the present we must wear our fetters, we are not debarred from extending the real horticultural work of the Society in the provinces and elsewhere in some one or other of the many ways in which, as we have often pointed out, good useful work may be done. Lord ALFRED CHURCHILL, who more than once has shown a broad comprehensive judgment of the duties of the Society, did indeed announce a proposal which is decidedly a step in the right direction. Many more of a similar character have been already pointed out, and might be adopted with very little cost and without prejudice to South Kensington interests. The re-establishment of a great provincial show is one powerful means for good, which we are glad to find is again under the consideration of the Council. Anything in fact, which is conceived in a broad liberal spirit in the interests of horticulture and of the general public, deserves support, and will certainly win approbation; while, on the contrary, any narrow, class or local policy is unworthy a great Society, and is sure to meet with the reprobation it deserves.

— SOME curious facts in connection with the *FLORA* of RODRIGUEZ have been set forth in a communication to the Linnean Society (February 1) by Dr. L. BALLEZ BALFOUR, son of the distinguished Edinburgh Professor. The vegetation is essentially insular, as might be expected, but dry and temperate rather than humid, and tropical in character; it is of Mascarene type, with affinities, however, bearing likeness to Polynesian and American regions, though Asiatic types prevail. It seems many common and wide-spread plants have been introduced, and the ancient flora of the island from various and unknown or doubtful causes in great part destroyed, in this respect calling to mind the St. Helena flora, well known to have been destroyed by man's agency. A somewhat remarkable and well marked feature is the heteromorphism exhibited in the leaves of many of the plants, especially shrubs. It seems that the young produce leaves, as it were, of a lower stage of development than the adult; and as the individual increases in age the leaves successively produced approach more nearly the mature form, until at a certain stage of its growth only typical leaves of the adult are found. Once this stage is reached all the leaves produced on the branches are of the adult form; but should any

adventitious shoots develop from the base of the trunk, or appear on the stem anywhere below its first branching, these always have the juvenile, and not the adult form of leaf. This heterophylly, as a whole, is in degree and kind somewhat variable, though among species pretty uniform in its variations.

— BETWEEN the years 1870 and 1875 Professor STEERE, of the University of Michigan, U.S., made a journey across South America, thence to the Philippines and other regions in the East, for the purpose of collecting objects of natural history to enrich the museum of his University. Among other things obtained was a collection of plants. His colleague, Professor HARRINGTON, has now worked some of these out, and at a late meeting of the Linnean Society (February 1) gave a list of the tropical *Ferros* met with. Among these many novelties from the little frequented islands of the Philippines have now been described, and Formosa has likewise yielded several new forms.

— Mr. DOWNIE has planted in front of his residence in the Pinckhill Nursery some thirty varieties of bedding Pansies and Violas, one row of each, for proving during the coming season, and he informs us that a white Pansy which he raised two years ago, and named *Profusion*, opened its first flowers on January 6, and is now nearly in full blossom, while there is hardly a flower to be seen on the other varieties.

— As illustrative of the retention of the dormant living power in the vegetable embryo when subject to a long-continued low temperature, Mr. R. LEVING LYNCH exhibited at the meeting of the Linnean Society (January 18) a MEMENTO OF THE ILL-FATED "POLARIS" EXPEDITION. This consisted of a pot of growing Wheat, sown from some of the grain left in Polaris Bay, Smith's Sound, 81° 38' N. lat., by the crew of the American Expedition. Captain SIR GEORGE NARES, who obtained it, in a letter to Dr. HOOKER says the grain lay exposed to all the rigours of the climate from 1872 to 1876. Nevertheless, the sample brought home, when sown at Kew, yielded about 64 per cent. as capable of germination. Two Peas also sprouted, besides a grain of Maize, this latter having a special interest from being a comparatively tropical plant.

— It is impossible to contemplate the beauties just now being developed in country gardens by names of many coloured Primroses, Polyanthas, double Daisies, early Violas and Pansies, the beautiful *Myosotis dissitiflora*, the rich vermillion *Anemone fulgens*, varied Hepaticas, crimson and golden Wall-flowers, and others of the charming hardy spring flowering plants, without feeling an anxious desire that some of these rural delights might be made to administer to the pleasure and happiness of our town-ridden poor, whose floral sights are chiefly confined to the exceedingly formal and, alas! too evanescent display of bedding-out arranged for their delectation during the summer months. To carry out spring gardening on a large scale might well prove too great a burden for any of our park superintendents, but in suitable spots and within convenient range it surely would not be impossible to create a small spring flower garden such as are now common even in well kept gardens. To be transplant Belvoir, Cliveden, or Glen Eyre, into the midst of London would be beyond the power of mortal, but to attempt even at a distance a humble imitation is not impossible. Such a spot as the garden adjoining Palace Yard would perhaps offer the desired space, and the introduction of hardy flowering plants in that locality in the early spring would, perchance, assist to shed a little sweetness where it is much needed. The requisite material need not be planted until just before the flowering period, and then the masses of colour would soon become prominent. Even if the result was not all that could be desired it is well worthy a trial.

— NEXT MAY the HORTICULTURAL SOCIETY OF VIENNA will hold a festival exhibition, to celebrate the fiftieth anniversary of its existence. According to the circular issued by the committee of organisation, the first flower show in Vienna was held on May 9, 1827, counting among its supporters Professor JACQUIN and Baron HUGEL, both names familiar to botanists in this country. Although the exhibition is

FIG. 35.—FUCHSIA ARABELLÆ, AS GROWN BY MR. LYE.

not to be of an exactly international character, foreigners are invited to take part in it. Dr. E. FENZL is the Secretary.

— In view of the proposed NEW FLOWER MARKET IN VIENNA, various reports on the markets and market plants of other countries have appeared in *Der Gartenfreund*. The list for the Paris markets during the first three months of the year may be of interest for comparison with the plants and flowers to be had at Covent Garden during the same period:—

1. Tropical and temperate plants grown for their flowers:—Azaleas, Camellias, Rhododendrons, Roses, Lilies, Hoteia japonica, Dutzira gracilis, Berberis, Lonicera, Erica, Echeverria retusa and coccinea, Frankia sinensis, Tulips, Crocuses, Mignonette, yucca Polargonium, various winter flowering Begonias, Lily of the Valley, Cyclamen, Violets, and Gardenias.
2. Tropical and temperate plants with ornamental foliage:—Chamcerops, Latisana, Areca, Coccoloba, Cocos, Rhipis, Philodendron, Dracaena, Fandanus, Ficus, various Ferns, Bromelia, Curculigo, Aspidistra, Cycas, artemifolia, Tradescantia, Peperomia, Oplismenus, Maranta, Echeverria, &c.
3. Hardy plants with ornamental foliage:—Acanthus, Aucuba, Eucyamus, Viburnum Tims, Heliosorus niger, Yucca, Hedera in variety, various Coelebs, &c.
4. Annual and other plants for bedding, &c. in boxes:—Alyssum saxatile, Arabis verna, Viola tricolor, Cheiranthus Cheiri, Aubrietia deltoidea, Bellis, Silene, Myosotis, Primula, Centranthus, Theris, Saxifrage, &c.
5. Trees and shrubs of all kinds.

— At the February meeting of the Edinburgh Botanical Society Mr. M'NAB laid on the table a bunch of what is generally called the FLORIDA MOSS (*Tillandsia usneoides*). This is a Bromeliaceous plant, the order to which the Pine-apple belongs, and named from its resemblance to the *Usnea barbata* (Old Man's Beard), a lichen found covering the bark of many trees in damp British woods. The Florida moss is sent to the United States for the purpose of decorating churches and dwelling-houses at Christmas. In Florida this plant is found in large quantities, covering and often killing the Live Oak (*Quercus virens*), the tree on which it is parasitic and mostly abounds. It is also extensively used for packing Oranges for exportation. The specimens exhibited by Mr. M'NAB were all quite fresh, as seen when exposed to heat and moisture, and were presented by Mrs. MASON, of Philadelphia, to Mr. M'NAB's two daughters before leaving America on January 25. It was with this plant that the Philadelphia Centennial Exhibition was decorated.

— THE HISTORY OF VEGETABLE GALLS is no unimportant study, and Mr. W. BEYERINCK, who is making them his speciality, has a wide field for operations. In a quite recent number of the *Botanische Zeitung* he gives the first of a series of articles on this subject. His idea is to work them out physiologically and systematically. An arrangement of galls based upon their animal occupants without regard to the nature of the perfectly developed galls, although to great extent in harmony with Nature, he would not regard as natural. All excrescences caused by insects are taken into account. The leading idea in the investigation is that every gall formation is the consequence of an effusion of fluid in the cells. The nature of this fluid is taken into consideration. When this scheme of arrangement is completed we shall probably give an outline of it.

— According to GODLEWSKI (*Bibliographische Berichte über die Publikationen der Akademie der Wissenschaften in Wien*, 1876), the first of a series of at least Borrera ciliaris, the one employed in the experiments, in darkness use up all the oxygen of the air, and exhale carbonic acid; and they form no other gas until there is available oxygen. The intensity of respiration increases with the temperature. In twenty-four hours they will appropriate about their own volume of oxygen when subject to a temperature of 62.6 Fahr.

— Our young contemporary, the *Journal des Roses*, describes in the February number a show of 6000 Roses held at Coulommiers towards the end of last September. One exhibitor sent a collection of 190 select varieties; another sent 500 flowers of the Rose du Roi and 220 of Paul Neyron. One of the features of many French shows, including the one

named, are the lady patronesses, who contribute separate prizes awarded by judges selected from their own ranks. The coloured plate in this number is the Rose Mrs. LAXTON, as drawn by MACFARLANE for the *Florist and Pomologist*. Among miscellaneous matter is a list of shrubs and trees in flower in the open air at Eric-Comte-Robert, including a plant of the Rose Camille Bernadine, with six half-expanded buds as fine as they are often seen in May or June.

— Sir WALTER C. TRÉVELYAN informs us that MANDRAGORA MACROCARPA, seeds of which he got many years ago on the Island of Cerigo, Greece, has been flowering freely in the open ground all the winter in his garden at Wallington, Northumberland.

— We learn that the named and certificated ROSES raised by Mr. LAXTON, viz., Dr. Hogg, Mrs. LAXTON, Charles Darwin, Emily LAXTON, and Marchioness of Exeter, are in the hands of Messrs. PAUL & SON, of Cheamstead. Mr. TURNER, as we mentioned previously, tendered for the purchase of the unnamed seedlings.

— M. SARATÉ has devised, and exhibited before the Horticultural Society of France, a gauntlet of chain armour to be used for removing the bark of the Vines, and with it the winter eggs of the PHYLLOXERA. The sulpho-carbonates are proved useful as an application to the roots, but it is necessary to attack the enemy in the cracks of the bark also, and for this purpose the rods are drawn through the gloved hand with the result of removing the old bark and the insects. The glove might be used for removal of moss from the bark of trees and for other purposes.

The following questions are proposed for discussion at the CONGRESS AT AMSTERDAM, and we are asked to give an opinion on the subject before February 20. As we have but just received the paper, it is impossible to express any opinion upon them. We may, however, say, that Dr. RAUWENHOFF, of Utrecht, is the Chairman of the Committee, and that Drs. Oudemans, of Amsterdam, Suringar, of Leiden, Mulder, of the Hague, and De Boer, of Groningen, with other eminent men, form part of it. The Congress will be divided into three divisions:—1, Botany; 2, Horticulture; 3, Vegetable Products. We subjoin the questions proposed to be discussed in relation to horticulture:—

What is the best way to organise experimental gardens and horticultural laboratories?

The best mode of conveying instruction in horticulture.

The permanence of varieties among bulbous plants.

The influence of manures on cultivated plants, especially on Hyacinths, Tulips, and Cabbages.

The best method of ventilating greenhouses.

The influence of coloured glass on the development of flowers.

— Mr. GAMMIE, of the Sikkim Cinchona plantations, has lately adopted the plan of FROOTING THE CINCHONA TREES, for the sake of the bark of the roots, which is found to be very rich in Cinchona alkaloids (8 per cent.). In this way thinning is effected, and through deep cultivation of the soil is effected, which may be replanted at once, allowed to lie fallow, or used for some other crop in rotation.

— According to M. DUBOST the total annual value of the following VEGETABLE PRODUCTS OF FRANCE may be estimated approximately as follows:—

—Cereals, 2430 millions of francs; farinas, 310; vegetables, 282; fruits, 180; wine and cider, 1200; miscellaneous, 531; woods and plantations, 350; straw and forage, 250. Total, 5533 millions of francs.

— From documents just received (though dated as far back as December 9, 1876) we learn that the opening of the AMSTERDAM INTERNATIONAL HORTICULTURAL EXHIBITION AND BOTANICAL CONGRESS will take place on April 12. We give the following abstract of rules, &c. —

Any one will be allowed to exhibit and compete for the prizes.

Those who intend to exhibit must notify their intention by writing (post-paid) before March 1, 1877, directed to the Secretary-General, with statement of the objects they wish to send, as each object must be notified on a separate form.

Those who have complied with the regulations will receive forms to fill up, and will be informed of the conditions on which a reduction of freight will be allowed by the different means of transport.

Foreign exhibitors will be duly informed as to the conditions on which free import, without examination on the frontiers, will be granted by the Minister of Finance.

The forms mentioned will have to be sent in properly filled up, in duplicate, to the Secretary-General before March 15 next.

All plants must be duly labelled, with the scientific name distinctly stated.

Plants newly introduced must bear, besides the name, as far as possible, the statement of their origin, the period of their introduction, and the names of the person or persons who have transmitted them, the places where they were introduced, and who first named or described them; hybrids, by whom reared, and their pedigree.

The articles must be forwarded carriage-free, and addressed to the Board of Commissioners of the International Horticultural Exhibition, Palace of Industry, Amsterdam, on April 6, 7, or 9 next.

Live flowers, bouquets, and fresh vegetables will also be admitted on April 12, before 9 o'clock A.M. Trees, shrubs or plants for the open air will be received from March 15 until March 31.

Plant-houses and other buildings, fountains, or such-like objects, requiring much time for their location, will be admitted only during the month of March. Exhibitors abroad will have exceptional facilities allowed as much as possible.

A jury, to consist of competent Dutch and foreign scientific gentlemen, will be invited to award the prizes. The jurors will assemble on April 20, at 11 o'clock A.M.

The exhibition will be open to the public from April 13 until May 2, 1877.

The objects shown must be removed on May 3 and 4. Objects not reclaimed three days after the closing of the exhibition, remain at the exhibitor's risk.

During the exhibition no objects may be removed without a special permission of the Commission.

In no case will it be allowed to deliver objects sold during the exhibition to the purchasers, or to remove them in any other way from the exhibition.

During the exhibition a Congress will be held, where opportunities will be offered for discussing subjects connected with the exhibition. Of this Congress a separate programme is issued.

Nearly seven hundred classes are mentioned in the schedule, for which gold, silver, and bronze medals, and certificates of various grades will be offered. In addition to the horticultural exhibition, there will be an exhibition of various vegetable products, as cotton, tobacco, cinchona, madder, indigo, caoutchouc and gatta-percha, fatty and oily substances, materials for making paper, cereals, catechu, vanilla, rhubarb and sarsaparilla. Medals and prizes will be awarded as in the case of the horticultural exhibition. The secretary is Mr. J. B. GROENEWEGEN.

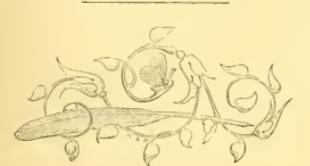

— Dr. GEORGE KING, the Superintendent of the Royal Botanic Gardens, Calcutta, has lately published a valuable MANUAL OF CINCHONA CULTIVATION IN INDIA, giving an account of the history of the Cinchona, the collection of the seeds in South America, the introduction of the plant into India, the modes of cultivation adopted in that country, the chemistry of the bark crop, and various appendices giving statistical details as to the condition of the plantations, the value of the products, and various other matters. The publication will be of very great value in all those colonies where Cinchona cultivation is practicable.

— Few people will assert that the prevalent style of STAGING CUT BLOOMS OF ROSES in this country is an artistic or pleasing one; but when the judging of the merits of perhaps one from half-a-dozen to a dozen collections has to be got through in about a minute, and this is not infrequently the case—it is out of the question to permit exhibitors to exercise their ingenuity in setting off their collections by auxiliary plants and flowers. Space, as a rule, is not wanting, but so much is sacrificed to time. This, doubtless, will continue to be the rule at most provincial shows, because, in the first place, it is next to impossible for some of the exhibitors to get their products staged unless they bring a sufficient number of hands with them to do the work—local committees commonly forgetting, or not knowing, that they should make it a part of their duty to provide men to assist in this work. Secondly, the managing committees of many provincial shows, although most

anxious for the success of their shows and energetic in their labours to secure it, do not include among their number, men of practical experience in making the most of the material at their disposition, and, being unaware of its importance, fail to secure the services of a qualified person to superintend the arrangements. The consequence is that a few of the early birds secure the most advantageous points for exhibiting their products, to the detriment of those who, through no fault of their own, arrive later; and frequently unsuccessful squabbles ensue, resulting in waste of time, dissatisfaction, and an unsuccessful show, so far as an effective display is concerned. But, if the most is made of the time, and a small, but well organised, staff of men be employed under an able superintendant, promoters, exhibitors and visitors alike are satisfied and gratified. And it is for the consideration of those who superintend the staging, whether some advantageous changes might not be made without adding too much to the labours of the usually overworked judges. It is quite unnecessary to dwell upon the blemishes in our shows, nor excluding many of those held in the metropolises. Of course so long as the plants, flowers, and fruits exhibited are limited to those in competition for prizes it is out of the question to treat them and arrange them as if they were contributed with the object of making an effective whole. But let somebody with the power and ability introduce some novelty in the hitherto almost unvarying monotony.

— In the *Botanische Zeitung*, Dr. O. DRUDE proposes a MODIFIED CLASSIFICATION OF THE PALMS, the basis of which is the separation of the New and Old World forms, based upon the facts that no species of Palm is indigenous both in America and the Old World; no genus is common to both worlds, and even the tribes are almost limited by the same areas of distribution. The arrangement is the following:—

1. *Colomaeo*.—Tropical Africa, Asia up to 30° N. lat., and the Sundia Isles and Australia to 30° S. lat.
2. *Rhaphie*.—Equatorial Africa, Madagascar, Mascarenes, and Polynesia.
3. *Mauriticeo*.—Tropical America, from 10° N. to 15° S. lat.
4. *Borassino*.—Africa, Mascarenes, Seychelles, and Western Asia to 30° N. lat.
5. *Corymbaceo*.—America, 25° N. to 23° S. lat.
6. *Areceae*.—All around the world from 90° N. to 40° S. lat.
7. *Chamedoriceo*.—America, 25° N. to 20° S. lat.; Madagascar, Mascarenes, and Seychelles.
8. *Triverteo*.—America, from 15° N. to 20° S. lat.
9. *Corymbaceo*.—Asia, to 30° N. lat.; Sundia Isles, Australia to 17° S. lat.
10. *Corymbaceo*.—All around the world from 40° N. to 35° S. lat.

Home Correspondence.

The Gardeners' Royal Benevolent Institution.—I have often considered that the circumstance that comparatively so few gardeners subscribe to this Institution must be somewhat disheartening to the many ladies and gentlemen who so kindly subscribe to its funds, and also to the lively interest in its prosperity. It may possibly be worth while to attempt to inquire into the cause or causes of this apparent lethargy on the part of those for whose special benefit the Institution was originally formed, and still continues to exist. I am perfectly aware that among gardeners generally, guineas are things by no means plentiful, but I do not think this circumstance the only or primary cause of this lukewarmness or apparent indifference on the part of gardeners. There are very few mechanics or even agricultural labourers who do not subscribe to a benefit society of some kind, and the sum subscribed seldom, if ever, falls under the amount of one guinea annually, indeed it is often considerably more; so that I can hardly think that among gardeners the inability to spare this sum can be the principal cause of preventing so many from subscribing to the funds of the Institution. I am

inclined to think that there is much in Mr. Findlay's letter at p. 147 which requires the serious consideration of all those interested in the prosperity of this excellent institution. I think it very likely that many gardeners may reason with themselves in this way, viz., "Supposing that I should subscribe to this Institution, and supposing also that at some future time I may be so unfortunate as to need its assistance, I am quite unknown to and can have no influence with any of the influential supporters of the Institution, and I should hardly have the shadow of a chance of being selected as a candidate. So I will not think of joining the Oddfellows, or the Foresters, &c., as the case may be." Therefore I feel quite inclined to think, with your correspondent, that the system of canvassing should as far as possible be discontinued, as it can be so judiciously disposed of by the selection of a portion of the candidates. Before an election takes place the secretary invariably takes care that every subscriber to the funds of the Institution is duly furnished with a list of the names of the proposed candidates, which list also states their respective ages, with the necessary particulars, as regards their circumstances, their ailments, &c., and to this me appears to be quite sufficient as a guide to subscribers who may have no personal knowledge of the candidates to enable them to make a judicious disposal of their votes. There is also another circumstance which I think may operate as a preventive to gardeners becoming subscribers, viz., the smallness of the pension itself when obtained; for if it ought to be increased from £16 or £12 per cent. to twenty-five or thirty years ago, go father towards furnishing the means of keeping body and soul together than £25 or £20 will do at the present time. For answer to this it may, of course, be said, and I am quite willing that the funds of the Institution will not admit of higher pensions being paid, unless the number of pensioners be allowed to diminish. In my opinion, however, even this very undesirable alternative would be preferable, as I cannot help thinking that it would be better that the number of pensioners should be reduced to a few, and deserving, although indigent brethren, in comparative comfort, than to keep double the number merely alive; at the same time I most sincerely trust that it may never be found necessary to have recourse to the alternative I have alluded to, viz., a reduction in the number of pensioners. And I beg to respectfully call upon my brethren of the spade, and more particularly upon my younger brethren, to show that they possess the essential *esprit de corps*, and put themselves at once in communication with Mr. Clegg, the excellent and indefatigable secretary of the Institution, who will I am sure, be pleased to receive and to acknowledge their subscriptions, which they will very likely, after all, miss less than they may now suppose. And they will tend in a great measure to enable the Institution in some degree to increase the amount of its pensions without reducing, but if needful increasing, the number of its pensioners. In conclusion I sincerely trust that every subscriber to the excellent Institution may never, in the slightest degree, require its assistance.

P. O'Brien.
I can fully indorse the remarks made by Mr. Findlay at p. 147 as to the growing evil of canvassing for votes at the election of pensioners of the Gardeners' Royal Benevolent Institution, especially as regards nurserymen. In some instances it even appears to be degenerating into a trade advertisement. I have had similar remarks to those quoted by Mr. Findlay made to me when recommending gardeners to subscribe, and know those who have withdrawn subscriptions chiefly on that ground. It certainly has become a growing evil, that requires a check. *J. A. P.*

Rainfall at Houghton Hall, Rougham, Norfolk.—I beg to hand you a report of the rainfall for this part of the county during the past year:—January, 1.95 inch; February, 2.7; March, 3.4; April, 5.17; May, 0.73; June, 1.78; July, 1.2; August, 2.38; September, 4.18; October, 0.58; November, 3.25; December, 4.34; total rainfall in the year, 32.36 inches. My rain gauge is a double cylinder, capable 3 inches in diameter made by Bryson, of Edinburgh. It is sunk 20 inches in the ground, and stands 4 inches above it. The fall in April seems to have exceeded anything I have noticed in the reports published in your columns. *J. Horvill, Bailiff, Houghton Hall, Norfolk.*

Veitch's Self-Protecting Broccoli.—This is undoubtedly one of the greatest acquisitions to gardeners that has been introduced for many years, and will be sure to find its way into every garden where a winter supply of so valuable a vegetable is desirable, as it is a most useful one when compared with other varieties. Mr. McIndoe, in his letter of recommendation at p. 83, appears surprised, as well he may be, that no mention had been made of it in your review of the fruits and vegetables of the past year, but to my mind it is very much to be regretted that it could have been deemed unworthy of the Royal

Horticultural Society's Certificate, which is of infinite more importance, because if "Royal Certificates" mean anything (which undoubtedly they do for those who obtain them), and even, for the sake of supposition, if they are valued only as an honorary award, why should their certificates have been withheld in the instance of one of those of *Tritoma Rooperi*, *Ruby Cullis*, *Dorlington*.

The Hardest Tritoma.—It is, perhaps, worthy of note that while the flower-spikes of the other species of *Tritoma* (*Uvaria media*, *Uvaria glaucescens*, and *grandiflora*) succumbed to the first frosts and drooped and withered at once, those of *Tritoma Rooperi* have borne the same low temperature uninjured, and many plants of this species, which have bloomed through the winter, are still showing flower in Messrs. Backhouse & Son's nurseries, at York. *T. Rooperi* is a dwarf species (from 14 to 2 feet high), well adapted for positions in groups or borders where the taller kinds might be considered too tall. It commences to flower later than *T. Uvaria*. *Elbor.*

Eucharis amazonica.—The plant of which I send you a photograph is in the possession of R. H. HANNEY, Esq., Poles, Wares. Much having recently been written about Eucharis, a few remarks upon its plant in question may be interesting. It was at its best on January 8, there being on it at that time forty-four flower-stems, the total number of flowers being 227. This same plant was in full flower on September 1st; it then produced thirty-six flower-stems, the number of flowers was not then recorded, but the flower-stems at that time were stronger than at the present, many of them then bearing seven and a few eight flowers. This same plant has now produced twenty-five flower stems, and in January, 1876, it produced thirty. Besides flowering three times last year, it flowered three times in 1875, and we hope to obtain similar results during the present year. Thus it will be seen this plant in January, 1876, has produced 135 spikes, each taking an average of five flowers on a stem (which is quite within the mark), gives a total of 675 flowers. One great point in the cultivation of this lovely flower is to grow each crop of leaves quickly and liberally, with an abundance of liquid manure at the root, and plenty of atmospheric moisture. *J. Hill, Poles, Wares.*

Ficus Cooperi.—A plant of this growing under glass in one of the plant-houses in the Dalkeith Nursery has produced thirty small well-set fruits. The plant, growing in an 8-inch pot, is, upon the whole, a very interesting and evergreen shrub, which I would be glad to see as I have seen it in the jungle on the Malabar coast, Goa territory, East Indies. *Charles Key, Dalkeith.*

Potatoes and Parsnips.—Believing as I do that the Colorado beetle will reach this country, and thinking of the havoc it would do to the potato in Ireland, I was pleased to see your notice in it in the *Gardeners' Chronicle* of the 3d. I hope the public will see the prudence of planting fewer Potatoes, and sowing more Carrots and Parsnips, the value of which, more especially of Parsnips, is very much underrated. *Richard Walker, Warrick Road, Upper Clapton.*

The Seasons.—In this mild and early season some of your readers may like to have their memories refreshed as to former ones, and to compare them with the present year. I see from my notes that during the last ten years those most like the present one were 1849, 1869, and 1871. In 1849 the winter was followed by a forward spring without a check. The last three weeks of January were mild and wet, February fine, March mild and wet, May magnificent; Walnuts, Spanish Chestnuts, and Ash in full leaf by the end of the month. I had a dish of Strawberries (Black Prince) fully ripe, the first of June and July were hot and dry, and the Wheat in this neighbourhood was carried by the end of July; my Hop-picking was over on September 11; a very good fruit year. I cannot recall another year without a check round the spring. In 1869 the winter was very wet, windy, and mild; by the second week in February Almond trees were in full blossom in London. [They were so at the present time in the S.W. districts, Eds.] In sheltered places near the sea many Blackthorns were in full bloom by February 10; abundance of wild Daffodils here by the 10th; on February 28 Hyacinths in flower in the open border; grass grew all the winter, and my lawn had to be mown by the middle of February. March was cold and wet, April fine and warm. In 1871 the Lilacs and Apples were in full blossom, Pears over. May a miserable cold month; much east wind, yet wet. June very cold. July a splendid month. A good year for common fruits, but hardly any wall fruit. In 1872, from the end of December to the end of February, the weather was very mild. Wild Daffodils abundant by March 4, and Ribes sanguineum by

March 8. The first half of March fine and dry, then snow. In April a good deal of cold and wet, but still a forward season. By April to abundance of Cowslips and Stellaria and some wild Hyacinths. On the 21st, by May 5 Lilacs in full flower, Laburnums, Horse Chestnuts, and Weigela coming on rapidly, and plenty of grass. May and half June wretchedly cold and wet; the weather improved on July 17, and some very hot weather in July. A very small white plant, *William Wackham, Bristled-Wick, Alton, Hants.*

— Wild flowers are following the example of their more cultivated relations, and blossoming early. For I picked in my walk on the 10th a very pretty nosegay of "wildings." The small white *Potentilla*, the pale yellow *Oxlip*, a lovely little pale blue *Veronica*, bright *Buttercups*, *Primroses*, and the catkins of the *Hazel nut*. On the 7th I saw a wasp, and on the 3rd a humble-bee enjoying the sunshine; so insects, like the birds, are evidently under the impression that spring has come. *Helix E. Watsony.*

Melanthus major.—To show the mildness of the past winter I have now a specimen of the *Melanthus major*, between 3 and 4 feet high, coming into bloom. This plant has been out several seasons, but usually dies down every winter and shoots again in the spring. This year it was kept in the greenhouse, and has had two blooms of the *Magnolia grandiflora* the middle of last month, and the trees continue to bloom now. *S. Hanbury, Bishopscote, Torquay.*

Garden Walks.—I should be much obliged to any of our readers if they would kindly tell me the best way of making garden walks. The gravel in this country is bad, full of clay, and the gravel walks consequently are covered with weeds and moss. I fear that the asphaltic walks, made of a mixture of tar and sand, would look black, and like the paths in the Black Country, which are very unsightly. Again, I have been advised to put down a lime and sand walk, made in the same manner as a cottage floor, but doubt much whether this would answer out-of-doors. I should be extremely grateful for advice from any one who has practically tried it, whether it is possible to combine tar and sand or gravel, so as to make a perfectly hard and lasting walk, and yet not present that dismal appearance which it generally has, giving also an estimate of the cost per square yard. I may mention that I have here any quantity of sea-sand of a beautiful colour. *Paulist St. Compton, Mapperton House, Beaminster.*

Fertilisation of Plants.—In Mr. Henslow's very interesting paper on the above subject, at p. 139, when alluding to *Pelargonium zonale*, he mentions the circumstance of my having influenced the colour of the flowers, as well as the foliage of *Geranium pratense* by using the pollen of various *Zonal Pelargoniums*, and says, "It would have been a desideratum to know what, if any, effect was produced by the crossing on the zones, but nothing is said about it. I can only say that, in the specimens alluded to, no indications of the transmission of zones to the leaves of the seedling *Geraniums* could be perceived, although this was anxiously watched for, and its appearance would have been regarded as an assurance that the cross had been effected." There were, however, the change of colour in the flowers of many of the plants, as well as the condition of variegation in the leaves of several of them, to lead to this belief, and although the variegation gradually disappeared as the plants grew, the plants themselves have been preserved in order to ascertain if the marking will again appear in the newly-produced foliage. I think I have already stated in a former communication on this subject, that the experiment was also reversed, that is, the *Geranium* pollen was used as fertiliser of *Zonal Pelargoniums*, and the same hopes are entertained that some change may also be induced in the colour of their flowers. Should this be found to be the case, the circumstance will in due time be made known. *F. Griseb.*

Royal Horticultural Society.—In a leading article on the fortunes of the Royal Horticultural Society, and in my paper mentioned as that of one of those who "have been with scant ceremony dismissed from their offices on account of insufficient funds," I however little cause the Society may have to applaud itself for some of its misdeeds of this kind, I think it only fair to say that conscience has nothing to accuse itself of as far as I am concerned; but, as a matter of fact, long after other sacrifices became necessary, the Council retained me in the employment of the Society, and I only abandoned it because, on receiving the appointment of Assistant Director in the Royal Gardens, I was pledged to give my whole time to the Government service, and had, therefore, no choice in the matter. I have little desire to plunge into the sterile field of horticultural politics, but I cannot refrain from saying a few words, not dissimilar to not view with regret and dismay the new

aspect which the affairs of the Horticultural Society have taken. Once again its face is turned from what is useful and honourable to what, in the opinion of sensible people, must seem useless and deplorable. I make Chiswick stand to horticulture as Kew does to scientific botany was a laudable, and in the present state of horticultural activity a perfectly feasible programme that that a great society in its last stage of decay should be so unwise as to attempt to attempt to maintain a stately but uninteresting garden as the summer lounge of a fashionable quarter, and should be complacently satisfied with the imperfect achievement of its undignified task, is most deplorable. *W. T. A. Dyer.*

As a lover of horticulture, and a twenty-guinea compeer, I feel a great interest in the future of our Society, and attended the annual meeting on Tuesday. I was much surprised at the very limited attendance of the Fellows, and the utter absence of any practical suggestions by those present. I appeared to me, from the address of the noble Lord in the chair, that the main obstacle to the resuscitation of the Society consists in the claims of the debenture-holders and the vacillation of the Council as to the recognition or otherwise of their claims. Now, as regards debenture holders either have a legal claim or they have not. If they have, the courts of law are as open to them as to any other class of Her Majesty's subjects who may happen to have made unprofitable investments; while if their claims are a moral or sentimental matter, and they are in distressed circumstances, doubtless subscription among their many wealthy friends in the neighbourhood might be inaugurated. But I protest loudly against the future welfare, or perhaps the very existence of our Society, being in any longer in the hands of a hesitating policy of Council, who sympathise with the unfortunate debenture-holders appears to culminate in the hope that somebody else will relieve them. *A Twenty-Guinea Fellow.*

My attention having been called to the paragraph in the *Gardener's Chronicle* of January 17, "dismissed with scant ceremony," by the Royal Horticultural Society, of Professor Dyer, Rev. M. J. Berkeley, and others, I cannot refrain from expressing my astonishment at your giving circulation to a statement which, as regards the first-named gentleman, is absolutely the reverse of the fact. As regards Mr. Berkeley the simple fact is the Council were most reluctantly, and, with his full concurrence in the necessity of the measure, compelled to deprive the Society of his services. The same reasons which forced the Council to do so, may be supposed to have led to reductions in the establishment, and nothing was or could be further from their intention in doing so than to act with any want of courtesy towards those with whose services they were obliged to dispense. *Robert Hoop, Secretary, Royal Horticultural Society, [W.]*

As regards the "scant ceremony" with which Professor Dyer. As to the "scant ceremony" in the other cases no doubt it was unintentional, but it was none the less unfortunate. [Eds.]

Currieria Wallisii, Mast.—I was much pleased to find in the *Gardener's Chronicle* of January 27 a figure and description of this fine new foliage plant, of which Mr. Wallis spoke very highly in his letters to me, specially pointing out the fine variegation and the neat dwarf and compact habit, which made it far superior to *C. Roezlii*. The dried specimens he sent me I handed over to Dr. Regel, who described them in the *Gartenflora*, October, 1876, under the name of *Homalomena Wallisii*. Dr. Regel does not recognise *Currieria* as a good genus, not being sufficiently distinct from *Homalomena* in his opinion. Dr. Masters, in describing the same plant, was without doubt not aware of this fact. *E. Ortleib, Botanischer Garten, Zurich.* [We are greatly obliged to our correspondent for indicating the prior publication of *Currieria Wallisii*, of which we were, of course, unaware; but the name of *Currieria* was not mentioned in the *Gartenflora*—not, as usually written, *Homalomena*—of which latter we intend to give a figure shortly. [Eds.]

The Clive House Seedling Grape.—I should not have been the least notice of the above, had my name been taken in amongst the contributors of Mr. Bell in the *Gardener's Chronicle* of last week. I can only say that I corroborate every word that my friend Mr. Bowie said about this Grape in your issue of January 20. Mr. Bowie knew the Grape for years before I ever saw it; and if seedling Vines ever were brought to this place, they were never seen or heard of by any one here as far back as I can trace. I have ample proofs that the Grape was raised by Mr. William Caseley in this garden some twenty years ago, and it has been grown and fruited here ever since. Mr. Bowie's mistake was to be a new Grape and a Clive House Seedling are problems I leave for the horticultural public to solve. The other Grape alluded to by Mr. Bell did not secure the same honours that his adopted child did from the Fruit Committee of the Royal Horticultural Society, simply because it was thought by some of the com-

mittee that the flavour came too near the Muscat flavour of that excellent Grape, Mr. Pinco's Black Muscat, to be distinct. As Mr. Bowie has not explained facts connected with this valuable late Grape, I shall take no further notice of the subject, whatever other fallacious statements may appear. *Alexander Ingram, The Gardens, Alwrick Castle.*

So thoroughly convincing was the truth of what I previously stated in the *Gardener's Chronicle* about this Grape, that I reiterated it without fear, having no interest to serve in this matter further than I there mentioned. For somewhat more than forty years I have been in the habit of paying a visit to the gardens at Alwrick Castle more than once every season, and by the different gardeners employed there during that time I have had every facility afforded me for seeing all that was considered worthy of notice. I distinctly remember having the seedling Grapes, which at that time were in reality all of which that in question is one), pointed out to me. I afterwards frequently examined them, and when they began producing fruit I had much pleasure in tasting and comparing it with that of other Vines. Nor, so far as I remember, have I ever heard the Grape called by any name but that of the Earl of Arundel, and that not only during the last summer, as Mr. Bell asserts, but for many years previously. Mr. Bell knows the conditions with which he promised to comply when he obtained the Grape from Alwrick Castle, but which at that time were in reality all of which that poor old Mr. Baillie should in his declining years have allowed himself to be made the scapegoat of Mr. Bell in this transaction. *Robert Bowie, The Gardens, Chillingham Castle.* [As the Fruit Committee of the Royal Horticultural Society, and I am, moreover, cancelled the name, it would serve no useful purpose to continue this discussion. [Eds.]

Effects of the Mild Weather.—Will you allow me to say that I have for many years taken great pains to note the difference between a mild winter and a severe one. All my experience goes to show that mild winters are generally followed by late springs, and often by fruitful seasons. Although we have in our hedgerows *Elder*, *Honeysuckle*, and a few other plants, showing signs of forward vegetation, yet this does not necessarily foretell an early spring, for these very early signs are generally common to a winter which, especially when we have had an early hard winter, followed by a mild February, such as we are having at present. The fact is, tree vegetation is much behind what it was in this time last year, and the Pear blossom-buds are more behind their usual state of development. The Angora Pear is the earliest leaving tree that I know, after the *Elder* and *Honeysuckle*, and it was in full leaf in February last year. I have examined it to-day, and see no appearance of its foliage being put forth. The heads of Elm and other trees are beginning to show, and about now, but this is always the case early in the season. Tree vegetation generally begins about the middle of December, before the sun has entered Aquarius; consequently their buds have made considerable progress before the winter sets in. I have already mentioned this early development to show that it has nothing to do with the mildness of the season, but is an effect of a change in the magnetical current, which appears to me to take place prior to the sun's return to perihelion on December 31. But I am not philosopher enough to be able to give a reason why the magnetical current should precede the sun, supposing it does so, as indicated by the growth of trees commencing, as I said above, early in December, or at least about the middle of it. Some of your correspondents have been very anxious to elucidate this interesting matter. *John Scott, Merriott.*

Scott's Wasp Destroyer.—I have seen nothing so effectual for destroying wasps as this mixture, which is also the best thing for destroying their nests that I have ever used. We have four large vineries here, and last summer the wasps were very troublesome in the garden, but by applying this mixture to the destroying mixture two or three times our Grapes were not in the least hurt. It is a boon to gardeners, and no one who has Grapes to grow should be without a bottle of it. It is very simple, and may be used by a boy or a gardener, and is as safe as the gardener. *Ed. Farr, Foreman, Sutton Park.*

The Colorado Abies Menziesii.—This tree, which was mentioned in your columns at p. 48 on one of the most charming of all the Spruces, and especially remarkable for the bright blue glaucous hue of the entire plant, is without any doubt, the same as one of the seeds which Mr. Roezli sent me in the autumn of 1874, together with seeds of the most beautiful *Picea concolor*, *Picea bicolor*, *Pinus aristata*, &c. Mr. Roezli spoke very highly of the decorative value of this Spruce, the foliage glittering in the sun, and the tree being called "Silver Spruce" and when once fairly known would be a great favourite.

He also took it for a variety of *Abies Menziesii*, but said that it never made such tall trees, and had a much better, much more compact habit. With the seeds he sent me also branches and cones; on comparison I found it to be the *Abies commutata* of Prof. Parlatore (*Abies Engelmanni*, Parry), and therefore adopted this name in distributing these seeds, which were of excellent quality. No doubt there must be now a great quantity of 2-year seedlings in the principal nurseries on the Continent and in England, where Messrs. F. Sander & Co. were entrusted with their sale. Those nurserymen who bought of these seeds will be glad to learn no doubt that their stock of small *Abies commutata* is the very same thing as the new Fir in the garden of Professor C. S. Sargent, at Brookline, near Boston, and will take all the better care of their little seedlings. *E. Ortgies, Botanic Garden, Zurich.*

Ancient Resuscitated Yew at Bettws Newydd.—The gigantic old Yew, of which the base here illustrated (fig. 36), is one of two now growing in the churchyard of Bettws Newydd, between Abergavenny and Usk in Monmouthshire. The original sketch was made by the writer last autumn during the meeting of the Cambrian Association in Monmouth-

the name the Government of Chili employed at the Vienna Exhibition to describe this gum. From the seed sent to India, Ceylon, and Australia, I hope soon to hear of a good result, although it is a difficult shrub to propagate. If any of your readers can assist in getting a further supply of this seed, it will be gladly welcomed, as my small stock of a few pounds is exhausted. *Thos. Christy, Jun.*

Mushroom Culture.—In your issue of Jan. 27 you give an account of a Mushroom-bed producing an extraordinary crop of very fine Mushrooms, as exhibited at South Kensington, and for the benefit of the readers of the *Gardeners' Chronicle* you also give Mr. Hopper's method of making, spawning, and subsequent working of the bed. A confessor I am somewhat alarmed, and most certainly should hesitate before adopting the treatment set forth at p. 115. Apart from having serious doubts as to the moasure getting a great deal too hot, and in a measure destroying the spawn, what strikes me most forcibly with fear is the very high temperature (90°) which is maintained in the house for a period of "three weeks." I certainly never heard of a Mushroom-house being kept at such a high temperature before, and I can well imagine what the Mushrooms would be like in No. 1 bed

been an object of admiration to every one who has seen it. Should Mr. Shrivess (p. 251) like to try it, I shall have great pleasure in sending him a batch of cuttings. *P. Davidson, Stanmore Park, Great Stanmore.*

—No bedding *Lobelia* of recent introduction has proved more useful and permanent in character than the semi-pamila *Blue Beauty*. This variety has flowers the size and colour of *speciosa*—not a purple tint, but the bluest of blue *Lobelias*—allied to the habit of *pamila*, but of a more robust growth. The plant forms an almost flat head of flower from the first, and maintains this desirable habit all through the season. It is a first favourite at the Crystal Palace, the Royal Horticultural Gardens, and at Heckfield, and in many other of the best flower gardens. I believe that *Blue Beauty* has not yet received the honour of a First-class Certificate at South Kensington, but that can scarcely derogate from its value, as some *Lobelias* that have recently received that honour there have never been seen in such good form since. The *Lobelia* is so entirely a bedding plant that it is somewhat strange the Floral Committee should grant certificates to any kind until they have been tested as bedding-out plants at Chiswick for a season; *Violas* and *Fansies* have to undergo that ordeal, and why not

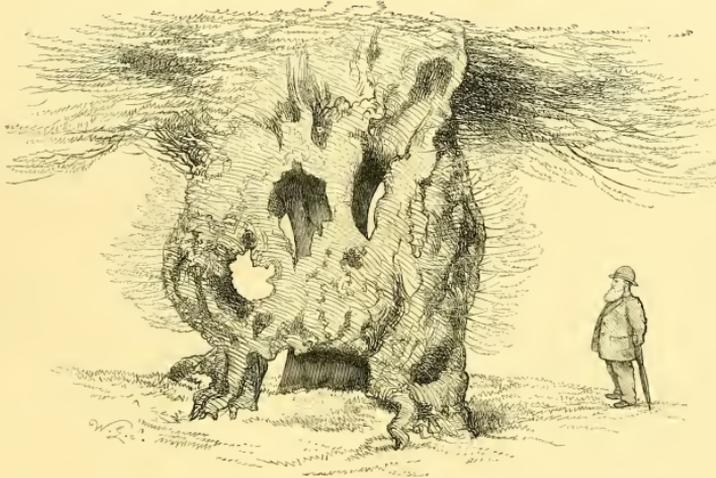

FIG. 36.—ANCIENT RESUSCITATED YEW AT BETTWS NEWYDD.

shire. The two great Yews at Bettws Newydd are considered remarkably large even in this district, where Yews of great size are common. The tree illustrated is 39 feet 6 inches in circumference at 5 feet from the ground, and is not only remarkable on account of its great size, but for its singular regrowth or resuscitation from within. The internal stem was probably at first an adventurous descending root, now it is a columnar stem of great size, which serves to support and feed the battered and time-riven old shell. Many descriptions of resuscitated trees will be found in the back volumes of the *Gardeners' Chronicle*, one of the best being by the late Mr. J. T. Moggridge, in the volume for 1870, p. 1248. *W. G. S.*
