THE

GARDENERS' CHRONICLE

A Weekly Illustrated Journal

OF

HORTICULTURE AND ALLIED SUBJECTS.

(*ESTABLISHED IN* 1841.)

VOL. XXXIII.—THIRD SERIES.

JANUARY TO JUNE, 1903.

LONDON:
41, WELLINGTON STREET, COVENT GARDEN, W.C.
1903.

BRADBURY, AGNEW AND CO., LTD., PRINTERS, 1903
LONDON AND TONBRIDGE.

INDEX OF CONTENTS.

JANUARY TO JUNE, 1903.

(For Special Headings see under Books; Certificates; Law Notes; Nursery Notes; Obituary; Plant Portraits; Plants New; Scientific Committee; Societies; and Illustrations.)

A

Abbotsbury, flowering shrubs, &c. at, 258
Aberdeen Public Parks, 201
Abutilon, a twin flowered, 156
Abutilons, grafted, 250
Acænas, 148
Æsculus indica, 139, 188
Africa, tropical (Flora of), 234
Agapanthus Mooreanus, 181; A. umbellatus, 181
Agave americana, 106; flowering of, 345; out of doors, 123; A. applanata var. Parryi, 342, 364
Agaves in Britain, 72
Ageratums, Swanley Blue and album, 149
Allamanda Hendersoni, culture of, 122
Alpine garden, the, 212, 292, 340, 386
Alpinia Sanderæ, 245; A. tricolor, 245
Alyssum pyrenaicum, 410
Alyssums, 386
Amiens, the market gardens of, 1
Androsace lanuginosa, 346
Androsaces, 202
Anemone blanda, pink coloured, 252, 265; A. b. Florizel, 212; A. b. Meteor, 212; A. intermedia, 243; A. Robinsoniana, 243
Anemone bed fungus (Peziza tuberosa), 203, 236
Angræcum sesquipedale, 100, 371
Anomatheca cruenta, 326
Antigonon leptopus, 277; A. l., how to flower, 299, 399
Antirrhinums, 83
Apiary, the, 55, 135, 167, 231, 263, 295, 327, 343, 359
Apples, American Mother, 253; Edward VII., 219; growing for profit, 68, 91; keeping, 251; Prince Bismark, origin of, 138; Round Winter Nonsuch, 253; from Nova Scotia, 9
Aquilegias, hybrid, from seeds, 182
Arabis aubrietioides, 212
Araucaria imbricata, 99, 172
Aroids, tuberous, 201
Arundinaria Simoni, 186
Asparagus-beds, draining, 424; salting, 277; forcing in open beds, 181; A. scandens, 339; A. Sprengeri var. falcatoides, 168
Asters, perennial, cultivation of, 29
Athletics and intelligence, 73
Aubrietia Dr. Mules, 324
Aubrietias, notes on some, 292
Aucubas, berried, 380
Auricula gossip, 259
Auricula Yellow Gem, 259
Auriculas in early spring, 150
Azalea indica alba, 372

B

Bailey, F. M. (Queensland Flora), 154
Baker, R. T. (Eucalypts), 228
Bamboo, a home-grown, 195
Bamboos, the flowering of, 245
Bananas, increased consumption of, 104; home-grown, 155
Barbados, volcanic ash from, 249
Barr, Mr. Peter, experiences in South Africa, 14, 194, 210, 290, 402; home again, 329
Basingstoke Farm School, 169
Batson, H. M. (see Books).
Beans, early Broad, 83
Beaumontia grandiflora, 395
Beech, 92 feet high, 236
Beeches, Weeping, at Ashwick Hall, 396
Begonia Bowringiana, 245; B. coralina, 406; B. Gloire de Sceaux, 155; B. Gloire de Lorraine, 59, 92; cultivation of, at Wexham Park, 29
Belgian horticulture, 289, 308, 322, 365
Belmont Castle, 113
Belvoir Castle, 121, 154, 186, 209
Benevolent Institution, Gardeners' Royal, 40, 51, 61, 62, 77, 168, 219, 330, (annual dinner) 423
Beschorneria yuccoides, 258
Birds and the fruit buds, 298, 365
Bletia Shepherdi and B. verecunda, 228; B. hyacinthina, 271
Blind worms and slugs, 326
Boilers, sectional, 156
Bois, M. D., 330
Bolus, Dr. Harry, 329

Books, Notices of.—A Book of the Country and the Garden (*H. M. Batson*), 297; Account of Cape Colony's Urban and Rural Industries, &c. (*Mr. Burton*), 135; All about Sweet Peas (*R. Sydenham*), 41, 57; Alpine Flowers for Gardens, &c., ed. ii. (*W. Robinson*), 330; Alpine Flora for Tourists and Amateur Botanists (translated by *Mrs. A. Gepp*), 330; A Manual of Indian Timbers (*J. S. Gamble, M.A.*, &c.) 30; Ampélographie (Grape Growing), 57; American Horticultural Manual (*J. L. Budd and N. S. Hansen*), 96; A Research on the Eucalypts (*R. T. Baker*), 228; A Text-Book of Plant Diseases (*Geo. Massee*), 394; A Third Pot-Pourri (*Mrs. C. W. Earle*), 243; Atlas der Krankheiten der Pflanzen, &c. (*Kirchner & Boltshauser*), 73; A Woman's Hardy Garden (*Helen R. Ely*), 372; Botanical Magazine, 41, 89, 169, 233, 296, 377; Cassell's Dictionary of Gardening, 25; Chrysanthemums and their Culture (*H. H. Balshaw*), 362; Country Life in America, 314; County Court Practice Made Easy, 331; Cultivation of the Tomato (*R. Holmes*), 372; Das Pflanzenreich, &c. (Cypripediums), (*Von E. Pfitzer*), 408; Dictionnaire Iconographique des Orchidées, 94; Die Einführung Auslandischer Holzarten (*John Booth*), 387; Die Veredelungen von Obstbäumen und Fruchtgehölzen (*Von Ph. Held*), 89; Die Rosenschädlinge aus dem Thierreich (Insect Foes of the Rose) (*F. Richter von Binnenthal*), 332; Edinburgh Seed Trade, 314; Etudes sur la Flore de Katanga (*Em. de Wildeman*), 153; Eucalyptus, Critical Revision of the, 378; Farm and Home Year-book and Farm Trade Directory, 41; Flora and Sylva (*W. Robinson*), 218, 234, 314; Flora Brasiliensis (*A. Cogniaux*), 164; Flora of Thanet (*G. M. Pittock*), 362; Flora Simlensis (*Col. Sir H. Collett*), 117; English Timber and its Economical Conversion (*Acorn*), 243; Gartenflora Index, 281; Greenwich Park, its History and Associations (*A. D. Webster*), 15; Hand-list of Trees and Shrubs (Royal Gardens, Kew), 26; Hortus Thenensis, 245; Icones Selectæ Horti Thenensis, 313; Il Crisantemo, Storia, Classificazione, Descrizione e Coltura (*Dario Formilli*), 388; International Scientific Series (*H. M. Vernon*), 405; Indian Planting and Gardening, 89; Journal of the Kew Guild, 25; Journal of the Royal Horticultural Society, 137, 360, 399; La Pepinière (*Chas. Baltet*), 25; La Vigne et le Vin chez les Romains (*M. Cartel*), 73; "Lindenia" Iconographie des Orchidées, 180; Melocactus (M. Valckenies Suringar) announcement, 330; My Garden Diary for 1903 (*Sutton & Sons*), 41; Nature Studies (*C. J. Scott Elliott*), 233; Natural Law in Terrestrial Phenomena (*W. Digby, C.I.E.*), 50, 188; Ootheca Wolleyana (*Alfred Newton*), 9; Our Poultry (*Harrison Weir*), 41, 89, 182; Parkinson's "Paradisus" (reprint announced), 345; People of the Whirlpool (Commuter's Wife), 396; Philosophical Transactions of the Royal Society, 396; Popular Illustrated Guide to S. E. & C. Railway Coast Resorts (*W. T. Perkins*), 361; Popular Science (*Cassell & Co.*), 198; Practical Instructions to ensure Shelter, &c., 396; Prodromus Floræ Britannicæ (*F. N. Williams*), 43; Publications Received, 7, 43, 70, 91, 121, 139, 202, 219, 282, 315, 331, 363, 396; Response in the Living and Non-Living (*Jagadis Chunder Bose*), 15; Rules for Judging, 137; Sertum Palmarum Brasiliensium (*B. Rodrigues*), announcement, 154; Shakespeare's Garden (*Rev. J. Harvey Bloom*), 274; Silva of North America (*Prof. Sargent*), 10, 40; Sweet Violets and Pansies (*E. T. Cook*), 385; The Amateurs' Greenhouse (*T. W. Sanders*), 96; The Ancient and Loyal City of Exeter, 314; The Book of British Ferns (*C. T. Druery*), 248; The Book of the Wild Garden (*S. W. Fitzherbert*), 243; The Country Gentleman's Estate Book, 313; The Dahlia: its History and Cultivation (*By several Authors*), 222; The Englishwoman's Year Book and Directory (*Emily Jarves*), 10; The Flora of the East Riding of Yorkshire (*J. Webber*), 51; The Fungus Flora of Yorkshire (*Geo. Massee and C. Crossland*), 43; The Garden Gazette (Australian), 138, 294; The Gardening Year Book, 89; The Handyman's Book (*Paul N. Hasluck*), 330; The Horticultural Directory, 153; The "House" Annual, 10; The Journal of the Board of Agriculture, 25; The Natural History of Plants (*Prof. Oliver*), 138; The New Forestry (*J. Simpson*), 10; The Orchid Review, 72; The Queensland Flora (*F. Manson Bailey*), 154; The Scottish Field, 313; The Soil (*A. D. Hall, M.A.*), 317; The Timber Trades Journal and Saw-Mill Advertiser, 249; The Transvaal Agricultural Journal, 10; The Veitchian Nurseries (*J. H. Veitch*), 233; The Year Book of New South Wales, 10; Traité Pratique de Cultures Tropicales (*J. Dybowski*), 10; Transactions of the Royal Scottish Arboricultural Society, 314; Trees and Shrubs for English Gardens (*E. T. Cook*), 15; Trees and Shrubs (*Prof. C. Sargent*), 90; Underground Irrigation in the British Isles and in India (*Jno. Grant*), 378; Vegetables and Flowers from Seed in Tropical, Semi-Tropical, and Temperate Climates (*Sutton & Sons*), 10; Webster's Foresters' Pocket Diary, 53; Willing's Press Guide, 56; World's Fair Bulletin, 362

Botanical congress at Vienna, 138
Botany, applied, 35; economic, usefulness of, 37, 69
Bothy, a royal, 363
Botticelli a botanist, 63
Bowood, 40, 56, 251
Broccoli Chelsea Favourite, 186; B. Cooling's Matchless, 140
Browne, Mr. W., retirement of, 105
Browning's plant (Orchis maculata?) mentioned in "May and Death," 316
Brunsvigia Cooperi and B. gigantea, 116
Bryophyllum crenatum, 59, 73
Buddleia variabilis, 379
Bud variation and bud selection, 361
Bulb-growing at Brentwood, 341
Bulbous plants for the conservatory, 326, 387
Bulbophyllum occultum, 130; B. Careyanum, 19
Bulbs destroyed by pheasants, 236, 325
Burlingtonia perpusilla, 18

C

Cabbage, Dickson's First and Best, 406; Methven's Edinburgh Market, 345
Cabbages in February, 186
Cactaceous plants at Holly Point, 170
Cacti, generic divisions of, 12; in sealed cases, 316
Calanthe Veitchi, 29, 115, 156, 188, 221; cultivation of, 139, 221; at Cliveden, 27; the flowering of, 11
Calanthes, Mr. Cookson's hybrid, 411
Calceolarias, herbaceous, 365
Camellia reticulata, 258
Camellias at Clare Lawn, 182
Campanula Barrellieri, seedlings from, 316, 348; C. latifolia, 92
Campbell's sulphur vaporiser, 253
Canada, emigration prospects in, 218, 277; map of, 401
Canna, a white, 318
Cannas, raising seedling, 70
Caoutchouc in Eucalyptus leaves, 33
Cape fruits, 377
Cardamine pinnata, 252
Cardiandra sinensis, 82
Carnation Nell Gwynne, 275
Carnation "Mrs. T. W. Lawson," 203
Carnations "Engadine," 76
Carnations Souvenir de la Malmaison, for market, 77; in large pots, 332, 380, 411
Cassava plant, causes sleeping disease, 115, 243; varieties of, in West Indies, 243
Caterpillars on Apple-trees, 352
Cattleya seedling flowers in eleven months, 125
Cattleya Mossiæ Wageneri, 388; C. Marquis de Wavrin, 164; C. Trianæi, 165; C. T. Leeana, 164
Cephalotaxus Oliveri, 227

Certificated Fruits and Vegetables:—Apple Edward VII., 206; Cucumber "Unique" (Supp., May 30).

Certificated Plants.—Acer palmatum lineari lobum purpureum gracile Crippsii, 301; Adiantum scutum ramosum, 382; Anemone coronaria fl.-pl. var. "King of Scarlets," 302; A. Hepatica triloba alba plena, 205; Asperula suberosa, 269; Aubrietia Pritchard's A1, 334; Begonias Lady Howe, Mrs. W. P. Neal, Hon. Lady Neeld, Sir Thos. Lipton, Mrs. Portman Dalton, and Mrs. Moger (Supp., May 30); B. The Queen, Countess of Warwick, W. Sparshott, and Gypsy Girl, 422; Boronia megastigma aurea, 205; Brasso-Cattleya × striata (Supp., May 30); Bulbophyllum occultum, 174; B. suavissimum, 108; Caladium mossamedes, 238; Canna "Papa Crozy," 301; Calochortus pulchellus verus, 382; Carnation Alma, 334; Carnations Lady Wolverton and Shiela, 422; Cattleya × Enid magnifica, 174; C. Mossiæ Alexandræ, 419; C. × Rohersiana, 419; C. Warneri alba, 419; C. × Whitei magnifica (Supp., May 30); Chrysanthemum Harry Whateley, 46; C. Miss Edith Davey, 46; C. Ruby Martin, 46; Coleus thyrsoideus, 45; Clivia T. E. Arnold, 173; Cordyline Père Charon (Supp., May 30); Cymbidium × eburneo-Lowianum concolor, 206; C. × Lowgrinum, 206; Cypripedium × Empress Alexandra, 46; C. × Hindeanum, 46; C. × J. Wilson Potter, 78; C. × Minos Young's variety, 108; C. × Mrs. Pitt, 239; C. × Samuel Gratrix var. Minnie, 46; Delphiniums Monarch and Rev. W. Wilks, 422; Dendrobium glomeratum, 335; D. × melanodiscus Sunray, 142; D. × Ophir, 142; D. × Salteri, 142; D. × splendidissimum var. Mrs. Haywood, 142; D. × Thwaitesiæ, 174; D. × Wiganiæ xanthocheilum, 108; D. Wiganianum album, 142; D. × Venus grandiflorum, 270; Epi-Cattleya × matutina, 383; Eremurus "Mrs. Ware," 422; Eulophia Coleæ (Supp., May 30); Ficus pandurata (Supp., May 30); Geum Heldreichi superbum (Supp., May 30); Heuchera hybrida Rosamundi, 383; Hippeastrum "Apple Blossom," 238; H. Black Prince, 238; H. Julius, 334; Incarvillea grandiflora, 205; Iris persica variety, 141; I. spuria (variegated form), 269; Irises, in, Chiswick trials, 400; Jasminum primulinum, 173; Kalanchoe × Felthamensis, 301; K. × Kewensis, 383; Kniphofia longicollis, 78; Lachenalia "Ruth Lane," 174; Lælio-Cattleya × Canhamiana Rex (Supp., May 30); L.-C. × Dora magnifica, 270; L.-C. × Fascinator splendens (Supp., May 30); L.-C. × Fascinator nobilior (Supp., May 30); L.-C. × Martineti Flambeau, 419; L.-C. × M. ochracea, 419; L.-C. × Wellsiana magnifica, 108; Lathyrus pubescens, 269; Lilium auratum platyphyllum, 422; L. Kelloggii, 422; Lourya campanulata, 108; Magnolia Campbelli, 174; Masdevallia × Veitchiano-Wageneri, 239; M. xipheres, 239; Megaclinium Imschootianum, 302; Narcissus Firelight, 206; N. Janet Image, 206; N. Mohican, 206; N., varieties of, 239, 270, 302; Nicotiana Sanderæ, 422; Odontoglossum × Adrianæ "Lady Wantage," 239; O. × Adrianæ "Swoboda," 206; O. × ardentissimum Fascinator, 419; O. × a. concinnum superbum (Supp., May 30); O. × a. numosum (Supp., May 30); O. × a. exquisitum (Supp., May 30); O. cirrosum "Pitt's variety," 302; O. cordatum aureum, 383; O. triumphans Crawshayanum, 239; O. × Bradshawiæ, 78; O. crispum Alpha, 239; O. c. Grace Ruby, 142; O. c. "Grand Duchess" (Supp., May 30); O. c. "Harold," 334; O. c. Cooksoniæ, 108; O. c. Grairianum (Supp., May 30, p. i.); O. c. "Lady Moncreiffe," 335; O. c. Persimmon, 239; O. c. "The Kaiser" (Supp., May 30); O. c. Truffautianum, 383; O. × loochristyense "Lord Howick," 108; O. Lucasianum var. Walkeri, 46; O. × Queen Alexandra, Rutherford's variety, 302; O. × Rolfeæ majesticum, 419; O. Rossii, Low's variety, 174; O. × Vuylstekei exquisitum (Supp., May 30); O. × Waltoniense, 46; O. × Wattianum Crawshayanum, 335; O. × Wilckeanum Rex, 108; O. × Wilckeanum venerandum (Supp., May 30); Oncidium triquetrum, 383; Pæonia Dawn, 422; P. lutea, 269; Papaver orientale Lady Roscoe, 422; Phaius × Chapmani (Supp., May 30); P. × Chapmani superbus, 383; P. × Harold, 206; P. × Clive, 142; Phyllocactus Deutsche Kaiserin (Supp., May 30); Pinguicula caudata superba, 185; Pink "Rubens," 383; Polypodium Knightiæ (Supp., May 30); Poppies, Iceland, 422; Psoralea pinnata, 302; Rehmannia angulata, 269; Rhododendron Duchess of Portland, 269; R. yunnanense, 334; R. molle "Floradora" (Supp., May 30); Richardia hybrida Solfatara (Supp., May 30); Rose (Polyantha) Blush Rambler (Supp., May 30); R. Madame N. Levavasseur, 238; R. multiflora "Waltham Rambler" (Supp., May 30); R. Rambler, 302; R. (Tea) Queen of Sweden and Norway (Supp., May 30); R. Souvenir de Pierre Notting, 334; Rubus moluccanus, 334; Saxifraga Grisebachii, 108; Schœnia cassiniana, 383; Schomburgkia Galeottiana (Supp., May 30); Selaginella Watsoniana (Supp., May 30); Tanakea radicans, 269; Trigonidium spatulatum, 335; Tulipa præstans, 239; Tulips, varieties of, 334; Vanda × Marguerite Maron (Supp., May 30); V. tricolor tenebrosa (Supp., May 30); Zygopetalum crinitum cœruleum, 142; Z. × Sanderi, 78

Ceylon Botanic Gardens, 392
Ceylon, new horticultural production in, 25
Chalk, action of certain organisms on, 401
Charlock, how to destroy, 153
Chestnuts, English, 43, 61, 188; disease in Sweet, 185
China, the public park at Shanghai, in, 127
Chinese flora, the, 57
Chinese Maples, 21, 62
Chiswick, the future of, 168; trials at, 298
Chloræa, species of; from Chile, 317
Chrysanthemum frutescens var. Golden Sun, 324
Chrysanthemum, the, as a market plant, 4; show at Lille, 345; hastening the flowers of, 192; judging, in America, 69; manures for, 200; new, 92; stopping and transplanting, 222; striking cuttings of, 34
Cintractia patagonica, parasite on grass, 14
Clare Lawn, East Sheen, 197
Cleaning by the vacuum method, 104
Clerodendron Myrmecophilum, 196, 291
Clitandra species yields rubber, 153
Cocoanut Palms in Ceylon, 331
Codlin-moth, the, 122
Coffea Laurentii (robusta), 306
Coffee, properties of, 345
Coleus thyrsoideus, 76, 106
Colonial flower-shows, 229
Columbine, the stellate, 418
Commissions, secret or corrupt, 152, 170, 172, 188, 204; Bill for preventing, 138, 296
Conifers, Chinese, 34, 66, 84, 116, 133, 194, 227
Cooke, Dr. M. C., awarded the Linnean Society Medal, 329
Cornish plants, 416
Corypha elata, 360
Cotton-growing in the West Indies, 361
Couch-grass amongst fruit-trees, 203
Covent Garden Market notes, 10
Crassula decipiens, 3
Crickets, to destroy, 93
Crinum rhodanthum, 315
Crocus Tauri, 212
Cucumber, curious, 297, 348; culture of, 12, 28; plants, the raising of, 34, 128
Cycads, new, from the Congo, 139
Cypripedium × Argus, 100; C. bellatulum and hybrids from it, 321; C. × Hindeanum, 53; C. × J. Bartels, 130; C. × Juno, 130; C. × J. Wilson Potter, 83; C. × Minnie, 130; C. montanum, 242; C. × Priam, 130; C. siamense, 242
Cypripediums, hardy, 307, 354, 378
Cytisus, proliferous, 395; C. scoparius var. Andreanus, 348

D

Daffodil names, 277; D. Sir Watkin, 178; the first, 106
Daffodils, at Ard Cairn, Cork, 278; dyed red by absorption, 185; frilled trumpet, 236; the forcing of, 82, 124
Dahlia, history and cultivation of the, 222
Dahlias, 123, 219; propagation of, 106
Daphniphyllum glaucescens, 417
Darnell, seed fungus of the, 396
Davidia involucrata, 236
Dehérain, the late M., 41
Dendrobium Bensoniæ, 389
Dendrobium atro-violaceum, 292; D. Boxalli, 164
Dendrobiums at Woodhatch Lodge, 228
Dendrometer, 11, 28
Diacrium bicornutum, 242
Dioscorea Fargesii, a new Chinese vegetable, 73
Disa grandiflora, 37
Douglas Fir, the Colorado variety of the, 244
Down, season in county, 11
Dracæna Broomfieldi superba, 245; D. kewensis, 245
Draper, Mr. W., Egyptian decoration for, 390
Drimys Winteri, 345
Droitwich experimental garden, 224
Druery, C. T. (*British Ferns*), 248
Dublin, damage to trees in Phœnix Park, at, 185
Durban market prices, 154

E

Earle, Mrs. C. W. (*Pot-Pourri*), 243
Eaton Hall gardens, notes from, 340
Echeveria retusa, 148
Echinocactus Delaeti, 170
Echiums, 347; shrubby, 345; two fine, 331
Edinburgh, the King's visit to, 332
Edwardsia microphylla, 259
Eggs twelve months old produce chickens, 324
Elastic threads in Eucalyptus leaves, 331
Electric-light, forcing by, 184
Elisena longipetala, 326
Ely, Helen R. (*A Woman's Hardy Garden*), 372
Engler, Professor, 43
Environment, effect of, on plants, 57
Eremurus Warei, 410; E., the species of, 381, 399
Escallonia macrantha and E. × Langleyensis, 416
Ether and chloroform used for forcing plants, 57, 143, 168
Eucalyptus coccifera, 345; critical revision of the, 378; elastic threads (caoutchouc) in, 92, 331; Mr. Baker's research on, 228
Eucommia ulmoides for yielding rubber, 104
Eulophiella Peetersiana flowering at Glasnevin, 169
Eupatorium odoratum, 356
Experimental Garden at Droitwich, 224

F

Fagus betuloides, 10
Fenn, Robert, V.M.H., 329
Fern names, British, 418
Ficus pandurata, 245
Fir Grange, Weybridge Heath, 186
Fir, Silver, 104 feet high, 236
Fitzherbert, S. W. (*Wild Garden*), 243
Florida, how to grow Oranges in, 353

Florists' Flowers, 4, 150, 219, 408
Flower Garden, the, 7, 23, 39, 54, 71, 87, 102, 118, 134, 151, 167, 182, 198, 215, 230, 246, 262, 279, 295, 311, 327, 343, 359, 375, 392, 413
Flowers, winter, in sunny climes, 81
Flowers from the Riviera, 25; in January, 41
Forcing plants by ether and chloroform, 143, 184
Food of plants, 154
Foreign correspondence, 14, 36, 407
Forestry, 372; facts and fancies in English, 246; new chair of, 264; question in the House of Commons upon, 137; report of the departmental committee on, 56, 66
French Beans and millipedes, 348
Frogmore Gardens, the alterations in, 363

THE MARKET GARDENS OF AMIENS.

THE word *hortillonage*, as applied to what we should call market gardens, is not to be found in ordinary French dictionaries. Even Littré does not mention it, at least it is not in the edition which is on our shelves. In Picardy, however, and especially around the city of Amiens, it is a word that one hears frequently; whilst the traveller on any of the lines of railway leading to the famous city is pretty sure, as he looks out of the carriage window, to make acquaintance with the thing signified. On the main line through Amiens to Paris, soon after passing Abbeville, the line runs through the valley of the Somme, bordered by chalk hills, and filled with alluvial deposits. The first indication the traveller gets of the nature of the district he is traversing is afforded by the little brick-like masses of peat he sees heaped up in stacks in the meadows by the sides of the streams. Perchance he may get a glimpse of the workmen in punts scooping out the precious fuel from the ditches, as shown in our illustration at fig. 4 (3), p. 9.

This may serve as an indication of the nature of the soil with which the Picard market-gardener has to deal—a light black sandy peat full of moisture, apparently rich in humus, but destitute of fibre, and, as we learn, deficient in lime. It is always more or less sodden with moisture, and not unfrequently flooded. In places the ground is traversed by an infinitude of narrow and shallow canals, which afford easy access to the beds, and secure a certain amount of drainage. By means of punts the workmen are enabled to carry out the necessary operations (fig. 1, p. 2), and by the same means they convey to the great city the produce of their industry (see fig. 4 (2), p. 9). It is a pretty and interesting sight to see the strings of boats laden with garden produce making their way along the stream, and finally depositing their contents on the side of the quay in the heart of the old town (fig. 2, p. 3), dominated by the glorious cathedral, which rises out of the flat plain as if it, too, were some gigantic outgrowth from the soil.

And what vegetables they are! We English people are apt to be a little conceited about the produce of our market gardens, but the comparison of what may be seen in the markets and shops of Amiens with the average produce exhibited in our own greengrocers' shops, will not be altogether to the advantage of our cultivators.

The peaty soil, left to itself, is not a fertile one. Its natural vegetation is one interesting rather to the botanist than to the farmer. To render it suitable for market garden purposes the soil must be drained to let off superfluous water, and secure aëration and the conversion of the inert nitrogen which it contains into nitrates, that can be utilised by the plants. Lime must be added to neutralise the acidity of the soil, and favour nitrification; potash in the form of kainit and superphosphates are also valuable adjuncts, but the Picard farmer prefers the use of stable-manure—and they do say that the sewage of Amiens contributes not a little to the fertility of the soil. If this be so, the consumption of salads or uncooked vegetables should be avoided when in that neighbourhood. Granted these ameliorations, the Amiens *hortillonages* may and do produce vegetables of superior quality, not only such leafy vegetables as Cabbages, Spinach, Lettuces, or Endives, but magnificent Cauliflowers, Vegetable-Marrows, bulbs such as Onions and Leeks, and even roots like Carrots, Turnips, and Radishes. Currants, Raspberries, Gooseberries, may even be seen, and occasionally fruit-trees, but these at a distance from the river, and so far as casual inspection may be trusted, not well cared for. Amiens, Abbeville, Lille, and other towns in the north of France, are supplied from these *hortillonages*, also called *hardines*, a perversion, we suppose, of *jardins*, as well as Paris. It is possible also that London may absorb some of the productions, but enquiries made on the spot did not lead to the impression that any large trade was done with England. One reason for this may be that the Amiens gardeners do not concern themselves with forcing vegetables or securing early crops. The dull climate of the district, sometimes called the reservoir of France, may account for this. The language spoken by the working-classes of Picardy is even less like French to the ordinary tourist than is the dialect spoken at Stratford-atte-Bow. Some documents relating to the *hortillonages* were placed at our disposal, but as they were written in the Picard dialect they proved to be almost entirely incomprehensible. Fortunately the object-lessons are easily read, and dispense with the necessity of any acquaintance with the Picard dialect.

In consideration of the Vegetable Exhibition and Conference to be held at Chiswick in the coming autumn, these notes, as well as those on a Middlesex market garden, of which an instalment was given in our last issue, may be of interest.

NOVELTIES OF 1902.

ORCHIDS.

IT is a significant fact that not a single new *species* of Orchid has received either a First-class Certificate or an Award of Merit at the Royal Horticultural Society's meetings during the past year, the only First-class Certificate taken by a species being for the fine old Zygopetalum rostratum, shown by Sir Trevor Lawrence, Bart., at the Temple Show on May 28. Even the Botanical Certificates awarded, a large number of which went to plants exhibited by Sir Trevor Lawrence, and some to the Hon. Walter Rothschild, tell of recognition of good old garden plants, with a very few examples of recent introduction. These facts indicate that the state of things we foretold years ago has happened, and that the hybridist has, perhaps unfortunately, overtaken the importer, and rendered his vocation too unremunerative to pursue, except in those fields likely to produce phenomenal varieties, such as Odontoglossum crispum.

But history repeats itself, and the time of the reveuge of the importer looms in the distance—the time when the large number of raisers already at work get their productions of the same parentage on the market together. Then it will be *sauve qui peut*, and values may go down to those of ordinary florists' flowers. Already the holders of large batches have to resort to expedients to get them off, although with the hybrids, as with the fine varieties of species, the really distinct and handsome command the market, and prices for such go up rather than down.

The number of new hybrid Orchids of the past year is so great, that only some of the most prominent can be enumerated. Of those standing head and shoulders above the average are the fine Cypripedium × Venus "Oakwood variety" of Norman C. Cookson, Esq.; the stately and richly-coloured Cypripedium × Mrs. Wm. Mostyn, of Francis Wellesley, Esq.; the gorgeous Lælia × Digbyano-purpurata Edward VII., and Lælio-Cattleya × Queen Alexandra, of Messrs. Veitch, two varieties which formed such an appropriate coloured supplement to our Coronation number; and the noble Cypripedium × Emperor of India of Messrs. Sander & Sons, which was illustrated in the same issue.

Norman C. Cookson, Esq., Oakwood, Wylam (gr., Mr. H. J. Chapman), also got certificates for Lælio-Cattleya × Cooksoniæ, Phaius × Ruby, P. × Phœbe superbus, Calanthe × triumphans, Odontoglossum × Wilckeanum Rothschildianum, O. × Rolfeæ Oakwood variety, and O. × Adrianæ Cooksoniæ, all of superior merit.

Baron Sir H. Schroder (gr., Mr. H. Ballantine), has during the year shown many of his superb Odontoglossums, among those selected for Awards being O. × Adrianæ "Memoria Victoriæ Reginæ," O. triumphans latisepalum, O. × Harryano-crispum "Duchess of York," and O. × Harryano-crispum delicatum.

Francis Wellesley, Esq., Westfield, Woking (gr., Mr. J. Gilbert), had for his best, beyond the one already named, the fine white and crimson Cattleya Mossiæ Arnoldiana Westfield variety, C. × Lady Ingram Westfield variety, Oncidium × Mantini superbum, Cypripedium × rubescens Ranjitsinghi, and Lælio-Cattleya × Zephyra alba.

H. T. Pitt, Esq., Rosslyn, Stamford Hill (gr., Mr. Thurgood), adds to his previously fine record, Odontoglossum crispum "Fairy Footsteps," O. c. Pittiæ, O. c. Lady of the Lake, O. Ruckerianum Pittianum, O. Hallii Queen Alexandra, Cypripedium × Wm. Pitt, C. × Felicity, Cattleya × Mrs. Pitt, Lælio-Cattleya × Ingrami Rosslyn variety, L.-C. × Isis Rosslyn variety, and others.

J. Gurney Fowler, Esq., Glebelands, South Woodford (gr., Mr. J. Davis), a keen appreciator of good Orchids, had awards for amateurs, notably Odontoglossums, and varieties of Lælia anceps, which form the specialties of De B. Crawshay, Esq. (gr., Mr. Stables); the very fine Odontoglossum crispum Lady Jane, by J. Wilson Potter, Esq.; O. crispum Robert McVittie, of W. Thompson, Esq.; Cypripedium × Miss Fanny Wilson, by Drewett O. Drewett, Esq.; the Odontoglossum crispum Marjorie, of R. Ashworth, Esq.; Lælio-Cattleya × Mrs. Chamberlain, of the Rt. Hon. J. Chamberlain.

Messrs. Jas. Veitch & Sons maintain the lead in the special class of hybrids which they effect. Besides the two superb examples already cited, they have secured awards for Lælio-Cattleya × Orphens, L.-C. × Digbyano-Schroderæ, L.-C. × Rosalind "Prince of Wales," L.-C. × Thorntoni grandiflora, L.-C. × Statteriana superba, L.-C. × Myra Princess of Wales; Cypripedium × Thalia, and Cymbidium × Lowio-grandiflorum, all very fine productions.

Messrs. Charlesworth & Co., of Heaton, Bradford, send out a continuous stream of good things, among those for which they secured awards during the past year being Sophro-Lælia × Heatonensis, Lælio-Cattleya × Dora, several forms of the superb Cattleya × Iris, C. × Adolphus superba, Odontoglossum Pescatorei Charlesworthi, O. crispum punctatissimum "Princess Maud," Oncidium varicosum Charlesworthi, Lycaste × hybrida, Cypripedium × Edithæ, and others.

Messrs. Sander & Sons, St. Albans, appeared at their best in their marvellous group shown at the Holland House Coronation Show on June 24, when they secured two First-class Certificates and eight Awards of Merit, chiefly for fine hybrids and rare blotched forms of Odontoglossum crispum, among which were O. crispum Imperatrix Reginæ, O. c. Princess Helène, O. c. Princess Victoria, O. c. Her Majesty, O. × loochristyense Princess Margaret, Miltonia vexillaria Queen Alexandra, Lælio-Cattleya × Aphrodite King Edward VII., Cattleya × Prince Edward, Lælio-Cattleya × Martineti Prince Arthur, and the elegant new bi-generic hybrid Zygonisia × Rolfeaua, the whole forming a record of which any firm might well be proud. Other fine subjects for which Messrs. Sander secured awards were the white Cattleya amethystoglossa Sanderæ, Cypripedium × Evelyn Ames superbum, C. Transvaal superbum, C. × A. Dimmock, Lælio-Cattleya × Clive var. Sanderæ, and the handsome Zygo-Colax × Wiganianus superbus.

Messrs. Hugh Low & Co. secured awards for the fine white Cattleya Trianæi alba var. Mrs. Ed. Sondheim, C. labiata, and C. labiata Amesiana; C. Grossii, and Odontoglossum × loochristyense enfieldense.

Various other exhibitors produced good novelties and useful additions to our garden plants.

The Continental Exhibits

Came chiefly from Messrs. Linden, of Brussels, whose Odontoglossum crispum Miss Lucienne Linden, and some other blotched varieties, were fine. M. Chas. Vuylsteke showed his fine group of spotted Odontoglossums of the O. × ardentissimum class at the Temple Show, taking awards for four; Mr. A. A. Peeters, of Brussels, showed good spotted Odontoglossum crispum, and other novelties; as also did M. Chas Maron, of Brunoy, France.

Among the new or rare Orchids illustrated in the *Gardeners' Chronicle* in 1902, are:—

Angræcum ichneumoneum, Supp., March 22.
Bulbophyllum Ericssoni, November 22, p. 383.
Cypripedium × A. Dimmock, March 8, p. 157.
Cypripedium × Brunhilde, May 31, p. 350.
Cypripedium × Emperor of India, June 21, p. 415.
Cypripedium insigne Holfordianum, Dec. 6, p. 413.
Cypripedium × Mrs. Wm. Mostyn, Feb. 1, p. 75.
Cypripedium × Transvaal superbum, Nov. 15, p. 361.
Cypripedium × Venus Oakwood variety, Feb. 8, p. 91.
Dendrobium taurinum, Feb. 8, p. 90.
Dendrobium Wardianum Fowleri, Feb. 22, p. 125.
Lælia anceps Chamberlainiana, Feb. 1, p. 71.
Lælia anceps Hollidayana Crawshayana, Feb. 22, p. 123.
Lælia × Digbyano-purpurata Edward VII., Coloured Supplement, June 21.
Lælio-Cattleya × Queen Alexandra, Coloured Supplement, June 21.
Lælio-Cattleya × Adolphus superba, Aug. 16, p. 111.
Maxillaria fractiflexa, May 31, p. 359.
Maxillaria scurrilis, October 4, pp. 243, 245.
Odontoglossum × Adrianæ Mrs. Robt. Benson, April 12, p. 249.
Odontoglossum × Adrianæ Cooksoniæ, June 14, p. 389.
Odontoglossum × ardentissimum, July 26, p. 50.
Odontoglossum × Edwardus Rex, June 21, p. 414.
Odontoglossum crispum Miss Lucienne Linden, May 3, p. 289.
Odontoglossum × Wilckeanum Rothschildianum, Supplement, December 6.
Oncidium × Mantini superbum, Nov. 15, p. 351.
Phalænopsis amabilis Rimestadiana, Supplement, October 25.
Phalænopsis Lowii, November 8, p. 343.
Zygo-Colax × Wiganianus superbus, March 8, p. 156.
Zygonisia × Rolfeana, July 19, p. 30.

FIG. 1.—AMIENS: A VIEW IN THE MARKET GARDENS. (SEE P. 1.)

Cypripedium insigne Fowlerianum, C. Wardianum Fowlerianum, and Lælio-Cattleya × Bletchleyensis Fowler's variety.

Sir Frederick Wigan, Bart., Clare Lawn, East Sheen (gr., Mr. W. H. Young), had for his best exhibits of the year, Phalænopsis Sanderiana Wigan's variety, Cypripedium Godefroyæ leucocheilum pulchellum, Sobralia × Wiganiæ, Cattleya × Wavriniana Wigan's variety, C. × Prince Edward, and Miltonia vexillaria gigantea.

Sir Trevor Lawrence, Bart., Burford (gr., Mr. W. H. White), still retains his partiality for fine species and rare botanical plants; no fewer than a dozen awards for new or rare species being given to specimens in his interesting group at the last Temple Show.

Captain G. L. Holford, C.I.E., Westonbirt (gr., Mr. Alexander), has been one of the largest exhibitors of the year, his best being Cypripedium insigne Holfordianum, Odontoglossum × Mrs. Robt. Benson, O. × Adrianæ Sibyl, O. × Loochristyense Lady Victoria Grenfell, and Sophro-Lælia × Orpetiana.

Good things were also shown by other

NEW OR NOTEWORTHY PLANTS.

CRASSULA DECIPIENS, N. E. BROWN (N. SP.).

THIS novelty has one of the most remarkable leaf-surfaces that I have seen, being quite unlike that of any other plant known to me save one, which is either another new species allied to the present one, or a variety of it, having the same kind of leaf-surface. As seen under a lens, the surface of the leaves is exceedingly pretty. Few people would be able to feel certain as to whether this plant, when out of flower, was a Cotyledon, a Crassula, or a Mesembryanthemum, so distinct is it from any described species, and yet bearing some indefinite resemblance to all three genera. It is perhaps more nearly related to C. namaquensis, Schönland and Baker, than to any other species. Living plants of it are in cultivation at Kew, where they were received this year from Mr. H. J. Chalwin, of Cape Town Botanic Garden; and a flowering specimen has recently been sent to Kew from the rich collection of Mr. C. Darrah, of Holly Point, Heaton Mersey.

A dwarf tufted perennial about 1½ inch high, exclusive of the flowering stem, breaking into numerous very short crowded branches close to the ground, densely leafy, without distinct internodes; leaves all radical, opposite, sessile, crowded, ascending-spreading, thick and fleshy, to 1¼ in. long, 3½ to 7½ lin. broad, ¼ to ⅓ in. thick, oblong, elliptic-oblong, or somewhat spatulate-oblong in outline, obtuse, flattened on the upper side, very convex on the back, whitish, light greenish-grey or somewhat bluish-green, with a very remarkable surface, the whole leaf being densely covered with blunt papillæ with hard, white tips (probably an incrustation of carbonate of lime); these papillæ are separated in a somewhat tessellate manner into small groups by the surface being traversed by numerous transverse and longitudinal irregular crack-like lines. Flowering stems terminal, erect, about 2 inches long, 1⅓ lin. thick, terete, densely covered with minute papillæ, slightly scabrous to the touch, whitish-green, bearing one pair of bracts below the middle, otherwise leafless. Bracts adpressed to the stem, 2½ lin. long, 1½ lin. broad, ovate-oblong, sub-obtuse, connate at the base, flat on the face, convex on the back, papillate like the stem, ciliate with short, deflexed hairs. Cyme terminal, three-branched, about ⅔-inch in diameter, convex at the top; branches about 2 lin. long, terminated by a small, dense head of ten to twelve sessile flowers. Bracts like those on the stem, but gradually smaller. Sepals five, erect, ¾ lin. long, ½ lin. broad, oblong, obtuse, papillate, with a few hairs on the back, ciliate. Petals five, free, erect, 1⅓ lin. long, rather more than ½ lin. broad, oblong, obtuse, with no distinct dorsal apiculus, slightly concave, glabrous, white. Stamens five, included, scarcely 1 lin. long, glabrous; filaments white, anthers yellow. Hypogynous glands ¼ lin long and broad, subquadrate, emarginate, concave, yellow. Carpels five, erect, ¾ lin. long, compressed ovoid, narrowed into a short style, glabrous, pale greenish. *N. E. Brown.*

THE GRANGE, HIGHBURY NEW PARK.

PASSING along a busy thoroughfare that is situated within 4 miles of Charing Cross, the attention of the passer-by is drawn to two massive pillars which flank the entrance to the grounds of F. Bishop, Esq., The Grange, Highbury New Park. The mansion is pleasantly situated, and the small estate is enclosed by a high wall; masses of fine shrubs exclude the public gaze, and once within the gardens it were easy to imagine oneself a hundred miles from London. Mr. Bishop is an enthusiastic horticulturist while Mrs. Bishop and their daughters share his good taste, and take a lively interest in everything that pertains to the garden. The grounds, more than 4 acres in extent, were laid out by the present owner, and his gardener, Mr. E. Easey.

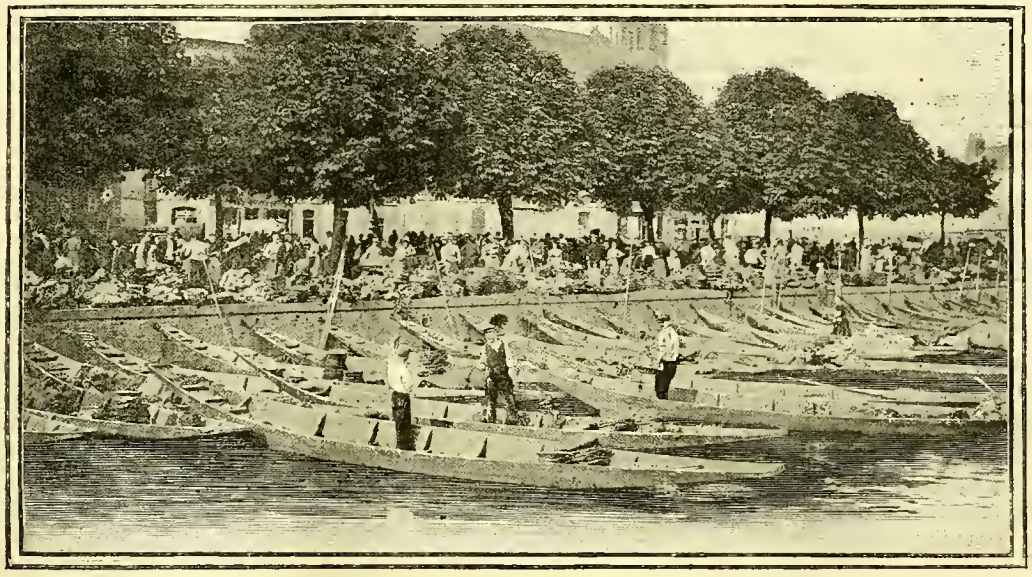

FIG. 2.—AMIENS: THE VEGETABLE MARKET ON THE QUAY. (SEE P. 1.)

PLANT NOTES.

GLAUCIUM FLAVUM TRICOLOR.

I NOTE that this fine plant, as showy in general effect as it is unique in colour, has this year reached the seedsmen. They generally describe it as an annual, but this is a mistake. It flowers the first year from seed, but in the autumn it pushes up strongly from the roots, and flowers again in the ensuing summer. Whether it would persist to a third year I cannot say, as I have always had to move my plants at the end of the third year, and they cannot stand such moving. The adjective tricolor makes one suspect a garden variety. The plant, however, is truly wild. It was discovered by Mr. Whittall on some mountains near Smyrna. Mr. Whittall was attracted from a long distance off by the extraordinary effect made by a colony of it. Its colour approximates more nearly to the Austrian Copper Briar than to any other plant I know. But the Briar lacks the wonderful metallic lustre of the Horn Poppy. In saying this, however, I must exclude the Persian G. Fischeri, which is possibly another form of the plant. From a garden point of view, however, G. Fischeri is very inferior; its flowers are smaller, they are so sparsely produced as always to fail in making an effect, and, at any rate, in my garden, they persistently refuse to open. *A. K. Bulley, Ness, Neston, Cheshire.*

Capital specimens of Hollies have been freely planted, with particularly pleasing effects. At the time of my visit Chrysanthemums were in full beauty. The plants numbered one thousand of all sections, and exceedingly well grown, Mr. Easey being a cultivator and exhibitor of repute. Special attention is given to trained plants, and in this direction Mr. Donald's mantle seems to have fallen on Mr. Easey. I observed more especially the group out of which were selected the plants that won premier prize at the National Chrysanthemum Society's November show. There were very fine examples of Miss Watson, Col. W. B. Smith, President Nonin, Com. Blusset, Eva Knowles, W. Trieker, and Cleopatra. The incurved varieties formed a very fine lot, and those of the Japanese section were most excellent.

As cut flowers are in great demand, bush plants are largely grown in early and late flowering varieties. At the time some fine Tuberoses were likewise in bloom. About five hundred Carnations, consisting of the more popular varieties, are grown in pots — fine healthy plants that promised a plenteous crop of flowers.

In the Orchid-house I observed well grown plants of Cœlogynes, Cypripediums, Cattleyas, Lælias, Dendrobiums, and Odontoglossums. The garden possesses a delightful fernery, and well-grown plants of Adiantum, Gleichenia, Cheilanthes, Pteris, &c., were plentiful. In the stove

representative collection of table plants and others, Codiæums, Dracænas, Cocos Weddeliana, Aralias, Kentias, Araucaria excelsa, and Pandanus are grown.

The vineries, which are large and lofty, are planted with Black Hamburgh, Muscat, and other varieties, all of which crop excellently. A few Grape-vines are grown in pots for early fruiting. There are two houses about 80 feet long, each containing magnificent specimens of Camellias of very large size, most of them being about 24 feet high. They were heavily set with flower-buds. In addition, there were in these houses some Orange-trees of large size, as well as specimen Dracæna lineata, and numerous Azaleas. Of other plants I noticed splendid specimens of Rhododendron Lady Ilume and R. arboreum.

The forcing houses contained Richardias, Eucharis grandiflora, Lilacs, Azaleas, Viburnums, &c. In the conservatory were to be noted Chrysanthemums, Begonias, large specimen of Kentia, Cyathea, Dicksonia, and Seaforthia. From the roof were suspended baskets of Ferns, Asparagus plumosus, and Begonias. There are a lawn, and tennis and croquet grounds all admirably maintained.

An orchard exists which contains most of the best varieties of Apples, Pears, and Plums; and small fruits are grown in large quantities. The kitchen garden affords in abundance most excellent vegetables.

Highbury is not quite an ideal district for successful gardening either indoors or out, but this notwithstanding, Mr. Easey, by patience and skill, manages to obtain results not to be excelled by good gardeners in country places. *Traveller.*

FLORISTS' FLOWERS.

THE CHRYSANTHEMUM AS A MARKET PLANT.

THE production of the Chrysanthemum for market is increasing, and its brilliance and durability makes it of great value in mid-winter, and especially at the Christmas season, when flowers are in such great request. One of the leading cultivators for market is Mr. Norman Davis, Framfield, Sussex, and the leading varieties he cultivates and sends into the market may be accepted as illustrating the leading varieties best suited for the purpose.

The market season may be said to commence in September, and the earliest variety to enter Covent Garden market is Madame C. Desgranges, a variety well known, and widely cultivated. It is grown in immense quantities, both as finished specimen blooms, and in the form of smaller blooms for bunching. Some growers for market cultivate Madame C. Desgranges by the acre: it is lifted from the open ground, and placed in houses which have been cleared of Tomatos; while others depend upon a supply of bloom from the open ground. Like many other once popular Chrysanthemums, it is losing its former vigour, and at no distant date may be entirely superseded.

Two good first early white varieties of more recent introduction are Market White and Mytchett White. The latter is the earlier, and produces flowers of greater purity, but it lacks the constitutional vigour so much desired in a market variety. A more recent introduction still is Parisianum, of the purest white, the blooms as large as those of Madame C. Desgranges, but more vigorous in constitution; the flowers are good, and very early, but being new, it has yet to stand the test of adaptability for market work.

For the first two or three weeks of the season, say, up to the second week in September, white Chrysanthemums are the only ones to find a ready sale; but after that time, other colours, and especially yellows and bright pinks, are in demand. Among the earliest of these colours to find their way to market are Mrs. Hawkins, the yellow form of Mme. C. Desgranges; Horace Martin, a splendid and most useful sport from Mme. Marie Massee, undoubtedly the finest yellow among the early varieties; O. J. Quintus, a pleasing rose-pink; Mme. Marie Massee and Mons. G. Grunewald, also of shades of pink; Harvest Home, crimson and gold; Louis Lemaire, bronzy yellow; and Queen of the Earlies, creamy-white.

Second early varieties go into the market from the end of September and through October; they are very numerous, but the following may be regarded as the most popular varieties:—William Holmes, bright crimson, and Crimson Pride, of a deeper shade of crimson; Roi de Précoces is also a useful bright-coloured variety; Ettie Mitchell and Source d'Or are the two leading varieties of a bronzy-orange tint; Raoul d'Allard is a rich orange-bronze of recent introduction, and is likely to become a great favourite for what are known in the market as cheap bunches, is exceedingly free of bloom, and possesses a good habit of growth; Goacher's Crimson is still another fine crimson of recent introduction, and promises to become popular; Ryecroft Glory is a well-known orange-yellow, and it is very largely grown, both as a pot plant and for cut bloom; Lady Fitzwygram is also largely grown as a pot plant, on account of its dwarf growth, and very fine plants in small pots are in great demand; Lady Selborne, a well-known white, is also largely grown for market. A little later, and merging into the mid-season varieties, comes Elaine, one of the oldest, and still one of the most useful Chrysanthemums grown; also Soleil d'Octobre, a very popular sort; and a bronzy-buff known as Bronze Soleil d'Octobre, which is also much cultivated as a pot plant.

The end of October and through November marks the mid-season time, when the varieties are very numerous; but a select few, such as those which produce good stems and leafage, are the leading types. Of these Viviand Morel, mauve, and its sport Charles Davis, bronze, find the greatest favour; Mrs. Barkley, and Mrs. George Mileham, both of recent introduction, have already become great favourites—both are of pleasing pink shades. There is still another of the same shade of colour, and one likely to supplant Viviand Morel, namely, Nellie Bean, of a charming shade of lavender-pink; this is most promising as a market subject. Good yellows are to be found in W. H. Lincoln, Phœbus, Mrs. Greenfield, like Phœbus, but with broader florets of a deeper tint; Clinton Chalfont, and Mabel Morgau, the latter a recent introduction of a rich butter-yellow colour, and an excellent habit of growth. Edwin has been the leading crimson for some years for cut blooms at this time of the year; but is likely to find a formidable rival in Violet Lady Beaumont, the colour is a rich deep crimson, the blooms solid, and carried on long stiff stems, while the habit of growth is excellent.

To follow Elaine, such whites as Gladys Roultaud, Mdlle. Lacroix, are grown, the former a very pretty Japanese having pure white flowers. Etoile de Feu is a bright crimson with a gold reverse, and is found very useful. Large exhibition blooms find but a limited sale at high prices when fresh and of good colours. Mr. Davis states that fine blooms of Madame Carnot, Mrs. Barkley, Richard Dean, G. J. Warren, and other large flowered varieties will fetch in the market from 9s. to 12s. per dozen.

Probably the most useful of all the market Chrysanthemums are the late varieties, those from which the market supply is drawn through December, and into the new year. One of the most popular varieties is Madame Felix Perrin, better known in the market as Framfield Pink, under which name it was originally introduced by Mr. N. Davis; this is an excellent variety on all points, and commands good prices. The leading late white Chrysanthemums are Mme. Thérèse Pankoucke, Niveum, Mme. Phillipe Rivoire, L. Canning, and Western King, the latter more especially in the character of specimen blooms, and it is one of the most useful. A new white recently introduced by Mr. W. J. Godfrey, Exmouth, is Winter Queen, a very beautiful variety, forming charming sprays of bloom, and it is one of the latest. Tuxedo and Miss Jessie Attie are the two favourite varieties with bronze shades; while King of the Plumes and Golden Dart are two capital late yellow flowered varieties. It may, of course, be taken for granted that Chrysanthemums which are most useful for purposes of the market are equally of service in other ways.

Single and other light decorative Chrysanthemums are now somewhat largely grown in private gardens for house and home decoration at this season of the year, but are of no value for market purposes, being too fleeting. The most popular singles are Mary Anderson, white; Miss Rose, pale pink; Earlswood Beauty, light primrose; Daisy Brett, pure white; Framfield Beauty, rich crimson; Eucharis, a fine white; Admiral Symonds, golden-yellow; Rev. R. Remfrey, bronzy-crimson; Miss Annie Mumford, bronze and orange-crimson; Edith Pagram, bright pink; Golden Star, golden-yellow; and Mrs. D. B. Crane, cerise-pink. Light decorative varieties are to be found in Mrs. Filkins, Mrs. Jas. Carter, Cannell's Favourite, Golden Thread, and the two miniature Pompons Snowdrop and its yellow form. *R. D.*

THE SWEET PEA.

MR. BROTHERSTON'S remarks on the Sweet Pea recall to mind that northerners have now amongst them a gardener who may be termed the champion exhibitor of the popular flower under notice, namely, Mr. W. Simpson, of Wemyss Castle, East Fife, and late of The Grange, Sutton. For two successive years Mr. Simpson proved his superiority as a grower by winning the principal prize at the National Exhibition of the Sweet Pea Society, effectively staging grand bunches of highly-coloured flowers. In many parts of the country the lateness of the flowering of Sweet Peas last year was almost as noticeable as the prolonged season of blooming mentioned by Mr. Brotherston. In southern Hampshire we could not pick a bloom before the last week in June, and this from plants raised in pots and carefully transplanted, which ought to have flowered at least a week in advance of those sown in the ordinary way.

The adaptability of the Sweet Pea for pot-culture, as a method for securing earlier flowers, is not so fully recognised as it might be, considering the popularity it has gained during recent years. A dozen or so of 12-inch pots, planted with various colours, afforded us delightful bunches long before we were able to cut from outside, and well repaid any extra attention required. Salopian, Gorgeous, Prince Edward of York, Queen Victoria, and Lovely were the varieties grown.

As every gardener knows, constant removal of the seed-pods is the chief point in lengthening the flowering season, more especially on thin, light soils. But late sowings must be resorted to, to maintain a succession of long-stemmed, high-class blooms in August and September, such as are favoured by florists and exhibitors. Thin planting or sowing is also another help to success, as every good seed will produce several strong growths, and without these it is useless to expect fine flowers.

The light blues or lavenders, orange-scarlets, and crimsons seem to catch the public fancy most, although some of the striped varieties are

quite as attractive in their way as are many of the fancy Carnations. All the distinct and varied colours could be included in two dozen varieties, yet new or improved varieties crop up every year. A good yellow has still to be found, and our nearest approach to a scarlet is still a few shades removed from that tint.

Of recent introductions Miss Willmott is one of the best, though differing but slightly in colour from Lady Mary Currie; Gorgeous, of a similar shade, though a smaller bloom, is the most distinct in this colour, more especially so in the bunch. Mr. Simpson staged this variety, beautifully coloured, at the National Society's show in July. With care, the Sweet Pea can be propagated from cuttings. This method is only useful to anyone who has been fortunate to raise a new variety, and has failed to obtain much seed. A good percentage of cuttings made from strong side-shoots will root, if inserted in sandy soil, and placed under a hand-light in a cool house. *T. H. Bolton, Baron Hill.*

PLANT PORTRAITS.

ARACHNANTHE CATHCARTI.—*Wiener Illustrierte Garten Zeitung*, December.

PEARBEURRÉ SUPERFIN.—*Bulletin d'Arboriculture, &c.*, December.

TRUSTED SERVANTS.

THE illustration (fig. 3) shows the garden staff at Wrest Park, the Bedfordshire seat of the Right Hon. Earl Cowper, K.G. Taking into account the long term of service of many of the gardeners there depicted, it is very questionable if such a record can be excelled in any other nobleman's or gentleman's garden in the country. The combined services of the *employés* form a record of 391 years, several of the men having been employed in the gardens for the long period of fifty-six, fifty-three, fifty-two thirty-two years, and so down to two years. After such a length of faithful service, they are still active, intelligent, and energetic, and seldom absent from their daily employment.

The married men are comfortably housed in several of the lodges in the park, and others in the beautiful and picturesque village of Silsoe, long renowned for its beauty and sanitary arrangements, also for its ample convenience as regards church, school, postal, and telegraph accommodation. The rents charged the garden *employés* for their cottages in the village are exceedingly low, but not quite nominal; and his lordship, with his usual generosity, when the allotment system was first introduced, had a large field in close proximity to the village laid out in allotments for the garden men and other workmen on the estate. Thus by successful cropping they can keep themselves well supplied all the year round with a bountiful supply of fresh vegetables, which are indispensable in the cottage of the peasant.

Another great feature is his lordship's coal club and the countess's clothing club. The garden *employés*, &c., pay into these clubs weekly, and at the end of the year there is a substantial bonus added to their weekly subscriptions. By this means they are able to get in their yearly supply of coals during the autumn, besides a great many more household comforts; and I am not exaggerating when I say the men are as satisfied and contented as are those of any employer, whoever he may be. *George MacKinlay, Wrest Park Gardens.*

FIG. 3.—THE GARDEN STAFF AT WREST PARK, AMPTHILL.

IRISH HARDY FRUIT.

As I happen to be the correspondent responsible for the original article written on the above subject, p. 426, ante, which Mr. A. Dean has done me the honour to read and corroborate, p. 443, I should like to supplement that report by adding that these conclusions are not arrived at from the experience of one season only, but from a series of seasons.

From conversation with one of the leading prize winners on the second day of the show, I gathered that these best coloured Apples were produced from an orchard under grass, and he advanced quite a new theory to me, viz., that Apples always coloured better when grown on grass land, than those grown on arable or cultivated land. Be this as it may, the colour was all that could be wished, the specimens were clean, large, and of perfect shape, but the names showed a little discrepancy. Personally, I am a little sceptical upon the above theory—what say other growers

I do not hold any brief for this Society, or even for Ireland, yet after seeing the repetition of such displays of hardy fruit, there can be "no possible shadow of doubt whatever," but that real high-class fruit is produced, and can be produced *ad lib.* in certain districts in "Ould Ireland," where skill and intelligence is brought to bear upon their cultivation; indeed, one can already hear of cultivators in the northern part of the country with their 20 acre and upwards plantations. Mr. Dean asks "Why should not Ireland as well as Canada, become a fruit producing country?" Doubtless she will in the near future, if she will apply the same principles to fruit-growing as she is already doing in the matter of creameries and exporting butter, especially if she will proceed on a similar system of co-operation, so as to create a registered brand, and a system of packing and grading, similar to that so advantageously followed by the Dutch, as portrayed in your leader on p. 438. As a matter of fact, the old country has also yet to learn this difficult problem, before real success in hardy fruit growing will be achieved.

In passing, I might say that I should like to see this progressive Ulster Society adopting the same conditions in future, as are imposed by the Royal Horticultural Society in the class for twenty-four dishes, viz., sixteen dishes culinary, and eight for dessert, shown in accordance with their code as to the distinctive sections. This brings the competitors more into line and uniformity, and establishes a standard for competitors and judges to work up to, and diminishes the risks arising from the vagaries of any individual judges.

So far as one could gather from conversation, the reason why we do not get any entries from the sister isle at the annual exhibition of British grown fruits, hitherto held at the Crystal Palace, to wit, class fifty-eight, open to Ireland only, seems to be that growers in that country are not aware of the facilities offered by the Royal Horticultural Society, whereby in addition to the first and second prizes, the exhibitor's railway fare is also paid to London, and there is a most expeditious service from Belfast to London, viâ Fleetwood.

It is to be hoped that now the matter is being ventilated, the proper authorities will in future place the necessary information before our Irish friends, extending the right hand of friendship so as to promote that healthy rivalry so beneficial to one and all concerned. I venture to predict that if the best growers can be induced to come over next season to Chiswick, they will be able to render a very good account of themselves, both in their own section and in many open classes. This need not be wondered at, for the nurserymen of that country are prepared to supply splendidly grown trees in large quantities. A chance visit to Messrs. Hugh Dickson & Sons, Royal Irish Nurseries, revealed quarter after quarter of healthy, vigorous, well-rooted trees, with the kindest and cleanest growth possible.

It is to be feared we old country fraternity do not always give our warm-hearted brethren of the sister isle all the credit that is justly due to them, forgetting that nowhere else in the United Kingdom can there be seen such marvellous collections of choice and extremely rare varieties of hardy flowering shrubs, trees, and Coniferæ, as are to be found at such places as Castlewellan Powerscourt, Narrow Water, &c. Besides, where is there such an interesting nursery of choice titbits and healthy rare plants as Smith's of Newry? to say nothing of the natural landscape of so many beautiful places; in fact, Ireland is an ideal place for the lucky gardener to spend his holiday. *W. Crump, Madresfield.*

The Week's Work.

THE KITCHEN GARDEN.

By JOHN FLEMING, Gardener to Sir C. PIGOTT, Bart., Wexham Park, Slough.

Hints on Work in General.—With the advent of the new year, all work in this department should be forwarded as far as possible, and preparatory work of all sorts should be pushed on with vigour. Trenching is of the utmost importance in most gardens, even if the soil be shallow, when it is advisable to turn the top spit in the usual manner, and break up the subsoil for another 12 or 18 inches, but leaving it in its place. In some places the gardener, owing to the smallness of the garden staff, is prevented from carrying out as much trenching as may be desirable, still some portion of the vacant land may be trenched, and such land will always afford the best crops. In cold, wet, and stiff soils trenching should be deferred till the end of the month of February or till March. Nothing is more useful in practice than a plan of the kitchen garden, showing the plots the various vegetables will occupy during the year.

The Seed Order.—Before finally making out this list, it is advisable to examine the nurseryman's catalogue, and indicate the probable quantities of each kind and variety of vegetable that may be required. Most gardeners are acquainted with the names of the varieties that succeed in the district in which their garden is situated, and with the nature of the soil. A few novelties should be ordered for trial, in order to ascertain their suitability or otherwise, but too much reliance should not be placed upon them. On the whole, that gardener is wise who relies chiefly upon tried favourite varieties.

Forcing Asparagus.—Whether dung-beds constructed about 3 feet high, or hot-water pits be employed, the top heat must not exceed 60° or 65°, and that of the bed 70° to 75°. The glass of pits or frames should be covered with mats and litter on cold nights, or mats simply if thicker covering be not needed. This admits of applying air in small quantities at night, and by day as much may be admitted as the heat of the frame or pit will allow, for if this be not attended to, the shoots will be drawn, and without much flavour. Roots that are beginning to produce weak shoots should be replaced with others. After planting in the bed, afford tepid water in sufficient quantity to soak the soil.

Seakale.—Continue to place crowns in the Mushroom-house, or any dark place where the temperature is kept constant at from 50° to 55°. The old method of forcing Seakale in pots in the open by means of fermenting tree-leaves and litter is seldom practised now, although the produce is much superior to that forced by any other method. The crowns should be slightly covered with finely-sifted coal-ashes, and over each clump a Seakale-pot should be placed, and the bed made up with the warm fermenting material. The heat of the bed should not exceed 75°, nor be less than 70°. Rhubarb may be forced in the same manner.

Tomatos.—The plants which were raised from seed early last month should be planted in large 48's, in moderately light turfy loam, with a small quantity of bone-meal and soot, and some coarse silver-sand mixed with it, the mixture being warmed so as to avoid checking growth. Place the plants near the glass in a house or pit having a temperature of 60°. Apply water carefully, and only when the soil has got dry. Pinch off the laterals as fast as they appear. Fertilise the blooms of plants of a fruiting age, using a camel-hair pencil in doing this, and afford liquid-manure twice a week. The fruits should be cut when they begin to colour. Maintain a fairly dry air in the house, and admit air on favourable days for a few hours. Sow seeds in well-drained pans for succession, in a mixture of leaf-soil three-quarters, loam one-quarter, and add some coarse silver-sand. Sow the seeds thinly, barely covering them, and as soon as the seedlings appear above ground, place the pans on a shelf near the roof-glass.

FRUITS UNDER GLASS.

By T. H. COOK, Gardener to His Majesty THE KING, Sandringham.

Vines.—The Vines started in November for producing early Grapes, whether in pots or borders, will have now burst their buds and commenced to form growths. Afford a slightly increased temperature, 55° to 60° at night, with a rise of 10° during the day, more or less according to the state of the weather. Syringe them with tepid water twice daily, and maintain a moist atmosphere by an occasional damping of the paths and walls. Husband all the sun-heat possible, and at no time heat the hot-water pipes unduly Ventilate sparingly by the top ventilators on very fine mild days.

Succession Vineries.—Prune, cleanse, and prepare succession Vines, and close the house for forcing as may be required. In pruning the canes, cut to a strong plump bud, whether it be placed two or more nodes from the base of the lateral, a good crop of Grapes being the first consideration, the trim appearance of the rods a secondary matter. If the Vines are young bearing rods, cut back the leaders more or less according to their strength, that is to within 2 to 4 feet of last year's growth. Regulate the spurs, which are often too numerous, so that each lateral may have sufficient space for the full development of its foliage. If the Vines were free from insect pests last year, a good washing with an approved insecticide will be all that is necessary to cleanse them; but if affected with red-spider, thrip, or mealy-bug, more drastic measures will have to be adopted. Remove all loose bark, and scrape and expose every possible hiding-place, great care being taken of the buds. Scrub over with an insecticide, and finish off by stopping up all holes or cavities around the spurs with coloured putty or similar material. This latter will be found most helpful in dealing with the complete eradication of these pests afterwards, mealy-bug in particular. Previous to dressing the Vines, wash down or (if necessary) paint the woodwork of the vineries; fill up with cement all holes and crevices in the walls, and finish off by lime-washing them.

Borders.—Scrape off and remove all loose soil, point over the surface soil, and give a top-dressing 2 to 3 inches thick of good loam, to every barrowful of which has been added a 7-inch potful of bone-meal, a little charred garden refuse or charcoal, and mortar-rubble. Previous to starting the Vines, apply water, so as to thoroughly moisten the soil, the quantity being determined by the depth and porosity of the borders. If not already done, cut and remove the bunches of late Grapes to the Grape-room, and afford the Vines all the air possible night and day. Close for forcing the early Muscat vinery or other houses from which ripe Grapes are expected in about five months' time.

Peach and Nectarine-Houses.—The trees in the early houses which are in flower or approaching that stage, should now have a night temperature of 50° to 55°, and during the day one of 10° higher. Maintain a buoyant atmosphere, and admit air by the top ventilators when the weather permits. Before the flower-buds burst, it is good practice to fumigate or vaporise the house, which will ensure freedom from aphis till some time after the flowers are set. Fertilise the flowers daily about mid-day, using a rabbit's-tail secured to the end of a long stick to distribute the pollen.

Melons.—Seeds should be sown in thumb-pots, plunged in a bottom heat of 75° in a propagating pit. Plants raised from seed sown a month later will often produce fruits as early as the plants raised at this date, but should the weather be fine, a slight advantage is gained by present sowing.

Cucumbers.—Plants in bearing at this season require an abundance of heat and moisture, and all the light possible; a night temperature of 65°

and one by day of 75°, and at this time of year as much higher as the sun may raise it. Slightly syringe the foliage with tepid water on fine days, crop lightly, and cut as soon as the fruits attain to a serviceable size, to enable those left the better to develop. Encourage root action by light top-dressings of sterilised leaf-mould three parts, and good loam one part. Sow as advised for Melons.

THE HARDY FRUIT GARDEN.

By CHAS. PAGE, Gardener to J. B. FORTESQUE, Esq.' Dropmore, Maidenhead.

Pruning and Cleaning Orchard Standards.—The present is a good time for carrying out this kind of work, and a commencement should be made by cutting out all intercrossing branches, leaving the remaining branches in such a manner as to secure an evenly balanced crown. Wherever a saw is employed in removing big branches, the cut surface should be smoothed with a knife or a pruning-chisel; the main branches should then be cleared of moss, a piece of bent hoop-iron being used for this purpose. In some gardens the old-fashioned practice of lime-washing the trunks and main branches is still carried out; but where time permits, it is better to use an alkali wash in February, as then all parts of the trees can be reached by the syringe or engine. If farmyard manure-water can be obtained, a good application at this date would benefit the trees, care being taken that it is used in a much-diluted state, and during mild weather.

Planting.—Where this remains to be carried out, no time should now be lost. In the case of aged trees, if the soil can be removed and replaced with fresh soil where the trees are to be planted, it will be of great help in affording them a good start. Make the holes 3 feet by 2 feet, and for strong-growing varieties of Apples let them be 24 feet apart. Good culinary varieties are Gloria Mundi, on heavy soils only; Wellington, Beauty of Kent, Blenheim Orange Pippin, Bramley's Seedling, Striped Beaufin, Lane's Prince Albert, Ecklinville, Alfriston, and Potts' Seedling; dessert varieties: Cox's Orange Pippin, King of the Pippins, Court Pendu Plat, Gravenstein, Irish Peach, Devonshire Quarrenden, Cornish Gillyflower, Sturmer Pippin, and Claygate Pearmain.

Pruning Pyramid Apples and Pears.—Take advantage of the present mild weather to push on with the pruning operations. Where the Apple is grown as bushes or pyramids on the Paradise stock, and root-pruning is practised, as it should be, not much pruning will be required. The varieties Irish Peach, Cornish Gillyflower, Cox's Orange Pippin, and a few others, mostly have fruit-buds at the ends of the shoots, a fact to be borne in mind when pruning the same. In the case of young trees of the Apple and Pear, the leading shoots should be cut back to a length of about 1 foot, taking the precaution to prune to a bud pointing in the direction the shoot is required to grow.

The Fruit Room.—Apples and Pears are not keeping well this season, and the fruits need frequent inspection, removing all decaying specimens. Pears in most gardens will soon be over, but Olivier de Serres, Duchess de Bordeaux, Winter Nelis, and Josephine de Malines, will assist in the dessert for some weeks longer.

PLANTS UNDER GLASS.

By J. MAYNE, Gardener to the Hon. MARK ROLLE, Bicton, Budleigh Salterton, Devonshire.

The Stove.—During the next few weeks the occupants in these structures should not be excited by affording them a high temperature, which usually induces an early infestation of the plants by insects, especially thrips and red-spider. A temperature of 60° on very cold nights, and 65° when the weather is mild, with a rise of 5° to 10° during the day, will be better for the health of the plants than a higher degree of warmth. Applying water to the plants is an important matter at this season. Before affording it, each plant should be carefully examined as to its needs; and the syringe should not be too frequently used. The early morning hours after root water has been applied is the best time for this operation, and it will suffice to damp the stages and floor once or twice a day. Flowering plants should not be syringed, or the display of many will be cut short. There will now be no lack of colour of Eranthemum pulchellum, Euphorbia Jacquiniæflora, and E. pulcherrima, Reinwardtia trigyna, Coleus thyrsoideus, Justicias, Plumbago rosea, and several Begonias, not omitting the beautiful Gloire de Lorraine, and Gloire de Sceaux, the latter just coming into flower, are grown. Where the lovely Rondeletia speciosa is planted out, in a narrow border and given plenty of light, there will be no lack of flowers during the next two weeks. Crotons, Dracænas, and similar large leaved plants, if infested with mealy-bug, should be sponged or syringed with warm soap-suds alone, or a wineglassful of petroleum may be put into four gallons of water and kept agitated while in use.

Conservatory or Greenhouse.—Endeavour to maintain these structures in as bright a state as possible, by introducing fresh flowering plants at intervals of a week or ten days. There are several varieties of Chrysanthemums still serviceable, viz., L. Canning, Madame P. Rivoire (a beautiful white), Mrs. C. Harman Payne, Jane Molyneux, Mrs. Barkley, Chatsworth (a lovely flower), Matthew Hodson, Francis Coppice, W. H. Lincoln, M. Simpson, and a single variety, Sir Redvers Buller. Among Azaleas there are Narcissiflora, Deutsche Perle, and Fielder's White, good for early forcing, requiring but little heat to get them into flower in the first month of the year. These, with Cyclamens, Primulas, Roman Hyacinths, Paper-white Narcissus, and the earlier Cinerarias, Salvia rutilans and Heeri, Cytisus, Freesias, and Coronilla glauca, help to make a good display at this season. The night temperature of the houses in mild weather should not exceed 50°, or fall below 40° on frosty nights. Afford ventilation by day on all favourable occasions, but avoid cold draughts.

Forcing-pit.—Introduce at short intervals Spiræa japonica and S. astilboides floribunda, Deutzias, Staphylea colchica, Dielytra spectabilis, Lily of the Valley, Azalea mollis, Narcissus, Tulips, and the white Italian Hyacinths, the last-named to follow the early Roman, which, having long spikes, are very useful as cut flowers. A gentle bottom-heat may be afforded Lilies, Spiræas, and Dielytras, which will suffice to bring them quickly into growth, if covered with moss and kept moist, and syringed two or three times daily over all. Let the night temperature be from 58° to 60°, with a rise of 5° or 10° by day, according to the weather.

THE ORCHID HOUSES.

By H. ALEXANDER, Orchid Cultivator to Capt. G. L. HOLFORD, Westonbirt, Tetbury.

The Heating of the Houses.—At this season all Orchids require artificial heat more or less, even those of the coolest house should have a little heat at all times, admitting air at the same time. This is preferable to keeping the house closed without warmth in the heating apparatus; yet, on the other hand, I do not hesitate to say, that more Orchids are ruined in this country by the excessive use of fire heat than from any other cause. I therefore advise the greatest care to be exercised in its use at all seasons. A common mistake in the heating of Orchid-houses in providing too little piping, with the result that the fires must be driven and pipes kept needlessly hot; whereas, were the pipes more numerous, the heat of the water might be much less, with advantage to the plants. Moreover, the extra cost of piping is as nothing compared with that of fuel in endeavouring to keep up heat with too little heating surface.

Temperatures.—It is not desirable to lay down a hard-and-fast rule in regard to temperatures, but the following figures will afford tyros a guide for the present. The higher figures are reached at noon, and the lower ones in the early morning, and in accordance with the state of the weather; and a few degrees lower than the lowest will not cause injury in very severe weather:—East Indian-house or stove, by day, 68° to 75°; by night, 60° to 65°. Cattleya-house, by day, 62° to 68°; by night, 58° to 62°. Intermediate-house, by day, 58° to 62°; by night, 55° to 58°. Cool or Odontoglossum-house, by day, 55° to 60°; by night, 50° to 55°.

Damping-down and Ventilating.—Particular attention should be paid to the atmospheric conditions of the house during the dull days of winter, and in mild weather, when but a small amount of heat is afforded, as at such times very little damping-down is required. In time of hard frost, when much fire-heat becomes necessary, damping-down is often called for to correct the dryness of the air. More especially should the space beneath the hot-water pipes be heavily damped-down, but on no account let the water come into contact with the heating apparatus so as to cause vapour to be thrown off, or much damage may be occasioned. Admit air to the various houses whenever the external conditions are favourable, and afford it in small quantity night and day by the lowermost ventilators, excepting in frosty weather.

THE FLOWER GARDEN.

By J. C. TALLACK, Gardener to E. MILLER MUNDY, Esq., Shipley Hall, Derby.

Protection.—The old adage, which tells us that cold strengthens as the days lengthen, should act as an incentive to all who grow in the flower garden and pleasure grounds things that are at all tender, to see that the various means used for their protection are applied or placed handy when the need to use them arrives. Yuccas should have many of their old leaves drawn up to a point and fastened in this position, and the stems, if tall, should have dry bracken tied round them. Kniphofias, when the leaves are dry, should have these twisted tightly together to protect the hearts of the plants, and if not planted deeply, as they should be, a cone of coal-ashes should be placed around each plant, though soil will answer nearly as well, but it is not quite so effective in a very cold winter. Gunneras and other tender plants will probably have had a covering of bracken put around them some weeks ago, but if this has got very wet replace it with dry material from the bracken stack. Tea Roses, which I prefer to leave unprotected until after the first moderately sharp frost, which is seldom of long duration, should have some soil pulled up well around the stems, using a hoe for the purpose. My reason for leaving these till now is to avert the injury to the buds by spring frosts, a likely result if protection be applied at a too early part of the season. Many bulbous and other plants, such as the Eremurus and Ostrowskia, may have a mound of soil drawn over them, and Iris reticulata covered with hand-lights. In the case of herbaceous Phloxes, Aster alpinus and speciosus, and other plants, the new shoots of which appear to attract slugs, a slight mound of ashes will be of great service. Aloysia citriodora, a favourite plant in many gardens, is often cut down to the ground-line and sometimes killed outright if left unprotected; but a mound of ashes will almost invariably preserve sufficient of the stem and roots to enable them to break strongly and make good bushes in the summer. Old-established plants of Pampas-grass are generally self-protective, but young plants should be helped through the winter by surrounding them at the base with a layer of dry bracken 1 foot thick.

Groundwork may be forwarded whenever the weather is not unsuitable. In frosty weather, all the necessary wheeling of manure and soil should be done, so as to have them in readiness when the work can be started. New beds may be made and the soil trenched where hardy herbaceous perennial or flowering shrubs are to be planted; and in case of both, plenty of farmyard manure should be incorporated with the staple. In dealing with old borders which have been manured with organic manure for years, a good dressing of quicklime will be found of great benefit to the plants, disintegratiug the over-abundant inert manure, and liberating the ammonia and other ingredients.

PUBLICATIONS RECEIVED.—From the Imperial Department of Agriculture for the West Indies: Pamphlet Series, No. 5. *The General Treatment of Insect Pests.* Second edition. By H. Maxwell-Lefroy. No. 9: *Bee-keeping in the West Indies*, by W. K. Morrison; and No. 17: *The General Treatment of Fungoid Pests*, by Albert Howard.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the Publisher.

Letters for Publication, *as well as specimens and plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Illustrations.—*The Editor will thankfully receive and select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.*

Local News.—*Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return the unused communications or illustrations, unless by special arrangement.*

APPOINTMENTS FOR JANUARY.

TUESDAY, JAN. 13—Roy. Hort. Soc. Coms. meet.

THURSDAY, JAN. 15 { Linnean Soc., Special General Meeting.

THURSDAY, JAN. 22 { Gardeners' Royal Benevolent Inst., Annual Meet. and Elect. of Pensioners.

TUESDAY, JAN. 27—Roy. Hort. Soc. Coms. meet.

SALES FOR THE WEEK.

MONDAY and FRIDAY, JANUARY 5 and 9—
Hardy Border Plants, Perennials, Violets, Carnations, Azaleas, Rhododendrons, Palms, Dutch Bulbs, &c., at 67 and 68, Cheapside, by Protheroe & Morris, at 12.

TUESDAY, JANUARY 6—
Roses, Lily of the Valley, Palms, Dutch Bulbs, &c., by Pollexfen & Co., at Pilgrim Street, Ludgate Hill, at 12.30.

WEDNESDAY, JANUARY 7—
Azaleas, Palms, and Bulbs, at Stevens' Rooms at 12.30.—Azaleas, Rhododendrons, Aspidistras, Roses in large variety, Dutch Bulbs, Perennials and Border Plants, Palms, Herbaceous Plants, Gladiolus, &c., at 67 and 68, Cheapside, by Protheroe & Morris, at 12.—Enormous consignment of Japanese Liliums, received direct, at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 5.

FRIDAY, JANUARY 9—
Important sale of Dendrobes and other Orchids, at 67 and 68, Cheapside E.C., by Protheroe & Morris, at 12.30.—Trade sale of Japanese Liliums, at the City Auction Rooms, 38 and 39, Gracechurch Street, E.C., by Johnson, Dymond & Son, at 12.30.

(For further particulars see our Advertisement columns.)

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three Years at Chiswick —36·3°.

ACTUAL TEMPERATURES:—

LONDON.—*December* 31 (6 P.M.): Max. 43°; Min. 36°. *January* 1 (9A.M.)—Dull; slight frost.

PROVINCES.—*December* 31 (6 P.M.): Max. 45, Scilly Isles; Min. 33°, N.E. Scotland.

1903.

In our last issue we took occasion to pass in review the principal events, so far as they concerned horticulturists, of the wonderful year that has just passed. The past has given way to the present, and we are called on to indicate the probabilities (one dares not speak more definitely) of the future. In spite of the uncertainties of the outlook, we have to prepare for the future. No body of men need to exercise forethought and aforehand preparation more than the gardeners. Forethought is the essence of good gardening, and this applies, not only to cultural details, but to affairs generally.

As the erection of a suitable home for the Royal Horticultural Society was uppermost in our thoughts last year, so must it be until this pressing need is adequately supplied. On the continent the Government or the municipal authorities would long ago have recognised the requirements of the case, and supplied them. We do things differently in this country, although there is an increasing tendency to call in State aid where formerly we relied on individual agency. It is not for us to discuss in these columns the superior advantages of one or of the other of these two methods of procedure, but this we do know, that it behoves those who were so eager last spring to secure the erection of a suitable Hall, to take every means in their power to secure the fulfilment of their desires. Shouting and votes by acclamation may afford temporary exhilaration, but unless they are followed up by practical effort, they are a mere waste of time and energy. A good beginning has been made—it is now for the rank-and-file to take up the matter, and by their numbers to force on the completion of the undertaking. It is not fair that the exertions and expenditure needed to carry out a scheme intended for the benefit of all should be confined to a few only of the vast numbers of those interested. For such a purpose everyone should contribute much or little, according to his means. All questions of detail and criticism can be left open for future consideration; the requirements at the present time are funds.

As for the other events of the year to which we may look forward, the most important, so far as we are concerned, is the Ghent Quinquennial. Once in five years in the quaint old Flemish city there is an Exhibition, by the side of which we must stand back, admire, and wonder when our turn is to come. Even more remarkable than the Exhibition is the assemblage of horticulturists and botanists from all quarters of the civilised world. There we may meet men whom we have read of, perhaps even corresponded with, throughout our career, but had no opportunity of meeting; there we may meet, with hearty greeting, our old friends; there, too, we may make new acquaintances; there, too, it must be admitted, we are chastened by the realisation of the losses that a period of five years necessarily entails.

From all we hear, the Royal Society of Agriculture and Botany of Ghent, presided over by the learned and ever genial Count DE KERCHOVE DE DENTERGHEM, is likely to surpass all previous efforts. Moreover, the claims of science will receive a fuller recognition than heretofore. Those of our readers who may not previously have had experience of the "Casino" at Ghent, will realise the more what is needed in the way of an Exhibition Hall and offices in London.

The arrangements made by our own Horticultural and Botanic Societies and the numerous provincial societies, are announced in the Almanac given as a Supplement with the present number. There is enough to show that we shall have our hands full. The Temple Show is so conditioned by circumstances that we fear little can be done to obviate its monotony; but at Holland Park conditions are different, and we trust every effort will be made to introduce novelty and to break away from tiresome conventionalities and formal arrangements so far as can consistently be done. Exhibitors do not need to be reminded that excellence of cultivation and interest are of far greater value than the mere area occupied, and superintendents of flower-shows might be invested with more power than they have, to exclude exhibits that have comparatively little but their bulk to recommend them.

The most interesting and important exhibition, even if it prove the least popular, will be the Exhibition of Vegetables, and the accompanying Conference at Chiswick. This will be doubly valuable, considering the enormous importance of the subject, and for the reason that it will be held in the historic garden of the Society, or in what is left of it—sufficient, at least, to show that we have still an establishment capable of rendering important services to horticulture, and supremely rich in honourable traditions of the past.

LINNEAN SOCIETY.—On the occasion of the general meeting held on December 18, 1902, Prof. SYDNEY H. VINES, F.R.S., President, took the chair. Notice was given from the chair that the next meeting, to be held on Thursday, January 15, 1903, at 8 P.M., will be made a special general meeting, to consider the advisability or otherwise of applying for a Supplemental Charter, in order to provide for the admission of lady Fellows. A ballot will be taken in respect of Mr. ARTHUR GROVE as a Fellow, and Mr. ANDREW SCOTT as an Associate.

ROYAL HORTICULTURAL SOCIETY.—The first meeting of the committees of the Royal Horticultural Society in 1903 will be held, as usual, in the Drill Hall, Buckingham Gate, Westminster, on Tuesday, January 13. An election of new Fellows will take place at 3 o'clock. To prevent misunderstanding, it may be mentioned that the committees of 1902 do not vacate office until the date of the annual meeting, 1903; and in like manner, all Fellows' tickets of 1902 are available until the end of January, 1903.

—— At a general meeting of the Royal Horticultural Society held on Tuesday, December 9, fifty-one new Fellows were elected, making a total of 1140 elected since the beginning of the year 1902.

ARRANGEMENTS FOR THE GHENT EXHIBITION.—According to a recent number of the *Revue de l'Horticulture Belge*, arrangements for the exhibition to be held at Ghent next April by the Ghent Royal Agricultural and Botanical Society are well advanced. The principal annexe will be semi-circular, following the outline of the main façade of the Casino, and the whole length of this building, covering an area of over 4,000 square yards, with an interior elevation of from about 21 to 37 feet from the ground-level to the beginning of the slope of the roof. It will be lighted by glazing large portions of the upright and sloping parts of the building. No expense will be spared to ensure the comfort of exhibitors, and merely decorative details, on exteriors especially, will be sacrificed for this object. A second annexe, covering about 550 square yards, will be erected as a supplement to the large hall towards the Coupure. This will be reserved for the Orchids, and will be appropriately decorated inside, access being only through the large hall. In fact, the whole of these temporary buildings, that are already well begun, will cover a surface of nearly an acre. The great annexe in 1898 covered 3,300 square yards only, and on that occasion was much larger than the one erected in 1893. These figures enable us to understand the scale on which the forthcoming exhibition will be arranged.

SEEDS AT LA MORTOLA.—The seeds collected in the garden of Sir THOMAS HANBURY, and available for exchange, are detailed in a list now before us. No seeds are sold, but those desirous of making exchanges should address Mr. ALWIN BERGER, the Curator, La Mortola, Ventimiglia, Italy. Sir THOMAS HANBURY notes among his *desiderata* succulents, trees and shrubs of extra tropical countries, plants of the Mediterranean region, Proteaceæ, &c.

GARDEN AND FIELD MANURES IN NATAL.—There has just been issued by the Agricultural Department at Petermaritzburg a pamphlet entitled "Manures on the Natal Market," the author being Mr. A. PARLY. The object of the *brochure* is to classify the fertilisers for sale in Natal, and to place them on a comparative basis, so that their relative values may be determined; and the list places before intending purchasers a uniform statement of the composition and comparative value of all manures now on the Natal market, and the prices asked for them. It might be worth while to extend the value of the pamphlet by adding the amount of chemical constituents removed from the soil by the various crops harvested. Market-gardeners and farmers in the South African colony are much indebted to the Department and Mr. PARLY for the work they have accomplished.

PARIS.—The committee meetings of the Société Nationale d'Horticulture for the new year are thus arranged:—Scientific Committee, on the second Thursday of each month at 1 P.M.; Vegetable, Fruit, Floral, Arboricultural, and Orchid Committees, all on the second and fourth Thursdays of each month at 1 P.M.; the Landscape Garden (*Art des Jardins*) Committee meets on the second Thursday of each month at 1 P.M.; the Committee for the "Industries Horticoles" meets on the fourth Thursday of each month at 1 P.M. The meetings of the Chrysanthemum section are on the fourth Thursday from January to August, and on the second and fourth Thursdays from September to December inclusive, at 1 P.M. The Rose section is timed for the second Thursday in each month, and also for the second and fourth Thursdays during May, June, and July, at 1 P.M. The Fine Art section is arranged for the second Thursday in each month at 5 P.M. The Pomological section holds its sittings on the second and fourth Thursdays in each month at 10 A.M. The Committee for Manures and Insecticides is summoned on the fourth Thursday in each month at 2 P.M.

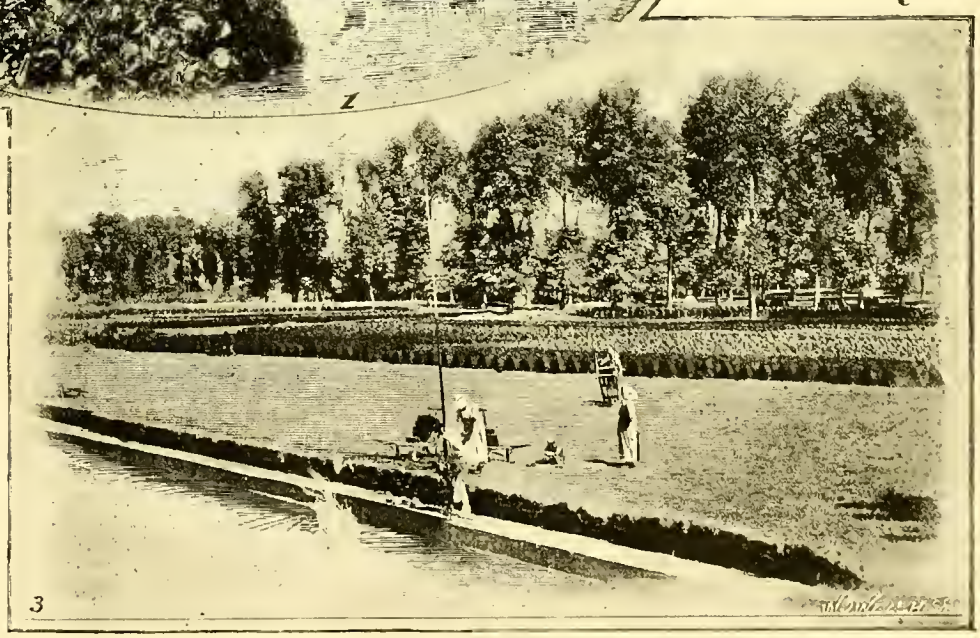

FIG. 4.—AMIENS: (1) THE "HORTILLONAGES." (2) BOATS CARRYING PRODUCE TO MARKET. (3) EXTRACTION OF PEAT FROM THE MARSH. (SEE P. 1.)

"OOTHECA WOLLEYANA."—An illustrated catalogue of the collection of birds' eggs formed by the late JOHN WOLLEY, junr., M.A., F.L.S., edited from the original notes by ALFRED NEWTON. Part II., Picariæ—Passeres. (London: R. H. PORTER, 7, Prince's Street, Cavendish Square.) A book, the completion of which has been long delayed, seeing that Part I. was published in 1864, while the issue of this second volume has, for various reasons, been postponed until this present year. Mr. WOLLEY was an enthusiastic collector and student of birds' eggs, and by his travels in Lapland and other out-of-the-way countries was able to add to his cabinets and lists many specimens of great rarity, and some hitherto regarded as extinct. From these stores, and from the letters and papers relating to them and committed to his care, Prof. NEWTON has published the book now under discussion. The text is well arranged for reference, and the coloured plates are excellent. A very interesting memoir of the late Mr. WOLLEY is appropriately included in the volumes.

THE EDUCATION BILL.—The St. Bride's Press, Ltd., who are the proprietors of the *County Council Times*, the official organ of the County Councils, and of various educational associations, will publish on the first day of the New Year a weekly paper to be called *Education: Primary, Secondary, and Technical*, which will deal mainly with the work of the authorities under the Education Bill.

NOVA SCOTIA APPLES.—According to a report furnished us by the Secretary for Agriculture, the fruit-crop in Nova Scotia has this season been very much below the mark, both in quantity and quality. Exports will be diminished by at least a third.

MANURES FOR VINES.—As a result of numerous experiments recorded in the *Comptes Rendus*, Messrs. GUILLON and GOUIRAUD show (1) that on a calcareous soil the effects of the application of chemical manures do not show themselves till after a considerable interval; (2) that potash salts are the most effectual, then phosphatic compounds, and lastly nitrogenous manures; (3) farmyard manure is highly valuable; (4) chemical analysis of the soil does not give sufficient indication of the kind of manure that should be employed. Experiments followed out during several years are alone capable of guiding the cultivator in his selection.

"THE ENGLISHWOMAN'S YEAR-BOOK AND DIRECTORY."—This is the twenty-third annual issue of this useful publication, and is edited by EMILY JANES. The contents include a Calendar, and are divided into sections dealing with: 1, Education; 2, Employments and Professions; 3, Industrial; 4, Medicine; 5, Science; 6, Literature; 7, Art; 8, Music; 9, Sports, &c.; 10, Public Work; 11, Philanthropy; 12, Temperance; 13, Homes and Charitable Institutions; 14, Religious Work. There are, further, a brief summary of the events of the year, and a Directory of names and addresses of prominent women workers; an index is also added. Agriculture and gardening, considered as employments for women, receive due attention, and the business of a florist is also described, with the addition of a few necessary truths concerning the hard work connected with it. The whole volume is valuable to the working woman. The publishers are ADAM & CHARLES BLACK, London.

ACCIDENT TO A GARDENER.—As Mr. THOMAS BANNER, foreman in the employ of Messrs. TOM B. DOBBS & Co., nurserymen, &c., Wolverhampton, was stepping backward to look at the position of some shrubs he was placing in the front of the Grand Theatre in that town, he fell through the glass roof of a verandah a distance of 14 feet. He alighted on his feet, but one of his hands was badly cut, and he received a severe shock. Mr. BANNER was for a period of twelve years foreman in the gardens of Wrottesley Hall.

"SILVA OF NORTH AMERICA."—The two supplemental volumes (xiii. and xiv.) have just been published, containing additional matter, indexes, &c. We shall take an early opportunity of noting their contents; but in the meantime we may congratulate Prof. SARGENT on the completion of his laborious undertaking, and we may also rejoice that horticultural literature is enriched by so magnificent a production. HOUGHTON, MIFFLIN & Co., of Boston, U.S.A., are the publishers, but the work can be had of WILLIAMS & NORGATE.

A WORTHY EXAMPLE.—When sending us a few particulars for the Almanac, published with this present issue, the Secretary of the Chesterfield District Chrysanthemum Society incidentally remarked that this Society has contributed during 1902 £41 10s. to the gardening charities, of which £31 10s. has gone to the Gardeners' Royal Benevolent Institution and £10 to the Royal Gardeners' Orphan Fund. The total income of the contributing Society was only £200. Surely this is a worthy example!

"VEGETABLES AND FLOWERS FROM SEED IN TROPICAL, SEMI-TROPICAL, AND TEMPERATE CLIMATES" (SUTTON & SONS, Reading).—We have here, in handy form, instructions for managing in distant climes many of those homely vegetables and flowers which are there so doubly welcome. The information is arranged alphabetically, and interspersed with many illustrations, and the name of the firm who issue the book is full guarantee for its reliability and value. The volume is clearly printed on good paper, and not overloaded with distracting advertisements.

"TRAITÉ PRATIQUE DE CULTURES TROPICALES," par J. DYBOWSKI, Préface de M. E. TISSERAND. Tome Premier. (Paris: AUGUSTIN CHALLAMEL, Rue Jacob, 17.) A contribution to tropical agriculture and horticulture, justified by the explanation that the increase in French colonial territories, and in their importance, necessitates due attention to their maintenance and welfare. Cultivation of the soil is an important side of foreign as of home industry, and any book that can be of service in this matter should be sure of a welcome. M. TISSERAND divides his book into sections, devoted respectively to Climate, Soil, Water, Manures, Propagation, and Plants Cultivated. The latter are treated of separately, and, for easy reference, are arranged alphabetically. The volume includes an index and many illustrations.

"THE TRANSVAAL AGRICULTURAL JOURNAL."—We have received a copy of the first part of a journal which is to be issued quarterly, and devoted to the interests of agriculture. It is devised to assist the farmers with expert advice, to place at the service of agriculturists the advice and services of veterinarians, entomologists, chemists, botanists, and practical men. It is published by the Agricultural Department, and bids fair to be a most valuable publication. Gardening, forestry, and fruit-tree culture are included in the programme.

"THE 'HOUSE' ANNUAL" (GALE & POLDEN, Ltd., 2, Amen Corner, Paternoster Row, E.C.).—This publication proves on examination to be compiled by Mr. W. A. MORGAN, of the Stock Exchange, in aid of the *Referee* Children's Dinner Fund." Many literary and artistic authorities have presented contributions, and members of the "House" and the public generally are requested to give yet further assistance. Previous books of a similar character have resulted in the raising of £1000 for the Fund, and it is hoped that many copies of the present volume may be sold at 5s. each. The contents being gratuitously contributed, call for no criticism; they are miscellaneous, including fiction, London notes, poetry, and other diverse subjects. The article most of interest to our readers is that on Chrysanthemums, by Mr. PERCY WATERER; it is illustrated, as are other of the papers in this annual. The *Referee* Children's Free Breakfast and Dinner Fund is doing a good work, and we wish it every success.

BRITISH INDUSTRIES.—In the *British Review* for December, we find an illustrated account of the origin and progress of the nurseries at and near Maidstone, belonging to Messrs. BUNYARD.

OAKWOOD, WISLEY.—The sale by auction of the late Mr. G. F. WILSON'S unique garden near Byfleet and Weybridge is to take place at the Mart, Tokenhouse Yard, on Tuesday, January 20, at 2 P.M. The estate is freehold, and comprises in all about 60 acres. Messrs. A. H. TURNER & Co., of 69, South Audley Street, Grosvenor Square, and of Weybridge, are the auctioneers.

"THE NEW FORESTRY."—A second edition of *The New Forestry*, containing additional illustrations and matter, by J. SIMPSON, will be published by Messrs. PAWSON & BRAILSFORD, Sheffield, early in the present year. The first edition was published three years ago.

A LARGE INDIAN MELON.—A very fine fruit of the Indian Melon (Cucumis Melo var. momordica) was grown at Government House, Singapore, in sandy soil. It was dark green, mottled with lighter colour, and weighed 16½ lb., with a length of 2 feet 3 inches and a circumference at the broadest end of 1 foot 10 inches. It had not much flavour, but is said to be very wholesome, and is an important article of food in India. *H. N. R.*

"THE YEAR-BOOK OF NEW SOUTH WALES."—This is compiled by the editor of the *Year-Book of Australia*, and published by authority of the Government of New South Wales, for circulation by the Agent-General in London, Westminster Chambers, 9, Victoria Street, S.W. It is a useful guide to the governmental, ministerial, legal, medical, military, trade and commercial, railway, and other interests of the Colony, the increasing importance of which renders all such authorised statistics as those now before us valuable to those in the Mother Country as well as to those resident in the Australian Commonwealth.

FAGUS BETULOIDES.

HERE in Cornwall, writes Mr. A. C. Bartlett, this tree is often called F. antarctica. There is a close resemblance between the two species, and they are both natives of the same country—that little-known extremity of South America, Tierra del Fuego; but the chief difference is that while F. betuloides is evergreen, F. antarctica is deciduous. Although noticed by Sir Joseph Banks some sixty years earlier, these trees were not introduced to this country until 1830. Unfortunately the evergreen Beech has not hitherto proved hardy, except in the southern counties; but where it does thrive, it is such a distinct and ornamental tree as to be well worth extra attention.

Fagus betuloides certainly does best when planted on a well-drained slope facing south or west. In its native country its size and appearance depend chiefly on the altitude in which it is growing. In the sheltered and fertile valleys it becomes a large tree—probably the largest southern tree in the world; while on the exposed heights it is so dwarf and compact that it may be walked upon.

The accompanying illustration (fig. 5) is that of a fine specimen growing at Pencarrow, Bodmin. The seed from which it was raised was sent from New Zealand in the early forties to Sir William Molesworth by his younger brother, Mr. Francis Molesworth, who was one of the first settlers in that country.

[To Mr. Bartlett's note we append the following extract from Hooker's *Flora Antarctica*:—

"The dense, dark forests which cover the shores of the Straits of Magellan and the mountain slopes of Tierra del Fuego, are principally composed of two Beech trees, the evergreen Fagus betuloides . . . and the deciduous-leaved F. antarctica. . . . F. betuloides forms the prevailing feature of the scenery of Tierra del Fuego, especially in winter-time, from having persistent leaves, and from its upper limit being sharply defined, and contrasting with the dazzling snow that covers the matted but naked branches of F. antarctica, which immediately succeeds it, and which even at Cape Horn ascends much higher than Fagus betuloides, and nearly to the summit of the mountains, which are 1000 feet below the line of perpetual snow, while at the sea-level it forms a larger tree." *Hooker's "Flora Antarctica,"* ii., 345; *Sargent's "Silva,"* ix. (1896), *p.* 23, *adnot.*]

COVENT GARDEN MARKET NOTES.

CUCUMBERS fetched good prices in the Christmas week, and these are likely to be sustained for a short period of time. Except for lack of sunshine, the weather has been in favour of the market-grower, and but little fire-heat has been required. The best Cucumbers were selling at 20s. per dozen, a price that would afford comfort to the grower, but more produce was sold at 12s. to 18s. per dozen.

APPLES.

Some persons may think this a quiet market, but even so, prices for good samples were well maintained. Much second and third-rate fruit comes into market, moreover much of the best

samples are not clear in the skin. Dessert fruits fetch from 8s. to 14s. per bushel. Culinary Apples were selling at from 4s. to 9s. per bushel, the latter price being for Wellingtons. There are fine Canadians in barrels on the market, which should be followed by well graded, good varieties from our own growers. *S. C.*

HOME CORRESPONDENCE.

THE SEASON IN THE COUNTY OF DOWN.—The season up to the present has been abnormally mild. Berberis Darwini, Escallonia pterocladon, E. organensis, Nandina domestica, Eucalyptus coccifera, and several other shrubs that do not usually flower till the spring months, are showing a fine mass of bloom. Lapageria rosea, against a west wall, is carrying a fine crop of flowers; while large clumps of Rhododendron Nobleanum and its pink variety are especially showy at the present time. The birds, too, have scarcely interfered with the berry-bearing shrubs, such as Cotoneaster frigida, C. Hookeriana, white and red Pernettyas, Cratægus Lelandi, showing that their supply of food from other sources has not yet been cut off by frost. *T. Ryan, The Gardens, Castlewellan, co. Down, December 20.*

THE FLOWERING OF CALANTHE VEITCHI.—I was interested in the note which appeared in these columns on December 20, descriptive of the flowering of Calanthe Veitchi, by Mr. E. Miles, Croydon, from the apex of the pseudo-bulbs annually. I may mention in this connection that among two hundred seedling Calanthes which flowered at Cliveden when I was there in 1897, quite half had from three to five spikes, and a few of the best pseudo-bulbs carried six spikes. The strongest flower racemes bore more than forty flowers. The racemes grew from alternate nodes, the strongest growing, as might be supposed, from the bottom of the pseudo-bulbs. I have never seen any Calanthes which flowered so well as those. Mr. Bacon was head gardener at Cliveden in '97. *F. W. Frensham.*

NEW ROSES—A CORRECTION.—Allow me to correct a very absurd mistake which was made in my paper on New Roses in the *Gardeners' Chronicle* for December 20. I am made to say:—"He had not succumbed to the much-to-be-condemned practice of judging his own Roses." It should have been, "over-dressing their Roses." This mistake was that of my amanuensis, not that of the compositor. *Wild Rose.*

A CAUSE OF PINK HYDRANGEA HORTENSIA COMING OF A BLUE TINT.—There is no doubt, as Mr. T. S. Goodrich states at p. 444, vol. xxxii., that certain soils have the effect of turning the pink Hydrangea blue. There may be other agencies, but soil is certainly one of them. When a boy in the garden, and my father was gardener to the Marquis of Camden, Wildernesse Park, Kent, I remember going annually to a kind of sand-pit to fetch soil for this purpose. No doubt the pit is still there; it was on the right-hand side of the walk leading from the gardens to the then gardener's house, and about 80 feet from the path. What the substances were in this sand which caused Hydrangeas to turn blue I do not know. This fact is a little mysterious, and although I was in first-class gardens and in business for over fifty years, I never met with any soil or sand, except that mentioned above, that had the effect of turning the flowers of the pink Hydrangea to a blue tint. *E. Bennett, Station Villa, Farnborough, Hants.*

SWEET PEAS.—*Apropos* of the discussion regarding the fertilisation of Sweet Peas, I may say that this subject interested Darwin forty-four years ago, *vide Gardeners' Chronicle*, 1857-58. The view propounded by S. Knight, *Gardeners' Chronicle*, p. 464, being virtually identical with that of F. Darwin, that "The Sweet Pea, not being indigenous, is not perfectly adapted for fertilisation by British insects. *M. A., Dec.* 22, 1902. [See Darwin, *Variation of Animals and Plants*, vol. ii. (1868), pp. 93, 94. ED.]

GARRYA ELLIPTICA.—My early impressions of this shrub would cause me to plant it only in well sheltered positions—and in one of our well-known hooks reference is made to it in the south of England, which by inference would imply that it needs shelter elsewhere; but, in an open part of a Glasgow nursery it may be seen growing freely, and is described by "as hardy as anything." This rambling shrub certainly looks very charming against a walt, but there appears to be no other reason why that position should be selected. *G. M. W.*

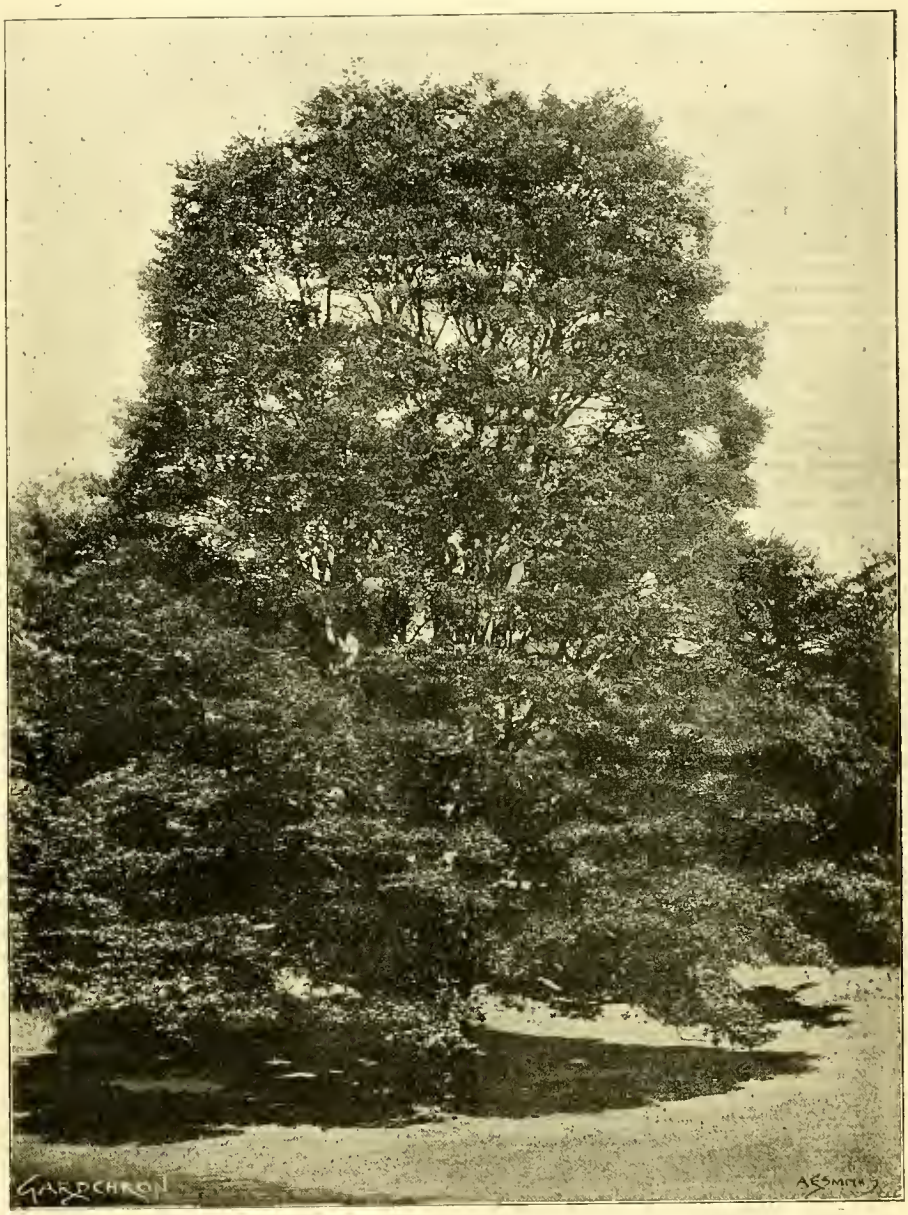

FIG. 5.—EVERGREEN BEECH (FAGUS BETULOIDES) AT PENCARROW. (SEE P. 10.)

DENDROMETER.—Can any of your correspondents, interested in this instrument, tell us of what practical use it is? I have measured a good many thousands of standing trees, as most timber is sold standing, and seen many measured, but I never saw a dendrometer in use for such purposes, nor knew a practical man who encumbered himself with such an instrument. It cannot be used in a wood, where most measuring is done, and in the open it is too troublesome to put in operation. Schlich, vol. iii., says that instruments for measuring the height of trees are all based upon one of two principles, geometrical or trigonometrical; and I suppose, where mathematical exactness is an object, these are the methods, but simpler means are available. I have long used light 5 or 10 ft. rods, that fit together easily by means of loose sockets, like a long fishing-rod, and I have given the pattern to many gentlemen, one of whom improved on mine by using light bamboo canes with brass sockets—quite an elegant set. Others may use these rods, but I never see any but my own. A boy can carry the rods, run them up a tree, and let them down again in a few seconds, and would measure the height of many trees while the dendrometer-man was getting his instrument into operation. One trusts to the eye a good deal in estimating height, but in case of dispute arising, it is best to have the tape and rods; and if someone would invent a handy instrument for finding the quarter-girth 30 or 40 ft. up, and of the big limbs out of reach, it would be worth something to the novice. There is a dendrometer-way of doing that, I suppose, but it is as worthless as the other, and trunks and all large limbs have to be estimated by the eye. It is surprising, too, how

near one will get to the contents in that way. I have had over 20,000 feet of Oak fall to the fellers measure within about 150 feet of the standing and selling estimate, in which all the girths were taken by the eye in averages all over the wood, and the difference was on the right side. *J. Simpson.* [The dendrometer is a very useful implement for the amateur. ED.]

—— Height-measuring instruments were in existence centuries before Mr. Duncombe's day, and the one I referred to as being figured about a hundred years ago was, as I indicated, a very old device then. If "D." would furnish a short description of the construction of Mr. Duncombe's instrument, or say where this is to be found, it would clear the matter up. *A. D. Richardson, Edinburgh.*

GENERIC DIVISIONS OF CACTI.—Your correspondent M. de Laet, in the *Gardeners' Chronicle* of December 27, 1902, prefers to retain the present generic divisions, with all their admitted errors, because he holds that there were still more errors in the older nomenclature. If we admit this, we are still faced with the fact that we have a bad system (or lack of system) left. What we require is, not something a little less unscientific than our predecessors put up with, but a system of generic division founded upon good generic differences. German botanists have recently given much research to this subject, though I should not like to express any opinion upon whether the system of Professor Schumann rectifies the errors of nomenclature. It is a very large field to consider. M. de Laet asserts that Phyllocacti have flat (2-edged) stems even in the seedling state; doubtless in many cases they have, but not in all, as my own experiments prove. It is this very lack of constancy that invalidates the present generic divisions founded, as we must believe, in ignorance of this. I have in fact seen both forms of stem on the same plant, and in most cases the seedlings of 2-edged species (Phyllocacti) will, as they approach maturity, outgrow their 3 to 6 edged stems, and resemble their parent. M. de Laet would have us believe that such plants have a strain of many-edged (Cereus) blood in them; probably this would produce a similar result in a seedling state. But surely the very fact which M. de Laet admits, viz., that the 2-edged and the many-edged species will interbreed, is not a strong argument for the retention of Phyllocactus and Cereus as separate genera. If they are admittedly reconciled, why continue to call them by different names? *A. Worsley, Isleworth.*

CUCUMBER CULTURE.—Mr. Lowrie, who wrote on Cucumbers, states ante, p. 229, vol. xxxii., that he has seen Cucumbers yielding enormous crops on the banks of the river Cauvery, which were only afforded water occasionally. Perhaps so, but he does not say that the roots were abundantly supplied with water, and had he dug a hole a foot or so deep he would have observed the hole was soon partly filled with water. The leaves, he states, were left untouched by moisture. This I can readily believe, as the leaves lie on the ground, and moisture would condense on the under surface on any plant near a river. I would naturally expect the upper surface to be bedewed likewise. I grew Cucumbers for eight years in a lean-to sunk pit without the syringe being in use at all. Along the centre of the pit was a narrow brick cemented tank through which the hot-water pipes passed to provide bottom-heat. The plants were put in during November, and were kept growing till November came again; and when pulled up, as many as a dozen Cucumbers of one sort or another would be found on a plant. When the plants began to bear fruit, water was put into the tank sufficient to touch or cover the pipes, and it was so kept for the season. The harder the firing, the more steam arose, and I invariably found dew deposited in the morning on the under surface of the leaves, consequently red-spider was a stranger. A thin coat of lime covered the glass during the sunniest part of the year, and very little air was afforded, but more at night than by day. I never had to do with a structure that gave so little trouble and such grand results as that one. It was built, I believe, at the suggestion of the late Lord Eversley. Mr. Lowrie speaks of the peculiar and unscientific modes of cultivation adopted by market gardeners. Now, I always thought that the methods of the born-and-bred market gardeners were as perfect as they could be, and that it was those who embarked in market gardening late in life, such as gentlemen's gardeners and aspiring amateurs, who failed and came to grief. I do not think that Mr. Lowrie can teach the trained market gardener how to grow Cucumbers, or any other market commodity. From what I have seen of the practice of market Cucumber growers north and south, they work on the express system, and get all they can out of their plants in the shortest possible time, Cucumbers not being much in demand after the end of July. It was once my lot to sell the produce of a garden. I took my first lot of Peaches to Covent Garden and got 36s. per dozen for them. I planted Cucumber plants to come in bearing at Christmas, took some a week before that festive season to the same fruiter to whom I took the Peaches; the head of the firm said, "My good man, who do you think wants a lot of Cucumbers this time of the year (it was bitterly cold)? had you brought some brandy and hot water, it would have been more sensible of you." A market grower would not have done that, perhaps. I left my Cucumbers, but got nothing for them, and returned home a wiser man, and cut off every Cucumber, small and big, and left the plants to grow on. The Cucumber-houses I have to deal with now are span-roofed, running north and south, and are entered by three steps at the lower end; they are naturally dry. We shade the plants, give little ventilation, never allow the plants to approach anything like dryness at the root, and in summer-time they are syringed three or four times daily, and always about 10 P.M., and in winter never less than twice, and we have from two to six fruits showing at a joint. Some planted last spring are still carrying fruit, but not being particularly wanted, the plants have not been top-dressed for some weeks. I fear Mr. Lowrie, with his reduced supply of moisture at the top and root, with more ventilation, and reduced temperature, would soon be landed in the bankruptcy court if he depended for his living on growing Cucumbers. One word more: Mr. Lowrie states that the growers use too much soil. Now, I have been amazed at the heavy crops produced in so little soil. A grower, not far from where I write, grows his in less than 8 ins. after two or three top-dressings; but the place is swamped with manure-water. *W. P. R.*

CROSS TRELLISES FOR PEACH-TREES.—I see that your correspondent "H. J. C., Grimston," holds the belief that good Peaches and Nectarines can only be grown near the roof of a forcing-house; he also says that he knows of two places south of the Trent where they are grown on cross trellises. I am not aware if one of the places is Blenheim Palace. If not, I can inform him that there is a large lean-to house in that garden which is planted with Peach and Nectarine-trees on cross trellises; and the back walls are planted with Peach-trees. A narrow stage runs along the front of this house suitable for standing Strawberry-plants in pots, &c. For ten years I had the opportunity of seeing the crops of fruit grown in this house, and I have always considered it to be a very useful Peach-house, the crops being good, and the fruits of a fair size, and a little in advance in point of time of those on outside walls. *J. H. Baker, Eynsham, Oxon.*

THE WINEBERRY.—Practically if Raspberries succeed, the Wineberry will also do so. The difference in the training of the canes is, that while Raspberry-canes are generally shortened at about 5 feet from the ground, the Wineberry grows 10 or 12 feet in length of shoots, which should not be shortened, but trained downwards. Good results are thus obtained, and an abundance of fruit fit for dessert gathered late in the autumn. All old canes should be removed at this season, but tying-in should be postponed for a few weeks. *S. C.*

IRISH HARDY FRUIT.—The interesting note by your correspondent, A. Dean, raises an additional question to the one with which he terminates his note, and that is, why should not England, as well as Ireland and Canada, become great fruit-growing countries? According to the Board of Trade Returns, published in the *Gardeners' Chronicle* of the same date, p. 440, for the month of November, we imported 606,156 cwt. of Apples, and 24,177 cwt. of Pears. It is possible to grow that quantity of hardy fruit in England, and afford employment to many gardeners, besides keeping money in the country. But why cannot we produce a sufficient quantity of fruit to meet the demand, and at a lower price? One reason is, that the working population here in England have not access to the land on such favourable terms as the people in our colonies. To verify this statement, I must refer to the *Times* of Saturday, December 13, 1902, under the heading, "Canadian Emigration," which reads, "Mr. Preston, Commissioner of Emigration for Canada, has authority for the statement that an English syndicate is being formed with a view of endeavouring to secure from the province of Ontario a similar concession to that which was granted recently by the Provincial Government to an American syndicate, whereby about 2,000,000 acres of land was sold to these parties at 4s. an acre." I have lived in this district for upwards of three years, and have ascertained that the land hereabouts belong to one or two persons, who let a large portion go out of cultivation, cultivate a portion, and let a small portion at a rental of 15s. to 30s. an acre, and this for inferior land 10 miles from the nearest market. If this is the state of things throughout England and Ireland, it is obvious that the working population cannot possibly attempt to grow hardy fruit. *C. P. Cretchley, The Gardens, The Honeys, near Twyford, Berkshire.* [We have always insisted that it is the peculiar conditions of land tenure in these islands which prevent us cultivating fruit in sufficient quantity for home needs. Added to these are the system of co-operation among foreign growers, their better system of grading and packing, and the handicapping of fruit and vegetable-culture here by excessive railway rates, which make it possible to bring French, Belgian, and Dutch produce in large quantities to our southern ports, send it by railway to London, and undersell the grower in the home counties. ED.]

HYBRID RUBUSES. — It was distinctly a feather in the cap of that veteran and most talented of hybridists, Mr. John Seden, that two of his products, so widely dissimilar as Damson and Raspberry, should have gained for Messrs. Veitch & Sons the honour of two Awards of Merit at one sitting of the Fruit Committee at the Drill Hall, honours which it is just possible may assume a higher form another year. When it is remembered that up to a certain period Mr. Seden worked chiefly amongst Orchids and other flowering plants, it has to be said that his labours amongst fruits do merit the warmest approbation. The new Raspberry, the third of fruits of this class, which has come as a cross product from Langley, and has been so descriptively named November Abundance, is the product of crossing the American Raspberry Catavissa with our fine variety Superlative, with the result that the progeny is, as seen from the sample branches sent to the Drill Hall on the 4th ult., not only wonderfully prolific, but is a late autumn fruiter. In that respect, it bids fair to put October Red and Belle de Fontenay out of court altogether. The fruits are large, roundish, not unlike those of Baumforth's Seedling, of deep rich colour, very juicy, and sweet. A few years since, Messrs. Veitch & Sons received an award of a First-class Certificate for Raspberry Queen of England, with yellow fruits, very fine indeed, and a superb summer fruiter. This was the product of crossing Raspberry Superlative with the Blackberry Rubus laciniatus, a very remarkable result from red and black-fruited parents, and no doubt far from being anticipated. Then there was an award made a year or two since to that very fine fruiting sour Blackberry, "The Mahdi," the fruits of which are of a deep crimson colour. The parents were the common Blackberry and Belle de Fontenay Raspberry. The variety fruits between the Raspberry and the Blackberry, and being so fine and richly flavoured, forms a valuable adjunct to the dessert table. These are real hybrid or cross-fertilised additions to our fruit lists, and they bear striking comparison to what is assumed has been done in the same direction elsewhere. The fine fruiting Rubus laciniatus seems to have its origin lost in

obscurity. It is yet by far the best of the non-wild Blackberries we grow here in gardens. The Loganberry, so-called, has been assumed to be the product of a cross in America, but that famous botanist, Mr. Bailey, holds that it is a natural species; as is also that would-be impostor, the Strawberry-Raspberry, so-called, but which is a species—Rubus palmatus. As to the very pretty Rubus phœnicolasius, the best novelty of its kind from Japan, no one claims for that a hybrid origin. It is a charming climbing or even bush plant, but hardly one of the species named can compare in edible value with the products of that skilful and honoured hybridist, Mr. J. Seden. *A. D.*

PARIS.

A HORTICULTURAL HALL WANTED FOR PARIS.

THE Société Nationale d'Horticulture de France held its autumn exhibition in the pavilions at Cours la Reine, that were erected for the Universal Exhibition of 1900. This was the first time this course was pursued. Before 1900 the Chrysanthemum shows had been held in the Tuileries Gardens. In 1900 all the Congresses and Horticultural Exhibitions took place in the erections built for the purpose on the banks of the Seine, but there were many objections to this, and in 1901 the autumn show was arranged in the Grand Palais du Champs Elysées, a lofty building rather dark and unheated, so that the plants suffered from the cold. This year the spring exhibition was at Cours la Reine and proved very successful, so that the same place was chosen for the autumn show. Unfortunately the houses are not heated, and as the exhibition was opened later than usual (December 12), exhibitors were much inconvenienced, as the show was open for a week, and after the 17th the weather became very cold, the plants for the last three days being in a temperature of 4° C. (39° F.). M. Lebaudys' fine Gloire de Lorraine Begonias, and many Orchids, were killed, others being saved by being covered with paper every night. It is again asked where the autumn meetings can best be held. The last exhibition was well managed: M. Jules Vacherot, President of the organising committee was universally congratulated upon his success, many exhibitors desiring that the stands and tents might be left permanently in place. But if another autumn show is held there, only Chrysanthemums will be staged, owing to the risk of exposing other plants.

The difficulty might be met by installing a heating apparatus, but this would be an expense, and the city of Paris would not be disposed to assist, as the buildings are but little used and may not always be left standing. The houses cost a great deal to keep up, and much glass is broken by children playing near, so that the municipal council may decide to take down buildings that are used for barely a fortnight each year by the horticulturists.

In fact it is desirable to find in Paris, as in London, a large and suitable building for flower-shows. Probably the authorities will soon provide one, especially as the agriculturists also desire a hall for congresses that for some years past they have not known where to hold. The Galerie des Machines, left from the 1889 exhibition, has been twice used for agricultural congresses, but they have since been taken down, parliament having passed a law by which the city was empowered to control the Champ de Mars. The land on both sides is let to private persons, who have erected mansions thereon, and the remaining ground is turned into a park, similar to the Parc Monceau.

Therefore it becomes evident that on the borders of Paris, near the Bois de Boulogne, it is desirable to build a large hall suitable for agricultural congresses and horticultural and other exhibitions. *G. T. Grignan.*

[It must be remembered that the Society has a fine suite of rooms for its offices in the Rue de Grenelle. ED.]

LAW NOTES.

GARDENER TO PAY FOR DAMAGE.

A REMARKABLE case was before Judge Mausel Jones at Rotherham County Court recently, in which the plaintiff sued a gardener for £14 damages, alleged to have been sustained by defendant negligently or wrongfully removing the terminal buds from 280 Chrysanthemum-plants. The gardener, it was stated, had been in plaintiff's employ as head gardener for three years, but left in September last. Before leaving he is alleged to have told an under gardener that he should "get even with the old man," and should destroy all his own stuff on the premises. When the new head gardener came he found the terminal buds had been removed from the Chrysanthemums. In reply to a lawyer's letter, defendant wrote "If anyone wants compensation it ought to be me, for half the plants on his place are what I have begged." Defendant denied having damaged the plants, and suggested that plaintiff had done it himself by "putting his own finger in the pie." The judge, however, made an order for the full amount claimed.

FIG. 6.—PROLIFIED ODONTOGLOSSUM.

A PROLIFIED ORCHID.

A VERY unusual malformation, so far as Orchids are concerned, has been set to us. It is a case of median prolification in Odontoglossum crispum, that is to say, one flower grows out of the centre of another flower. The lower blossom has no ovary, but it has three sepals and three petals in regular symmetrical alternation and regular form. There is no column, but in its place a pedicel an inch or more long, bearing at its extremity a distorted flower with two sepals and two petals placed crosswise, the second petal being a lip. In the centre is a column with indications of two anthers. This second flower, therefore, shows that very common tendency in Orchids to arrange the parts of the flower in twos (see fig. 6).

ENQUIRY.

ENGADINE CARNATION.—Will some correspondent kindly inform "C. J. H." what plant is meant by Engadine Carnation, and how best to cultivate it?

NURSERY NOTES.

MR. ICETON'S, PUTNEY.

MR. W. ICETON, of the Granard Nurseries, Putney Park Lane, which were established in 1866, was among the first to force quantities of Lilies of the Valley for sale in Covent Garden Market, and he continues this work in larger proportions than formerly. Others may force even greater quantities, but it is generally conceded that there are no better or stronger flowers than those sent to the market from Putney. Huge numbers, indeed millions, of selected German crowns arrive to Mr. Iceton's order during winter in several consignments, and they are packed away in a cool chamber of the Cold Storage Co. for use when required. The flowers sold during Christmas have been produced by crowns which were imported last February, and similar crowns will afford blooms during the month of January. Towards the end of this month, however, the first batches of new crowns will be boxed up and put into warmth in a position from which light may be excluded until the flower-spikes have advanced out of the sheath. Then the sale of retarded crowns and flowers from such crowns may be said to have finished, for directly the new crowns are on the market, everyone prefers them to retarded ones. If there remain a few crowns in the cool chamber, however, they may still serve a useful purpose, as they will produce a fine lot of valuable foliage that can be used in bunching-up the new flowers, for all growers have found that the crowns forced earliest, say, in January and February, though they may yield good blooms, are not capable of developing much foliage.

When visiting the nursery a few days ago, we saw some of the later batches of crowns from the cool chamber, some of which, impatient of the retarding to which they had been subjected, had commenced to grow even in the cool chamber. Little harm is done if the crowns elongate there to some extent so long as the flower-spike is not in the least visible when they are removed; but if this be the case, then they are useless. Mr. Iceton's crowns are put thickly into wooden boxes, almost square, which hold 100 each, and unless these are sent to market as they are grown, the flowers are cut and put up into neat bunches containing twelve spikes each with additional foliage. For four or five days previous to Christmas we were informed that there were sent to market about 100 such boxes of growing plants, and 100 dozen bunches of cut blooms each day.

To such an extent has the retarding system upset the limitations the seasons formerly imposed, that Mr. Iceton sends "Valley Lilies" to market on every alternate day throughout the year. Roman Hyacinths are marketed in bunches of six spikes each, but it is very early for these yet, and prices are discouraging. A few early trumpet Daffodils are in bloom, and those varieties that force best will soon make a feature in the market. We noticed hundreds of plants of Lilium longiflorum in bloom, or approaching that stage, and also a few plants of L. auratum.

Most of our readers know that Mr. Iceton cultivates Palms and other foliage plants in unusual numbers, for use in the furnishing and decorative trade. There are good specimens of nearly any size, representing most of the popular species of Palm, also a few good plants of Araucaria excelsa, a capital batch of Eurya latifolia, Aspidistra lurida, Fatsia japonica, Dracæna Lindeni, Asparagus, Bamboos, &c. The Kentias are the most popular among Palms, and they stand well in the atmosphere of a dwelling-room; but we have found the more delicate-looking, graceful Cocos Weddelliana to succeed for an equal length of time in the same condi-

tions. Phœnix rupicola makes a very pretty vase plant, and is the handsomest of the genus. Mr. Iceton, jun., declared that it will continue in good condition in a dwelling-room as long as most Palms.

Mr. Iceton has another nursery at Chiswick, which contains Palms, and where a little forcing of flowering bulbs is practised. Florists have found the general furnishing and decorative trade not very brisk for some time past, and Christmas festivities in town would probably have been more numerous but for the exodus of so many of the richest members of society to attend the famous Durbar at Delhi.

FOREIGN CORRESPONDENCE.

NEW WINTER RHUBARB.

In a recent number of your valued paper, I noticed some remarks regarding the New Winter Rhubarb that had been exhibited by different parties and under different names at the Drill Hall exhibition. In a number of the *Horticultural Advertiser*, of more recent date, there appeared a clipping from your paper on the subject. I suspected that the Rhubarb offered as Sutton's Crimson, Topp's Winter, and what we have in the States under the name of Crimson Winter, were the same. I sent on the clipping to Luther Burbank, of Santa Rosa, Cal., for his opinion, and am just in receipt of his reply, which reads as follows:—

"Yours just received with the clipping from the *Horticultural Advertiser*. All the Rhubarb mentioned is without any doubt Topp's Australian Crimson Winter Rhubarb. Topp's Crimson Winter or Crimson Winter, is the name it goes by in Australia and New Zealand. I introduced it to America about eight years ago, and have sent much of it to England, among the parties being some of those mentioned in the clipping. I enclose circular describing it."

This communication may be of interest, and I trust it will suggest the propriety of seed and plant dealers continuing to offer varieties under the names given them by the originators. These much multiplied synonyms, are both harmful and expensive.

It may not be out of place to mention that Mr. Burbank advises me that he has raised from the Topp's Australian Crimson Winter Rhubarb, "a new hybrid variety bearing stalks about six times as large, and in flavour surpassing any Rhubarb ever known." It is not yet for sale.
Archibald Smith, Boston, Mass.

MARKET GARDENING.

HYDRANGEA PANICULATA FOR FORCING.

The present is a good season for potting this plant, 7 and 8-inch pots being the most useful size into which to put them. The plants are saleable from March to August, and although great numbers are sold, the demand for them never abates. With this potting the "cut backs" are potted at the present season. Market men generally purchase the plants from the trade, and the shoots on these plants will be some 3 feet in length, and from 6 to 12 inches have to be cut off, in order to make the plant symmetrical, and induce buds at the bottom to break, good foliage being an important item.

As these plants are potted, they are stood on dung-beds made about 2 feet deep, the heads of the plants however being entirely in the open. This hot-bed treatment encourages the growth of roots, and the ammonia given off benefits the top growth. In about a month later the first batch of plants will be removed to a span-roofed house, which is heated with two rows of pipes 3 inches in diameter on each side and underneath the bed, the object being to keep the roots active. Red-spider is kept under by copious syringing and humidity, especially in the early part of the season. *S. C.*

AN INTRODUCED PARASITE ON GRASS.

Twelve years ago, specimens of Bromus unioloides and Festuca bromoides, attacked by a parasitic fungus, were received at Kew from Patagonia and Bahia Blanca. This fungus proved on examination to be undescribed, and was named Cintractia patagonica, Cke. & Mass. Cintractia was at one time included in the older genus Ustilago, the species of which produce "smutted" corn. Nowadays, the name Ustilago is confined to those fungi whose spores form a loose, sooty powder, which is blown away at maturity. In Cintractia, on the other hand, the spores, which are formed in the ovary, as in Ustilago, are compacted into groups or spore-balls, that do not separate at maturity, but collectively form a hard black mass, and are only dispersed when the diseased grain has decayed on the ground, or has passed through the alimentary canal of some animal.

Some time ago an English traveller in South America observed that Bromus unioloides was grown mixed with Lucerne, for fodder. Seed of the Bromus was brought home, sown, and in due course produced not only fruit, but also its parasitic messmate, Cintractia, both quite as vigorous and well-developed as when growing in their original home.

It will be interesting to note whether host or

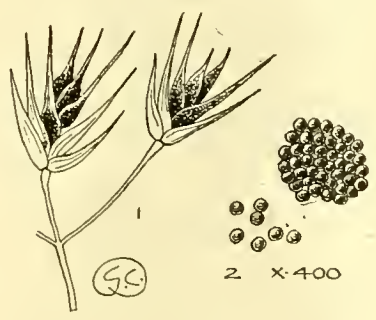

Fig. 7.—Cintractia patagonica on grass.

parasite, or both, can establish themselves in this country. There are plenty of species of Bromus and Festuca in Britain to choose from, if the fungus is desirous of trying a new host-plant, and its presence will be acceptable as a new botanical curiosity; but we trust the line of attack will be confined to wild grasses, and also in moderate quantity. We have already a superabundance of cereal diseases caused by fungi.
Geo. Massee.

SOUTH AFRICA.

THE FLORA OF ELANDS-LAAGTE, &c.

The visit to Elands-Laagte was very unpromising. A storm was brewing, but I ventured, getting back after sundown with an empty bag, there being very few flowers.

On the flat lands between Elands-Laagte, Glencoe Junction, and Dundee, the flowers were abundant, amongst them some highly-coloured Crinum longifolium, and still the rose-coloured form of Sparaxis pulcherrima. I had not at this point reached the purple, far less the black-coloured variety, Mr. Medley Wood expected I should meet with. These flat lands are about 4,000 feet above sea-level.

My next objective was Newcastle, further north, and the centre of the Natal coal-fields. It is not unworthy of notice that New South Wales and Natal should both name their coal-fields after Newcastle in the Motherland. Newcastle is a well laid out town, and should it develop and cover its building area, it will enjoy roomy streets I noticed in Spain, as in Natal, that where there are coal deposits, flowers are not abundant.

My next move was to Charlestown, in the extreme north territory of Natal, the railway skirting and surrounding the famous Majuba Hill, the scene of the reverse which cost so much blood, and money, on the British side, to wipe out. Shortly after 8 A.M., October 30, I started from the hotel to visit this famous hill, and ascended to 6,000 feet above sea-level, and estimated that there were still 2,000 feet to cover before reaching the summit; so decided to leave this part of the hill to younger feet and content myself with a walk round and see where Colley went up in the night unknown to the Boers. It was such a climb as none of our troops have been called upon to undertake in this last great war with the Boers.

I found many flowers on the south side of Majuba, and I recommend it as a good hunting ground. Unfortunately, I lost my list of names, but from the bottom to the point I reached, there were many genera and species. The most interesting to me was a Scilla, I think, with rich pink flowers, and bright green leaves, spotted black. Some of these I collected and posted to London for Kew, Cambridge, Glasnevin, and Max Leichtlin, and one plant for Mr. J. Medley Wood for a name, not that it is so rare as I supposed at the time, as I have since found it pleutifully in the Transvaal, but all the same it is to my eye a beautiful bulbous plant for pot culture, with leaves about 6 inches long; flowers about 4 inches, and one to six flowers to a bulb, according to size. The bulbs on Majuba were the size of small Walnuts, those I have since found on the veldt are as large as a medium-sized Hyacinth. I have collected seeds on the veldt, but fear they will not ripen.

Natal is a truly British Colony, made up mainly of British, Indians, and Kaffirs, the latter at Pietermaritzburg come into the town quite dandies. Standing at the police-station, I saw quite a bevy of strapping young Kaffir girls pass, elegantly attired in their blankets, and over this a loose net, their skins well oiled. I asked the black policeman who these were, and he replied "Unmarried Kaffir ladies." I said "How are the married ones distinguished?" This it was pointed out was done by drawing the hair at an angle from the top of the head in the shape of a bottle without the neck and by using some composition to make it solid, also by colouring the hair red. The young Kaffir belles are looking forward to the establishment of barracks at Pietermaritzburg, and for Tommies as husbands.

At Howick I spent some time going from one store to the other, chatting with the proprietors, as they usually sit outside their shops enjoying the air, and on the alert to catch buyers. The buyer in most countries has little national sentiment. He spends his money where he can get the most for it in return, and I suppose the Indians, who are commercially very important here, can offer the best value. Their headquarters are at Durban, where there are merchants of great wealth who supply these smaller traders. Messrs. Harvey Greenacre & Co., very large and rich merchants, anxious to extend their premises called upon their neighbour, an Indian, and asked him what he would take to clear out. He replied, "I have been thinking these last few weeks to call and ask you how much you would take to let me have your premises to extend my business."

When in Durban, I went out to one of the extensive Sugar plantations, and saw the whole process from the culture of the cane to the production of the white crystallised article ready to put on the market. The manager told me they were much hampered for want of labour. The Costal Sugar plantations wanted this year 18,000 coolies as a necessity, but did no

expect that they would get more than 6,000. As in Fiji, a portion of these manage to remain or return as emigrants, and thus Natal bids fair to be an Indian settlement. As labourers they are superior to the Kaffir, being an intelligent race. They act as railway porters, as labourers on the permanent way, &c. One of these latter went out with me one day, and I found him as keen at the search as I was, and I advise any botanist doing South Africa to engage Indians as guides and carriers.

The farming prospects of Natal are great, and if the whites take to the land, and the Indians look after the shops, there is no reason why this fine colony should not be rich and prosperous. Of course, the British will have to learn how to handle the Kaffir, leaving those on the spot to be the best judges, and ceasing to judge other people's knowledge by their ignorance. I do not suppose the whites will give up the commercial element in the towns without a struggle. Some say the Indian is at present master of the position as regards commerce. I am not of that opinion, but Sir Albert Hine must know how things stand, and by the introduction of smart business men there may yet be a chance to save the colony, commercially and agriculturally, for the British race. *Peter Barr, V.M.H.*

NOTICES OF BOOKS.

Greenwich Park: Its History and Associations. By A. D. Webster. (Greenwich: Richardson.)

This book contains chapters on: The early history of the Park—Laying out the Park—Rangers and Keepers of the Park—Greenwich Castle—Royal Observatory—Ancient Barrows—Underground Passages and Conduits—Interesting Finds in the Park—Greenwich Fair—Royal Sports and Pastimes—Historic Houses around the Park—Distinguished Persons who have visited the Park—Changed Appearance—Deer in the Park—Fauna and Flora of the Park—Trees and Shrubs in the Park—Entomology of the Park—Fungi in the Park—Geology of the Park—Roman Remains in Greenwich Park, with descriptions of finds, lists of Coins and Emperors—Miscellaneous Notes, &c.—together with illustrations of many rare maps and drawings of the Park."

The summary of the contents above given will serve to show the amount and nature of the interest attaching to this, the oldest and by no means the least interesting of our public parks. It dates, indeed, from 1433.

The most important feature of the Park, as it now exists, consists in its noble specimens of the Sweet Chestnut, with their spirally twisted bark. When they were planted is not told in Mr. Webster's book, so far as we have observed. The Elms have long since passed their prime, but the Purple Beech, the Tulip-tree, the Ailanthus, and very many others, are still in full vigour. Mr. Webster tells of a Thorn fully 50 feet high, and over 7 feet in girth of stem; whilst in the enclosed ground near the pond no fewer than 1,300 kinds of trees and shrubs are to be seen, affording truly an excellent object lesson. Greenwich is becoming more and more smoky as London extends, but for all that, hardy Bamboos, Roses, and numerous aquatic plants, are to be seen in a thriving condition. Aponogeton distachyum produces in abundance its curiously shaped and deliciously fragrant flowers. Cypripedium spectabile, Orchis foliosa, Arundo Donax, Gunnera manicata, and Eryngium pandanifolium are among the interesting plants noted by Mr. Webster, and the few we have cited will serve to show the great interest which attaches to this noble Park. Bulbous plants have been planted in the grass in great abundance, and whilst the ordinary "bedding out" is nearly unrepresented—"the beautifully undulating and well-wooded character of the grounds being far too natural to admit of such a system." One of the principal objects aimed at has been to cherish and retain as far as possible the wild and natural character of this royal heritage.

A useful map and numerous illustrations add to the value of the work. We have necessarily only alluded to the features which fall more especially within our own province, but the antiquarian, the lover of animals, the entomologist, the geologist, and the naturalist generally, will find much to interest them in these pages. A description of no fewer than 115 coins found within the Park, ranging from the time of Marc Antony, who slew himself B.C. 31, to that of Honorius, who died in 425, comprising some forty Emperors, is given.

Trees and Shrubs for English Gardens. By E. T. Cook. (*Country Life* Office.)

A good book on trees and shrubs is a real want. Few books are more often enquired for, and until now we have had a difficulty in replying to our correspondents who have asked for information on the point. By far the best are the publications of Loudon, the *Arboretum* and the *Encyclopædia of Trees and Shrubs*, but these, however excellent in their way, are now long out of date, and moreover, they cannot readily be obtained. They comprise also a great deal of information which people ought to require but do not. Mr. Cook has steered clear of this difficulty; he has not added to the bulk of his volume by the insertion of matters which the public does not want. In this no doubt he has done wisely, but if it was not desirable to enenmber his pages with what the general reader might deem superfluous, he might have indicated more fully than he has done the sources from which further information may be derived. We do not find, for instance, any mention of Prof. Sargent's *Silva*, though that book contains a perfect mine of information relating not only to North American trees, but to trees and shrubs generally.

The plan followed by the author of publishing discursive chapters on generalities necessarily leads to repetition. The varying length and style of these chapters, or sections of the book, for the word chapter does not occur in it, suggests that they were written by different hands; and indeed the contributions of Mr. Bean and others are freely acknowledged. The chapter on pruning flowering shrubs is a valuable one, as condensing information that is troublesome to get; but of all the sections into which Mr. Cook's book is divided, that entitled "Some Hardy Flowering Trees and Shrubs" is the most useful. This is an alphabetical list, comprising the names of the principal genera and species, with details relating to their native country and peculiarities of growth. The habitat of the Horse-Chestnut, now known to be in the mountains of Greece, is given as the mountains of Tibet. It is strange how long it takes to dislodge an error of this kind, in spite of repeated correction. The spelling of Daboecia and of Hippophae are points on which differences of opinion may exist, but uniformity is at least desirable, and as a general rule, the *Index Kewensis* is the safest guide to follow.

The plant called Lycium barbarum, so useful by the seaside and for keeping up the soil on sloping banks, is, as Mr. Nicholson has shown, L. sinense.

Mr. Cook's book will do great service by calling attention to a somewhat neglected phase of gardening, whilst it will also be of service to the amateur by putting before him a mass of information that he would otherwise have to seek in a variety of other books. In these days of trashy gardening books, it is a pleasure to come across one which bears the stamp of original observation, judicious inference, and industrious research. If such a book be occasionally faulty in detail, the reader will readily condone the defect when the immensity and variety of the subject are borne in mind—and in view of the mass of useful information that is placed within his reach. Tree lovers have reason to be grateful to Mr. Cook and his publishers.

Response in the Living and Non-Living. By Jagadis Chunder Bose, D.Sc. (London: Longmans.)

The uninitiated reader might think that the work whose title is given above was a treatise on table-turning or on ghostly apparitions. It is really a record of experiments and observations made by a Professor in the Presidency College, Calcutta, on the effect produced by a stimulus of any kind on living or dead matter. The best method of conveying an idea of the nature and scope of the book is to quote the author's own summary:—

"We have seen that stimulus produces a certain excitatory change in living substances, and that the excitation produced sometimes expresses itself in a visible change of form, as seen in muscle; that in many other cases, however, as in nerve or retina, there is no visible alteration, but the disturbance produced by the stimulus exhibits itself in certain electrical changes, and that whereas the mechanical mode of response is limited in its application, this electrical form is universal.

"This irritability of the tissue, as shown in its capacity for response, electrical or mechanical, was found to depend on its physiological activity. Under certain conditions, it could be converted from the responsive to an irresponsive state, either temporarily as by anæsthetics, or permanently as by poisons. When thus made permanently irresponsive by any means, the tissue was said to have been killed. We have seen further that from this observed fact, that a tissue when killed passes out of the state of responsiveness into that of irresponsiveness; and from a confusion of 'dead' things with inanimate matter, it has been tacitly assumed that inorganic substances, like dead animal tissues, must necessarily be irresponsive, or incapable of being excited by stimulus—an assumption which has been shown to be gratuitous."

* * * *

"We have seen that amongst the phenomena of response there is no necessity for the assumption of vital force; they are, on the contrary, physico-chemical phenomena, susceptible of a physical inquiry as definite as any other in inorganic regions.

"Physiologists have taught us to read in the response-curves a history of the influence of various external agencies and conditions on the phenomenon of life. By these means we are able to trace the gradual diminution of responsiveness by fatigue, by extremes of heat and cold; its exaltation by stimulants, the arrest of the life-process by poison.

"The investigations which have just been described may possibly carry us one step further, proving to us that these things are determined, not by the play of an unknowable and arbitrary vital force, but by the working of laws that know no change, acting equally and uniformly throughout the organic and the inorganic worlds."

Timber in South Africa.—If tree-growing in South Africa be not a rapidly expanding industry, its consumption of timber is becoming noteworthy; as for example we noted the other day that some £300,000 worth of timber is imported annually by Cape Colony. The department at Pietermaritzburg in Natal is attending to the afforestation of that important Colony, and have just received the report of an expert, which we believe covers the whole subject of site, soil, and variety suited to locality—and generally all matters connected with the planting of wood in favourable localities.

Obituary.

JOHN PEED.—We regret to have to inform our readers of the death of the senior partner of the firm of J. Peed & Son. He passed away at his residence in Streatham Park on the 24th ult., after about five weeks' illness. The deceased was in his seventy-second year, and had been connected with gardening all his life, having commenced at the early age of eight as a garden boy. He started business in the year 1860 as a gardener and florist at Brixton, afterwards removing to Roupell Park Nurseries, and later on opening a branch establishment at Streatham Park. The interment took place at Norwood Cemetery on Saturday, the 27th ult., a great number of friends and employés being in attendance.

SOCIETIES.

DEVON & EXETER GARDENERS'.

AT the fortnightly meeting of the Devon and Exeter Gardeners' Association, held at the Guildhall, Exeter, recently, an instructive paper entitled "The Fuchsia and its Culture," was read by Mr. G. CAMP, gardener at Culver.

BECKENHAM HORTICULTURAL.

ON Friday evening, December 19, Mr. W. Beale, gr. Hayes Place, read a paper on that gem of a winter-flowering plant, Begonia Gloire de Lorraine, which does its best to liven many a winter day with its bright green handsome foliage, and beautiful rosy flowers. Since M. Lemoine, of Nancy, raised the plants, endless attempts have been made to secure seed, but so far the flowers of B. Gloire de Lorraine absolutely refuse to be fertilised. From about thirty varieties of winter-flowering Begonias grown at Hayes Place, only two really produce pollen, viz., B. Corallina, and B. Erfordia. The various sports were discussed, together with the details of propagation by cuttings and leaves. *M. W.*

NATIONAL SWEET PEA.

DECEMBER 29.—The annual meeting of this Society was held at the Hotel Windsor, on Monday last, when Mr. Geo. Gordon presided over a good attendance. The following paragraphs are extracted from the Committee's report.

"The closing of the Royal Aquarium forces the Society to seek a new home for its exhibitions. After the most careful consideration your Committee decided to endeavour to make arrangements with the authorities at Earl's Court . . . . . and subsequently the Earl's Court management offered the Society a donation of £10 10s. towards the prize fund, free admission to all members, and the erection of tabling in the spacious Prince's Hall."

"Upon the completion of the judging on the first day of the last exhibition, a meeting was held to consider the merits of the new varieties, of which some two or three dozens were shown. The judges were invited to participate in the proceedings. First class Certificates were awarded to Dorothy Eckford (Eckford), exhibited by the Rev. Leslie Knights-Smith, Brightstone, Isle of Wight, and to Golden Rose (Burpee), exhibited by Messrs. I. House & Sons, Westbury-on-Trym, Bristol. Florence Molyneux (Dobbie), exhibited by Messrs. Dobbie & Co., Rothesay, was Commended."

The balance sheet shows that there is a sum of about £30 to the Society's credit at the bank.

Mr. R. Dean resigned the position of Exhibition Secretary, and the duties of this office will be carried out by Mr. H. J. Wright, General Secretary. The next show will be held on July 15 and 16, at Earl's Court.

READING AND DISTRICT GARDENERS' MUTUAL IMPROVEMENT.

AT the last meeting for the year 1902 there was a large attendance of members present, presided over by Mr. Leonard Sutton. The subject arranged for the evening was "A Chat on Bouquet Arrangements," by Mr. J. T. Powell, gr., Park Place, Henley-on-Thames. This proved to be one of the most interesting meetings held by the Association. Mr. Powell, in introducing his subject, referred to the various events for which bouquets were required, and then gave a practical demonstration of the making of a bridal shower-bouquet, explaining which he considered the right method of wiring flowers, &c. Mr. Powell was requested to take up the subject of sprays and button-hole-bouquets at the first ordinary meeting in the new year.

NATIONAL CHRYSANTHEMUM.

THE SHOWS GO TO THE CRYSTAL PALACE.

DECEMBER 29.—A special meeting of the Executive Committee was held at the Royal Aquarium, to receive a report from the Sites Sub committee appointed to inspect suitable places in which to hold the meetings of the Society.

The report set forth that various halls had been inspected, and visits had been made to Earl's Court, Agricultural Hall, &c., some being found inadequate as to size, some difficult of access, while the terms asked for others were practically prohibitory. The committee were still negotiating with a view of securing a suitable place for the business meetings of the Society, and hoped shortly to make a report. Communications had been opened with the Crystal Palace authorities, with the result that a provisional agreement had been come to by which the Board of Directors of the Crystal Palace agreed to the National Chrysanthemum Society holding three shows at Sydenham, the first on Oct. 6 and 7; the second (a large one) on November 10, 11, and 12; and a third show, for two days, during the second week in December. Towards the prize schedules of the first and the last, the Crystal Palace authorities are prepared to give the sum of £25, and medals to the value of £3 at each show; to the large one, in November, the sum of £150, and medals to the value of £10. The necessary staging would be provided, and the Crystal Palace authorities would advertise the show in the daily and weekly papers. The agreement would contain a proviso to the effect that the sum of money given should be paid within twenty-one days of the holding of each show.

In the face of these terms, it was obvious that a revision of the schedules of prizes was necessary, and the committee recommended that the medals of the Crystal Palace Co. should be given to miscellaneous exhibits, supplemented by honorary awards. That all exhibitors in the miscellaneous class should become members of the Society, subscribing a sum of not less than two guineas annually, which would entitle them to exhibit at all the shows held by the Society in any one year, this subscription to take the place of the sum usually charged for space at the November exhibition. That in the cases of the large classes in which unusually large sums of money are offered as prizes, a special entrance fee not exceeding five shillings be charged, in addition to an exhibitors' entrance fee of five shillings, and in addition to the annual subscription.

In order to safeguard the interests of the growers of small collections who enter into the minor classes, it was resolved after a long and somewhat involved discussion, "that in all classes under eighteen blooms in the open and amateurs divisions, an entrance fee of one shilling per class be charged for all entries made at each show of the Society. It was further resolved that affiliated Societies enter for competition in the trophy class on payment of an entrance fee of five shillings. With these modifications, the amended report of the committee was adopted, with the addition of the arrangement that the December exhibitions take place on December 2 and 3, instead of December 9 and 10

ANSWERS TO CORRESPONDENTS.

APPLE-TREES AND RABBITS: *X.* Procure a pailful of whitewash; stir into it a small quantity of soot and clay, or cow-dung, add a wine-glassful of spirits-of-tar, and therewith paint the stems to a height of 3 feet. It may be necessary to renew it in the course of three months, but rabbits do not gnaw the bark of trees when other food can be obtained.

BOOKS: *R. H., Belgrave.* There is no book in the English language on the subject. 1, Ruscus aculeatus; 2, Poa aquatica.

CALLA FLOWER: *J. M.* This condition is not uncommon. We receive many such specimens. —*J. K.* The double-spathed Calla is not uncommon. If it could be fixed it would be valuable.

CHRYSANTHEMUM, VINE, AND CARNATION DISEASED: *J. E. S.* Leptosphæria Ogilviensis, B. & Br., forming black streaks on Chrysanthemum stem. Carnation-leaf disease caused by punctures of aphides. Black spots on Vine-leaf caused by Coniothecium viticolum. Against the fungus employ liver-of-sulphur half an ounce in a gallon of water. The aphis may be killed by fumigation with Tobacco, or the XL-All vapour. *G. M.*

ERICA CARNEA, AND E. C. ALBA: *C. J. H.* The first, a very dwarf, early flowering species, native of Germany; the second, merely a white flowered variety of the same. There are white and pink flowered varieties of E. tetralix, which is a common British species. What you mean by "common pink and white Heather" we do not know, but suppose you mean Calluna vulgaris.

GLASSHOUSES AND GARDEN LABOUR: *A. McK.* You have much more to look after than you can attend to properly, and instead of yourself and and a boy doing the work, there ought to be three men and a boy.

NAMES OF PLANTS: *Correspondents not answered in this issue are requested to be so good as to consult the following number.*—*A. J. R.* 1, Cymbidium Tracyanum; 2, C. giganteum; 3, Cattleya labiata.—*B. C.* Dendrobium speciosum. It will grow well in a warm conservatory; give plenty of sunlight when possible.—*Foreman.* 1, Begonia manicata; 2, B. nitida; 3, B. argyrostigma; 4, B. fuchsioides; 5, Dracæna marginata.—*T. L., Surrey.* One of the hybrids of Rhododendron, like Nobleanum, but whether a named variety or not we cannot say.—*E. T.* Odontoglossum gloriosum, which some authorities include under O. odoratum. Yours is a very good variety of it.—*R. J., Stratford.* Ornithogalum lacteum.—*Enquirer.* 1, Hibiscus Cooperi; 2, Abutilon marmoratum; 3, Begonia incarnata metallica; 4, B. Ingrami; 5, Carex japonica variegata of gardens; 6, Nephrolepis tuberosa.—*F. S.* Dendrobium fimbriatum. —*J. V. S.* Epidendrum (Nanodes) Medusæ.—*Perthshire.* 1, Juniperus communis; 2, Vaccinium myrtillus; 3, V. Vitis-Idæa.—*Poppy.* A species of Protea.

PELARGONIUM-LEAVES BLOTCHED: *E. R.* There is no trace of Melon-leaf blotch present on the Pelargonium-leaves. The fungus is Botrytis. Spray with a solution of permanganate of potash; soak the soil also with the same solution. *G. M.*

PLANTING JAPANESE IRIS (KÆMPFERI) AND BAMBOOS: *E. B.* The Irises may be planted just previous to the commencement of growth, or when growth has almost ceased in early autumn, planting shallow, that is not covering the rhizomes with soil, although a few bits of stone to steady the plants do no harm. In this country it is not advisable to keep them constantly under water. The Bamboos, if imported in autumn or winter, should have the balls of earth and roots soaked in water, and then be potted and placed in the greenhouse for the winter. The soil must not be kept too wet. The leaves, or the bare culms if the leaves have fallen, should be syringed twice daily. Harden off in May, and early in the following month plant them out permanently. Do not disturb the roots at all, even if pot-bound; and apply water at the root in the absence of copious rain.

THE LOT OF THE GARDENER, WAGES, &C.: *A. B., and others.* Nothing that gardeners themselves may do in forming trade unions, mutual help associations, writing letters to the press, &c., will bring about the desired amelioration in the condition of many of the gardeners in small places in this country; and the only way out of the *impasse* is for parents, guardians, head gardeners, and others, to refrain from putting young men and boys to the trade. It would ease the present crowded state of the ranks of gardeners if a few thousands would betake themselves to Canada, and other colonies, where the services of experienced cultivators of the soil would be highly valued, and where the chances of making a good living are superior to what they are in old England.

"WINTER IRIS": *C. J. H.* What is doubtless meant by this term is the new hybrid, early flowering, alpine Irises, raised by Mr. W. J. Caparne of Guernsey, and described by him in *Gardeners' Chronicle*, November 30, 1901, and accompanied by figures of flowers of natural size. They flower very early in the spring.

29	Tu	W. E. Gladstone born, 1809.
30	W	Av. mean temp. at Chiswick, 39·1°.
31	Th	Horse and Dog Licenses expire. Sun rises 8h. 8m.; sets 3h. 59m.

THE GARDENERS' CHRONICLE

("THE TIMES OF HORTICULTURE")

A Weekly Illustrated Journal

(ESTABLISHED 1841)

Among our Correspondents and Contributors to recent Volumes the following, out of many Hundreds, may be named:—

ALPINE AND HERBACEOUS PLANTS:—
ARNOTT, S., Dumfries.
BOWLES, A., Cheshunt.
CORREVON, H., Geneva.
DOD, Rev. C. Wolley, Malpas.
ELLACOMBE, Rev. Canon, Bitton.
ELWES, H. J., Andoversford.
FOSTER, Prof. M., Cambridge.
HARTLAND, Baylor, Cork.
JENKINS, E., Hampton Hill.

AMATEUR GARDENING:—
RENNETT-POË, T. J.
BOYLE, Hon. Mrs. "E. V. B." ("Days and Hours in a Garden").
BULLEY, A. K., Neston.
CORDEROY, Justus
ELLACOMBE, Rev Canon.
FITZHERBERT, G. W.
GUMBLETON, W. E., Belgrove, Cork.
HINDMARSH, W. T., Alnwick.
REDESDALE, Lord.
SCHRODER, Baron Sir Henry.
TILLETT, C., Norwich.
TUCKWELL, Rev. W.
WEIR, Harrison, Appledore.
WILKS, Rev. W., Shirley, Surrey.
WILLIAMSON, Rev. D., Kirkmaiden.

ARBORETUM, &c.:—
ANNESLEY, the Earl of.
ACTON, T., Kilmacurragh.
BEAN, W. J., Kew.
BOOTH, J., Berlin.
CROUCHER, G., Ochtertyre, Crieff.
DUCIE, the Earl.
NICHOLSON, G., late Curator, Royal Gardens, Kew.
POWERSCOURT, Viscount.
RASBLEIGH, J., Menabilly.
SARGENT, Prof., Arnold Arboretum, Cambridge, U.S.A.
STRICKLAND, Sir C., Bart

CHEMISTRY:—
CHURCH, Prof., F.R.S.
DEHERAIN, Prof., the late, Paris.
DYER, Bernard.
MITCHELL, W. S.
MÜLLER, Dr. Hugo, F.R.S.
TRUFFAUT, Georges, Versailles.
WARINGTON, R., F.R.S.
WILLIS, J. J., Rothamsted.

DISEASES OF PLANTS:—
BIDGOOD, John, Gateshead.
BOS, Dr. Ritzema, Wageningen.
COOKE, Dr. M. C.
KLEBAHN, Dr., Bremen.
MASSEE, G., Kew.
MURRAY, G., British Museum.
PLOWRIGHT, Dr. C. B.
PRILLIEUX, Prof., Paris.
SMITH, Worthington G., Dunstable.
SMITH, Dr. W. G., Leeds.
SORAUER, Prof., Proskau.
WARD, Prof. Marshall.

FERNS:—
BAKER, J. G., Kew
DRUERY, C. T., Acton.
HEMSLEY, A.
SCHNEIDER, G., Chelsea.

FLORISTS' FLOWERS, &c.:—
CANNELL, H., Swanley.
DEAN, R., Ealing.
D'OMBRAIN, Rev. H. H., Westwell.
DOUGLAS, J., Great Bookham.
ENGLEHEART, Rev. G., Andover.
HORNER, Rev. F. D.
MOLYNEUX, E., Swanmore Gardens.
PAYNE, C. Harman.
SMITH, Martin, The Warren, Hayes Common.

FOREIGN CORRESPONDENCE:—
ALBOFF, Dr. the late, Odessa.
ANDRÉ, E., Paris
BAILEY, Prof., Ithaca, N.Y.
BARRON, L., New York.
BARBEY, W. Valleyres.
BIERBACK, O., Belgrade.
BOIS, D., Paris.
BOSSCHE, M. Van den, Tirlemont.
BRITTON, Dr., New York.
BUDDE, J. K., Utrecht.
CARLES, W. R., Tientsin.
CHRIST, Dr. Basle.
CORCORAN, M., Odessa.
COSTERUS, Dr., Amsterdam.
CLOS, Prof., Toulouse.
CRÉPIN, late Director, Botanic Garden, Brussels
CRIÉ, Prof., Rennes.
DAHLMARK, N. E., Gothenburg.

FOREIGN CORRESPONDENCE:—
DAMMER, Dr. Udo, Berlin.
DAVEY, J. Burtt, Univ., California.
DEBONO, F., Malta.
DE CANDOLLE, Casimir, Geneva.
DINTER, K., Great Namaqualand.
DRUDE, Prof., Dresden.
ENGLER, Prof., Berlin.
FORSTER, O., Scheibbs, Upper Austria.
FRANCESCHI, Dr., Sta. Barbara, Calif.
GOEZE, Dr., Grietswald.
GRIGNAN, G., Paris.
HANBURY, Comm., La Mortola.
HANSEN, G., California.
HANSEN, Prof. Carl, Copenhagen.
HENRIQUES, Prof., Coimbra.
HENRY, Dr. A.
KERCHOVE, Comte de, Gand.
KOLB, Max, Munich.
KRELAGE, Haarlem.
LAET, Frantz de, Contich.
LEHMANN, H., Popayan.
LEICHTLIN, Max, Baden-Baden.
LEMMON, J. G., Oakland, California.
MACFARLANE, Prof., Philadelphia.
MICHELI, M., the late, Geneva.
MONTEIRO, Chev., Lisbon.
MOTTET, H., Sceaux.
NELSON, W., Johannesberg.
OLIVEIRA, J. D., Oporto.
PAUL, Baron St., the late.
PENZIG, Prof., Genoa.
PIROTTA, Prof., Rome.
PROSCHOWSKY, A. R., Nice.
RODIGAS, E., the late, Ghent.
RODRIGUES, Barbosa, Rio Janeiro.
ROEBELIN, Bangkok.
ROVELLI, Sig., Pallanza.
SCHINZ, Hans, Zurich.
SCHROTER, D., Zurich.
SOLMS, Prof. Count, Strasburg.
SPRENGER, C., Naples.
TRELEASE, Prof., St. Louis.
VAN TUBERGEN, C. G., Junr., Haarlem.
VALLANCE, J., California.
VILMORIN, Maurice de, Paris.
WAUGH, Prof. Amherst, U.S.A.
WIGMAN, Bot. Garden, Buitenzorg.
WILLKOMM, Prof., Prague.
WILSON, E. F., China and London.
WITTMACK, Dr., Berlin.
WITTROCK, V. B. S., Stockholm.

FORESTRY:—
BOULGER, Prof.
BRANDIS, Sir Dietrich, Bonn.
FISHER, Prof., Cooper's Hill.
FORBES, A. C., late of Bowood, Wilts.
FRANCE, C. S., Aberdeen.
MAYR Dr., Munich.
PARDÉ LEON, Senlis.
ROGERS, Capt. H., Plymouth.
SCHLICH, Dr., Superintendent, Forest Department, Cooper's Hill.
SIMPSON, J., late of Wortley.
WEBSTER, A. D., Greenwich Park.

FRUIT CULTURE:—
BALTET, C., Troyes.
BARRON, A. F., late of Chiswick.
MAYNE, J., Bicton.
BUNYARD, G., Maidstone, Kent.
CASTLE, L., Richmond.
CHEAL, J., Crawley, Sussex.
CRUMP, W., Madresfield Court.
MARKHAM, H., Wrotham Park.
RIVERS, T. F., Sawbridgeworth.
ROUPELL, W., Streatham.
TURTON, T., Sherborne Castle Grdns.
WOODWARD, G., Barham Court Grdns.

GARDEN BOTANY:—
BAKER, J. G., F.R.S.
BALFOUR, Prof. B., Edinburgh.
BROWN, N. E., Herbarium, Kew.
BURBIDGE, F. W., M.A., Botanic Gardens, Dublin.
CLARKE, C. B., Kew.
DUNN, S. T., Kew.
DYER, Sir W. T. Thiselton, Director, Royal Gardens, Kew.
ELWES, H. J., Andoversford.
HEMSLEY, W. B., F.R.S., Kew.
HOOKER, Sir J. D., K.C.S.I., late Director, Royal Gardens, Kew.
JACKSON, J. R., late of Museums, Royal Gardens, Kew
LEICHTLIN, Max, Baden-Baden.
LINDSAY, R., Edinburgh.
MOORE, Spencer.
NICHOLSON, George.

FRIEND, Rev. H., High Wycombe.
McLACHLAN, R., F.R.S.
MICHAEL, A. D., F.R.S.
NEWSTEAD, R., Chester.
WATERHOUSE, C. O.
WESTWOOD, Prof., F.R.S., the late.

INDIA AND THE COLONIES:—
ADLAM, R. W., Johannesburg.
BAILEY, Prof., Brisbane.
BIRDWOOD, Sir G.
BOLUS, H., Capetown.
BROADWAY, W. E., Botanical Gardens, Grenada, W.I.
BUCHANAN, D., Mackie, Queensland.
BUTTERS, J. J., Port Elizabeth.
CARRUTHERS, J. B., Ceylon.
CRADWICK, W. Hope Botanic Gardens, Kingston, W.I.
CURTIS, C., Penang.
DUTHIE, J. F., Saharunpore.
FAWCETT, W., Superintendent, Botanical Department, Jamaica.
FORD, C., Hong Kong.
GUILFOYLE, W. R., Melbourne.
HART, J. H., Superintendent, Botanical Department, Trinidad.
HOLZE, M., Adelaide.
IM THURN, Everard, Ceylon.
JENMAN, G. S., the late, British Guiana.
KING, Sir George, F.R.S., late Director, Royal Botanic Gdns., Calcutta.
MACOWAN, Prof., Cape Town.
MACOUN, Prof., Ottawa.
MAHON, F., Brisbane.
MAIDEN, J. H., Sydney.
McMILLAN, H. F., Peradeniya, Ceylon.
MORRIS, D., Imp. Commissioner, W.I.
MURTON, H. J., Siam.
PENHALLOW, Prof., Montreal.
PRAIN Surgeon Major, Calcutta.
RIDLEY, H. N., Superintendent, Botanical Department, Singapore.
STOREY, H., Oodeypore.
TUTCHER, W. J., Hong-Kong.
WOOD, Medley, Botanic Garden, Durban.
WOODROW, C. M.

LANDSCAPE GARDENING:—
ANDRÉ, E., Paris.
CHEAL, J., Crawley.
GOLDRING, W., Kew.
JACKMAN, J., Woking.
MAWSON, H. T., Windermere.
MILNER, H. E., London.

ORCHIDS:—
ALEXANDER, H., gr. Westonbirt, Glos.
BOUND, W. P., Gatton Park
CHAPMAN, H. J., Wylam-on-Tyne.
COGNIAUX, Prof., Nivelles.
COOKSON, N., Wylam-on-Tyne.
DE B. CRAWSHAY, Sevenoaks.
HURST, C. C., Burbage.
KRÆNZLIN, Dr. F., Berlin.
LAWRENCE, Sir Trevor, Bart., M.P., President, Royal Horticultural Soc.
LINDEN, Lucien, Brussels.
O'BRIEN, James.
PFITZER, Prof., Heidelberg.
RENDLE, A. B., Brit. Mus.
ROLFE, R. A., Kew.
ROSS, Comm., the late, Florence.
ROTHSCHILD, Hon. Walter.
SANDER, F., St. Albans.
SMEE, A. H., the late, Wallington.

ROUSDON.

ABOUT midway between Lyme Regis and Seaton, and consequently on the borders of the two counties of Dorset and Devon, stands, close to the coast, on the top of a cliff some 500 feet above the sea, the estate known as Rousdon, the seat of Sir Wilfrid Peek. The estate forms a distinct parish of the same name, but variously spelt—Rousdon, Roosdown, or Rosedown. It contains about 254 acres, and in 1871 had a population of only sixteen, which in 1886 had increased to forty-four. I was unable at the time of my visit to obtain the return of the last census, but considering that the parish and the estate are practically one and the same, the population since the acquisition of the property by Sir Henry Peek cannot be a very fluctuating one. Rousdon is said to be one of the smallest, if not the smallest parish in England, having its own rector—the first rector of Rousdon dating from 1279. The value of the living was given in the King's Books at £2 10s., but prior to the advent of Sir H. W. Peek, and the erection by him of the new church, the advowson was a sinecure, no services having been held in the old church for many years. It is recorded, indeed, that the building had been degraded to the use of a farm-cellar and outhouse. It is unfortunate, however, that there is no trace of the old building left, which was it is stated, in the perpendicular style of architecture. The style of the new church has been described as a combination of Franco-Norman, Early English and Decorated, and the value of the living has been brought up to £303 with house. It is difficult to conceive a more compact estate, for here is not only dwelling-house, but church, parish-schools, a museum and observatory, in fact, a whole parish, which is adjoined to that of Axmouth, situated as its name indicates at the mouth of the river Axe, which, rising at Chiddington, near Crewkerne, winds its tortuous way, forming loops and double loops through the valley around Axminster, till it enters the sea at Axmouth, covering a distance of about 23 miles in a direct line, but extending to 50 miles by its winding course.

Rousdon was purchased by Sir Henry Peek in 1871, and the mansion was commenced about that time and completed in 1883, costing, it is said, some £70,000. It is in the Elizabethan style (fig. 8), and whether looked at from the land or sea-front, has a decidedly imposing appearance. It is built of grey flint with Purbeck stone dressings The south front is about 200 feet in length, at the north-east angle is a tower about 90 feet high; from the south front there is an unlimited sea view, and also an extensive view of the coast line of Dorset and Devon from Portland Bill on the east to Start Point on the west, presenting some of the finest coast scenery in England, and showing the chalk formation of Portland and the dark red cliffs of Budleigh Salterton, Exmouth, and Dawlish. Almost contiguous to Rousdon is one of the most romantic "bits" of scenery on the coast, known as the Landslip, which consists of a portion of the cliff about a mile long, from seventy to eighty yards wide, and from 100 to 200 feet in depth. This enormous mass of cliff separated from the mainland on Christmas-day, 1839. It is now covered with a luxuriant growth of vegetation, and forms a really wild bit of country.

Returning to a further consideration of the mansion for the purpose of showing the wide scope of Sir Henry Peek's plans, it may be stated that the interior decorations are of a sumptuous nature. The banquetting-hall is of great richness and beauty, the windows are filled with coloured glass representing historical portraits and local historical events. This hall is said to have been the scene of many notable gatherings. The library faces east, and is filled with many thousands of valuable works. The museum collection, which occupies one of the largest rooms in the mansion, is of a very varied character, consisting of fine examples of Chinese and Japanese art workmanship, weapons from the Pacific Islands as well as from eastern and central Africa; besides which there is a fine collection of British birds, said to be one of the most complete in England—indeed it is stated that out of the list of British birds enumerated by the British Ornithologists' Union, five only are not represented in this collection.

Another branch of science, and that an important one, which receives a considerable amount of attention at Rousdon, is that which is carried on in the well equipped Observatory. This building "stands upon a plateau, at an elevation of 516 feet above mean sea-level, and about a quarter of a mile back from the cliff. To the south there is an uninterrupted horizon over the English Channel; to the west and north-west are the distant hills of Devon; and to the east and south-east are the distant Stonebarrow Hills, Golden Cap, and the high land of Portland. No better position could be found for astronomical observations. The situation is, however, much exposed, and as the building encounters the full force of the south and south-westerly gales which sweep the Channel, it was necessary that it should be of a substantial character, a condition which is met by a construction of teak-timber framing, filled in with cement concrete between the timbers, and resting on a base of stone with flint facing."

The observations made at the observatory, which is classified as a Second Order Station of the Royal Meteorological Society, are regularly transmitted to, and published in the returns of the Society. Eighteen annual volumes of observations have been published, first, under the superintendence of the late Sir Cuthbert E. Peek, F.R.Met.Soc., and since his death by the Hon. Lady Peek, who is also a Member of the Royal Meteorological Society. It is necessary to say that in this work they have been most ably assisted by Mr. C. Grover, who is in charge of the Observatory, and to whom I am indebted for much of the information already given, as well as for the photographs.

Altogether, Rousdon is an ideal modern estate, and as such its founder has had all the most recent appliances introduced for the comfort and advantage of the residents. Thus, on entering the garden department, over which I was most courteously conducted by Mr. W. E. Bailey, the head gardener, I was shown the bothies, where sleeping accommodation is provided for five men in separate cubicles, dining-room, kitchen, and a room set apart as a hospital; also a good lofty and spacious reading-room, well stocked with books in general literature, together with newspapers. The whole of the fittings of this building are of stained and varnished Pine. The same conditions of space, airiness, cleanliness, and good repair were shown in all the potting and packing sheds, as well as in the conservatory and other glasshouses and frames. It is possible that some of the houses may not be up-to-date as to the most recent requirements for perfect culture, but everything has been well carried out, and kept in good order and condition. The same may be said of the plants themselves, for though nothing is grown of a special character, and flowers and fruit are cultivated only for the supply of those on the estate, all the contents of the glasshouses and grounds appear to have an equal share of attention. Gloxinias and Begonias, both single and double, were at the time of my visit at the beginning of August making a fine show. The plants, not being crowded as is too often seen, were, so to speak, individualised, so that the shape and growth of each showed compactness, uniformity, and health. The same may be said of a group of Kalanchoe flammea which, I was informed, had been in flower for a period of six weeks. A group

of red and yellow Celosias were prettily arranged, and produced a striking effect. In the Camellia-house, which is a spacious building, I was struck with the numerous pendent baskets filled with a luxurious growth of the beautiful Asparagus Sprengeri. Nor does the floral or decorative side of the garden seem to occupy Mr. Bailey's whole attention; Melons, Grapes, and the usual fruits are grown with equal success, though he told me that Apricots do not succeed at Rousdon.

In this part of Devon the Bay Laurel thrives as a hedge plant more or less in many gardens, but the finest one I have seen is that along one side of the kitchen garden at Rousdon — a thick, compact, healthy green hedge between 4 and 5 feet high, and 300 feet long. Nor is this the only hedge worth noting, for in another part of the gardens is one equally well grown of about the same height, and of great length, entirely of Escallonia macrantha, which was beautifully in flower at the time of my visit; and still again another hedge, of Cotoneaster microphylla, which droops over a 4-feet wall on to the main road on each side of the lodge gates. The garden also possesses two pergolas: one of these, about 500 feet long, is chiefly covered with Cotoneaster Nummularia, which was intended to be used entirely, but the plant, it is said, was found to have an injurious effect upon the men engaged in cutting it. The second pergola is covered with trained fruit-trees.

In concluding the notice of this interesting place, it should be stated that included in the plan of Sir Henry Peek's scheme when laying out the estate, a school was erected for the children of the parish as well as model farm-buildings and houses for cottagers; further, each child attending the school is given half-a-pound of nutritious food at noon every day.

Besides those already mentioned as lending me much assistance on the occasion of my visit, I have to thank the Hon. Lady Peek for courteously giving me permission to view the grounds. *John R. Jackson. Claremont, Lympstone, Devonshire.*

FIG. 8.—VIEW OF ROUSDON. (SEE P. 17.)

NEW OR NOTEWORTHY PLANTS.

BURLINGTONIA PERPUSILLA, *Kränzlin.**

THIS singular little Orchid belongs undoubtedly, by the form and structure of the column, to the genus Burlingtonia; the other parts of the flower, reduced to minimum dimensions as they are, do not contradict their systematical position. Burlingtonias, generally speaking, do not range among the "great Orchids," the best of them being medium-sized, but making a tolerable effect when arranged a dozen bulbs or more in a pot. The little plant now in question seems to have a very clear conscience of its smallness, and forms dense tufts in the way of the smaller Masdevallias, as the only chance of not being overlooked. Nevertheless, a Burlingtonia scarcely 1 inch in height is very difficult to be seen, and this is why the plant has been overlooked for so long, even in the neighbourhood of Campinas, a well-known Coffee-producing place. The plant flowered at the beginning of November in the Botanical Garden at Darmstadt. I received from Mr. Purpus, inspector of the garden, several Brazilian Orchids, all collected at the same place, and all well known since many years, except this little thing. *Dr. F. Kränzlin, Berlin.*

RHIPSALIS GRACILIS, *N. E. Brown (n. sp.).*

This species has probably been in cultivation for several years, as it is the plant which is erroneously figured and described by K. Schumann

* *Burlingtonia perpusilla, Kränzl., n sp.*—Planta pusilla dense cæspitifica, foliis infrabulbosis brevi-articulatis, lamina ut illa bulborum terete subulata; bulbis brevi-ovoideis vivis profunde rugosis ad 5 mm. (4 lines) longis, 3 mm. (2 lines) crassis, læte viridibus, foliis infrabulbosis 2 cm. (10 lines) longis, 1—1 5 mm crassis, densissime purpureo-adspersis, racemis ex axilla cataphylli scariosi albidi orientibus pauciforis (3—4), rhachi fractiflexa; bracteis minutis; sepalo dorsali petalisque subsimilibus oblongis acutiusculis, sepalis lateralibus sublatioribus oblongis apice obtusis basi excavatis mentulum formantibus; labello simplice ligulato antice triangulo acuto; gynostemio brevi, brachiis quam ipsum longioribus protensis acutis; anthera 1-loculari longe producta antice retusa, polliniis 2 parvis, caudicula longa filiformi, glandula angusta, rostello longo ornithorhyncho. Flores minuti albi roseo-suffusi et minutissime punctulati, omnes partes vix 4 mm (2 5 lines) longæ—Brazil, Sta Caterina, near Campinas.

as R. penduliflora, and is probably known by that name on the continent, although totally different from that species; and as I cannot discover that it has been published under any other name, I describe it as new. Two nice plants of it (which differ slightly in habit, one being more compact than the other) have been presented by Mr. Justus Corderoy, of Blewbury, Didcot, to the Royal Gardens, Kew, where they have been in flower for some time past.

Main stems with internodes 3 to 11 inches long, 1⅓ to 1⅔ lin. thick, and main branches 1 to 4½ ins. long, ⅔ lin. thick, terete, smooth, glabrous. Ultimate branchlets very slender, pendulous, ¾ to 1 inch long, between ½ and ⅔ lin. thick, terete, not thickened towards the ends, light green, smooth, with a few minute scattered white scales ⅛ lin. long, and about ⅓ lin. broad, transversely oblong, subtruncate or with a very minute apiculus, often with one bristle-like hair ⅓ to ½ lin. long in their axils, and sometimes also a few very minute woolly hairs. Flowers one or two to a branchlet, terminal or lateral a little below the apex. Ovary 1 lin. long, subglobose, smooth, light green, glabrous, not immersed. Perianth-segments six, unequal, ¾ to 2 lin. long, ⅔ to 1 lin. broad, oblong, obtuse, recurved-spreading, whitish, semi-transparent. Stamens about thirty, erectly spreading, 1¼ to 1½ lin. long, whitish. Style about 1½ lin. long, whitish; stigma three-lobed; lobes ovate, acute. *R. penduliflora*, K. Schum., in *Fl. Bras.*, vol. iv., pt. 2, p. 276; and *Monog. Cact.*, p. 628; not of N. E. Br. *N. E. Brown.*

ORCHID NOTES AND GLEANINGS.

MAXILLARIA PUNCTATA.

A PRETTY variety of this floriferous and fragrant-flowered Orchid is in bloom in the garden of Ludwig Mond, Esq., The Poplars, Avenue Road, Regent's Park, the densely set flowers on short stalks almost concealing the pseudo-bulbs from the bases of which they rise. There is great variation in size, and in the density of the spotting of the flowers of this species, some of the larger forms being nearly equal in size to those of M. picta. The flowers, of cream-white to pale yellow tints, have small purple spots on the segments. Mr. J. O. Clarke, the gardener at The Poplars, attributes the great profusion of flowers on this plant, and the regularity with which they are produced, to the fact that he grows it in a basket suspended near the glass of the roof in a cool intermediate-house. Generally the species is grown in pots.

SOPHRO-LÆLIA × PSYCHE.

An inflorescence of this brilliantly coloured hybrid between Sophronitis grandiflora and Lælia cinnabarina is sent by Messrs. Charlesworth & Co., of Heaton, Bradford, the raisers, who state that the plant is a very satisfactory grower and profuse bloomer. The flowers are of that brilliant dark scarlet seen in the best forms of Sophronitis grandiflora, and the form of the flower more nearly approaches Lælia cinnabarina, on which in every respect it is a great improvement. Messrs. Charlesworth state that they have never had an unsatisfactory cross with Sophronitis grandiflora, some of the crosses with it, such as Sophro-Lælia × heatonensis, being their most brilliant autumn and winter flowers.

BULBOPHYLLUM CAREYANUM.

A pretty variety of this Burmese Orchid is sent by Mr. J. W. Moore, Cragg Royd Nurseries, Rawdon, near Leeds. The species, as formerly known, varied much in colour, ranging from yellow spotted with red to greenish-brown; but a small lot sent by Mr. Moore's late brother, who was instrumental in introducing so many good Indian Orchids, bore densely set cylindrical, elongated spikes of white flowers, tinged and speckled with rose colour. The variety now sent is the best in colour of this rose-tinted type, and a much more worthy plant for garden purposes than the older and duller-coloured form; it is a very free grower, and would thrive suspended in a warm conservatory.

ONCIDIUM GARDNERI AND ALLIES.

These handsome Brazilian Oncidiums, chiefly from the Organ Mountains, were at one time considered difficult plants to grow, until it was found that suspended in a cool intermediate-house they do remarkably well. Until the last few years they used to be rare in gardens, but on their durable flowers being found excellent for florist's purposes, importers turned their attention to them again. In the nursery at Southgate of Messrs. Stanley, Ashton & Co., the largest importers of these Brazilian Oncids, there is nearly always a quantity of them in flower. Even in this dull season there is a good show of the fine, fragrant, brown and yellow blooms. O. Gardneri (fig. 9), and its ally O. curtum, are among the best, although the flowers of O. crispum, O. Forbesii, and O.

FIG. 9.—ONCIDIUM GARDNERI.

prætextum, are larger. Their Brazilian collector has also sent a large lot of reputed hybrids of the O. × Mantini and O. calophyllum class. There are also large numbers of the clear yellow O. concolor.

LÆLIA × AUTUMNALIS CINNABARINA.

A flower of a singular hybrid between Lælia cinnabarina and L. autumnalis is sent by Eustace F. Clark, Esq., Teignmouth, after whose son it is named. At first sight it might be taken for a rather small L. autumnalis, with all the segments narrower than usual, the colour, unless closely examined, being also similar to that species. The sepals and petals are rosy-lilac, with a very faint tinge of copper colour. The side lobes of the lip are yellowish-white tipped with rose, and with several purplish lines at the base; the disc chrome-yellow, and the ovate front lobe rose-purple. Although the evidence of L. cinnabarina is not so clear as might be expected, there are traces of it in the wavy-edged front lobe of the lip, the deeply cleft side lobes, and in the coppery shade over the other segments, the copper tint deepening as the flower decays until the lilac tint is lost. This assertion of an almost obliterated agent in a hybrid may often be found by watching the change in the flower as it fades. The pseudo-bulbs are said to be longer than those of L. autumnalis. It is illustrated in a recent issue of *Iconographique des Orchidées*. *J. O'B.*

NOVELTIES OF 1902.

(*Concluded from p.* 3.)

STOVE AND GREENHOUSE PLANTS.—The novelties in this class consist chiefly in improvements in favourite decorative plants rather than in really new introductions.

Messrs. Jas. Veitch & Sons, of Chelsea, as in former years, have made great improvements in winter-flowering Begonias, Gloxinia-flowered Streptocarpus, greenhouse Rhododendrons, showy Phyllocacti, and other flowers, especially their fine strain of Hippeastrums, several of which have received certificates during the year, the best being Sylvanus, Nysa, Mrs. Bilney, Queen Alexandra, and General Buller.

In Hippeastrums too, Captain Holford, C.I.E., of Westonbirt (gr., Mr. A. Chapman), showed many fine varieties; and this ornate class of flowers is being worked by several other growers.

Messrs. Sander & Sons, of St. Albans, had produced a number of new plants during the year, a fine selection of them being shown in their remarkable group at Holland House. Those specially noted were Helicenia Edwardus Rex, with large entire leaves of metallic copper colour, with polished red mid-ribs, the older leaves passing to olive-green; Dracæna Alexandræ, a stately plant of the D. Massangeana class, but with narrower and more recurved leaves, green, striped with cream-yellow; Ficus pandurata, of the habit of the useful "India-rubber plant," but with broadly pandurate dark green leaves; Alocasia Alexandra Regina, a hybrid raised by Messrs. Sander out of A. Sanderiana, and a really distinct and strikingly handsome novelty; and Alocasia Sandersoni albescens, a showy plant, the spathes of which are nearly white.

Mr. William Bull of Chelsea, showed the new Epiphyllum delicatum, Hydrangea Hortensia nivalis, and other novelties, and most of the other firms produced good novelties, the greater part of which are enumerated in the appended list of new and rare plants illustrated in the *Gardeners' Chronicle* in 1902.

HARDY PLANTS.

The good varieties and novelties in Roses, were fully enumerated in the articles in the *Gardeners' Chronicle*, Dec. 6 and Dec. 20, 1902, and Chrysanthemums and other florists flowers have been recently dealt with in like manner; there remains therefore but to set forth some of the best incidental introductions of the year.

Messrs. Jas. Veitch & Sons are getting good results from their introductions from China, and some of the best plants of the year are among them. Good introductions of Messrs. Veitch are Astilbe chinensis Davidi, Moschosma riparium, Senecio clivorum, Libocedrus macrolepis, Primula imperialis, Corydalis thalictrifolia; and among other good novelties shown, Narcissus Mrs. H. J. Veitch, a monster Golden Ajax, and other new varieties. Narcissi secured many awards at the hands of the Narcissus Committee, chiefly to varieties of these charming flowers shown by Miss Willmott, the Rev. G. H. Engleheart, Messrs. Barr, and Messrs. Veitch. Some Tulips also received recognition, and among pretty dwarf Iris, Miss Willmott received awards for Iris Warleyensis, and I. bucharica, and also for the new Fritillaria askhabadensis.

NYMPHÆAS

increase in favour, and the coloured and hybrid Water-Lilies now form fine features in many gardens. The earlier rose-coloured and crimson forms were so good that it is difficult to get novelties which are improvements on them. Shades of blue and purple have been the colours aimed at, and the Nymphæa (stellata) "W. Stone," violet coloured with yellow centre, for which Mr. Jas. Hudson, gr. to Leopold de Rothschild, Gunnersbury House, Acton, secured a First-class

Certificate at the Temple Show, and his Nymphæa "Mrs. Ward," a rosy-purple, which also secured an award, are very fine new departures.

ASTERS

of the "Michaelmas Daisy" class are now receiving much attention, and the Floral Committee selected eight from those on trial at Chiswick for awards, chiefly to Mr. Beckett, and Miss Willmott, on September 24; and other varieties have come into prominence.

DAHLIAS

supplied many novelties, chiefly in the "Cactus" class.

Mr. Jas. Douglas and others secured Awards for new Carnations, Auriculas, &c., and Messrs. Kelway, Cannell, Turner, H. J. Jones, and other

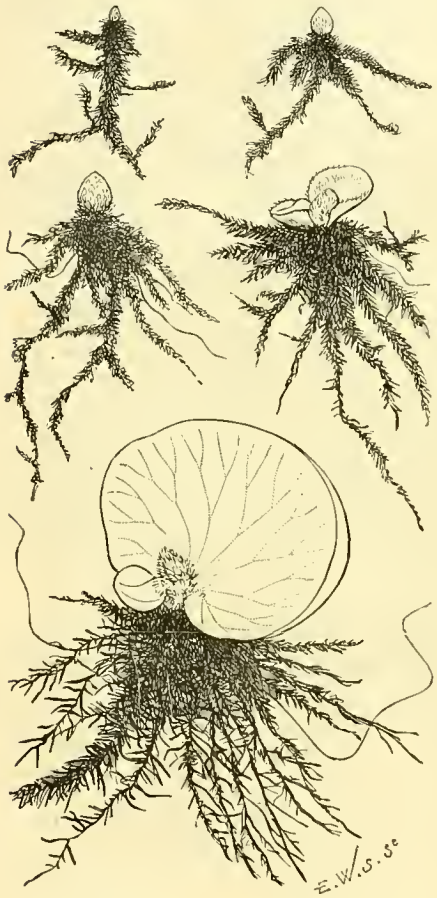

FIG. 10.—PRODUCTION OF BUDS ON ROOTS OF PLATYCERIUM (*W. Watson*). (SEE P. 21.)

great florists, have done good work in the production of novelties. Perhaps the most useful of all are the numerous novelties in flowers to be obtained from seeds. Messrs. Sutton of Reading, Messrs. Jas. Veitch & Sons, Messrs. Carter, and a few other large firms, exercised wonderful skill and patience in selecting and perfecting the strains of the very large number of florist's flowers they grow, and last year there was a good proportion of novelties in all the large classes.

Bulbous plants are specialties of Messrs. Wallace of Colchester, famous for their Lily and Calochortus culture. Iris Sofrana magnifica, Freesia aurea, Henchera brizoides gracillima, and others have been Certificated to them.

The following new or rare plants were illustrated in the *Gardeners' Chronicle* in 1902—

Acanthus arboreus, April 5, p. 222.
Anthurium seedlings, June 14, p. 395.
Apple "Norfolk Beauty," December 20, p. 453.
Apple "The Houblon," January 4, p. 11.
Archontophœnix Alexandræ, Jan. 11, p. 19.
Aristolochia pontica, May 24, p. 335.
Aster Novi-Belgii floribunda, Oct. 11, p. 258.
Aster Novi-Belgii Perle Lyonnaise, Oct. 11, p. 259.
Aster Shortii, October 11, p. 269.
Astilbe chinensis Davidi, August 9, p. 103.
Banana, "The Ribu-Ribu," Dec. 27, p. 471.
Begonia Buisson Rose, March 29, p. 204.
Begonia crested, November 29, p. 395.

FIG. 11.—PLATYCERIUM WILLINCKII.
Showing the erect, sterile fronds and the pendulous fertile fronds with spore-cases, &c. (see p. 24

Begonia Perle Lorraine, March 29, p. 205.
Calochortus, six species and varieties, Supp., February 16.
Celmisia coriacea, September 13, p. 191.
Cereus dasyacanthus, October 4, p. 252.
Cereus Houlleti, October 4, p. 253.
Cereus senilis, July 19, p. 35.
Chimaphila maculata, November 1, p. 318.
Chrysanthemum indicum, wild form, May 10, p. 302.
Chrysanthemum morifolium, wild form, May 10, p. 302.
Chrysanthemum Nellie Pockett, November 8, p. 334.
Cineraria cruenta, and florist's var., May 10, p. 305.
Citrus medica digitata (Buddha's Fingers), August 2, p. 71.
Clematis aristata, July 26, p. 55.
Clematis florida, July 26, p. 51.
Convallaria majalis prolificans, Aug. 23, p. 133.
Corydalis thalictrifolia, Supplement, Oct. 18, and p. 289.
Cotoneaster horizontalis, August 9, p. 91.
Crab, the Langley, December 13, p. 435.
Crocus Scharojani, November 1, p. 321.
Dædalacanthus parvus, October 25, p. 311.
Dahlia President Viger, September 13, p. 190.
Dermatobotrys Saundersii, February 22, p. 131.
Drymophlæus Normanbyi, January 11, p. 21.
Echinocacti and Melocacti, July 19, p. 34.
Epiphyllum delicatum, December 6, p. 411.
Erica propendens, October 18, pp. 278, 279.
Exacum Forbesii, February 8, p. 93.
Exogonium purga, November 1, p. 319.
Fritillaria askhabadensis, April 12, p. 238.
Hæmanthus imperialis (Linden), Feb. 8, p. 99.
Helichrysum Guilielmi var. Meyeri, Jan. 4, p. 2.

Helichrysum Volkensii, March 15, p. 170.
Hydrangea Hortensia nivalis, Dec. 20, p. 455.
Iris bucharica, June 14, p. 387.
Iris Leichtlini, October 4, p. 242.
Iris Warleyensis, June 14, p. 386.
Latania aurea, Supplement, March 1.
Layia (Tridax) Gaillardioides, July 26, p. 61.
Lindenbergia grandiflora, September 20, p. 213.
Livistona Muelleri, December 13, p. 431.
Lycoris Sprengeri, Supplement, December 27.
Meliosma myriantha, January 11, p. 31.
Moschosma riparium, February 22, p. 122.
Musa Wilsoni, December 20, p. 451.
Primula sinensis, wild form, cultivated, April 26, p. 271.
Primula viscosa Spring Beauty, May 3, p. 297.
Pteris aquilina varieties, Sept. 27, p. 227.
Raspberry November Abundance (Veitch), Nov. 22, p. 375.
Rodgersia pinnata, August 23, p. 131.
Rosa Banksiæ, wild form, June 28, p. 439.
Rosa indica, wild form, June 28, p. 438.
Rose Auguste Barbier, July 5, p. 9.
Rose Frau Karl Druschki, Dec. 6, p. 421.
Rose Lady Roberts, July 5, p. 2.
Rose Mrs. Oliver Ames, July 5, p. 3.

CHINESE MAPLES.

The Maples of Central China are a good example of the extraordinary richness of the flora of that region. During an excursion which I made in 1898 in the mountains of Hupeh, I found sixteen species of Acer, of which nine turned out to be new species. On this trip I also discovered Dipteronia, a new genus, which differs from Acer in having the fruit winged all round, and in having leaves which are pinnate with many pinnæ. Recently I have been looking through a bundle of specimens of Maples brought home by Mr. E. H. Wilson from Hupeh, and I find that he has obtained several species which escaped my notice. In Yunnan, 10° to the south, a second species of Dipteronia has turned up. In the highly mountainous and unexplored provinces of Kweichow, Hunan, and Kwangsi, lying somewhat between my two collecting points, Ichang and Mengtsz, I expect numerous additional species of Maple and Dipteronia to occur.

As many of these Maples are now in cultivation at Coombe Wood, some remarks concerning them will be timely. But first with regard to Dipte-

Fig. 12.—Platycerium grande. (see p. 24.)

Narcissus Margaritæ "Iolanda," Mar. 15, p. 172.
Narcissus Peter Barr, May 3, p. 295.
Narcissus Sprengeri elmensis, March 15, p. 173.
Narcissus Sprengeri vomerensis, March 15, p. 173.
Passiflora actinia, July 12, p. 15.
Passiflora ambigua, March 15, p. 171.
Passiflora maculifolia, Mast., Supp., Nov. 8.
Pinanga Kuhlii, Supplement, Feb. 8.

Pinus Laricio var. pindica, May 10, p. 304.
Podocarpus chilina, Supplement, Feb. 15.
Podocarpus nubigena, with male catkins, Feb. 15, p. 114.
Primula sinensis, wild form, April 26, p. 270.
Rose René André, October 18, p. 283.
Scolopendrium vulgare Drummondiæ superbum, January 4, p. 5.
Senecio clivorum, Supplement, September 20.
Shortia uniflora, May 24, p. 337.
Sparaxis Fire King, July 5, p. 8.
Stapelia bella, March 1, p. 138.
Streptocarpus multiflora, November 1, p. 327.
Trichinium Manglesii, September 6, p. 181.
Tulipa ingens, July 12, p. 14.
Tulipa Micheliana, May 31, p. 353.
Tulipa nitida Gesneriana var., May 31, p. 151.
Typhonium giganteum Giraldi, August 30, p. 151.
Viburnum Carlesii, October 11, p. 261.
Washingtonia filifera, January 18, p. 39.

ronia, there is no doubt of its close affinity to Acer; and Pax, the latest monographer, confines the tribe or sub-order Aceraceæ to these two genera, out of which has been thrown the curious Himalayan Dobinea. This genus has been transferred to Anacardiaceæ. The American Negundo, with three species, is now reduced to Acer; it differs in floral structure from the Asiatic trifoliolate Maples; and it is only in a popular sense that the name Negundo can be applied loosely to all Maples with tri-foliolate or pinnate leaves.

DIPTERONIA.

This genus includes two species. They are trees with opposite imparipinnate leaves, serrate in margin. The flowers are polygamous, and disposed in terminal panicles. The fruit consists of two carpels, diverging and connate at the base, each being surrounded by a membranous wing all round. In each carpel there is a solitary exalbuminous seed.

1. *Dipteronia sinensis*, Oliver.—A tree of central China, now in cultivation in Coombe Wood. It occurs in Hupeh mountain forests at considerable elevations, and will be hardy in this country. The leaves have four to seven pairs of lanceolate or ovate-lanceolate leaflets, which are petiolulate or subsessile; and they are sharply serrate. Each fruiting carpel is obliquely obovate, about an inch long by ¾ inch broad. The leaves and inflorescence are glabrous; occasionally, however, the leaves have a slight pilose pubescence.

2. *Dipteronia Dyerana*, Henry (*nov. sp.*).—This was found, only once, in the forests east of Mengtsz in Yunnan, at about 7,000 feet elevation, occurring as a small tree 10 feet high. It possibly attains much larger dimensions, as in China many trees which grow to a great size, flower at an early period. The flowers are unknown. It is easily distinguished from the last species by its pubescent leaves and inflorescence, and its very large fruit.

The following description is drawn up from my specimen, No. 11,352, in the Kew Herbarium: A small tree, 10 feet high. Leaves opposite, imparipinnate, with six or seven pairs of pinnæ, about a foot long, including a petiole of 4 inches long. The leaflets are opposite, subsessile, ovate-lanceolate, from an oblique base, and terminating in a long acuminate apex; the margin has a few distant sharp serrations. The petiole; also the mid-rib and veins of the underside of the leaflets, are beset with a dense brown pubescence; on the upper surface the veins are slightly pubescent. The inflorescence is a broad terminal panicle, covered with a dense brown short pubescence. The fruit, that of the genus, consists of two divergent carpels, connate at the base, the solitary seed being imbedded in each carpel in the centre of a membranous orbicular wing. The carpels are each about 2½ inches broad by 2 inches long. The seed is ½ inch wide and ⅜ inch long, and is reniform in section with a cordate base.

I associate this interesting plant with the name of the Director of Kew, whose help and encouragement to me during many years have been constant and invigorating. *Augustine Henry.*

(To be continued.)

Showing portion of fertile frond with sori; sporc-cases, spores, stellate hairs, &c. (See p. 24)

The Week's Work.

THE ORCHID HOUSES.

By H. ALEXANDER, Orchid Cultivator to Capt. G. L. HOLFORD, Westonbirt, Tetbury.

Cleansing of the Houses and Plants.—The present month affords a suitable time for cleansing the plants and houses in every part, and the various operations should be pushed on with vigour. In smoky parts of the country and the suburbs of big towns, the deposit of greasy blacks on the roofs and sides of the houses should be removed by washing, and the interiors washed with soap-suds and petroleum. Clear away all rubbish from beneath the stages, which if allowed to remain forms hiding-places for cockroaches, woodlice, ants, &c. After the cleansing of the walls, glass, and wood-work is finished, that of the pots and pans should be undertaken; and finally the plants may be freed from scale and mealy-bug. For destroying the latter, apply methylated spirits with a soft camel's-hair pencil a few hours before the plants are washed with warm water and a piece of sponge. There are many insecticides on the market that are perfectly safe to use on plants, if care be taken not to use them of so great a strength as the directions given with them advise. Brown and white scale infest Lælias and Cattleyas, concealing themselves under the outer sheathing of the pseudo-bulbs. In cases of bad infestation this sheathing must be stripped off, and methylated spirits applied to the scale insects. When the plants are staged anew, let them be so arranged that each obtains its due share of sunlight as far as is practicable. Thrips in some gardens give much trouble during the winter months, but frequent vaporising with XL-All will lessen their numbers considerably; and ants cause a lot of harm by carrying insects—mealy-bug, black scale, &c., from place to place as food. Here we are troubled very much with ants; the best remedy that has come under my notice so far is Vall's Beetle-traps, an article obtainable at most chemists. This is likewise one of the finest means for eradicating cockroaches and wood-lice from Orchid-houses.

The Resting of Orchids.—Many of the plants are now at rest more or less, and as a consequence no plant is in need of much moisture; nevertheless, any excessive drying of the materials should be avoided. The gardener should make an inspection of the potting materials, condition and number of the roots, the size of pots, &c., how much water may be afforded, so as to keep the pseudo-bulbs plump and the roots healthy. Avoid the practice of applying water to the surface, but leaving the roots at the bottom of the pot in a perfectly dry condition, a state of things that is responsible for the loss of many of the roots. In the case of a healthy plant possessing plenty of foliage, and many roots becoming dry, the better practice is to plunge the pot up to the rim in a vessel of tepid water. This is, however, inadvisable if a plant is potted in leaves, with only one crock for drainage, as it might cause the death of the plant; but plants with many roots which are afforded ample drainage materials will take a fair supply of water during the resting season to keep them healthy.

THE KITCHEN GARDEN.

By JOHN FLEMING, Gardener to Sir C. PIGOTT, Bart., Wexham Park, Slough.

The Mushroom House.—Collect fresh horse-dung and short litter from the stables for the making of a new bed, spreading these in an open shed, cart-house, &c., in the form of a flat heap about a foot thick, and allow the mass to ferment and get rid of the more rank ammonia, hastening the process by turning it once in two days. When sufficiently sweetened, if the manure is somewhat wet, add one barrow-load of dry loam to every five or six of the manure, when constructing the Mushroom-bed, thoroughly mixing the two together. A Mushroom-bed may be 1¼ to 1½ feet in depth, the materials being beaten together firmly with a spade or mallet as the work proceeds. Having made the bed of the required size, let it alone till the warmth has gone down to 80° as tested with a bottom-heat thermometer, and a this degree of warmth the bed may be spawned. Break up the bricks of spawn into pieces 1½ inch square, and insert these in shallow holes made at intervals of 8 inches apart, and cover with a handful of the materials. Place a thin covering of long litter on the bed, and leave it for one week, when it may be covered with adhesive sifted loam to the depth of 1½ inch, making it firm and smooth, and replace the litter. The soil should be warmed before it is applied. The temperature of the house may range from 55° to 60°, and the air kept moist by damping the walls and paths with tepid water.

Potatos for very early forcing may be grown in pots; medium sized sets being selected of such varieties as Sutton's May Queen, Sharpe's Victor, or Veitch's Early Ashleaf. After the eyes or buds have grown to about an inch in length, they are ready for planting. A useful pot is one of 10 or 12 inches in diameter, these being readily portable. A light compost should be used, preferably one consisting of loam one part, leaf-soil two parts, and spent-bed Mushroom materials one part, with a good sprinkling of wood-ashes. Let the pots have good drainage, and be half filled with soil pressed down firmly. Reduce the eyes to one, the strongest; and place three sets in each pot, putting the soil to three-quarters of the depth of the pots, which will leave space for a manurial mulch later on. Place

in a house or pit having a temperature of 50° to 55° by day, and a somewhat lower one by night; anything stronger than this at the start pushing the top-growth too much in advance of the roots, and if the stems get drawn or weakly, tubers do not readily form. Potatos planted last month in pots or mild hotbeds should be afforded all the sunlight possible, and kept close to the glass. Afford air more or less according to the state of the weather, and apply water sparingly; adding fresh soil when earthing becomes requisite, covering the glass at night when the weather is severe.

PLANTS UNDER GLASS.

By J. MAYNE, Gardener to the Hon. MARK ROLLE, Bicton, Budleigh Salterton, Devonshire.

Chrysanthemums.—The middle of the present month is a good time to insert cuttings of these plants, choosing sturdy shoots growing at the base of the stock plants, discarding weakly shoots or those having flower-buds. The cuttings should be from 2½ to 3 inches in length, and be cut close under a joint, and be inserted singly in 2-inch pots, or four in a 3-inch pot, around the sides, which should be clean, and carefully crocked. The soil may consist of about equal parts of loam and leaf-soil, with a liberal addition of river or coarse silver-sand, with just a sprinkling of sand on the surface to work down with the dibber. Make the cuttings firm in the soil, and apply water with a fine rose can. In Devon, the cuttings may be rooted in cold frames, but a surer method to employ anywhere is to erect long, narrow propagating-boxes on the stage of a glasshouse having a temperature from 40° to 50°; cover the bottom with finely sifted coal-ashes, and cover with close-fitting sashes or large panes of glass, kept in place by a few tacks. No shading is necessary, but the glass must be kept clean, and the condensed moisture wiped off the glass every morning. Water will, as a rule, not be required till rooting takes place; but should any of the cuttings droop while the sun is on them, a light syringing will revive them. Four to six weeks generally will elapse before roots form, and when this is seen to be the case, the plants should be removed to other frames or hand-lights, where a small quantity of air can be admitted to them, the quantity being increased daily. In about ten days, stand the cutting-pots on shelves near the glass, but away from cold draughts.

Roses in Pots, &c.—Roses should be pruned a few weeks previously to putting them into a forcing-house, and the plants should have been established in pots for, at the least, one year, otherwise the blooms will be thin and few in number. Before forcing is begun, make the drainage secure, cleanse the pots, scrape off the surface-soil, and apply a top-dressing of loam, and a sprinkling of bone-meal, mixed well together, making it firm with a rammer. As regards pruning, H.P.'s require to be cut back somewhat hard, and always to a plump bud; while the Teas, Noisettes, and such-like, may merely require the weak wood to be removed, and the main shoots kept well apart when training the plants. Where no Rose-house exists, the pots may be brought into a peachery or vinery about to be started, and where a temperature of 45° to 50° can be afforded the plants for a few weeks, increasing it in about three weeks. Apply air freely in mild weather, afford the plants a light part of the house unshaded by other things, syringe once or more often daily as the case may require; and if aphides appear, apply weak tobacco-water, or Quassia extract, which is as good as any, and hunt for the Rose-maggot, found in the centre growths or curled leaves, which so soon destroy the flower-buds. The Roses which are fastened to the walls and rafters of a Rose-house or greenhouse should have their shoots thinned, and be afforded a top-dressing like that advised above for pot-Roses. Against mildew, employ flowers-of-sulphur, washing it off the foliage after twenty-four hours.

Brugmansias.—Those planted in beds or borders (where they succeed much better than in pots) will have been kept somewhat dry at the root for the last month or two, and may now be pruned hard back, and still be kept dry at the root for another month. Plants grown in tubs and pots may be pruned, and kept dry at the roots, and cool for the present.

THE HARDY FRUIT GARDEN.

By CHAS. PAGE, Gardener to J. B. FORTESCUE, Esq. Dropmore, Maidenhead.

Raspberries.—In mild weather get the canes thinned if no thinning was performed last June, and secure the remainder to two or three wires strained horizontally to wooden posts or iron standards; and if a row of planks be laid between the rows, the ground need not be trodden at this season whilst the work is being carried out. The canes should be kept at about 8 in. apart if laid in all over the trellis, and if strong well-ripened they may be left at about 5 ft. in length when the tying is finished. Afford a coating of spent hot-bed manure, and lightly prick it in near the stools, but deeply in the middle track of the alleys, or allow it to lie as mulch on the dug ground.

New plantations.—If the ground has been trenched, and plenty of manure applied at the bottom, a matter of importance, the plantation generally lasting for ten or twelve years, get the planting finished forthwith; and if wire trellis is going to be used, the ground should be marked out, the rows marked out at six feet apart. The posts for supporting the wire should then be put in their places, but the wires not being required till next season, these need not be used. The canes should be fifteen inches apart in the rows, and be cut back to about two feet from the base after planting, and mulching them, the canes being finally cut down to three inches from the ground towards the close of March. Good varieties for planting are Superlative (the best of all the red varieties), Baumforth's Seedling, Yellow Antwerp, Yellow Superlative, and Guinea.

Peaches and Nectarines.—The mild weather in the south is causing the buds on these fruit trees to develop, and the trees should immediately be loosened from the wall. Doing this will retard growth and enable the gardener to cleanse the wall, stop up holes, draw nails, &c. Not much pruning will be required if disbudding was well attended to last summer. If there is scale on the wood, make use of an insecticide, employing a syringe, and choosing a quiet day for the job. I do not consider that anything is gained by keeping the trees some distance from the wall, as do some gardeners, with the idea of retarding the buds, but I proceed with pruning, nailing, or tying forthwith. Lay in the main branches first, beginning at the bottom, letting them radiate regularly around the centre; then lay in the young shoots at about 4 in. apart, keeping a few shoots near the main branches so that the leaves may afford shade to these from the too ardent sun.

Miscellaneous.—Collect the prunings of all kinds of fruit trees and burn them forthwith. In frosty weather, wheel manure on to the fruit quarters, borders, &c.; and in wet weather cut and sort shreds, heat nails and studs, throwing them into oil, whilst still hot; cut and point stakes, saving much time later on.

FRUITS UNDER GLASS.

Strawberries.—Introduce batches for succession from heated pits where the plants have been started on a bed of tree-leaves to the Strawberry-house, or to shelves fixed up close to the roof-glass in an early forcing-house. Afford the plants weak liquid manure, and if they have been prepared as advised in previous calendars, they will throw up vigorous flower-trusses, the flowers of which should be fertilised daily. After the fruits are set, make a selection of six or eight of the best, removing the remainder.

Figs.—Those plants that are being grown in pots for affording early fruit, and which are plunged in a hotbed as advised in a previous Calendar, should now be afforded a temperature of 50° to 55° at night, and one of 10° to 15° higher by day, the lower temperatures ruling in very cold weather. Syringe the plants morning and afternoon, and in other ways maintain a moist atmosphere. The early house having been closed for the past week, a night temperature of 45° to 50°, and one of 10° higher during the day may be applied, treating the trees in the manner advised for Figs in pots. Succession trees which may have made gross, unfruitful growth, should be severely root-pruned; and if the roots have an unlimited run, enclose them in small enclosures formed of brick set in cement, so as to have the roots under proper control, it being an easy matter to apply manure when it is wanted. This method of confining the roots, results in short-jointed, fruitful wood. In pruning, thin out the branches, and train-in young shoots from the bottom of the trees, which will in time take the places of the thick, and often unfruitful branches towards the centre of the tree. Trees in pots or borders having most of the fruit-bearing wood at the top, may be cut down to points from which young branches are desired, these forming readily below the point of severance; and curtail the roots in proportion to the pruning of the top. Thoroughly cleanse the trees and houses, scrape off all loose soil from the borders, and lightly dig in a dressing of charred garden-refuse and bone-meal, afterwards dressing with good loam and mortar-rubble to the depth of 2 or 3 inches.

Tomatos.—Plants which have been growing in pots since last June or July, under cool conditions for the production of fruits, and may still be bearing a quantity of useful fruits, should be encouraged to ripen these fruits by affording a temperature of 55° to 60°, with plenty of air in mild weather, and a dry atmosphere. Most of the fruit will now be found at the tops of the plants, but if young, healthy shoots from the bottom are laid-in, a useful lot of fruit will be obtained during the early spring months. Remove entirely the old foliage as the young shoots extend. Sprinkle some fertiliser on the soil, pointing it in, or affording water, so as to carry the nutriment to the roots. Plants raised from seed last August, or from cuttings at about the same time, will, if grown under favourable conditions, produce quantities of fruit, and should receive the same kind of treatment as the older plants. Fertilise the open flowers daily by gently tapping the flower-clusters. Pinch out lateral growths, but do not remove any of the foliage except to expose the fruit to the sun's rays. Pot off seedlings as soon as they show a leaf beyond the cotyledons, making use of a compost consisting of equal parts of leaf-mould and good loam; afford a temperature of 60° to 65°, and set them upon a shelf near to the glass. Sow seeds in pans of light soil, and place in propagating-pit. Four good varieties are Frogmore Selected, Sutton's A1, Acquisition, and Ham Green Favourite. *T. H. C.*

THE FLOWER GARDEN.

By J. C. TALLACK, Gardener to E. MILLER MUNDY, Esq., Shipley Hall, Derby.

Pruning.—Climbing plants, if numerous, should be pruned and fastened to walls, trellises, and bowers, and it is very important that Clematis shall be dealt with early, so as to avoid the entanglement of the shoots that is sure to occur if this work be postponed. Each section of Clematis must be pruned according to its habit of growth, which should be well understood by the pruner. Those of the C. lanuginosa and C. florida types, together with most of the species, should have the number of shoots reduced, and those that are retained, lightly shortened. C. Jackmanni and C. viticella with their varieties may be cut down almost to the ground-level, more especially young plants that are getting established, and aged plants whose shoots may have become much entangled and the plant top heavy. Bignonia radicans may have the main shoots spurred-in like a Vine or Currant-bush; deciduous climbers may be dealt with in their turn, pruning much or little accordingly to the time of flowering and habit. Plants that flower on last year's wood should be pruned after flowering. Climbing Roses should be pruned in the spring. It is frequently necessary to remove some of the oldest and bare branches so as to make space for laying-in new shoots.

Lawns.—Ply the roller frequently, and where the grass is poor afford dressings of basic slag, 4 oz. to the square yard. Bone-meal, sifted wood-ashes, fresh soot, and organic manure well mixed together form a beneficial dressing.

Carnations.—After sharp frost, press the soil firmly around the plants in beds and borders, doing this gently with the hands only. Hardy herbaceous perennial plants newly planted should be examined, and if found to be lifted out of the soil by frost, the soil should be pressed firmly around them.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the Publisher.

Letters for Publication, *as well as specimens and plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Illustrations.—*The Editor will thankfully receive and select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.*

Local News.—*Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return the unused communications or illustrations, unless by special arrangement.*

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY, JAN. 13 { Roy. Hort. Soc. Coms. meeting. Hort. Club Dinner at the Hotel Windsor.

THURSDAY, JAN. 15 { Linnean Soc., Special General Meeting.

SALES FOR THE WEEK.

MONDAY and FRIDAY, JANUARY 12 and 16—
Hardy Herbaceous Plants and Bulbs, Perennials, Pinks, Carnations, Azaleas, Rhododendrons, and Dutch Bulbs, at 67 and 68, Cheapside, by Protheroe & Morris, at 12.

TUESDAY, JANUARY 13—
Palms, Bays, Roses, Lily of the Valley, &c., by Pollexfen & Co., at Pilgrim Street, Ludgate Hill, at 12.30.

WEDNESDAY, JANUARY 14—
Azaleas, Rhododendrons, Palms, Roses, Herbaceous Plants, Gladiolus, Perennials, and Dutch Bulbs, at 67 and 68, Cheapside, by Protheroe & Morris, at 12.—Palms and Bulbs, Fruit Trees, &c., at 12.30; Japanese Lilies, at 2.30, at Stevens' Rooms.

FRIDAY, JANUARY 16—
Orchids in great variety, at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.30.

TENDER.

Laying-Out Grounds, Clerk to the Board, Brentwood.
(For further particulars see our Advertisement columns.)

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three Years at Chiswick —36·6°.

ACTUAL TEMPERATURES:—
LONDON.—*January* 7 (6 P.M.): **Max.** 54°; **Min.** 41°. *January* 8 (11 A.M.).—Black fog; mild.
PROVINCES.—*January* 7 (6 P.M.): **Max.** 49°, Scilly; **Min.** 35°, N.E. Scotland.

Universal Exposition of St. Louis, 1904.

A DOCUMENT relating to the proposed exhibition at St. Louis in 1904, has reached us, a document full of interest even for those who are not likely to participate in the exhibition itself. The average Englishman knows little or nothing of the history of Louisiana, and would be puzzled if called on to indicate its extent and relation to the other States of the Union. In the pamphlet before us, a brief summary of the history is given showing how the vast territory of Louisiana which had been Spanish, became French, and was eventually sold a century ago by Napoleon to the United States, which thus obtained an area as large as the original territory of the United States as defined by the treaty of 1783. The subdivision of this province, extending over a million square miles, into some fourteen States, and their subsequent marvellous development and progress, is told in few words, but with all the more force and directness. A well-contrived map illustrates the text, and serves vividly to impress the leading facts on the mind. But it is not with historical summaries that we are concerned in these pages, nor even with the general details of the huge exhibition it is proposed to hold. Our concern lies almost exclusively with the products of the vegetable world, a sufficiently large subject.

Agriculture and forestry have naturally vast importance in these central States of the union. Fruit culture and horticulture generally must also assume enormous proportions among a population which has increased from over three millions in 1880, to fourteen and a half millions in 1900, or, at the rate of about seventy-nine per cent. in twenty years! These figures refer exclusively to the fourteen States carved out of the old Louisiana. But this area is wedged in between the Eastern and the Western States, and St. Louis is approximately in the centre of the States, and in direct communication by rail or river with the whole of the United States, east and west, north and south, with Mexico, and with Canada. These facts will give some idea of the numbers of producers and of consumers for whom this exhibition will cater, not to speak of foreign countries which, no doubt, will largely participate, whether as visitors or as exhibitors.

We extract from the pamphlet before us the following details relating to the subject which will most interest our readers :—

HORTICULTURE.

There will be a splendid conservatory for the reception of exotic and other decorative, ornamental, and useful plants, including those of the greatest size. This will constitute a portion of the home of horticulture, which is to cost 200,000 dollars, about £41,500. The frontage is arranged for 800 feet, and the depth will be 400 feet. The aim is to make in this palace of fruit, foliage, and flowers, a complete display of the gardening world. The exhibit is open to appliances and methods of pomology, viticulture, floriculture, and arboriculture; and in addition to tools of every description for gardeners and nurserymen, this includes greenhouses, aquariums, garden architecture, plans, models, pictures, and literature dealing with the subject.

VITICULTURE.

As to the Vine, it is such an important branch of horticulture, that the idea is to make viticulture a separate group. The section is open to types of buildings, implements, appliances, and tools, relating to the culture. A collection of Vines is another object in view. Methods of making and preserving of wine, and of dealing with diseases of Vines, are also open to illustration by exhibitors.

CHOICE FRUITS.

By artificial aids, rare fruits have become daily necessities, so that what was once a select trade, now belongs to the category of universal business. The schedule of the group permits the exhibit of pomaceous and stone fruits, i.e., Apples, Pears, Plums, Peaches; citrus fruits, as Oranges, Lemons, Limes; tropical and sub-tropical growths: Pineapples, Bananas, Mangos, Figs, Olives; and of Strawberries, Raspberries, Gooseberries, and Currants, classed as small fruits; Almonds, Hickory-nuts, Filberts, and Walnuts. For historical and decorative purposes, the schedule includes casts and models of fruits in wax and plaster.

TREES, SHRUBS, AND PLANTS.

As ornamental gardening has now become both a fashion and a necessity, arrangements have been made for a display of ornamental standard trees and shrubs, plants for the park or garden, herbaceous plants, such as Dahlias, Chrysanthemums, and mosses and baskets of flowers. Further, it is part of the plan to show the working results of forced culture, including specimens from as many different countries as possible, of forced vegetables and fruit, varieties of plants cultivated for ornamental purposes, plants for houses of moderate and extreme temperatures.

SEEDS AND YOUNG TREES.

Seeds and plants for gardens and nurseries are included, i.e., collections of vegetable seeds and young trees, whether seedlings or grafted. Another group in the Department will be devoted to ornamental trees and shrubs, fruit trees, the Vine, and small fruits; while, with the idea of presenting the full scope of the profession of gardening, methods of propagating, planting, training, and pruning, as in use for any member of the species, will form a part.

FORESTRY.

The indoor exhibits of forestry and of fish and game will be covered by the same roof. The approximate cost of the temporary building is 350,000 dollars (about £72,900), and the structure will have a frontage of 400 feet, with a depth of 600 feet. The forest plays such a leading part in newly-settled lands, and in the peopling of such tracts, that the endeavour is to let the display be both wide in its scope and practical in its aims. The exhibit will extend over nearly 6 acres, and will show collections of seeds and plants and of indigenous or exotic forest-products, equipment for tree-culture, and processes of culture and management. It will also illustrate forest topography and botany, geographical distribution, forest work, terracing and replanting, with maps, plans, and literature, relating to the craft of forestry.

In the products of the forest will be displayed everything relating to logs, wood for cabinet-work and building, fuel, construction, the dyers' uses, and scientific purposes. Products of forest industries will form a section in the group, i.e., coopers' stock, basket-work, wood-ware, corks, charcoal, &c. A side of the industry less familiar to the general public included in the schedule is appliances for gathering wild crops or products of the soil without culture, as Mushrooms, Truffles, and edible wild fruits; also plants, roots, barks, and leaves, used by herbalists, pharmacists, dyers, and manufacturers of paper. Room is also open for an exhibit of specimens of indiarubber, gutta-percha, gums, and resins.

We have only to add that Mr. G. F. PARKER is the resident representative in Great Britain, and that his offices are at Sanctuary House, Tothill Street, Westminster, S.W.

PLATYCERIUMS.—Our Supplementary Illustration shows a group of these tropical Ferns as growing in the establishment of Messrs. J. HILL & SONS, of Edmonton. This firm makes a specialty of market Ferns, and from time to time exhibits fine groups at the Royal Horticultural Society exhibitions. Platyceriums, apart from their noble appearance, are interesting as possessing two kinds of foliage, the one sterile, flat, and comparatively little lobed, reminding one of a huge prothallus; the other erect and deeply lobed, with dense masses of brown spore cases on the under surface. They grow naturally on the branches of trees to which the sterile foliage is appressed, and most of them produce off-sets by means of which they may be propagated. In some cases buds are formed on the roots, as shown in one of the figures. They are thus best grown on blocks. They are widely distributed in the tropics of W. Africa, the Malay Archipelago, and North Australia (see figs. 10, 11, 12, and 13).

PLATYCERIUMS AT KEW.—The tropical Ferns at Kew have greatly improved in health in recent years. This is largely due to the reconstruction of the house (No. 2) in which they are grown, and to the substitution of clear or white-sheet for green-tinted glass in the roof. Ferns which, before this change was made, were difficult to keep in health, are now generally remarkable for the size and luxuriance of their fronds. This is particularly the case with the Platyceriums

which are grown in what is termed the natural way, that is, instead of being planted in pots or pans, they are attached to tree-trunks to which cork-bark has been nailed in such a manner as to form pockets to hold sphagnum-moss and peat. Thus treated, the plants can be freely afforded water, without any danger of the soil becoming soured; and that these conditions are suitable is abundantly evident from the growth of the plants. The specimen of P. biforme is probably the largest ever seen in Europe. P. madagascariense was introduced accidentally from Madagascar, along with Cymbidium rhodochilum, which invariably grows on the mass of barren fronds formed by the Platycerium. A few sporelings came up on one of these plants at Kew, and these have now grown into nice little specimens. The species and varieties grown at Kew are:—

P. æthiopicum (Stemmaria), Tropical Africa.
P. angolense, Tropical Africa.
P. alcicorne, Australia.
" " var. Hillii, Australia.
P. biforme, Malaya and Philippines.
P. grande, Tropical Asia and Australia (fig. 12, p. 21).
P. madagascariense, Madagascar.
P. Veitchii, hab. ?
P. Willinckii, Java (fig. 11, p. 20). *W. W.*

A GOOD EXAMPLE SET.—The Cornwall Daffodil and Spring Flower Society has unanimously voted a sum of £20 from its funds towards the building of the Royal Horticultural Society's New Hall.

NEW HORTICULTURAL PRODUCTION IN CEYLON.—In the course of his address at the opening of the recent Legislative Council, the Governor stated that, as regards new products, Pará rubber is the most prominent, and is recognised as a regular object of cultivation in the island, with every prospect of a great success. It is hoped that this may be known on the home market as representing high-quality rubber. The trees introduced into Ceylon in 1876 by the Department of Agriculture are now most vigorous, and have this year (1902) again produced a large crop of seed, a quarter of a million of which has been distributed through the island for planting. Tobacco-culture is also proving a success, the areas having extended. Camphor has been planted-out on various up-country estates and will prove a useful additional cultivation to Tea. Cocoa has throughout the island been producing very good crops, and where the rules for exterminating canker have been carried out, the freedom from this dangerous fungus is most encouraging. The amount of crop harvested for the half-year is larger than for any previous half-year.

THE ALPINE-HOUSE AT KEW.—This little house in one corner of the herbaceous ground at Kew, close to Museum No. 2, is now interesting, as it contains a collection of early-flowering hardy bulbous plants, such as delight the lover of alpines. The genera represented are as follows. Those marked with an asterisk are in flower now:—Anemone, Brodiæa, Bulbocodium, *Crocus, *Colchicum, *Cyclamen, Chionodoxa, Corydalis, Fritillaria, *Galanthus, Gagea, Hyacinthus, *Iris, Muscari, *Merendera, *Narcissus, Romulea, Scilla, Sooliopus.

"CASSELL'S DICTIONARY OF GARDENING."—With the issue of the twentieth part this useful publication is terminated. The preface sets forth distinctly what is included and what is omitted. One main object was "to save space whenever it could be reasonably saved, and to reserve it for practical matters alone." The reader knows what to expect; and if the information is less encyclopædic than is the case with some other publications, it is none the less useful for the class for whom it is specially intended. It is well got up, and within its set limitations well carried out.

PINEAPPLES.—The November number of the *Bulletin of the Botanical Department of Jamaica* contains the report of an interesting lecture by Mr. C. E. SMITH on "The Cultivation of Pine-apples in the W. Indies." The soil, though poor, must be light in texture, and thoroughly drained. The plant is propagated by "suckers" or "ratoons" (ratoons being suckers produced below the surface), and "slips" (the "gills" of English gardeners), which are the shoots produced at the base of the fruit. "Eternal vigilance" is required, not only in the cultivation of the plant, but especially in preparing it for market. It must have attained its full size before being gathered, else it will decay before it ripens. Some eighteen varieties are mentioned, of which the smooth Cayenne and the Ripley are considered to be the best.

"THE JOURNAL OF THE BOARD OF AGRICULTURE" for December contains, among other articles, notes on some Potato-diseases, including the black scab (Œdomyces leproides), which produces irregular wrinkled outgrowths from the surface of the tuber. The substance of the tuber is not materially affected. Diseased tubers should be burned to prevent the liberation and dissemination of the spores. Stock should on no account be fed with these diseased Potatos. Gas-lime may be applied to the soil. II. Bacteriosis.—In this disease the leaves soon wither, the stem becomes discoloured and marked with brown streaks along the course of the vascular bundles. In the tuber the bacteria also give rise to a coloured, finally blackish, zone in the tuber, which ultimately rots, while the skin remains intact. The important point to be attended to is the destruction of insects which feed on the leaves. This may be accomplished by the use of Bordeaux Mixture as a spray. Potatos should not be planted in soil that has produced a diseased crop. III. The Sclerotium disease of the Potato.—In this instance the tubers are not directly attacked, but their growth is checked by the fungus which attacks the base of the stem in the form of a fluffy, white mould. After a time, small hard black masses of the size of a grain of Wheat are formed—these are the sclerotia. From the sclerotia the perfect fungus is under favourable conditions developed. This fungus is not peculiar to the Potato, but attacks almost any plant. A diseased plant thrown on the rubbish-heap, or mixed with the manure-heap, is placed in the most favourable conditions for its multiplication; hence, diseased plants should, if possible, be burnt, and gas-lime applied to the land. The Dutch Onion industry, which forms the subject of an article, has already been referred to, as has also the Eelworm Disease of Cucumbers and Tomatos, and the disease of young fruit-trees caused by Eutypella prunastri. The cultivation of medicinal plants is too precarious to be recommended on a large scale.

"LA PEPINIÈRE" (CHARLES BALTET: Paris, Masson).—We could wish that we had more space at our disposal to comment on this, the latest product from the fertile pen of Mr. CHARLES BALTET. It supplies the French nurseryman and cultivator with a practical treatise on the formation and organisation of a nursery or fruit-plantation, of the method of stocking and maintaining it, the cultural details relating to pruning, grafting, and other methods of reproduction, and transplantation. After these generalities, the details concerning the several kinds of plants cultivated in nurseries for use or ornament are given, with numerous illustrations, indexes, &c. Coming from the hands of so able a practitioner and one of such large experience, the book is of special value, and we should be glad to see a translation of it into English. In the meantime, those who read French will find the book very useful to them.

DISAPPEARANCE OF A FAMOUS OAK.—During the last week (says the *East Anglian Times*), the famous Oak in Wayland (or Wailing) Wood, at Watton, Norfolk, was removed from its historic position. It was purchased by a firm of timber merchants at Brandon, and was drawn to the G. E. R. Station by five powerful horses. The wood is situated on the south side of the town, and is confidently believed by the country people to have been the scene of the murder of "The Babes in the Wood," by their uncle! The Oak, according to tradition, is the identical one under which the babes were found. A carved mantleshelf, displaying the story, belongs to an ancient mansion in this wood. The age of the timber, according to experts, corresponds with the probable date of this tragic affair. The dimensions of the tree were about 35 feet long and 12 feet in circumference; it was the largest tree in the wood. It had a most beautiful outspreading top, reaching a considerable distance. *Daily Graphic.*

FLOWERS IN WINTER.—It is often complained that our country is turned into a dumping-ground for the surplus stocks of foreign producers, whose tariff arrangements are anything but favourable to our returning the compliment; but surely none can complain of the "dumping" process when beautiful flowers are sent to our markets. Our remarks are induced by the facts recorded in a daily contemporary, to the effect that a new trade in cut flowers between the south of France and England has been started this winter, and has met with much success. The flowers are packed in small cardboard boxes on the Riviera, and sent through in bulk in hampers as far as Dover, where they are unpacked, stamped, and posted for distribution. Surely many a sick-room will be rendered more bearable by the added daily presence of beautiful flowers, fresh from a land of beauty.

HORTICULTURAL CLUB.—The next house dinner of the Club will be held on Tuesday, January 13, at 6 P.M., at the Hotel Windsor, when Mr. OWEN THOMAS has promised to open the discussion, after dinner, upon "Wasted Opportunities in Fruit-growing in English Villages."

"THE GARDENING WORLD."—This journal has passed into the hands of Messrs. MACLAREN & SONS, 37, Shoe Lane, E.C., by whom it will in future be published as a thirty-two page paper, at the cost of twopence weekly, instead of one penny as at present.

"JOURNAL OF THE KEW GUILD."—The tenth number of the second volume dated December, 1902, has been issued. To those who have been, or are directly, or even indirectly connected with Kew, this publication is of the greatest interest. Nor is the interest confined to those who can proudly style themselves "Kewites," for horticulturists of all degrees will find much in these pages to attract them. The present number opens with a portrait of Mr. J. R. JACKSON, the late Curator of the museums, together with a brief sketch of his long and useful career at Kew. Mr. JACKSON took charge of the museum in succession to the late ALEXANDER SMITH, when it was comparatively a small collection, and has seen it grow under his hands till the one small museum has developed into three large ones, the richest of their kind in the world. This account of Mr. JACKSON's career serves as a preface to the annual report, which shows a satisfactory financial state. Mr. WATSON has become President in place of Mr. NICHOLSON, and Mr. BEAN takes the duties of editor and treasurer. The report of the proceedings at the annual dinner, as well as the record of what has been done at Kew during the year have, of course, been anticipated in the weekly press, but many old Kewites will gladly possess them in a more compact form,

and indeed it is most pleasant to have one's recollections refreshed by this summary of events. Of special value are the notes from old Kewites in all parts of the world. If the Kew Guild did nothing more than publish these notes, it would sufficiently justify its existence. The doings and adventures of Kewites "at the front," or in the more peaceful colonial gardens, are narrated so simply, yet so vividly, that they form historical documents of all the greater value in that they are unpretentious records of the impressions of the writers. As Morocco is attracting much attention just now, and little or nothing is known of the horticultural aspects of the country, we append an extract from Mr. T. W. Brown's letter, dated from Fez, on the 28th of June last:—

"I have been here three months. When I landed in Rabat in January I found the Court there, and had to wait until it moved up here. It took us ten days to come up. The weather was wet, and in consequence the rivers were flooded, and the country was soft and swampy. There are no made roads and very few bridges, so that travelling is not lacking in adventure. The country through which we passed is almost entirely devoid of trees, and even here there are none with the exception of Olive and other fruit-trees.

"Fez is, I think, the most picturesque town I have yet seen. It is situated at the mouth of a deep valley, through which flows the river Fez to join the river Sebou a little below the town. High mountains rise on either side, on the lower slopes of which stand Olive-groves, and orchards of Figs, Peaches, Plums, &c. The town is surrounded by a high wall, part of which is in ruins. As in all Moorish towns, the streets are narrow and dirty. The decoration of some of the mosques is very fine, particularly the mosaics wrought with little glazed tiles on the floors and walls. The climate is most agreeable. Of course, it is rather warm just now (last week we had 99° in the shade), but we experience no violent changes.

"I am engaged in making a flower garden within the palace walls. The greater part is to be laid out in geometrical designs; the surroundings do not allow of much rustic or natural gardening. I have sixty gardeners, and as many labourers as I want. The gardeners are men who have been working in the orchards and vegetable gardens around the town. They are not, however, a very intelligent set. Of course, horticulture and agriculture are carried on in the most primitive fashion. The ground is tilled with simple wooden ploughs drawn by oxen, the corn is cut with sickles which leave a foot of straw standing, and everything else is done in the same imperfect manner. It is interesting however, and gives one an idea of how things were done in the far past. The Moors do not believe in change, and have preserved all the ways and customs of their ancestors."

THE MAN WHO SERVES THE KITCHEN.—A good service has been rendered in the *Gardeners' Magazine*, Dec. 27, by a writer who describes the services rendered by the gardener, to whom falls the duty of conveying the produce of the garden to the kitchen. How important his duties are when conscientiously carried out is well told in the article in question.

"HAND-LIST OF TREES AND SHRUBS."—A second edition of the catalogue of trees and shrubs cultivated at Kew, has been lately issued after revision, and the addition of newly introduced subjects. The number of hardy shrubs and trees now enumerated amounts to no fewer than 4,500, exclusive of the Conifers which form the subject of a separate list. The value of these "hand-lists" as records of what is in cultivation, and as affording standards of authorised nomenclature and synonymy, can hardly be over estimated. References to figures are freely given, and these are most serviceable, but for the sake of those who are not botanists, an explanation of the abbreviations made use of, would be desirable in future editions. The asterisk prefixed to some of the species, presumably indicates that the plants so marked are tender at Kew.

THE CROYDON AND DISTRICT HORTICULTURAL MUTUAL IMPROVEMENT SOCIETY will hold their third annual dinner and smoking concert on Wednesday, January 14, at the Café Royal, Croydon. Particulars may be had upon application to Mr. H. BOSHIER, 62, High Street, Croydon.

WATER SUPPLY FOR GARDENS AND HOT-HOUSES.

THE question of water supply to gardens and glasshouses, &c., is a very important one, and this is specially the case in isolated districts where skilled labour is often difficult to procure. A few hints, therefore, on the general principles of the subject may not be out of place, but the writer desires to state that this article will deal with the raising and distribution of water by simple and easily obtained means, as it is obvious that the arrangement and care of the more costly steam, gas, oil, and electrically driven pumping installations can only be properly dealt with in the special text-books procurable on the subject.

Where water exists, it is, of course, only a question of locality to arrange for its distribution, and if a spring exists on high ground and the spot to be supplied is at a lower level, the distribution is a matter of ease (care being taken to lay the pipes as nearly as possible in a straight line, and to avoid following the irregularity of the ground as far as possible, for if this is done, air will often accumulate in the bends of the pipes and cause a good deal of trouble). Few situations, however, are so favoured, and recourse therefore must be had to some means of raising the water from its source to a point sufficiently high to permit it to fall by its own gravity to the point supplied. These will be described as far as possible, but before doing so, a few remarks may be briefly given on the general arrangement of pipes, and also on pumps generally.

Commencing with the pipes, these should always be as large as possible, and laid at least 3 feet below the ground to avoid damage by frost. Not only do small pipes rapidly "fur" up, but often the supply is seriously obstructed thereby. Where it is absolutely necessary to carry the pipes above ground they should be protected by felt or similar material, such as asbestos; and where they are carried across open ground, marks, such as square pieces of stone, should be placed to show the course of the same. A stop-valve should always be placed close to the reservoir, to permit the supply to be shut off at any time for obtaining access to the pipes or other purposes.

Of the various means of water raising, a pump of some kind forms the simplest and best method of carrying out this object, but it is not possible to enumerate the countless forms of this useful appliance, and there would be little utility in doing so. The writer can only mention the forms commonly made use of, referring those interested to the numerous treatises on pump construction for fuller details.

By far the commonest form of pump is the "lift" or common house-pump familiar to everybody (fig. 14, p. 27). A few words may be given to its action, as it will assist towards the understanding of the general action of pumps as a whole. Water cannot follow the bucket of a pump beyond a depth of about twenty-eight feet, and if the suction-pipe of a pump is very long, it is always a good plan to place a valve at the end of it, termed a "foot" or "retaining" valve, the object of which is to keep the pipe full of water to enable the pump to start easily when stopped for any length of time. The "lift" pump, then, should not be used where the depth exceeds the above amount.

This pump like many of those to be described, consists of a "body," "barrel" or "cylinder," a "bucket," and two "valves," one in this case covering an opening in the "bucket," the other closing the opening of the suction-pipe leading to the well, or other source of supply. When the "bucket" is pressed down, the valve in it opens and closes; when the "bucket" is drawn up, the water is drawn up with it, and discharged at the spout. At the same time, the "bucket" in rising causes a "vacuum" or sucking action beneath it, and the air pressing on the surface of the water in the well or pond, causes it to rise through the valve at the bottom of the pump-barrel, which closes on the descent of the bucket for another stroke.

The force pump, which is employed where the well is deep, or where the water is to be forced a long distance, differs from the lift pump by the bucket (which in this case is often termed a "ram" or "plunger") being solid. There are two valves, like the former; but while one is placed at the bottom of the barrel, the other is placed in the pipe which conveys the water from the pump, and is termed the "rising main," or delivery pipe. When the bucket is raised, the water follows it as before, but on its descent the bottom valve closes and the one in the delivery-pipe opens, allowing the water to be forced through it by the bucket up the pipe; when the bucket rises again the delivery valve closes, and the action is repeated. This form of pump is generally placed as near the supply as possible, and if in a well, is worked by a long rod, which is carried down to it from the surface of the ground. An air vessel is often placed on the delivery-pipe, and should be as near the pump as convenient. The sketch (fig. 15) shows the usual form adopted when the pump is worked by power of some description.

In very many cases where water has to be raised to upper floors of houses, or similar duties these two different kinds of pump are combined; when the pump is of this nature, it is known as a "lift-and-force" pump, and is constructed as follows:—The pump "barrel" and bucket are exactly like a lift pump, and it also has the valve at the bottom of the "barrel," in the same manner; but the "rising main," or delivery pipe, leaves the pump at the top, which is closed in by a tight-fitting cover, and the rod working the bucket passes through it by a "stuffing-box," which is an opening with a hollow plug through which the rod passes. The plug screws into a socket, which is filled with greased tow, and which allows the rod to work easily, but prevents the water from coming out.

Now the action is exactly the same as to the down stroke as the lift pump, but when the bucket rises it will be seen that the water is forced before it through the delivery valve (which like the force pump is placed close to the pump), and

up the delivery pipe. If water is wanted on the spot, a tap is placed close to this valve, and by opening this a pail, &c., can be filled (see fig. 16).

The last description of pump is used only for shallow wells or pits, and is often employed for liquid-manure tanks; this is the chain pump, which is the simplest of all, and consists of a series of what may be called round plugs fixed to a chain passing over a wheel at the top of the pump, turned by hand or other means. When these are put in motion, they enter the pump-barrel which they do not quite fit, except for a short length at the bottom, and each carry up a small quantity until it is discharged at the spout. On account of much power being lost by friction, and the fact that as the lift becomes deeper it

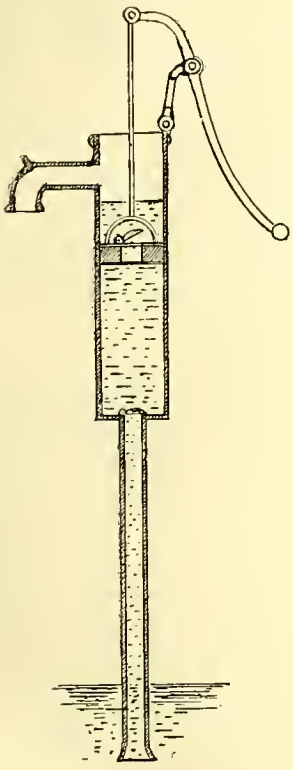

FIG. 14.—COMMON LIFT PUMP.

requires a great expenditure of power, this pump is not employed for deep wells.

These are the main principles underlying pump construction; but it must be understood the arrangement of details is often very varied, and can only be studied by reference to the many text-books thereon.

RAMS.

We must now, however, briefly enumerate the various methods by which (other than by hand or animal power) water is raised, and one of the oldest and simplest of these is what is known as "The Hydraulic Ram." This instrument occurs in many forms, but the principle is very simple, and is the fact that a large quantity of water falling from a low elevation by its force can be made to force a small quantity any height desired. By reference to fig. 17, it will be seen water descending the pipe *a* has just sufficient force to close the heavy valve *b*, and the momentum given to the water by its force being suddenly checked causes it to open the delivery valve *c* at the bottom of the air-vessel *d*, and rise through the delivery pipe *e*, to almost any height. The heavy valve *b*, then opens, and the water rushes out until its force closes it, when the action is repeated. This instrument will work for weeks together without attention, but it will not work properly without an air-valve *f*, on the air-vessel *d*, which in this case is a self-acting one, and requires no attention. The quantity raised depends largely on the height to which the "ram" has to force it. If only a short distance

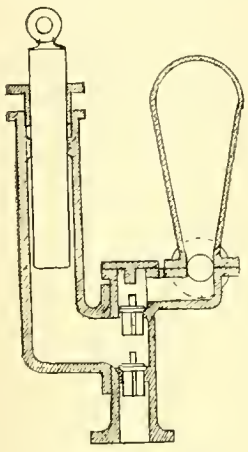

FIG. 15 FORCE PUMP, WITH AIR-VESSEL.

from the "ram," and not greatly higher than the supply, the machine will raise nearly one-third of the water; but if, as is frequently the case, the water has to be carried a considerable distance or height, the quantity raised will not exceed one-eighth, or even less. It will be

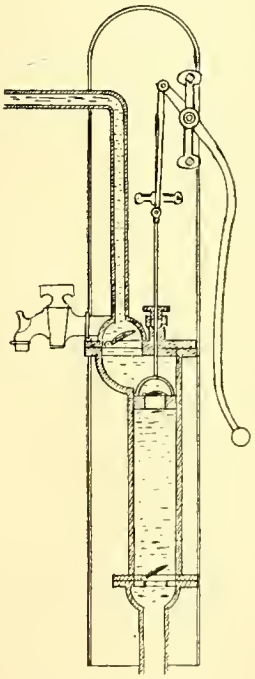

FIG. 16.—COMBINED LIFT AND FORCE PUMP.

easily seen, therefore, that the "hydraulic ram" should not be employed unless the supply is either abundant, or else of small value. In the latter case, "rams" are often fixed to work at intervals, and the supply is arranged so that on reaching a certain height it opens a valve which admits the water to the "ram," which commences to work until the water sinks below the valve, when it closes until the pond refills.

This is the most satisfactory of all the self acting water-raisers, for although several make-shift devices exist, the "ram" is so cheap to erect that it is almost always adopted. The simplest of these devices, apart from the "ram," is a wooden trough, divided by a partition in the centre, and hung upon pivots in the stream, which need only be bayed back sufficiently to allow the trough to move, and for the water to fill it. The water flows into the trough, and as it is balanced the weight causes it to descend, emptying that side, and allowing the opposite side to fill, when the operation is repeated. One end of the trough is connected to the handle of a pump, which therefore becomes self-acting.

This plan is simple and cheap, but very wasteful of water (perhaps more so in proportion to the amount raised than the hydraulic ram),

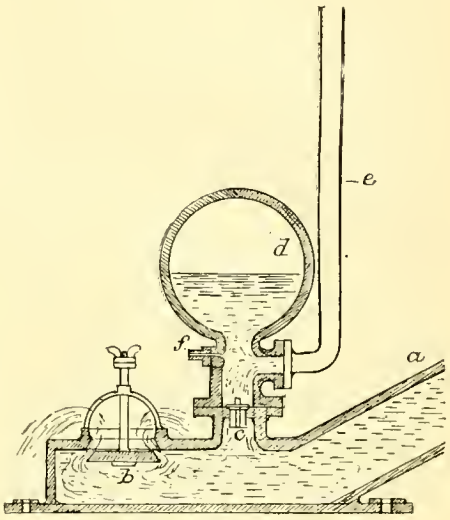

FIG. 17.—THE HYDRAULIC RAM.

and only suitable for raising water to a small height. There are, however, circumstances where it may be found useful. *Sydney Russell.*

(To be continued.)

HOME CORRESPONDENCE.

CALANTHE VEITCHI AT CLIVEDEN.—I wish to add to my statement concerning the plants mentioned, that they were not seedlings; and Mr. Bacon was foreman in charge at Cliveden at the time, and not head gardener. He succeeded Mr. A. Wadds, who was then head, a short time afterwards. *F. Williams, Frensham Hall Gardens.*

RAINFALL IN 1902 AT PENCARROW, BODMIN.—The total rainfall was 42·55 inches, as against 40·17 inches in 1901, and 46·22 inches in 1900. The number of days on which ·01 or more fell were thirteen more than in 1901, and exactly the same number as during 1900. The 1·73 ins. measured at 9 A.M. on Nov. 28 last constitutes a record here for twenty-four hours. *A. C. Bartlett.*

THE NATIONAL CHRYSANTHEMUM SOCIETY.—I congratulate this body on the change it is to effect in the autumn in the place of its exhibitions. The Crystal Palace will certainly furnish an atmosphere that is morally as well as physically pure, where the side-showmen's potent lungs do not make demoniacal discord. There too can, with the ample space at disposal, a really grand show be made. Whether the old frequenters of the shows will follow to the Palace has to be seen. It is just possible, however, that should they not, many other true flower-lovers may do so. *F.R.H.S.*

BEGONIAS. — Having had many letters of inquiry about Begonias, I am taking the liberty of sending you a sample, thinking it may be of some interest. If not too late, I should like to add to the notes sent last week (should you think them of any value to you) that the plants here, 3 feet each way, are not staked out, but slung up to one centre stake in each pot. The natural habit and growth of the plant is never interfered with. The injurious system of stopping cannot be too strongly condemned. *John Fleming, Wexham Park Gardens.*

DENDROMETER. — Mr. Simpson deprecates the use of the dendrometer, but that does not detract from its value and usefulness. No doubt some men are able to accurately estimate with the eye the approximate amount of useable timber in a tree, there are numbers in the country who have had sufficient practice and experience to do so; but the "eye-man" could not possibly give one the exact height, or even to a few feet, of the fine specimens of Conifers growing in the country. For his own purpose, Mr. Simpson's rods are undoubtedly useful and handy, but are scarcely adapted for measuring such trees as the 130 feet high Douglas Fir at Dropmore. One needs only to run the eye down the "List of Conifers and large specimens," compiled by the late Malcolm Dunn, to realise what an impossible task it would be to measure by rod well furnished Conifers of over 40 feet where accuracy is desired. Some dendrometers are, I know, troublesome to use, but Mr. Simpson cannot be acquainted with the pattern described, or he would not characterise it as such. I have recently measured considerably over 100 specimens, and found it very easily used, and preferable to a rod for trees of even 25 to 30 feet in height. In conclusion, I would draw your correspondents attention to the illustration in your advertisement columns. *A. C. Bartlett, Pencarrow.* [We have used this instrument with much satisfaction. ED.]

HYDRANGEA PANICULATA FOR FORCING.—Your correspondent, "S. C.," in his article on the above in the *Gardeners' Chronicle* of the 3rd inst., mentions "that shoots on these plants will be some 3 feet in length, and from 6 to 12 inches have to be cut off." I am afraid if any grower were to follow his advice they would obtain very indifferent results, as this would cause the top buds only to break, and these being the weakest would only give poor heads of bloom, and also leave unsightly bare stems below. The better plan is to prune back to within three or four buds from the base, by which means you get the strongest buds to break, which will give the grower fine heads of bloom, and also leaves, as near to the pot as it is possible to obtain them. *E. B.*

THE ROYAL HORTICULTURAL SOCIETY. — On reading your leading article, p. 1, January 3, as to the erection of a suitable home for the Royal Horticultural Society, and hinting at the increasing tendency to call in State aid, I may say that surely there was never a better time than the present to seek such assistance. What is the object and purpose of a horticultural hall? Is it not to increase and assist the maintaining of the State in advising and discovering the best means of making the most of the soil, both in horticulture and agriculture? In the present day, the knowledge learnt in the garden is turned to good account in the field. The Society can boast of the elect of the nobility and Members of Parliament as subscribers. Is there not one out of this great company that can make application in the right quarter for the necessary funds for such a national want? and let the hall be called the National Horticultural Society. Are we in England going to continue in the present state of things, and see millions year after year going out of the country for fruit alone? Land half cultivated that would produce millions if properly handled. Nothing would bring the labourer back to the land quicker than an extension of fruit growing. The time has come when something should be done to bring about the desired end. The market for fruit in England is assured—proved by the millions of pounds sterling we are paying for the imported article. Let the foreigner see that the State is waking up to the necessity of keeping this money in the country, by encouraging the production of its own fruit; they would soon look to other climes for the disposal of their's. Sooner or later this country must acknowledge that corn-growing is a dying industry. *W. H.*

THE HORTICULTURAL HALL.—I am sure everyone interested in the cause will endorse your words, "that this subject has been treated, and rightly so, as if it were a national matter;" and being a national matter, affecting the whole community, it should from the very first have the utmost publicity. At the least, every Fellow of the Royal Horticultural Society should have an opportunity of expressing his opinion upon the vital points, amongst which are the plans of the Hall. Allow me to take exception to the words "all questions of detail and criticism can be left open for future consideration; the requirements at the present time are funds." I feel sure that to command success no stone should be left unturned to obtain the very highest professional skill, so that a building worthy of a national institution should be erected. An exhibition of competitive designs would attain this object, and by giving the Fellows a voice in the selection materially strengthen the position of the Society, inspire confidence in those most interested, and as a natural result, funds would be readily forthcoming for a scheme which had the general approval. This is not a "detail which can be left open for future consideration." Allow me to ask if the plans which have been circulated are finally approved? If so, of course further comment is unnecessary. *James L. Wood, F.R.H.S.* [Perhaps the Council would authorise the Secretary to reply to this question. We have no definite knowledge. ED.].

HYBRID RUBUS. — In my note on these hybrids on p. 12 last week, I am, by an error, made to term the new Blackberry, The Mahdi, as "sour." What I wrote was, "true" Blackberry, to distinguish it from others that were more properly classed as Raspberries. The context shows that the word used was a misnomer. *A. D.*

RAINFALL IN 1902 AT THE ROYAL GARDENS, WINDSOR.—Although the past year may be described as wet, owing to frequent rains and dull unsettled weather, the total rainfall, 22·07 ins., was about 3½ ins. less than the average, 25·50 ins., for this district; which amount has not been reached since 1894, when the great floods occurred, and the total rainfall was 30·27 inches.

Month.	Total Depth.	Greatest fall in 24 hours.		Number of Days on which ·01 or more fell.
	Inches.	Depth.	Date.	
January	0·88	·25	1 & 26	11
February	1·16	·27	24	12
March	1·97	·76	14	14
April	1·07	·17	15	13
May	2·19	·33	3	24
June	3·63	·94	13	19
July	1·12	·24	9	13
August	3·88	·89	18	26
September	1·58	·59	11	10
October	1·57	·43	9	18
November	1·97	·45	28	15
December	1·36	·32	17	12
Total	22·07	...	...	186

Last year rain ·01 (or more) felt on 186 days. June was the highest total, 3·62 ins.; and the heaviest rainfall in twenty-four hours was ·94 in., on the 13th of that month. *T. Edwards.*

INCOME-TAX RECOVERY.—The tax-collector is beginning to make his presence felt, but before satisfying his demands, readers of the *Gardeners' Chronicle* should carefully ascertain whether the amounts they are asked to pay are correct. Having regard to the high rate at which the tax now stands (6¼ per cent. of the income), it is surprising that so many of the great middle class fail to avail themselves of the relief provided by the Acts. Where profits assessed under Schedule D show a falling off for the current year, it may be possible to get the amount of the demand adjusted to the proper amount before payment of the tax; alternatively, repayment of the amount overcharged should be claimed. Where the whole of the income for the year has already been received, claims for repayment of tax overcharged can in many cases now be made for four years, and the sums repayable may exceed £82, even in the case of incomes of £500 per annum. We shall be pleased to advise anyone, without charge, whether a claim for repayment can be made in respect of income from rents, dividends, interest, annuities, &c., on their sending us full particulars of their incomes and a stamp for reply. *The Income-tax Adjustment Agency, Ltd., Poultry, London, E.C., January* 1, 1903.

CUCUMBER CULTURE.—Allow me to reply to "W. P. R." in a few words with reference to his remarks in the last issue of the *Gardeners' Chronicle*. "W. P. R." cannot have the faintest idea of the state of an Indian river during the period of Cucumber-growing on its banks, otherwise he would not have made the mistake of stating that if a "hole a foot or so deep" had been dug, it would soon have been "partly filled with water." If this were correct, we should, methinks, hear less of the deplorable results of famine in India. "W. P. R.'s" experience for eight years in Cucumber-culture seems to have been most satisfactory, and agrees in some important points with what I have been advocating. I think it a pity, for his own sake, that his subsequent operations have not been on the same lines. Whilst adhering firmly to all I have written with regard to Cucumber-cultivation as it is now almost universally carried out, I am willing to admit my limited capabilities as a teacher; at the same time, I fancy that in the gardening profession the balance is about equally adjusted between those who are too willing to teach and those who are unwilling to learn. *J. Lowrie.*

LATE GOOSEBERRIES. — I read with some interest the article under the above heading, in your issue of Dec. 20, p. 451, and while I agree with Mr. Cook that free-setting varieties will bear freely on a north wall, I consider they are not worth the space they occupy, the fruit being small, sour, and tough skinned, and quite unfit for dessert. Nor have I found it necessary to protect the fruit in any way from birds, wasps, flies, &c., for the reason, I suppose, that the flavour is not suited to their tastes. Even the best flavoured varieties from the open quarter are not much sought after for dessert, as the supply of better class fruit at that season is plentiful. Only fancy a dish of Gooseberries from a north wall, being placed in company with Grapes, Melons, Peaches, Nectarines, &c. I picture to myself the peculiar expression on the face of the person who might be tempted to taste one after partaking of a well finished Melon, Peach, or Nectarine. A good supply of ripe Gooseberries can be had over a long season by a careful selection of varieties at planting time, of early, midseason, and late sorts in a sunny position, as it is only from there you can expect good flavour. It would be interesting to have the opinion of other readers of the *Gardeners' Chronicle* on the subject. *James Fulton, Grimsdyke, Harrow Weald.* [We have a pleasant recollection of good flavoured fruits of the Red Warrington variety, from a north wall in a garden in the north of England. ED.]

PEAR JOSEPHINE DE MALINES.—Usually the fruits of this excellent variety of Pear are in use till the month of February, but this year it has been very disappointing at Wrotham Park. The crop was a very good one, and the fruits were of a fair size, and very clean in the rind; but to my surprise they commenced ripening at the end of October, and were good for a few weeks only, in fact by the middle of December I had not a sound fruit left. The flesh of a nicely ripened fruit of this variety is usually tinged with red, but this year ours were lacking in this respect to a great extent, owing probably to the absence of sunshine, and several of our Pears have been of poor flavour this year from this cause. Our best Pears were Doyenné du Comice, Williams' Bon Chrétien, Winter Nelis, Beurré Superfin, Emile d'Heyst, and Pitmaston Duchess, the latter being better than I have usually found it to be. Apples, too, have kept very badly, compared with previous years. On bushes, our heaviest cropping Apple was Lane's Prince Albert; other less useful varieties we hope to replace with Lane's in the spring. *H. Markham, Wrotham Park, Barnet.*

POINSETTIAS AT LEIGHTON, WILTS.—When the Chrysanthemum ceases to afford blooms, Poinsettias take up the floral display, and rarely with greater effect than at Leighton, Wiltshire. The head gardener at that place, Mr. Bound, a brother of the writer of the Orchid Calendar in the *Gardeners' Chronicle* in 1902, extends the propagation of Euphorbia (Poinsettia) pulcherrima from May to July, taking suitable cuttings when they offer. He attaches some importance to the choice of two-year-old plants for furnishing the cuttings, because of the greater solidity of the shoots as compared with younger stock plants. Bottom-heat in a close case causes rapid rooting—a point of importance. When rooted, and carefully accustomed to the air, the young plants are afforded less warmth, so as to prevent an undue lengthening of the stem. The plants observed at Leighton ranged from 1 ft. to 3 ft. in height, and their bracts are of good size. Two varieties are grown, the early form with bracts of a lighter shade of colour, and greater compactness of head; but the old E. pulcherrima is still the best. A later batch of cuttings inserted in September furnish dwarf plants in small pots, very useful for setting narrow stages and for the dinner table. *S.*

BINDING GRAFTS. — Having been a constant reader of your paper from the days of Dr. Lindley to those of the present editorial staff, I have derived during those years great pleasure and profit from the writers of the various contributions which have appeared. I am now about the same age as your correspondent who wrote on the subject of grafting without clay or wax. I quite agree with him, and had myself as a lad bound up many a thousand grafts, under such men as Mr. Colley, of Orchid Bateman's fame. I also served under the Townshend and Fancourts propagators, who always bound their grafts with twisted matting, so as to be able to see the working of the sap. It may be said this applies more to Camellia and indoor grafting. In later years, I, with my own hands, grafted thousands in the same way out-of-door, and with the best of results, with matting or raffia alone, a little more care being required in covering at the top of the cut-off stock. *W. B.*

CALANTHE VEITCHI. — So much has been written in different issues of the *Gardeners' Chronicle* respecting Calanthe Veitchi, I think a summary of their cultivation may be of use to readers. In a great many places this Orchid is very much neglected, but when grown well, there is nothing to surpass it for Christmas decorations, and it may be freely used for house, conservatory, or table. We have at the present time many racemes measuring over 50 ins. from the base to the summit, the flowers of good size and splendid colour. This I attribute to the pseudo-bulbs not being too large, and also not being too much hurried into flower. After finishing their growth, a lower temperature suffices. The best time for potting this species is the month of March, when growth has recommenced. The cultivator should never cut away all the old roots, but leave plenty to support the pseudo-bulb in position at the top of the soil, which should be quite half or even an inch above the rims of the flower-pots; in no case should too large ones be used, sizes 48 and 32 being quite large enough. The compost should consist of one part turfy-loam, two parts turfy-peat, one part sphagnum, with an addition of small pieces of dry cow-manure, but not using any sand. Special care should be taken to use no fine material whatever, letting the roots ramble with as much freedom as possible. Firm potting should not be resorted to, the fingers being sufficient. In finishing off, use a stick and an old pair of Vine-scissors for cutting off the rough material used. Then place in a temperature not less than 60° for the first month, after that the stove temperature will suit them, but be most careful in watering during the first period of their growth; also avoiding strong sunshine, as it is apt to burn the foliage. When growth is completed, which would be in September, a lower temperature is essential, gradually exposing them to the sun to ripen the bulbs. During the growing season, applications of manure-water are beneficial, but in no case use artificial manures. Damping between the pots with manure-water is of great benefit to the foliage; syringing should not be resorted to at all, as it often causes that black spot which is seen on the pseudo-bulbs. An occasional sponging of the foliage is all that is necessary to keep in check red-spider and scale. After the flowering period is over, Calanthes should be rested in a temperature not less than 60°. *W. Fulford, Castle Eden Gardens.*

A LARGE VINE AT FINCHLEY. — Your recent note respecting the old Vine at Hampton induced me to call and see a large Grape-vine at Finchley. This Vine, a Black Hamburgh, is aged about forty years, and of it much has been written. It will, I fear, have to make way for the ubiquitous builder, who is at Finchley, as in many other London suburbs, covering the land rapidly with houses. The Vine was planted by the late Peter Kay in a border that is entirely outside, and it now fills a span-roofed house measuring 100 feet by 20 feet. Planted on the west side towards the middle, it spreads equally on each side, and consists of five main branches which have, however, been supplemented by training four other branches, one between each pair of the originals, with the result that the vinery is fully furnished. Some rods run horizontally from the main stem, which is across the house from side to side. The house is about 8 feet to the ridge, and a sunken path affords room for attending to the Vine. It is an excellent house for early forcing, the flow-pipe on each side of the house being carried well up each side, and it falls into two return-pipes on each side of the path. The Vine bears regularly a full crop, and shows no loss of vigour. *S. C.*

CULTURAL MEMORANDA.

BEGONIA GLOIRE DE LORRAINE.

On p. 451, last vol., "H. W. W." recommends cultivators to pinch out the points of the growth and afford the plants cold frame treatment, with a free circulation of air day and night during the summer and early autumn. In my experience, I have unfortunately found that these Begonias resent such treatment. The constitution of the plants gets weakened, and they soon become infested with thrips and disease. The secret of growing these plants well, is to do so quickly in a warm moist atmosphere, from the time the cuttings are put in, until the flowering period. In the first place, procure healthy cuttings. For very early propagation, leaves with about an inch of stem may be dibbled into cocoa-nut fibre, and shaded from sunshine; these will soon emit roots, and each leaf will produce two or three growths. Insert these when large enough, as they are better cuttings than can be taken from the base of the old plants during the winter. Then apply water and plunge the pots to the rim in cocoa-nut fibre in a propagating-ease, having a bottom heat of about 75° or 80°. In about three weeks the cuttings will have rooted, when they may be gradually inured to a cooler position near the roof glass. The plants should be shifted on into 3-inch pots before they become pot-bound, using a compost of three parts good fibrous loam, one part leaf-soil, and the remaining part of fine crushed charcoal and coarse sand. The soil made use of at the final potting should contain a fair quantity of dried cow-manure, and the loam and charcoal should be used in a rougher state than in the case of the earlier potting. Do not pot too firmly, or the growth will be stunted; nor use too large pots when repotting, but afford thorough drainage. Afford water sparingly until the plants are well rooted into the fresh soil, then may be used abundance of stimulants. Clay's Fertiliser, with alternate doses of liquid cow and sheep-manure, and occasional applications of soot-water, are as good as any that can be used. A low span-roofed house or pit, having a temperature of about 65°, allowing the thermometer to run up with sun-heat, will suit them well; by closing the structure early in the afternoon during summer, very little or no fire-heat will be needed. Freely syringe the plants with rain-water, and shade them from strong sunshine. Under such treatment, plants rooted during March and April, and potted-on into 16 or 24-sized pots, and kept in such a congenial atmosphere that not the slighest check to growth is ever experienced, will by the autumn produce plants 3 feet in height and 3 feet through. Plants for flowering in small pots should be propagated during May and June. I find it more difficult here to obtain height than width The growths should never be stopped, but the flower-buds must be pinched off until the plants are required to bloom; grown thus, thrips or mites will never make their appearance. I have an idea (I am aware some readers will say an erroneous one), but I am writing from close personal observation and experience, that these plants and similar subjects such as Poinsettias for winter-flowering, grown on this rapid system of cultivation will keep the plants in vigorous growth from first to last, and give them a strong constitution which will enable them to survive and last a longer time in perfection when placed in rooms or in a cold conservatory. It is a question of constitution, rather than one of affording the plants cool treatment during their growing season. *John Fleming, Wexham Park Gardens, Slough.* [Our correspondent has exhibited the finest plants of this Begonia we have seen this season. ED.]

PERENNIAL ASTERS.

Those who have aged plants of Aster ericoides, elegans, &c., will do well to lift from the open ground, putting them in pots or boxes, and bringing them under glass. When growth begins, they may be divided or cuttings taken. Not much artificial heat is required. Asters are hardy plants, but, as is usual with new varieties, they are worked up too rapidly, and the young plants require careful treatment, as do likewise the stock plants. Some varieties are very shy in forming shoots, and the trade find a difficulty in fulfilling orders. Asters make excellent pot plants, and in years to come they will be largely grown. The pot plants, when well rooted, should be plunged on a cool border, in order to prolong the flowering season. Much rain is a drawback to the late-flowering plants, hence some kind of temporary protection is necessary. *S. C.*

VARIORUM.

THE GARDENER'S WAIL

Wauken, my muse! yer loodest wail,
Lend to proclaim the waefu' tale,
O' a' the ills that do assail
The gairdener's occupation.
If ere by chance ye meet a chiel,
Wi' careworn face an' een that reel,
An' doonbent head, then mark him weel—
His wark is cultivation.

Auld Milton said—I have heard tell,
When Adam's curses cam' pell-mell,
That maistly on the ground they fell,
As aff his head they glinted.
I weel believe't: the son o' toil,
Wha's lot hae fa'en to till the soil,
For want o' care will never spoil—
His sorrow's never stinted.

Lang syne, when Adam sawed his seeds,
Ere he began his evil deeds,
He ne'er was bathered pu'in' weeds—
Sae says the auld narrator.
But noo, as sune's we tak' a spade,
An' get oor bit o' gairden made,
'Gainst us we quickly find arrayed
The very pooers o' natur'.

If even the seasons had the grace
To come in turn an' keep their place,
We wadna' hae sae much to face,
Nor view wi' consternation.
In summer, when we look for heat,
We're cursed wi' shooers o' hail an' sleet;
An' autumn's early frosts complete
The work o' devastation.

The rain has ruined oor crap o' Peas,
The blight has spoilt oor Aipple trees,
Oor grozers covered wi' greeu flees;
An' then the festive snailes
Did quickly seal oor Cabbages doom;
Sma' wonner tho' we fret an' fume
To see oor best Chrysthan'mum bloom
Nabbed by the forky-tailies.*

Oor foes are mair than mind can grasp—
The grub, the weevil, bug, an' wasp,
Worms for the Carrot an' the Rasp—
In truth their name is legion.
But, faith, I'll shak' the gairden mud
Frae aff my feet afore I'm wud,
An' quickly pack ilk stick an' dud,
An' try some ither region.

Hortus, in the "People's Journal," N.B.

Obituary.

JAMES WARD. — This well-known member of the staff of the Royal Nursery, Slough, and head of the office department, died at Slough on the 5th inst., at the age of sixty-three years. James Ward was the son of a gardener, who for many years had charge of the gardens at Shottesham of the late Rev. Charles Fellowes, one of the most noted florists of the last century, and came to the Royal Nursery, Slough, in 1853, when fourteen years of age, and commencing as a crock-boy, gradually worked himself up through the various departments, until he obtained the headship of the office, a position he filled for many years past. His father died last year, at the age of eighty-seven.

J. MCKENZIE.—We regret to inform our readers of the death of Mr. McKenzie, head gardener to F. S. W. Cornwallis, Esq., Linton Park, Maidstone. The deceased had been ailing for some months past. Many will remember the very fine Apples that he exhibited at the Crystal Palace for several years, always holding his own against the very best growers; he was also very successful some years ago with Chrysanthemums, taking several prizes at the National Chrysanthemum Society's shows at the Aquarium. He leaves a widow and small family, the youngest being about fifteen.

NOTICES OF BOOKS.

A MANUAL OF INDIAN TIMBERS. By J. S. Gamble, M.A., C.I.E., F.R.S., late of the Indian Forest Department. New and revised edition. (London: Sampson Low & Co., 1902.)

MR. GAMBLE has done good service by writing a second and much-improved edition of his *Manual of Indian Timbers*. The former edition was due to the initiative of Sir Dietrich Brandis, then Inspector-general of Forests in India, who prepared a collection of Indian woods for the Paris Exhibition of 1878, several identical collections being sent to the chief Indian forest officers, to the museum of the Royal Gardens at Kew, and to a few similar institutions in Europe and America, as well as to the Imperial Forest School of Dehra Dun. Mr. J. S. Gamble and Mr. A. Smythies were Brandis' assistants in this work, and to Mr. Gamble was entrusted the preparation of the first edition of this manual, which was published by the Government of India in 1881. Twenty-one years have therefore passed since its first appearance, during most of which time Mr. Gamble served in the Indian forests, and he has made it a labour of love to collect further specimens, to examine other collections, and study the properties and uses of Indian woods, the growth and habitats of the trees which produce them, and the scientific and vernacular names of the species. The difficulty attached to these vernacular names is clearly brought out in the introductory chapter, as in the Himalayan region alone almost every valley has different names for even well known trees, and about fifty different Indian languages are referred to, though they are probably not more than one-fourth of the languages spoken in this vast country, to say nothing of Ceylon, the words of which are now, for the first time, included in the Mannal.

The forest regions where the timbers grow are as follows, each being denoted by a letter imprinted on the specimens:

H. The western Himáláya, from the river Indus to the Nepál frontier.

P. The dry region of the Punjáb, Rajputáua, and Sindh, with Báluchistán.

O. Plains and sub-Himáláyan tract, as far as Bengal.

C. Central India, between the Jumna and Godavery rivers, with Orissa and the Circars.

E. The eastern Himáláya from Nepál; the Khásia Hills, Assam, Chittagong, and the Sundurbans.

D. The Deccan and Carnatic, chiefly in Madras and Mysore.

W. The west coast of the peninsula, viz., the western Ghâts, and the coast region.

B. Burma and the Andaman Islands.

No letter is given for Ceylon.

In spite of the author's explanation that this was not done, it seems a pity that a map was not supplied of these regions, with their comparative rainfall, and with lines showing the incidence of frost, as frost and rainfall are the chief determining factors of Indian forest growth. The forest growth of each region is briefly described in the introductory chapter, and in the body of the work some account is given of the mode of growth and sylvicultural requirements of the more important trees. It may be noted here that the Oaks, for which the author states that the Khasia hills are chiefly remarkable, are confined to a few hill-tops, the great mass of the upper Khasia hills being covered with grass-land, in which the Khasia Pine flourishes whenever it escapes from the annual fires lit by the Khasias, who burn the grass to make clearings for their cultivation.

It is noted that the Indian Forest Department administers about 118,000 square miles of forest, of which 81,000 are demarcated as permanent forest reserves. This is about 8½ per cent. of the territory of British India; but no mention is made of the extensive forests under native rule. The Native States of India are chiefly situate on hilly land, where agriculture can never flourish as well as it does in the more level country under British rule, and where, consequently, forest conservancy is most urgent. Most of these Native States have their own Forest Departments, the more important of which are supervised by trained British officials, while their superior and subordinate executive staff is to a large extent recruited from the Imperial Forest School of Dehra Dun. It is now time that a second school, as well equipped as that of Dehra Dun, should be established in the more tropical forests of the Bombay or Madras Presidencies, where the conditions of growth differ considerably from those of the north of India, especially as the Government of India could not recently at Dehra Dun find room for students from Mysore, one of the most important of the Native States of India. The French also intend to send their foresters from Tonquin and Cochin-China to study at an Indian forest school.

The Ceylon Forest Department is also under trained management, and sends its foresters to the Dehra Dun Forest School, so that this manual will be welcomed by the large staff of forest officials in India, Ceylon, and the French Asiatic possessions, as well as by a great number of Indian planters, timber-merchants, and by the numerous owners of private forests throughout these countries. It will also be accepted throughout the world as the authority on Indian timbers.

Altogether, 1,450 species of woody plants are described, and Mr. Gamble has estimated the number of trees, shrubs, and woody climbers in India at about 5,000. Very many, however, of these are merely of botanical interest, and as termites make short work of most Indian softwoods, we may feel assured that no important woody species has been omitted. There is a short account of Indian grasses, many of which are of commercial importance for fibres, paper making, and other purposes; while the account of the Indian Bamboos is extremely good, and probably includes all valuable species, as the author has specially studied this subject.

Criticism of the matter contained in this book is hardly called for, considering the great amount of labour which Mr. Gamble has bestowed on it, and the fact that he is probably better qualified than any other person for the task. I should like, however, to make a few remarks regarding the introduction of the Sweet Chestnut into the Indian Hills. This tree grows well in Dehra Dun, and bears fruit which is sold in the bazaars, and its further introduction would afford cheap food for the people, as it does in the south of Europe. Mr. Gamble notes that the fruit is not of the size and quality of that produced in Europe, but the fine Chestnuts grown in Spain and the south of France come from a grafted variety, which will not grow in England. Just as the wild Indian Walnut-tree produces worthless fruit and good timber, so the wild Castanea sativa produces good timber but only small fruits. Why does not the Indian Government procure grafted plants of the fruit-producing variety, and plant them in suitable localities in the Indian hills? Mr. Gamble names this tree C. vulgaris; it is generally known as C. vesca, but the *Index Kewensis* names it C. sativa.

As regards the form of the manual, the printing is excellent, and so are the reproductions of ninety-six photographic enlargements (3½ × 1) of transverse sections of wood. These are similar to the sections of European woods in Prof. Boulger's *Manual of Wood*, and are due to the initiative of Mr. Barber, formerly Instructor in Botany at the Royal Indian Engineering College, and now Director of the Botanical Survey of Southern India. They were prepared by Mr. Deane from some of Dr. Nordlinger's wood-sections. Four plates illustrating forest growth in India are given, but these are poor, and do not add much to the interest of the book. It is hard to say anything to detract from the merit of this excellent manual, but there is an insufficient margin to the pages, and the binding is of a flimsy nature, and not likely to last, as did that of the first edition, for twenty years and more. There are three excellent indices for scientific, English, and vernacular names of the species described. *W. R. Fisher, Cooper's Hill.*

ENQUIRY.

WILL some reader of the *Gardeners' Chronicle* kindly inform "A. J. A.," as to the parentage of the following Sarracenias, viz., S. Farnhami ×, and S. Sanderiana ×.

ROBIN HOOD AND THE KEITH BOILERS.—Will some of our readers obligingly furnish their experiences for garden purposes of the two sorts of boilers whose names are given above.

* Earwigs.

Remarks.—Another week of dull, dark, showery weather, with a low temperature generally. A heavy hailstorm, accompanied by thunder and lightning, passed over the district on the 3rd inst.

GENERAL OBSERVATIONS.

THE FOLLOWING SUMMARY RECORD of the weather throughout the British Islands, for the week ending Jan. 3, is furnished from the Meteorological Office :—

"The *weather* during this period was of a very unsettled type generally. During the earlier half of the time rain was of very frequent occurrence in the south, and rain, hail, or snow in the more northern districts, while later on, when the air became milder, the rain extended to all districts. Thunderstorms were experienced at some Scotch stations on Sunday (Dec. 28), and on Saturday (Jan. 3) sharp thunderstorms, accompanied by heavy hail, occurred in many parts of England and the north of Ireland.

"The *temperature* did not differ greatly from the mean, but was a little below it in Ireland and Scotland, and a trifle above it in most English districts. The highest of the maxima were recorded on Jan. 1 in Ireland, on the 2nd over England, and on irregular dates in Scotland. They ranged from 55° in Ireland, S., 54° in the Midland Counties and the Channel Islands, and 53° in England, S. and S.W., to 47° in Scotland, E. The lowest of the minima were registered, as a general rule, during the middle or latter part of the week. In Scotland, E. the temperature fell to 14°, and in Scotland, N. to 21°, but elsewhere the lowest readings varied from 24° in England, S., E., and N.W., to 29° in Ireland, N. and England, N.E., and to 36° in the Channel Islands.

"The *rainfall* was more than the mean in all districts excepting England, E. In nearly all the western and northern parts of the kingdom the excess was large.

"The *bright sunshine* exceeded the mean amount in all the English districts, and also in Scotland, W.; elsewhere it was deficient. The percentage of the possible duration ranged from 29 in England, S.W., and 28 in England, E., to 19 in Scotland, W., 17 in Ireland and in Scotland, E., and to 4 in Scotland, N."

THE WEATHER IN WEST HERTS.

AN exceptionally warm week. On several occasions the temperature in the middle of the day was 12° or more above the average for the time of year. The ground has now become very warm, the temperature at 2 feet deep being 3°, and at 1 foot as much as 6° warmer than is seasonable. Rain fell on all but one day, and to the aggregate depth of 1½ in., making this the wettest week recorded here since December 18, 1901. On the 4th, light rain was falling continuously for eighteen hours, and on the 3rd, shortly before 8 A.M., there was a short but very sharp shower of rain and hail. During the five minutes that it lasted, the rate of fall was about an inch per hour. The sun shone on an average for only about an hour a day. The winds varied greatly in strength, but were, as a rule, unusually high. Notwithstanding the frequent rainfall, there was less than a seasonable quantity of moisture in the air. The last Rose-bloom of the season was blown to pieces by the high wind on the 30th ult., or three weeks later than the average date of its destruction in the previous seventeen years. The Winter Aconite came first into flower in my garden on the 5th; this is the earliest date I have yet recorded here during the sixteen years over which my observations extend.

DECEMBER.

In the last sixteen years there have been only three other Decembers as warm as the past month. There occurred ten cold days early in the month, but during the rest of it the weather remained continuously warm. The exposed thermometer never showed more than 17° of frost, which is a high extreme minimum for December. Rain fell on fifteen days to the total depth of 1½ in., which is not much more than half the average for the month. There were a few light falls of snow and sleet, but at no time was the amount deposited sufficient to cover the ground. This was the most gloomy December for six years. The winds proved, as a rule, unusually high, but on only one day was a gale recorded. During the cold period of the month the winds came almost entirely from some point between north and east. In only three of the last sixteen years has the atmosphere been, on the whole, so dry.

THE WEATHER OF THE PAST YEAR.

All the months of the summer half of the year were more or less cold, but during the rest of the year there occurred only one unseasonably cold month, and that was February. In the last forty-six years there have been only two other years at Berkhamsted with as scanty a rainfall, viz., 1884 and 1898. This was also, with two exceptions, 1833 and 1889, the most sunless twelve months recorded here during the last sixteen years.

OUR UNDERGROUND WATER SUPPLY.

The deficiency in rainfall for the first three months—that is to say, since the winter half of the drainage year began—amounts to exactly 3 inches, which is equivalent to a loss of rain-water on each acre in this district of as much as 68,0.0 gallons. Unless the first three months in the current year prove very wet, the amount available for our underground water supply must once more prove unusually limited. *E. M., Berkhamsted, January* 6, 1903.

MARKETS.

COVENT GARDEN, January 8.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Thursday, by the kindness of several of the principal salesmen, who revise the list, and who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but often several times in one day. ED.]

POTATOS.

Various samples, 70*s.* to 90*s.* per ton; Dunbars, red soil, 105*s.* to 115*s.* *John Bath*, 32 & 34, *Wellington Street, Covent Garden.*

FRUITS AND VEGETABLES.

GLASGOW, *January* 7.—The following are the averages of the prices during the past week :—Apples, American Baldwins, 11*s.* to 14*s.* per barrel; Canadian ditto, 14*s.* to 16*s.*; ditto, Kings, 20*s.* to 26*s.*; Greenings, clear fruits, 15*s.* to 18*s.*; various high-class red, 14*s.* to 18*s.*; green, 16*s.* to 18*s.*; Oranges, Valencias, 420's, 7*s.* to 18*s.* per box; large ditto, 9*s.* to 12*s.* ditto; 714's, 8*s.* to 9*s.* ditto; Lemons, 4*s.* to 5*s.* per box, and 7*s.* to 12*s* per case; Grapes, English, 2*s.* to 3*s.* per lb.; Scotch ditto, 9*d.* to 2*s.* 6*d.* lb.; Almeria ditto, 12*s.* to 20*s.* per barrel; Mushrooms, 1*s.* per lb.; Onions, Valencia, 5*s.* to 7*s.* per cwt.

LIVERPOOL, *January* 7.—*Wholesale Vegetable Market.*—Potatos, per cwt.: Main Crop, 3*s.* 5*d.* to 4*s.*; Up-to-Date 3*s.* to 3*s.* 9*d.*; Bruce, 3*s.* 3*d.* to 3*s.* 9*d.*; Turnips, 6*d.* to 8*d.* per dozen bunches; Swedes, 1*s.* 2*d* to 1*s.* 4*d.* per cwt.; Carrots, 5*d.* to 7*d.* per dozen bunches, and 2*s.* 3*d.* to 2*s.* 9*d.* per cwt.; Onions, English, 4*s* 6*d.* to 6*s.* 6*d.* do.; do, foreign, 2*s.* 6*d.* to 3*s.* 6*d.* per bag; Parsley, 8*d.* to 8*d.* per dozen bunches; Cauliflowers, 2*s.* to 2*s.* 6*d.* per doz.; Cabbages, 6*d.* to 10*d.* do.; Celery, 6*d.* to 1*s.* 3*s.* do. *St. John's.*—Potatos, 1*s.* per peck; Grapes, English, 1*s.* 6*d.* to 2*s.* 6*d.* lb.; do., foreign, 6*d.* do.; Pines, English, 4*s.* to 6*s.* each; Apples, 2*d.* to 4*d.* per lb.; Tomatos, 4*d.* to 6*d.* per lb.; Asparagus, 1*s.* per bundle; Cucumbers, 2*s.* each; Mushrooms, 1*s.* 4*d.* to 3*s.* per lb. *Birkenhead:* Potatos, 10*d.* to 1*s.* per peck; Grapes, foreign, 6*d.* to 8*d.* per lb.; Mushrooms, 1*s.* per lb.; Filberts, 8*d.* do.

SEEDS.

LONDON, *January* 7.—Messrs. John Shaw & Sons, Seed Merchants, of Great Maze Pond, Borough, London, S.E., write that a strong and cheerful feeling now animates the seed market, and especially as regards Red Clover-seed, holders exhibit great and increasing confidence. This article, now the most favoured one, comes to-day dearer from all quarters; and in view of the light stocks and short crops, it does not look improbable that for once the supply may fall short of the demand. Meantime, Trefoil, Alsyke, and White command full prices, but Ryegrasses are quiet. There is very little inquiry just now for either Mustard or Rapeseed. Winter Tares are held for more money. Rye is, however, neglected. Canary-seed marks a further upward step on its way to three figures. Turkey now cables 85/3 cif. Other bird-seeds are without interest. Blue Peas continue slow of sale, but Haricot Beans register a further advance. In the dearth, in fact, almost famine of German Scarlet Runners, there is a good sale for Dutch Giant Beans, a very few of which are still obtainable at 22*s.* per bushel.

CORN.

AVERAGE PRICES of British Corn (per imperial qr.), for the week ending Jan. 3, 1903, and for the corresponding period of 1901, together with the difference in the quotations. These figures are based on the Official Weekly Return:—

Barley	26 7	23 11	— 2 8
Oats	19 10	16 10	— 3 0

Answers to Correspondents.

ARTICLES ON LANDSCAPE GARDENING: *D. H. S.* None have appeared in recent issues of the *Gardeners' Chronicle*. You would have to go back to the eighties, copies of which are not in stock.

BASIC SLAG AND SUPERPHOSPHATE OF LIME: *F. H. B.* These substances are, as top-dressings of 3 or 4 oz. per square yard, useful on grassland in increasing the growth of the finer grasses, which in turn drive out the coarser-growing species and weeds.

BEGONIA-LEAVES BLOTCHED: *A. O. W.* We believe the blotches are the result of drip or of precipitation of moisture, due to sudden lowering of temperature.

BOOKS: *C. L.* We do not know the price. Apply to the publishers, Messrs. Sutton & Sons, Reading.—*E. C.* The second volume, only, of Elizabeth Blackwell's *Herbal*, published in 1739, is only of value as a curiosity. Some second-hand bookseller might purchase it for a small sum.

BROAD-LEAVED GRASS: *F. H. B.* Can you not send a specimen plant? Perhaps you mean Dactylis glomerata.

CINERARIAS: *A. P.* The injury to the leaves is not due to a fungus or to insects, but probably to some adverse atmospheric influence, or to fumigation. Keep the atmosphere of the pit as sweet as possible, and by affording fresh air on every favourable opportunity the leaves will be strengthened, and made less liable to injury or disease.—*H. S.* We cannot tell unless we examine a specimen. Possibly it is the work of eelworms, which may be detected by the presence of wart-like excrescences on the roots.

COBNUTS AND FILBERTS: *W. J. S. G.* The first is a roundish oblate nut, the second of an elongated oval shape. There are numerous varieties of each.

FRUIT TRADE JOURNAL: *A. M. C.* We do not know.

GALVANISED IRON BANDS TO SUPPORT ADDED SOIL TO A POT ROSE: *Constant Reader.* The galvanised metal would do no harm, so far as we know of.

GRASSES FOR MENDING THE SURFACE OF A RACECOURSE: *F. H. B.* If the land is to be laid up for hay, Avena elatior is a good early-growing grass, suitable for clayey land, if not too wet; it should be sown in the autumn. Cynosurus cristatus, Dactylis glomerata, good on stiff, damp soils. Festuca pratensis; it attains maturity in three years. F. ovina is a small, succulent grass, useless for hay, does well on chalk, does best if not highly manured; and F. duriuscula. You should apply to some of the specialists who deal in grass-seeds for different purposes.

MAGNUM BONUM: *W. J. S. G.* The words mean (1) large and (2) good.

MOSS AND LICHENS ON FRUIT-TREES: *K. R. H.* The ordinary alkali or soda-wash is an effectual cleanser; made by dissolving ½ lb. of washing soda in a 3-gallon-pailful of boiling water.

MUSA CAVENDISHI, WHEN TO COMMENCE TO GATHER THE FRUITS: *Macdaunder.* The bunch begins to ripen at the base, or thick end, which is eventually uppermost, and it is at that part you should begin to gather. The fruit is better if left on the plant till it is fit to eat. Unless you fear the dampness of the stove at this season will cause rotting, there is no need to remove the bunch from the plant—in fact, dryness tends to preserve the fruit from decay, and to improve flavour. The present is not the best season in which to have Bananas in fruit.

NAMES OF PLANTS: *Correspondents not answered in this issue are requested to be so good as to consult the following number.*—*Tib.* 1, probably the leaf of a Gesnerad—send when in flower; 2, Euphorbia Jacquiniæflora.—*E. G.* 1, Eriobotrya japonica, the Loquat; 2, Tecoma jasminoides; 3, Hibiscus rosa sinensis; 4, Cissus discolor.—*A. J. & G. P.* A rather distinct form of Cypripedium Dayanum.—*W. Davies.* 1, a variety of Thuya orientalis; 2, Cupressus Lawsoniana; 3, Pseudotsuga Douglasii; 4, Cupressus Lawsoniana erecta viridis; 5, Thuya gigantea; 6, Thuya gigantea.—*W. W. G.* Polypodium vulgare.—*Arton.* 1, Pteris tremula; 2, Pteris cretica albo-lineata; 3, Cyrtanthus lutescens; 4, Oncidium flexuosum; 5, Oncidium excavatum; 6, Stanhopea graveolens.—*F. T. H., Southampton.* 1, Catasetum macrocarpum; 2, Gongora quinquenervis; 3, Gongora cassidea.—*Victor.* 1, Bulbophyllum auricomum; 2, Bulbophyllum hirtum.—*O. T.* 1 and 2, both known in gardens as Carex japonica variegata, the more slender being often called "gracilis"; 3, a Ginger-wort. Send in flower; 4, Dichorisandra vittata; 5, Abutilon Savitzii; 6, Bougainvillea glabra variegata; 7, Elæodendron orientale.

NOVELTIES OF 1902: *J. Coene.* We have not so much space at our disposal as would permit of every certificated plant being mentioned; a selection has therefore to be made.

ORCHID BLOOMS WITHERING: *A. B. C.* Failure to expand the buds of Phalænopsis, and the withering of the flowers of those and other Orchids, similar to the specimens sent, is a common thing at this season of the year in or near towns. In the neighbourhood of London and other towns where fogs prevail, the influence of foggy weather is the cause assigned. But it is not difficult to understand that similar effects might be produced on Orchid flowers, the inflorescences of which were probably commenced early enough to admit of their blooms being expanded under favourable conditions some weeks ago, but which could not develop through lack of light, and especially sunlight. Of course, such mischief might result from excessive heat, and defective ventilation, or from the hot-water piping being newly blacked with improper colouring; but absence of light is most probably the cause of the trouble you complain of.

PALMS DISEASED: *A. B., Epping.* The fungus is Graphiola phœnicis. Burn the affected leaves, and keep your plants clean, using a fungicide if necessary.

PAYMENT OF WAGES DURING ILLNESS: *Constant Reader.* The gardener who falls sick cannot claim, as a right, payment of his wages during his absence from his employer's garden; but we doubt if many employers go to the length of paying no wages at such times, if the man's character is good, and his illness of no great length.

PELARGONIUMS: *Preston.* The plants have grown when they should have been at rest, and have collapsed from too much heat and moisture, and too little ventilation. The Ivy-leaved varieties are more hardy.

POA PRATENSIS ROOTS: *F. H. B.* Not injurious to turf.

POTASH MANURES: *F. H. B.* Woodashes—a weak form of potash, kainit, nitrate of potash, sulphate of potash, and carbonate of potash. All of them are the safer for being mixed with leaf-mould, bone-meal, road scrapings, or rotted Couch-grass roots. The sulphate is too dear for general use on a large scale.

PRIMULA VERTICILLATA: *R. V. & Son.* The grubs are those of a weevil; and you know how destructive they are, and how to deal with them, as well as we can tell you.

SAMPLES OF GARDEN SOILS, &c.: *J. Barker.* We do not believe it is possible to grow even passable kitchen-garden crops in such soil as that sent, unless it undergo great amelioration. The soil is so compact, and so destitute of stones, sand, humus, or anything that would assist in its aëration, that no plant could make healthy growth in it. It should be heavily dressed with half-decayed stable-dung, being content for the first year or two to bastard-trench it, going deeper with the digging and manuring in the following years until a depth of 2½ feet to 3 feet is reached. You would find that heavy dressings of coal-ashes, mortar rubble, quick lime, road scrapings, sand, ballast, and superphosphate of lime, are of great benefit to the crops. The drainage may also be faulty, and this should be put into good order. If you could cultivate the crops of Cabbage, Brussels Sprouts, and Brassicas generally, in an adjoining field, you would, in the course of a few years get rid of the slime fungus, Plasmodiophora, by a process of starvation, otherwise matters are sure to get worse, the seedlings getting infected in the seed-beds. If it were possible to lay part of the garden fallow for the better part of a year, such portions could be heavily dressed with gas-lime, and afterwards afforded dressings such as those named above. Whale-oil is a good remedy against American Blight on Apple-trees, but more than one application is needed; moreover, the roots of the trees should be laid bare and drenched with soap-suds, fresh soil being used to cover them. This must be done more than once a year.

THE SLOE: *E. E. K.* The true Sloe, Prunus spinosa, is, we presume, blackish-blue. The so-called white-fruited Sloe is the common Bullace.

TOP-DRESSING ON HEAVY LAND: *F. H. B.* The proposed sea-sand is good; also fine coal-ashes, wood-ashes, road-scrapings, ditch-scourings, mortar-rubble finely broken, partially decayed stable-dung, &c.

TRIFOLIUM REPENS: *F. H. B.* This plant being a Clover, would not be included among grasses in a work on Gramineæ.

TULIP-TREE (LIRIODENDRON) TULIPIFERA: *G. T. R.* Stratify the seeds in sand or sandy loam in a garden-frame, and prick off into beds when the first pair of leaves appear, shading them for a time with pea-sticks laid on a wooden frame. Only a certain percentage of the seeds will vegetate.

VINE ROOTS: *H. J. C.* Found dead, cause unknown. No Phylloxera.

MENDEL'S METHODS OF PLANT BREEDING.*

THE first hybrid plant raised by hand appears to have been recorded by Richard Bradley in 1717 as a cross between the Carnation (Dianthus caryophyllus ♀) and the Sweet William (D. barbatus ♂), having been raised by Thomas Fairchild, of the Hoxton Nurseries, near London. Since then, many hybrids and crosses in many genera have been raised by many persons in many countries. Among others, the names of Kölreuter, Knight, Herbert, Gärtner, Godron, Naudin, and Darwin stand pre-eminent; the culminating point of all these being the experiments, researches, and broad generalisations of Charles Darwin, which mark off a distinct epoch.

The new epoch seems to have begun actually in Darwin's time, though apparently unknown to himself and to his contemporaries. In 1866, about two years before Darwin published his monumental work on the *Variation of Animals and Plants under Domestication*, Gregor Mendel published at Brünn the records of his remarkable experiments in crossing distinct races of Pisum. Curiously enough, his work remained in obscurity until 1900, when it was brought to light by the researches and experiments of De Vries in Holland, Correns in Germany, Tschermak in Austria, and Bateson in England. So that although 1866 marked the beginning of the new epoch, yet it was not until the close of the nineteenth century that any marked advance was made. The "psychological moment" had then arrived, and during the past two years the progress in certain directions has been phenomenal. Experiments with various kinds of plants and animals, carried out on Mendelian lines, have yielded large numbers of facts, which on the whole practically confirm the results obtained by Mendel himself. At the same time, it is only fair to state that on every hand apparent exceptions are fairly numerous.

In face of these exceptions, and notwithstanding the many confirmations of Mendel's results by others in other kinds of plants and animals, it seems to be too early yet to regard Mendel's principles as of general application to plants and animals.

At the same time, Mendel's experiments are a great advance on what has been done before, and will probably prove a stepping-stone towards the final solution of the problems of inheritance. For the present, it may be wise to suspend our judgment and wait for further facts; but while we wait, let us also work and help to secure those further facts, altogether regardless of whether they happen to confirm or deny the principles laid down by Mendel.

In order to accomplish this, it will be necessary to work strictly on Mendelian lines, and to study Mendel's methods with great care. Mendel, after surveying the work of his predecessors, started with a clear conception of what he wanted to investigate, and arranged his experiments accordingly—

(1) He wished to determine the number of different forms under which the offspring of hybrids appear.

(2) To arrange these forms with certainty according to their separate generations.

(3) To definitely ascertain their statistical relations.

The careful judgment, skill, and forethought which guided Mendel in carrying out his experiments were evidently the products of a master mind, and his experiments may, for some time to come, serve as a model for the hybridist who wishes to attack the perplexing problems of heredity.

The object of this paper is to give a brief outline of Mendel's methods, and to endeavour to show how superior they are to the methods of his predecessors. The writer does this also in the hope that the hybridists and breeders of the New World, with their progressive ideas, their many opportunities, their vast system of experiment stations, and their practical knowledge of breeding, will take up and test the matter on a much larger scale than we can ever hope to do in the Old World, and thus help to bring the question to a speedy and definite issue. So convinced is the writer of the superiority of Mendel's methods, that he has already in hand a large number of experiments on Mendelian lines in Pisum, Lathyrus, Papaver, Primula, Berberis, and Paphiopedilum (Cypripedium), also in various breeds of poultry and rabbits, the results of which he hopes to publish in due course.

MENDEL'S METHODS.

1. *Single Characters.*—Perhaps the most fruitful source of confusion in the older records of experiments in cross-breeding has been the selection of the individual plant as the unit for the results. The individual plant is, as a rule, made up of a large number of characters—organs, structures, whatever one may term them—distinctly marked off from one another, having points of difference, great or small, in form and colour. In working out the inheritance of specific characters in Orchid hybrids in 1899, the writer became much impressed with the possibilities of variation in individuals when a number of characters in each were considered together. Some characters showed dominance of one parent, some of the other, while others were intermediate. When these several variations occurred in twenty or more characters, the possibilities of variation among the individual hybrids became very considerable; so much so, that taking the individual as the unit, the results were quite unmanageable. Since then the writer has been compelled to consider each single character on its own merits. It is true, that correlation of characters in many cases serves to modify this result to some extent, but in the case of the Orchid hybrids in question, the correlation was not very evident.

These experiences probably go far to explain the many apparent contradictions in the older records, some observers taking one character, and others another; the result depending entirely upon which character was observed. It follows, therefore, that in any statistics of inheritance, a definite result can only be determined by taking each character separately. Mendel was very careful to do this in his experiments with Pisum, with remarkable results.

2. *Constant characters.*—Next comes the important question of ancestry. From the earliest times it has been observed that in many instances offspring have resembled their grandparents, and even more remote ancestors, rather than their actual parents; so that in experimental crossing, if two parents be chosen, each of whose ancestry is unknown, or perhaps consists of complicated factors, the resulting offspring are either incomparable and incomprehensible, or they vary among themselves in bewildering confusion. The result in any case is chaos, and goes a long way to account for the many contradictory records which we find in the experiments carried out under the old *régime*. Mendel, carefully and skilfully, avoids this confusion in his experiments with Pisum, by crossing together only constant and fixed races, i.e., each parent has been the product of repeated self-fertilisations, so that its ancestry has been practically the same for many generations. This effectually disposes of the possible complications caused by the influence of the immediate ancestors at any rate, though how far it affects the possible reversion to more remote ancestors is difficult to say.

The writer, in his experiments with Orchids, has chosen distinct species as parents, and in this way perhaps reduces the possibilities of reversion still more. De Vries, Correns, Tschermak, and Bateson, have all for the most part followed Mendel's method by crossing constant races; and i

* Read at the International Conference on Plant-Breeding and Hybridisation, New York City, Sept. 30, 1902, by C. C. Hurst, Burbage, Hinckley.

is quite possible that some of their apparent exceptions to Mendel's results may be due to their crossing, unwittingly, more or less inconstant races. As we have seen, Mendel carefully avoided this by selecting parents of pure descent, and side by side with his crossing experiments, he was careful to carry out control experiments with the original parents by further testing their constancy and fixity through all the generations. Consequently, all his results with Pisum were uniform and without exceptions. *Charles C. Hurst.*

(To be continued.)

CHINESE CONIFERS.

[MESSRS. JAS. VEITCH & SONS, having kindly confided to me for examination the collection of Coniferous plants obtained in Central China by their collector, Mr. E. H. Wilson, I propose from time to time to call attention to some of the more interesting of these plants. Mr. Wilson's specimens are mostly excellent; some represent new or undescribed species, others are of special interest from some cause or another—indeed, all are more or less noteworthy. These notes will therefore be complementary to those published in these pages by Lindley and Andrew Murray on the Japanese species, collected by the late J. G. Veitch, and to those published by myself in these columns, on the plants sent home by the late C. Maries from Japan. The latter also formed the subject of a communication to the *Journal of the Linnean Society* in 1880, vol. xviii.

The enumeration of the Chinese Conifers by myself in Hemsley's *Index Floræ sinensis* (*Jour. Linn. Soc.*, Botany, vol. xxvi., p. 540), was unfortunately published just before the receipt of Mr. Wilson's specimens. This is the more unfortunate, as some of Mr. Wilson's specimens have not previously been described. It may also be said that young plants of most of these Conifers are growing in Messrs. Veitch's nursery at Coombe Wood, and at Kew, so that in due time we shall hope to be able to report upon them in the living condition. *Maxwell T. Masters.*]

PINUS KORAIENSIS.*

We are glad to be able to give good illustrations of this species, which has been imperfectly and confusedly described by various anthors.

The branches are greyish-brown, roughened by the scars left after the fall of the leaves. The leaves are in fives, slender, about 9 cent. long, and 3-sided. In cross-section it may be noted under a low power of the microscope that the hypoderm or layer of thick-walled woody cells beneath the epiderm is nearly wanting. The meristele or central bundle is circular or ovoid in section, surrounded by an endoderm of some twenty cells. The fibro-vascular bundle is umbranched. The resin canals are in the centre of the cortex or leafy substance of the leaf. The bud-scales are deciduous, membranous. The male flowers are small, ovoid, in sub-globose clusters. The anthers are destitute of crest, and the pollen cells as here observed and figured by Mr. W. G. Smith, two-winged.

The cones (fig. 19) are shortly stalked, pendulous, about 18 cent. long by 7 cent. wide, rounded at the base, cylindric-conic, slightly tapering towards the apex; the lower cone-scales smaller, and more markedly recurved than the upper ones; scales, from the middle and upper part of the cone are thickened near the apex, broadly triangular, more or less recurved at the tips.

The seeds are wingless. The figure of the cone given by Siebold and Zuccarini was acknowledged by the authors to be incorrect, and the specimens in herbaria are not always correctly named, on which account we are glad to figure the fine specimen collected by Mr. Wilson (n. 597!).

The species occurs in Mandshuria, Japan, China, in the provinces of Shensi, and in Corea. Mr. Wilson's specimens were collected in West Hupeh.

FIG. 18.—PINUS KORAIENSIS.
Showing shoot, foliage, male flowers, tip of leaf magnified, anther, pollen grain × 300, and wingless seed.

MARKET GARDENING.

CHRYSANTHEMUMS: SELECTING AND STRIKING THE CUTTINGS.

No time should be lost in putting in the desired complement of Chrysanthemum cuttings of approved market varieties—varieties which with generous and intelligent treatment will yield a profusion of flowers from the end of August on to November (in the absence of frost) out-of-doors, and into the new year when plants of late flowering varieties are lifted from the open ground and transplanted under glass in Cucumber and other houses on the approach of frost. Abundance of strong, short-jointed cuttings of most of the varieties which have flowered out-of-doors are now available. These should be taken off close to the ground about 3 inches in length, and inserted 3 inches apart in boxes filled with fairly light mould and surfaced with sand, making the soil moderately firm

* *Pinus Koraiensis*, Siebold and Zuccarini, *Flor. Japon.*, ii., p. 28, t. 116; Mayr, *Monog Abiet. Japan.*, i., 73, p. 3, tt. 5-6, fig. 18; Murray, *Pines and Firs of Japan* (1863), p. 6; Masters, in *Journ. Linn. Soc.*, Bot., vol. xxvi., p. 541, where references to the literature may be found.

about the cuttings in putting them in. Place the boxes closely together on strips of wood laid on a Vine or Peach-border, or any cool-house or pit that may be available at the time. Water through a rose water-pot to settle the soil about the cuttings, and allow the former to become fairly dry on the surface before repeating the operation. Cuttings thus treated will root in due course, and grow into good, sturdy plants by planting out time, the points being pinched twice during the interval.

The following are well known and thoroughly trustworthy early-flowering market varieties:—Madame Marie Massie, pink; Madame Desgraves, white; G. Wermig (syn. Yellow Desgranges), Harvest Home, red tipped with gold; Soleil d'Octobre, yellow; Queen of Earlies, white; Ryecroft Glory, good October yellow; White Quintus, pure white, the habit of growth being everything that could be desired; A "Mum," Source d'Or, bronze; Lady Selbourne, white; Madame la Comtesse Foucher de Cariel, bronze; O. J. Quintus, fine October pink. Late varieties for transplanting under glass:—Dazzler, fine crimson (November); Elaine, grand white (November); Lady Osborne, light pink (December); Niveus, white; W. H. Lincoln, yellow; La Triomphante, pink; and Mrs. J. Thompson is a good December white. All being well, a cultural note as to the planting out and subsequent treatment of the plants for market purposes will be contributed to the *Gardeners' Chronicle* in March.

Raising Cucumber Plants.

Prepare the necessary number of 3-inch pots forthwith for the reception of Cucumber seed, by placing a piece of crock hollow side down over the hole in the bottom of the pots, and fill the latter three-parts with a mixture of light, fresh, loamy soil, and well-decayed stable-manure, in about equal parts; deposit one seed in each pot, cover lightly with soil, and press gently. Stand the pots closely together in a house in which a minimum temperature of 70° is maintained, and cover the pots with paper, the paper having been placed in the house twenty-four hours before being used. Examine the soil two or three days after sowing, and if found to be rather dry on the top, afford a small quantity of tepid water through a spray distributor. As soon as the young plants appear through the soil, remove the paper and transfer them to a shelf near the roof-glass, and top-dress with slightly-warmed compost as soon as the plants have attained a little strength and thickness of stem, filling the pots up to the rims in two separate top-dressings. Put a small stick to each plant, and shift into 32's before the roots get matted, using the same kind of compost as that indicated above. In the meantime the houses should be put in order for the reception of the plants a few weeks hence. If not already done, the soil forming the old ridges should be wheeled out, and flowers-of-sulphur burnt in the houses with a view to destroying any insect enemies that may have effected a lodgment therein during the last nine or ten months. This done, cleanse the glass and woodwork with water, and the brickwork with a wash made from quicklime; then strew some quicklime over the floor-space on which the ridges are to be formed, cover this limed space with freshly-cut turves, grassy side down, digging 6 or 9 inches deep of the soil from which the turf is taken, using this and peat manure in the proportion of four parts of the former to one of the latter, to form the ridges, when well mixed. At first, a ridge about 15 inches wide and 9 inches deep will be sufficient for the plants, if set out at 2 feet apart. Make a deposit of soil, to be used later at intervals when moulding up becomes needful, up to within a few weeks of the time of the plants having yielded all that it is possible in the way of Cucumbers. Rochford's Market is still a general favourite with growers. *H. W. Ward.*

APPLIED BOTANY.

One of the four meetings arranged by the Technical Education Board of the London County Council in connection with its annual conference of science teachers was devoted to Botany. Hence, on the morning of January 10, Professor Farmer presided at the South Western Polytechnic. He had much to say on the value of botany, even of a systematic kind, if taught properly, as a means of training, and in his subsequent remarks alluded to the economic value of the science.

One of the points which he brought forward in this connection was that of grass below Apple-trees, which often delayed their bearing as long as seven years. He thought that perhaps in interesting children in Nature the question of the removal of oxygen by the grass need not be raised, but that the absorption of water by the

FIG. 19.—CONE OF PINUS KORAIENSIS, COLLECTED BY MR. WILSON.
(SEE P. 34.)

herbage that would otherwise get to the roots might well be studied.

Miss Lilian Clarke, B.Sc., who gave an address on "The Rational Teaching of Botany," explained that she was not responsible for the title. She described minutely how the school garden had been utilised, not merely for growing plants various orders, but for Nature-study work on the pollination of plants. The way in which plants were successfully grown in solutions containing all the necessary food constituents was gone into, and the ill effects of leaving out iron, magnesium, and so on, alluded to. Great enthusiasm is shown in connection with this work, which should, in spite of Miss Clarke's contention—as was pointed out in the discussion—be considered as above the plane of Nature-study. The excellent work done upon the rambles, the drawing of natural objects, and other correlated pursuits of a Nature-study character at James Allen's school were also characterised.

The second address was on "Experimental Plant Physiology," and was given in connection with a remarkable exhibition of experiments in the Natural Science Laboratory of the South-Western Polytechnic, by Mr. H. B. Lacey, who is responsible for the teaching there. We should very much like to describe in detail many of the simply-constructed but most effective pieces of apparatus, but must for the present content ourselves with singling out the contrivances for demonstrating the growth in height of a plant, the revolving water-wheel for holding seedlings, and the dark box for etiolation experiments, which could also be adapted for growing plants under coloured light with more success than in smaller jacketted glass vessels, where the increased temperature of the air may give rise to growth which might be set down to other causes.

THE ROSARY.

PLANTING NEW BORDERS.

In making new borders of Roses for the decoration of the mansion and grounds, the staple soil should be taken out to the depth of 18 inches, putting on the bottom a layer 4 inches thick of good clay, unless there is a clay subsoil; then fill in with new soil composed of six parts of fresh loam, dug from an old pasture, and two parts of good rotten dung. These should be well mixed together, and then filled in to the depth of 14 inches. After planting at distances from 18 inches to 2 feet apart, according to the habits of different varieties, mulch the surface of the border with some good rotten dung, which will serve as a protection to the roots of the Roses and as a nutrient. Upon receiving the plants from the nursery, on no account allow them to be exposed to winds before planting. Everything should be made ready for planting before they arrive, that they may be put into the ground directly.

There are so many very fine varieties in Teas Hybrid Teas, and Hybrid Perpetuals, to meet the tastes of all lovers of this beautiful flower, that I strongly advise planters of any or all sections to arrange the varieties in groups, say at least a dozen in each colour, so as they do not clash one with the other. In selecting, be sure to get those varieties most reliable for continuous blooming, and varieties that travel best as cut flowers, for we must not forget the needful supply of blooms to the town house as well as the country mansion. After these groups are thoroughly established, you will have no difficulty in furnishing a dinner-table or drawing room with blooms all of one colour. The Rose is then one of the most useful decorative flowers. What has a better effect than a good and well arranged vase of the variety Mrs. John Laing, or Madame Lambard? But there are many other well-known varieties equally effective that I need not mention. *F. Capp, gardener to Hugh Andrews, Esq., Toddington, Gloucestershire.*

FOREIGN CORRESPONDENCE.

PINES IN THE AZORES.

While on a visit to St. Michaels, Azores, recently, I was much interested in the Pineapple cultivation which is extensively carried on in that island, and I was particularly struck with the method usually employed by the growers for hastening the plants into flower. When the plants have reached an advanced stage of growth, and are apparently fully grown, a slow smouldering fire of damp and green leaves is made in the glasshouses and kept up for about eight or ten days, not longer. The windows and doors are kept securely closed during this time so that the atmosphere in the houses becomes densely charged with smoke. It is generally believed that the smoke stimulates the plants to bloom, and not the heat generated by the fire, which is said to be not appreciable. Should the plants prove stubborn, the process is repeated after an interval of several weeks; but one application of smoke is, I understand, generally sufficient. I was told that the life of the plant was artificially shortened in this manner, from eighteen to eleven months. The plants are timed to attain their full growth in August or September, the "smoke" is then given, and the fruit matures in December or January, when the best values are obtained. The discovery of the smoking process, which dates back to more than a decade, was made quite accidentally; a planter having made a smouldering fire in one of his pineries for the purpose of destroying an insect pest, was surprised to observe that his plants burst into flower prematurely.

I should be glad if you, or any of your readers, could throw any light on the physiology of the process, and whether anything similar is employed in Pineapple cultivation elsewhere. *M. Grabham, Madeira.*

IS LILIUM AURATUM A HYBRID?

In a recent number of the *Garden* it was said: "It would be a strange thing, but one not inherently impossible, if Lilium auratum were really a hybrid of Chinese origin, which has become wild in certain parts of Japan."

I have at various times intended to write about this theory, which has often been mentioned before, but now that so great an authority as Mr. Henry has written concerning it, I wish to add a few words on the subject. It seems to me that no one who has seen Lilium auratum in its native land can doubt that it is a distinct species, original to Japan, for it seems impossible that any hybrid introduced into Japan could have spread over the country to such an extent as we find Lilium auratum has done. This Lily grows in the Nikko mountains, the Hakone mountains, in fact on the mountains and hills almost all over the eastern and northern parts of the island of Nippon, the most central and largest of this Island Empire; unfortunately, however, no longer in such quantities as formerly, owing to the immense quantities exported, for the farmers simply take their planting-stock each year from the mountains, not having the thought to cultivate the bulbs either from scales or seed.

In support of this theory it may be mentioned that on the hillsides too steep for the foot of man to reach, there the Lilies are still to be seen in masses, all of which leads one who has formerly seen the Lily growing here to conclude that it is a native Japaneso plant, and doubtless a true species. The question is often also asked, why the early travellers here did not mention Lilium auratum. The answer to this is, I think, that before Japan was opened to the world, foreigners were only allowed to live on the small island of Decima, in Nagasaki harbour, and all plants which they described and sent home came from that region where Lilium auratum does not grow.

Another reason is, that the Lily was so common here that the Japanese botanists who helped Siebold and the other foreigners probably never thought of this blossom as being an important one—still the reason why the Japanese to-day rarely use it in their gardens, seeming to care very little for this Lily so prized abroad. *Alfred Unger (L. Rochmer & Co.), Yokohama.* [It will be remembered that Lilium auratum was first made known in English gardens by the late John Gould Veitch, and that it was described and figured for the first time by Dr. Lindley in our columns in 1862, p. 623. ED.]

NATURE IN WINTER.

This season of the year, though generally regarded as a period of decay, full of tempestuous winds and melancholy monotonous rains, has many consolations for the reverential spirit, which they who love not Nature can hardly realise. In many sheltered places, for example, familiar and favourite wild flowers may still be found. In a sequestered corner of my garden the Primrose, whose mild splendour is usually associated with the floral revelations of May and June, is in premature bloom. Near it is that hardiest and most heroic of woodland flowers, the pink Campion, still adorning at green intervals the garden wall. There also may be found the miniature Linaria, which has all the characteristics which pertain to sylvan flowers. The Woodbine still retains, with beautiful persistence, its glossy leaves. This plant has quite a tropical aspect in the woods environing Logan House, the residence of the chief proprietor in this parish, where, climbing up the trees, it sometimes reaches a height of 20 feet, forming a series of most artistic pictures during the month of July.

Though the wild Roses have only a short summer season of transitory bloom, their clustering scarlet berries are richly effective at this season of the year. Exceedingly graceful are those of the Holly, one of the loveliest of winter trees, which has tender Christmas associations; links of sacred memory between the everfading present and the steadfast past. The Hawthorns also are radiant with berries, whose utility is even more apparent than their beauty; a providential provision for the helpless birds. And thus while Nature in winter is not unbeautiful, and by no means unsuggestive, she is also full of hope. "Nature," says the great Wordsworth, in one of his most thoughtful and most memorable poems, "never did betray the heart that loved her; 'tis her privilege through all the years of this our life to lead from joy to joy." And this is the feeling which she imparts at this season to the patient cultivator, that the spirit of the re-awakening and vivifying spring is not very far away. Already, as early as December 15, the first-born of the Snowdrops, gleaming pendulously in my garden, gladdened my gaze.

The Crocus, its brighter but not lovelier successor, is already disclosing its closely folded, embryonic leaves, through which its floral brightness ere long will reappear. The Daffodil, whose growth, though slow and laborious till it feels the warm impulse of the vernal rays, has nevertheless begun, and attests by its aspect that there is preparation for the future at work underground. This, indeed, is the noblest prerogative of Nature; that her work, however marvellous,

is accomplished in repose. There is no sound to indicate the greatness of her efforts, which are not the less momentous because so silently transacted; beneath the thunder of the elements her "still, small voice" is that of God.

And thus, while in spring and summer and autumn she ministers most graciously to our instinct for beauty through the gentle medium of those flowers that bless our troubled lives, and grow upon our graves, she teaches us at this season of seeming death and desolation deep lessons of patience and faith and steadfast hope. Beneath the shroud-like covering of the stainless snow her great heart is beating with the pulsations of the spring. The heavens may be clouded, the atmosphere in mourning, but the Snowdrop has arisen from the grave of Nature's beauty, and the vernal resurrection has already begun. *David R. Williamson.*

DISA GRANDIFLORA.

OUR illustration (fig. 20), represents a very remarkable specimen of this fine scarlet terrestrial Orchid, which is often called the Pride of Table Mountain. We have illustrated the species before, and have often had photographs of good specimens sent to us, but have never seen one so fine as that from which our illustration was taken, and which was sent by the grower, Mr. W. Kilfour, gardener at Edge Hall, Milltimber, Aberdeen. The specimen bore fifty-four flower-spikes, having together one hundred and twenty-two blooms, one spike having five of them. The plant was remarked on in the *Gardeners' Chronicle*, December 6, 1902, p. 413.

ECONOMIC BOTANY.

WE take the following extracts from an address recently delivered in Edinburgh by Professor Bower, as printed in the *Journal of the Pharmaceutical Society*. Addressed to a body of pharmacists, they are, *mutatis mutandis*, fully applicable to cultivators of plants, whether agriculturists, foresters, or gardeners.

After dealing with the pursuit of pure science, on which future progress so materially depends, Professor Bower went on to the consideration of the applications of science, and especially of the applications of botanical science, to practical ends:—

THE SUPPOSED USELESSNESS OF BOTANY.

There is, perhaps, no science which seems to the average man so futile. The name "botanist" is, to those who know least about it, almost synonymous with that of a "mild and harmless visionary." He does no harm to anybody, they would say, and, under their breath, add, that he does no good either. Yet this same average man eats vegetable foods daily; even his beef and mutton are indirectly of vegetable origin; he drinks beverages of vegetable origin, solaces himself with vegetable narcotics, depends upon vegetable textiles for many of his clothes, uses wooden articles for all manner of purposes; he is liable to fall a victim to diseases of vegetable origin, which he will try to cure by the help of vegetable drugs. Why, if this be so (and the average man can hardly be ignorant of it), does he take so unfavourable a view of the student of those organisms which are the very mainspring of his life? I cannot help thinking that the botanists are in a measure to blame. In the past, perhaps more than now, they have entrenched themselves behind a barrier of terminology, and make little endeavour to show that many of the terms are in themselves an evil. Accordingly, the conclusion is that the botanist sets store by repulsive trifles, and is, therefore, worthy of contempt. But, further, in this country we have been slow to adopt the practical applications of botany to agriculture, forestry, manufactures, and the arts; this is, perhaps, the chief reason why the average man has not yet consented to take the science of botany quite seriously.

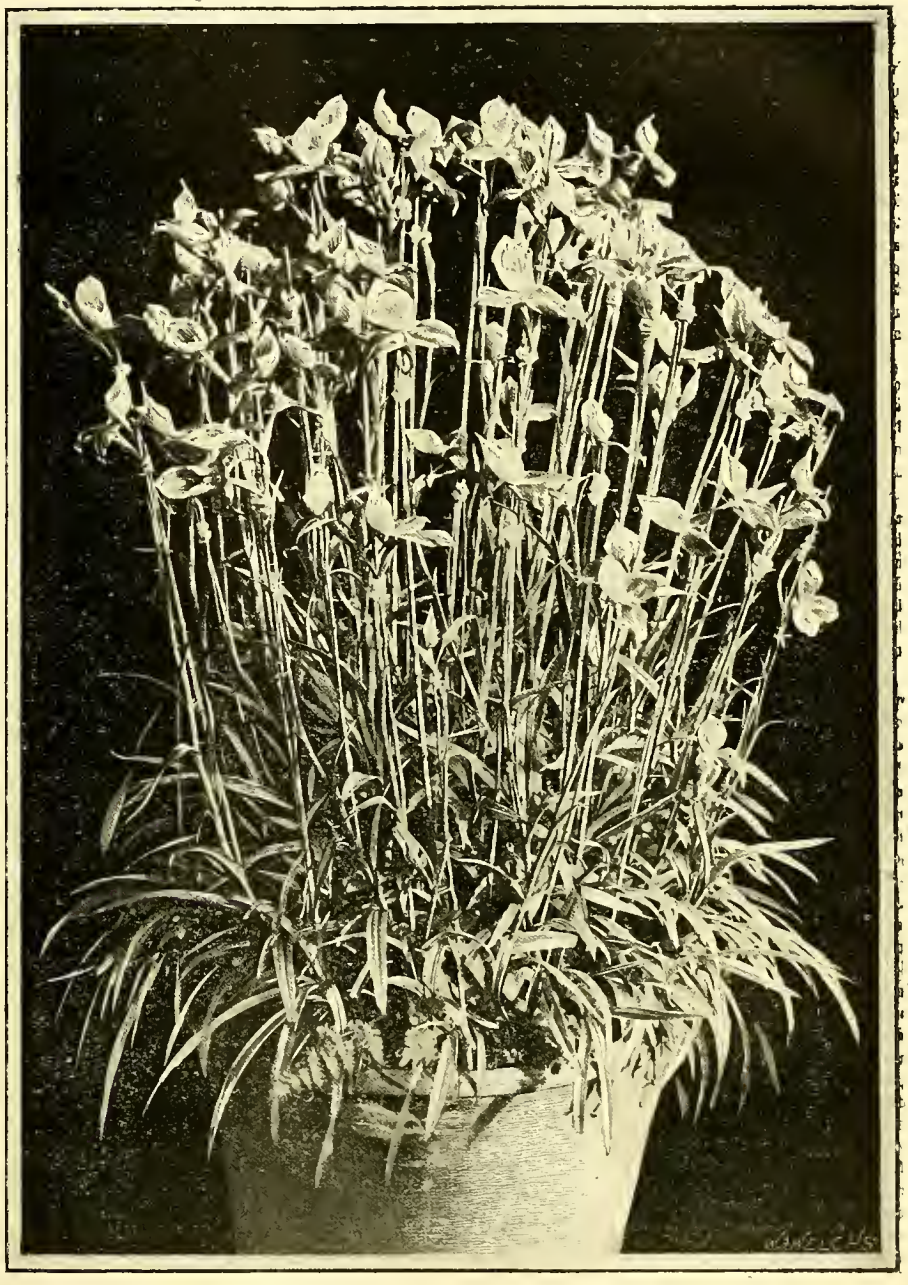

FIG. 20.—SPECIMEN PLANT OF DISA GRANDIFLORA, CULTIVATED IN EDGE HALL GARDENS, ABERDEEN.

THE TEACHING OF AGRICULTURE.

As a consequence of the great increase in the introduction of cheap food materials from abroad, coming on the back of a series of bad seasons at home, the agriculture of the country fell into such difficulties as to draw general attention to the need for more precise and economical methods. The edict went forth, as a sudden consequence of panic, that agriculture was to be taught locally; and at once an army of teachers, some newly appointed for the special duty, others having this duty thrust upon them, engaged in this task with little or no previous practical knowledge of it. Naturally, it was not difficult for the practical farmer, or even the farmer's boy, to ask questions of these teachers, which received answers at times not calculated to convince those practical audiences; and so a praiseworthy effort to meet a pressing need was for the time discounted before the public—the reason being that it sprang from a spasmodic action under panic, and found the country unprepared. The true method should have been for the Government to have foreseen what was coming, and to have met it by the establishment beforehand of agricultural

colleges, and the systematic planting of the finished student, grounded in pure science and practised in its agricultural application, in country districts. A generation of disrepute would thus have been saved. We indulge in wearisome reiteration of the statement that the sun never sets on the British Empire, but we still wait wearily for the dawn of that era when a British Government shall foresee and provide for what is inevitably coming upon us, and not trust to our fatal propensity of muddling through somehow.

While as regards the teaching of agriculture the country has thus floundered into a position which, though far from being ideal, is certainly less unsatisfactory than that of twenty years ago, what do we see abroad? I need not do more than mention the widely-spread "Versuchsstationen" in Germany, which are truly scientific institutions. The only equivalent of these in Britain is Rothamsted, the noble result of private munificence. But our best lesson is from America, from people of our own race. The case has lately been stated as follows, in one of Mr. Foster Fraser's articles which have attracted so much attention in our public papers:—

"Scientific agriculture is, I know, regarded somewhat contemptuously by the sturdy, broad-shouldered, bright-cheeked, and bluff-mannered Briton. Scientific farmers are good-naturedly regarded as 'cranks,' who generally lose their money.

"In America, the modern farmer is a college man. At twenty-one he is little more than a theorist, and the young Briton can 'chew him up' in rough-and-ready knowledge; yet, admitting all this, I am convinced that the American is on the right tack, for in farming, as in engineering, the technically scientifically trained man is bound to win."

This, it should be remembered, is not the opinion of a specialist or expert in agriculture, but of an uncommonly observant man of general education.

The case for the systematic study of vegetable economics is at the moment comparable to that of agriculture before the Government edict, though its deficiencies can never be brought home to the public mind in the same way as were those of our largest home industry. The facts I believe to be as follows:—Our wide-spread dependencies are capable of producing almost all the varied vegetable products of use to man; hitherto we have dominated the markets of some, and held our own in others, while the British ports have been centres of distribution for a great part of the civilised world. Now other nations are making vast strides in colonial development; they are growing and importing their own supplies in increasing quantities, and doing so on a basis of technical knowledge, with which we have made no organised effort to keep pace. While in Germany, Austria, and elsewhere, technological institutes, and even university departments, are regularly employed in the microscopical study of raw materials, and in tracing their botanical origin (subjects which are even obligatory on students in the High School in Vienna), Great Britain, with the greatest colonial interest in the world, is, so far as I am aware, without any organised teaching of these subjects. And where is it that we find the best modern book on these matters published? Curiously enough, in Vienna, the capital of a country which has no colonies of its own. The cynic might argue from these facts that the higher study of vegetable economics is immaterial for colonial success; but those who remember how recent has been the acquisition of such systematised knowledge, and who carefully watch the trend of commerce, will know how false a conclusion this really is. Past colonial success is a very different thing from colonial success in the future.

(To be continued.)

The Week's Work.

THE HARDY FRUIT GARDEN.

By CHAS. PAGE, Gardener to J. B. FORTESCUE, Esq Dropmore, Maidenhead.

Fruit-trees on Walls.—Pear, Plum, and Cherry trees planted in the autumn of last year, now that the soil has settled and become firm, may be pruned and nailed or tied forthwith. In the case of young maiden trees from a nursery, let them be cut back to 1 foot, pruning to a wood-bud. Trees of bearing age which were transplanted from other stations should have their shoots spurred-in closely; and varieties such as Josephine de Malines, Jargonelle, and Winter Nelis, which form fruit-buds at the ends of short shoots should, when grown too long, be cut back to a wood bud. Plums and sweet Cherries bear mostly on spurs, and require the same kind of treatment. When the trees are nailed, lightly point the alleys with a digging-fork, and lift the mulch of litter over the roots of newly-planted trees.

Gooseberries and Currants.—Proceed with the pruning of the bushes. Directions were given in the *Gard. Chron.*, vol. xxxii., p. 457, on pruning and protecting the buds from tomtits and bullfinches, so that there is no necessity to repeat what is there said. Where these mischievous birds are numerous, as at Dropmore, the gun and dust-shot must be used against them.

Selecting Grafts.—Where it is intended to graft Apple, Pear, and Plum-trees, suitable shoots should now be selected, i.e., those that are of middle-size, well-ripened, clear in the rind, and free from the least trace of disease. These should be tied in quite small bundles of a dozen or less, furnished with a stout wooden label, upon which the name of the variety should be plainly written, and the bundles laid in the earth in a cool, sheltered spot, making sure that the butt-ends rest on the soil.

Labelling.—Let all recently-planted wall trees be labelled, with the name plainly stamped on lead, or written in indelible ink, or with a black-lead pencil on twice-painted wood, and secure the labels with wire to a stout nail or staple driven into the wall for standard and bush trees. In fastening the wire, allow plenty of space for the expansion of the branch

The Strawberry.—Alpine Strawberries should be raised from seed sown thinly in cutting-boxes, and placed in a warm pit, and when the plants appear keep the boxes close to the glass. Afford air in fine weather, and when large enough prick off into other boxes, and gradually harden off, planting them out in April on well manured ground.

PLANTS UNDER GLASS.

By J. MAYNE, Gardener to the Hon. MARK ROLLE, Bicton, Budleigh Salterton, Devonshire.

Cyclamens.—It is my practice to sow the seeds towards the end of the month of September; and the seedlings are now being pricked off into light sandy soil in seed-pans at 4 inches asunder. The corms are only half buried in the soil, as if planted deeper the foliage is apt to be lost, and sometimes the entire plant. Place the pans within 18 inches of the glass roof in a house having a night temperature of 58° to 60°, syringe them daily, and afford no other water for a few weeks. Vaporise lightly with XL-All should green-fly infest the plants. The plants in flower should be assisted with weak guano-water once a week, not allowing it to go over the corm, or many of the flower-buds will damp off. In gathering the flowers pull them out so that nothing remains to set up decay. Cyclamens are more successfully grown when kept fairly near to the glass, and plenty of air afforded.

Hippeastrums.—These are among the most useful subjects we have for flowering during winter and early spring, and where there is a good stock of bulbs it is an easy matter to maintain a supply of flower from November till June, by introducing bulbs into heat in alternate weeks. Those started in the autumn and up to the new year are the better for not being disturbed at the roots, but shaking them out and repotting them after they are passed out of flower. From now onwards repot as soon as growth begins, shaking away all soil and stripping off any loose skin or decayed roots. Clean pots, varying from 4 to 7 inches are suitable sizes for single bulbs, and good loamy soil, with a little leaf-mould, crushed charcoal, and a good percentage of coarse silver-sand should form the compost. Work the soil carefully down among the roots so as not to bruise them, but making it quite firm. Place in a house having a warmth of 60°, and if a slight bottom heat can be applied so much the better. But little water is required for several weeks afterwards, but a syringing twice daily is necessary. Keep H. aulica that have recently flowered in a growing temperature for the next two months, then place in the greenhouse. Seeds may be sown forthwith, dibbling them in edgeways, in which position they are not so liable to decay as when laid flat on the soil.

Richardia africana.—If spathes are pushing up, the plants may be afforded manure water twice weekly. Keep the plants under close inspection, as green-fly is apt to infest them, spoiling the appearance of the spathes.

Tree-Carnations.—Side shoots being now plentiful, and in a fit state for making cuttings, pull out some of the stronger, and cut them just below a joint. Insert them in 3-inch pots of sandy soil, not pressed too firmly, keeping them close to the sides of the pots. Apply water to settle the soil, and place under hand-glasses or in a propagating-box in a light position in a temperature of about 60°. A thin shading may be employed while the sun shines direct on to the cuttings. In about four weeks they will be rooted, and may then be gradually inured to the air of the house, and stood near to the roof for a week. Later, pot off singly into 3-inch pots, in soil consisting of equal parts of loam and leaf-soil, with plenty of sand, taking great care that the roots do not get broken, and return the plants to the same house.

Luculias.—This plant as it passes out of flower should be treated similarly to the Brugmansia, but it must not be pruned so hard, as the flower-trusses form more freely on shoots of medium size than on those that are of extra strength.

THE ORCHID HOUSES.

By H. ALEXANNER, Orchid Cultivator to Capt. G. L. HOLFORD, Westonbirt, Tetbury.

Plants in Bloom.—At the present season several interesting plants are in flower, and in the intermediate-house Cypripediums still contribute a fine display. C. Charlesworthi, C. Spicerianum, C. insigne, and C. Leeanum and its varieties, are among the first to flower late in the autumn, and these have now passed out of flower; and C. villosum, C. Boxalli, and their hybrids, C. Lathamianum, C. Calypso, C. nitens, C. J. Howei, C. Sallieri Hyeanum and its variety aureum, C. Mons. de Curte, C. Euryale, C. Exul, C. Tityus, C. Pollettianum, are now flowering. Cypripediums have the best effect grouped by themselves than when they are associated with other showy Orchids. Plants that are in flower, and those just passed out of flower, should be afforded sufficient water to keep the materials moist. I never allow Cypripediums to become very dry at any season. Cypripedium Winnianum is also in flower in the intermediate-house; the flowers are of an ivory-white tint, and they last a long period of time in perfection. Water should be sparingly afforded to this plant until it starts again into growth, but the materials must not be allowed to get very dry. Lycaste Skinneri, L. aromatica, L. Deppei, L. plana, and the beautiful hybrid Mary Gratrix (L. Skinneri × L. plana), are now pushing up their flowers, and an increased quantity of water at the roots will assist in the development of the flowers.

Cattleya House.—The hybrid Cattleyas help greatly in keeping our houses gay during the winter, and where hybrid Cattleyas and Lælio-Cattleyas exist in quantity, there are nearly always a few in flower. One of the most beautiful now in flower is L.-C. Charlesworthi, whose orange-scarlet flowers are carried on long stalks. It is one of the finest of the winter-flowering hybrids. Lælio-Cattleyas grow freely, given a position at the warmest end of the Cattleya-house whilst growth is being made; they need much moisture at the root and humidity in the air. When the plants

begin to grow in the spring, the back pseudo-bulbs should be partly removed from the under side, a small surgical saw being very useful for this purpose; and the buds behind the cut will then come away freely. Plants so treated by me last spring have now three or four flower-spikes each, some of which are bearing seven flowers on a spike. Let the plants be placed in the cooler part of the house, and afforded sufficient water at the roots to keep them healtby. A plant of L.-C. Sunray is likewise in flower, and is accorded the same kind of treatment. Cattleya Trianæi and C. Percivalliana are now pushing up their flower-spikes, and will be afforded more water at the root than hitherto. The latter often fails to open its flowers satisfactorily, but the failing will not be so great if the plant be removed to a warm part of the house.

Preparations for Potting.—Obtain an ample supply of fresh sphagnum, turfy-peat, and leaf-soil, a good supply of new or clean pots and pans, crocks, wire suspenders, &c., so that these materials may be in readiness when the busy season begins. It often happens that at a little later date repotting has to be deferred because the sphagnum is locked up by frost.

Protection of the Houses with Garden-mats, &c.—When the sides and ends of an Orchid-house consist chiefly of glass, and the position is an exposed one, protecting materials of some sort should be used in frosty weather. It will happen that plants placed near the roof, or the glass ends of a house, are found in the morning with heavy dew on the leaves, a state of things not conducive to the welfare of the plants; and in order to prevent it, Russian mats or thick canvas should be nailed over the glass, and made secure against the wind. This covering need not be removed till the end of next month or in March, if mats are rolled along the lower portion of the roof at night, they should be removed when the temperature begins to rise in the morning. A 2-inch hot-water pipe running along on the inside of the lower portion of the roof, about 6 inches or a foot away from the glass, is likewise of great value during spells of severe weather. Such a pipe, if kept only moderately warm, does not injure the plants. It should be in use only at such times.

THE KITCHEN GARDEN.

By JOHN FLEMING, Gardener to Sir C. PIGOTT, Bart., Wexham Park, Slough.

Peas.—Peas sown in December in pots and boxes for carrying a crop of pods in the same, must be kept near the roof glass, and afforded plenty of air whenever the weather is not raw and cold. The treatment of Peas in pots from start to finish should be that known as "cool." Place thin Birch spray to the plants betimes, or secure the haulm within bands of matting held up by neat stakes. Sow for succession to be grown under glass, such varieties as Sutton's May Queen, Early Giant, Carter's Early Morn, or Daisy, all of which are trustworthy. The variety Chelsea Gem is invaluable for pot and frame culture especially, and being of small stature, &c., it can be grown where the space at the disposal of the gardener is small. Sow likewise in pots or on strips of turf under glass or in troughs with moveable sides for planting out-of-doors. Sow new seed thinly, and never force the plants into weak growth by warmth. Be cautious in sowing Peas out-of-doors as yet, the ground being cold and not favourable to the early vegetation of the same. If a dry, sunny border, consisting of light and rich soil, is available, Peas may be sown at this date; but when the soil is heavy, defer to sow till February. The Peas sown in the autumn, being now of some height, should be protected by evergreen or other twigs placed on both sides of the rows, and be afforded a light sprinkling of quick-lime in powder, or of fresh soot.

Broad Beans.—One of the best Beans for early sowing is Early Mazagan, and next to that is Beck's Dwarf Green Gem. The usual treatment accorded Peas suit these early varieties of the Broad Bean.

Autumn-sown Cabbage.—On light land it is advisable to steady and make firm all plants loosened by frost and wind, trampling lightly when the soil is not sticky on each side of the rows, and afterwards moulding up the plants so far as the lower leaves. Gaps in the rows should be filled up.

Brassicas Generally.—Sow in small quantities in boxes and place in frames, or on a slight hot-bed seeds of Cauliflower in variety, Brussels Sprouts, Red and White Cabbage, also Cos and Cabbage varieties of Lettuce. Allow the seeds in every case to germinate slowly. Carrots may be sown in frames placed on slight hot-beds, the covering of which should consist of a mixture of light sandy loam and leaf-mould in equal proportions together with wood-ashes and road grit, and a sprinkling of Clay's Fertiliser, the whole being passed through a sieve with ¼-inch mesh. The soil may have a depth of 15 inches, and it must be pressed firmly together. Sow in drills drawn at 8 to 10 inches apart. The French or Early Short Horn are reliable varieties, good for the present sowing, as is the Early Dutch Horn. Radishes may be sown in small quantities at fortnightly intervals in a similar kind of hot-bed frame.

Onions.—Seeds should now be sown in small flower-pots or in boxes having a depth of 4½ inches for the production of large bulbs. The compost may consist of fibrous loam one-half, leaf-soil a quarter, and a quarter of dried horse-droppings, with some coarse sand added. Sow thinly, and only just cover the seed with fine soil, and make all quite firm. Place in a forcing-house just started. Onion seed should germinate slowly, and the plants be kept stocky and vigorous. For exhibition purposes Ailsa Craig is one of the best.

Frames.—Afford air to Cauliflowers, Lettuces, Endive, and Parsley, keep the plants free from decayed leaves, and do not allow crowding, or the plants will be worthless.

FRUITS UNDER GLASS.

By T. H. C.

Vines.—Disbud early Vines as soon as the most fruitful shoots can be readily distinguished, leaving one to a spur. Stop the laterals to one or two joints beyond the bunch, according to the space allotted to each. Disbudding or stopping the laterals should always be done by the finger and thumb, never allowing the shoots to attain the size when a knife is necessary to remove them. Afford a night temperature of 58° to 62°, with a rise of 10° during the day, according to the state of the weather. Admit air by the top ventilators upon every favourable occasion. Shut up early to enclose sun heat, lightly syringe the rods, and maintain a moist condition of the atmosphere. Start succession houses as required without artificial heat for the first week or ten days, except in severe weather, when a temperature of 45° may be maintained.

Propagation.—The best and most common practice of raising young Vines, is from eyes or buds of the previous year's growth. When pruning, laterals containing good plump buds should have been inserted in damp sand or soil; these should now have the buds with an inch or so of the lateral removed, cutting it half through on the under side. Insert these singly in 3-inch pots, or thinly in pans or boxes in a light compost of two-thirds good sandy loam, and one-third leaf-mould, to which may be added a little fine charcoal and mortar-rubble. Plunge the pots, &c., in a bottom heat of 75° to 80°, and a top temperature of 65° to 70°. When rooted, pot on, and grow quickly in a stove temperature with plenty of moisture. At subsequent potting, never allow the plants to become pot-bound. With successful management and close attention to the smallest details, good canes for next year's pot-Vines may be grown, which are in many ways preferable to "cut backs."

Forcing Pines.—Houses or pits should now be got in readiness for succession fruiting plants. Lime-wash the walls and sides of the plunging pits, cleanse the structures, particularly the glass, so that it may at this season admit every ray of light. If the heating power of the old plunging material is exhausted, renew it with fresh, which may consist of tanner's bark, or Oak and Beech leaves. If unable to wait until the bottom heat subsides to a safe plunging temperature, open out wide holes 2 feet apart, and stand the plants on inverted flower-pots free of the plunging material, and when the heat declines plunge to the rims. Very little water is necessary at this season, but when applied sufficient in a tepid state should be given to thoroughly moisten the ball of soil. Withhold water from plants ripening off their fruit, otherwise the flavour will be impaired. Afford a bottom-heat of 80° to 85°, a night temperature of 65°, and one of 10° higher more or less during the day, according to the state of the weather; ventilate when the weather permits. Whenever good strong suckers are available, detach them from the old plants and propagate singly in 5-inch pots, using a rich loamy compost, pressed firmly round the base of the sucker. Plunge in a brisk bottom-heat, close up to the roof-glass in the propagating-pit. Keep a sharp look-out for scale and other insect pests, as they are easily dealt with in the early stages of the plant's growth, and need not prove troublesome afterwards.

THE FLOWER GARDEN.

By J. C. TALLACK, Gardener to E. MILLER MUNDY, Esq., Shipley Hall, Derby.

Bedding Plants.—Where the autumn-struck cuttings of zonal and Ivy-leaved Pelargoniums are sufficiently plentiful for all purposes, let the points of the shoots be pinched out, so that a bushy habit may be the more readily induced before the time comes to repot or box off the plants a few weeks hence.

Verbenas, Dwarf Lobelias, Heliotropes, Iresines, Alternantheras, and, in fact, any bedding plants which are propagated from stock-plants, should now be put into warmer quarters for the production of shoots, and if the stock of plants is low, several batches of cuttings may be needed. In the cold propagating-frames such plants as Antirrhinums and Calceolarias should have the points of the shoots pinched out, and strong-growing Violas may be served in the same manner. Stir the surface-soil in the pots, and remove decayed leaves. The ventilation of cold frames should be constantly attended to during the winter, or the plants will suffer. A hotbed should be now made in a warm, sunny position, sufficiently large to accommodate a one, two, or three-light frame, in which may be sown seeds of East Lothian Stocks. It is necessary to raise these early, and if grown in quantity, sowing in frames will be found better than raising the plants in boxes in a forcing-house, as there is less fear of loss by damping-off. The soil must be sweet and wholesome, and mixed with a considerable quantity of finely-sifted old mortar. To those who have not grown it, I recommend strongly the comparatively new "rose coloured," a variety which is very constant and good.

Lobelia cardinalis.—In gardens where this plant is difficult to keep during winter, let the plants in stock-boxes be placed in heat, the doing of which usually checks canker, and brings the clumps into condition for early division. Here we depend largely upon seedlings, and sow the seeds in the summer. The favourite L. c. Queen Victoria comes true from seed, but the fine L. c. Firefly rarely ripens seeds, and the stock of this and some others must be kept up by division.

Hollyhocks.—The seeds should be sown early to get good flowering plants the first season, and where they are treated as annuals it is time now to sow seeds. I prefer to treat the plant as a biennial, sowing in July. There is no question but that Hollyhocks raised from seeds are not so liable to the orange-fungus as are those raised from cuttings.

Cannas.—The seeds should be sown forthwith in a hot, moist house or hotbed-frame, plunging the seed-pots in leaf-mould or Cocoanut-fibre. Before sowing, notch the seed-capsules almost or quite through.

Liliums.—The bulbs of L. auratum, L. speciosum, and other hardy Lilies, should be planted out during the first mild weather after they arrive, as keeping them out of the soil is always injurious. In choosing a position for the bulbs, plant them among low shrubs, the branches of which afford shelter to the stems in the spring.

Mossy Saxifrages.—If employed as edgings to flower-beds, press them lightly with the foot, which will tend to keep the tufts dense and the lines in good form.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the Publisher.

Letters for Publication, *as well as specimens and plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Illustrations.—*The Editor will thankfully receive and select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.*

Local News.—*Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return the unused communications or illustrations, unless by special arrangement.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.*

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY, JAN. 19 { Surveyors' Institution (Junior), Meeting.

THURSDAY, JAN. 22 { Gardeners' Royal Benevolent Institution: Annual Meeting and Election of Pensioners, at 3 P.M., at "Simpson's," Strand.

SALES FOR THE WEEK.

MONDAY and FRIDAY, JANUARY 19 and 23—
Herbaceous and other Plants, Azaleas, Rhododendrons, Bulbs, Perennials, &c., at 67 and 68, Cheapside, by Protheroe & Morris, at 12.

WEDNESDAY, JANUARY 21—
Azaleas, Rhododendrons, Roses, Palms, Hardy Border Plants and Perennials, &c., at 67 and 68, Cheapside, by Protheroe & Morris, at 12.—At 5 o'clock, 1,610 cases of Japanese Liliums, also Palm Seeds, &c., at 67 and 68, Cheapside, by Protheroe & Morris.—Roses, Hardy Perennials, Bulbs, Fruit Trees, &c., Stevens' Rooms, 12.30.—Collection of Orchids, St. James' Hall, Leeds, by Mr. J. Cowan, at 12.30.

FRIDAY, JANUARY 23—
Sale of Burmese Dendrobes, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.30.—Collection of Orchids, Coal Exchange, Manchester, by Mr. J. Cowan, at 12.30.

(For further particulars see our Advertisement columns.)

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick—37·5°.

ACTUAL TEMPERATURES:—
LONDON.—*January* 14 (6 P.M.): Max. 34°; Min. 29°. *January* 15 (9 A.M.).—Fine, cold; 23° F.
PROVINCES.—*January* 14 (6 P.M.): Max. 42°, West Ireland; Min. 30°, Eastern Counties.

Sylva of North America.*

THE first volume of this imposing publication was issued in October, 1890, at a time when the number of trees and shrubs native in the forests of N. America proper was thought not to exceed some 422 species. It was considered that twelve volumes containing 600 plates would suffice for the description and illustration of these plants. But during the progress of the work many new species have been discovered, and much light thrown on those previously known. The result has been that the preparation of two supplementary volumes has been necessitated, so that the completed work contains the description of 585 trees and shrubs, and no fewer than 740 plates.

We have already on more than one occasion spoken in terms of admiration of this magnificent publication. For the accuracy of the descriptions, the wealth of illustrative notes and bibliographical notices, the skill and care with which the geographical distribution of the several species is worked out, the book is truly a most remarkable production; nor can we speak less highly of the illustrations drawn by Mr. FAXON. Without any pretence of display or artistic subtlety, they are most faithful representations of the several trees, whilst the carefully-executed details supply just what is necessary for the botanist. With the system of nomenclature adopted in some cases, we are not always in full sympathy, but this is largely a matter of opinion; and as the synonymy is fully detailed, the student need not be much inconvenienced by the adoption of unfamiliar names selected on principles which are different from those mostly (but not wholly) acted on in this country.

In one of the present volumes much attention is given to the genus Cratægus. Several species are described as new, and even these, we are told, do not include all the forms which may be found in N. America. Rightly to understand these would require many years of observation in the field, and rather than delay the publication of the Sylva, these are passed over for the present. The number and arrangement of the stamens, and the colour of the anthers, are relied on to distinguish these species, in addition to other characteristics of less constancy. Prof. SARGENT gives a list of eighty-four species grouped in an analytical table under two main headings—the Macrocarpæ, with medium-sized fruits; and Microcarpæ, with small, depressed, globose, scarlet fruits. Other subdivisions are made according to the size and colour of the fruit, the ridges or furrows on the seeds, the texture of the leaves, the colour of the anthers, the nature of the calyx and of the inflorescence, the presence or absence of glands, &c.

Practical experience in the field or the arboretum can alone be relied on to enable the student to test the diagnostic value of these characters; but whatever the verdict of subsequent enquirers may be, there can but be one feeling of gratitude to Professor SARGENT for the pains he has taken to get this troublesome group into order. Without some such guide as he has here given, it would be difficult, if not impossible, to disentangle the intricacies of this genus.

The inclusion of Florida necessitates the admission of several tropical or subtropical species, such as the Papaw, Carica Papaya, and the Opuntia, of which three species are noted, viz., O. fulgida, O. spinosior, and O. versicolor, Serenoa arborescens, Thrinax floridana, T. keyensis and T. macrocarpa, and Coccothrinax jucunda—all fan Palms with panicles of globose fruits.

As to Juniperus virginiana (the Red Cedar), Prof. SARGENT, from his studies of the tree in the field, splits it up into three, viz., 1, J. virginiana, of the Northern States, which ripens its fruit at the end of the first season; 2, the Red Cedar of Florida and Jamaica (J. barbadensis), with more slender, pendulous branches, which spread into a broad, open head, and smaller fruits, ripening at the end of the first season; 3, the Red Cedar of W. America (J. scopulorum), with rather stouter branchlets, fruit which does not ripen until the end of the second season, and lighter-coloured, usually reddish-brown wood. The Florida Cedar is not distinguishable from the J. barbadensis of the West Indies. The names barbadensis and virginiana both date from 1753. The differences in the fruit and its period of ripening are doubtless good differential characters; but those derived from the habit of the tree, and even from the foliage, are hardly to be depended upon.

The history of these Junipers is given at some length in the *Journal of Botany* for January, 1899; but the Western form, J. scopulorum of SARGENT, is not well known to us.

Cupressus pygmæa is the name given to what has been previously considered to be a form of C. Goveniana.

The work ends with a few corrections and additions that have been found necessary, and with a complete index of the genera and species mentioned in the fourteen volumes. We should have been glad if the author could have seen his way to give an index to the names of authors, travellers, and collectors mentioned in his pages, and to the works cited in his bibliographical notes; but he has added already so largely and so effectively to our possessions, that this wish may expose us to the charge of being insatiable.

* *The Sylva of North America*, vols. xiii. and xiv., by Charles Sprague Sargent. (Boston, and New York: Houghton, Mifflin & Co.)

BOWOOD.—Our Supplementary Illustration represents a portion of the Italian garden at Bowood, the seat of the Marquis of LANSDOWNE near Chippenham. The orangery is said to have been erected from the designs of ROBERT and JAMES ADAM, the architects of the Adelphi, and is in imitation of the Emperor DIOCLETIAN'S palace at Spalato. The garden shown is on the west side of the house, and occupies a terrace some 285 feet in length, with formal beds filled with flowers and appropriate shrubs. Above it is a second terrace running along the front of the orangery, and supported by an ornamental wall, with vases at intervals. It is obvious that in such a situation, a "formal" garden is more appropriate than one of a more "picturesque" character. The walls are covered with Roses, Magnolias, and other ornamental shrubs. We shall probably enter into fuller details relating to this garden on another occasion; meanwhile we may cite the remark made by a correspondent who visited Bowood in 1891, "Everything at Bowood is spacious and grand."

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—The sixty-fourth Annual General Meeting of the members and subscribers of this Institution will be held at "Simpson's," 101, Strand, London, W.C., on Thursday, January 22, 1903, at 3 P.M., for the purpose of receiving the report of the committee and the accounts of the Institution (as audited) for the year 1902; electing officers for the year 1903, and for the election of fifteen pensioners on the funds; also to submit the following resolution:—"That the action of the committee, graciously approved by the President, H.R.H. the Prince of WALES, in placing on the funds the eleven unsuccessful candidates, formerly subscribers to the Institution, to commemorate the Coronation of their Majesties the KING and QUEEN, patrons, be and is hereby confirmed." The Chair will be taken by HARRY J. VEITCH, Esq., Treasurer and Chairman of Committee, at 3 o'clock. The poll will open at 3.15 o'clock and close at 4.30 o'clock precisely, after which hour no voting papers can be received. During the year 1902 the following widows of pensioners have been placed on the funds without election in accordance with Rule III., 13:—

1. MACKINTOSH, MARY E., aged 71.
2. TRUTTER, SARAH, aged 81.
3. WILDER, MARY ANN, aged 69.

After the Annual Meeting (also at "Simpson's," and for the last time in the present building), the usual friendly supper will be held at 6 P.M. Mr. ALFRED WATKINS (Messrs. WATKINS &

SIMPSON) will preside. Friends desiring to be present should send early intimation to the Secretary at 175, Victoria St., Westminster, S.W.

—— Very recently I was permitted (says a correspondent) to make to gardeners generally an appeal on behalf of this valuable Institution. But now comes to hand a far more potent appeal, although one which falls into the hands of existing subscribers only, in the form of the ballot or voting paper relating to the next annual election of pensioners, and which takes place on the 22nd inst. The paper informs those to whom addressed that there are fifteen persons to be elected, and there are no fewer than forty-six candidates. These are distressing facts, because they show that of the latter number no fewer than thirty-one applicants will have to be left out in the cold. It is painful, indeed, to find that in gardening there should be so many aged persons so helpless that they are compelled to appeal thus for help to exist. It is not less painful to find that, for lack of that universal support which so noble an institution should receive at the hands of British gardeners, so many aged and unfortunate ones should fail to obtain the much-needed pensions. It is very interesting to find that out of the forty-six applicants, no fewer than thirty-one either have been subscribers or are the widows of subscribers. Of those nine are widows, and thirteen are males. Of the fifteen non-subscribers, two are widows, and thirteen males. Of the subscribing section one applicant is eighty-one years of age, thirteen range from seventy to seventy-nine, fifteen from sixty to sixty-nine, and two, both evidently quite physically prostrate, range between fifty and fifty-nine. It is, indeed, sad to find men thus struck down physically whilst in the prime of life. Of the thirty-one subscribing members, every application is for the first time, and some of these for their subscriptions in the past start with many aggregated votes. Thus, there are eleven that begun in that way with 2,000 votes and upwards, whilst seventeen have from 1,000 up to nearly 2,000 votes to their credit. It need hardly be said that all these, because they were subscribers in the past, have a strong claim on the suffrages of the electors. In the non-subscribing section it is seen that of present applications, one is the seventh, one the sixth, one the fifth, two the fourth, four the third, four the second, and one the first. These figures show how much in relation to securing an election non-subscribers are handicapped. The notes appended to each applicant's name are indeed sad reading. Nothing can more touchingly appeal for help than do these descriptions. Younger men may well ask themselves whether such may not be in old age their lot. As an almoner in one case I visited on New Year's day, the pensioner, a white-haired, nearly blind old man, occupying, with his aged wife, one room. Since his election on to the Fund, he has removed from a small, stuffy, back room into a larger front room; but the physical decay and utter helplessness remain. But for the Benevolent Fund these old people must ere now have gone into the workhouse.

FLOWERS IN JANUARY.—In a cold garden, on an undrained, heavy clay soil, with a north aspect, in Middlesex, Primroses and Snowdrops were gathered on the 8th inst., together with Hellebores and Jasminum nudicaule. The Honeysuckle-buds are nearly expanded, the Rose-buds, especially Crimson Rambler, completely so. How far north, or how high up, does the Honeysuckle grow?

GEO. MONRO, LTD.—Many of our readers are acquainted with Mr. GEORGE MONRO, and with his well-known business in King Street, Covent Garden, and will be interested to note the change in the name of the firm. A company has been formed to take over the business, established in 1871, and of this Mr. GEORGE MONRO is Founder and, now, Governing Director. The company is private, with no public issue, and no outside capital has been brought in, the matter having been arranged for the more convenient working of the very large business carried on by Mr. MONRO and his sons. A pamphlet has been issued, containing portraits of the head and of the chief members of the firm, and this forms an acceptable souvenir of the incorporation of the new company, as it includes a brief description of the business and of its wonderful growth.

M. DEHÉRAIN.—In the *Comptes Rendus* for Dec. 22, 1902, is published the report of the President of the French Academy, M. BOUQUET DE LA GRYE, upon the events of the year. In his speech, M. DE LA GRYE paid tribute to the memory of members deceased during the past twelve-months, making the following reference to our late friend and correspondent, M. DEHÉRAIN:—"M. DEHÉRAIN succeeded M. BOUSSINGAULT in the Rural Economy Section. In addition to his connection with the French Institute, the former was a member of the Société Nationale d'Agriculture, a Professor at the Museum at Grignon, and held other honourable positions in Associations where his work was known and valued. His labours were peculiar for their practical utility. For instance, he thoroughly understood that the truest wealth of France lay in her agricultural industries, and that as regards Wheat (for example), a crop that varied from 1,500 kg. to 3,000 kg. per hectare, represented for every 100 kg. of increase, an augmentation of a hundred million francs to the agricultural revenue. M. DEHÉRAIN's experiments were made with cereals, roots, and tubers. He studied the distribution of crops, the best foods for them, and the varieties that were most appropriate for cultivation under different circumstances. It must not be forgotten that he took a great part in discovering the formation of nitrogen in lands covered by leguminous crops, as well as in recommending the use of natural phosphates. M. DEHÉRAIN continued his valuable investigations for fifteen years, and all interested in agriculture will appreciate his labours and regret his loss.

"MY GARDEN DIARY FOR 1903."—This little publication, from Messrs. SUTTON & SONS, Reading, is, like its predecessors of former years, full of useful notes for each month. It has a pretty coloured cover, and some inside illustrations also, with a calendar and the usual information connected with it. There is plenty of room for memoranda on each page, and the whole is of handy size for the pocket or desk.

"FARM AND HOME YEAR-BOOK AND FARM-TRADE DIRECTORY."—This annual for 1903 is, as usual, full of hints on stock, dairying, manuring, poultry, and laws relating to farming. Information on the latter subject has been included by request, and is certainly useful to many when offered in this convenient and accessible form. Articles will here be found dealing in detail with the important subjects of contracts for sale and purchase of farming produce and live stock, workmen's compensations, laws as to fencing and trespassing, land tax and water rights. We recommend the publication to all who are interested in farming. It is published at the office of *Farm and Home*, 17, Furnival Street, Holborn, E.C.

SOWERBY'S "ENGLISH BOTANY" SUPPLEMENT.—The copy of this work in the library of the Royal Botanic Gardens, Kew, is incomplete, wanting plates 2912 to 2960, with letterpress and index; also plates, with letterpress, 2964, 2977, 2978, 2983, 2987, 2988 to 2999. The Director appeals to the public to assist him in completing this classical work on British Botany, either by presentation or sale.

"BOTANICAL MAGAZINE."—The plants figured in the January number are:—

Ruellia macrantha, Martius, t. 7872.—A splendid Brazilian Acanthaceous shrub, with shortly-stalked oblong, lanceolate leaves, and large rosy-purple veined flowers, with a trumpet-shaped tube, and a full-lobed spreading limb. See *Gard. Chron.*, December 28, 1901, p. 467.

Muscari paradoxum, Carl Koch, t. 7873.—A Persian species, one of the most handsome in the genus, with broad, strap-shaped leaves, and dense racemes, 3½ in. long, on long stalks, flowers about ⅓ in., oblong, campanulate, deep blue, with yellowish margins to the lobes.

Chrysanthemum indicum, Linnæus, t. 7874.—The editor refers under this heading to the papers of Mr. HENRY in the *Gardeners' Chronicle*, and to the article published on the same subject by Mr. HEMSLEY in our columns in 1889, which is described as "a model for the treatment of such a subject," and from which the synonymy and bibliographical references as here published are copied.

Allium Ellisii, Hooker fil., t. 7875.—A very handsome Khorasan species, with very broad leaves, and globose heads of rosy-violet-coloured flowers. Introduced by Hon. CHARLES ELLIS, Frensham Hall, Haslemere.

Diervilla Middendorffiana, Carrière, t. 7876.—A yellow-flowered "Weigela." See *Gard. Chron.*, 1890, vol. i., p. 581, fig. 94. Native of Mongolia, Manchuria, and Japan. *Kew.*

OUR POULTRY.—The last issued parts of this fine publication, produced by Mr. HARRISON WEIR, contain an illustrated account of the development of the chick from the earliest stage to its complete development, a process so wonderful that if it were not such an every day occurrence, we should be lost in amazement. The first requirement of the emancipated chick is food; consequently the requirements of the reader who is more concerned with the practical care of the fledgings and the fatting of poultry than with the marvels of their development, are duly provided for.

"ALL ABOUT SWEET PEAS."—Under this title Mr. ROBERT SYDENHAM, of Tenby Street, Birmingham, has published a little treatise, the profits from which are to be handed over to the Gardeners' Royal Benevolent Institution, on which account alone we should be justified in calling attention to it. But the pamphlet has intrinsic merits of its own which should commend it to Sweet Pea lovers. There is a descriptive list of all the best known varieties arranged alphabetically, and instructions how to grow them. Mr. SYDENHAM has obtained information showing the relative estimation in which certain varieties are held from thirty-three growers, and the results are so striking that we think there can be no doubt as to the superiority of the varieties named. Thus, Blanche Burpee was placed first among whites seventeen times. The numbers given after each of the following names show the relative degree of merit in each class arranged according to colour: Duchess of Sutherland, blush, 16; Countess of Lathom, cream, 11; Hon. Mrs. Kenyon, pale yellow, 25; Prima Donna, pale pink, 20; Miss Willmott, salmon-rose, 22; Mrs. Dugdale, pale rose, 22; Prince of Wales, deep rose, 17; Salopian, deep fiery or intense crimson, 30; Lady Grisel Hamilton, lavender, 30; Duke of Westminster, dark magenta, 24; Duke of Clarence, dark purple, 17; Navy Blue, blue, 21; Black Knight, very dark, 19; Blanche Ferry, pink and white, 11; Gorgeous, orange and pink, 28; Prince Edward of York, carmine bicolor, 14; Jeanie Gordon, mixed bicolor, 20; George Gordon, mixed bicolor, dark, 17; America, light stripe, 16; Princess of Wales, dark stripe, 16; Lottie Eckford, Picotee-edge, 19. Those who

wish to have further details should consult the pamphlet itself, where they also find statistics showing the number of times particular varieties were exhibited at the leading shows in 1902. The ten best varieties, arrived at by a process of selection and elimination are: Countess of Powis, orange and pink; Fascination, lavender; Golden Gate, lavender-blue, Picotee-edge; Queen Victoria, pale primrose; Stanley, bronzy-chocolate; Duchess of Westminster, pale salmon-buff; George Gordon, carmine standard, paler wings; Lottie Hutchins, pale buff, flushed with pale rose; Oriental, rosy-salmon; Royal Rose, rosy-carmine. Mr. SYDENHAM has taken great pains, and his lists are correspondingly valuable.

M. MILLARDET'S OBSERVATIONS ON VINES.—The services rendered to viticulture by the late M. MILLARDET, the originator of the famous Bordeaux Mixture, are well known to specialists, and M. BORNET, in the *Comptes Rendus* for December 29, 1902, gives an excellent summary of them, from which we extract the following particulars:—"M. MILLARDET, after being assistant Professor at Strasbourg, was transferred to Nancy, and then, in 1876, nominated Professor of Botany to the Bordeaux Faculté des Sciences. He arrived in the height of the devastation caused by the phylloxera, was sent out by the Phylloxera Commission to study the wild Vines of the United States, especially with respect to their insect-resisting powers. He accomplished his work with scientific accuracy of observation and skill in experimenting in the laboratory. M. EMILE PLANCHON had observed that certain of the American Vines resisted phylloxera, but he had not sufficiently gauged their degrees of resistance. M. MILLARDET determined these exactly, and made known the details of variation in wild species and their value as stocks for grafting. He was one of the first to suggest hybridising the European with the American Vines. With the aid of M. GRASSET, he himself raised no fewer than 12,000 hybrids. If some of these did not, as had been hoped, produce Vines capable themselves of replacing the old French Vines, some of them, especially the hybrids raised by crossing the wild Vines among themselves, furnished very valuable stocks for grafting. The planting of resistant species or hybrids was at first undertaken rather at random, as it was not known under what conditions the American Vines grew naturally. But when M. VIALA returned from the United States with precise information containing the circumstances of their growth, it was seen in what direction hybridisation should be done, that the resultant plants should be both disease-resisting and adapted to the various conditions of soil in which they were to be grown. Vine-growers have also reason to remember the investigations of M. MILLARDET concerning various Vine diseases induced by fungus, and particularly by peronospora, mildew, and most important of all, those which brought to light the means of efficiently resisting these pests by the use of solutions of copper, the preparation and application of which were first made known by MM. MILLARDET and GAYON. The former authority will also be remembered for his investigations on the false hybrids of Strawberries which reproduce the type of father or of the mother, but never exhibit the different characteristics of the two parent species in association. These curious results, which the experimenter met with also in Vines and in Brambles, furnish an explanation of facts which hybridisers frequently observe, but for which they had hitherto been unable to account."

THE PRODUCTION OF ORANGES AND LEMONS IN ITALY.—According to recent advices from Naples, the production of Oranges, Mandarin ditto, Lemons, &c., in 1901-2 was about 3 per cent. less than the average annual production. In 1901 the total produce of Italy was 41,815,000 hundreds; last year the figures were 44,085,000 hundreds. The production in the southern provinces formed about 25 per cent. of the whole production, and that of Sicily 72 per cent. The total export of the fruits to the United Kingdom in 1901 was 473,140 quintals.

CHINESE PLANTS.— We understand that Messrs. JAS. VEITCH & SONS have, with great generosity and public spirit, distributed the herbarium of about 15,000 specimens, collected in Central China by Mr. E. H. WILSON on behalf of the firm, among the following establishments:—Kew Herbarium (the most complete set), Kew Arboretum (ligneous plants), Herbarium New York Botanic Garden, Herbarium Paris, Herbarium Edinburgh, Herbarium Dublin, Herbarium St. Petersburg, Smithsonian Institute, Washington, U.S.A.; Hamburgh Botanic Museum, Arnold Arboretum, Boston, U.S.A.; Dr. HENRY, &c.; Dr. MASTERS, F.R.S., *Gardeners' Chronicle*, &c. (Conifers); Dr. CHRIST, Bâle (Filices); JAMES VEITCH & SONS, Ltd. (horticultural plants), E. H. WILSON.

STOCK-TAKING: 1902.—The Board of Trade Returns for the past month and the year just closed are to hand, and of them it may be said, things might have been worse. For the month of December the imports were £48,170,628, against £46,770,097 for the corresponding period in 1901—an increase of £1,400,531. The gains are to be found in raw materials for textile manufactures, manufactured articles, articles of food and drink (duty free), raw materials for sundry industries and manufactures, parcel post, animals (living) for food, and tobacco (dutiable). The exports for the month foot up at £24,219,240, against £24,313,777—a decrease amounting to £94,537. There was a great drop in ships, and heavy rises in metals and articles manufactured therefrom (except machinery and ships), articles manufactured or partly manufactured, and articles of food and drink, machinery and millwork, apparel, &c.; also various raw materials. Turning now to the year's foreign trade, we note the total of £812,400,264, as against £802,012,574—or an increase of £10,387,690. Breaking these up into imports and exports, the former foot up at £528,860,284, as against £521,990,198—an increase of £6,870,086. The greater advances are to be found in articles of food and drink, duty free (over 3¾ millions sterling), but that is almost balanced by the drop in the dutiable branches. There is an increase of nearly 5½ millions sterling in manufactured articles; tobacco increased by over a million, and so also did miscellaneous articles. The decreases range under animals (living) for food, raw materials for textile manufactures, and metals. The following are extracted from the "summary" table of imports during last year, compared with those for 1901:—

IMPORTS.	1901.	1902.	Difference.
	£	£	£
Total value ...	521,990,198	528,860,284	+6,870,086
(A.) Articles of food and drink—duty free	97,675,609	101,452,142	+3,776,533
(B.) Articles of food & drink—dutiable	112,736,817	108,998,634	−3,738,183
Raw materials for textile manufactures	79,286,268	78,570,555	−715,713
Raw materials for sundry industries and manufactures	57,981,249	58,631,448	+650,199
(A.) Miscellaneous articles	17,311,145	18,822,945	+1,511,800
(B.) Parcel Post ...	1,262,462	1,327,588	+65,126

It is worth while noting respecting timber, that the value of last year's imports was £25,189,021, against £24,562,445, an increase of £626,576 over 1901. The record of fruit importation for the year may now be taken in hand, and surely it will well repay such consideration as may be given to it—

IMPORTS.	1901.	1902.	Difference.
Fruits, raw:—	Cwt.	Cwt.	Cwt.
Apples	1,830,210	2,843,701	+1,013,491
Apricots and Peaches	13,463	16,187	+2,724
Bananas... bunches	2,228,672	2,805,700	+577,028
Cherries	212,683	166,359	−46,324
Currants	70,402	76,080	+5,678
Gooseberries	21,735	27,557	+5,822
Grapes	679,885	633,932	−42,952
Lemons...	1,071,534	1,003,288	−68,246
Nuts—Almonds ...	111,322	148,987	+37,665
Others, used as food	904,224	784,160	−120,064
Oranges...	5,281,657	6,518,067	+1,236,410
Pears	348,866	491,906	+143,040
Plums	263,700	541,136	+277,436
Strawberries	38,604	40,211	+1,607
Unenumerated, raw...	535,247	500,679	−34,568
Fruits, dried—			
Currants, for home consumption ...	963,631	1,186,561	+222,930
Raisins „	554,410	604,366	+49,956
Vegetables, raw:—			
Onions ... ...bush.	7,295,418	7,606,119	+310,701
Potatos ... ... cwt.	7,076,726	5,699,090	−1,377,636
Tomatos... ... „	793,995	783,894	−10,101
Vegetables, raw, unenumerated ...value	£389,829	£467,022	+£77,193

Not a word of explanation is here required—each item as set forth, speaks for itself. Firstly, we have briefly to notice the year's

EXPORTS.

The total of these for 1902 were £283,539,980, against £280,022,376 for 1901, an increase of £3,517,604. The increase is made up from metals and articles manufactured therefrom, except machinery and ships; articles of food and drink; apparel, and articles of personal use; all other articles either manufactured or partly manufactured; machinery and millwork, and chemical and mechanical preparations. Among the items of decrease may be noted new ships, raw materials, parcel post, and yarns and textile fabrics. It only remains to express the hope that the increase in next year's returns may be more marked than at present is the case.

CHRISTMAS TREE AT THE CRYSTAL PALACE.—The large Christmas tree standing in the south nave of the Crystal Palace, which has caused such delight to many hundreds of children during the holidays, was kindly given by Mr. J. COLMAN, of Gatton Park, near Reigate. It stands over sixty feet high, and laden with all sorts of good things, was certainly one of the features of the Christmas attractions.

WOODCRAFT.—We are glad to call the attention of our readers to a little treatise on "Sylviculture," by M. MOUILLEFERT, and dealing with the principal forest trees (essences forestières). It is published in Paris by FELIX ALCAN, but may be had from WILLIAMS & NORGATE, or other foreign booksellers. After some introductory remarks on forestry in general, and the conditions under which it may be practised, the author proceeds to consider in detail the Oaks, Chesnuts, Elms, and other trees grown for their timber in France. Illustrations of many of the species are given, together with representations of the wood as seen under a low magnifying power. The principal insect and fungus pests are noted. The book thus contains, within small compass, much that it is requisite for a forester to know.

"PRODROMUS FLORAL BRITANNICÆ."—Mr. F. N. WILLIAMS, in the third part of his useful publication, has not shrunk from the task of preparing and publishing a revision of the British Hawkweeds (Hieracium). We congratulate him on his courage and industry, which must in any case greatly contribute to the understanding of this intricate genus.

THE FUNGUS FLORA OF YORKSHIRE.—A commencement has been made in the compilation of a complete list of the fungi known to occur in Yorkshire. How many more there may be may be conjectured from the circumstance that "nineteen-twentieths of the county yet remain to be thoroughly investigated!" This seems to presage the future appearance of a supplement. Mr. GEORGE MASSEE and Mr. C. CROSSLAND are responsible for the present instalment, which is published at Leeds for the Yorkshire Naturalists' Union.

MOSQUITO-BANE.—Mr. SHIPLEY records in *Nature* the belief entertained in Western Africa that mosquitos are driven away by a particular plant, some leaves of which have been sent to Kew, and have been identified as belonging to Ocimum viride. Captain LARYMORE, the Resident of the Kabba province, northern Nigeria, confirms the notion of the efficacy of the plant, for he says, that by placing three or four of these plants round his bed at night he was able to sleep unmolested without using a mosquito-net. Mr. SHIPLEY collects a considerable amount of evidence to show that the plant has valuable medicinal properties, and may possibly be of service in banishing the gnats, which are the carriers of the malaria poison.

GERMAN PROFESSORS. — In the January number of *Gartenflora* it is stated that the Keepers of the Botanical Museum of Berlin, Dr. ERNST GILG and Dr. GUSTAV LINDAU, have received the title of "Professor." From the same source we learn that the "extra-ordinary" Professor of Botany at Freiburg in Breisgau, Dr. FRIEDRICH OLTMANNS, has been appointed "ordinary" professor of this department. — *Gartenflora, Jan.* 1, 1903, *p.* 32

NATURE STUDY.—The more lectures that are given in the sensible spirit that inspired Mr. HEDGER WALLACE at the College of Preceptors on Saturday, the better for the future of Nature-study, the peace of mind of teachers, and the progress of education. No one wishes to limit the field of operations, or the matters for investigation in Nature-study, the informality of which is its greatest claim to consideration; but what is the good of an educational unknown quantity, in which, as Mr. WALLACE points out, there is no recognised body of principles or practice? Mr. WALLACE also made clear the ridiculous position of some who make Nature-study so beautifully vague and so vaguely beautiful that they cannot explain what it is, though when hard pushed, they sometimes advance what is merely an old and valued friend—elementary natural science. In the address which he gave, Mr. WALLACE also went deeply into what has been done, and laid down some valuable lines of limitation and division of Nature-study, which have recently been strenuously advocated by himself and also others who have the future of the movement at heart. We cannot go into detail, but we may say that, recognising the objects sought, informal "nature-lore" may be separated from "nature-knowledge," which may find a definite place in the time-table.

PROF. ENGLER.—The Director of the Royal Botanic Garden at Berlin, Professor ENGLER, has returned from a successful journey through East Africa. He travelled from Cape Town through the Transvaal to Lorenzo-Marquez, and from there to Tanga, in order to make a longer stay in East and West Usambara. Thence he went to Kilimandscharo, and to Voi, by the Uganda railway, journeying as far as Nakuru. He returned by way of Mombassa to Daressalam, and has brought back to Europe many treasures with which to enrich the Botanic Garden and Museum of Berlin. *Gartenflora, January* 1, 1903, p. 32.

PUBLICATIONS RECEIVED.—From the Agricultural Experiment Station of the Louisiana State University and A. and M. College:—Bulletin No. 66. *Sugar cane: Experiments in Cultivation*, by Wm. C. Stubbs, Director and State Chemist. Bulletin No. 67. *Broom Corn: How to Grow and Cure It*, by W. R. Dodson. "Broom Corn" is a name for Sorghum vulgare. This contribution contains useful illustrations. Bulletin No. 69. *Pecans*, by F. H. Burnette, Wm. C. Stubbs, and H. A. Morgan. The "Pecan" is a species of Hickory—Hicoria pecan. This bulletin is also illustrated.—From the University of Illinois Agricultural Experiment Station:—Bulletin No. 80. *Methods and Results of Field Insecticide Work Against the San José Scale*, 1899-1902 (illustrated), by S. A. Forbes, State Entomologist.—*Vinton's (late Morton's) Agricultural Almanac for* 1903, is the forty-eighth issue of this publication. Its pages are occupied with agricultural statistics, and with such articles as: Field Experiments, by Prof. Wrightson; Progress in Fruit Growing, by Mr. W. E. Bear; Larch Disease, by M. C. E. Curtis, &c.—*Journal of the Department of Agriculture of Western Australia*, November. This contains numerous notes and reports on the Wanneroo district, Cereals at Hamel Experimental Plots, and from other stations.—*The Transvaal Agricultural Journal*, October, vol. i., No. 1. —*The Agricultural Journal, Cape of Good Hope*, December. Contents: Destruction of Rammenas, Cuzco Maize at the Cape, Electro culture in Clifton, Erinosis in Vines, Blue Gums as Forest Trees, by Mr. C. H. McNaughton, &c.—*Circulars and Agricultural Journal of the Royal Botanic Garden, Ceylon*, vol. ii, No. 2. Further Observations on Helopeltis, by E. Ernest Green.—*Annual Report on the Gardens of His Highness Maharana Fateh Singhji Bahadur, G.C.S.I., of Udaipur, Mewar, for* 1901-2. "The season was, on the whole, favourable. The gardens were kept in good order all through the year." —*Annales Agronomiques*. December 25. Containing a memoir of M. P. P. Dehérain, founder and editor of the publication, and well known for other agricultural and botanical work.—*Illustrirte Flora* (Vienna) December, 1902.—*Der Handelsgärtner*, December 27.—*U.S. Department of Agriculture, Division of Entomology*, Bulletin No. 37.—*Proceedings of the Fourteenth Annual Meeting of the Association of Economic Entomologists;* and Bulletin No. 38, *Some Miscellaneous Results of the Work of the Division of Entomology*, vi.—*Journal d'Agriculture Tropicale.*—*Bulletin du Jardin Imperial de Botanique*, St. Petersburg.—*Italia Agricola.*—*Möller's Deutsche Gärtner-Zeitung.*—*Revue de Horticulture Belge.*—*Agricultural News*, Barbados.—*Pharmaceutical Journal.*—*Webster's Foresters' Diary*, Rider & Son.—*Farm and Home Year Book.*—*Bulletin, Agricultural Station, Louisiana and Illinois.* —*English Mechanic.* — *Comptes Rendus Etat Indepondant du Congo.*—*Die Garten Welt.*—*North Riding County Council Technical Instruction Committee.* — *Builder.* — *Botanische Zeitung.* — *Le Jardin.* — *Florists' Exchange.* — *American Florist.*

HOME CORRESPONDENCE.

ENGLISH CHESTNUTS.—Chestnuts quite large enough to be worth eating are produced in this country in favourable summers, and even occasionally at Kew. Not many years ago a sack was sent up from Gloucestershire, and fetched £3 at Covent Garden with a request for a further supply, as it was earlier in the market than imported fruit. Mr. Fisher in his review of Mr. Gamble's *Manual of Indian Timbers*, states that: "The fine Chestnuts grown in . . . . . the South of France come from a grafted variety which will not grow in England." But we grow in the Arboretum at Kew the Marion de Lyons and Gros Merle, and both produce fruit. In these varieties the large size of the fruit appears to depend on only one or two being developed in each involucre, the rest being suppressed. *W. T. Thiselton-Dyer, Royal Gardens, Kew.*

FASCIATION IN VINES.—Some four years ago, I saw at T. Rochford & Sons' about half the Vines in one span-roofed vinery with very distinct foliage, dark and finely serrated. The shoots consisted of a curious mixture, but they were chiefly doubled or flat. The bunches of Grapes also presented much the same kind of defect, and they were with difficulty thinned. The berries were of a good colour but larger and rounder than ordinary ones. Mr. Rochford sent a fine sample to a meeting of the Royal Horticultural Society, but it was passed over. Recently I was asked to inspect an Alicante Vine, which possessed a double rod, the one rod being of the true form, but the other similar to those I saw at the Turnford Nurseries. I can suggest no cause for this kind of malformation, nor suggest a remedy, and I would pull up every Vine thus affected. The lateral growth being poorly matured, the crop gets less annually, the Vines weaken, and many of the spurs die back or refuse to break. It would be folly to propagate Vines from these defective rods. The same thing happened to some Vines of mine some years ago, when residing in Norfolk, and although various experiments were tried, no actual improvement took place, and they were pulled up. We always take it for granted that Meredith raised this variety of Alicante in France, or at least introduced it, else one might be inclined to think it is a sport, and now occasionally the Vine runs back. Meredith was the first to bring this variety into repute. *Stephen Castle.*

SCOTTISH HORTICULTURAL ASSOCIATION.—Having seen a proof copy of the Chrysanthemum show prize-list for 1903, I should like to point out to those in authority the reckless waste of money that is proposed. A new class is introduced, named the Queen Alexandra Prize, offering £15, £10, £7 10s., and £4, as prizes for twelve vases of Chrysanthemum blooms in twelve varieties, three of each, "confined to growers within the municipal boundaries of Edinburgh and Leith." The association is not a provincial one, rather is it international. Its membership is drawn from all parts of the three kingdoms, and competitors from the sister countries exhibit successfully at the annual November show in Edinburgh. Already a class is confined solely to Scottish exhibitors, and known as the "Scottish Cup" class. Now it is proposed to curtail competition by providing more valuable money prizes "for growers within the municipal boundaries of Edinburgh and Leith" than they offer for the whole of Scotland. As well might growers within the municipal boundaries of Glasgow, Dundee, or Aberdeen, have classes provided for them at this our international Chrysanthemum show in Edinburgh. In looking through the recent official catalogues of entries published each year, I note that with one exception, no exhibitor within the "municipal boundaries of Edinburgh and Leith" has ever made an entry in the larger classes for cut blooms. Where are they to come from now? It might be urged that it will encourage new exhibitors to come forward; but why should such a limited area be so favoured above all Scotland? If they cannot gain a prize when competing with other parts of Scotland, should they be encouraged so liberally to show inferior stuff? A sum of £15 in prizes will induce the same amount of competition, and be a considerable saving in money to the association. I cannot think the people of Edinburgh would appreciate exhibits of poor quality having the name "Queen Alexandra" tacked on to it. Rather let our Queen's name be associated with a worthier class for competition than is possible from the limited area of a municipal boundary. *A Country Member.* [We quite agree with our correspondent's contention. ED.]

VEGETABLES AS FOOD. — Mr. Alleyne in his eulogium of the West Indian Yam, Dioscorea Battatas, or the Sweet Potato, Convolvulus Battatas, is treading over well trodden ground. Not only in the past have efforts been made to popularise the Sweet Potato as an article of consumption in this country, but also to get it grown, and so far with no success. With tastes so much in favour of the starch Potato of South America, now one of our great articles of vegetable diet, we seem to have no appreciation for the Sweet Potato of the West Indies, much as that root may be appreciated in hot countries where starch Potatos such as ours are cannot be grown. Writing of the Sweet Potato in *The Vegetable Garden*, M. Vilmorin states that it can hardly be grown in France, and will not grow in England. Now were we to adopt this Yam as an article of vegetable food, we should but be adding to our indebtedness to other countries for our food supplies, and still further be weakening the public taste for those free-cropping, hardier vegetables we can grow at home. I have often thought, should England, Scotland, and Ireland be at any time by act of

war so blockaded that supplies of food from other countries were cut off, what a condition of want and starvation would exist! The suggestion of such a possibility, having regard to the teachings of history, seems wildly improbable, but it is desirable that every contingency should be provided for. In such a case, on what could the nation rely for food so well as upon those immense supplies of vegetables which the land of the kingdom, under high pressure of culture, could produce? Unfortunately, our tastes in relation to food are far from being simple or natural. It is not merely that we have created myriads of wants of an artificial kind that it needs the produce of the whole world to satisfy, but we have become so habituated to the sweet cheap products of hot climates that the taste for home-grown products is weakened rather than strengthened. The vaunted Sweet Potato is not more pleasant to the taste, nor does it contain greater nutriment than does our own Parsnip, but the latter is far from being a popular vegetable, due very largely, no doubt, to the production of large watery roots and cooking them very defectively. Beets are really most nutritive roots, and we can have them, if enough be grown and cared for, nearly all the year round; whilst the Potato is always with us, and no human being would starve, indeed might lead a healthy life if fed on these three roots solely. Beyond these roots, however, what a wealth of wholesome substantial food we could find in Carrots, Onions, Turnips, Salsafy, of Peas and Beans of all kinds, Vegetable-Marrows, Tomatos, in Cabbages, Cauliflowers, Broccolis, Kales, Sprouts, or Lettuces, Radishes, Cucumbers, Celery, Seakale, and many other things, all furnishing fine food first hand, and devoid of all disease-elements. Beyond all that, there could be immensely enhanced fruit supplies if we would but produce them, rather than as we do now, allow millions of acres of land to run almost to waste, producing only trivial crops of food, as compared with what they could be made to produce were they but under spade-cultivation. Were such the case, not only would profitable labour be found for hundreds of thousands of men now seeking work in vain, but our home food supplies would be so enormously increased that all fear of famine, should any outside trouble occur, would be soon swept away. It is to be deplored that in growing rich, the nation is far from being strong, healthy, or wise. We ignore our capacities of production and resource, whilst running after the sweet products or cheap meats of other countries. Some day, perhaps, we may wish we had earlier been wiser. *A. D.*

PAYMENT OF WAGES DURING SICKNESS.—In your answer to "Constant Reader," respecting wages during illness, in *Gardeners' Chronicle*, January 10, 1903, you say a gardener who falls sick, cannot claim, "as a right," wages during such illness. Please allow me to say he has a legal claim. I myself put a gentleman into County Court last July, and recovered eleven weeks' wages for illness. I may say his solicitor offered five guineas in settlement of claim. I refused, and consulted my solicitor; he put in claim for eleven weeks' wages, and the week before trial they paid full claim with costs into court. I shall be glad to give further particulars if required, in confidence to "Constant Reader," if you will send his address. *X.*

LATE GOOSEBERRIES.—I am very pleased, Mr. Editor, to see in your issue of January 10, p. 28, that you put in a word in favour of the humble Gooseberry. I am afraid your correspondent, Mr. Fulton, has not been fortunate enough to be in a locality where the Gooseberry does well, or he would not be so severe in his condemnation of them as a dessert fruit. I can assure him, that the best flavoured varieties, such as Keepsake, Companion, High Sheriff, Green Gascoigne, and Red Warrington are appreciated very much, not only by my employers, but by visitors also, from whom I have heard such expressions as, they "Did not know Gooseberries were so good before." I quite agree that unless well cultivated and kept free from insects, it is almost an impossibility to get good fruit on a north wall so far south as this, where our greatest enemy is red-spider; and I can quite understand that fruit grown under such adverse conditions would not be very tempting to either birds or wasps. Mine are grown both as cordons and bushes; the bushes being 8 feet between the rows, with a 5-feet fence planted with cordons running between each row; from these (if the wasps would only leave them alone), I should have no difficulty in keeping up a supply of fruit well into September. In confirmation of the above remarks, I have a little bit of silver reposing in a case that was once awarded me by the Royal Horticultural Society for a collection of the above. Since then I am known among some of my brethren of the fraternity as *Old Gooseberry*.

HYDRANGEA PANICULATA FOR FORCING.—It may be of interest to "E. B." to know that to-day, when calling on Mr. C. T. Kirby, of North Finchley and Covent Garden Market, I saw a batch of 1,000 of these in pots, standing on the remains of the manure-bed, which had some 12 ins. cut off the tops, and outside a covering of bracken. This I found had been here done for convenience, the plants when received from Holland being tall, and the potting-shed low, there was not room for the heads without cutting down. I trust "E. B." did not conclude that by my statement of reducing top shoots that this was *the* pruning. The fact of any top growth being shortened does not practically affect the plant growth in any way, the probability being that the winter would kill this soft wood to a point far below the point at which the shoot would be cut, but the shorter top keeps the plants from blowing over. According to the season at which plants are wanted to come into bloom, so must the actual pruning take place. Thus February and March, for June and July flowering; April being a good time for August blooming. The pruning, as rightly noted by "E. B.," would then be down to two to four buds. There are exceptions, however, to every rule, as last May I saw a lot of 200 plants that had had the shoots left longer for extremely late flowering, and these did well, excepting that the heads were not individually fine ones. *S. C.*

CROSS-TRELLISES FOR PEACH-TREES.—That good crops of fruits may be gathered from trees planted cross-wise in the house, and for years in succession, cannot be doubted. My earliest knowledge of a house so planted was in 1876, and at that time the house in question was not new, it must have been erected some thirty years ago. The house in question (I forget its name) was in a garden on Sydenham Hill, and adjoining it was "Hitherwood," the residence of the late Latimer Clark, Esq. Not only did the trees so planted produce excellent crops of fruit annually, but the trees on the back wall bore their complement of fruit. If objection could be taken at all, it was to the lack of room for the full development of the trees towards the front. This was apparent at the time of which I write, and was due to the front wall being much too low. This, with the very sharp angle of the house, caused some little disfigurement of the trees, through excessive curtailment of growth. With this item modified, the cross-planting method was not inferior to others, while it afforded space for a larger number of trees than is the case with the usual ones. *E. J.*

SHIPLEY HALL, DERBY.

THE gardens at this place, the residence of E. M. Mundy, Esq., are at all times interesting, but especially so just at the present time, owing to the extensive alterations and improvements in the gardens. A special feature is the construction of a fine pergola from east to west, through the old walled-in garden, and the walk continues at either end, joining the lawn on the east, the famous Beech avenue on the west, thus connecting two distinct parts of the pleasure-grounds. The pergola is furnished with an arched roof and four domes placed at equal distances apart. The wood used is Oak, and the supports consist of slender pillars of brick in cement. Instead of the usual grass or gravel path underneath, ornamental York flagstones are used.

A small rockery connects the pergola with a fernery, planted with a mixture of alpines, now getting nicely established. A path runs through the centre, and is banked with tufa. On the eastern side of the lawn a Lily-pond has been constructed, and numerous species and varieties were in flower on the day of my visit. The pond has a margin of tufa, and forms a pleasing feature, the whole being surrounded with groups of bog and other hardy flowering plants.

In another part of the garden, the head gardener, Mr. Tallack, drew my attention to a border planted entirely with autumn-flowering, hardy, herbaceous, and perennial plants. This idea of planting hardy flowers that come into bloom at the same season all together is a praiseworthy one, and obviates the untidiness usually observed in mixed borders.

The Vines and fruit-trees in the forcing-houses are looking well—the Vines are strong, healthy, and fruitful. Of Figs, I noted a tree of the Brown Turkey, whose branches entirely cover the roof of a large glasshouse, and afford two crops a year. This tree is allowed to grow at will, and no pruning or stopping curtails its growth excepting in the winter, when some strong branches require to be removed to afford space for young growths. The crop this year numbered more than 1,000, and was continuous from May till the end of October.

Some time ago it was considered advisable to remove all of the span-roofed plant and Orchid-houses, so that instead of running east and west as formerly, they should run north and south. These houses are approached from the pergola on either side. Some of these are filled with clean well-grown Orchids, the outcome of many years of collecting. In flower were numerous Dendrobium var. Phalænopsis Schroderi, a splendid strain with highly coloured flowers. Leaf-mould is extensively used with good results, for the plants in general are superior to those grown in peat and sphagnum, but the greatest care has to be exercised in affording water at the roots. The centre of the fruit-house range consists of a large span-roofed house, which is devoted to the cultivation of Anthurium Schertzerianum in great variety, and some of the specimens are of huge size (see fig. 21, p. 45).

There are many other plant-houses filled with plants used for indoor decoration, and for supplying flowers for cutting. Among these is Begonia Gloire de Lorraine, plants of which when in flower are suspended from the roof of the glass corridor with rockery walls, which connects the mansion with the conservatory. The latter was filled with Palms, showing remarkable health and vigour. Fairly large batches of Chrysanthemums, Richardias, Euphorbias, Genistas, Salvia splendens, Francoas, Campanulas, and the usual run of forcing plants are grown. Winter Carnations only are grown in quantity, the selected being Mdlle. Thérèse Franco, Miss Mary Godfrey, R. Godfrey, Lucifer, Firefly, Jubilee, &c.

A long border in the walled-in garden was filled with Roses, and I noticed in various parts of the grounds large beds of the R. rugosa varieties, which flower abundantly in the autumn, a season when the family is in residence. In the upper part of the garden, and to the south of the pergola before mentioned, large quantities of Sweet Peas are grown, supplying cut blooms; and near by were conspicuous lines of Montbretias. The soil at Shipley evidently suits these plants.

Mr. Tallack is a many-sided gardener, and his vegetable gardening shows as excellent results as the other departments of the garden. *G. Burrows.*

SOCIETIES.

ROYAL HORTICULTURAL.

JANUARY 13.—Although the meeting held on Tuesday last in the Drill Hall, Buckingham Gate, Westminster, was the first in the new year, and the only one that has occurred for five weeks, the sudden decline in temperature since Saturday night was sufficient to prevent the display being large. The cold was so intense on Tuesday that it was a wonder that so many plants even as were shown were subjected to the risks of transit. Orchids were fairly numerous, but they were chiefly cut flowers.

The FLORAL COMMITTEE recommended a First-class Certificate to Coleus thyrsoideus, and three Awards of Merit to seedling varieties of Chrysanthemum. The Road, Chelsea, which occupied one whole side of one of the long central tables. It was composed of Coleus and Begonias. At the back was a double row of plants of the new blue-flowered Coleus thyrsoidens (see *Gardeners' Chronicle*, January 19, 1901, fig. 18), some of them in 8 inch pots, and reaching 3 feet to 4 feet high, with fine erect racemes nearly a foot in length. They well illustrated the effectiveness of this winter-flowering plant, of a colour too uncommon at this season. These were faced with a fine lot of Begonias, including Winter Cheer, Agatha, and Agatha compacta (Silver-gilt Flora Medal). Messrs. Jas. Veitch & Sons also showed the yellow-flowered Lindenbergia grandiflora, figured in these pages, September 20, 1902, p. 213, and Bryophyllum crenatum.

Messrs. W. CUTBUSH & SON, Highgate, London, N., had an attractive group of plants, in the centre of which were some good plants of the old and fragrant Millar Mundy, was shown by Mr. J. C. TALLACK, Shipley Hall Gardens, Derby. The colour of the flowers is crimson, with a silvery flake upon each petal. They are very fragrant, but the calyces appear to burst.

Mr. FYFE, Lockinge Gardens, Wantage, showed flowering sprays of Ipomœa rubro cœrulea.

Messrs. W. WELLS & Co., Earlswood Nurseries, Redhill, showed a pink-flowered Chrysanthemum named C. W. Payne, a sport from Princess Victoria; also a seedling decorative variety named Christmas Crimson.

Messrs. BARR & SONS, King Street, Covent Garden, London, W., exhibited flowers of Christmas Roses. There were several varieties of Helleborus niger, of which Invernis appeared best, and others shown included H. caucasicus luteus, H. olympicus, H. orientalis, &c. There were blue flowered Primroses, Galanthus Elwesii, Narcissus (corbularia) monophylla, Saxifraga Burseriana, Iris stylosa, &c.

FIG. 21.—SPECIMEN OF ANTHURIUM SCHERTZERIANUM WITH SEVENTY SPATHES, CULTIVATED IN SHIPLEY HALL GARDENS.
(SEE P. 44.)

first Chinese Primulas of the season were seen in a collection from Messrs. H. CANNELL & SONS.

The FRUIT AND VEGETABLE COMMITTEE made no award to a novelty. The exhibits included a collection of Black Alicante Grapes from a garden at Hampstead, and some samples of West Indian Yams (Dioscorea) and Sweet Potatos (Ipomœa Batatas).

At a meeting at 3 o'clock, P.M., there were 101 new Fellows, Associates, and affiliated societies, elected to the privileges of the Society.

Floral Committee.

Present: W. Marshall, Esq., Chairman; and Messrs. C. T. Druery, H. B. May, Jas. Walker, R. Dean, H. J. Jones, J. F. McLeod, J. Jennings, W. Howe, G. Renthe, Chas. Dixon, C. J. Salter, Chas. Jeffries, C. E. Pearson, R. W. Wallace, Rev. F. Page Roberts, H. J. Cutbush, J. W. Barr, J. A. Nix, C. E. Shea, R. Wilson Ker, E. H. Jenkins, R. C. Notcutt, E. Molyneux, J. H. Fitt, M. J. James, Chas. Blick, Ed. Mawley, and George Nicholson.

The most imposing exhibit was one from Messrs. JAS. VEITCH & SONS, Ltd., Royal Exotic Nursery, King's Daphne indica rubra, and on either side of these, small groups of Erica hyemalis, E. melanthera, and E. gracilis, all good, well-bloomed plants, and some dwarf plants of Citrus sinensis, very freely fruited. In addition to these were some beautiful flowers of choice varieties of Carnations, amongst which were Mrs. S. J. Brooks (white), Mrs. T. W. Lawson, Sir Hector MacDonald, pink and white; Winter Beauty, bright crimson; &c. The Souvenir de la Malmaison type was represented by Mrs. Martin R. Smith, Calypso, Nautilus, Jane Seymour, &c. (Bronze Banksian Medal).

Messrs. H. CANNELL & SONS, Swanley, Kent, exhibited a group of plants of Coleus thyrsoideus, Moschosma riparium, and Arum sanctum, all in bloom; also a good lot of Chinese Primulas in single and double varieties. Some of the more conspicuous of the single varieties were Mrs. Kennard, pink; Empress Queen, Eynsford White, White Swan, Snowdon, Eucharis, and Sea-gull (all white); Surprise, purple, shaded crimson; Dr. Nansen, deep crimson; Cannell's Pink, Eynsford Red, and H. Cannell, bright red (Silver Flora Medal).

A new winter-flowering Carnation, named Mrs. Mr. J. RUSSELL, Richmond Nurseries, Surrey, exhibited a group of plants of Aucuba japonica, and A. longifolia, all of which bore abundant richly-coloured berries. A few of the plants were trained as standards 3 feet high (Bronze Banksian Medal).

An unusual feature in the Drill Hall was provided by Mrs. MARY HARRIS, Kinross, Manor Road, Bexhill-on-Sea, who showed two handsome "table centres." They were said to be hand-painted, after being poker-worked on velvet with a hot electric needle. On one were represented Sunflowers, and on the other red Roses, with natural foliage in each case.

A patent tree clip was shown by Mr. W. FYFE, Lockinge Gardens. It is made of steel, and covered with gutta-percha. They have a certain amount of spring, and the tree is forced into the clip, and held by the simple contraction of the clip. Whether they can be made sufficiently cheap for general use, and will hold the tree against strongest winds, must be proved.

Awards.

Coleus thyrsoideus.—This plant has been given an Award of Merit previously, and was illustrated and

described in these pages on Jan. 19, 1901. Shown by Messrs. JAS. VEITCH & SONS, and Messrs. H. CANNELL & SONS (First-class Certificate).

Chrysanthemum Harry Whateley.—This is a sport from the well known variety Niveum. The sport is white, and the florets being forked at the points, the flowers appear fimbriated. It is described as blooming three weeks later than Niveum. From Mr. H. WHATELY, The Nuraeries, Kenilworth (Award of Merit).

Chrysanthemum Miss Edith Davey.—This is a light red-coloured sport from the popular Framfield Pink, which it resembles in other respects than colour. Shown by Mr. MILTON HUTCHINGS, Field-heath Nurseries, Hillingdon, near Uxbridge (Award of Merit).

Chrysanthemum Ruby Martin.—A brownish-red coloured decorative flower, 4 inches across, with narrow florets, slightly forked at points. From Mr. J. J. MARTIN, Linslade Nursery, Leighton Buzzard (Award of Merit).

Orchid Committee.

Present: Henry Little, Esq., in the Chair; and Messrs. Jas. O'Brien (Hon. Sec.), J. W. Potter, H. A. Tracy, W. H. White, W. H. Young, F. J. Thorne, W. Boxall, J. W. Odell, T. W. Bond, E. Hill, J. Charlesworth, H. T. Pitt, W. A. Bilney, F. A. Rehder, W. Cobb, R. B. White, H. Ballantine, and de B. Crawshay.

There was a very fine show of Orchids, although in consequence of the frosty weather many of the subjects which it had been intended to show as plants in bloom had the flowers cut for exhibition, the plants remaining at home.

Captain G. L. HOLFORD, Westonbirt (gr., Mr. H. Alexander), staged a very effective display, principally of cut flowers, arranged in groups with plants of Maidenhair Fern. Among them were two bouquet like arrangements of the handsome bronzy-orange Lælio-Cattleya × Charlesworthi, L.-C. × Sunray, Lycaste Skinneri atro-sanguinea, spikes of Cymbidium × Winnianum, Lælia anceps Schroderiana, and fine examples of about fifty kinds of Cypripediums, including fine forms of C. × nitens, C. × Mrs. Tautz, C. × Mona. de Curte, C. × Facinator, &c. A fine plant of the prettily spotted Odontoglossum crispum "Ian" was also shown with two spikes (Silver Banksian Medal).

Messrs. JAS. VEITCH & SONS, Chelsea, staged a group composed principally of fine hybrid Cypripediums. Fine forms of most of the best varieties of the season were shown, and a very showy novelty named C. × Dryope (Harrisianum superbum × Charlesworthi), with a uniformly rose purple coloured flower, with white margin to the dorsal sepal. Hybrid Dendrobiums, Calanthe × gigas, Cattleya × Elvina, and the remarkable Angræcum × Veitchi (eburneum × sesquipedale) was also shown (Silver Banksian Medal).

JEREMIAH COLMAN, Esq., Gatton Park (gr., Mr. W. P. Bound), staged a very pretty group of cut spikes, elegantly-arranged with Asparagus Sprengeri. They included several fine spikes of Cymbidium Tracyanum, C. × Winnianum, Zygopetalum Mackayi, and the finer Gatton Park variety; good examples of Lælia anceps, Calanthe × Veitchi, C. × Bryan, and C. × Wm. Murray (Silver Banksian Medal).

FRANCIS WELLESLEY, Esq., Westfield, Woking (gr., Mr. Gilbert), showed the fine Cypripedium × Samuel Gratrix var. Minnie (see Awards), the beautiful C. × Memoria Jerninghamæ, a fine flower of unrecorded parentage, with pure white upper sepal with emerald-green base, purple markings, and broad central purple band; the broad, many-edged petals and labellum were heavily tinged with brownish-purple, except at the margins, which are yellow. Mr. Wellesley also showed two forms of Lælio-Cattleya × Helena var. Miss Laura Webb, with bronzy-orange flowers, and ruby-red colour on the lip, and Cypripedium × Hera punctatissimum.

Messrs. SANDER & SONS, St. Albans, staged a small group of rare hybrids, two of which secured Awards (see list). The best of the others were Cypripedium × Louis Sander (Calypso Oakwood var. × nitens Sander's variety), a very handsome and richly-coloured flower. The upper sepal is white, with a broad purple band and suffusion of rose-purple, the petals and lip being dark bronzy-yellow, with a polished surface; C. × The Durbar (Morganiæ × hirsutissimum), a very distinct novelty, the upper sepal of which is nearly black, with white margin; petals honey-yellow, tinged with rose and spotted with dark purple; lip bronzy-yellow. Others shown were C. × Miss Louisa Fowler, and Zygocolax Wiganianus.

Messrs. CHARLESWORTH & Co., Heaton, Bradford, showed the pretty Lycaste × Balliæ, with thirteen flowers; Cypripedium × Lathamianum splendens, and other hybrids.

Mr. A. A. PEETERS, of Brussels, showed five very finely grown and distinct forms of Cypripedium × anreum, including the rare greenish-yellow and white variety "Surprise," for which M. JULES HYE-LEYSEN, secured an Award of Merit, February 28, 1899. The others were C. aureum Hyeanum, a very large form with a darker tint; C. × a. Œdipe with purple colouring in the dorsal sepal; C. × a. Cyrus, with a broad purple band up the middle of the upper sepal; and C. × a. Virginale, the dorsal sepal of which is white, with a small green base. M. PEETERS also showed C. × Lathamianum splendens, similar to that shown by Mr. CHARLESWORTH.

M. OTTO BEYRODT, Marienfelde, Berlin, sent six fine flowers taken from a large number of Cattleya Trianæi, now in bloom, and ranging from nearly pure white to rose with fine crimson labellum; also Odontoglossum × Adrianæ, and another hybrid of the same class; a peculiar form of Cypripedium insigne, and a finely-coloured hybrid, said to have been imported with Cypripedium callosum.

J. WILSON POTTER, Esq., Elmwood, Croydon (gr., Mr. J. W. Young), showed Cypripedium × J. Wilson Potter, a hybrid of C. × Harrisianum superbum, and a very finely formed and richly coloured flower, of an almost uniform dark purplish-rose colour, the veining being darker in tint, and the margin of the upper sepal white.

J. GURNEY FOWLER, Esq., Glebelands, South Woodford (gr., Mr. J. Davis), showed Cypripedium × Leander reticulatum.

DE B. CRAWSHAY, Esq. (gr., Mr. Stables), showed Lælia anceps Theodora, a pretty white suffused over the whole surface with very pale blush-pink.

Major JOICEY, Sunnydale Park (gr., Mr. F. J. Thorne), sent Dendrobium spectabile, D. Johnsoniæ, and a hybrid Cypripedium.

J. T. BENNETT-POË, Esq. (gr., Mr. Downes), showed Dendrobium spectabile.

J. BRADSHAW, Esq. (gr., Mr. G. Whitelegge), showed Lycaste Skinneri Enchantress.

W. THOMPSON, Esq. (gr., Mr. W. Stevens), showed the fine Cypripedium × Thompsoni.

GEO. SINGER, Esq., Coundon Hall, Coventry (gr., Mr. Collier), sent fine flowers of Cypripedium × aureum Surprise, C. × Mme. Jules Hye, and C. × Olivia.

Baron Sir H. SCHRODER (gr., Mr. H. Ballantine), sent Cypripedium × Lecanum Clinkaberryanum.

Mr. H. A. TRACY, Twickenham, showed Cypripedium insigne Pouparti, a pretty yellowish flower, finely spotted and tinged with chestnut-brown.

Mr. A. WRIGHT, Reading, sent Dendrobium × Cybele, with the erroneous record (nobile × Jamesianum).

H. E. GORDON, Esq., Aikenhead, Glasgow (gr., Mr. Boucher), showed hybrid Cypripediums between C. Druryi and C. Boxalli superbum, and C. Harrisianum and C. insigne punctatum violaceum.

Awards.

FIRST-CLASS CERTIFICATE.

Cypripedium × *Hindeanum* (Godefroyæ × insigne Harefield Hall variety), from Messrs. SANDER & SONS.—A noble flower with the dwarf habit characteristic of bellatulum and Godefroyæ hybrids, and the massive flower of fine substance to be expected with the C. insigne Harefield Hall as a parent, this being probably its finest progeny. Upper sepal large, cream-white, veined and spotted purple. Petals broad, primrose colour, tinged and marked with purple. Lower sepals nearly round, whitish, with spotted lines of purple; lip and staminode yellow, tinged with rose.

Odontoglossum × *Wallonienne* (crispum ♀, polyxanthum ♂), from W. THOMPSON, Esq., Walton Grange (gr., Mr. W. Stevens).—A very beautiful hybrid, which might easily be mistaken for a large yellow form of the best type of O. crispum. Sepals and petals broad, the latter slightly fringed; canary-yellow, with a darker golden hue on the sepals; lip broad, slightly fringed, whitish-yellow, with one large, irregular, reniform, chestnut-brown blotch in front of the callus. All the evidence of the brown spotting of O. polyxanthum consisted in a single obscure brown blotch on one of the segments.

AWARDS OF MERIT.

Cypripedium × *Samuel Gratrix var. Minnie* (Lecanum superbum × nitens superbum), from FRANCIS WELLESLEY, Esq., Westfield, Woking (gr., Mr. J. Gilbert).—A perfectly formed flower of great beauty. Upper sepal large, flat and circular, pure white, with a green base, and uniform purple spotting on the lower two thirds; petals and lip broadly proportioned, glossy, yellow, tinged with purple-brown.

Cypripedium × *Empress Alexandra* (Godefroyæ × nitens), from Messrs. SANDER & SONS.—A distinct and pretty flower. Upper sepal greenish at base, white on the upper half, and with dark purple markings; petals and lip tinged with purple of various shades.

Odontoglossum Lucasianum var. Walkeri, from Messrs. HUGH LOW & Co., Bush Hill Park.—A supposed natural hybrid of O. Hallii, the form of which species it closely approaches, the yellowish-white labellum spotted with red-brown being similar to that species. The sepals and petals are dark brown, tipped and slightly margined with yellow.

Fruit and Vegetable Committee.

Present: A. H. Pearson, W. Poupart, J. Willard, Geo. Wythes, Jas. H. Veitch, Geo. Norman, F. Q. Lane, J. Jaques, H. Markham, Ed. Beckett, Horace J. Wright, W. Fyfe, W. Pope, A. Dean, S. Mortimer, W. Bates, Jos. Cheal, O. Thomas, G. Kelf, and M. Gleeson.

A dish of fine fruits of Pear Beurré Rance was shown from Earl ILCHESTER'S garden at Holland House, Kensington (gr., Mr. Dixon), (Vote of Thanks).

Messrs. SUTTON & SONS, Reading, exhibited some good heads of a new Broccoli, known as Superb Early White. They had been cultivated without any protection having been afforded, and the variety is described as being unusually early and hardy.

Samples of West Indian Yams (Dioscorea) and Sweet Potatos (Ipomœa Batatas), from the Barbados, were shown by Messrs. WILLIAM PINE & SONS, 114, Commercial Road, Portsmouth, who import the roots in quantity. These were referred to in a note published in the *Gard. Chron.*, Dec. 20, p. 484. Circulars were placed with the roots, which described several methods of using these foods practised in the West Indies. This information was supplied originally by the Imperial Department of Agriculture for the West Indies, with a view to creating a demand for the products in this country.

Mr. R. C. NOTCUT, Wood's Nursery, Woodbridge, Suffolk, exhibited some fruits of Pear Winter Orange, a variety suitable for stewing, which has been shown on former occasions.

A collection of twenty-eight bunches of Black Alicante Grapes was shown by W. SHUTER, Esq., Hampstead (gr., Mr. T. Armstrong). The bunches were of fair average size, and the berries well coloured, especially as they were cultivated within 3 miles of Charing Cross (Silver Banksian Medal).

MEETING OF THE CHAMBRE SYNDICALE AT GHENT.

JANUARY 5.—At the meeting on the above date of the Chambre Syndicale des Horticulteurs Belges and the Société Royale d'Agriculture et de Botanique of Ghent, the following Certificates of Merit were awarded:—For three Phalænopsis amabilis var. Rimestadiana, from M. TH. PAUWELS (*par acclamation*); for Cattleya rubescens (C. dolosa × C. labiata, from M. A. PEETERS, of Brussels (*à l'unanimité*); for Cymbidium Tracyanum hyb. Hookerianum × giganteum, from M. L. DE SMET-DUVIVIER; for a group of Begonia Turnford Hall, from M. PYNAERT VAN GEERT (*par acclamation et avec félicitations du jury*); for Lælia autumnalis atro-rubens, from the Marquis DE WAVRIN; for Cypripedium Madame Alfred Janssens (callosum × Curtisii superbum), from MM. JANSSENS & PUTZEYS, of Merxem, Antwerp; for C. Putreysii (Albertianum × Sylhetense) (*à l'unanimité*), and for C. Caroline (Chantini × Boxalli), both these also from MM. JANSSENS & PUTZEYS; for cut Chrysanthemums (*à l'unanimité*), from M. FIRMIN DE SMET; and for a cut flower of Cattleya labiata, from M. F. DE BIEVRE, head gardener of the Royal houses at Laeken.

CHESTERFIELD AND DISTRICT CHRYSANTHEMUM.

JANUARY 8.—The annual meeting of this society was held on the above date, Mr. Steele, head master of the Central Schools, presided. The hon. sec., Mr. W. R. Bloxham congratulated the society on the success attending the show of spring flowers held in April at Wingerworth Hall, and the autumn exhibition of Chrysanthemums; and also the members of the Chesterfield Society for having won the Cup and £5 offered by the Sheffield Chrysanthemum Society for competition by affiliated societies.

Mr. Burr, F.G.S., the hon. treasurer, presented the balance sheet for 1902, showing the society to be in a healthy financial condition. Beginning the year with £13 7s. 1d. in hand, to which the year's working brought in receipts amounting to £191 4s., making a total of £234 11s. 1d. The sum of £ 32 12s. 5d. has been expended, £11 10s. given to gardening charities, £10 to the Chesterfield Hospital, and there is a balance in hand of £49 18s. 2d. The show of spring flowers, by invitation of J. E. Clayton, Esq., President for 1903, will be held at Thornfield House on April 22; and the Chrysanthemum show at the Stephenson Memorial Hall, Chesterfield, on November 11 and 12.

Places at which spring shows have been held under the auspices of the society during the past eight years are Ashgate Lodge, Tapton Grove, Ashgate House, Wingerworth Hall, Tapton House, Whittington Hall. The committee will again provide vans where necessary for the conveyance of plants to the spring show, but gardeners and amateurs will receive no other reward beyond that which comes from a knowledge of having assisted to carry out the objects of the society—to foster the love of flowers in the midst of much that is unlovely, and to help the gardening and other charities from time to time.

Schedule of prizes for the autumn show to be revised; and a paper on "Pruning" is to be read on January 22.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

JANUARY 8.—A fine display of plants was made on this occasion, and several groups were worthy of special notice.

Mr. J. CYPHER, Cheltenham, had a very good collection of plants, amongst which were two fine specimens of Cypripedium × Leeanum var. giganteum, C. × Leeanum var. magnificum, C. × Leeanum Cypher's var.; C. Leeanum var. burfordense, C. insigne Sanderæ, C. i. Harefield Hall var.; half-a dozen splendid plants of Sophronitis grandiflora; Angræcum sesquipedale, and several fine forms of Lælia anceps. A Silver Medal was awarded to this group.

O. O. WRIGLEY, Esq., Bury (gr., Mr. Rogers), staged a nice group of Cypripediums, for which a Silver Medal was awarded. Cypripedium Pollettianum var. superbum, received an Award of Merit; similar Awards were made to C. × Melia and C. × Tityus var. superba; Cattleya chocoensis var. albens was also shown in the group.

M. A. A. PEETERS, Brussels, exhibited several good Orchids, the choicest being Cypripedium × aureum var. Surprise, which received an unanimous vote of a First-class Certificate. This lovely plant has now passed into Mr. S. Gratrix's collection. Other plants shown by this well-known cultivator which received notice from the Committee were Cypripedium × Cardosoanum, C. × Madame A. Bleu, both of which were given Awards of Merit, and for the collection a Bronze Medal was awarded.

G. W. LAW-SCHOFIELD, Esq., Rawtenstall (gr., Mr. Shill), who, we are happy to know is rapidly recovering from his recent serious illness, staged several good Cypripediums, a few of which have already been dealt with by the Committee. Two new seedlings, the parentages of which are unknown, received first-class Certificates. C. × Adrastus var. Mariæ, C. × Thompsoni, C. × Cyrus, were also shown. A Bronze Medal was awarded the exhibitor for this group.

S. GRATRIX, Esq., Whalley Range (gr., Mr. Cypher), received a First-class Certificate for a beautiful form of Cattleya Percivalliana called West Point var.; and an Award of Merit for Cypripedium × "Great Rex," the parents of which are C. insigne Sanderæ × C. villosum.

JOHN COWAN & Co., Ltd., nurserymen at Gateacre, received an Award of Merit for Cypripedium × "Kubele," of which the parents are C. œnanthum × C. Youngianum.

Messrs. HUGH LOW & Co., Bush Hill, Enfield, received a Bronze Medal for a miscellaneous group, the same Award being given to Mr. A. J. KEELING for a group consisting mainly of good forms of Cypripedes. *P. W.*

ABERDEEN CHRYSANTHEMUM.

THE annual meeting was held in the Union Club Buildings, Aberdeen, on Saturday evening, 10th inst., when Mr. William Bisset, the Chairman of the Society, occupied the chair. The annual report, which was read, showed that there was an increase in the membership and in the funds of the Society. The exhibition held on Nov. 21 and 22 last, was most successful, and there were about fifty more entries than in any previous year. The quality too of the exhibits was excellent. The financial statement was also favourable, the credit balance for the year being £23 9*s.* 8½*d.*, the total funds now amounting to the respectable figure of £139 18*s.* 8*d.* In moving the adoption of the report, the chairman characterised the year's transactions as most successful, and extended to all who had contributed to the success of the year's working the thanks of the Society. Mr. J. D. Smith seconded the motion, which was unanimously agreed to. The following gentlemen were elected office bearers for the ensuing year:—Chairman, Mr. William Bisset; Vice-chairman, Mr. G. C. Minty; Secretary and Treasurer, Mr. M. H. Sinclair. A committee of twenty members was appointed, who will form the executive for the present year. The date of this year's show was fixed for November 20 and 21. A motion was put to the meeting that the show should last for three days, instead of two, as in former years, but it was rejected by a large majority. Messrs. W. McHattie and William Cocker were elected auditors.

SOCIÉTÉ FRANÇAISE D'HORTICULTURE DE LONDRES.

ON Monday evening last, the Annual Dinner of the above Society was held at the Imperial Restaurant, Strand. Mr. Thomas Bevan occupied the chair, being supported by a numerous company, both English and French, among whom were, Mr. Geo. Schneider, the President of the Society; Mr. Geo. Nicholson, late of Kew Gardens; Mr. S. T. Wright, of the Royal Horticultural Society Gardens, Chiswick; Mr. Harman Payne, Mr. H. J. Jones, Mr. Drost, Mr. B. Wynne, Mr. W. Cutbush, and others.

The first toast to be honoured was that of the 'King," which was proposed by the Chairman, the company joining in the singing of the National Anthem.

Mr. George Nicholson then followed with "the health of the President of the French Republic," which was accompanied by the Marseillaise.

Mr. Schneider in a few appropriate words, then proposed "the health of the Chairman," reminding those present that his title to occupy that position, was that he had not only worked as a gardener in France, but had kept in touch with what was being done on both sides of the Channel, and had preserved a friendly regard for his continental confrères.

In his reply, the Chairman briefly alluded to the good work the Society was doing, which was largely owing to the excellent feeling that existed amongst its officials. Not only were places found for young

THE LATE JOHN McKENZIE, GARDENER AT LINTON PARK.

Frenchmen in England, but also places were found for young Englishmen who desired to go on the Continent; several of these being also present that evening. It was stated that the Society annually found situations for about eighty young men in this way. As one who knew the difficulties that beset young men on setting foot for the first time on foreign soil, he was sure that the young friends present much appreciated what the Society did for them in every way.

Mr. Schneider replied in the name of the Society, reviewing past work and reminding them that fifteen years ago no one could foresee the progress the Society was destined to make. This he was grateful to say was largely helped by the kindness of English friends in the nursery trade, who made a point of taking some of their young men. He was glad to see there present several young English gardeners who had in like manner been abroad. He would ask them to drink to "the health of the visitors;" which was very cordially done.

Mr. Harman Payne replied for the visitors, and Mr. B. Wynne for "the Press."

Mr. S. T. Wright felt it to be a great honour to meet so many French gardeners; he thought that such meetings could not fail to increase the bonds of friendship between two great nations, who had done so much for the civilisation of the world.

Songs and recitations were given by various friends of both nationalities, and a presentation was made to Mr. George Schneider of a pair of gold sleeve links as a mark of respect from the young members of the Society. Several new members were proposed, among whom were Mr. Peter Kay, of Finchley, who also sent an invitation for the members to visit his establishment during the summer. Others included Mr. S. T. Wright, Mr. Sander of St. Albans, Mr. Lewis Castle, &c.

CROYDON & DISTRICT HORTICULTURAL MUTUAL IMPROVEMENT.

THE annual meeting of the Croydon and District Horticultural Mutual Improvement Society was held at the "Sunflower" Hotel, George Street, on Tuesday evening, when Mr. W. J. Simpson was in the chair. Mr. Frank Lloyd was re-elected President, and Mr. G. Curling was added to the list of Vice-Presidents, all of whom were re-elected. Mr. P. F Bunyard once more undertakes the duties of treasurer, while Mr. H. Boshier fulfils the onerous post of hon. secretary in the place of Mr. J. Gregory, who resigned his position on account of the pressure of other engagements. The Chairman and Vice-Chairman were re-elected. A quantity of new blood was elected to the committee, which may do the society some good

The report and balance-sheet were read, the latter showing the society to be in a very flourishing condition.

The annual dinner took place on January 22, and was well attended, 105 taking part. The annual summer outing took place on August 27, the places visited being Paddockhurst and Werth Park. A special vote of thanks is due to Mrs. Montefiore for her subscription of £2 towards defraying the expenses of the outing. The committee regretted that the prizes offered to young members for an essay on "Propagation" had not met with more success, only one member having sent in for the competition. They also regretted to report that the contributions to the Gardeners' Orphan Fund box had fallen short of the previous year, the amount this year being only 6*s.* 4*d.* Mr. Bunyard moved the adoption of the report, and said the society was in a fairly healthy condition. Mr. Harris seconded, and the report and balance-sheet were unanimously adopted.

THE HORTICULTURAL CLUB.

JANUARY 13.—At the monthly dinner of this Club, at the Hotel Windsor, held under the chairmanship of Mr. HARRY VEITCH, on Tuesday, Mr. OWEN THOMAS, V.M.H., read a paper on "The wasted opportunities in fruit and vegetable culture among the rural population." Mr. Thomas's remarks had for their chief object the holding of a special Conference for the purpose of discussing and remedying the difficulties at present attending fruit and vegetable culture by the rural population on the land available for such purposes. A fundamental need, apart from education such as is being afforded by County Council lecturers, is that of establishing some connection between producer and consumer, thus ensuring the labourer some reward for his extra toil on such allotments of, say half an acre, which Mr. Thomas advocated should be provided for him, mainly for fruit and perennial vegetable culture, which involve the minimum of arduous labour. In the subsequent discussion, which was a lively one, participated in by such authorities as Messrs. Assbee, H. Veitch, Pemberton, T. W. Sanders Reed, Waterer, C. Pearson, Amos Perry, and others Mr. Perry cited the case of the Dutch labourers, who, by intelligent co-operation, manage to grow extensive crops of Onions, Gherkins, Cauliflowers, &c., for pickling purposes, to store them in brine, wait their opportunity, and eventually sell them to good advantage to our pickle manufacturers here; an eloquent example of what our own people ought to do, and could do, if they would throw off their old-fashioned conservatism, and learn to do things on the right lines. The entire discussion, as well as the paper itself, was fraught with instruction, but space precludes entering into full details, which will, however appear in due course in the Royal Horticultural Society's *Journal*.

Obituary.

J. McKENZIE.—The portrait upon this page represents the popular Scottish gardener, whose death at Linton Park, near Maidstone, it was our painful duty to publish last week. John McKenzie passed away on the first Sunday in the new year. Two years ago he was stricken down with a severe illness, which it was hoped he had overcome, but a return of the disease proved fatal in spite of his strong constitution. We take from a local paper a few details, and hope to publish a fuller account of his career in our next issue. Mr. McKenzie was ever ready to help a young man on the start of life, never happier than when playing with children and amusing them with stories of his own childhood, or explaining in simple phrases to them some of Nature's workings. He had a memory full of anecdote, and was a broad-minded, well-read man, beaming with good nature and sympathy in the work of his

contemporaries. Small wonder that so many met to pay their last respect at his graveside. For over twenty years he had charge of the gardens and grounds at Linton Park, in which post of trust he enjoyed the entire confidence of his employer, and the esteem of the staff under him. At the Crystal Palace, the Aquarium, and other exhibitions, his face and figure were well known and heartily welcomed, and his successes as an exhibitor were on a large scale. At the fruit exhibition at the Crystal Palace in September last, Mr. McKenzie was particularly successful in the classes for single dishes of Apples; and in 1897 he won 1st prizes in twenty-nine classes. His mature knowledge of Apple-culture, the treatment of Vines, the different varieties of Conifers, the growth of Chrysanthemums, and other horticultural subjects, kept him in constant correspondence with all the leading gardeners and growers of the day; his garden was his main study, and he did right well that which was his special task.

Regarding his enthusiasm for Apple-culture, we remember Mr. McKenzie remarking to us four years ago, when he accompanied us through the beautiful grounds at Linton Park, that he could never lose that enthusiasm. His exact words were as follows: "When once a gardener has undertaken fruit-growing with zest, he can never give it up. The love of it will remain with him to the end. I have grown Chrysanthemums as a specialist, and have been enthusiastic in the showing of other plants; but Chrysanthemums lost their novelty. Fruit has not, nor will it."

Mr. McKenzie, who was once foreman in the gardens at the Viceregal Lodge, Dublin, leaves a widow and four children, all grown up, two sons and two daughters. The loss of two children some years ago was a terrible blow to the deceased, who was so greatly affected that he rarely visited a horticultural exhibition for three years afterwards.

MARY WOODMAN. — We note in the *Daily Telegraph* of January 7 an announcement of the death of Mary Woodman, on January 1, at Huratmonceux, Sussex, widow of the late William Robert Woodman, M.D., of Exeter, aged sixty-five. The lady's husband has often been mentioned in the *Gardeners' Chronicle* in connection with the nurseries of Lucombe & Pince of Exeter; and quite recently a correspondent, Mr. W. Napper, sent us a note concerning some furniture made from the Lucombe Oak in the possession of the doctor's widow.

TRADE NOTICE.

MR. G. P. BENT, late nurseryman at Flixton, near Manchester, ceased to carry on business some years ago, a fact that he made public at the time.

ANSWERS TO CORRESPONDENTS.

ACACIA MAIDENI: *M. B.* The following is the reference for which you ask:—F. V. Mueller, in Macleay Mem. Linn. Soc., New South Wales (1893), 222, t. 29, ex *Index Kewensis*, Supp. i., p. 2.

ADDRESS: *Enquirer.* We hope to print it in our next.

BOOKS: *M. S. H.* The only book on the subject that is worth studying is now out of print, and may only be met with at the old book shops.

CARNATION DISEASE: *W. P.* There are several diseases of these plants. Can you not send for inspection an affected plant?

CARNATION BLOOMS NOT BURSTING THEIR CALYCES IN 1901, BUT DOING SO THIS YEAR: *L. A. W.* The bursting may be due to excess of vigour, and the calyces not being strong enough to the pressure of the petals. Last year there may have been less vigour in the plants.

CHRYSANTHEMUM CHANGING THE COLOUR OF ITS FLOWERS: *E. W. E.* We have no knowledge of any such change in colour being induced by soils, as in the case of Hydrangeas. There are slight variations in tint induced by rich feeding and bud selection, but that is all.

CHRYSANTHEMUM LEAVES: *B. H.* The leaves are affected by the grub of leaf-miner, a two-winged fly. Hand-picking is the only remedy.

CORRECTIONS.—HORTICULTURAL BUILDINGS IN PARIS: We understand from our correspondent, M. Grignan, that the Galérie des Machines at the Champs de Mars has not yet been taken down, as we lately led our readers to understand, but that its demolition will probably be effected this year. Also, that the temperature in the conservatories at Cours la Reine during the last days of the autumnal exhibition was —4° C. (24·8 F.), and not 4° C. as priuted. In the "Orchid Houses" Calendar in our last issue, for Vall's Beetle-traps, read Vall's "Beetle-cute." Lælia × autumnalis cinnabarina, on p. 19, read Lælia × autumnalo-cinnabarina; and delete the words "after whose son it is named" in the third line.

CROTON DISEASED: *Croton.* No disease, perhaps the appearances are due to too deep potting, and to sudden alternations of temperature and moisture.

CYMBIDIUM LOWIANUM: *Enquirer.* That which you purpose doing should bring the plant back to health and vigour. The pot should be of good size, so as easily to accommodate the long, fleshy roots. Do not afford more water than will just keep the materials moist till growth of roots recommences. It should be placed in the Cattleya-house, or one similarly treated.

DISEASED MUSHROOMS: *J. A.* The disease unfortunately is not uncommon, but without remedy. The gills are distorted and swollen, and rotting soon follows. It is caused by a fungus parasite which some ascribe to Mycogone alba, but your specimens do not afford sufficient evidence to affirm what is the specific parasite that has caused the mischief. The beds must be destroyed, and the place thoroughly disinfected. It should not be used again for Mushrooms for two or three years, until it is entirely free from fungus spores. *M. C. C.*

HYACINTHS: *J. G.* The tips of the roots are dying or dead, from some cultural defect which you must know better than we can tell you; the soil is good.

NAMES OF FRUITS: *W. J. K.* 1, Lady Henniker; 2, Round Winter Nonsuch; 3, Sweet Lading; 4, Gooseberry Pippin; 5, too small for recognition.—*Cerus.* 1, Hollandbury; 2, Ashmead's Kernel.—*H. B. S. C.* Apple Pile Russett.—*Hortus.* 1, Léon Leclerc de Laval. The rest were either bruised or rotten, and beyond recognition; send a week or two earlier next season.

NAMES OF PLANTS: *Correspondents not answered in this issue are requested to be so good as to consult the following number.*—*W. P.* All three are varieties of Cypripedium × Leeanum, the largest one being equal in size to C. × L. giganteum. Many forms of this plant have already been named, and yours are not distinct enough to warrant distinctive names. —*Veritas.* Not a Lælia, but an imperfectly formed Cattleya Percivalliana.—*A. D. Weston.* Eriobotrya japonica (Loquat), an edible fruit.—*Paddy, from Cork.* Polypodium vulgare (common Polypody). Yours is a very good form of it. It is often sold in small quantities by florists.—*G. C.* 1, Euonymus japonicus medio-aureus; 2, Euonymus japonicus variegatus; 3, Euonymus japonicus; 4, Euonymus latifolius argenteus. The Rhododendron is one of the hybrida of Rhododendron arboreum. — *T. C.* 1, Rhœo discolor vittata, commonly called Tradescantia discolor vittata; 2, Niphobolus Lingua; 3, Carex japonica gracillima of gardens.—*G. W. S.* 1, Pinus, perhaps muricata; 2, Abies amabilis; 3, Picea sitchensis; 4, Cedrus, perhaps Deodar; 5, Abies amabilis; 6, Atriplex Halimus; 7, Baccharis halimifolia. It is almost impossible to name some of the Conifers without seeing the cones.—*J. W.* 1, Tillandsia Lindeni; 2, Billbergianutans; 3, Dracæna Sanderiana.—*W. D., Bedford.* 1, Cupressus Lawsoniana; 2, Juniperus excelsa; 3, Thuya gigantea; 4, Retinospora squarrosa; 5, Taxus baccata; 6, Cupressus Lawsoniana var.

PAYMENT OF WAGES DURING ILLNESS: *G. F.*, and *X. Y. Z.* Since our last issue was published, we are informed that the gardener being regarded at law as a "domestic," and as such a yearly servant, can demand that his wages be paid him for the time he is incapacitated by illness. See case, p. 44, in the present issue.

PROPAGATION OF SHRUBS AND TREES: *H. S. Winton.* The information you require is scattered through many different works, and cannot be obtained in one volume. As regards methods of propagation in the briefest possible terms, you would find *The Nursery Book*, by L. H. Bailey, Rural Publishing Company, New York, of use. It can be obtained through a foreign bookseller.

RATING NURSERY LAND: *Enquirer.* On p. 130 in our issue for August 12, 1899, is an account of the decision arrived at in the Court of Appeal, presided over by the Master of the Rolls, who upheld the distinction between "land" and "buildings;" and this judgment was agreed with later by the Lord Chancellor, together with Lords Watson, MacNaghton, and Morris, with the result that those portions of market gardens under glass are in future not to be rated as agricultural land, but are to be assessed on the same scale as land on which immovable buildings are constructed. Your cottage garden with its glasshouse is rightly assessed at the higher value, and the landlord who has paid the rate hitherto must also pay the higher rate.

ROMAN HYACINTH: *W. L.* There is no disease, but the top-growth has taken place before the roots were produced to support it.

SERVANTS' TAX: *H. C.* It is customary to have the gardener and his foremen, if any is employed, taxed; but not boys and garden workmen. Your employer or his estate-agent should appeal against the payment in such a case.

SOUVENIR DE LA MALMAISON CARNATIONS GROWN IN GARDEN FRAMES IN WINTER: *A. W.* There is no mystery about the cultivation of this practically hardy plant. Grow the plants under glass without codling; afford air by day and night abundantly when there is no actual frost. Apply water only when the soil has got into a really dry condition. Place the plants so that the foliage nearly touches the glass, keep it clean, also the glass, and do not syringe it. Vaporising or fumigation are the best means of destroying insects, and sponging about the worst. If artificial heat can be applied to mitigate the effects of the dampness, always a danger in the winter in a frame, it would be beneficial.

TOMATOS GOOD FOR FORCING OR OTHERWISE: *Oxonian.* Frogmore Selected, scarlet fruited, and Veitch's Golden Jubilee, both heavy croppers and handsome fruits.

VIOLET BARONESS ROTHSCHILD: *E. W. E.* We do not know. Apply to a large grower of Violets, or hardy flowers. We cannot recommend dealers.

VIOLET AMIRAL AVELLAN: *E. W. E.* Princess of Wales is the more popular variety, not the Amiral. Perhaps the blooms have the longer footstalks when grown under like treatment. As you know, the distance of the plants from the lights causes differences of this sort.

ZONAL PELARGONIUMS AND FUCHSIAS: *Oxonian.* Of the former choose double Henri Jacoby, Erl König, V. P. Raspail, Rosa Bonheur, and Colossus, all double flowered; or Aurore Borealis, Barbara Hope, Chaucer, Edward VII., Gen. Buller, single-flowered vars. Of the latter, choose alba coccinea, Beauty of Trowbridge, and Delight, single-flowered; and Avalanche and Kinaburyana, double-flowered.

COMMUNICATIONS RECEIVED.—J. Roberts—C. A. B.—R. Cairns.—J. R. J.—G. M.—W. R.—E. R. R., we shall be pleased to give what assistance we can.—F. W. B.—W. M. W.—S. R. G.—W. R.—W. H. D.—J. H. V.—W. J. GARDENING UNDER GLASS.*

THREE years ago I read a paper on "Gardening under Glass," in which I dealt with the construction of plant-houses, and temperatures, shading, ventilation, water, and soils, in their relation to indoor gardening. This paper was afterwards published in the *Gardeners' Chronicle* in January, 1900. In the present paper I propose to deal with the subjects of water, light, air, and heat, in so far as they affect the growth and health of plants, particularly those grown under glass. The cultivator who has some knowledge of how a plant grows, and how its growth and health are influenced by these factors, has an advantage over the cultivator who knows nothing of them.

WATER.

"It is a fact that the older a gardener grows, the more care he takes in the watering of his plants; for year by year his experience teaches him more definitely that careless watering is the indirect, if not the direct, cause of a very large number of the diseases of plants. The difficulty in watering lies in the fact that plants require various amounts of water, according to their species, their age, their situation, the season of the year, and their actual state of health or development. The amount of water which is sufficient at any given time may be very much too large a month later, and may therefore cause considerable injury." *Sorauer.*

Water forms not only the bulk of the plant itself, it is also the medium by which all the food-salts from the soil, and essential to growth, are supplied to it. These salts are made available by the action of water, as they can only be absorbed by the roots in the form of aqueous solutions. In addition to the water retained by the plant for purposes of growth, large quantities also pass through it and evaporate through the leaves, in much the same manner as most of the water supplied to the soil in watering a plant after passing through the soil escapes through the hole at the bottom of the pot. Kerner describes this process of transpiration as a perpetual stream running through the living plant whilst growth is active, and points out that the supply of water must be regulated with exactitude if the nutrition is not to be disturbed or development hindered.

A healthy plant requires a larger supply of water at the root when growth is vigorous, than it does when growth is nearly or quite at a standstill. We do not always, however, in practice make that difference in the quantity supplied which this knowledge should lead us to make. On the contrary, many gardeners appear to believe that the soil about the roots of all plants in leaf should always be wet. The injury that results from this is due largely to the fact that soil requires aëration if plants are to be healthy in it, roots requiring to be supplied with fresh air just as much as the upper portion of the plants do; for all the living parts of a plant breathe, obtaining oxygen from the air as animals do, and when they cannot obtain it they are suffocated and die. Now, if the soil is always saturated with water, air cannot get to the roots; moreover, acids, and other injurious compounds, are formed in the soil, and these act as poison to the roots. It is the craving for fresh air that causes the roots of a plant to cling to the inside surface of a pot, and to creep down amongst the drainage, where the supply of air is greater, as a rule, than in the soil itself.

The injurious, and often fatal, results of excessive watering are not always recognised, and are too often set down to some other cause.

More harm is done to plants by overwatering than by the other extreme; this is especially the case in winter, when the conditions are unfavourable to growth. The sickness and death so prevalent among plants in that season are largely, if not entirely due to excessive watering.

A comparison of the usual condition of the soil in which plants make healthy growth in the open air with that of pot-grown plants under glass will show that, although the supply of water in the former case is not excessive, yet growth is healthier and better in every way than that made under glass. A Rhododendron or a bedding Pelargonium growing in the open border is rarely, if ever, saturated at the roots, the water passing away too freely for this to happen, even in wet weather; and yet they grow and flower better than when grown in pots and regularly watered. The careful cultivator weighs all the conditions that affect growth: when the light is defective and the temperature low, growth is sluggish or quiescent, and the water required by the plant is then little or none.

The nature of the plant itself must not be overlooked. Some plants, particularly those that have fleshy roots and large leaves, will do with a liberal allowance of water at all times. Succulent plants, the leaf structure of which is such as to prevent loss of water from transpiration, may be kept dry at the root for long periods without suffering, although when they are growing vigorously under the influence of bright sunshine they enjoy copious supplies of water. Generally, plants with small leaves and fine hair-like roots, require careful watering at all times.

"All perennial plants have a period of rest. It is either the cold which stops all vital processes, or, as in tropical regions, the excessive drought of the hot season. During this latent period plants require very little nourishment, and even those greenhouse plants which retain their green leaves require an infinitesimal amount of water and of nutritive salts." Good cultivators of Orchids recognise the need of this period of rest, for all Orchids, after new growth has been made, the duration and nature of the rest being varied according to the nature of the plant. Thus, a Dendrobium which, whilst growing, revels in water, requires a long, dry rest after growth has been made; whereas an Odontoglossum is sufficiently rested if the supply of water is withheld from the roots for a month or six weeks. Many plants appear to grow and flower without this rest; but only for similar reasons to those which account for some men living under conditions which are opposed to the laws of health.

The transpiration or perspiration of plants may now be considered. The breathing pores or "stomata," which are generally situated on the under-surface of the leaves, under favourable conditions give off water in the form of vapour, in quantities varying with the moisture of the surrounding atmosphere; in other words, plants perspire freely in a warm, dry atmosphere, and less freely in one that is moist, in much the same way as animals do. Anything that interferes with this function is as bad for plants as it is for animals. There are in the leaves of plants numerous ingenious contrivances for regulating transpiration, the pores opening wide when the conditions favour the free escape of moisture, and closing when they are unfavourable. The flagging of leaves caused by drought has the effect of closing the stomata, so as to stop the further loss of water. The rush or "perpetual stream" of water from the roots to the leaves, other conditions being favourable, is the accompaniment of active, rapid growth. We should therefore endeavour to maintain just that condition of soil and atmosphere which will keep this stream moving.

What happens when we keep the soil as wet, the air as moist, and the temperature as high in winter, when light is defective, as we do in the height of summer, when light is good? We find that the growth made is often of a sickly yellowish hue, and wanting in what we call "bone," indicating that some essential has been wanting whilst growth was forming. Growth made in insufficient light cannot be healthy. There are

* Paper read before the Kew Mutual Improvement Society, January 5, 1903, by Mr. W. Watson, Curator.

of course, many plants, such as those used for forcing in winter, which appear to make perfect growth in these ill-balanced conditions, but we know that they require much nursing afterwards to restore them to a healthy state; indeed, a plant that has been severely forced is, as a rule, only fit for the rubbish-heap afterwards.

There is a marked difference between the growth and behaviour in winter of the plants in the drier houses and those in the moist houses at Kew. If a plant has proved refractory in a stove, we have sometimes found it worth while to try it in No. 5, wherein the succulent plants are grown, and generally the results have been satisfactory. The air in this house is always drier than in any other,

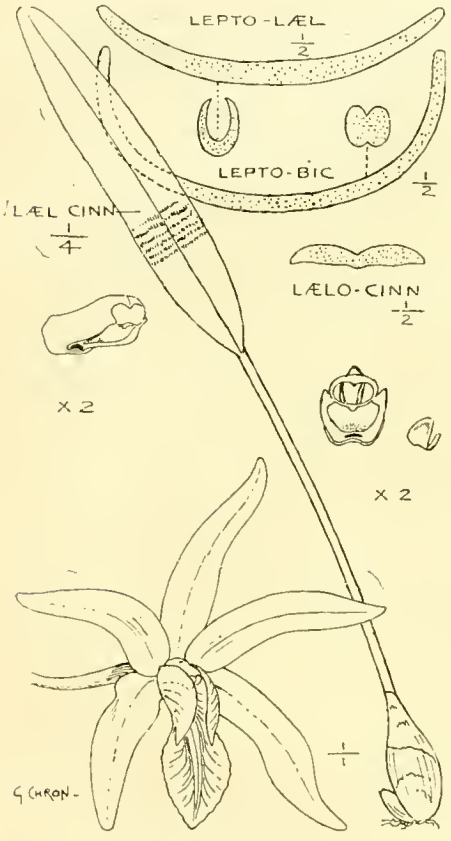

FIG. 23.—LEPTOLÆLIA ×.

Above placed across the figure are reduced illustrations of the leaves of Leptolælia ×, and of Leptotes bicolor with cross-sections. The larger leaf stretching from the top to the bottom of the illustration is that of Lælia cinnabarina, one-fourth of the real size; to the right of it is a cross-section; and lower down the column of the hybrid, seen from the front with a separate pollen-mass (magn. 2 diam.). To the left of the reader is the column seen from the side, and at the bottom the complete flower of the hybrid of the real size.

especially in winter, when very little water is given to the plants.

The success of our grandfathers in the cultivation of plants which we can scarcely keep alive, such as hard-wooded Cape Ericas, Phœnocoma, Aphelexis, Genetyllis, &c., was, I believe, largely due to the care they took over the watering. This was considered by far the most important of the gardeners' duties; and it was by no means unusual for the head gardener to attend to it himself—for all his best specimens, at any rate. I have seen fine specimens of Erica killed in a week by an overdose of water at the root. *W. Watson.*

(To be continued.)

ORCHID NOTES AND GLEANINGS.

LEPTOLÆLIA ×: A BIGENERIC HYBRID.

A HYBRID between two reputed genera of Orchids is likely to be of interest to orchidists, whatever view they take of the facts. The hybrid in the present case was raised in the establishment of Messrs. James Veitch & Sons, and was exhibited by them last spring before the Royal Horticultural Society. It was raised out of Leptotes bicolor by Lælia cinnabarina.

Leptotes was considered by Bentham as not generically different from Tetramicra, a circumstance which does not affect the assumed bigeneric character of the plant, though it may raise a question as to what should be the correct designation of the plant. For the present we adopt the name Leptolælia × Veitchi, under which name flowers and leaves were sent to us for examination. We may briefly refer to the leading characteristics of the two parents, and of the resultant hybrid.

Lælia cinnabarina has an oblong or ovoid pseudo-bulb, from whose apex springs a solitary leaf, with a stalk about 19 cent. long (7½ ins.), bearing an oblong blade about 23 cent. long (9 ins.), 4 cent. wide (1½ in.), flattish, except along the centre, where it is deeply depressed on the upper surface, and marked on the same surface with transverse wavy wrinkles.

The flowers of Lælia cinnabarina are of a reddish-orange colour, the sepals and petals lanceolate, the lip convolute and crisped.

Leptotes (or Tetramicra) bicolor, the female parent of our hybrid, has a rudimentary pseudo-bulb, and its leaves are spreading, often overhanging the sides of the pot in which it is growing, 14 to 15 cent. (5½ inches) long, 4 to 5 mill. wide, cylindric, strongly curved, deeply channelled above and below, as shown in fig. 23, marked "Lepto-bic;" and also in fig. 24, seen in section, and magnified 15 diameters.

The flowers are white, sepals and petals narrow, lip three-lobed, lateral lobes short, front lobe oblong, nearly as long as the petals, white, streaked with purple.

In the hybrid plant the leaves are erect, curved, about 11 cent. (4½ inches) long, neither flat nor cylindric, but deeply folded or "conduplicate," as shown in the enlarged section at B, fig. 24.

The flowers (see fig. 23) are about 4 cent. (1½ inch) long, with spreading, lanceolate, cream-coloured segment, flushed with pink; the petals of the same shape, but rather narrower than the sepals. The projecting lip is about the same length (25 mill.) as the outer segments, three-lobed; the lateral lobes about 1 cent. long, somewhat roundish, oblong, convolute over the column; anterior lobe 15 mill. long, oblong, lanceolate, flattish, undulate at the margins, yellowish near the base, elsewhere palo rosy-pink. The anther-cap was cushion-shaped, with a terminal lilac tip, and two small projections, one on each side. The pollen masses were imperfect in the flower examined, arranged in two pairs with a fifth smaller and imperfectly developed, waxy, obliquely oblong, ovoid compressed.

This description, of necessity imperfect, may nevertheless be of interest, as showing how curiously intermediate the hybrid was between its parents. *M. T. M.*

THE WEATHER FORECASTS.

IT is one of the venerable beliefs of mankind that the weather is in some way controlled by stellar or lunar influences. Three centuries B.C. Aratus looked to the constellations for signs of coming changes in the weather; and to-day, in the twentieth century A.D., it is still a common belief that the moon is in some way responsible for the weather we enjoy, or which we have to endure.

Mr. Hugh Clements, whose name has for some years past been more or less familiar to readers of the daily papers as the author of certain weather forecasts, is a lunarist who professes to have found a complete explanation of all terrestrial weather changes; and in the volume entitled *Natural Law in Terrestrial Phenomena*, an attempt has been made to explain his methods and the results at which he has arrived. It is, however, rather curious that this explanation does not emanate at first-hand from Mr. Clements himself, but from Mr. William Digby, C.I.E., a disciple who appears to have quite recently studied Mr. Clements' work, but to have become so much impressed with it that he has now stepped forward as Mr. Clements' champion.

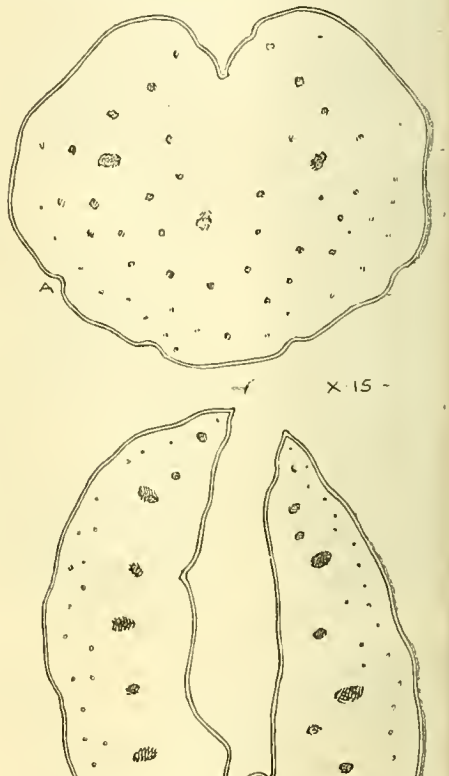

FIG. 24.—CROSS SECTIONS OF LEAVES.
(*Magnified.*)
A, Leptotes bicolor. B, the Hybrid.
(See Text.)

Mr. Clements finds in "the tangential pull of the moon" the cause of every variety of atmospheric phenomenon; and we are told that "certain combinations of the sun and moon produce in the atmosphere of the earth certain results. Given those combinations, and they are ever being repeated in harmonious sequence, the results are always identical" (p. 267). Mr. Clements himself says (p. 281) "every 186 years the apsidal, nodal, and tidal positions of the moon are similar; the result being that at intervals of 186 years there is very considerable agreement in the character of the weather, e.g., the years 1692 and 1693 were the exact meteorological counterparts of 1878 and 1879." When such a statement as this is made, one has a right to expect that it has been in some way verified. It is, therefore, disconcerting to find on the next

page an admission of the fact that, "we have no detailed daily information of the weather 186 years ago," with which to make a comparison.

But, indeed, dogmatism of this kind is a characteristic of too many of the statements contained in the book. Weather is not the only thing capable of prediction by means of Mr. Clements' "discovery." Earthquakes and volcanic eruptions are, we are assured, capable of as certain prediction as rainfall and the height of the barometer.

We cannot think that the present effort of Mr. Digby and Mr. Clements attains its avowed object as an explanation and justification of Mr. Clements' "discoveries." The claim made that they "solve existing problems in relation to the weather," and that they have been "fully demonstrated on the lines of strictly scientific research," is, in our opinion, hardly justified. The truth of a statement does not depend upon the emphasis with which it is asserted, but so far as the data given in the volume enables us to judge, there is no other justification as yet for the statement made on p. 334, that "The truth of the matter is, I can predict the weather for any number of days, weeks, months, or years ahead, upon a scientific system from which the element of chance is eliminated."

Unfortunately for th statement, under the heading of "Samples of Weather Predictions and Verifications," Mr. Clements gives us an opportunity of testing the accuracy of some of his forecasts. For instance, on p. 330, we find his predictions for every day in February, 1895, placed side by side with a description of the actual weather recorded on each of those days at Greenwich Observatory. Now, if a comparison be instituted, it will be found that some rain fell on fourteen days during that month at Greenwich, bnt for only five of those days was any rain predicted by Mr. Clements. Then, again, on five other days when rain was predicted in the same month by Mr. Clements, there is no record of any rain having fallen at Greenwich. After this, it can scarcely be contended that the element of chance has been altogether eliminated from Mr. Clements' forecasts.

Messrs. Clements & Digby, like all previous upholders of lunar influences on the weather, having failed to make good their claims, we are reluctantly compelled to revert to the opinion held by all leading meteorologists, and that is, that in the present state of our knowledge, it is impossible with any degree of certainty to forecast coming weather in these islands for more than about twenty-four hours in advance. For that reason alone, such "long distance" forecasts as those issued by Mr. Clements must always be received with considerable hesitation. *Edw. Mawley.*

GARDENERS' ROYAL BENEVOLENT INSTITUTION.

SOME years ago you kindly gave me a portion of your valuable space to give my ideas to my fellow gardeners on the good work done by the above-named Institution; while acknowledging to the full the excellent letters on the same subject by other writers up to quite recently, I am writing to ask you to give me a small amount of space once again. Like other supporters of the Gardeners' Royal Benevolent Institution, I have recently received my voting-paper for the recent election. As on previous occasions, it shows a great amount of needy cases. There were forty-six of them all examined by the committee, yet only fifteen vacancies. What a number of them must be disappointed! My main object in writing is to bring to the notice of the rising generation of gardeners the hopelessness of non-subscribers being put on the pension-list in the future. The practical application of the new rules, which for my purpose is summed up in Rule 3, Section 5, will bear out my statement. I would urge all gardeners who may be disposed to put off the good day of becoming subscribers to send for a copy of rules, and read it carefully over. Under that rule all have to be elected, whether subscribers or not. The main advantage the former get is that for every guinea sent to the Institution they will receive a hundred votes if at any future time they are candidates for the Pension Fund. This is only simple justice to the subscribers, and I for one congratulate the committee on putting it on the statute-book. To illustrate my statement, we will suppose one man, say at forty, pays a guinea each year up to sixty-five, and another at forty-five pays ten guineas as a life subscriber, that both are anxious at sixty-five to become pensioners, the former would have 2,500 votes to start with, and the latter 1,000. Of course, being a Benevolent Institution, there is the odd chance of the late or non-subscribing candidate being elected, but the risk is a great one. Once again I would appeal to gardeners as a body to make up their minds in time and become subscribers, and also to the wives of the married ones to spur their husbands on and help them in doing it. I feel sure they will never regret the matter if carried out. If it will help them in doing this, I do not mind saying that when I paid my first guinea in 1880 I had not another guinea in the world, and had seven motherless little children in my house. It was the late Mr. Wildsmith, of Heckfield, who urged me to do this, and if for no other reason, I respect his memory for it. On referring to the last published list of subscribers, I find much fewer than a thousand of them are gardeners, and yet the *Horticultural Directory* contains fully ten times that number! Why not be as anxious to have one's name in the former as well as the latter? *Yorkshire Gardener, Jan.* 12, 1903.

ODONTOGLOSSUM × WALTONIENSE.

OUR illustration (fig. 25) represents this fine yellow hybrid between Odontoglossum crispum ♀ and O. polyxanthum ♂, raised by Mr. W. Stevens, gr. to W. Thompson, Esq. It received a First-class Certificate at the Royal Horticultural Society's meeting on January 13, and was duly noted in our report of the show (January 17, p. 46). Considering the very marked character of the brown blotching on O. polyxanthum, it is singular that so little evidence of it is seen in the hybrid, which is practically a bright yellow O. crispum with a large reddish-brown lip. It is one of the finest of home-raised hybrid Odontoglossums.

FIG. 25.—ODONTOGLOSSUM × WALTONIENSE.

BOOK NOTICE.

THE FORESTS OF UPPER INDIA AND THEIR INHABITANTS. By Thomas W. Webber, late Dg. Conservator of Forests in India. (London: Edward Arnold, 1902.)

MR. WEBBER, the author of this very interesting book, is already known as the writer of an excellent account of the "Natural Oak Forests of Sussex," in a volume of *Reports on Forest Management*, published by the Government of India in 1873.

The present volume gives a vivid account of the author's life in the forests of India, with his travels in the Himalayas and Thibet, and although much is said about forests, there is probably more about travels and sport, for as he says: "I have always found a good rifle and a kukri (Gurkha hunting-knife) the most useful weapons; whilst to be able to ride on an elephant all day without feeling the sun, and to camp-out in all seasons of intense heat on the plains, and of intense cold on the highest hills in the world without taking fever, and to be always ready for a long march on foot, horse, or elephan t

and for a good venison steak at the end of it, were the most approved capabilities of a forest officer." Mr. Webber had the good luck to be in the Indian Forest Department from 1861 to 1871, when its chief work was the selection of reserved forests, and long and indefatigable marching was indispensable, while his lot was chiefly cast in the North-West Provinces of India, with probably the finest climate in the world from November till April, while he could spend the scorching months of May and June in the cool hills.

The account he gives of the habits of the wild forest creatures is most picturesque, and shows the instincts of the true naturalist, as well as of the keen sportsman. The elephants, buffaloes, tigers, bears, monkeys, wild hunting dogs, deer and antelopes, and the great Himalayan sheep, are all described in their respective haunts; while peafowl, pheasants, partridge, quail, and the Indian bustards, are all depicted. The following extract shows the wealth of bird-life in India:—

"The trees are swarming with beautiful bright birds, and green pigeons cooed softly in them. The pretty little turtle-doves picked on the path at grain, and fluttered in the bushes; and light-running hoopoes raised their fan-like crests, chasing the insects. Everywhere flying is the lovely little metallic sun-bird, which dances as it flies, wings expanded as a butterfly, and then sails kite-like with angular tail spiked with two long feathers. There are twenty species of Indian sun-birds, so profuse is the supply with which Nature decorates the landscape. Some are purple, and some yellow, and they shine in every sun-ray. Their little nests, like pears, hang by a cord from the ends of boughs near the ground, and are beautifully woven. High up in the dark recesses of the Banyan-tree, one hears all day the 'coppersmith' striking his anvil with metallic twang, the crimson-crested green barbet with thick strong bill. There are sixteen species, large and small, and they are very industrious."

The hill and plains-people are sympathetically dealt with, and the account of the Hunias is most amusing. These people live in Hundesh, beyond the Tinkar Pass, and are subject to Thibet. The following description is given of their country:—

"To the south, the best roads are but dangerous tracts, where the most surefooted might slip and fall into depths unseen. To the north is an endless stretch of smooth surface, where a coach and four might be driven without fear of an upset. To the south is a climate where the rainfall for half the year is 200 to 300 inches, and the snow-line 16,000 feet above the sea. To the north an almost rainless climate, with a snow-line at an elevation of 19,000 to 20,000 feet. Towards India, dense forest; to the north, not a tree in a thousand miles, or perhaps ten thousand; not a bush to be seen, scarcely a blade of grass—nothing but stones, gravel, shingle, or clay. To the south, a region of rains and torrents, perpetually roaring and cutting up the soil into an endless network of deep ravines and water-courses. To the north, vast and arid plains where, except for scantily melting snow, no water was to be found."

Here the difficulty was to cook food, as water boils at 180° instead of at 212°; but the Hunia cavalry, who were met on their little rugged ponies by the Thibetan Government to stop Mr. Webber's party, form a most ridiculous picture when we compare them with their ancestors, the formidable Huns described by Gibbon, with whom Attila overran Europe. The kiang or wild ass inhabits these plains, and is well described; while the geological changes that have taken place are well shown by the fact that huge ammonites 4 feet across are found in the rock-formations of Thibet at about 18,000 feet elevation. Mr. Webber speaks very highly of the Bhutias, and says that their children are nearly as well taught as European children.

The Sal forests of India are well described, but the author is wrong in stating that this valuable forest tree grows in Mysore and Tenasserim. In Jhansi, south of the Ganges, the teak is first met with, as this tree cannot withstand the frosts of N. India; and here the African Baobab also grows 50 feet in girth, and 40 feet high. The destructive practice of jhúming (termed dáhya in Central India), is also described, and its pernicious effect on forest-growth shown, as well as the excellent results in the regeneration of the forests that are due to fire-conservancy. Wolves appear to abound in Central India, and kill many children.

Teak grows rapidly in the Satpura Hills, saplings being said to reach 25 and 30 feet in the second season—straight stalks, with half a dozen leaves at the top. A good description is given of the fine teak plantation made in 1844-57 by Mr. Conolly, and 3500 acres in extent. The trees, 1000 to the acre, were to be thinned out to 70 to the acre, of 225 cubic feet each, at 60 years old.

The account of the Máhua tree (Bassia latifolia) states that in Monghyr there were in 1878 over a million of these trees, each producing annually 2 or 3 cwt. of corollas, which fall to the ground in March and April. The natives collect and dry them as an article of food, which saves thousands from death in famine years, as it is a crop which never fails, however dry the season. From the sweet stuff, which keeps dried any length of time, like raisins, the natives distil Máhua spirit, which can be easily freed from essential oils, and makes an excellent spirit, resembling whiskey; while Máhua oil is three times as valuable as linseed oil, being as good as Cocoa-nut oil for candles. In Monghyr these trees yield 100,000 tons of nourishing food annually, and the Sonthals in consequence suffer no famine, and are a plump and happy race.

The book terminates with an Appendix on the scientific treatment of forests. Mr. Webber states that recent land legislation in Ireland and succession duties place a premium on the destruction of home woodlands, and that if one-tenth of our waste lands were planted, their proceeds would pay the interest on the National Debt, £25,000,000 a year, as their capital value would be £200,000,000, compared with the actual value £900,000,000 of the German forests. To the objection that home timber is of inferior quality, he replies that Scotch Pine found in Irish bogs contains timber of great length and thickness, sound, fine-grained, solid, and straight, and so excellent that it is used by coach-builders as superior to Memel timber, or the finest mahogany. Where such timber grew, 10,000 years or more ago, similar material might be produced to-day if the woods were properly managed. To prove this he gives the actual dimensions of Scotch Firs grown in Ireland:—

Grown 30 to the Acre, with Spreading Crowns.		Grown 200 to the Acre, with Small Crowns.
Girth	5 feet	5 feet
Height	50 feet	75 feet
Age	40 years	Age 100 years
Diameter ...	20 ins.	Diameter 20 inches
Rings, per inch, 4, uneven		10, regular
Heartwood ...	12 ins.	19 inches
Sapwood... ...	8 ins.	1 inch
These trees are quickly grown on deep, soft soil, liable to be blown over; timber coarse, knotty, light and perishable; fully 4 inches of sapwood.		These trees were slowly grown on a hillside on poor and stony soil; standing close they resist storms. The timber is fine-grained, hard, heavy, durable, and equal to best Memel; scarcely any sapwood.

There are several good maps to illustrate the author's travels, although there is a want of scientific accuracy in some of the statements made, and the author's Indian experiences are about thirty years old. The general tenour of the book is very good, and it gives a most graphic account of a very interesting subject, and should be in the library of every lover of Indian forests. *W. R. Fisher.*

THE RAINFALL AT ROTHAMSTED IN 1902.

According to the records from the rain-gauge at the Rothamsted Experimental Station, Hertfordshire, which was constructed fifty years ago, and is one-thousandth part of an acre in dimensions, stands 2 feet above the surface of the ground, and is about 420 feet above sea-level, we find that the rainfall for the year 1902, recently ended, amounted to nearly 21 inches, which is $7\frac{6}{10}$ inches below the average record for this district, extending over a period of forty years.

The following table shows the rainfall of each month for the past year at Rothamsted, with the average amount of rainfall for each month of the previous forty years, and the difference of 1902 above or below the average:—

Rainfall at Rothamsted, Herts, for each month of the year 1902, and the average and total yearly rainfall.

Months.	Rainfall, 1902.	Average rainfall of forty years.	1902. Above or Below the Average.*
	Inches.	Inches.	Inches.
January	0·83	2·47	−1·64
February	1·25	1·74	−0·49
March...	1·49	1·73	−0·24
April	0·83	1·97	−1·14
May	2·20	2·34	−0·14
June	3·33	2·42	+0·91
July	1·24	2·72	−1·48
August	3·54	2·60	+0·94
September	1·05	2·60	−1·55
October	1·88	3·20	−1·32
November	1·95	2·65	−0·70
December	1·39	2·21	−0·82
Yearly total ...	20·98	28·65	−7·67

* The sign (−) signifies below the average, and the sign (+) above the average.

The above figures show that the yearly total of rain, frost, and melted snow, of which there was about an aggregate depth of 2 inches from ten small falls, for the past year is 20·98 inches, against an average of 28·65 inches for the previous forty years, showing a deficiency in the twelve months of 7·67 inches. There were but two months in the year, namely, June and August, when the rainfall exceeded the average record, consequently there were ten months of deficiency. This is the smallest yearly rainfall since 1898, when 20½ inches only were measured. Notwithstanding this small amount of rain, there were but 63 days out of the total 365 for the year when the gauge was quite empty. The number of recognised rainy days, when the gauge recorded 0·01 of rain or more, was 168. The maximum fall in twenty-four hours occurred in June, and gave 0·72 inch.

In the previous year of 1901, the deficiency of rain at Rothamsted was 5·48 inches; this amount, added to the deficiency of 1902, makes a shortage of 13·15 inches of water in the two years. In order to understand what this deficiency of 13 inches of rain means to our natural springs of water, and to vegetation, it may be explained that this amount represents a total of 1,328 tons of water, equal to the enormous quantity of 298,817 gallons of water on each acre of land; accordingly the well-springs and other supplies of water in this district show a falling off which is thus easily to be accounted for.

During the past year the more shallow-rooting plants did not appear to suffer much for the lack of moisture, the constant small deposits of rain, with the comparative absence of hot summer sun, kept them going; but very deep-rooting plants, such as fruit trees, suffered considerably. There was an abundance of fruit blossom formed, but the greater portion of this fell to the ground; and on Apple-trees, even after the fruit was set,

much of it dropped prematurely, and a large proportion of that which remained developed but indifferent fruit.

The heavy rains of June assisted the grass-crops, also the corn, so that nearly average returns were obtained. The constant rains of August, however, considerably damaged the crops of Wheat after they were cut, and there was much sprouted grain to be seen in the shocks as they stood in the fields. This is now deteriorating the quality of the output of grain from the threshing-machines. *J. J. Willis, Harpenden.*

CULTURAL MEMORANDA.

HIPPEASTRUMS FROM SEEDS.

HIPPEASTRUMS having been brought to such a state of perfection, it is no wonder that we often see them in comparatively small collections. But alas! how often we see them grown in a very unsatisfactory condition, sometimes mere bulbs just existing in pots either altogether too large or too small, often with half the soil washed out by a very careless use of the watering-can; and yet these lovely greenhouse bulbs are very easily managed, provided ordinary careful treatment be accorded them.

During the flowering period, when the plants are giving a wealth of colour, is the time to mark the best forms for seed production. In selecting the different forms individual taste will, of course, play an important part; some growers prefer self-coloured forms, others have a fancy for the striped ones. There is, however, one hard-and-fast rule that can be laid down, viz., that only the strongest plants should be selected for the production of seed. If this rule is rigidly adhered to, the result will be large and well filled pods of seeds, from which consequently strong seedlings may be expected.

It is good practice not to allow more than two pods on each plant to ripen seeds, as more than this number are detrimental to both seeds and parent bulb. Should any particular flower be fertilised by its own or other pollen, it is safer to enclose the whole flower or flowers in a piece of muslin, to prevent bees or other insects carrying foreign pollen to the stigma. After fertilisation has taken place the pods soon begin to swell, and do so rapidly until they burst and expose their black seeds; these are ready for sowing at once, and the sooner they are sown the better, as they germinate more quickly than if allowed to lie by for a time.

The seeds may be sown in the ordinary seed-pan, which suits them admirably. The pans should be thoroughly clean and well crocked, with a layer of coarse leaf-soil placed over the crocks. A light sandy soil should be prepared and made quite level, not forgetting to press the whole moderately firm, especially in the corners if the pan be a square one. When all is ready, place the seeds evenly over the surface about 1 inch apart, and cover lightly with soil; give a good watering with a fine rose-can, and place the pan in a temperature of from 65° to 70° F., in a close and shaded part of the house. The seedlings appear in about one month, and should be kept moderately moist. Having made good growth in the course of the year, they should be taken carefully out of the pan, and transplanted 4 inches apart into beds of rich and coarser soil than that used for the seeds. By planting them out into a prepared bed of soil much time and labour are saved, and also a larger percentage of the plants. The potting-up from the seed-pan cannot be recommended, as this method entails too much labour, and is not nearly so satisfactory. By the planting-out system I have had seedlings in flower in less than two years. When in the bed, the syringe should be freely used morning and afternoon to keep down red-spider and thrips, and to promote a moist, growing atmosphere.

After having been planted in the bed for two seasons, the bulbs should be carefully lifted, taking great care that all roots are left intact; they should be sorted into two sizes, the larger to be placed in pots, and the smaller ones to be replanted in the bed to be ready for pots the following season.

The larger bulbs may be placed in 5-inch or 6-inch pots, which should be thoroughly clean and well drained. A good compost consists of equal parts of good turfy loam, leaf-soil, and coarse sand, with a sprinkling of Clay's Fertiliser. A good plan to adopt when the bulbs are freshly potted is to plunge them to the rim in Cocoanut-fibre or spent tan. Little water is needed until growth has commenced, and at no time does the Hippeastrum like a large quantity of water. I have for a long time been convinced that there are more Hippeastrums killed or crippled by a too copious supply of water at the roots than by any other means.

There seems also to be an idea among some that the Hippeastrum cannot be grown satisfactorily without a great deal of heat. As a matter of fact, they may be grown without any artificial heat whatever during the year. Forms of H. vittata will even stand a few degrees of frost, providing they are dry at the roots, and dormant. I have had this form frozen in pots, and have brought them round safely by syringing them with ice-cold water, and placing them in a dark frame for three days, where the thermometer registered 34° F. I marked these bulbs, and placed them amongst the others in the house; when they flowered, they were apparently none the worse for their being subjected to frost, the size of flower and the colour being as good as in those treated in the ordinary way. *J. W. Miles, Isleworth.*

CYPRIPEDIUM × HINDEANUM (GODEFROYÆ × INSIGNE HAREFIELD HALL VARIETY).

A FIRST-CLASS Certificate was obtained by Messrs. Sander & Sons, of St. Albans, for this noble cross, at the Royal Horticultural Society's meeting on January 13. It supports the fact which we have often urged, that where fine forms even of common species are used in crossing, remarkable results are to be obtained. The plant is of dwarf, compact habit, and the flower of fine form and substance; indication of the rich marking of C. insigne Harefield Hall var. being plainly distinguishable. The upper sepal is cream-white, with pure white margin and dark purple spots; lower sepals whitish with purple spots. The remainder of the flower honey-yellow, tinged and marked with purple.

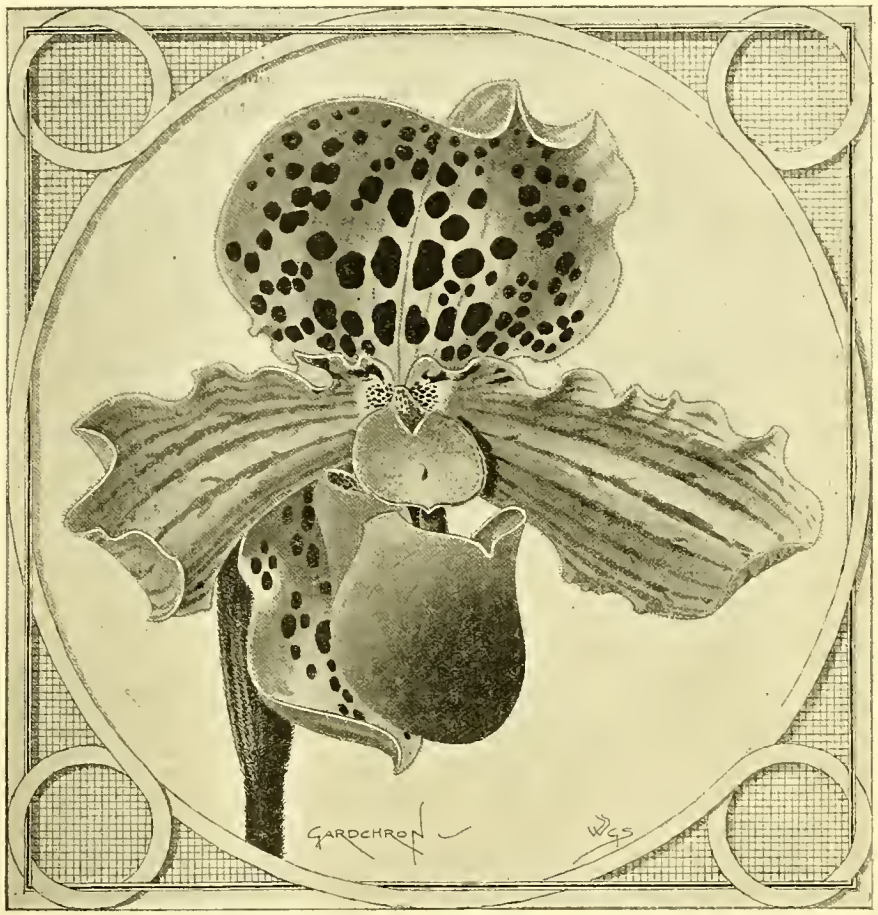

FIG. 26.—CYPRIPEDIUM × HINDEANUM.

"WEBSTER'S FORESTER'S POCKET DIARY," published by W. RIDER & SON, 164, Aldersgate Street, is a convenient and useful little publication, the value of which is in inverse ratio to its size. In addition to the ordinary contents of a diary, there are numerous articles and tables of special interest to foresters.

The Week's Work.

THE ORCHID HOUSES.

By H. ALEXANDER, Orchid Cultivator to Capt. G. L. HOLFORD, Westonbirt, Tetbury.

Dendrobiums. — The deciduous species and hybrids of these plants having been afforded a long rest in a cool, airy house, are now pushing forth flower-buds. The most forward of these, that have their buds separated from each other, should now be moved into the intermediate-house, and afforded a little more water at the roots, to enable them to expand satisfactorily. The earliest to flower are D. Cybele, D. melanodiscus, D. xanthocentrum, D. Schneiderianum, D. Clytie, D. Aspasia, D. Aurora, D. Clio, D. Wiganianum, D. Ophir, D. Findlayanum, D. crassinode, D. Wardianum, and the numerous varieties which flower in late winter and early spring. New growths will soon arise from the base when given warmer quarters, and water will still require to be applied carefully, as any excess may cause the loss of many young growths. The flower-buds on plants which flowered freely last year, and failed to make strong growth, should be removed, which will have the effect of strengthening the growth this year. Dendrobium Wardianum is a species which is imported in quantity, and the plants grow satisfactorily for a few years, but they soon get exhausted from excessive flowering. Newly imported plants received at this season should be thoroughly cleaned and suspended in a cool-house for a few weeks, and then potted and placed in a light plant stove or similar house.

The Odontoglossum-house.—Many plants in this house will now be showing flower-spikes, and keen watchfulness will be needed to capture slugs and snails. Lettuce-leaves, sliced Carrots and Potatos, may be used as bait, and a small quantity of bran in small saucers, placed about in the house. These baits should be inspected the last thing at night, and a search made for the pests amongst the plants by lamp-light. Cotton-wool placed around the base of the flower-spikes will sometimes prevent slugs from injuring the spikes. Very valuable plants should be placed on inverted flower-pots standing in saucers containing water. Even the small shell-snails do much damage to the tender roots, and should be sought for in the potting material. A genial even temperature must be kept in this house at this season, never allowing the thermometer to fall below 50°, excepting in very severe weather, for the plants being in full growth must be supplied with a fair amount of moisture at the root and in the air. A low temperature, where the atmosphere is charged with moisture, often causes the tips of the leaves to decay, which when trimmed off give the plants a shabby appearance.

PLANTS UNDER GLASS.

By J. MAYNE, Gardener to the Hon. MARK ROLLE Bicton, Budleigh Salterton, Devonshire.

Gardenias.—Afford water very carefully to the earliest plants that have their flower-buds well advanced, or deformed flowers will result. Clear soot-water, if well diluted, is a good manure for these, but do not apply water unless really necessary. The atmospheric temperature should be 65° to 70°, and the plants may be sprayed lightly overhead twice daily. Gardenias will withstand a greater cold when kept fairly dry at the roots than is generally known, and if the temperature falls to 50° on very cold nights during the resting period, no harm will accrue to the plants, but when introducing them afterwards into heat and moisture it should be done gradually. If the plants must be taken into the dwelling-house when in flower, they should be grown without bottom-heat. Young plants produce the largest flowers, and when grown in 6-inch pots they are useful for decoration, having six or eight flowers open at the same time. The growth at the base of the buds should be pinched out as soon as the buds have swelled, but not before.

Lachenalias.—Now the flower-spikes can be seen, a little artificial manure, such as Thompson's or Clay's, should be sprinkled over the surface of the soil, but it must be kept out of the axils of the leaves, or the spikes may decay. These plants are most satisfactory when grown on shelves within 12 or 15 inches of the glass-roof in a cool structure, protected from frost and cold draughts.

Mignonette resents much fire-heat, and too frequent root waterings. Very weak manure-water from the cow-yard, or that prepared from deer's-dung that has been placed in a bag, and the strength withdrawn in a tub of water, suits Mignonette admirably. They should be grown in a similar position as Lachenalias. A further sowing may be made at the end of this month in a compost of fibrous loam, dry cow-manure rubbed through a quarter-inch sieve, and a little lime-rubble or old plaster broken up small. Sow the seeds in clean 5-inch pots. Be careful to provide good drainage, and make the soil very firm to within 1 inch of the top of the pot. Then sow the seed thinly, and cover it with a quarter of an inch of fine soil. Place the pots in a temperature of 50°, and when the seedlings are large enough, thin them out, leaving three only in each pot. The varieties Miles' Spiral or Machet always give satisfaction.

Gloxinias.—An early batch of these may be introduced to a temperature of 60° to 65°, and as soon as they have commenced to grow, shake the soil from the tubers, and repot them into pots of the same size, or a trifle larger than they are in at present. Light fibrous loam, half-decayed leaf-soil, and good peat, the former predominating, make a good compost, if sufficient sand be added to keep it porous. Make the soil moderately firm, place the pots in a light position, and afford no water to the root for a few days, but spray the plants overhead with the syringe once or twice daily. A pinch of seed may be sown in a 5-inch pot or shallow pan, on a level surface of fine soil which has been watered a few hours previously. Distribute the seed thinly, and put merely a pinch of sand over this; cover them with a piece of glass, or place the pot in a close case, where there is a little bottom-heat, removing it to a shelf or other light position as soon as the seeds have germinated. Shade the seedlings from the direct rays of the sun, and avoid too much moisture for the next few weeks.

THE FLOWER GARDEN.

By J. C. TALLACK, Gardener to E. MILLER MUNDY, Esq., Shipley Hall, Derby.

Seeds which may now be Sown.—Seeds of some species of plants employed in the flower garden must be sown early in the year in heat, and grown on freely to get them in a forward state to plant out in May or June. Among these there are of the tuberous-rooted Begonias, B. semperflorens, Gaillardias, Grevillea robusta, Acacia lophantha, Wigandias, and Solanum Balbsii, the latter being a very handsome plant, not quite so well known as it deserves to be as a subtropical. The Begonias having very minute seeds, must be sown on the surface of a mixture of sandy loam, peat, and leaf-mould, in well-drained shallow seed-pans, and kept covered with a piece of tile or slate till germination has taken place. Grevillea seeds germinate freely if lightly dibbled in edgeways in the soil. A mixture of peat and loam is good for this species.

Roses may be planted in mild weather during the next few weeks, and when the soil is in a good working state. By planting Roses as early as weather permits, the wood will have time to plump up before pruning takes place in March. In order to assure success, the land for Roses should be afforded a heavy dressing of animal manure, which should be dug into it deeper than the roots of the plants. The varieties of R. rugosa being unusually showy plants, should be freely planted in the foreground of shrubberies. Deciduous trees and flowering shrubs may also be planted, the latter being grouped in their respective kinds rather than planted indiscriminately, the effect when in flower being then much finer.

Lily of the Valley.—Any beds of this plant which have been in existence for several years should be dug up, the clumps divided into one, two, and three-year-old buds, and then replanted in new beds at about 4 inches apart. The land should have been well manured, and a thick mulch of decayed manure and leaf-soil spread on the beds. The Lily of the Valley does best in a semi-shaded position, and if the beds are systematically broken and replanted, home-grown crowns are the equal of the best imported ones. The youngest bud will bloom in three years, and the next size in two. The same bud does not flower again.

Solomon's Seal (*Polygonatum multiflorum*).—A Liliaceous plant, nearly allied to the Lily of the Valley, should be similarly treated to it. There are several varieties, one having double flowers, and another with variegated foliage. The plant likes a moist situation, and in good soil it reaches a height of 3 feet. The stems, when in flower, are very ornamental, and the plant is easily forced.

Rockeries.—The present affords a convenient season to overhaul the rock-garden, and where the space covered by a rockery is small, it should not be neglected, valuable plants of small growth being apt to get smothered out of existence by others of stronger growth planted temporarily, and the latter must be much curtailed, or entirely rooted out. Without some such care, a rockery soon develops into a wilderness, affording no pleasure to the owner. Again, it may be proposed to plant some novelties which require special soil, and at this season the pockets, ledges, crevices, &c., may be prepared and labelled for these, leaving nothing but the actual planting to be done when the plants come to hand. When ordering alpines and plants generally from the nurseryman in very small pots, it is prudent to state that they are not to be sent till the proper planting season has arrived, as a change of locality has sometimes a bad effect on them if they have to remain unplanted for some long time.

Evergreens and Vermin.—Rabbits and field-mice cause much injury to some species of evergreens, notably to Hollies, by gnawing the bark near the ground-level in snowy weather. A safe and simple means of protection is to wind strips of old fishing-net round the stems for about 1 foot from the soil. I have never known this simple remedy to fail. Rabbits ought never to be allowed to exist in the pleasure-grounds, but means of access will occur, and snow-drifts afford them a means of entry occasionally.

Planting.—If not urgent, this operation is better left alone for the present, although during a mild spell the work may be pushed on, as regards Roses and many of the hardy herbaceous perennial plants, providing that they are not kept out of the soil for any length of time, and that frost is kept from the roots. In any case, neither lifting nor transplanting should be carried out on a large scale, and no plants should be moved whose roots are inactive during the winter.

THE KITCHEN GARDEN.

By JOHN FLEMING, Gardener to Sir C. PIGOTT, Bart., Wexham Park, Slough.

French Beans.—Sow five seeds each in 7-inch or 8-inch pots filled to half their depth with a rich loamy compost in a roughish condition, and cover them with fine soil to the depth of 1 inch, and place in a house or pit having a moist warmth of about 65°, and keep as near the glass as possible after germination has taken place. Syringe the plants twice a day. Ne Plus Ultra and Magnum Bonum are excellent forcing varieties.

Leeks.—If large specimens are needed for special dishes or for exhibition, one seed should be sown at a depth of ½ inch in the middle of the required number of drained 60's, the soil used being turfy-loam one-half, leaf-mould, one-quarter, dried horse-dung one-quarter, and as much wood-ashes and coarse sand as will afford porosity; passing the whole through a sieve with a ¼-inch mesh. Place the pots in a pit or house having a temperature of 50° to 55°, and cover with sheets of glass or brown paper; and as soon as the seedlings are well above the soil, remove the plants to a shelf near the roof, so that stocky growth may result.

Work in General.—Take advantage of frosty weather to wheel manure upon vacant land; make ready the necessary number of Pea and Bean-sticks, tying them in bundles of various lengths. Let all garden rubbish that is not readily reduced to plant food be burned or

charred, and return the ashes to the land. Prepare the various kinds of soils and manures in readiness for use, screening or sifting them when necessary. Examine stored roots; clear out and whitewash tool-sheds, and examine all tools, repairing those that are broken or replacing them with new ones. See that the Globe Artichokes, Celery, Cardoons, &c., are sufficiently protected against frost by means of bracken or litter, but removing some of this in mild weather. Store a sufficient number of Parsnips, Artichokes, and Turnips, in the root-store for use as will furnish supplies during a spell of severe frost.

THE HARDY FRUIT GARDEN.

By CHAS. PAGE, Gardener to J. B. FORTESCUE, Esq., Dropmore, Maidenhead.

The Protection of Fig Trees.—If protection has not been applied, no time should be lost. Let the branches be taken down from the wall and tied loosely in small bundles, and wind them round with thick bands of hay or straw, and fasten the former to the wall, putting short litter on the border at the foot of the trees.

Protecting Materials.—Let all protecting materials be kept in readiness for use when hard weather seems imminent. The stakes for keeping protecting nets away from the face of the walls may be pointed, put into bundles, and secured with willow-rods or string. See that the fishing-nets and tiffany for placing over the trees, covering window openings, &c., are put into good order.

Manuring Fruit-quarters.—Every advantage should be taken of spells of severe frost to get the whole of this sort of work completed. Where the soil is heavy, a dressing of charred earth and wood-ashes greatly improves the tilth, and are of benefit to surface-rooting plants.

Strawberries.—Where the gardener is in a position of obtaining as much farmyard manure as he needs, the present season affords an opportunity to get it wheeled on to the Strawberry quarters, laying it between the rows, and spreading it later after the Dutch-hoe has been plied between the plants.

The Fruit-room.—If no frost-proof fruit-room exists, and fruit is stored in lofts, Apples and Pears should be covered with Wheat-straw or clean hay 6 inches deep, covering this with garden-mats. Examine the fruit weekly, and remove all that are showing decay; and keep the surroundings as clean and sweet as possible.

FRUITS UNDER GLASS.

By T. H. C.

Borders.—In the late houses attend to the watering of borders; if they are light and shallow they should not be allowed to become very dry, even in the winter months. In regard to borders for young Vines, it is the best practice to make them gradually, adding at a time from 1½ to 2 ft. of good compost, enclosing this by a temporary retaining brick wall, which is easily removed each time the border is added to. A good compost should consist of good fresh turfy loam, to every barrowful of which has been added an 8-inch pot of half-inch bones, the same of charcoal, and enough old mortar-rubble to keep the whole porous. When using a good loam, I prefer not to give artificial manure at this time, but would apply it to the borders when the roots are more active and ready to take advantage of its quickening powers.

Peaches and Nectarines.—Old trees that have been previously forced, and are approved early varieties, may always be depended upon to set and ripen a satisfactory crop of fruits, provided the previous year's treatment has been proper. Young trees do not force so readily, and are more liable to grow strongly, at the expense of short-jointed fruitful wood. Trees started in November will have their flowers set and the young growths partially disbudded. Disbudding at this season should be carried out first at the bottom of the trees, owing to the influence of the heat in the pipes, starting the branches nearest them into growth. Under more natural conditions the trees break evenly, and then disbudding should be commenced towards the top, and carried out gradually. First of all, remove all foreright and badly placed shoots, and treat the bottom half of the tree similarly in a few days time, more or less according to its growing condition. Syringing having been discontinued during the setting period, should be resumed immediately setting is effected; it should be done twice daily if the weather be fine and bright, but if dull and cold syringe in the forenoon only with warm water, but otherwise maintain a moist condition of the atmosphere. Afford air by the top ventilators upon every favourable opportunity towards the middle of the day, but guard at all times against cold, chilling draughts. Keep a sharp look-out for aphides, and upon the least sign of their existence vaporise with XL-All, or syringe with diluted Quassia extract. Adopt preventative measures, and much time, expense, and after labour will be saved. The old adage "A stitch in time saves nine," is never more applicable than when dealing with insect pests. At the evening damping down, sprinkle on the paths a little of the drainings from the cowsheds and stables, the fumes of which are invigorating to the foliage, and help to keep down red-spider. A night temperature of 58° to 60° should be maintained, except in severe weather. It is better to let it fall below these figures than to heat the pipes unduly. A day temperature of 5° to 10° higher, according to the weather should be ensured. Second house: Trees started in December will now be in flower. Maintain a slightly drier atmosphere, especially towards the middle of the day, when the flowers should be fertilised. Endeavour to have a circulation of fresh air daily, and ventilate as advised for the earliest house. A night temperature of 50° to 55°, rather less than more, and 60° to 65° by day, should be ensured. Hasten the pruning and cleaning of

FIG. 27.—BEARING SHOOT OF PEACH AS PRUNED.

succession-houses and trees, as with the lengthening days the flower-buds begin to expand, when care is needed not to injure them when cleaning and tying up. Old-established trees making short-jointed shoots thickly studded with buds, flower-buds predominating, require little else in the way of pruning than to cut out the old fruiting wood and thin out the shoots left, so that they are thinly disposed over the tree. When tying the trees to the trellis again, bear in mind that a little later on, next year's fruiting shoots will also need tying-in, and hence sufficient space for their proper development should be left. Young trees, on the other hand, require slightly different pruning, and care and forethought are needed, no matter upon which system they are to be trained in the foundation branches of the future tree. Shortening of the shoots is necessary, in order to secure an even distribution of the branches, always shortening to a wood-bud, which is easily distinguishable from a flower-bud by its sharp conical shape; and which, if possible, should point in the direction you wish the future branch to extend. Autumn is the best time to plant, but if planting is still contemplated lose no time in carrying it out.

Melons.—Plants raised from seed sown at the beginning of the month are best fruited in large pots plunged in a hot-bed. Pot on the plants into 5-inch pots, using a compost of two-thirds good turfy loam, and a third leaf-mould, to which may be added a slight sprinkling of Veltha (powder). Plunge the pots in a brisk bottom-heat, and after root action becomes vigorous, gradually withdraw the pots, and return to a shelf close to the glass in a temperature of 70°. Place a stake to each, and tie in as growth proceeds. Sow seed for succession towards the end of the month.

Cucumbers.—The early Cucumber-house should now be got in readiness for early plants. Thoroughly cleanse the glass, wood-work, and walls; clear out every particle of the old soil, and hot lime-wash the walls that enclose the border or bed. At this season bottom-heat is essential, and if the beds are not provided with hot-water pipes, a hot-bed of half stable-manure and half Oak-leaves 2½ feet deep should be provided; and on top of this, or on the grating, below which are the hot-water pipes, place turves of loam, and at intervals of 4 feet raise little hillocks of soil, consisting of half good loam, one-quarter leaf-mould, and one-quarter old Mushroom-bed. Before planting, allow the soil to become of the same temperature as the house.

THE APIARY.

By EXPERT.

Wax Extracting.—Many shillings can be saved every year by the bee-keeper if he collects all loose pieces of comb and pieces of foundation, and at the end of the season makes them up into cakes for sale in a manner most suitable for his customers. Some like it in the form of cakes, such as a small pie-dish or saucer will hold, or for tailoring purposes in small pieces about the size of an egg. By doing this, not only are these odd pieces turned to account, but the bees are kept from robbing, which often occurs through small pieces of comb being left about containing honey, and to a great extent the wax-moth is prevented from breeding. When there are many hives, it pays to purchase a wax-extracter, which does the work well and with very little trouble. The method is very simple: the bottom part of the extractor is filled about three parts full of water, and placed on the fire; the top part is then filled with wax, and the steam from the hot water will gradually melt the wax, and as this proceeds keep filling up the top with old combs, &c., until you think you have sufficient quantity to make several good cakes. When this is nearly all melted down, gently tilt the upper part forward, and pour out into a basin of cold water, when it will quickly set. As soon as this is done, place the wax again into the extractor with clean water in the boiler part, and boil up again. This time the wax will generally turn out fit for market, but if it is not very good, boil up a third time, and then run out into saucers, or pans, or egg-cups, to suit your customers. The extractor should be cleaned when hot, as the wax will come off much easier and cleaner than if it is left for another time. When only a few stocks are kept, and it is not convenient to have an extractor, place the wax in a meat jar and put in the oven; when melted, run out into a pan, and as soon as this is set, place again in the oven until you have it clear—this is rather a tedious way, and the former is much preferable.

General Hints.—See to leaky roofs, and when possible place on a cake of candy, which can be easily made from the receipt given below. Examine the outer covers of straw skeps to see if mice are getting into them, but do not in any case disturb the bees more than can be avoided.

Receipt for Candy Cake.—Place a clean pan on the fire, and put into it half a pint of water and 3 lb. of crystallized cane sugar; begin stirring at once till the sugar is dissolved, to prevent it from burning. Let it boil for a few seconds, then cease stirring, and let a few drops fall on a plate; if this sets at once so that it does not stick to the finger when pressed, it will do; but if sticky, it contains too much water, and boiling must be continued to drive off the excess of liquid. When the right condition is reached, take it from the fire and set the pan in cold water, stirring briskly all the time until it begins to turn white or granulate, and becomes rather stiff, when it may be poured into any mould suitable, and lined with paper for easy removal and to prevent sticking to quilts. The candy so made will, when cold, be of such consistency as to become quite soft and buttery" when scraped with the finger-nail.

SECTIONAL BOILER.—We are informed by Mr. J. G. WILSON, the gardener at Chevet Park, Wakefield, that Mr. SQUIBBS, the gardener at Eshton Hall, will allow any gardener interested in this form of boiler for garden purposes, to view one that is in use in the gardens at that place.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the Publisher.

Letters for Publication, *as well as specimens and plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Illustrations.—*The Editor will thankfully receive and select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.*

Local News.—*Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return the unused communications or illustrations, unless by special arrangement.*

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY, JAN. 27—Roy. Hort. Soc. Coms. meet.

SALES FOR THE WEEK.

MONDAY and FRIDAY, JANUARY 26 and 30—
Herbaceous Plants, Perennials, Azaleas, Plants, &c., at 67 and 68, Cheapside, by Protheroe & Morris, at 12.

MONDAY, JANUARY 26—
Clearance Sale of Fruit Trees at Cliffe, near Rochester, by order of Messrs. W. Horne & Sons, by Protheroe & Morris, at 11.30.

TUESDAY, WEDNESDAY, and THURSDAY, JANUARY 27, 28, and 29—
Unreserved Sale of Nursery Stock, at The Nurseries, South Woodford, by order of Mr. John Fraser, by Protheroe & Morris, at 11.

TUESDAY, JANUARY 27—
Roses, Liliums, Azaleas, Border Plants, Palms, Bay Trees, 50 000 Lily of the Valley, &c., by Pollexfen & Co., at their Rooms, Pilgrim Street, E.C.

WEDNESDAY, JANUARY 28—
Azaleas, Rhododendrons, Roses, Perennials, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.—Japanese Lilies, Gladioli, Tuberous Begonias, Gloxinias, Hardy Flowering Perennials, Roses, Standard and Dwarf, &c., by Mr. Stevens, at his Rooms, 38, King Street, Covent Garden, W.C.

FRIDAY, JANUARY 30—
Imported and Established Orchids, at 67 and 68, Cheapside, by Protheroe & Morris, at 12.30.

(For further particulars see our Advertisement columns.)

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick —38·7.

ACTUAL TEMPERATURES:—
LONDON.—*January* 21 (6 P.M.): Max. 45°; Min. 38°.
January 22 (NOON): Overcast; 46°.
PROVINCES.—*January* 21 (6 P.M.): Max. 46°, Holyhead; Min. 42°, Norwich. Dull or rainy in most places.

Forestry.

THE report of the Committee appointed to consider the present condition and future prospects of forestry in Great Britain has been issued as a Parliamentary paper. The Committee was presided over by Mr. MUNRO FERGUSON, M.P., and included, in addition to sundry gentlemen of official position, such experts as Dr. SCHLICH, Col. BAILEY, Prof. J. R. CAMPBELL, and Dr. SOMERVILLE. The witnesses comprised landowners, agents, foresters, and scientific men.

The Committee endorse the conclusions of the Select Committee of 1885-87 as regards the neglected condition of forestry in Great Britain, the possibility of improvement, and the necessity for the provision of better means of education. As regards the question of the extension of the forest area, the Committee point out, as cited in the *Times*, that there is on the highest authority in these islands an area of waste, heather, and rough pasture, or land out of cultivation, amounting to 21,000,000 acres, on a large proportion of which afforestation could be profitably undertaken. The area of waste land which might be afforested becomes a matter of grave national concern when it is remembered that, according to experts, the world is rapidly approaching a diminution of, if not actual dearth in, its supply of coniferous timber, which constitutes between 80 and 90 per cent. of the total British timber exports. The committee believe that the question of planting suitable waste lands under the control of the Crown, or over which the Crown exercises manorial rights, is worth the attention of the Commissioners of Woods and Forests.

Dealing with the question of education, the Committee state that, even where access may be had, for purposes of instruction, to private woods, it is exceedingly desirable that collegiate instruction in forestry should be illustrated by means of example plots, a total area of 100 to 200 acres at each educational centre being necessary and sufficient for this purpose.

They place on record the growing feeling that no scheme for the general improvement of present conditions can be satisfactory which does not provide for the establishment of two large State forests to demonstrate the most perfect technical and economic developments of the art of forestry, and to be managed as commercial undertakings, so as to produce the best financial results.

The final recommendations of the Committee are as follows:—

(*a*) That two areas for practical demonstration be acquired, the one in England and the other in Scotland, of not less than 2,000 acres, nor over 10,000 acres in each case. They suggest that the Alice Holt Woods in Hampshire be made available as soon as possible to serve as a demonstration area in England; and that a suitable estate be purchased in Scotland, as convenient as possible to Edinburgh, for the same purpose.

(*b*) That additional facilities for instruction be afforded, by the appointment of a lecturer on forestry in connection with each of the Universities of Cambridge and Oxford, and that example plots be provided in connection with each of these centres and with Edinburgh.

(*c*) That a good grounding in forestry form an integral part of the curriculum of the colleges providing instruction in agriculture in Great Britain; and that short courses of instruction suitable for the requirements of young foresters be also provided there. Instructors should also be available for giving practical advice in connection with the management of woods, the owners of which desire an expert's opinion.

(*d*) That provision be made for the education of foresters and woodmen by employing students to work in both the demonstration forests; and that suitable buildings be erected on the ground for the instruction and, where necessary, for the accommodation of these student-foresters.

(*e*) That lectures be given, under the auspices of the county councils, in neighbourhoods where there is a considerable area under wood; and that scholarships be offered in such counties to enable working foresters to attend courses of lectures.

(*f*) That the inequality shown to exist in the levy of the estate duty on timber be redressed.

(*g*) That the Government be urged to secure the early enactment of a Bill to protect owners of woods against loss by fire caused by sparks from locomotives.

(*h*) That the inquiry conducted in 1895, concerning the area of woodlands, be repeated by the Board of Agriculture, and that details concerning the character of the timber crop grown upon them be ascertained.

(*i*) That the attention of corporations and municipalities be drawn to the desirability of planting with trees the catchment areas of their water supply.

BOWOOD (Supplementary Illustration).—Since Lord LANSDOWNE returned from Canada and India, where he has acted as Viceroy, extensive alterations have been made at Bowood in the gardens and pleasure grounds, to which we shall have occasion to refer in a future number. Our supplementary illustration shows a portion of the terrace gardens, which are laid out in the Italian style, and the wide walks, broad stairways, marble fountains, and other architectural features, add greatly to the effect. The view from the upper terrace, with the lake in the foreground, the park, and the woods, with the downs in the distance, forms a delightful bit of landscape.

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the Royal Horticultural Society will be held on Tuesday next, January 27, in the Drill Hall, Buckingham Gate, Westminster. A lecture on "The Cultivation of the Blue Nymphæa" will be given by Mr. JAMES HUDSON, V.M.H., at 3 o'clock. At a general meeting held on Tuesday, January 13, ninety new Fellows were elected, amongst them being the Countess of DUDLEY, Lady CLAYTON EAST, Lady BROOKE, Lieut.-Col. H. W. APPERLEY, and the Hon. Mrs. BOURKE.

FLOWERS IN SEASON.—Messrs. W. BULL & SONS, of King's Road, Chelsea, brought to our notice on the 19th inst., some blooms of choice varieties of Primula sinensis. Among the single, flowered varieties we noticed Sunshine, crimson-shaded with carmine; Mont Blanc, pure white; Pink Beauty, fulgens almost scarlet; Imperial Blue, alba oculata-lutea; and Comet, of brilliant crimson colour. The old fimbriata alba and rubra were very fine. Of double-flowered varieties there were alba, rubra, fulgens, and Blushing Beauty. All the varieties are good types of this popular decorative plant.

"WILLING'S PRESS GUIDE."—The well known scarlet and black cover of *Willing's Press Guide and Advertisers' Directory and Handbook* now encloses the thirtieth annual volume. It has been duly brought up-to-date, and contains alphabetical lists of newspapers and periodicals; catalogues of provincial publications, and a mention of colonial, American, and continental newspapers. With this wealth of titles, addresses and other epitomised information, the Guide is invaluable to everyone connected with the press.

THE SURVEYORS' INSTITUTION.—The next Ordinary General Meeting will be held in the Lecture Hall of the Institution on Monday, January 26, 1903, when a discussion will take place on Mr. H. T. SCOBLE'S paper, entitled "Rural Drainage and Sewage Disposal." The attention of members is specially called to the fact that the rooms of the Institution are open daily, and are available for reference to the library, for arbitrations, writing, appointments, or other business purposes.

GARDENERS AT FOOTBALL.—H. B. MAY'S (Edmonton), and T. ROCHFORD'S (Turnford).—The return match between elevens representing the *employés* of the above well-known firms took place on January 17 on Mr. H. B. MAY'S ground at Angel Road, Edmonton, the victory resting with the home team by four goals to two goals. The previous match was played at Turnford in October last, and resulted in a drawn game, each side scoring four goals.

RATING NURSERY LAND.—We have received from the Horticultural Trades' Association of Great Britain and Ireland, whose hon. sec. and treasurer is Mr. CHAS. E. PEARSON, of Lowdham, Notts, the following communication: "In your reply to 'Enquirer' (p. 48 last issue), you take it for granted that the decision given by the Law Lords in connection with the Agricultural Rates Act of 1896 (and applying to that alone), upsets the previous decision by the same authority in

Purser *v.* The Worthing Local Board. If this were the case, this Act intended for the relief of agriculture would do an immense injury and injustice to the horticultural industry by converting glasshouses from 'trade fixtures' into 'buildings,' and rendering them liable to be rated as such, instead of being taken into account as raising the letting value of the land upon which they stand, which I believe is the present state of the law. The two decisions referred to certainly differ in principle, but were given on entirely different issues, and although certain isolated authorities have tried to take advantage of the latter one to increase the assessments on glass used for commercial horticulture, the matter is being contested, and will, if necessary, be again fought out to a finish, as such a change on the top of the low prices now prevailing would probably involve the closing of a very large number of glass establishments in highly-rated districts."

ENTERTAINMENT TO THE EMPLOYÉS OF THE ROYAL AQUARIUM. — On the evening of the 14th inst., Mr. R. BALLANTINE, one of the Vice-Presidents of the National Chrysanthemum Society, and Mr. R. DEAN, General Secretary, assisted by some members of the Society, entertained at supper at Fumagalli's Restaurant, Wilton Road, Victoria Station, about thirty of the *employés* at the Royal Aquarium, by way of acknowledging the great assistance and courtesy received from them on the occasion of the exhibitions of the National Chrysanthemum Society, Some of them had been engaged within the building during the twenty-seven years the Chrysanthemum shows had been held there. In the unavoidable absence of Mr. BALLANTINE, in Yorkshire, who sent a warmly sympathetic letter, the Chair was taken by Mr. R. DEAN, supported by Mr. J. W. WILKINSON, the Secretary of the Royal Aquarium; Mr. H. J. JONES, who, assisted by friends, provided an excellent musical entertainment; Mr. G. PRICKETT, who sent a number of Chrysanthemum blooms for the decoration of the tables; Mr. J. MCKERCHAR, Mr. E. F. HAWES, of the Royal Botanic Society, and others. After a substantial meal, there were kindly speeches and song, and at the close "Auld Lang Syne" was sung with much feeling. The cost of the entertainment was defrayed by private subscription.

"ALL ABOUT SWEET PEAS."—In our note last week upon this interesting little pamphlet by Mr. ROBERT SYDENHAM, we stated on p. 42 that ten varieties there enumerated were recommended as the best ten for cultivation. This was a clerical error, those varieties being the best ten remaining for cultivators of more than forty varieties. The actual best dozen varieties as voted by twenty-seven cultivators are Black Knight (23 votes), Blanche Burpee (21 votes), Coccinea (18 votes), Countess of Lathom (16 votes), Duke of Westminster (23 votes), Hon. Mrs. Kenyon (27 votes), Lady Grisel Hamilton (27 votes), Miss Willmott (22 votes), Navy Blue (20 votes), Prince of Wales (21 votes), Prima Donna (22 votes), and Salopian (26 votes).

PRESENTATION.—The staff at Longford Castle gardens, on Saturday, January 17, presented Mr. HAZELTON with a handsome marble clock, bearing a suitable inscription. Mr. HAZELTON severs his connection with Longford at the end of this month, and will carry with him the well-wishes of all those with whom he has been associated.

THE LATE MR. WILSON'S GARDEN AT WISLEY, which has been advertised for sale by auction on Tuesday last at the Mart, Tokenhouse Yard, London, by Messrs. ALEX. H. TURNER & CO., was not sold on that day.

NEW WORK ON VINES AND GRAPE-GROWING. —We understand that Messrs. VIALA & VERMOREL have undertaken the publication of *Ampélographie*, a new work on Grape-growing, that is to be issued also from 5, Rue Gay Lussac, Paris, and Villefranche-sur-Saone, Rhone. The work will appear in the form of six volumes of from 400 to 500 pages each, with 500 coloured, and between 1000 and 1500 black-and-while illustrations. No pains have been spared in the preparation of the *Ampélographie*, for which the collaboration of the best-known authorities on the subject has been secured. The information given is comprised under the following headings: —1, Synonymy; 2, Bibliography; 3, History and Origin; 4, Geographical Distribution; 5, Comparative Ampélographie; 6, Cultivation; 7, Wine-making. In fact, the author's aim is to publish a detailed study of the Vine, its life-history, and its products. The work promises to be of unusual importance, and although too costly for the majority of gardeners, it will be a most valuable book of reference in garden-libraries.

PRIZES OFFERED BY THE ACADEMY OF SCIENCES.—The Institute of France has published in the *Comptes Rendus* for December 22, 1902, the list of prizes to be awarded for scientific research during the years 1903 to 1906. In the botanical section the list is as follows :—

Grand Prix des Sciences Physiques.—For research and demonstration of the various methods of formation and development in Ascomycetes and Basidiomycetes.

Prix Bordin.—For demonstration, after study of many types and varieties the principles of the phenomena of double fecundation or digamy, that is to say, simultaneous formation of an egg and of a "trephime" in Angiosperms.

Prix Desmazières (1,600 francs).—For a paper, by French or foreign author, published during the preceding year, treating of some or of all Cryptogams.

Prix Montagne (1,500 francs).—To be awarded entire, or in two portions of 1,000 and of 500 francs respectively, to the author or authors of important works dealing with the anatomy, physiology, development or description of the lower Cryptogams (Thallophytes and Muscine). Open to native and naturalised Frenchmen only.

Prix Thore.—For the best work on the cellular Cryptogams of Europe.

Prix de la Fons-Mélicocq.—Awarded every three years for the best manuscript or publication which shall be a botanical treatise dealing with the north of France; that is, with the Departments of Nord, Pas-de-Calais, Ardennes, Somme, Oise, and Aisne. This prize will be awarded in 1904.

FORCING BY MEANS OF ETHER.—A correspondent of the *Times* in alluding to the method of etherisation, frequently adverted to of late in these columns, says "that horticulture is essentially a progressive industry, but in England its general motto would seem to be the Aldine one of *festina lente.*" Our cultivators are, indeed, not very ready to adapt new methods or to avail themselves of new resources. They prefer to wait to see what others do. It is from this ultra-conservatism, for instance, that the use of the electric light for cultural purposes has made little or no progress in spite of the really astonishing results of the experiments made by the late Sir WILLIAM SIEMENS, and which were recorded at the time in these columns. We are pleased, however, to learn from the *Times* correspondent that "So far as England is concerned, at least one grower has tested on an extensive scale the value of the etherisation of plants. Mr. T. JANNOCH, of Dersingham, near Sandringham, immediately on hearing of the discovery, had a special ether chamber or tank made, and the results of his experiments, which I have been permitted to examine carefully, are far beyond any reasonable anticipations. Next season Mr. JANNOCH, doubtless in common with all other cultivators who have tested the system, has determined to enter into yet more extensive experiments. The developments in this and other countries will be watched with much interest by a very wide community of flower growers and the public generally.

THE ARTS AND CRAFTS EXHIBITION.—The seventh exhibition of the Arts and Crafts Exhibition Society is now open at the New Gallery, Regent Street, and includes, as usual, pictures, drawings, designs, and specimens of various ornamental crafts. Mr. WALTER CRANE contributes several designs for wall-papers, carpets, &c.; Mr. LEWIS F. DAY, Mr. C. F. A. VOYSEY, and other well-known artists and craftsmen are also well represented. Many of the exhibits come from technical schools; there are specimens of bookbinding from the Kelmscott, the Chiswick, and other presses; and much fine embroidery, furniture, metal-work, glass, enamelled and jewelled ornaments from schools and guilds, as well as from private individuals. The Society aims at improving the artistic standard of ornamental handicrafts, and their present exhibition is satisfactory as regards both the number and the merit of the contributions included in it.

EFFECT OF ENVIRONMENT UPON PLANTS.—M. GASTON BONNIER has recently laid before the Académie des Sciences a report upon some interesting experiments undertaken by him to determine the influence of environment in modifying certain characteristics in plants. He divided the plants of species native to the district of Paris into halves, and cultivated one portion of them at Fontainebleau, and the remaining half in the same soil taken to Toulon. While the former set developed normally, those portions of the same plant cultivated on the shores of the Mediterranean gradually exhibited much modification under the influence of their new surroundings. At the end of three years the resisting powers of their wood, and the thickness of their leaves had increased, so that they to a certain extent resembled species of the same kind of southern origin. The fixing of certain characteristics of adaptation might induce one to consider them of specific value. This consideration is thus connected with the problem of the origin of species, and on this account it is of value to record the results of these experiments of M. GASTON BONNIER.

THE CHINESE FLORA.—Lately we had occasion to express our satisfaction that quicker progress was at last being made with the publication in the *Journal of the Linnean Society* of the enumeration of the plants of the Chinese Empire. Our satisfaction is enhanced by the issue dated January 1, of another part consisting mainly of the Orchid, elaborated by Mr. ROLFE. The delay in publication has been so long, that a supplementary part or parts containing the additions that have been made while the work has been in progress, will be absolutely essential. In the meantime, it is no slight boon to have as much as we have.

THEFT OF ORCHIDS. — We learn that the Deputy Magistrate of Sealdah has, after a protracted hearing, sentenced two native nurserymen to two months' imprisonment, and a fine of Rs. 200 each, and in default of payment of fine, two weeks' additional imprisonment. These two men were charged with receiving stolen Orchids with a guilty knowledge. The Orchids were stolen from a local Bengali nurseryman, some of which were recovered by the police from the garden of a well-known amateur gardener of Calcutta. *Indian Gardening.*

THE RAINFALL.—Messrs. SOWERBY WALLIS and H. R. MILL have published in *The Times* a most interesting series of tables dealing with the rainfall at fifty-two stations in the British Isles

during 1902. At only four stations was the amount above average; in all the rest it was below, and in some cases much below the average of thirty years. For the last eighteen years there has been an average deficiency of 7 per cent., so that the repeated and continuous defect is assuming serious proportions.

LAW NOTES.

PEER AND NURSERYMAN.

APPLICATION FOR A BANKRUPT'S DISCHARGE.—At Northampton, Lord Lyvedon, described in the bankruptcy petition as Courtenay Robert Percy Vernon, nurseryman, of Stanwick, Northampton, applied for his unconditional discharge. His lordship was adjudicated bankrupt in 1894 with unsecured debts amounting to £4,400. A dividend of 4*s.* 4*d.* was paid. In January, 1900, his discharge was granted by His Honour Judge Snagge on condition that he consented to judgment for an amount making the dividend equal to 10*s.* At this time he was earning a living as ship's purser. The following month, on the death of his uncle, he succeeded to the title. It was afterwards discovered that a large quantity of silver plate, supposed to be entailed, became his absolute property. It was sold by the Official Receiver, and realised sufficient to pay a supplementary dividend of over 10*s.* Fresh proofs amounting to £4,700 were, however, put in. His Honour was now informed that a dividend of 9*s.* 3¾*d.* had been distributed on the whole indebtedness. The money would have paid 10*s.* had not expenses been incurred in a law suit. His Honour granted the discharge.

Obituary.

HERMANN WENDLAND, whose death on the 12th inst. after a long illness, we greatly regret to have to announce, was one among the many Germans who have "graduated" in horticulture at Kew, and who was the distinguished Director of the famous Royal Gardens at Herrenhausen, Hanover, stands out conspicuously as one who has accomplished much in the fields of both botany and horticulture. We take the following particulars from the *Journal of the Kew Guild*, 1900.

"He was born in October, 1823, in Herrenhausen, where his father and grandfather preceded him as Director of the Gardens, and where he received his early training. He left his father to study under Professor Bartling in the Botanic Gardens at Göttingen and Dr. Schott at Schönbrunn, proceeding thence to Kew. Here he was employed nearly two years as a gardener, leaving in 1849 to return to Herrenhausen, where he worked as assistant until his father's death which occurred in 1870, when the son was appointed Director. In 1857 he was sent on a botanical expedition into Guatemala and Central America, where he collected many new and interesting plants, and introduced many by means of seeds, &c., afterwards distributing them from Herrenhausen. One of his best known discoveries was Anthurium Scherzerianum, which he found in Costa Rica, and which flowered at Kew in 1862, when a figure of it was published in the *Botanical Magazine*, t. 5319, where it is described as "a very singular little plant."

Herr Wendland prepared and published in 1854 a list of the Palms cultivated in European collections. This was followed by researches amongst the plants of this difficult Order with so much zeal and activity that he soon became the recognised first authority upon Palms. Sir Joseph Hooker acknowledges his indebtedness to Herr Wendland's monographs, &c., in the preparation of the *Genera Plantarum*. He has also made a specialty of the cultivation of Palms, the collection at Herrenhausen rivalling that at Kew. There has always been a ready interchange of living examples between the two establishments.

Orchids have also been objects of special attention with Herr Wendland; the collection he has formed and cultivated with exceptional success for many years being described by his bosom friend, the late Prof. Reichenbach, as by far the richest in botanical species that had ever been formed. Until within the last few years, Herr Wendland visited Kew annually, spending several days amongst the cultivated Palms, Orchids, &c., and endearing himself to the officials by his urbanity. His knowledge of tropical plants and their cultural requirements

THE LATE HERMANN WENDLAND.

is exceptional, and his readiness to impart this knowledge to others made his visits profitable as well as enjoyable.

In 1891 Herr Wendland celebrated his fiftieth year of professional work. He was present at the Ghent Quinquennial in 1898, and officiated as a judge."

If we remember rightly, he exhibited there as a novelty the now popular Saintpaulia ionantha.

SEED TRADE.

THE FLOWER-SEED CROPS OF THE PAST YEAR.

THE county of Essex is the great centre of flower-seed production in this country, and many acres are devoted to the culture of annuals, biennials, and perennials for the production of seeds. This branch of the great seed industry has been affected by the weather of the past summer; there is a serious shortage of crop in some cases, and a partial deficiency in most.

ANNUALS.

Generally speaking, there is an average crop of some which are grown in Essex, but there is an advance in price, mainly caused by the extra expense incurred in cleaning and dressing the seeds, owing to the waste which follows imperfect maturation. Labour has also become dearer, and so slight advances in price may occur in the cases of all the common annuals.

Asters.—This is one of the most important of our popular annuals, and Germany has to be largely drawn upon for a supply of seed. There is in Germany soil highly favourable to the culture of the Aster, and especially about Erfurt and Quedlinburg, more particularly at the latter place, where they do well in the free loam which abounds. It is reported that there are about two-thirds of an average crop of seed of the early varieties, and of these the now popular Comet strain are leading favourites. The Comets, of which there are now several varieties, follow a type of Aster known as The Queen of the Market, a strain which includes several varieties, the flowers having large yellow centres. Of the late-flowering types, represented by the Victoria, Truffaut's Pæony-flowered, &c., there is about one-third of an average crop. The single Aster seeds come mainly from France, and for these there is both an extensive and growing demand. As owing to the dearth of sunshine, seeds of Asters were imperfectly matured, and as the germination of many will doubtless be weakly, it is recommended that sowing be deferred later than usual in the coming spring, until warm growing weather appears probable. The most popular of the double Asters is the Victoria type; for pot culture the dwarf Chrysanthemum-flowered, the Victoria, and Truffaut's Pæony-flowered are preferred, but all do well in good soil in the open ground.

Stocks.—The early flowering Stocks, such as the Wallflower-leaved varieties, have done well on the whole, but of the large late-flowering strains the crop of seed is said to be very small; much of the seed saved from plants in the open ground will, it is believed, show imperfect germination.

Wallflowers.—Though seeds of these are by no means plentiful, they have produced better than some of their relatives, the Stocks; it is possible some of the choicer varieties may become scarce as the season progresses.

Sweet Peas and Mignonette. — These two are bracketed together because there are no two other annuals in greater demand. The home crops of both are only moderate, still there is no likelihood of scarcity. Seeds of Sweet Peas especially, now come in from many parts of the world, and the Californian crops are exceptionally good. It is not too startling a statement to make, to say that California grows more Sweet Peas than all Europe put together. Of Mignonette, much of the home supply comes from the continent. The two most popular varieties are the Machet and the Crimson Giant, with their sub-varieties, making a group of about twenty. It may be assumed there are about half a dozen distinct types of Mignonette. The Machet is perhaps the best for pot-culture and market work, and the Crimson Giant for the garden—but of the newer introductions, it has been said none can equal the old form for perfume; the Golden Queen is considered the most fragrant.

Pansies.—The commoner varieties have given plentiful crops of seed. The Pansy likes spells of wet weather, and yet for the same reason the fine selected large flowered types have produced no seed at all. It is doubtful if ever before there has been in any one season so poor a crop of seed.

Tender Annuals.—Such subjects as Verbena, Phlox Drummondi, Zinnia elegans, and Marigolds, so extensively grown in Germany, were all in full vigour up to the early days of October, then came frost, and the Marigolds in particular went down before it. Seed of the fine selected striped varieties is very scarce, as the plants had matured but very little seed when the frost came, owing to the retarding character of the summer; and all the best of other types are a very short

crop. A late summer and the early frosts combined to seriously limit the supply.

Nasturtiums.—Next to Sweet Peas, the Nasturtiums have made the greatest advance as a popular flower, and their popularity is still on the increase. It is said that in America the Nasturtium is actually supplanting the Sweet Pea in popular favour. Taking the whole of the seed-growing districts of Europe, the tall Nasturtiums show a fair average crop. The varieties of the improved Tom Thumb section, as distinct from the common yellow and scarlet varieties, are a very short crop, more especially on the Continent. In this country, the yield appears to have been generally better.

Biennials and Perennials.

These generally are an average crop taking them as a whole, and as they produce seeds generally earlier than the annuals, they had rather the best of the most favourable weather of the summer. Sweet Williams seeded indifferently in places; a fungoid growth which attacks the foliage in autumn and winter, destroyed many plants in some places. The absence of sun affected the crop of Canterbury Bells in some districts, but generally they and the stately Foxgloves seeded well. Pentstemons, always late in maturing their seeds, even in the case of one-year-old plants, had barely time to ripen their pods before the frost came; but the crop is not abundant. Biennial stocks formed promising seed-pods, but ripened them quite late, and some had to be gathered in a half-green state. *Pisum.*

BRYOPHYLLUM CRENATUM.

Most botanical students are familiar with the leaves of the common Bryophyllum calycinum. When pegged down on the surface of moist soil, the leaves produce, from the notches in their margins, little shoots capable of reproducing the plant. Morphologists, at any rate, those of the old school, will remember the pretty inferences which were drawn from these facts. Others not interested in such matters nevertheless acknowledged the attractiveness of the plant, and will feel interested in the illustration (fig. 29) which we now give of a species newly introduced into gardens from Madagascar, by Messrs. Veitch. Detailed description is unnecessary, as Mr. Worthington Smith's drawing from a plant exhibited before the Royal Horticultural Society gives a sufficiently good idea of the plant. The leaves were of a greyish-green colour, the calyces purple, and the petals pale yellow. The plant was botanically described by Mr. Baker in the *Journal of the Linnean Society*, xx. (1884, p. 139).

HOME CORRESPONDENCE.

BEGONIA GLOIRE DE LORRAINE.—With reference to the culture of this beautiful winter-flowering plant, I quite agree with Mr. Fleming (*Gardeners' Chronicle*, Jan. 10, p. 29), and cannot understand anyone who has succeeded in growing the plant to recommend "stopping;" but it is not on that point that I would draw attention. Mr. Fleming's success is undoubtedly due to taking cuttings at the proper time. So many growers are too impatient, and take cuttings which are not suitable. With regard to the cuttings, my experience differs a little from that of Mr. Fleming. I find that the best cuttings are obtained from the base of old plants which have been allowed to continue flowering, and have not had the tops taken off. The flower-stems may be taken off, and the plants kept as clean and healthy as possible; they will then start naturally from the base in April or perhaps earlier, and the short shoots should be taken before they begin to show flower. Almost any little shoot will root, and those taken above the point where they have begun to flower may, if stopped, form a bud at the base; but it takes a long time, and it is far better to avoid such cuttings. It is probable that it is such cuttings that "H. W. W." refers to, for it would be impossible to get the short-jointed cuttings from the base of the plants at the time he recommends propagating. I have propagated and grown large quantities of this Begonia, and find, as Mr. Fleming states, the secret, if any, is in starting with good cuttings, and keeping them growing freely from the start to the finish. Light and air are essential, but cold draughts must be avoided, and also a very low temperature; but many are inclined to give too much heat. Last season I found those more fully exposed to sun and air were more satisfactory than those under shade and more warmth. The Turnford Hall variety has proved equally free, as was seen by the plants exhibited by Mr. Fleming and others. Mrs. Leopold de Rothschild is also good, but I rather prefer the old variety as the colour is better. *A. Hemsley.* P.S.—I should have added that I have propagated from leaves, but have found them give more trouble than the stem cuttings, and grown side by side the stem cuttings have made equally good plants. In the spring of 1901, I propagated about 3,000; but last season we did not strike so many, but we had a good batch of Turnford Hall. *A. H.*

—— It may interest some of the readers of the *Gard. Chron.* to know that in these gardens there is growing a very fine seedling plant of Begonia Gloire de Lorraine, which has not as yet lost a leaf. The flowers are circular in form, a little larger than those of the parent plant, and paler in colour. It is growing in a 5-inch flower-pot. We grow about two dozen plants, and have had them in flower since the last week in August; and at the time of writing they are in very fine condition. *Chas. Wakefield, gr., The Cottage, Elmfield. Westbury-on-Trym.*

Fig. 29.—Bryophyllum crenatum: calyx purple; petals pale yellow.

HORTICULTURAL HALL.—I presume that those who are busy criticising the plans for the new Hall are among those who have earned the right to do so by the liberality of their contributions. If, as is extremely unlikely, they spoil the scheme, we shall know whom to blame for disloyalty to the cause. I hardly think the critics realise the responsibility they are incurring, or they would for once make an united effort to obtain what we all want. *An Old Kewite.*

SWEET PEAS.—Probably many growers will soon be sowing seed out-doors. It is a risky proceeding, as apart from the coldness of the soil checking germination, there is yet time for much

hard weather, whilst further, birds and ground vermin may do the too early plants much harm. It is very doubtful whether a sowing made early in March does not give better results than those made now will do. The best way to secure early plants is to sow about nine seeds in 5-inch pots that have been filled with good soil, standing them in a cold frame or house, where if germination be slow, it is certain, and by the time the plants are 4 inches in height, they can be turned out of pots and planted out to form separate clumps, the best of all ways to grow Sweet Peas. *D.*

A FINE IRISH YEW TREE.—In the gardens of Seaforde House, co. Down, there may be seen in robust health, a magnificent specimen of the so-called Irish Yew, Taxus hybernica, or Florence Court upright growing Yew. The measurements which I have taken are rather under than over the mark, and are as follows: height, 35 feet 6 in.; circumference taken 18 feet from the ground, 73 feet. Should any reader of this note know of a superior specimen of the above, would he kindly afford the editor its dimensions and where growing, as I believe the Seaforde tree is one of the finest specimens in the country. *A. F. Grubb, gr., Seaforde House.*

THE LATE JOHN McKENZIE.—Some of Mr McKenzie's many friends may be interested in the following details of his life. Born at Knockbain, Beauly, in Inverness-shire, he served his apprenticeship under Mr. W. Westwood, at Belladrum gardens, N.B., the seat of the late James Merry. He was next a journeyman at Drumlanrig Castle, under Mr. Thomson for two years. From thence he went to be foreman under Mr. J. Garrett, at Whittinghame Gardens. His next place was Wrotham Park, the seat of the late Earl Strafford, where he stayed for a year. From there he removed to the Viceregal Lodge, Dublin, as foreman under the late Mr. G. Smith, where he remained three years. Mr. McKenzie was then appointed head gardener to Lord Inchequin at Drumolond, County Clare, but stayed there only a short time, and returned to Scotland and served for a time under the late Mr. Dunn, at Dalkeith gardens, where he awaited a head place. He also went to Mr. David Thomson, when the latter opened Craigleith Nurseries. He next became head gardener to the late Dowager Duchess of Montrose at Riddlesworth Hall, Norfolk, in March, 1877; and finally was appointed gardener at Linton, under the late Viscountess Holmesdale, in August, 1882. On her death in 1884, he was engaged by the present owner, Mr. F. S. W. Cornwallis. It will be seen that Mr. McKenzie had a varied and first-class experience in many of the best known gardens in the country. *S. M.*

GOOSEBERRIES ON NORTH WALLS.—Mr. J. Fulton has been unfortunate in his selection of varieties, or the soil in his garden is unfavourable to their proper development. My experience with cordon-trained Gooseberries on walls having a northern aspect, has been altogether satisfactory. A member of the staff of the *Gardeners' Chronicle* visited these gardens in the year 1898, and referred to the cordon Gooseberries; mention was made to them appreciatively in the issue for October 29 of that year. I have proved for the past six years that fruit of better appearance and flavour for dessert can be grown by this method than any other. The Gooseberry, when well grown and ripened, has a flavour all its own, and is appreciated by a great many employers as much as a dish of Grapes, Peaches, or a Melon, especially late in September and October, when the glut is over, and I find by the empty dishes that they are highly appreciated. Gooseberries are extensively grown in these gardens on the cordon system, both on trellises in the open garden and on walls having a north aspect, and in both instances the results are so good that we do not grow them by any other mode of training, nor intend so to do. The advantages of the cordon system may be summed up thus: the trees obtain the maximum amount of sun and light, they take up less room than bushes; the fruit being well away from the earth, the fruits are not splashed with soil as they are apt to be on bushes; the fruit can be easily protected from birds, and by placing a double thickness of fish-netting over the trees the ripening of the fruits is retarded without detriment to their flavour; and if wasps attack them a piece of wasp-proof netting will preserve them; finally the fruit can be gathered with greater convenience. It would be hard to find a more lucrative fruit for planting against north walls than the Gooseberry. The plant is not overfastidious as to soil, though it delights in one having a dry, gravelly subsoil. The situation must be an open one, well away from the influence of large trees. The trees we have on a north wall 180 feet in length, and 10 feet high, are disposed 10 inches apart, and the surface of the wall is wired at 6 inches from wire to wire from the ground to the top of the wall. We prune them twice a year, viz., in the summer, when the young growths attain 9 inches or a foot in length, and again in the winter, when the spurs are shortened back to within two or three buds of the old wood. The trees are all trained on the single cordon system. The varieties grown for late use are chiefly Warrington, Pitmaston Greengage, Gregory's Perfection, and White Lion, though we depend chiefly upon the first-named. The thick-skinned varieties are without doubt the best for hanging late, as is the case with other fruits, notably Grapes. For trellises in the open garden we depend mainly upon Whinham's Industry, Whitesmith, Crown Bob, Red Champagne, Sulphur, and Antagonist. *H. T. Martin, Stoneleigh Abbey Gardens, Kenilworth.* [The results are excellent. ED.]

—— Your correspondent, p. 28, *Gard. Chron.*, Jan. 10, seems to me to wish to depreciate the Gooseberry as a dessert fruit. I am quite sure he has very much to learn if he thinks for one moment that the Gooseberry is not a popular fruit. My idea when I wrote the paragraph was to show that good, sound, and delicious fruit could be grown in the manner described. I said nothing about small, badly-flavoured fruits. Your correspondent seems to have drawn his own conclusions. Most gardeners when engaging with an employer study in every possible manner to cultivate those fruits, &c., which their employer desires. Some gardeners, I know, like to do the contrary. In cultivating Gooseberries to carry fruit late in the season, I was carrying out the wishes of my employer, who informed me that his favourite fruits were Gooseberries and Figs, and that Gooseberries he must have at any cost, because they contained the chemical properties which suited his ailment. Naturally, I turned to account every means to obtain fine fruit for as long a season as possible, nor was I confined to any number of bushes or varieties. Now, as to flies, wasps, and bees: your correspondent must have been very lucky to have alighted on a spot where none of these pests spoil the fruits. In a hot, dry season, if precautions are not used, a crop of sweet Gooseberries is soon cleared, and sometimes in spite of all the gardener can do, and not only Gooseberries, but Morello Cherries. Now as far as the merits of the Gooseberry or Melons are concerned, that is matter for individual opinion. Personally, I like a nice Gooseberry fresh from the bush in preference to the best Melon ever grown. In the north country, Gooseberries are much prized and splendidly grown, and in great variety and well shown. I consider all fruits are good when well grown, and some are highly valued by everyone; all of us have our likes and dislikes, and I for one claim that the Gooseberry makes a most welcome change in any dessert. *W. A. Cook, gr., Erlestoke Park.*

—— Mr. James Fulton must not imagine that everybody's taste is the same as his own in the matter of fruits. I planted a north border half the length of the kitchen garden, probably 80 or 100 yards, and 5 yards wide, with Gooseberries, mostly Red Warringtons, at Longleat, for the late Marquis of Bath, and covered it with ½-inch wire-netting. This supplied Gooseberries till very late in the season, frequently into November; and although the noble Marquis and his guests were not without other fruits of good quality, the Gooseberries were very much appreciated. *W. M. Taylor.*

—— It would, I think, have been more interesting if your correspondent "Old Gooseberry," had confined his remarks more strictly to the heading of my note "Late Gooseberries on a North Wall as a Dessert Fruit," but as he has not done so, it is unnecessary for me to say any more on the subject, unless to inform him that my experience in Gooseberry culture has not been confined to one locality as he seems to suppose, but in widely separated parts of this country, Scotland, and Ireland; and comparing the results of experience thus acquired, I have come to the conclusion already stated, viz., that the Gooseberry on a north wall is absolutely useless where fruits for dessert are required. *James Fulton, gr., Grims Dyke, Harrow Weald.*

AUDIBLE GROWTH.—There is a passage in Mr Peter Barr's communication from the Cape in your issue of December 20, 1902, where he alludes to the grass growing with such rapidity after rain that "you can hear it whistling," which receives a curious corroboration from Lieut.-General Sir Charles Warren's recent volume, *On the Veldt in the Seventies.*" At p. 95, Sir Charles writes: "A few days ago I lay down at the foot of a hill on the bare ground, shortly after the first rains, not a blade of grass near me, all night long I heard little clicks all about me, and at last I struck a light and waited till I heard a click, and then located it; then I found it came from a tiny blade of grass which had been folded up in its sheath and had suddenly escaped with a click. I am glad to have heard grass actually growing. I wonder who invented the term 'springing up,' as applied to grass, it exactly describes the operation." *W. T., Ipswich.*

ROSE MARIE LAVALLÉE.—Superlatives are greatly abused forms of speech. But for the benefit of those who grow climbing Roses it is worth saying that a Rose named Marie Lavallée was this year by far the most brilliant and conspicuous of some hundreds of different Roses on a pergola 150 yards long. I believe I got it from Nabonnand, but as I have not his catalogue I cannot be sure. I think it is offered by Guillot as Marie Levalley; I have not yet seen it in an English catalogue. *A. K. Bulley, Ness, Neston, Cheshire.*

VIBURNUM TINUS.—A few remarks on this plant, *anglice* Laurestinus, may be of interest to those who contemplate planting winter-flowering shrubs. Our bushes in early December were clothed from top to bottom with flowers and flower-buds, making a gay display. These plants are in fully exposed situations, and yet they were not at all injured by the severe frost which had occurred shortly before. For cutting purposes the flowers are valuable for their lasting qualities and beauty. A hedge of a height of 5 or 6 feet, and a proportionate width, is truly a fine sight when in flower; and this is a good mode of planting the Laurestinus. *J. Murray, Sopley Park, Christchurch.*

HYDRANGEA PANICULATA AS A FORCING PLANT.—Your correspondent, "S. C.," says, "I trust 'E. B.' did not conclude that this was *the* pruning." I cannot see how I could arrive at any other conclusion, as immediately following the sentence I quoted from his article he says, "In order to make the plant symmetrical, and induce buds at the bottom to break." He also gives details of housing the plant, but mentions nothing about any further pruning. I should not have troubled to take up any more of your valuable space on this subject, only that the proper pruning of this plant is an important factor in its successful culture, and I maintain that a beginner would not obtain the best results by following the lines of "S. C.'s" article; and in these days of competition, it is only a waste of time and money to put inferior and badly-grown stuff on the market. *E. B.*

ENGLISH CHESTNUTS.—Not to be guilty of a misnomer, I may be permitted to say Sweet or Spanish Chestnuts are produced abundantly, of goodly size and ripeness, in South Wales, if not "English." In the extensive park at Dynevor Castle, South Wales, a domain second to none in the British Isles for expanse and the beauty and variety of its views, numerous large fine trees produce freely of large well-coloured nuts six years out of every seven. Indeed, it is the rule for them so to do, the exceptions being very rare. So well do these trees bear that they are sought for each year by residential trespassers. I have not seen the tree mature the "nuts" in any

other part of England to anything like the same extent. Judging by the excellence of these Welsh nuts, there seems little doubt that crops may be grown in that part of the Principality; and certainly, they have been usually superior to the poor examples sold in this country during the present winter. But well known, early ripening, good varieties, such as Prolific, Downton, Masters' Canterbury, &c., should be grafted on stocks of La Châtaigne de Bois, &c., and the best of the French Marrons. *William Earley.*

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

JANUARY 13.—*Present:* Dr. M. T. Masters, F.R.S. (in the Chair); Messrs. Baker, Odell, Saunders, Worsdell, Bowles, and Holmes, Drs. Rendell and Cooke, Revs. W. Wilks and G. Henslow (Hon. Sec.).

Mezereon dying.—Mr. HOLMES showed specimens, and remarked upon the suddenness with which they died off. Dr. COOKE undertook to examine and report upon them.

Ranunculus arvensis.—He also referred to this plant as said by Sowerby to be poisonous to sheep.

Cedrus Deodara.—Mr. BOWLES exhibited a male catkin of this tree, which had become branched, bearing several branches, all being staminiferous.

Pinus Bungeana, bark.—Dr. MASTERS showed a specimen of the bark of this tree from China, which was silvery-white and scaling off. He mentioned that Abies arizonica had a similar bark, both resembling that of the common Birch.

Maize androgynous.—Dr. MASTERS also showed specimens, received from Mr. F. M. Bailey, of Brisbane, Queensland, of which the following were typical examples:—(1) This had one small cob of grains arising from the base of nine male spikes; single female flowers were scattered at intervals on the latter, both near the bases and summits. (2) Fifteen male spikes had one terminated with a small cob; isolated female flowers were scattered throughout among the male flowers. (3) This had about twelve male spikes, all being female below and terminated by male flowers above; the whole formed a dense mass of small cobs, giving the appearance of a prolific cob with male flowers above.

Practical Pollination. — Mr. DAVIDSON, of Fanners, Wickham Bishops, Essex, described an ingenious method of artificial fertilisation of flowers, as follows: "I have adopted a method of economising pollen, the ordinary camel's-hair brush being very wasteful. If a stick of sealing-wax be rubbed briskly on the coat-sleeve as for electrical experiment, and then presented to the flower, the pollen flies to it and adheres. Every particle can thus be utilised far more easily than with a brush."

Climbing Plants.—Mr. DAVIDSON also forwarded the observations he had made on Hoyas, &c.—"I have had a number of Hoya carnosa plants under observation for a considerable time, and though they twist resolutely enough in one direction during the day, the hours of darkness usually appear to have been a period of indecision, the work of the day being sometimes more or less undone during the night. While they are decided enough in twisting their way up living plants, they show no such decision in climbing up dead supports. For instance, if I slightly untwist a Hoya from a growing plant, it coils round again in a very short time; whereas, if a stick is substituted for a plant, the Hoya scarcely ever regains its old position without assistance." It was thought by the Committee that this difference was more due to the smooth or rough nature of the surface than the fact of the support being either alive or dead.

Yucca recurva.—Mr. WORSLEY sent some leaves, upon which Dr. COOKE reported as follows:—"The leaves of the Yucca recurva exhibit long dark streaks, which I have observed before, but could never attribute to any specific form of fungus. In the present instance I have failed to discover any hyphæ or spores, but probably if watched there might be some future development. At present there is no evidence of fungus parasitism, and I do not remember that any has been recorded as affecting the leaves of Yucca.

Loganberry Roots. — Mr. F. SHARPE, of Westbury, Wilts, sent some roots bearing nodules, upon which Mr. COOKE reports as follows:—"The nodules on roots of this plant resemble most of the root nodules which I have examined in giving no definite clue to any parasitism. There is no evidence of the presence of bacteria so far as I can detect (350 diams.); and nothing has resulted from preserving them for twelve days in a damp atmosphere."

Celeriac. — Dr. COOKE reports as follows upon the specimens sent to the last meeting:—"Roots marked with discoloured blotches or stains internally, and sometimes in circles or segments, at a short distance from the periphery. The discolored tissue did not exhibit any trace of hyphæ or anything further than the discoloration of the cell contents. I can see no indication or suspicion of fungus parasitism." The thanks of the Committee were given to Dr. COOKE for his report.

Peas Attacked by Grubs.—Mr. BAKER brought a sample of wrinkled Peas badly attacked by grubs, upon which the following report was made:—"There is nothing whatever in the condition of the Peas to indicate any injury beyond that produced by the magget which is common in green Peas. It is always the case in shelling culinary Peas that a certain proportion is maggoty. The condition of the sample is entirely due, in my opinion, to the fact that the wet and cold summer greatly increased the proportion of maggoty seeds. Not one of the seeds appeared to be attacked by the Pea-weevil, and wrinkled Peas grown in England are very seldom weeviled. The only Peas of English growth usually attacked are the early, round-seeded kinds, and then only in hot, dry summers, and when grown on light, dry soil. I doubt whether any sample of English Peas of last year's harvest was at all seriously attacked by the weevil owing to the absence of sun and heat."

Statistical Variations.— Mr. HENSLOW drew attention to a paper in the *Botanical Gazette*, vol. xxxiii., p. 462, on "The Numerical Relation of the Ray Flowers of Compositæ," by Mr. E. Mead Wilcox, in illustration of the mathematical and statistical study of variation, as throwing light upon the origin of species. Mr. Henslow expressed his disbelief in any advantage accruing from the statistical method, because such statistics are only based on "individual variations," which do not give rise to variations of which systematists can take any account—i.e., as long as the plants are living under the same conditions of life. They are merely fluctuating details, due to the qualities of growth.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.

WORCESTER AUXILIARY.

THE annual meeting of the Worcester Auxiliary of the Gardeners' Royal Benevolent Institution was held at the Guildhall on Saturday evening, the 17th inst., Mr. C. E. Pipe in the chair. The seventh annual report expressed thanks to Earl Beauchamp for allowing his grounds and gardens at Madresfield Court to be thrown open for the benefit of the Fund, the proceeds of which realised £45 12*s.* 10*d.* It recorded that Mr. Jno. Bates, the Worcestershire candidate, who was supported at the last election of pensioners, obtained 1,528 votes, and solicited further support. To commemorate the Coronation of the King and Queen (patrons of the Institution), the general committee, London, voted £5 from the "Good Samaritan Fund" to each unsuccessful candidate who had not previously subscribed to the Institution, including Mr. Bates. All the unsuccessful candidates who had subscribed were put on the funds without further election.

The accounts showed receipts amounting to £123 2*s.* 4*d.* Expenses, including a grant of £110 to the parent society, having been paid, a balance in hand was left of £5 14*s.* 3*d.* The accounts had been audited by Mr. C. E. Pipe. Mr. White added that a grant of £50 would be made shortly, which would bring the contributions of the auxiliary to £670 for the seven years it had been in existence.

The accounts and report were adopted on the motion of Mr. Crump, who said that in sending up to the parent society nearly £100 a year they had done better than any other auxiliary. Mr. Hurlstone seconded. Mr. G. Gough moved, and Mr. Hurlstone seconded, the election of Lord Beauchamp as president, which was carried.

Mr. Crump moved that some scheme be adopted for systematically canvassing the gardeners employed in the county to become subscribers to the Institution. Mr. Crump's motion was carried. The committee was re-elected, with the substitution of Mr. Myatt for Mr. A. Russell.

A sum of £12 from the proceeds of the opening of Madresfield Gardens was offered to eight members on the condition that each paid five guineas, and the total of ten was sent to the parent society as a life member's subscription, and that the member became an annual subscriber.

BRISTOL & DISTRICT GARDENERS' MUTUAL IMPROVEMENT.

A VERY successful meeting of this association was held at St. John's Rooms on the evening of Thursday, when Mr. J. C. House, Coombe Nurseries, Westbury-on-Trym, delivered an excellent lecture on "Hardy Herbaceous Perennial Plants." Lieut.-Col. H. Cary Batten, J.P., presided over a good attendance, and was accompanied by Mrs. H. Cary Batten, their presence adding much to the enjoyment of the evening.

Mr. House advocated the more general employment in the garden of these beautiful plants, not to the exclusion of bedding plants, but to the reduction of the numbers of the latter, and as a means of adding floral beauty to the garden to the latest time possible in the autumn.

The lecturer gave a comprehensive list of the more beautiful plants that would succeed in Bristol and the surrounding district.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

TWELVE new members were elected at the last meeting, four of these, however, being over thirty-five years of age, are elected subject to the production of their certificate of birth. Nine members were reported on the sick-fund. Messrs. W. Gunner and T. H. Puzey were re elected to audit the accounts for the past year.

INTERESTING PRESENTATION.

THE Gloucestershire Root, Fruit, and Chrysanthemum Society celebrates its fortieth anniversary this year, and in recognition of the conspicuous and valuable services rendered to the Society by Mr. Sidney S. Starr, the secretary, he was presented by the members on Saturday, January 17, with a handsome gold watch and a purse of gold.

The Society has done excellent work in the county in bringing about improved results in farming, and in the more general culture and love of the Chrysanthemum; but it has also suffered in its earlier history from the very prevalent complaint, "want of funds." In 1895, when Mr. Starr was appointed secretary, a deficit was turned into a balance in hand, and to-day the Society is more popular than ever, with a score more classes in the schedule than formerly, over 200 more entries at the last show, and about 100 more subscribers, while some £50 more was offered in prizes. That this improved condition of things is mainly due to the energetic labours of Mr. Starr was recognised by the valuable presentation of which he was made the recipient on Saturday.

NATIONAL FRUIT-GROWERS' FEDERATION.

JANUARY 12.—The above committee held a meeting at the Westminster Palace Hotel on the above date. There was a large attendance, and Col. C. W. Long, M.P. (President of the Federation), occupied the chair. The following members were present:—Messrs. A. Grant, W. Horne, H. Leney, F. Smith, Jno. Wood, C. H. Hooper, A. Miskin, A. S. White, W. Idiens, J. Idiens, A. H. H. Matthews, G. Manwaring, W. Freemantle, J. Evans, T. May, and A. T. Matthews (Secretary). The most important business at this meeting was the consideration of the best type of ventilated van for the conveyance of fruit, as to the building of which, certain railway companies are consulting with the Advisory Committee, and the official reply to the letter of the Board of General Managers in answer to the deputation of November 4. This reply was carefully drawn up, and directed to be despatched. It will be remembered that at the conference at the Clearing House it was proposed that a special advisory committee of the Federation should be appointed to confer with the railway officials on the details of the proposed reforms, and it is understood that this arrangement is already being carried out, and working very successfully. This gives the Federation a standing-ground never before even thought of by a growers' society, and justifies the expectation of great results. Meanwhile the organisation is spreading throughout the country, and its list of members growing steadily from week to week.

READING & DISTRICT GARDENERS' MUTUAL IMPROVEMENT.

THE annual general meeting of the above association was held on Monday, the 12th inst., and was well attended. The report and the balance-sheet were presented by the secretary, and showed the association to be in a flourishing position. There had been an increase in the membership during the year; the total at the end was 223. The officers and committee were elected as follows:—President, Mr. Leonard Sutton,

for the third year in succession; Chairman, Mr. J. T. Powell, gr. at Park Place, Henley-on-Thames; Vice-Chairman, Mr. W. Barnes, gr. at Bear Wood; Librarian, Mr. E. J. Dore; Assistant Librarian, Mr. F. W. Exler; Treasurer, Mr. F. W. Macdonald; and Hon. Sec., Mr. H. G. Cox, were re-elected to their respective offices.

SCOTTISH HORTICULTURAL ASSOCIATION.

JANUARY 13.—The annual general meeting of the Scottish Horticultural Association was held at 5, St. Andrew Square, Edinburgh, on the above date—Mr. Charles Comfort, President, in the chair; there was a large attendance. The annual report, which was read by the Hon. Secretary, Mr. Peter Loney, stated that the past year had witnessed continued success in the affairs and objects of the Association. The papers read during the year had been full of interest and of educational value, and the attendance had been large and representative. The exhibits at some of the monthly meetings had also been highly creditable. The membership was now 1,180; 147 new members having been added during the year of whom fifteen were life members. Several names had been deleted from the roll, owing to the want of addresses and other causes. The Association tendered hearty thanks to those who, by their willing assistance, had contributed to the success of the show. Mr. McHattie, in moving the adoption of the report, said a hard but well won fight was the reflection with which they had closed their ledger for this year, and they opened the new one with the knowledge that they were able and willing to engage in a struggle to maintain the reputation of the Association, if necessary. He hoped they would all support the Association heartily. The report was agreed to. The financial statement showed a credit balance on the Chrysanthemum show of £91 8*s.* 3*d.*, and the funds of the Association at December 31 amounted to £378 12*s.* 2*d.* A short discussion ensued as to the circumstances under which the Association held thirty-five votes on the Gardeners' Benevolent Association, and it was agreed that the President and Council should look into the matter, and report to the next meeting. The financial statements were approved of. The following office bearers were appointed:—Hon. President, the Most Noble Marquis of Lluithgow; Vice-Presidents, James Whytock, Dalkeith; Charles Comfort, Bloomfield gardens, Davidson's Mains. Council, Thomas Fortune, Alexander Johnston, George Wood, J. Anderson, Alexander Sclater, David W. Thomson, W. Copeland; President, J. W. McHattie. *The "Scotsman."*

CROYDON HORTICULTURAL MUTUAL IMPROVEMENT.

THE third Annual Dinner and Smoking Concert in connection with the above named Society was held at the Café Royal, Croydon, on the 14th inst., under the Chairmanship of Mr. J. J. Reid, one of the Vice-Presidents of the Society; Vice-Chairman, Dr. J. Brooke Ridley, and a pleasant evening was spent.

ROYAL CALEDONIAN HORTICULTURAL.

JANUARY 14.—The Annual General Meeting of the Royal Caledonian Horticultural Society was held on the above date in Dowell's Rooms, George Street, Edinburgh, Mr. D. P. Laird presiding over a large attendance.

Mr. P. Murray Thomson, Secretary, read the Council's Annual Report, which stated that the change of the date of the spring show last year from the beginning of April to the beginning of May proved a success as regards the attendance, and as an exhibition of horticulture the show did not in any way suffer. The entries numbered 511, compared with 500 in 1901. One encouraging feature was the interest shown in the competition for plans prepared by under gardeners, twenty one plans being sent in: and the Council had pleasure in reporting that Sir John Gilmour had again placed at their disposal the sum of £5 to continue this competition. The total entries for the autumn show of 1901 were 2,182, and for the same show in 1902 were 2,410. A special effort was made towards the close of last year to increase the membership, when the President (Lord Balfour of Burleigh) issued a letter containing printed particulars of the Society. The effort met with good result. During the year the Society lost by death and resignation 36 members, while 19 life members and 154 annual members had joined, a nett increase of 137 1901 was the first year when gardeners and horticultural *employés* might be enrolled at 5*s.* Thirty-eight were then enrolled; and during the past year 43 new members had been enrolled. The surplus of the fund raised to provide a memorial of the late Mr. Malcolm Dunn, gr. at Dalkeith Palace, had been invested for the purpose of providing an annual prize in horticulture, and the trustees had offered the prize for the first year to the Society. It would be given as the 1st prize at the autumn show for a collection of Apples grown in Scotland. The financial statement showed that the ordinary receipts amounted to £1 272, being £1 15*s.* 10*d.* more than the payments, while the capital account received an addition of £165 18*s.* from life members' subscriptions. The funds amounted to £715 17*s.* 7*d.*, as against £557 a year ago.

On the motion of Mr. William Mackinnon, seconded by Mr. David Thomson, the Report and the balance-sheet were adopted.

Mr. J. Martin White, of Balruddery, was elected Vice-President, and the following members of Council were appointed:—gardener, Mr. J. W. McHattie, Edinburgh City gardener; nurseryman, Mr. John Methven, Edinburgh; independent member, Mr. A. D. Richardson, Edinburgh. *The Scotsman.*

GARDENERS' ROYAL BENEVOLENT INSTITUTION.

ANNUAL MEETING AND ELECTION OF PENSIONERS.

JAN. 23.—The sixty-fourth annual general meeting of the members and subscribers of this excellent Institution, was held at "Simpsons," Strand, on Thursday last, as these pages were passing through the press.

Mr. Harry J. Veitch, Treasurer and Chairman of the Committee presided, and there was a satisfactory attendance. After the reading of the minutes, the report of the Committee, and the accounts of the Institution (as audited) for the year 1902 were adopted unanimously and with satisfaction. Officers for the ensuing year were elected, and other business of a routine character transacted.

The Chairman read the following letter from Mr. N. N. Sherwood, a generous supporter of the Institution:

"I am grieved indeed to see there are so many applicants for the Pension this year who cannot possibly be elected. I read with great interest the letter in the [*Gardeners'*] *Chronicle* of last Saturday, and I wish to give each of the unsuccessful candidates, who have been subscribers, the sum of £5. I do this with great pleasure as a thank-offering for my recent recovery from my illness."

The following resolution was passed with acclamation, "That the action of the Committee, graciously approved by the President, H.R.H. the Prince of Wales, in placing on the funds the eleven unsuccessful candidates, formerly subscribers to the Institution, to commemorate the Coronation of their Majesties the King and Queen, Patrons, be, and is hereby confirmed."

The Committee reported that during the year 1902 the following widows of pensioners have been placed on the funds without election in accordance with Rule iii., 13:—Mary E. Mackintosh, aged 71; Sarah Trotter, aged 81, and Mary Ann Wilder, aged 69.

The Committee also recommended that fifteen candidates be elected pensioners on the funds that day. The poll opened at 3.15 and closed at 4.30 P.M., with the following result:—

1	JANE KENT	6741 Votes
2	JANE TEMPLE	4216 ,,
3	W. B. GLASSCOCK	3308 ,,
4	EMMA HONESS	3195 ,,
5	JOHN BATES	3063 ,,
6	W. J. STACEY	3056 ,,
7	RACHEL TEGG	3046 ,,
8	CHARLES PUZEY	3015 ,,
9	GEORGE R. ALLIS	2991 ,,
10	STEPHEN BRACEBRIDGE ...	2968 ,,
11	WILLIAM WALL	2878 ,,
12	WILLIAM DARVEL	2850 ,,
13	ROBERT C. ALLISTON ...	2825 ,,
14	JAMES LEVELL	2761 ,,
15	ELIZABETH GOWER ...	2602 ,,

There were thirty-one unsuccessful candidates. Of the fifteen elected ten had contributed to the Institution, and five had not. Mary Dounan and John Price, each of them 83 years of age, were subsequently placed on the Funds by a right vested in the Committee.

In the evening the Annual Friendly Supper took place also at "Simpsons."

NATIONAL DAHLIA.

THE schedule of prizes to be offered at the next grand annual exhibition of this society, to be held at the Drill Hall, Buckingham Gate, Westminster, on September 1 and 2, will include a new departure of considerable interest to exhibitors. As the result of a general subscription amongst members, three Silver Challenge Cups will be offered for competition, namely, a Ten guinea Cup in the premier Cactus Dahlia class for nurserymen (eighteen varieties in bunches of six blooms each); a Ten-guinea Cup in the premier Cactus Dahlia class for amateurs (nine varieties in bunches of three blooms each); and a Five-guinea Cup in the premier class for show and fancy Dahlias, amateurs (twenty-four blooms, distinct).

In addition to the above, Messrs. Dobbie & Co., Rothesay, will present a Gold Badge, value three guineas, for twenty-four blooms Cactus Dahlias, distinct varieties (amateurs), the gift to be repeated at the two following exhibitions of the society in 1904 and 1905. The prize-money in this class (Class 24, which is altered from eighteen blooms to twenty-four blooms), and in that for nine varieties in bunches of three blooms, has been increased, and three new vase classes have been added.

The annual report and schedule for 1903 will shortly be issued to members.

CHINESE MAPLES.

(*Continued from p.* 22)

ACER.—The Chinese species of Maple exhibit, if we exclude the peculiar American Negundo, practically every type that is known in the genus. The primitive type of foliage in Acer is the simple entire leaf, such as occurs in Acer oblongum. From this we proceed to simple toothed or dentate leaves; then we have species with tri-lobed leaves, and others with five to seven-lobed leaves. Trifoliolate species mark in China the limit of evolution. In American Negundo, the leaves become further decompound in the species with five leaflets arranged in pinnate fashion. In the following list, I make a few remarks concerning each species, noting those that may be seen now in Coombe Wood. I omit species that have not been collected by Mr. Wilson and myself, and it is possible when the whole of Mr. Wilson's specimens are examined carefully, that other species may be added.

SIMPLE-LEAVED SPECIES.

1. *Acer oblongum*, Wall.—This is a common tree in Hupeh and other parts of China. It also occurs in Formosa and in the Himalayas. It grows wild in a diversity of climates, and is as much at home in the Botanic Gardens of Calcutta as in the mountain forests of the Himalayas. It has oblong or ovate acuminate coriaceous leaves, quite entire in the margin. It displays great variation, both in fruit and in foliage, and Pax enumerates several distinct varieties, as—

(*a*) *A. glaucum*, Schwerin.—This is the commonest form; in it the leaves are glaucescent underneath.

(*b*) *A. latialatum*, Pax, with fruit having broad wings; this occurs in Hupeh.

(*c*) *A. concolor*, Pax.—The leaves underneath are green, and not glaucous. Hupeh.

The variety *microcarpum*, Hiern, of the Mishmi Hills, with small fruit, is also met with in the Loochoo Islands. In the Kew herbarium, my 3199A from Hupeh is perhaps the most interesting variety; it may be styled *var. triloba*, Henry. In this the leaves become tri-lobed, and the margin is remotely but sharply serrate. This specimen was taken from a lower branch of a very large tree growing near Ichang. The foliage of the upper part of the tree was of the ordinary type.

2. *Acer lævigatum*, Wall., occurs in Szechwan, and also in Hong Kong and the Himalayas. This has foliage like the last species, but distinctly reticulate, and green on both sides.

3. *Acer, sp. nova* (?)—Collected by Mr. Wilson, in Hupeh. This resembles the two preceding species, but seems distinct.

4. *Acer cordatum*, Pax.—The leaves are papery, reticulate, cordate at the base, and minutely serrulate. Hupeh.

5. *Acer stachyophyllum*, Hiern.—This has serrate, ovate, caudate-acuminate leaves, hoary-velvety on the under surface; it is in cultivation at Coombe Wood, and is a pretty species. It was described by Hiern from Himalayan fruiting specimens, the flowers being unknown. Pax described a new species, *A. tetramerum*, from young flowering branches, collected by me in Hupeh; and he had only male flowers. I think this species of Pax will turn out, when Mr. Wilson's specimens are examined, to be the same as Hiern's earlier-described species.

6. *Acer Davidi*, Franchet.—Hupeh and Szechwan. This has coriaceous, acuminate, simple crenulate-dentate leaves. It is in cultivation at

Coombe Wood, and is close to *A. Hookeri*, Miq., a Himalayan species. Two forms occur, one with the leaves somewhat tomentose beneath, and the other glabrescent in the adult stage.

7. *Acer sikkimense*, Miq.—A variety of this with serrulate leaves occurs in Yunnan (my No. 10,640). This species is close to the last-named; but the fruit is borne on very short pedicels, or is almost sessile.

8. *Acer laxiflorum*, Pax.—This was described from specimens found by Mr. Pratt, at Tachienlu, on the confines of Tibet. The leaves and flowers are contemporaneous. The leaves are dentate-lobulate, and sharply serrate; they are borne on long petioles, and have long acuminate points. This species was found by Wilson in Hupeh, and is in cultivation at Coombe Wood. *Augustine Henry.*

(To be continued.)

WAS BOTTICELLI A BOTANIST?—In a picture in the National Gallery, representing the Ascension of the Virgin, the lid of the tomb is represented in process of removal, and showing the interior of the sarcophagus filled with white Lilies, some twenty or thirty, perhaps, in number; but all, without exception, with five segments to the flower. In another picture by GIOVANNI BELLINI, representing St. Dominic, the Lily is also represented with five perianth-segments. We fear the artists painted from fallacious memory, and that the addition of a sixth petal since the fifteenth or sixteenth century is not to be regarded as the result of evolution.

Remarks.—A dry week, with very cold, north-east winds, and rain on the evening of the 17th inst.

GENERAL OBSERVATIONS.

THE FOLLOWING SUMMARY RECORD of the weather throughout the British Islands, for the week ending Jan. 17, is furnished from the Meteorological Office:—

"The *weather* during this period was very cold and wintry. Snow fell in many places during the first day or two, but the conditions subsequently became dry generally until Friday or Saturday. On the former day rain was experienced over the south-western parts of the Kingdom, heavily in the south of Ireland, and on the latter, sleet or cold rain fell over the western, central, and southern parts of England. Thunder was heard at Fort William both on Wednesday and Friday, and there was a "silver thaw" in London, on Saturday evening.

"The *temperature* was as much as 16° below the normal in the Midland Counties, 9° in Scotland, W., and the western half of England, and between 8° and 6° in other parts of the Kingdom. The highest of the maxima were recorded as a general rule, towards the end of the period, and ranged from 50° in the Channel Islands, and 49° in Ireland, S., to 40° in Scotland, E., England, N.E., and the Midland Counties. At inland stations the daily maxima during the week were frequently below 32°, and at Lairgon, on Tuesday, the highest reading was no more than 20°. The lowest of the minima were mostly recorded about the middle of the week. In Scotland, N. (at Braemaron, on the 13th), the screened thermometer registered a minimum of 1°, and on the following day, that at Lairg, Scotland, N., fell to 6°. Elsewhere, however, the minima ranged from 12° in England, N.W., and 13° in the Midland Counties, to 20° in Ireland, S. and 25° in the Channel Islands.

"The *rainfall* was less than the mean, and in some districts the fall was scarcely appreciable.

"The *bright sunshine* exceeded the mean generally, but was deficient in Scotland, E. and W., and England, N.E. The percentage of the possible duration, ranged from 41 in England, N.W., 39 in the Midland Counties, and 37 in England, E. and S., to 13 in Scotland, E., and to 12 in Scotland, W."

THE WEATHER IN WEST HERTS.

THE present cold period, which has now lasted ten days, has been chiefly noteworthy for the dry and searching character of the easterly winds in the early part of it, and during the last few days, for a "silver thaw," followed by a singularly calm and moist atmosphere, also for the almost entire absence of snow. On five consecutive nights the exposed thermometer registers from 15° to 19° of frost—the latter by no means an exceptionally low reading for January. The ground is now about 10° colder at one foot than before the frost set in. Rain, hail, and sleet fell several days, but the total measurement amounted to little more than a ¼ inch. The fall of rain, sleet, and ice crystals on the night of the 17th, on reaching the frozen ground caused what is termed a "glazed frost," or "silver thaw," so that on the following day the roads and pathways were covered with a thin sheet of ice, and consequently extremely slippery. For only one day was the passage of water through the percolation gauges entirely stopped by the frozen state of the ground. For the seven days ending the 16th, the record of clear sunshine averaged nearly four hours a day, but since then the weather has been exceptionally gloomy. The winds and light airs have come exclusively from some easterly point during the whole of the cold period. The 18th was a particularly cold day, the mean rate of movement of the air being less than a quater of a mile an hour. The atmosphere remained very dry until the 18th, but since then it has been saturated with moisture. On the 14th, the relative humidity of the air at 3 o'clock in the afternoon (100 being taken as complete saturation) was 52, indicating a drier air than any yet recorded here in the month of January. *E. M., Berkhamsted, January 20, 1903.*

MARKETS.

COVENT GARDEN, January 22.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Thursday, by the kindness of several of the principal salesmen, who revise the list, and who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but often several times in one day. ED.]

REMARKS.—Cape Peaches per box of 18 to 24, made from 12*s.* to 24*s.*; Apricots, boxes of 24 to 30 made 10*s.* to 12*s.*; Grape fruits are 10*s.* to 12*s.* a box; Sweet Potatos per cwt., 12*s.* to 14*s.* The late frost stopped the supply of English Spinach; that which is quoted is French produce. Apples remain much about the same in price as last week, and the only English fruit in request are good Wellingtons. There are no good Pears on sale at the present time.

POTATOS.

Various samples, 77*s.* to 90*s.* per ton; Dunbars, red soil, 105*s.* to 115*s.* *John Bath, 32 & 34, Wellington Street, Covent Garden.*

FRUITS AND VEGETABLES.

GLASGOW, *January 21.*—The following are the averages of the prices during the past week:—Apples, American Baldwins, 11*s.* to 14*s.* per barrel; Canadian ditto, 14*s.* to 16*s.*; ditto, Kings, 20*s.* to 26*s.*; Greenings, clear fruits, 12*s.* to 14*s.*; various high-class red, 14*s* to 18*s*; do., green, 16*s.* to 18*s.*; Oranges, Valencias, ordinary, 420's, 6*s.* 6*d* to 7*s.* per box; large ditto, 9*s.* to 12*s.* ditto; 714's, 8*s.* to 9*s.* ditto; Onions, Valencia, 4*s.* 9*d.* to 5*s.* 6*d.* per cwt.; Lemons, 4*s.* to 5*s.* per box, and 7*s.* to 12*s.* per case Grapes, English, 1*s.* 9*d.* to 3*s.* per lb.; Almeria ditto 12*s.* to 20*s.* per barrel.

LIVERPOOL, *January 21.—Wholesale Vegetable Market.*—Potatos, per cwt.: Main Crop, 3*s.* 6*d.* to 4*s.*; Up-to Date, 3*s.* 2*d.* to 3*s.* 6*d.*; Bruce, 3*s.* 3*d.* to 3*s.* 9*d.*; Turnips, 6*d.* to 8*d.* per dozen bunches; Swedes, 1*s.* 2*d.* to 1*s.* 3*d.* per cwt.; Carrots, 2*s.* 3*d.* to 2*s.* 9*d.* do.; Onions, English, 4*s.* to 5*s.* 6*d.* do.; do, foreign, 2*s.* 9*d.* to 3*s.* 6*d.* per bag; Parsley, 6*d.* to 8*d.* per dozen bunches; Cauliflowers, 1*s.* 6*d.* to 2*s.* per doz.; Cabbages, 6*d.* to 10*d.* do.; Celery, 6*d.* to 1*s.* 3*s.* do. *St John's.*—Potatos, 10*d.* to 1*s.* per peck; Cucumbers, 6*d.* to 1*s.* each; Grapes, English, 2*s.* to 3*s.* per lb.; do., foreign, 6*d.* to 8*d.* do.; Pines, foreign, 3*s.* 6*d.* to 6*s.* each; Filberts, 8*d.* per lb.; Mushrooms, 1*s.* 6*d.* do. *Birkenhead:* Potatos, 10*d.* to 1*s.* per peck; Grapes, English, 1*s.* 6*d.* to 3*s.* 6*d.* per lb.; do, foreign, 6*d.* to 8*d.* do.; Mushrooms, 1*s.* per lb.; Filberts, 8*d.* do.

CORN.

AVERAGE PRICES of British Corn (per imperial qr.), for the week ending Jan. 17, 1903, and for the corresponding period of 1901, together with the difference in the quotations. These figures are based on the Official Weekly Return:—

Description.	1902.	1903.	Difference.
	s. *d.*	*s.* *d.*	*s.* *d.*

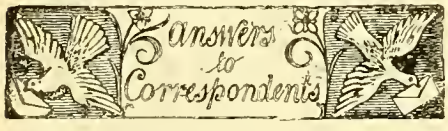
Oats	20 0	16 10	— 3 2

ENQUIRY.

SOUVENIR DE LA MALMAISON CARNATIONS FOR MARKET.—Will some readers of the *Gardeners' Chronicle* kindly furnish a note describing market growers' methods of cultivating this plant for the information of *A. W.*?

REPLY.

AUSTRALIAN MATCHES.—With reference to the enquiry in the *Gardeners' Chronicle* of Sept. 13, as to the woods used for matches in the Australian colonies, I beg to say that matches are not at present made in these colonies. We use an enormous quantity of wax matches; and the wooden matches are chiefly imported from England, Sweden, and Japan, the woods used in which are, of course, well known to you. *J. H. Maiden, Sydney.*



⁂ NOTICE.—Owing to the crowded state of our columns, several reports of society meetings and other communications are being held over till our next issue.

⁂ EDITOR AND PUBLISHER.—Our correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all communications relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication, or referring to the literary department, and all plants to be named, should be directed to the EDITOR. The two departments, publishing and editorial, are quite distinct, and much unnecessary delay and confusion arise when letters are misdirected.

AMERICAN BLIGHT ON APPLE AND PEAR-TREES: *Anxious.* Strong soap-suds made with soft soap, at the rate of 4 oz. per gallon of hot water, is a safe and effective remedy. First spread a sheet, new garden-mat, or tarpauling beneath the infested tree, and with a knife scrape and cut away all rough bark, especially in crevices and angles of the branches, then with a stiff scrubbing-brush apply the soap-wash to every part. Clear away the sheet, &c., and burn everything that has dropped on to it. A second application may be made before the wood-buds burst. Uncover the roots, and dreuch the soil about them with soap-suds, wheeling away the excavated soil and burying it at a spot widely distant from the trees; or better still, char it. Fresh soil may be placed over the roots, and made very firm. More than one annual application is needed to rid trees of the blight.

CRICKETS: *A. G.* As all other methods of killing and trapping have failed, we would advise that bell-glasses or 10-inch flower-pots be sunk in the bed, so as to be flush with the surface of the Melon-bed; a piece of slate or tile being placed under the pots and glasses, and some kind of bait put into each. By this means thousands can be caught.

CUTTING SEVERELY BACK THE LIMBS OF AN EVERGREEN OAK: *J. G.* The tree may be operated upon at the present season with every chance of your obtaining a good break of shoots in the course of the year. Let the wonnds be painted with lead colour, and afford them sheet lead cappings if you would make them impervious to wet for a number of years.

DESTRUCTION OF HORSE CHESTNUT-TREES: *A.D.W.* The fungus causing the death of these trees, as reported, and from the specimens sent, is Stereum purpureum, which has never before been charged with killing trees, although it is common on dead bark. Possibly, like its congener, Stereum hirsutum, it is a "wound parasite," and thus effects its purpose. It would be interesting to learn how it attacks the trees it destroys. Stereum purpureum is charged with causing the silver-leaf disease of Peaches. *M. C. C.*

ETHER IN FORCING PLANTS: *X. Y. Z.* This subject was mentioned in the *Gardeners' Chronicle* in the last volume, at pp. 379, 459, and 475.

FUNGUS ON STALE CHICKEN-FOOD: *G. H. E.* Phycomyces nitens—a mucor, commou on fat and greasy substances generally. *M. C. C.*

HABENARIA SUSANNÆ: *W. M.* We have not noticed the flowers of Habenaria Susannæ turn brown. Probably the dull weather may account for yours having done so this year.

NAMES OF FRUITS: *W. B.* 1, not recognised; 2, The Queen; 3, Edmund Jupp; 4, very fine fruit of Scarlet Pearmain.—*E. L.* Dumelow's Seedling.

NAMES OF PLANTS: *Correspondents not answered in this issue are requested to be so good as to consult the following number.*—*Land.* 1, Plantago media; 2, Dryas octopetala; 3, Cystopteris fragilis; 4, Phyteuma spicatum (Campanulaceæ); 5, Valeriana officinalis (not an Umbellifer.—*J. J. B.* The plant belongs, probably, to Galiaceæ; but something more than a mere sketch without flowers is wanted to determine the order with certainty.—*P. J. P.* Male flowers of Garrya elliptica.—*C. S. & S.* Quercus cuspidata. If the percentage of salt is not more than ·010, we do not think there would be much risk in planting Rhododendrons or Camellias. Can you not try on a small scale first?—*Vesta.* 1, Cattleya Percivalliana; 2, Cattleya Trianæi; 3, Cattleya labiata; none of these are properly developed, and we are not surprised that you should not see the difference in the two last named, although the plants were bought under the names we give. —*G. G.* Odontoglossum maculatum; the variety is peculiar, in that it has but few markings on the lip.—*Foreman.* 1, Restrepia antennifera; 2, Phaius grandifolius; 3 and 4, Odontoglossum crispum; 5, Odontoglossum tripudians.—*Bromfield.* 1, Cypripedium Lecanum; 2, Begonia carminata rosea; 3, Lastrea lepida; 4, a form of Adiautum capillus-veneris; 5, Davallia polyantha, so far as we can judge by the immature barren frond; 6, a distinct form of Cypripedium insigne.—*X. Y. Z.* 1, Dendrobium × Ainsworthi; 2, Dendrobium nobile Cooksoni; 3, Dendrobium nobile.

PELARGONIUMS: *J. T. Y.* We have seen many such cases this year. There is no fungus visible, and we can only suppose that the plants have been growing when they should have been at rest, and that the new growths have suffered from the fluctuations of temperature and moisture, to which they have been exposed.

THE ORCHID-HOUSES IN OUR LAST ISSUE. *A.* Bad caligraphy was the cause of C. Euryades being given as C. Euryale, the latter a summer or late spring flower.

ZONAL PELARGONIUMS: *Zonal.* Being autumn-struck plants, you should pot in large 60's at the commencement of February, in loam two-thirds, and one-third leaf-mould or decayed horse-dung, and a small quantity of sharp sand, and place in an intermediate-house 50° to 60°, standing them near the roof so as to avoid spindly growth. Pinch out the point of the stem, afford water sparingly at the first, repot when the roots have permeated the soil, this time in 6-inch pots, and still keep them in the intermediate-house; tie out the shoots, nip out the points once more, afford air whenever the weather admits, and when the roots have reached the sides in great numbers afford a shift into 8-inch pots, place in a greenhouse, and keep slightly close for a week or two. The potting at each stage should be done with firmness, but no rammer must be used, and plenty of room should be left at the top of the ball for applying water. Do not crowd the plants, or allow them to get infested with aphids.

COMMUNICATIONS RECEIVED.—W. R.—R. I. L.—G. B., with thanks—M. M. Bruant-A. W.—J. W. McHattie—J. M.—G. H. G—A. W.—S. C.—F. J. F.—C S. & S.—W. Lewis—J. W., Ipswich—J. M.—W. C.—H. J. C.—Expert—J. F.—A. DIED.—Many of our readers will learn with regret of the death, on the 19th instant, of Christina, youngest daughter of Mr. John Forbes, nurseryman, at Hawick, Roxburghshire, at the age of 21 years.

GARDENING APPOINTMENTS.

MR. J. WALLACE, for the past nine years Head Gardener at North Runcton Hall, King's Lynn, as Gardener to Mr. T. WILD, The Vineries, Drayton Road, Sipson, Yiewsley, Middlesex.

Mr. THOS. HATTON, until recently Head Gardener at Badgemore House, Henley-on-Thames, as Gardener to the Earl of CLANWILLIAM, at the same place.

Mr. D. M. MCKINNON, Gardener to F. A. NEWDIGATE NEWDEGATE, Esq., M.P., Weston-in-Arden, Nuneaton, as Gardener to that gentleman at Arbury Priory, Nuneaton.

Mr. JAMES STEWART, for the past five years Foreman in the Gardens, Belleisle, Ayr, N.B., as Head Gardener to Lady EMILY and W. VAN DE WEYER, New Lodge, Windsor.

Mr. G FREEMAN, Gardener for twenty years at Akeley Wood House, Buckingham, as Head Gardener to R. A. POLEHAMPTON, Esq., Field Burcote, Towcester.

Mr. H. B. JOHNS, recently Gardener at Burton Hall, Wirral, as Head Gardener to Sir HENAY COCHRANE, D.L., Woodbrook, Bray, co. Wicklow. Entered on his duties November last.

DAME PERTELOT'S HERBS.

THOSE acquainted with the works of Chaucer, cannot but have been amused while reading the chiding bestowed by Dame Pertelot on Chaunteclere for imagining that his dreadful dreams were omens of impending evil; while she, void of sentiment, attributing their occurrence to biliousness, warned him of real ills that would certainly overtake him if her advice was neglected. Happily for Chaunteclere, his wife, like other old-world dames, while able to diagnose the disease, was also in a position to prescribe the remedy. One of the latest and best editions of Chaucer gives her prescriptions as follows:—

"A day or two ye shul have digestyves
Of wormes, er ye take your laxatyves
Of lauriol, centaure, and fumytere,
Or elles of ellebor that growith there,
Of catapuce, or of gaytres beryis,
Or erbe yve growing in our yerd that mery is."

The text, however, varies with editions, but that is by no means strange if we consider how Chaucer himself, concerning Adam Scrivener, tells how—

"Ofte a day I mote thy werke renew,
It to correct and eke to rubbe and scrape,
And all is thorow thy negligence and rape."

Later Scriveners we may be sure were equally negligent, and having no one to correct their work, misreading would grow apace. However, that by the way. The remarkable thing at the present day is the lack of unanimity existing among those who have set about identifying the plants represented by these simple names. Among the reasons for this may be mentioned a neglect to recognise the fact that all the plants are more or less strong purgatives, and also that a name in more than one instance represents more than one plant.

Taking the names seriatim, the "lauriol," our Spurge Laurel (Daphne laureola) is invariably correctly named. "Centaure," sometimes "Century," is referred by Prof. Skeat to "Centaurium," but as this is an incomplete designation, and may mean either Centaurium magnum (Centauria Centaurium), or C. parvum (Erythræa Centaurium), readers are left in doubt which to accept. The point, however, is made clear by referring to the "virtues" recorded as possessed by each, from which we gather that "the roote of the small or lesse Centorie (Erythræa Centaurium) is of no purpose for medicine, but the leaves, flowers, and juice of the same are very necessarie;" and as a medicine "it purgeth cholerique, &c., humours." Moreover, it is a not uncommon indigenous weed, while the other is exotic, and the root is the part used, and for complaints of a different character than those of Chaunteclere. With regard to "fumytere" it need only be said that all agree that the common fumitory is the herb meant. Like a few other common weeds, it enjoyed a very high reputation for its beneficial effects as a medicine. As regards "ellebor," however, there are differences of opinion as to what the plant cultivated by the widow might be. Professor Henslow, for instance, chooses Veratrum album; but as the root of this plant was the only portion used, it could be of no use to the afflicted cock. In many ways it is an interesting plant, for, as Neesewurt or Nosewort, it reminds us of a time when snuff was used medicinally, the powdered root having been employed, as Tobacco-snuff was afterwards, simply for physical reasons.

Another plant thought to be the representative of "Ellebor," is Veratrum nigrum, and so far as it is true that the foliage contains the "virtues" desiderated by Dame Pertelot, this plant would meet the requirements. Lyte, however, declares it to have been a rare plant, cultivated only in the gardens of certain "herboristes." Helleborus fœtidus, known in Chaucer's day as Ellebor and Saturgrasse, has many points to recommend it. It conforms as to medicinal qualities; it is a not uncommon indigenous plant, and on account of its supposed value in veterinary practice, it would be indispensable to the "pore wydow," as a ready-at-hand remedy in cases of disease among her "thre kyn, and eek a sheep that highte Malle." Gerarde gives a curious account of "settering" cattle, for which this plant was used, and hence called Setterwort and Setter-grass. Veratrum album has been called "Lingwurt," but this is obviously, too, the true Lungwort or Lyngwort, so named because in cases of lung disease in cattle, they were "settered" with portions of the root, or else small pieces were placed in the ears of the cattle, the idea being to extract the disease at the parts treated.

"Catapuce" has never been doubtful. It is the old Spurge, or "Purge," Euphorbia Lathyris. "Gaytres beryis," on the other hand, presents a difficult problem. It is spelled in a great variety of ways, and at one time was thought to mean the "gay tree." Later authorities, however, have referred it to gate-trëow or goat's-tree, or it may be "gate rys," the goat's bush, the more modern form, Gatteridge (with which compare Piperidge, the pipe-bush), being favourable to that meaning. Prof. Skeat thinks goat-tree to be identical with Rhamnus catharticus, the berries of which are purgative. Then there are those who, following Gerarde, assume that Cornus sanguinea was the plant; but the fact that this shrub possesses absolutely no medicinal property, disposes of its claims. At the same time, it is a curious coincidence that the berries, which are similar in appearance to those of the Buckthorn, were at one period imposed on purchasers of the latter as its fruit.

The Cornus has also a connection by name with Euonymus europæus, the following being common to both, namely, Dogwood, Prickwood, Spindle-tree, Catteridge-tree, and Gatteridge-tree. The latter designation connects it with "Gaytres," and inasmuch as the berries are strongly purgative they have been thought worth noting. There are, however, two considerations at least from which we cannot escape, which make it difficult, if not impossible, to accept either of these as Chaucer's plant. Pertelot, it may be remembered, offered to teach the terrified cock of herbs for his health—

"And in oure yerd tho herbes shul I fynde."

And he was advised to—

"Pike hem up right as they growe and et hem in."

These are counsels which in the case of large shrubs or low trees, like Buckthorn and Euonymus, it would be hard to follow. But the case is yet stronger against these when we recall to mind that their fruit is ripe in September, and the dream occurred, as Dryden has it, when—

"The pale Primroses and blue Violets spring."

There is a way out of these difficulties if we assume that "gaytres" in any of its varied spellings is not the word the poet used. We may take Ellebor as a case in point, which in Bell's edition has Elderberries instead, though of course wrongly. "Gladdin," also spelled in many ways is very near the word. Its common old name of "Spurgewort" indicates its affinity to the other plants from the poet's point of view. It was cultivated in gardens, though wild, and its berries, which were used as well as the roots, possess the property of remaining in their capsules till spring.

Concerning "erbe yve," there is room for some discussion, as the name has been appropriated by three plants, namely, by Plantago coronopus, by Ajuga Chamæpitys, and by Nepeta Glechoma. The common Ivy, too, has been brought forward, but mistakenly. The Plantago was known in Chaucer's day as Erbe Ivy, and is so named by Turner, Gerarde, and others, though Culpeper confounds it with Senebiera coronopus. As it acts as an astringent, it may be dismissed on that account. Ajuga Chamæpitys has been named as the herb Chaucer had in his mind, and between Nepeta Glechoma and it, there is only a slight distinction, as both seem to have been employed medicinally for the same purposes. The first named is known

to be a rare plant comparatively, and it is an annual. The other is extremely common, and is almost like the Nettle in making itself at home near the abodes of men, and may be picked up at any season of the year. In the words of Sir W. Temple it "is . . . of the most excellent and most general use and virtue of any plant we have among us;" and I imagine it has everything in its favour to securing it a place among the laxatives growing in the widow's garden.

There is just one appellative more which may, perhaps, not be one of Chaucer's—"wormes," to be taken as a "digestyve." These, no doubt, form a usual part of the food of poultry, and an old writer on the subject advises that hens be allowed to take their chickens "to worme." But it would seem that Chaunteclere had been already feeding to repletion, and on the face of it, "wormes" might be expected to aggravate rather than mitigate his symptoms. The word resembles so very closely the old name of Wormwood, a herb to this day highly valued as a stomachic, or as an old writer has it, "it quickly refresheth the stomach after large eating and drinking," that the point may be worth the consideration of those in a position to investigate it thoroughly. *R. P. Brotherston.*

FRUIT REGISTER.

GOOD JANUARY PEARS.

I HAVE this season found Passe Crassane in capital condition, and I have never had it so good. At Compton Basset the soil is of a heavy character, and unless the season was very hot, it was not of good quality. Another variety that is keeping well this year is Glout Morceau, which, when brought into warmth gradually, is very good eating. Knight's Monarch is another late variety which I have kept in good condition till the month of May. Ne Plus Meuris is just now beginning to colour, and will be a valuable fruit in the dessert till the end of March; and if grown liberally and thinned well, it is a Pear of passable flavour. *W. A. Cook.*

CHINESE CONIFERS.

PINUS ARMANDI.*—This is a five-leaved Pine of the Cembra section, with smooth bark, slender leaves, and oblong cones. It differs from P. koraiensis in the cones being broader in proportion to their length, and in the cone-scales not being reflexed at the tips. From P. parviflora it differs in its longer leaves, larger cones, and wingless seeds.

The branches are smooth, greyish in colour, the pale green leaves in tufts of five, with a very short deciduous sheath. Each leaf is about 14 to 15 cent. in length, three-sided, serrulate, triangular in section, with the resin canals median. The section of the central vascular cylinder or meristele is circular, and the fibro-vascular bundle is unbranched. The male flowers figured by Beissner are cylindric-oblong, each about 2 cent. long. The anther-scale is notched. The stalked cones are 10 to 11 cent. long, 4 to 5 cent. broad, oblong-obtuse, not tapering much either at the base or at the apex. The cone-scales increase in size gradually from the base to the middle of the cone, are slightly thickened at the tips, the upper exposed portions broadly ovate-acute, somewhat triangular, slightly pointed, and not reflexed. The seeds are wingless and edible. The whole cone has much the appearance of that of W. American P. flexilis.

The illustrations were drawn by Mr. Worthington Smith from specimens collected by Wilson in Yunnan (*sine numero*)! This Pine has been met with in Chensi, the Tsinling Mountains, *David!*

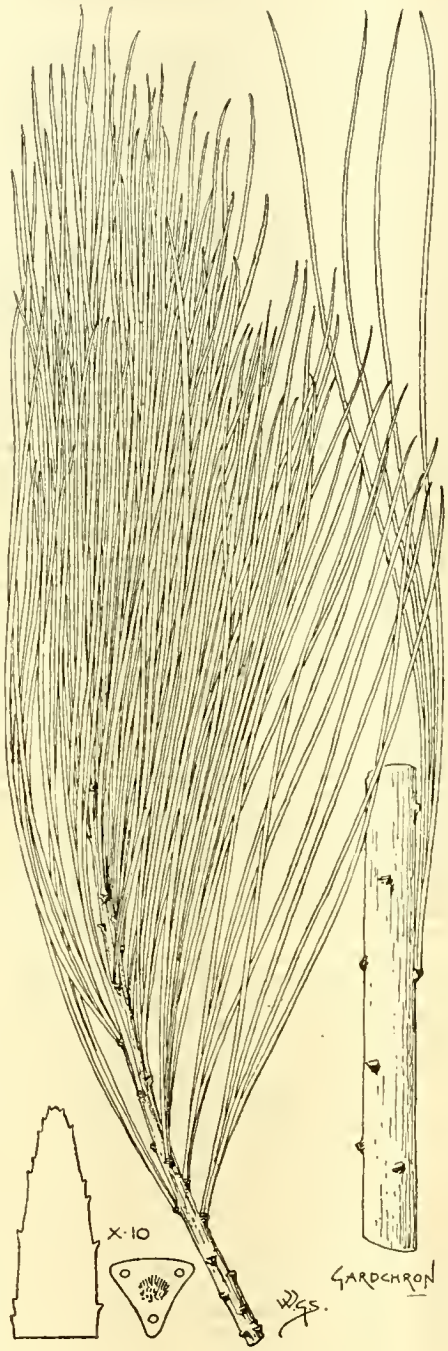

FIG. 30.—PINUS ARMANDI.
Shoot and foliage, real size; tip of leaf mag. 10 diam. Plan of leaf-section.

Szechuen, *Farges!* Yunnan, *Delavay!* but, so far as is at present known, does not occur in Japan.

Franchet suggests, and not without reason, that the cone figured as that of P. parviflora by Murray in *The Pines and Firs of Japan* (1863), p. 12, fig. 13, may really have belonged to the species now known as P. Armandi. Seedling plants are, we believe, in cultivation in Messrs. Veitch's nursery at Combe Wood. *M. T. M.*

REPORT OF THE COMMITTEE ON FORESTRY.*

As might have been anticipated from the constitution of the Forestry Committee, a thoroughly practical though modest Report, as already alluded to in your columns, has been issued, any desire for more heroic measures being checked by the knowledge that after the South African war much State money is not available for the improvement of forestry. Ireland was not within the scope of the enquiry, as there is an independent Irish Agricultural Department not under Mr. Hanbury's influence, but Professor J. R. Campbell, one of the assistant secretaries of the Irish Agricultural Department, was a member of the committee. A separate inquiry will probably be held into Irish Forestry after effect has been given to the recommendations of the British Committee.

The report commences with a list of the witnesses, comprising the Earl of Selborne, Lord Glanusk, and Sir J. W. Ramsden, representing owners of woodlands; some of the best-known estate-managers, such as Mr. A. Vernon, President of the Surveyors' Institute; Mr. D. W. Drummond, agent to the Earl of Cawdor and to Sir James Drummond; Mr. A. Slater, land steward to His Majesty, at Osborne; Mr. W. B. Havelock, forester to the Earl of Yarborough; Mr. A. C. Forbes, forester to the Marquis of Bath, and Mr. A. Pitcaithley, forester to the Earl of Mansfield. The delegates of the Forestry Societies of Great Britain were Mr. J. Michie, from Balmoral; Mr. D. Robertson, forester to the Duke of Sutherland; and Mr. J. Davidson, land-agent to the Admiralty, and secretary to the English Arboricultural Society. Mr. S. Margerison and Mr. C. Hopton gave evidence on behalf of the Timber Trades Federation, and Mr. J. H. Croxford as a timber importer; Mr. A. D. Webster on behalf of the Royal Horticultural Society. Evidence was also given by three members of the committee, Dr. Schlich, Col. Bailey, and Dr. Somerville by a representative of the Post Office, Mr. M. F. Roberts, as regards the use of imported and home grown timber for telegraph poles; by Major P. G. Craigie, C.B., of the Board of Agriculture, regarding woodland statistics; by Mr. C. O. Minchin, of the Inland Revenue Board, regarding succession and estate duties; and by the English and Scottish Local Government Boards regarding local rates. Prof. H. Marshall Ward gave evidence for the University of Cambridge; and Mr. J. Parry, water engineer to the Liverpool Corporation, gave evidence as to the afforestation of catchment areas. The appendices with all this evidence are not yet published, but the selection of witnesses has been good, and they have afforded most valuable information to the Committee.

The Committee considers that the world is rapidly approaching a shortage, if not an actual dearth of Coniferous timber, which constitutes about 85 per cent. of the total British timber imports. There are in Britain about 21 million acres of uncultivated land, and the afforestation of suitable portions of this area is a matter of grave national concern; in order to increase the yield of home timber, and also as a means of providing remunerative labour to an increased rural population. At present, sheep-rearing in the highlands employs one man in 1,000 acres, at least ten men would be required were the same area under trees. The Committee therefore recommend that steps should be taken by the Government Department charged with the collection of land-statistics, to compile a statement of areas suitable for afforestation in Great Britain,

* Report of the Departmental Committee appointed by the Board of Agriculture on British Forestry. London: Printed for His Majesty's Stationery Office by Wyman & Sons. To be purchased through any bookseller, 2*d*.

and measures are recommended for more detail to be given in the statistics of existing woodlands.

As regards the preference now shown for foreign timbers, it is pointed out that properly grown Scots Pine and Spruce will yield as good material in Britain as abroad; this is certainly the case with Scots Pine, as is clearly shown in the appendix by Mr. Webber's recent book on Indian forests.

EDUCATION.

This desired improvement in methods of growing timber leads the way to education in forestry, and here the Committee have made some excellent suggestions. The most important of these are the setting aside of the Alice Holt Wood in Hampshire, and of an area to be purchased in Scotland for £50,000, to serve as demonstration areas for foresters and others. The student-foresters will work in the woods under a director, who will teach forestry; and an assistant, who will teach forest botany and entomology, as well as the constitution and properties of soils. Accommodation should be provided for the teachers, with rooms for the student-foresters. The cost of these practical forest training-grounds are estimated at £1,500 a year, and about £15,000 for buildings. It has already been asked, in the *Morning Post*, why an area in the Forest of Dean was not chosen, instead of in Hampshire? but the only suitable area in the Forest of Dean is the High Meadows Wood, and this the Commissioners of Woods and Forests could not make available, while they already receive forest-students in the Forest of Dean, whom one of the officers there is fully competent to teach.

Alice Holt, in Hampshire, contains both broad-leaved and coniferous trees, the soil varying from sand to a strong loam, and regular fellings can be made forthwith, so that it is very suitable for a demonstration area, and it is more accessible to the south of England than the Forest of Dean. Foresters and woodmen would be thus trained for three years, after appointment by County Council Technical Committees or otherwise.

The proposals for Lectureships in Forestry at Oxford and Cambridge, and that example plots of about 150 acres each be provided at Oxford, Cambridge, and Edinburgh, where there is already a Forestry Lecture-chair, are excellent. Besides these, regular lectures in forestry are recommended at all Agricultural Colleges receiving grants from the Board of Agriculture, and it is suggested that in counties such as Northamptonshire and Aberdeenshire, where there is much woodland, lecturers in forestry should be appointed by the County Councils, and scholarships offered if necessary to secure the attendance of woodmen.

The foundation of a State Forest School for the Empire at one of the Universities is also recommended, and it is suggested that this could readily be done at very small expense were the Indian Forestry Branch at Cooper's Hill to be transferred to a university. If the Indian Office, in the interests of the Empire, would consent to this transfer, a school of forestry comparable to one of the excellent continental forest schools could be at once established, which, besides teaching forestry to our landowners and land-agents, would supply India and our Colonies with foresters and lecturers for the forest schools that must eventually be established throughout the Empire, as well as furnish forestry lecturers for our agricultural colleges and county councils. Until this foundation for forestry education throughout the Empire has been laid, the Colonies will continue to look abroad for foresters, while no permanent improvement in forestry throughout the empire can be secured.

The report concludes with recommendations regarding the abolition of extraordinary rates levied for the carriage of timber on roads. These are highly unfair, as the plantations have paid rates for years while they were growing up, and before this extraordinary traffic occurs. Estate duties on woodlands also require readjusting, as under present conditions they frequently compel the realisation of immature timber. It was also suggested that young plantations should not be rated so long as they yield no return, though unfortunately no recommendation on this important point was made by the committee. A Bill is called for to afford adequate security against the destruction of plantations by fire from railway engines. The owner of plantations who keeps down ground-game should be compensated for damage done by his neighbours' ground-game.

As regards State loans for planting, the Committee prefer that good instruction in forestry should take the first place, and that the question of loans should stand over until the improvement in the condition of our woodlands becomes apparent.

Finally, the attention of Corporations should be drawn to the desirability of planting with trees the catchment areas of their water-supply; these blocks would eventually furnish demonstration areas for forestry instruction. It is interesting to learn that Birmingham is proposing to plant up 20,000 acres of the catchment area of their water-supply in Wales. *W. R. Fisher.*

FIG. 31.—PINUS ARMANDI: CONE OF REAL SIZE. COLLECTED BY MR. E. H. WILSON. (SEE P. 66.)

There are two points in Mr. Fisher's interesting and learned article which should perhaps receive a word of comment. In the first place, as he alludes to what is evidently a portion of the as yet unpublished evidence, we cannot be aware of the specific reasons which have led to the particular recommendations of detail made. In naming Alice Holt, the Report says that, while those woods cover less than the minimum area indicated as desirable, they could more easily be brought into working order, and made serviceable at an earlier date, than could the larger area of the Forest of Dean with High Meadow Woods. Mr. Fisher says that the Forest of Dean is unsuitable, though High Meadow Woods are suitable but could not be made available; and states that Alice Holt Woods contain coniferous trees as well as other timber, and have soil varying down to sand. One of our correspondents, who knows all the Crown forests of England, and who is specially well acquainted with Alice Holt and with Dean Forest, tells us that there is little sand in Alice Holt, and that in his opinion the greater portion of the soil of that Wood is unsuitable for the growth of good timber.

A large portion of Dean Forest is rendered unsuitable by coal-mining under the surface, but the area of Crown woods and Crown lands within reach of the houses belonging to the Crown situate in central portions of Dean Forest is so large as to give great resources of every kind. Alice Holt Woods have hitherto been let at a good rent for sporting purposes, and are full of rabbits. Dean Forest and a portion of the neighbouring woods are free from destructive game, and there are buildings available, at present unoccupied; whereas the Crown Lodge in Alice Holt is let, apparently (from the Woods and Forest accounts), for a long term.

The other point arising out of Mr. Fisher's article to which attention may be called, concerns the recommendation of the Committee that legislation is necessary to afford security against the destruction of plantations by fire from railway-engines. The strength of the railway interest in Parliament is so great that it is wise that we should not forget decisions on the existing law, which show that the case as it stands need not be given up without a fight. Attention was called in these columns on November 30, 1901, p. 395, to a case in which the County Court Judge of Cumberland gave a gentleman, whose plantation of young Scotch Fir had been set on fire by sparks from an engine on the North Eastern line, his claim. The Company, who were represented by counsel, stated that they should appeal, and the judge expressed his view that this was only natural, considering the great importance of his decision. A meeting of the directors was called upon the subject, and, after most careful consideration, the Company decided not to appeal, and the decision stands. The circumstances of the case were such that, although it is necessary to show negligence in order to recover, there is no case in which recovery ought to take place which would not be met by the principle laid down. For example, in all cases where the incline is such as to make puffing usual in leaving a station, there would be

continuing negligence. There being no chance that Parliament will go further, it is perhaps more desirable to cause proprietors of plantations to be informed of their position under the present law, than to induce them to expect a fresh Parliamentary remedy.

APPLE-GROWING FOR PROFIT.*

THE object of this short paper is to direct attention to what has proved to be a profitable industry in Ireland when careful attention has been given to it. Much has been written in recent years about fruit-growing in the British Isles, but a large proportion of both writings and lectures on this subject has been misleading and illusory; roseate pictures have been painted of enormous profits, certain crops, unfailing markets—all attained with little labour; but it may be taken for certain that fruit-growing will pay only when it is thoughtfully undertaken and carefully carried out. Under these conditions, it will pay—and pay well. For certain classes of fruit there is a continuous and steady demand, especially for Apples; yet, strange to say, in Ireland, whilst the sale of American Apples is very large, and steadily increasing, one of the most difficult things to get is a good home-grown Apple, either for eating, or for cooking purposes. This is not due to any fault of soil or climate, for as good Apples, especially cooking Apples, are grown in Ireland, as in any country in the whole world. One of the leading market growers in England recently remarked to me, "I can see no reason why Ireland should not grow first-rate Apples; in fact, I know it can be done;" and this remark came from a man who knows Ireland well. Many years ago he explored Ireland as a fruit-growing country, but relinquished the enterprise owing to the then imperfect means of conveyance, and owing to market difficulties. Since then much has been done to improve these matters, and the supply of fruit has also largely increased; in fact, from November to January, inclusive, a first-rate supply of good imported eating Apples can generally be obtained. A very general opinion prevails that American Apples are much superior to home-grown Apples; but this is far from being the case, and there is plenty of room for the home-grown Apple. I do not recommend growing eating Apples which come in season at a time when there is a large supply of attractive-looking imported fruit; what I strongly urge is, the cultivation of early season eating Apples, and good quality cooking Apples for all seasons.

EATING APPLES.

First, as to eating Apples. During the holiday season—July, August, and September, especially the two latter months, when bush fruit and Strawberries are over, there is a steady demand for good eating Apples, and a very limited supply. The poor green uninviting-looking rubbish that one sees displayed in windows and on stalls, could easily be replaced with sound attractive fruit, pleasant to look at, and pleasant to eat. There is a good demand for this class of Apple, and good prices are attainable. For instance, during September, Cox's Orange Pippin sold from the tree, in London fetched from 11s. to 13s. per bushel of 42 lb., or nearly 1*d.* per Apple. Devonshire Quarrenden, Worcestershire Pearmain, and Washington Apples were selling at 7*s.* to 11s. per bushel, which must be regarded as highly remunerativo prices. It is important for the grower to note that these early Apples can be sold direct from the tree, without the expense and trouble of storing. The question arises—have we Apples suitable for our Irish climate which will ripen early? The following list of ten varieties may be relied on:—Gladstone (July), Beauty of Bath (July and August), Irish Peach-Apple (August), Devonshire Quarrenden (August), James Grieve (September), Lady Sudeley (September), Kerry Pippin (September), Worcester Pearmain (September), American Mother (September), Cox's Orange (October). These are well proved varieties, prolific, and reliable. The Duchess of Oldenburg might be included in this list, but as the flavour is rather acid for some tastes, it is better to reserve it for the list of cooking Apples, and to include Cox's Orange Pippin, which, although rather late, is probably the best eating Apple grown, and the Apple which commands the highest price. If old decrepit trees, which abound in most farm gardens, were cut down and burnt, and the ten varieties named planted, a great improvement would be made in Irish fruit growing.

COOKING APPLES.

Secondly, as regards cooking Apples. The home grower of good cooking Apples has practically no foreign competition to contend against, and thus starts with a distinct advantage, as compared with the grower of eating Apples. It is well known that many Apples which are good for eating are comparatively worthless for cooking purposes, and this is especially the case with the American Apples. Yet strange to say, the supply of good cooking Apples is far below the demand; in fact, both early in the season—August and September—and late in the season, from the end of November on, it is extremely difficult to buy a good cooking Apple. It may be thought that the scarcity is owing to poor prices; but this is not the case. Good cooking Apples, i.e., good large sound fruit of good varieties fetch more per Apple than eating Apples. They readily sell at 5*s.* to 9*s.* per bushel, and naturally there are fewer of these large Apples to the bushel than of the smaller eating Apples. The greater part of the cooking Apples grown in Ireland are sold in England and Scotland, and owing to the good prices given, much more attention is now given to them, both as to the varieties grown, and as to skilful cultivation. If they are now in many districts a remunerative crop, they could be made much more so if attention were directed to growing and storing the good late keeping varieties. It is in this branch of fruit growing that I have most faith for the future, and I strongly recommend it to all practical men who intend planting fruit-trees for profit. There are, no doubt, gentlemen present who are versed in market matters, wholesale and retail, who could give some startling facts as to the prices obtainable from Christmas to April for good cooking Apples. The list of varieties of cooking Apples is much larger than that of eating Apples, and many more varieties than should be grown are to be found in catalogues, and are recommended by practical growers. It must, however, be borne in mind that each variety will not grow equally well in every soil, and a man may with perfect honesty and good faith recommend as the best Apple one which may be comparatively useless when planted [in another situation]. As a guide as to what to plant we must look to the market, in order to see what sells well, and to the market garden and large orchard, to see what is being planted. I have been through some of the best-managed orchards in Kent, Surrey, and Essex. I have interviewed growers and salesmen, and at the present moment the following ten varieties are those which I most recommend for planting, in order to secure a profitable crop:—Duchess of Oldenburg (August), Early Victoria (September), Lord Grosvenor (September and October), Stirling Castle, or Grenadier, or The Queen (October), Wellington (November), Lord Derby (November), Bramley's Seedling (November to May), Bismarck (November to May), Lane's Prince Albert (November to May), Newton Wonder (November to May). In omitting several old favourite and well-known Apples, such as Blenheim Orange, Warner's King, Lord Suffield, &c., I have been guided by what I have seen, and by my own limited experience. I do not say that each of the ten varieties mentioned will do well when planted, but the majority will do so, and a selection can be made in a few years; in fact, it will make itself.

Having decided on what to plant, the grower has to consider (1) where, (2) when, and (3) how to plant.

(1) The question of soil is an all-important one. Being gross feeders, Apples naturally delight in a deep rich loam; but this is not everywhere available. Growers must remember that Apples, although not very fastidious, give infinitely better results in a good position, than when stuck away in any corner; therefore, they should be given the best position available, with good exposure to sun, and shelter from winds when possible. It is a great mistake to plant close to large trees, as the young plantation is robbed of sun, air, and nourishment; but if planted on an exposed site growth is very slow, and good heavy fruit is blown down before reaching maturity. If no shelter is to be had, hedges should be planted. The Damson will be found to be an excellent hedge plant. It makes a thick close hedge, and a paying crop of fruit can be got from the hedges.

(2) As regards the time of planting, October is the best month. If young trees are planted in October they get settled in the soil before winter; the soil being still warm, new roots are rapidly formed, and the wounds heal up quickly. Further, far better plants can be had in October than later on, when stocks have been reduced and the best trees sold.

(3) The question of how to plant requires consideration. Is the plantation to be a grass orchard, or a general fruit plantation? If a grass orchard the permanent trees must be standards or half-standards on the Crab stock. They should be planted in rows 24 feet apart, and between each tree a dwarf bush tree on the Paradise stock should be planted. These dwarfs should be moved, or cut out, about the tenth year, before which time they will have yielded a handsome profit. For several reasons, I am strongly opposed to meadowing orchard ground. I believe this practice has a most injurious effect on the trees, and the price got for hay is more than lost in the crop of Apples. It is much better to graze sheep; or small plantations may, with excellent results, be used as a "run" for poultry.

If a general fruit plantation is to be made, only dwarf bushes on the Paradise stock should be planted. These should be 12 feet apart every way, and if labour is scarce an extra tree may be planted between each four trees, this extra tree to be removed as the permanent trees grow. The advantages of dwarf bushes are that they come earlier into bearing, the fruit is easier to gather, and the fruit is less liable to be blown down. Between the rows bush fruit or Strawberries may be grown.

For bush fruit I recommend Gooseberries and Black Currants. The following are the best Gooseberries for general cultivation:—Crown Bob, Keepsake, Langley Green, Lancashire Lad, Whinham's Industry.

The best Black Currants are Baldwin and Victoria. It is well to draw attention to the demand there has been in recent years for Black Currants—a demand which has far exceeded the supply. This year, both in England and in Ireland, 40*s.* per cwt. has been the regular price for good Black Currants.

A word may usefully be said as to the treatment of the trees. The branches should be shortened back before planting, always cutting to an outside eye; and the roots, where broken or injured, may also be cut back to where the wood

* Paper read at the Fruit Conference, Cork, on October 17, 1902, by Mr. F. W. Moore, A.L.S.

is sound. Growers should be careful not to plant too deeply, and should spread the roots out in every direction. Manure should never be given to young trees. Manure will not be necessary until the trees begin to carry crops; then regular and liberal manuring will be required. The second season's pruning will consist in shortening back the gross shoots, removing ill-placed or superfluous shoots, and ensuring that the centre of the trees is kept open. Summer pruning is a debatable question, and although I advocate it, I believe the extent to which it is to be carried out is largely dependent on soil and situation. I think it is advisable to stop the shoots in July, especially in young trees. In fruiting trees very little pruning is necessary; the fruit has a restraining influence on growth, and more leaves are required to provide material for forming fruit.

All these details may have been carefully attended to, and yet the results may be unsatisfactory, although there may be a heavy crop, if special care is not given to gathering and marketing. Careless gathering, and, worse than careless, dishonest, marketing can easily turn what should be a handsome profit into a dead loss. Apples must be very carefully handled; each fruit should be picked separately and placed in a tray or basket, to be carried to the packing shed or store. They should never be shaken off the trees or thrown into the receptacle. They are easily bruised and disfigured, the bruises turn black, and rot quickly sets in, and bruised and disfigured fruit, of course, commands but a poor price.

(To be continued.)

ECONOMIC BOTANY.

(*Concluded from p.* 38.)

Danger of Ignoring the Study of Vegetable Economics. — Thus, as I said before, this country is ignoring the study of vegetable economics, just as twenty years ago it ignored the scientific study of agriculture. We shall wait till a check in our commerce, probably caused by a fall in prices of our own products (a natural consequence of technically imperfect methods of production, preparation, or collection), brings us face to face with the fact that we are suffering for our ignorance. Then will follow the usual panic, and the usual forcing of square men into round holes, for which, by a little timely rounding off by the necessary education, they might have been gradually and efficiently prepared. Or, worse still, we may resort to the ignoble refuge of wholesale importation of experts from abroad. I propose no heroic measures. A slight modification of our current methods should meet the requirements; but such modification will require time for its proper development.

Under the revival of the study of botany which has taken place in this country during the last quarter of a century, the leeway of a former generation has been made up. At many universities more men are now duly qualified by their scientific training to pass into the professional ranks as pure botanists than there are places for them to fill. There is, in fact, a block in promotion. This should be the opportunity for strengthening the applied study of the science. A very slight encouragement from Government, or otherwise, would lead to the addition of an extended course of vegetable economics to the ordinary courses of some of our universities or technical colleges; especially this would be suitable in such commercial centres as Glasgow, Liverpool, Birmingham, and Belfast, in which there is less opportunity for the development of agriculture or forestry. This would lead to the production of a body of experts, trained up to a certain point which their degree or diploma would indicate, and such experts the Empire will be certain to require.

It was in the full conviction of the importance of this that, on a recent occasion, when an opportunity was given me of stating the immediate needs of my own department in Glasgow, I suggested as the most pressing need the appointment of a lecturer on vegetable economics, who should also be the keeper of the botanical museum. A course such as he could give, added to those of physics, chemistry, and botany, together with certain optional subjects, should form a curriculum well worthy of a degree of B.Sc., with a special diploma in vegetable economics. So far nothing has resulted.

(*Photographed by Mr. Fitzherbert.*)

FLORISTS' FLOWERS.

American Chrysanthemum Judging.

I beg to enclose the scales of points for the judging of Chrysanthemums, arranged by the Chrysanthemum Society of America, thinking it will interest your readers. You will observe the difference between this and the English method. Cut blooms are exhibited in vases with long stems, so that the foliage and stem counts as well as the flower, and when six are exhibited in a vase together they are certainly

seen to advantage. Usually each variety is exhibited in a separate vase, excepting in one or two classes. The following are the scales of points:—

Scale A.—For bush plants and standards, single specimens, or any number up to six, in an exhibition where the class under consideration does not form the chief feature in the Exhibition Hall—

Equality of size and form of plant	40
Excellence of bloom	35
Foliage	25
Total	100

Scale B.—For bush plants, exhibits of more than six, or for any number of specimen plants in an exhibition where the class under consideration forms the chief feature in the Exhibition Hall—

Excellence of bloom	40
Equality of size and form of plant	35
Foliage	25
Total	100

Scale C.—For plants grown on single stems. A height of not more than 3 feet is recommended for plants in this class, and pots of not more than 6 inches in diameter—

Excellence of bloom	40
Compact and sturdy growth	35
Foliage	25
Total	100

Scale D.—For specimen blooms for commercial purposes—

Colour	25
Form	25
Fulness	15
Size	15
Stem and foliage	10
Substance	10
Total	100

Scale E.—For specimen blooms for exhibition purposes—

Distinctiveness	25
Colour	15
Form	15
Size	15
Stem	10
Foliage	10
Fulness	10
Total	100

J. H. Blackman, Bryn Mawr, Pa., U.S.A.

CULTURAL MEMORANDA.

CANNAS.

THE seed of the Canna is extremely hard, and takes a long time to germinate, so that an early start should be made in getting the seed prepared and sown. I have repeatedly soaked the seeds of Cannas twelve and more hours previous to sowing them, and after sowing stood the pans in a nice warmth, but the young seedlings have kept coming through the soil at intervals for some weeks. As the young plants appear, they should be transferred to small pots and kept growing gently, and when large enough, re-potting should not be neglected. Cannas should be afforded a rich loamy compost, and plenty of manure-water during the season of growth. *H. Markham, Wrotham Park, Barnet.*

PUBLICATIONS RECEIVED.—*The Transactions of the Yorkshire Naturalists' Union.* Part 26. Contents: Yorkshire Macro-Lepidoptera in 1897, by William Hewett; Report of Yorkshire Botany for 1890, Phanerogamia, by C. P. Hobkirk and P. F. Lee; Report on Yorkshire Botany for 1894, by A. H. Pawsou; Report on the Bryological Flora of Yorkshire for 1897, by T. J. Marshall; also notes on Meteorology and Reports.—Also the above Transactions, No. 27: *The Alga Flora of Yorkshire*, a complete account of the known fresh-water Algæ of the county, by W. West and G. S. West.—*Proceedings and Journal of the Agricultural and Horticultural Society of India*, July-September, 1902. This mentions trials with infused Tea-leaves as manure, which so far have produced but little result, unless in the colours of the flowers of a few Cannas. The pamphlet includes a mention and plate of Phalænopsis Schilleriana.

The Week's Work.

THE KITCHEN GARDEN.

By JOHN FLEMING, Gardener to Sir C. PIGOTT, Bart., Wexham Park, Slough.

Rhubarb.—This is a suitable season for forming plantations. The land should have been manured and deeply trenched in the autumn, and the beds formed in a sunny yet sheltered part of the garden. Let the roots be so divided that a bud is preserved on each piece, and plant the divisions in lines 3 to 5 feet apart each way, according to the strength of the variety. Place the roots so that the bud is about an inch below the surface of the ground; apply a mulch, and leave the whole of the first season's growth undisturbed, but cut away all flower-heads. The Sutton, and Daw's Champion are excellent early varieties; Myatt's Victoria, although an old variety, is still one of the best. The Champagne, for its good flavour, should not be forgotten. Successional batches of Rhubarb should be brought into the Mushroom-house in accordance with the needs of the family.

Jerusalem Artichokes.—Any tubers still remaining in the ground should now be trenched out, being careful to remove every scrap of root. The useable tubers may be stored in sand or coal-ashes out-of-doors, and the middle-sized and best-shaped ones put on one side as sets. If first-class produce is desired, the soil and treatment recommended for Rhubarb are suitable, and the sets planted 6 inches deep and 1 foot apart, and the rows 3 feet apart.

Winter Spinach.—In dry weather, when the soil is not sticky, stir the ground with a hoe, draw a little soil against the stems, applying a dressing of soot before the hoeing is begun. Seed may be sown on a south border in shallow drills drawn at 12 inches apart, and the produce from this sowing will come in usefully when the autumn-sown crop is getting short. The Victoria Round is one of the best Spinaches.

Seasonable Hints.—Broccoli with heads formed or forming will need protection, which is best afforded by lifting them with roots intact, and heeling them-in, in soil in a cold turfen or brick pit, &c. Apply linings of warm manure and tree-leaves to hot-beds. The lights must be covered up every night, but in such a manner that the fumes are not conducted through the air-opening into the frames. Put a number of sets of early Potatos in shallow boxes, and place them in a light house or pit in warmth of about 50°; the sets for planting out-of-doors may likewise be placed thinly in a light, cool, frost-proof place.

Carrots and Parsnips.—Any roots left in the ground should be lifted and stored on the north side of a wall, with a quantity of sand or ashes between the different layers; sheets of corrugated iron may be used to throw off the rain.

FRUITS UNDER GLASS.

By T. H. C.

Cucumbers.—When setting out the plants, turn them carefully out of the pots, and put one into each hillock of soil. The plants will have a portion of bare stem between the cotyledons and the surface of the soil in the pots, and this should have some soil gently pressed against it close up to the seed-leaves, the result being the emission of vigorous roots, much to the benefit of the plants. Place a stake to each plant, and tie-in the bine as growth proceeds. Very little water will be required before the roots take possession of the new soil, and then it should be always applied in a tepid state. Maintain a night temperature of 65°, except in severe weather, when a few degrees less would be better, rather than to heat the hot-water pipes excessively. The day temperature may range from 5° to 10° higher, and even more with sunshine will be beneficial, with plenty of humidity in the air always. Our old-bearing plants are now growing freely, and showing plenty of fruits. Encourage root action by an occasional sprinkling of a fertiliser on the surface of the soil, and immediately apply warm water. When the roots appear at the surface, top dress as previously advised; remove decaying leaves and some of the barren bine, encouraging young growths in its place. Crop lightly, remove entirely all male flowers and tendrils, and where an extension of growth is not required, stop the shoots at a leaf beyond a fruit. Look out for red-spider, and if the foliage is affected, syringe with "Spideracide," diluted according to the directions sent out with this special preparation, and keep the foliage clear of red-spider afterwards by forcible syringing with clean tepid water. If aphides give trouble, employ XL-All. Syringe the plants once or twice daily, according to the state of the weather; and maintain temperature and atmosphere as advised for young plants.

Tomatos.—I know of no plant that may be grown in such a diversity of ways, and if intelligently managed, always with success. It will accommodate itself to the shallowest of greenhouse shelves with 3 or 4 inches of soil for a rooting medium, or to the house of the market man covers a part of the ordinary garden soil; the only preparation it receives being a liberal dressing of farmyard-manure incorporated with the top spit. This forms the border into which the young plants are planted out in rows, and trained up strings to the roof, where they usually fruit well. For the earliest crop I would recommend growing the plants in 10-inch flower-pots. The house intended for these, and especially if Tomatos were previously grown in it, should be thoroughly cleansed in every part, and if the least sign of disease appeared in the plants last year let the house be disinfested with burning sulphur, keeping the house air-tight. When doing this remove every plant from the adjoining houses, and stop up every crevice. Procure the necessary number of 10-inch pots, and after well crocking them, fill them to the extent of three-quarters with a compost consisting of three parts fresh turfy loam and one part leaf-mould, with a small quantity of charred garden refuse, mortar-rubble, and a sprinkling of Veltha Powder, the latter as a disease preventative and slight fertiliser. Into this put the young plants, ramming the soil firmly about the roots. At subsequent top-dressings the pots may be filled up to within an inch and a half of the top. Place them close to the roof-glass; maintain a moderately dry atmosphere, and a temperature of 55° to 60°, rising a few degrees higher with sunshine; afford air when the weather permits. If not convenient to put into large pots forthwith, shift into 5-inch pots, and keep the plants close to the roof-glass, and either plant out in a bed, or shift into pots when convenient.

THE ORCHID HOUSES.

By H. ALEXANDER, Orchid Cultivator to Capt. G. L. HOLFORD, Westonbirt, Tetbury.

Calanthes.—The value of the deciduous Calanthes as flowering plants is well known, and some of them may be met with in most large gardens where Orchids generally are not much grown. These plants are now passing out of flower, and as soon as the flower-spikes are removed, water at the roots should not be afforded, and the pseudo-bulbs should be put away to rest till the season of growth comes round. They should be left in the flower-pots, unless exigencies of space forbid, when they may be turned out of the pots and stored in boxes, covering the roots with dry sand, the boxes being placed on a shelf at the warmer part of the Cattleya-house where the temperature is never lower than 58°, and sunshine can reach them most of the day. Resting Calanthes in cool or damp quarters is responsible for the disease known as "spot."

Pleiones lagenaria and P. maculata.—The proper time for repotting Pleiones is immediately after the plants have ceased to flower, i.e., in November, more especially if they are kept in the intermediate-house—the one best suited to their needs. When grown in a cool-house, the plants flower later. Any plant which may require repotting, should receive attention forthwith. A suitable mixture is one consisting of turfy-peat, loam, and leaf-soil, in equal proportions, and adding some coarse silver-sand. Shake the pseudo-bulbs out of the soil, remove dead roots, but leave as many good roots as will steady them in the soil, and let each bulb stand at about an inch apart. Fill the pots or pans to about half their depth with clean crocks, make the compost moderately firm, afford a surfacing between the pseudo bulbs

of clean sphagnum, and when the potting is finished the pseudo-bulbs should stand about half out of the compost. Place in a light position in the intermediate-house, and apply water sparingly for some time.

Miltonias. — Examine the late summer and autumn-flowering species and hybrids, viz., M. spectabilis, and its varieties Moreliana and bicolor, M. candida, M. Clowesii, M. Regnelli and their hybrids, M. Binotii, M. Bluntii, M. leuco-glossa, and M. Peetersiana. These plants are making new growth, and any that require to be repotted, or which have become bare in the centre, should be broken up, the dead roots and useless pseudo-bulbs removed, and be afforded fresh material. A "leaf-soil" compost is suitable, used in a rough state, to the extent of two-thirds, all the finer particles being sifted out. Oak-leaves or the Belgian leaf-soil is the best, to which may be added one-third turfy-peat, chopped sphagnum a small quantity, and a sprinkling of coarse silver sand; cover the bottom of the pots with a 1-inch layer of clean crocks, then a layer of sphagnum, pot moderately firmly, keep the base of the plants on a level with the edge of the pot, and finish off with a layer of fresh, clean sphagnum, which clip over smoothly. Water must be applied with discretion, but the pots and stages may be often damped. Providing the potting materials are in a moist state when used, no water will be needed for some time, that is, till the roots have seized upon the compost. M. vexillaria and its varieties being now in full growth, water may be applied freely to them. I prefer to pot these plants when growth recommences in the autumn; but plants not attended to at that time, which are in a bad condition as regards the compost, may be attended to now, placing these in a shady part of the Cattleya-house when sunshine gets stronger. Thrips are very partial to Miltonias, and if not destroyed they soon disfigure the leaves. One of the best insecticides to use against this pest is XL-All, which should be used on their first appearance on the plants.

PLANTS UNDER GLASS.

By J. MAYNE, Gardener to the Hon. MARK ROLLE, Bicton, Budleigh Salterton, Devonshire.

Fuchsias.—Old plants started in mild warmth at the end of the year, as advised, will have pushed shoots fit to form cuttings, which need not be longer than 2 inches; and if such can be taken with a bit of the old wood attached, and dibbled into pots 4 inches in diameter, filled with sandy soil, they will quickly form roots if placed in slight bottom-heat, kept close, and shaded from the sun. As soon as rooted, pot them off singly, and stand near the roof-glass in a temperature of 55° to 60°, syringing them overhead once or twice daily, and lightly fumigating in the evening should aphis appear on the plants. The general stock of Fuchsias should have the shoots pruned back to a prominent bud, and be placed in a light position in warmth of about 50°. When fairly started into growth, shake off the exhausted soil, trim the roots a bit, and repot into pots of the same or smaller sizes. No water should be afforded for a few days, except by means of a syringe, but do not let them suffer from lack of moisture when in growth. Plants struck last September or October should be kept in a growing state, and be repotted when necessary. These make good pyramids if the side shoots are duly pinched, flowering early in July. The compost used may consist of loam two-quarters, dried cow-manure or fresh horse-droppings one-quarter, and one of half-decayed leaf-soil, with coarse river sand one-quarter. Fuchsias grown on pillars, rafters, and glass partitions, should have the shoots thinned, and the lateral shoots spurred back to two buds beyond the point of the last year's pruning.

Pelargoniums (Show).—Assuming that these had their final potting back in December, growth will soon become more active, and the shoots stand in need of being tied out, so as to give each sufficient space in which to develop; this is best done by placing a piece of wire around the pot just below the rim, securing the shoots with raffia to the wire, and as growth advances a few neat stakes may be placed in the pots, to which the shoots should be tied. Do no further pinching of the shoots unless late flowering is required, and keep the plants on a shelf or near to the glass, admitting air plentifully on mild days, but avoiding cold draughts. Fumigate the plants once in alternate weeks. Zonals for producing flowers next autumn and early winter need propagating early in the year, and where there are plants of no decorative merit, these will afford cuttings of the right sort, that is firm and stocky. Cut these close up to a joint, insert them singly in thumbs, and place on a shelf in a not too warm house; afford but little moisture at the root or overhead. When rooted, pot off in sandy loam, with a small quantity of manure added; pot firmly, and grow on in a temperature of 50°. By this means fine plants may be obtained by September.

Hydrangea Hortensia.—A few plants well established in pots may be placed in a forcing-house having a warmth of 50°, standing them on a shelf near the glass. When growth commences, apply manure-water once or twice a week. The white flowered variety, Thomas Hogg, is very good for early work.

Euphorbia pulcherrima.—As these plants pass out of flower, keep them dry at the root, and place them in a fairly light position, where the temperature does not fall much below 40° during the coldest night. A mean temperature of 45° is suitable.

THE FLOWER GARDEN.

By J. C. TALLACK, Gardener to E. MILLER MUNDY, Esq., Shipley Hall, Derby.

The Wild Garden.—In that portion of the pleasure garden in which the natural or wild style of gardening is carried out, trouble is often occasioned by the gardener endeavouring to combine it with the tidyness characteristic of a well-ordered garden. Many of the plants used in the wild garden flower in the spring, and some of them will be in growth at the present date, the winter Aconite and the Snowdrop for example, and some of the Narcissus, the Crocuses, and many others will be showing above the ground; and Anemones, such as appenina and blanda will show signs of growth. Such being the case, it is a difficult matter to clear up the tree-leaves which may have got blown among the plants. Undoubtedly, it is best to leave them alone, or to cover them with a thin sprinkling of good soil. But as it is not practicable always to leave them thus, their removal should be entrusted to someone who knows every inch of the ground and what it contains, so that the least possible injury may be caused. Wild gardening is generally carried on where there is a considerable amount of shelter from trees or shrubs, so that the ground is generally workable when that in more open parts of the garden is frozen hard, and in the case of further extension of planting this sort of gardening preparation may go on, leaving nothing but the actual planting to be carried out at the right time.

Out-of-doors Chrysanthemums.—At this place it is found advisable to pot-up before winter as many of these plants as will supply the required number of cuttings; and young plants are much to be preferred to old ones. Such lifted plants will now furnish numbers of cuttings, which should be dibbled thickly into boxes of sandy soil, in which they will soon take root if placed in a pit and kept fairly close, and treated similarly to the ordinary stock in pots.

Sweet Peas.—Where flowers are desired at an early date, and the soil is cold and heavy, seeds should be sown at this date in 5-inch pots, six seeds in a pot, and placed in a cold frame, where they may remain until planted. Refuse soil from the potting-bench is suitable for filling the pots, and a few small lumps of turf should be placed over the crocks. I have found it best to raise even the main sowing of the named Sweet Peas in pots, and if they are carefully planted when about 6 inches high, the flowering season is not at all shortened, nor is growth checked.

Deciduous Flowering Shrubs.—There is still time to plant these and afford them a good start, provided the work is properly carried out, the soil is not in a frozen or sodden state, and a mulch of manure or tree-leaves be placed over the roots. Most flowering shrubs require pruning, either to restrict growth or give a natural and pleasing form, some as soon as they have flowered; but as this is usually a busy time, it may be carried out at this season. The chief point is to treat each species according to its natural habit, and in such a manner that the current year's flowering-wood is not removed. For example, most of the shrubby Spiræas will bear pretty hard cutting, and will still flower freely; while the same treatment would spoil for a year at least the Pyruses, Weigelas, and Viburnums, which flower on the previous year's growth.

Penzance Sweet Briars.—These make a beautiful display in the early summer months, and where there is ample space the plants should be allowed to grow away in an almost wild condition, though it may be necessary to tie in, or down, some of the long shoots made the previous summer. When grown as hedges they should be kept neater, and have many of their shoots shortened. Briars are the better for a good soil and manure about the roots, and should be well mulched in the spring.

Ground Work.—Any alterations that may be contemplated should be pushed forward rapidly. Box-edgings may be relaid when there is no frost. Sometimes a walk across lawn-grass has to be made, but there are objections sometimes to having such a walk much in sight; but by sinking the walk a few inches below the general level, and letting the turf slope down to it on either side, this deffect is considerably or entirely obviated, and if the walk is narrow, it is quite hidden from some points of view. When a walk is of small width, a raised centre is not necessary, but is rather an undesirable feature; and if such a walk is well made and properly trapped, the surface water will not collect on it.

THE HARDY FRUIT GARDEN.

By CHAS. PAGE, Gardener to J. B. FORTESCUE, Esq., Dropmore, Maidenhead.

Medlars.—Standard trees may, if it be found necessary, have the branches thinned, and intercrossing ones removed, so as to produce an evenly balanced head. If mussel-scale infests the bark, use the alkali wash next month. Young trees may still be planted. The Dutch Medlar has the larger fruit, but the Nottingham is much the better as regards flavour.

The Quince grows and fruits well in damp soils and situations, and may advantageously be planted by the margins of streams or ponds. The branches of bearing trees should be well thinned, and much of the spray removed, so as to allow the sun to reach the fruit—an important point if fine fruit is required. The Pear-shaped variety is the best for general use.

Cobnuts and Filberts.—If pruning has not been performed, let it be taken in hand forthwith. The usual form of bush is basin-shaped, with a clear stem of 2 feet in height. In pruning, remove all of the young shoots of last year's growth not required to form new branches, or to replace those that have become barren. Care should be taken to leave some shoots carrying male flowers (catkins) for fertilising the flowers later on. Pruning being finished, clear away all weeds, and afford the plantation a dressing of rotten hotbed-manure or woollen rags, and lightly point it over with a fork.

Strawberries.—Where from lack of space, &c., Strawberries could not be planted last August or September, and the plants have been wintered in small pots, let the ground intended for them be now trenched, but leave the planting till the end of the month of March. Plenty of farmyard or other manure should be placed at the bottom of the trenches, and in the case of heavy soils the surface should be left rough, so as to enable frost and air to penetrate to a good depth.

Hints on Work in General.—Where advantage has been taken of the recent frosts to wheel manure on to the fruit quarters, the work of digging can be carried on without hindrance. In gardens where the Gooseberry sawfly-caterpillar caused trouble last spring, remove the soil from beneath the bushes and char it, or place on the smother-fire, and replacing it with fresh soil from another part of the garden. Examine the Gooseberry and Currant cuttings inserted in the autumn, making firm those which have been lifted by the frost. Scions for grafts laid in on north borders should also have the soil pressed firmly about them.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the Publisher.

Letters for Publication, *as well as specimens and plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Illustrations.—*The Editor will thankfully receive and select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.*

Local News.—*Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return the unused communications or illustrations, unless by special arrangement.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.*

APPOINTMENTS FOR FEBRUARY.

TUESDAY,	FEB. 3	National Auricula Society (Midland Section) Meet. at Hôtel Métropole, Birmingham.
THURSDAY,	FEB. 5	Linnean Society's Meeting (Botany).
SATURDAY,	FEB. 7	Société Française d'Hort. de Londres meeting.
MONDAY,	FEB. 9	Surveyors' Institute meeting; United Hort. Ben. and Prov. Soc. Com. meeting.
TUESDAY,	FEB. 10	Royal Hort. Soc. Coms. meet; also Ann. Meeting of Fellows.
FRIDAY,	FEB. 13	Roy. Gardeners' Orphan Fund, Ann. Meet. at Cannon Street Hotel.
SATURDAY,	FEB. 14	Royal Botanic Soc. meeting.
THURSDAY,	FEB. 19	Linnean Society meeting.
FRIDAY,	FEB. 20	Surveyors' Inst., Ann. Dinner.
MONDAY,	FEB. 23	Surveyors' Institute meeting.
TUESDAY,	FEB. 24	Royal Hort. Soc. Coms. meet. Lecture on "Some Unappreciated Plants."
WEDNESDAY,	FEB. 25	Royal Botanic Society meet.
THURSDAY,	FEB. 26	Irish Gardeners' Assoc. meet.

SALES FOR THE WEEK.

MONDAY and FRIDAY, FEBRUARY 2 and 6—
Perennials, Herbaceous Plants, Azaleas, Roses, &c., at 67 and 68, Cheapside, by Protheroe & Morris, at 12.

MONDAY, FEBRUARY 2—
Clearance Sale of Glass Erections and Nursery Stock, at Putney Nurseries, Clarendon and Dryburgh Roads, Putney, by Protheroe & Morris, at 12.

TUESDAY, FEBRUARY 3—
Clearance Sale of 100,000 Fruit Trees, at Sipson, Yiewsley, R.S O., Middlesex, by order of Messrs. J. Smith & Son, by Protheroe & Morris, at 11.—Sale of Japanese Liliums, Azaleas, Begonias, Herbaceous Plants, Fruit Trees, Lily of the Valley, &c., by Pollexfen & Co., at their Rooms, Pilgrim St., E.C.

WEDNESDAY, FEBRUARY 4—
Azaleas, Roses, Perennials, Herbaceous Plants, Bulbs, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.—Roses, Rhododendrons, Azaleas, Lilacs, Hardy Flowering Perennials, Lily of the Valley, &c., by Mr. Stevens, at his Rooms, 38, King Street, Covent Garden, W.C., at 12.30.

FRIDAY, FEBRUARY 6—
Sale of Dendrobiums, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.30.

(For further particulars see our Advertisement columns.)

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick —39·3.

ACTUAL TEMPERATURES:—
LONDON.—*January* 28 (6 P.M.): Max. 50°; Min. 43°.
January 29 (Noon): Fine, mild; 47°.
PROVINCES.—*January* 28 (6 P.M.): Max. 48°, S.W. Ireland; Min. 39°, N.E. Scotland.

"The Orchid Review."

WE are reminded by the issue of the January number of this periodical that this number begins the eleventh volume. That fact alone shows how useful the periodical has become to the orchidist. Many lovers of these plants will remember the consternation caused by the death of Prof. REICHENBACH, who took up LINDLEY'S work, and, so far as cultivated Orchids were concerned, made these pages the vehicle of his communications. Many too will remember the disgust universally felt at the Professor's testamentary dispositions. For a time it was feared that the progress of Orchid knowledge would be seriously affected by the locking up for twenty-five years of the specimens and memoranda made by the Professor. But somehow, as in the case of the terrible curse pronounced at Reims and told in the *Ingoldsby Legends*, nobody appears to be one penny the worse for the strange dispositions of the Hamburg Professor. One reason for this fortunate state of things may fairly be attributed to the *Orchid Review*. Month after month, orchidists have had placed before them the newest and most trustworthy information concerning Orchids. Difficult and entangled questions relating to nomenclature and synonymy have received attention. The raising of hybrids has also been carried on to an extraordinary extent, and, but for the *Review*, the confusion, great as it is, would have been much greater. The specialisation and division of labour, which are so marked features of the times, necessarily bring with them the need for a special journal. Specialisation in botany is, however, as it is in everything else, only advantageous when a thorough grounding in general botany has been obtained beforehand. It is needless to say that this requisite has been fully attained in the *Orchid Review*, which has thus secured the confidence of Orchid-growers, and will, we trust, long retain it.

AGAVES IN BRITAIN.—A few days ago we were assured that the climate of London at that particular time was 10° warmer than that of Nice. Any one looking at our illustrations of Agaves in this week's issue (see fig. 32, p. 69, and Supplementary Illustration) might be led to the conclusion that not only the south-west coast, but even the East of London was as favoured as the coast of Provence. Who would imagine that our Supplementary Illustration was a reproduction of a photograph taken in Victoria Park—yet so it was! In the warm climate of South Devon we are not so surprised at seeing these noble plants, for we have often figured them from the Scilly Isles and the adjacent coast. Our present illustration (fig. 32) is taken from a plant in the gardens of R. F. WILKINS, Esq., Kingswear. There were about ten large plants at Victoria Park, where they have remained for some thirty years. The first flowering occurred in 1901, and during the past season two others developed flower-stems, and were planted as central objects in a great bed of succulents, and the illustration shows the central portion of that bed. A peculiarity with this variety of Agave is the rapidity with which the flower-stem is formed in its early stages, growth taking place at the rate of nearly 6 ins. in twenty-four hours. "The two plants," says Mr. MOORMAN, the Superintendent, "grew in a house 12 feet in height, and the glass had to be broken so as to allow them to develop, and the weather was not fine enough to allow me to place them safely out of doors. Each of the flower-shafts averages about 24 feet in height, and is furnished with several whorls of dull Lily-like flowers, and can only be said to be attractive when their yellow stamens appear conspicuous above the cluster of calyces. The summer of 1901 was warm enough to permit fertilisation of the flowers then open, and on the approach of frost the plant was placed in its withering state under glass without root or soil, and the seeds were in this manner fully ripened, and germinated a few days after sowing them, with the result that I have now nearly 100 young plants so raised. I send you a pod of seed, and a young plant raised from the seed sown on February 2, 1902."

LINNEAN SOCIETY.—The next meeting of this Society will be held on Thursday, February 5, 1903, at 8 P.M., when the following paper will be read:—Prof. F. W. OLIVER, "On the Structure and affinities of Stephanosperma, Brongniart, and other fossil Gymnosperm seeds." Exhibition: Median Prolification in Geum rivale, illustrated by specimens from the herbarium of Sir J. E. SMITH, and other sources.

THE SWEET PEA SOCIETY.—The schedule of prizes to be offered by the National Sweet Pea Society at the next exhibition on July 15 & 16, at Earl's Court, has just been received, together with the Committee's report and balance-sheet for the past year. There will be a special class for nineteen varieties of Sweet Peas, to illustrate the colour distinctions in the Society's classification, the Committee having classified them by colour alone into nineteen sections. Then follow classes for thirty-six, twenty-four, and twelve bunches of Sweet Peas, distinct, with duplicate classes from which members of the trade are excluded. A number of classes is devoted to competitions with two bunches of Peas of stated colours, and the remaining classes are designed to show the effectiveness of Sweet Peas in table and other decorations. The Secretary is Mr. H. J. WRIGHT, 132, Dault Road, Wandsworth.

MR. JAS. HUNTER, OF LAMBTON CASTLE GARDENS.—The following circular concerning Mr. J. HUNTER has been sent to us for publication:—"Mr. JAS. HUNTER'S retirement from the supervision of Lambton Castle gardens has evoked a wide-spread and earnest feeling that some tangible recognition should be tendered him for his eminent services to horticulture and to horticulturists, for his never-failing courtesy to the numerous visitors to the gardens, and in appreciation of his good qualities as a friend and neighbour. At an influential meeting held at the Queen's Head Hotel, Chester-le-Street, it was unanimously resolved to invite the co-operation of working committees in Edinburgh, Sunderland, Newcastle, and South Shields, to work in conjunction with the Chester-le-Street Committee, thus giving Mr. HUNTER'S numerous friends, over as wide an area as possible, the opportunity of showing their appreciation of the object in view, and by their subscriptions to bring it to a successful termination. Secretaries, M. D. THOMPSON, the gardens, The Hermitage; THOS. GARNETT, estate office, Lumley Castle. Subscriptions may be paid into Lloyd's Bank, Chester-le-Street, payable to F. C. BULLOCK, Treasurer; or will be received and acknowledged by Mr. W. H. MASSIE, 1, Waterloo Place, Edinburgh; Messrs. FINNEY & Co., seedsmen, Newcastle-on-Tyne; Mr. J. SUMMERS, florist, Fawcett Street, Sunderland; Mr. BARNARD COWAN, superintendent, Harton Cemetery, South Shields; Messrs. M. D. THOMPSON and T. GARNETT, Chester-le-Street; G. H. COOKE, Lambton gardens, Fence Houses; Mr. D. THOMSON, 24, Frederick Street, Edinburgh; and Mr. ALDERSON, 149, High Street, West Sunderland."

ROYAL GARDENERS' ORPHAN FUND.—The fifteenth annual dinner in aid of the above Institution will take place at the Hotel Cecil, Strand, W.C., on Tuesday, May 5, 1903, under the presidency of the Right Hon. the Earl CARRINGTON, P.C., G.C.M.G., &c. The Secretary will be glad to receive the names of any gentlemen who may desire to act as stewards, or to be present on this occasion, and will be pleased to furnish any information that may be required with reference thereto. Subscriptions, to be placed on the chairman's list, are earnestly solicited.

THE NATIONAL CHRYSANTHEMUM SOCIETY will hold its annual meeting on Monday next, February 2, at the Albert Hotel, Victoria Street, Westminster, at 7 P.M., Sir A. K. ROLLIT, M.P., President, in the chair. In addition to the ordinary business of such meeting, some alterations and additions are proposed to Rules X., XIII., and XIV. In view of previous correspondence, it is interesting to see that it is proposed to add to Rule XIV., "No member of any committee of the Society shall be eligible for nomination as a judge at any of the Society's exhibitions.

VEITCH MEMORIAL FUND.—At a meeting of the Trustees held on the 27th inst. (Dr. MASTERS in the chair), it was decided to offer to the Royal Horticultural Society, two Medals and prizes of £5 each for competition at the Chiswick Show, to be held on September 29, and two following days, one Medal and prize to be awarded to fruit, and one Medal and prize to vegetables. It was also decided to offer the Birmingham and Midland Counties Fruit and Floricultural Society, a Medal and prize of £5 to be awarded to fruit; also a Silver Medal to Mr. STOLLARD, of Clay Cross, Derbyshire, in recognition of his long and faithful services to horticulture, extending over a period of sixty years as Secretary of the Clay Cross Horticultural Society. It was further resolved to contribute the sum of fifty guineas towards the fund being raised by the Royal Horticultural Society for the erection of a New Hall and Offices.

DONATION BY MR. T. SUTTON TIMMIS. — Horticultural visitors who saw the fine stove and greenhouse plants staged for the past two seasons at the Shrewsbury show by Mr. B. CROMWELL, gr. to T. SUTTON TIMMIS, Esq., Cleveley, Allerton, Liverpool, will learn with satisfaction that not only to horticulture does Mr. TIMMIS' sympathy extend, but his name is prominent in every good work. The latest gift is a sum of £10,000, which this gentleman has vested in trustees for the investigation of the origin and the cure of cancer, the researches to be carried out at the Liverpool Royal Infirmary, and the new laboratories of experimental medicine at University College.

BRYOPHYLLUM CRENATUM. — We learn that the plant figured in our last issue from Messrs. VEITCH'S establishment was originally obtained from Kew, and that the authorities of the Royal Gardens were in their turn indebted for it to Messrs. VILMORIN, ANDRIEUX ET CIE., of Paris. See *Revue Horticole*, 1900, pp. 175, 362.

DISEASES OF PLANTS. — Messrs. KIRCHNER & BOLTSHAUSER have published the sixth series of their *Atlas der Krankheiten, &c.* It is principally devoted to the diseases and insects affecting the Vine, and consists of a number of coloured plates of 8vo size in a portfolio. The plates are beautifully executed, so that the fact that the explanatory text is in German need not deter anyone not familiar with that language. The work is published at Stuttgart by EUGEN ULMER, but it may be had from WILLIAMS & NORGATE.

LADY FELLOWS AT THE LINNEAN.—It will be seen from the report in another column that the proposal to obtain a new Charter, in accordance with which women may be elected Fellows of the Society, was adopted in a meeting of seventy-one Fellows by fifty-four to seventeen.

FROGMORE.—The KING has recently inspected the buildings which have been completed since his last visit to Windsor, and which have already been alluded to in these columns. A large substantial house has been erected for the accommodation of twenty-four young unmarried gardeners, who hitherto had to live in small cottages scattered about the grounds. The men are stated to be highly pleased with their new home, in which each man has a well-ventilated cubicle as his sleeping apartment, and there are dining, reading, and reception rooms for general use. The Palm-house in the grounds has been converted into a luncheon and tea hall for large parties in the summer, and will no doubt be used a great deal during the Ascot weeks.

FRUIT FROM TASMANIA: SEASON 1903.—Respecting the deliveries of the on-coming season's fruit by the Peninsula and Oriental Company's vessels, we have received the following data from the officials of that Corporation :—

Name of Ship.	Due in London.
"India"	April 5 (about).
"Oceana"	April 19 (about).
"Australia"	May 3 (about).
"Victoria"...	May 17 (about).
"China"	May 31 (about).
"Himalaya"	June 14 (doubtful).

Should fresh arrangements be made in any case, these will doubtless be published in time.

THE FRUITERERS' COMPANY.—At a banquet of the Company held on Monday last, Mr. LEWIS CASTLE was presented with the Company's prize of 25 guineas and a Gold Medal for the best essay on "Fruit and Vegetable Packing for Market."

TECHNICAL INSTRUCTION IN THE NORTH RIDING.—We have before us the eleventh Annual Report of the Technical Instruction Committee in connection with the North Riding County Council, and it is of a highly satisfactory character. The following is the scheme of instruction, as divided into sections:—1, agriculture and allied subjects (horticulture, veterinary subjects, poultry-keeping, dairy work, &c.); 2, elementary school teachers' classes for art and Nature-study; 3, aid to secondary (including science) schools; 4, schools of art and science and art classes; 5, evening schools; 6, domestic economy, carpentry, shorthand, beekeeping, &c.; 7, award of scholarships and exhibitions; 8, grants in aid of the purchase of apparatus suited to technical instruction. In the second section the classes were very full. Twelve Nature-study lessons were given at Northallerton, the subjects treated of including the structure and functions of a green leaf, structure and germination of seeds, a winter branch, and methods of seed dispersal. It was somewhat unfortunate that the classes being held in winter, outdoor study was conducted under difficulties. Mr. ALFRED GAUT, Extension Lecturer for the Victoria University, reports very favourably upon the interest and intelligence evinced by the students. The total number of students receiving technical instruction in Section 7 was 1,290, out of a grand total in all sections of 6,342. Considering the diversity of subjects undertaken, this is a large proportion, and shows the interest for agriculture and allied subjects shown in the Riding.

A NEW CHINESE VEGETABLE, DIOSCOREA FARGESII.—"Under the French title of Igname de Farges, young roots of this interesting new edible tuber, which attain their full size in about three years, are, writes Mr. Gumbleton, now being offered for the first time by Messrs. Rivoire, of Lyons, at the moderate price of nine francs for ten tubers, or a franc for one. The tubers are round, and of the form of a small orange, and weigh when fully grown from 3½ to 4 oz. They have the great advantage over the ordinary Yam or Sweet Potato of growing and reaching their full size in ordinary garden soil, whereas the Yam (Dioscorea batatas) requires for its successful culture from 2½ to 3 feet depth of soil, and is so brittle that without extraordinary precautions and care, it is almost impossible to extract the tubers from the ground without breaking and spoiling them. The plant also produces numerous bulbils above ground which greatly facilitate its propagation and increase; these can be had for ten francs the hundred, twenty-five for three francs, or ten for one franc and a half. It is said to be hardy, and should, we think, be an acquisition to our vegetable gardens."

THE VINE AND THE WINE IN THE TIME OF THE ROMANS.—Under the title *La Vigne et le Vin chez les Romains* (Paris: G. NAUD, 3, Rue Racine), M. CURTEL has published a very interesting account of the Vine and its products in classical times. He deals with the subject not so much from the point of view of the classical scholar as from that of the Vine-grower; he has studied the Roman authors, such as CATO, COLUMELLA, PLINY, as well as the poets, and comes to the conclusion, from a comparison of all the available evidence derived from these sources, that the Romans were every bit as good cultivators as their modern representatives. The author goes on to show that the processes of wine-making did not differ essentially in Roman times from those practised now; and he concludes that modern wine-growers might find more examples to follow than of errors to avoid in studying the practices of their predecessors. The book is arranged with that method and lucidity which are characteristic of the best French books, and those interested in the Vine and its products will find much to interest them in M. CURTEL'S pages. We may add that M. CURTEL is director of the Œnological Institute of Burgundy, and is therefore well qualified for his task, the more so that he has not forgotten his Latin.

RELATIONS BETWEEN ATHLETICS AND INTELLIGENCE.—In the *Proceedings of the Royal Society* (vol. lxxi., No. 469), is a paper on "The Correlation of the Mental and Physical Characters in Man," by ALICE LEE, MARIE A. LEWENZ, and KARL PEARSON, F.R.S. The following is a brief summary of the statistics collected and tabulated:—"While the intelligent are only slightly the more healthy, the athletic are notably the more healthy element in the community. Further, the athletic are considerably more intelligent than the non-athletic; they are the more popular and more noisy element, and they tend to quick rather than sullen temper. We may in general terms describe the athletic boy as healthy, quick-tempered, and intelligent, when compared with the non-athletic boy. He certainly under all three headings should make a better soldier than the non-athletic, and it is hard to discover any statistical evidence in school life for such expressions as 'the flannelled fool at the wicket,' or 'the muddied oaf at the goal.' What happens in later life can only be determined when ample statistics are available for reduction and comparison. Failing such data, we can argue only from the vaguest of impressions." To avoid extremes would here as elsewhere seem to be the wisest course to pursue.

UTILISATION OF ATMOSPHERIC NITROGEN.—The discovery within the last few years that certain plants are capable of storing up nitrates, absorbed by the agency of bacteria from the nitrogen of the atmosphere, in their roots in the form of nodules, has led to experiments in America which promise wonderful results. A description of how the nitrogen of the atmosphere has been utilised for the manufacture of a commercial fertiliser is described, the pioneers of this industry being Messrs. BRADLEY and LOVEJOY. They have succeeded in producing nitrate of calcium at less than half the cost of nitrate of soda, which is found in a state of nature in Chile; not only so, but when it is stated that nitrate of calcium is superior to nitrate of soda as a fertiliser, the importance of the invention will be fully understood. *Indian Gardening.*

WATER SUPPLY FOR GARDENS AND HOTHOUSES.

(*Concluded from p. 27.*)

WATERWHEEL.—Where a "ram" is not suitable, for various reasons, it becomes necessary to adopt some other means, and there are almost always pumps of various descriptions driven by some kind of power. Where there is a running stream, and the water can be held back by a "bay" or dam, the most economical of these is a water-wheel, which may be either an "overshot," a "breast," or an "undershot" wheel. In the first the water passes over the wheel into buckets surrounding it, and acting by its weight causes the wheel to revolve. The second receives the water about the centre, sometimes into buckets as before, but more often upon "floats" surrounding the wheel, like a paddlewheel; these buckets or floats work close to a curved wall built of timber or brickwork, which confines the water to the wheel until it escapes at the bottom. The "undershot" wheel

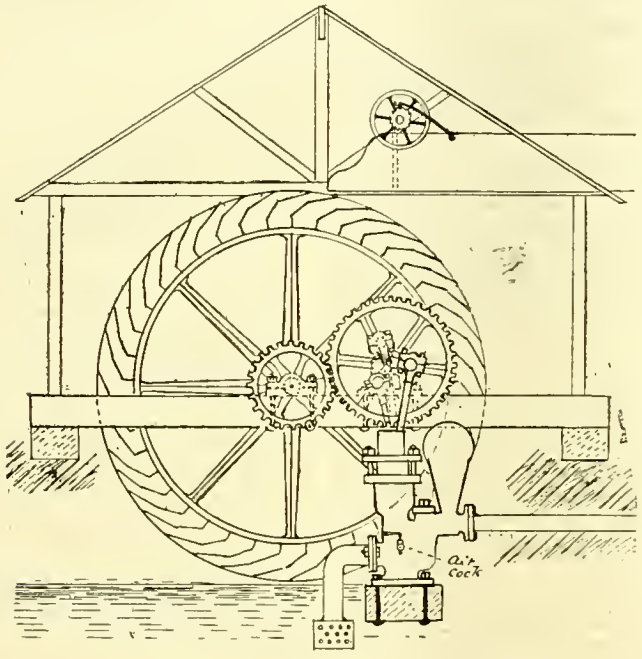

FIG. 33.—WATERWHEEL FOR PUMPING PURPOSES.

(fig. 33) takes the water underneath, or only a short distance from the bottom of the wheel. This wheel is a floatwheel, and as the water rushes under it, it strikes the floats and drives the wheel round.

The "overshot" wheel is by far the best where there is sufficient height for it to work. The "breast" wheel is the next in efficiency, while the "undershot" should never be employed unless there is an abundant supply of water.

When a waterwheel is employed to work pumps, it generally is connected to them by cogwheels to reduce the speed, and the pumps are driven by a crankshaft to which one wheel is attached, the other being on the waterwheel shaft or axle. In order to obtain a steady flow of water the pumps, which are almost always of the "forcing" variety, are arranged in a set of two and often three pumps, so that one is always delivering or beginning to do so while the other is drawing (see fig. 33).

WINDMILL.

In some cases, however, there is not sufficient water to work a wheel, and resort must be had to other sources. The cheapest and simplest of these is a windmill, but the positions where a windmill can be applied are necessarily limited. Assuming, however, that the well or other source of supply is situated so that a windmill can be applied, there are several methods of fixing them. The ordinary description of mill used for the purpose is usually shaped like a wheel, and fitted with a number of flaps or "shutters," which can be closed or opened to stop the mill. When the wind blows very hard, the shutters open, and allow it to pass through, closing when the wind sinks. The older kind of windmill has four arms or "sweeps," which are also provided with "shutters," and are kept closed by a spring or weight, as in the circular windmill.

The writer, however, has seen a windmill made in a very much simpler manner, which acted almost as well, in which the "sweeps" were nothing more than four boards secured to the ends of two pieces of timber crossing each other, the boards being set at an angle to catch the wind. The axle to which the pieces of timber were fastened had a crank which worked the pump-rod, this rod having a swivel joint to allow the mill-sweeps to be turned to the wind by a long and wide board, like a bird's tail or a weathercock. Although this mill looked somewhat clumsy, it performed its duties extremely well. Fig. 34 shows a mill copied from this, with dimensions.

EMPLOYMENT OF ANIMALS.

Lastly, animal power can be employed to drive the pumps, this being a very common device. The pumps, either "lift" or "force," are connected by gearing to a "horse-gear," which is too familiar to require description, and to which the animal is attached. The great drawback of this method however is, of course, the attention required to drive the animal, and the frequent circumstance that very often it is required at the same time for other duties.

Where wind power is employed, there is, of course, a certain amount of uncertainty as to its operation; but this is seldom such as to prove a serious drawback, and can in great part be overcome by arranging the reservoir of such size as to supply the garden, &c., for more than a certain period of time, as in many districts there are seldom days when there is insufficient wind to drive a windmill of light construction in a favourable position. Care should be taken of the pumping machinery in frosty weather; and on stopping the air-cocks of the pumps should be opened and all water drained out to prevent cracking or bursting the pumps. If a waterwheel is employed, and it is constructed of cast iron, it should be carefully protected by a temporary shed formed of hurdles thatched with straw, unless already placed in a house, as in fig. 33.

In conclusion, circumstances are so varied that the writer can in this article only offer suggestions, and where a system of water supply is about to be installed, it is by far the best course to seek expert opinion, which can often only be given on the spot.

DESCRIPTION OF THE WINDMILL PUMP (FIG. 34).

a. Cross placed over well, and forming a foundation for the mill, made of two pieces of timber 4 ins. by 4 ins. Length depends on size of well.

b. The post, 4 ins. diameter (height depends on circumstances). The post is bored to take the pump-rod, as shown.

c. The shores supporting post, 2 ins. by 3 ins. (Only two shown.)

d. Frame of mill. (A fair size would be 4 ft. high by 2 ft. wide.) Made of 2 in. by 3 in. stuff, finished with a pointed roof, and covered with light weather boards or not, as preferred.

e. Centre beam carrying weight of mill, 3½ ins. square in middle, tapered to 3 ins. at ends, bored to take a brass bush to receive the pivot *f*, formed of a piece of steam pipe (fitting the pump-rod), with a flange (*g*) screwed and brazed on the lower end. This flange is held on the post by three screws fitting three nuts, let into the post as in a bedstead.

h. The sweeps. A fair size would be, each 6 ft. long by 1 ft. wide, formed of ½-inch board, with a piece of ½-inch lath on the outer edge.

i. The two pieces carrying the sweeps, 6 ft. long, halved together, and thus reaching half way down the sweeps. These are bevelled at their opposite ends to receive the sweeps, to an angle of about 22° at their upper end, and about 15° at the extremity.

These two pieces are 3 ins. square in the middle, tapering to 2½ ins. at ends, and would be better if of Ash, but if Deal they must be strengthened by a piece of iron forged like a cross about 1 ft. long, and screwed to the back of the pieces. The iron has a square-tapered hole to take the axle (*j*), of 1½-inch iron, round or square, which must be turned with three bearings, and formed with a crank exactly in the centre to work the pump. The stroke of the pump for a windmill must not be too long—about 8 ins. is a fair proportion.

The bearings at each end of the axle (*j*) run in brass bearings (*k k*), and the centre bearing, which is on the crank, works the pump-rod (*l*), by the sling (*m*), which is carried by the guide (*n*) fixed across the mill.

The axle (*j*) has a nut and screw at its outer end, by which the pieces (*i*) are secured to it. If the pieces (*i*) are of Oak or Ash, the iron cross may be dispensed with, but a small plate with a square hole must be screwed to the back of them to receive the axle.

o. A swivel-joint on the pump-rod, to allow the mill to turn to face the wind. This can be dispensed with if preferred, but the mill works far better with it.

p. The "tail" or vane, 6 ft. long by 3 ft. wide, of ½-inch stuff, with a centre rib 6 ft. long, 2 inch by 3-inch stuff, and three cross ribs to strengthen it, 2 ins. by 2 ins. This vane is for keeping the sweeps to the wind, and should just balance the weight of them.

q. Three iron stays of ½-inch iron rod (only two shown) to steady vane.

NURSERY NOTES.

EXTENSIONS AT READING.

THE enterprising seedsmen, Messrs. Sutton & Sons, of Reading, have for many years past provided a New Year's show of Primulas and Cyclamens in the months of January and February. It is an exhibition that never fails to please a gardener with an interest for winter flowers, and who delights to see the finest strains obtainable cultivated to a degree that appears to leave little or no room for improvement. The student who examines the progressive variations obtained in the process of developing the strains is also specially interested.

This season the plants are on view in a new range of houses which have been built in the trial-grounds (or "The Farm," as it is known at Reading), an area of about 80 acres, which forms a very prominent feature of the landscape just before one enters the town by the London & South Western Railway.

Until now, the plants have been cultivated at a smaller establishment in the town itself, where the late James Martin laboured in the congenial work of cross-fertilisation now carried on by his successor, Mr. McDonald. The firm had several good reasons for transferring the work to the trial-grounds, as stated by Mr. Arthur Sutton, on the 23rd inst., when a consider-

able party of horticulturists were invited to Reading to inspect the houses. It was desired to have the indoor plants upon their own ground, the trial-grounds being the firm's freehold property, and at the same time to avail themselves of the better conditions for the plants which exist in the open position 1½ mile out of the town. Like all other cultivators of plants, Messrs. Sutton have found that the purer the atmosphere, and the more rural the site upon which the plants make their growth, the easier may the gardener obtain the perfection for which he strives. It is true that there is the satisfaction of recording from time to time instances of successful culture in town gardens; but these instances are never the result of the prevailing conditions, but in spite of them.

THE NEW HOUSES.

The new range of houses has been built by the well-known horticultural builder Mr. Duncan Tucker, and consists of twelve span-roofed houses, grouped on either side of a large pavilion or Palm-house, and most of them may be entered from corridors, without the visitor having occasion to go into the open air. The pavilion has been provided with large double doors so that a van may be taken inside, and the packing and unpacking of plants be carried out under suitable conditions. The houses are 60 feet long and 14 feet wide and are eminently suitable, together with the new pits and frames, for the cultivation of Primulas, Cyclamens, Achimenes, Gloxinias, herbaceous Calceolarias, and other such plants, that the Reading firm make specialties.

Arrangements have been made to afford fresh air to the plants without injurious draughts, and the fullest provisions exist for collecting an abundance of rain-water, thus showing that the superior qualities as an aid to growing plants of rain-water over hard-water from taps is appreciated. A simple contrivance for saving labour in regard to the transportation of plants is so very simple that one wonders the method has not been common long ago, but the writer does not remember to have seen it in practice previously. The houses are provided with paths through the centre, and there are shelves on either side; in most cases these have iron supports, and corrugated zinc laid across them covered with gravel. Along the iron fronts of the shelves there is a ledge 2 inches wide, extending towards the centre of the path, and flat trolleys have been made with small wheels that fit this gauge; consequently one man may push the trolley or tray on the same level as the shelves to the further end of the house, fill it with plants, and push it to the other end with the greatest ease and convenience, and owing to the arrangements in the corridor, the repotting of the plants can be carried out close to this point. Every gardener will realise how much better this arrangement is than the carriage of a hand-barrow in and out of the houses, which requires two persons, or even than the common method of employing a sieve.

There are four powerful Trentham or Cornish boilers, contained in two convenient stokeholes, and in ordinary weather the work is done by two of these. The arrangements for cleaning the flues, bringing the clinkers, &c., away by means of pulleys, and the provision of safety-valves to the boilers, all show that the importance of securing efficiency in these details has been recognised. Valve indicators have been affixed to the hot water-pipes, which show exactly to what degree the valve is opened.

THE DISPLAY IN THE HOUSES.

Chinese Primroses.—The collection of plants in bloom consists of from 1,200 to 1,300 plants, in about forty varieties. The writer was particularly pleased with the large batch of plants representing the new variety known as The Duchess, for it showed how fixed it has become, and that there is little difficulty in propagating it truly from seeds. It was figured in these columns on February 3, 1900, and most of our readers are familiar with the zone of reddish-rose colour around the yellow eye which characterises the variety. There is, therefore, no need to describe it minutely now, but it may be remembered that the variety was obtained from a cross between Crimson King and Snowball. A batch of plants of The Duchess produces an effect quite distinct to any previously afforded by Chinese Primroses. The characteristics of The Duchess have been imparted to a double-flowering variety, and the plants, with fine double flowers, having the colour concentrated in a zone around the centre, represented the best novelty in the collection this season. One plant of The Duchess type produced flowers last year of stellate form, and it was hoped that from it a race of Star Primulas having the coloured circle might be got, but the seedlings from that plant have this year reverted to the exact type of The Duchess. However, there may yet be "star" Duchesses to grace future collections.

There were many selections from crosses that have not yet been fixed; the first seedlings from any cross have always dissimilar characteristics, and the best of them are subsequently "fixed" by careful selection. Of these first seedlings it would serve no purpose to write in detail now although the variations in them have such absorbing interest for anyone really interested in these plants. The older varieties have been described appreciatively on previous occasions, and are worthy of high praise.

Among white varieties there is Snowdrift, always popular because it blooms early, blooms abundantly, and its flowers open white and remain white so long as they last. Pearl has a more proper habit from the florist's point of view: it blooms later, its flowers are larger and of better form, but after expanding they blush a little; Royal White is remarkable because it and one other white variety have dark-coloured foliage.

Of pink-flowered varieties there were noticed Reading Pink, and Sutton's Pink. Reading Pink possesses deep colour, and the flowers are beautifully fringed; and Sutton's Pink, whilst having a better habit, has paler flowers and is therefore less attractive. Rosy Queen, a beautiful Fern-leaved variety might also be classed with the pinks, but the colour is richer and more Rose like. Brilliant Rose is a capital variety, rich in colour, and appears always to grow and flower well and freely. Of reputed Blue Primulas, Reading Blue is the deepest in colour and produces fine bold trusses of large flowers. Blue Fern-leaved is of the same type except in respect to the character of the foliage; but a variety that has been much admired for three years or more, is that known as Cambridge Blue: the colour is paler than in the two varieties already described, and the flowers have a fine fringe and generally a margin of white—it is a favourite with most visitors. Reading Scarlet and Crimson King may be recommended for their exceedingly rich colours. A batch of Crimson King has a splendid effect, and it blooms continuously for a long period, but as is frequently the case in such varieties, the colour is somewhat fugitive.

The Giants were coming nicely into bloom, but are naturally rather later than the others. Giant strains may be had in pink, white, terra-cotta, and crimson.

If space and time permitted, one could write an essay on the beauty and usefulness of Messrs. Sutton's double flowering Primulas. Reference has been made already to the newest of this type, but the older varieties in blue, pink, white, Carnation-flaked, and scarlet, are all to be highly recommended. Pink Beauty is especially rich in its colour effect.

The Stellata section is still popular in gardens, and is used largely for decorative purposes; this type is represented in pink, blue, white, and carmine. The variety Mont Blanc, white, is particularly handsome.

Cyclamens.—Most readers of this Journal are familiar with Messrs. Sutton's Cyclamens. Some of the most popular varieties are the Giants, in white, cherry-colour, rose, pink, crimson, purple, and crimson and white. White Butterfly of a somewhat different form than the others, is liked everywhere; and Vulcan is indispensable for its exceeding rich crimson colour. Phœnix is also pretty; but one of the most distinct, and a variety of especial charm to the writer is Salmon Queen — its colour is so rare in Cyclamens, and so pleasing withal.

It only remains to be said that the Cyclamens for next season could be seen just in their first seed leaves, and that the Gloxinia tubers had commenced to make growth.

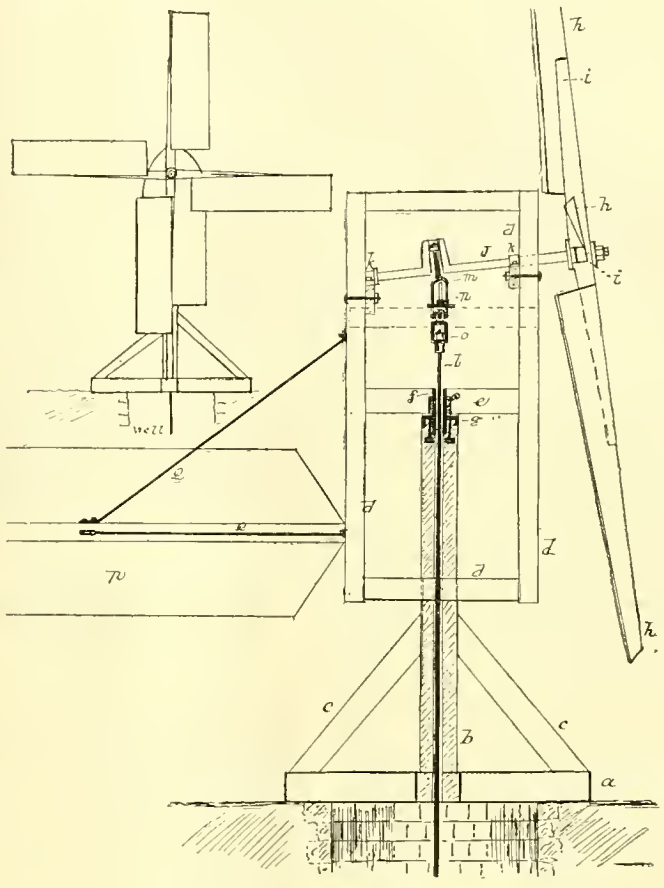

FIG. 34.—WINDMILL FOR PUMPING PURPOSES. (SEE P. 74.)

WINTER-FLOWERING BEGONIAS AT PENRHYN CASTLE.

THERE is always something of more than ordinary interest to be seen at this establishment, and something that is worthy of one of Britain's foremost gardeners, who has long and ably directed matters horticultural there. This time it was the Begonias, and the three houses, containing Gloire de Lorraine in three distinct stages, were much the best I have ever seen. The plants were growing in 5, 6, and 7-inch pots, according to the vase requirements in the Castle, and many of them were 3 feet high and nearly 2 feet through at the top of the pot, trained up in a loose pyramidal shape, and covered with large, deeply coloured, pink blooms. The plants had evidently received the most generous treatment, having received abundance of heat, light, air, and stimulant. The succession batches were equally promising, but the white form cut a poor figure alongside.

There were several of the new scarlet section in variety, such as Winter Cheer, Mrs. Heal, Ensign, &c., all of which did credit to the man in charge, and which will, doubtless, as soon as stock can be worked up, become a fine feature to our invaluable winter-flowering Begonias.

There is a large batch of that later species Socotrana, one of the parents of Gloire de Lorraine, although a tuberous-rooted kind, of which Mr. Speed speaks most highly; which coincides with my own opinion. Gloire de Sceaux, one of the dark foliaged varieties, is another useful variety grown there. *W. Crump, Madresfield Court.*

MENDEL'S METHODS OF PLANT BREEDING.*

(*Concluded from p. 34.*)

3. *Differential Characters.* — The third point in Mendel's method is that the characters selected for crossing must not only be single and constant, but also differential in the two parents. If the single characters be nearly alike in the two parents it will be impossible to determine which parent the offspring resembles in that character, because all three would be nearly alike; on the other hand, the wider the difference between the single characters of the two parents, the more clearly defined would be the characters in the resulting offspring, and the easier it would be to refer the resemblance in the offspring to either parent. Mendel, in his experiments with Pisum, takes single and constant characters in the parents, which are at the same time distinctly differential, and which therefore can be clearly defined in the offspring.

4. *Dominant Characters.*—The fourth point in Mendel's method is distinctly new, and that is the crossing together of dominant and recessive characters only, i.e., one of the characters of the differential pair must be always distinctly dominant over the other one, which is known as the recessive character. This gives uniformity in the first generation, and avoids the great difficulty of working on to the next generation with results that are not uniform, e.g., if the pair of characters were of equal potency, they would, on the whole, be intermediate—either blended or mosaic—tending towards one and the other parent alternately. It is obvious therefore, in cases like these, when one wished to carry on the experiment to further generations, the lack of uniformity in the first generation would make matters so complicated as to be almost unworkable. Mendel avoids this by the selection of dominant and recessive characters only, and his results can therefore be easily recorded and tabulated numerically.

5. *Large Numbers.* — The fifth point in Mendel's method is also very important, and far superior to the methods adopted by the earlier experimenters. In the older experiments, for the most part, only a few individuals of each cross were raised and observed, hence the range of variation apparent was either extreme or scarcely perceptible, according to chance and circumstances. This no doubt accounts in some measure for the very different results obtained by different observers at different times. Mendel avoided these difficulties by raising large numbers of individuals in each generation, and in this way practically gauged the total range of variation in each case.

6. *Many generations.*—Now we come to the sixth and last method of Mendel to be noted here, and that is, he was not content to stop at the first generation or even the second, as so many of his predecessors did. In all cases Mendel carried out the experiments to the third, fourth, and fifth, and in two cases actually to the sixth generation; and this work, though it must have been laborious, was absolutely necessary, and once more shows the thorough and painstaking industry with which Mendel overcame all obstacles in his pursuit of truth.

To sum up the methods:—Those hybridists who wish to follow in the footsteps of Mendel, or those of his disciples, and thus help in the elucidation of the baffling problems of heredity, will find it essential to select in the original parents characters for crossing which are at once single and constant, and differential and dominant; with the further proviso that large numbers of individuals in many generations must be observed and compared. By these methods alone will definite results be obtained.

In conclusion, I will give as an illustration of Mendel's methods his own selection of characters in Pisum:—

PISUM SATIVUM.

(*Constant Races of Garden Peas*)

	Dominant × *Recessive.*
1. Form of ripe seeds... ...	"round" × "wrinkled."
2. Colour of cotyledons ...	yellow × green.
3. Colour of seed-coats (coloured)	brown × white.
Colour of flowers (coloured)	purple × white.
4. Form of ripe pods	inflated × constricted.
5. Colour of unripe pods ...	green × yellow.
6. Position of flowers... ...	axial × terminal.
7. Length of stem ("haulm")	6–7 feet × ¾–1½ feet.

Charles C. Hurst.

* Read at the International Conference on Plant-Breeding and Hybridisation, New York City, Sept. 30, 1902, by C. C. Hurst, Burbage, Hinckley.

HOME CORRESPONDENCE.

ENGADINE CARNATIONS. — A correspondent writes, in answer to an enquiry in the *Gardeners' Chronicle*, January 3, 1903, by "C. J. H.":—I know of no Carnation of that name, and I think that "C. J. H." means Double Grenadin, of which there are two varieties, scarlet and white. They can be obtained of Messrs. J. Veitch & Sons, nurserymen, King's Road, Chelsea, S.W. The seed should be sown in March, placed in a cold frame, and kept close till the seedlings appear, then afford plenty of air to prevent damping. Should the plants damp-off, prick them into boxes or pans, and when large enough to handle, prick them into a nursery-bed at 9 inches apart, and in October transplant them at 18 inches apart to the beds or borders where they are to bloom. Such plants will begin to flower late in June. Double-flowered Grenadins should be raised from seed annually, as they rarely produce "grass" fit for layering. *W. Daniels, gr., The Warren, Cromer.*

COLEUS THYRSOIDEUS —As a winter-flowering plant Coleus thyrsoideus is an acquisition in gardens where much decorative work has to be carried out, it being valuable as a pot-plant for furnishing flowers for cutting. When used for the latter purpose the flower-spikes should either be cut in the early morning and placed in cold water or left on the plant till just before they are placed in the glasses, it being liable to flag. The plant is easy of cultivation, and cuttings strike very readily. Whilst in full growth in the summer it should receive plenty of liquid-manure, and occasionally soot-water. It is invaluable for its colour. We have just finished cutting up a batch of fifty plants, obtained from one small plant purchased last spring; the largest are in 8-inch pots, 3 feet high, and have thrown up some splendid long spikes of bloom, which have been much admired. The smaller plants are placed in silver vases to adorn the dinner-table, and they have a very light and pretty effect. During the winter months ventilation should be afforded whenever the weather is suitable, so as to harden the plants for use in the mansion, a night temperature of 55° to 60° being high enough. *A. B. Wadds.*

GOOSEBERRIES ON NORTH WALLS.—I cannot agree "that fruit grown on a north aspect is usually small and insipid, and totally unfit for the dessert table." True, the fruits are not so sweet as those grown in the open quarters; nevertheless, a dish of ripe fruit in the months of September and October is of value when one has to provide eight or ten different kinds of dessert fruits. Moreover, many persons prefer having fruit from the open to that ripened under glass during the months mentioned, and few despise ripe Gooseberries; and there are some who never partake of Grapes, Melons, or Peaches. It may be owing to the genial climate of Devonshire that the fruit from north walls requires to be netted to preserve it from the birds. The fruits are neither small, sour, or extra tough in the skin. The names of the varieties that grow here on the north wall are London, Clayton, Speedwell, Progress, Leveller, Snowdrop, Trumpeter, Keepsake, Railway, Mitre, and Australia. *J. Mayne, Bicton.*

—— May I put in a word or two in favour of the Gooseberry? In the early sixties I was employed as journeyman in the gardens at The Hall, Sutton Forest, York. The gardener was expected to put as many varieties of fruit on his master's table as possible late in autumn, and a good bit of the north wall was covered with the old Rough Red Gooseberry, which is a variety that bears well, swells to good size, and will keep to the end of September or the beginning of October. The flavour was not to be despised. The wall was high, being the back of lean-to vineries. Other fruits used to be done well, viz., autumn-bearing Raspberries and Red Currants, the fruit of which was kept till frost came. I well remember on one Sunday afternoon the head gardener sent round for all hands to turn out and gather the Raspberries, as it looked like frost. We set to work, and gathered over a peck of very good Raspberries; and it was well that we did so, for that night a sharp frost occurred that finished our Raspberry-gathering for that year. *W. Shrives.*

GARRYA ELLIPTICA. — I note attention is directed at p. 11 of the *Gardeners' Chronicle* to this plant. It was at one time thought that the plant needed protection of some sort, and it was seldom planted in the open. Until about three years ago there stood a pair of Garryas in a wayside garden in this district that were not less, I suppose, than 10 feet high, and as much in diameter. These plants were then known to be nearly thirty years old, and were planted upon a slightly raised bank of poor and, in summer, very dry soil. A main limb out of many (for in their fullest glory the gardener "pruned" them with a saw to within a little distance of the ground), one of the pieces sawn off, I placed before the Floral Committee of the Royal Horticultural Society, two years ago, was nearly 3 feet long, and averaged 2½ inches in diameter. Such strong branches indicated the suitability of the soil and the environment. Although this plant was under my notice for many years, I had never observed the foliage to be browned in the winter. In certain instances there are good reasons for planting trees and shrubs against sheltering walls, but to confine a bush-growing plant of the size stated to such positions is to lose much of the charm with which it is endowed, and that in a special degree fits it for the open garden or the lawn. But I do not think the plant is suited for very rich soils of any kind, and a poor, rather light, well-drained soil is the most likely to be productive of catkins. *E. Jenkins, Hampton Hill.*

SCOTTISH HORTICULTURAL ASSOCIATION.—The able letter in your issue of the 17th inst. by "Country Member," calling attention to the "Alexandra prize" offered by the Association for city-grown Chrysanthemum blooms, has been read

here by many members with general approval. It might offer a strong temptation to dishonest showing, as competitors with their inferior town-grown flowers, &c., might conceivably be induced to seek the aid of country growers, and the prize-money so generously offered would cover all the incidental expenses. *Town Member (Edin.).*

THE LOGANBERRY. — I beg to thank those kind writers for replying to my note on the Loganberry, for they all bear out my statement, that the shoots need support, the plant being a semi-trailer, and I quite believe it was raised from that very fine Californian Blackberry called "Aughianbaugh," and a red Raspberry. I think this Californian Blackberry was sent out about twenty-six years ago. In shape it is very like the Loganberry, and both are very distinct from any other fruits yet raised, "being intermediate in all characters," and although the Loganberry is thought by some to be a true species, and "no hybrid," yet those who have seen the Aughianbaugh Blackberry will have no doubt as to its true origin. *W. C. Leach, Albury Park Gardens.*

SOUVENIR DE LA MALMAISON CARNATIONS FOR MARKET.—Enquiry is made at p. 64, on behalf of "A. W.," concerning the above group of Carnations for market-work, which is equivalent to growing for profit. It is unfortunate "A. W." has not made known the locality in which he desires to grow the plants, for even with intelligent cultivation, much depends on this matter, viz., the influence of altitude. To briefly explain this, it may be said generally, that in certain low-lying districts in or quite near the valley of large rivers, as, e.g., the Thames, Malmaisons are so susceptible to the terrible rust-fungus, Helminthosporium echinulatum, as to render it impossible to grow the plants at all—at least, so as to successfully flower them—much less so for profit. Until a few years ago, these Souvenir de la Malmaison Carnations were grown in the district of Hampton by the thousands, and I could name several who were most extensive growers at the time. For my own part, I was a grower of a few hundreds. But whether by the hundred or thousand, whether in one house or half a dozen, the result was the same, and the constant picking off affected portions so reduced the plants that in less than three years there was perhaps hardly a plant left in the district. This occurred after some two or three years of successful cultivation generally. It mattered nothing whether the plants were layers only six months rooted, or fine old examples in 12-inch or 15-inch pots; the effect was the same, and the huge host went to the rubbish-fire, where the smouldering remains of some thousands day by day was in no wise an edifying spectacle. This is scarcely an answer to the question at issue, yet it so materially affects the would-be balance on the right side, that it is here placed before any actual system of cultivation. Now as to the method adopted, or to be adopted. The best way is to start with well-rooted layers, and given my choice, I would buy preferably from an elevated part of the country, and always purchase to sample. The best time to buy is in September or October—that is, when ground layers are bought, as opposed to potted ones; pot them forthwith, if found satisfactory; if not, return them without delay to the sellers. From the start treat every plant separately; if dry at the root, apply water with a spouted can; there must be no slipshod method of applying water to the lot overhead. From the first the Malmaison Carnation should be under cover; the sides may be opened continuously, but it is essential to success that the leafage be not wetted overhead continuously. To near the end of the year this open frame may be used for the plants, or a cold house fully ventilated day and night is better still. During December, January, and February, not only a dry state overhead, but a comparatively dry condition at the root should be maintained. This is easily done if the application of water is controlled as suggested. The plants need never be more than kept from freezing. Artificial heat is bad; and worse still, a close, muggy state of the house. The potting-soil should consist of a rather heavy loam, with bone-meal, charcoal, sand, or old mortar in lieu of the first, added liberally; avoid the use of manure. Good drainage, with moderately firm potting, and only moderate root-room, are essential. The first flowering would, in the event of success, take place in April and May; each plant should carry from three to five moderate-sized blooms. After flowering, afford a small shift, and grow-on a second year, for it is at this flowering, if at all, that the word "profit" has any meaning. Altitude, in conjunction with good air, according to my experience, is a very important factor, and the plant that at 200 feet or 300 feet or more above sea level may be grown with comparative ease is a source of worry, and is generally unsatisfactory in a low district, subject to fog, much humidity, and lack of sunlight for weeks in succession. If "A.W." has to contend with such inimical conditions, I would not advise him to touch these plants. *E. Jenkins, Hampton Hill.*

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—That any letter of mine to the *Gardeners' Chronicle* on the recent election of pensioners to the "Benevolent" should have helped to call from Mr. N. N. Sherwood such a munificent gift as he has just promised to make to the unsuccessful subscribing candidates for election, is indeed something to be proud of. There are twenty-one such unsuccessful candidates, and Mr. Sherwood's splendid gift to each one of £5 will require from him a total of just 100 guineas—a most generous act, such as we horticulturists are proud to find come, as so many other generous acts have come, from our own ranks. That Mr. Sherwood should have limited his gifts to the subscribing candidates, shows that he is most anxious to increase the number, at present far too small, of gardener subscribers. Now recovered from a great illness, long may this generous donor be spared to assist horticulture with his presence and his aid. *The Writer.*

MARKET GARDENING.

FORCING POT ROSES FOR MARKET.

The outlook is very promising at Mr. Chas. Thos. Kirby, of North Finchley, with regard to Roses. Apparently every bud on the plant is breaking better than usual. I witnessed the potting of many of these Roses, which as they left the hands of the workman were placed on slight hot beds out-doors, thereby encouraging early rooting. This method of Rose forcing is quite safe, and fire heat is very cautiously employed. A third batch of plants is now being taken in, these filling an entire house. In frosty weather, straw, bracken, and other protecting material is thrown over the tops of the plants in beds outside. Some 20,000 pot-plants are being thus treated for market purposes.

PRIMULAS.

While taking notes of the exhibit of Messrs. H. Cannell & Sons, at the Royal Horticultural Society's meeting, on the 27th, I could not but feel sorry for the market grower, for the purchase of Primulas by the public is quite off, and this too, is not only this season, though perhaps, this is the worst, but for several years past. It is not a question of quality, for they are excellent, but they sell slowly and prices are low. The varieties in Messrs. Cannell's collection were such as, Swanley, white and red; Eynsford, red, purple, and white, each of the true strains, and suitable for market purposes. These are but a few of the varieties, and there were others equally good *Stephen Castle.*

ENQUIRY.

Pheasants in the Garden.—A correspondent asks for information as to the most efficient means of preventing pheasants from up-rooting and eating bulbs, especially freshly planted Tulip bulbs. Wire netting has been tried with little success. Perhaps threads of twine inter-crossed and attached to sticks, some six inches above the soil, might be useful. A statement of the experience of some of our correspondents is desired.

SOCIETIES.

ROYAL HORTICULTURAL.

January 27.—The second meeting of the Committees of the Royal Horticultural Society held since Christmas, took place on Tuesday last in the Drill Hall, Buckingham Gate, Westminster. It was a disappointing meeting, for although the weather was mild, and favourable for the transportation of plants, yet there were fewer exhibits than on any similar occasion during the winter. It is noteworthy that larger displays were made at the two preceding meetings, yet on each occasion the air was intensely cold, and there were piercing north-east winds. The explanation will probably be found to be that many exhibitors are holding back, preferring to make a display at the next meeting, when the Society's annual meeting of Fellows will also be held. If this prove to be so it is a pity, because on the occasion of the annual meeting it has frequently happened that there have been more exhibits than could be conveniently displayed, whilst the attendance is much larger than usual, consequently more room is required that visitors may move about without discomfort. None of the Committees had much work to do on this occasion. The Orchid Committee recommended three Awards to novelties, and the Floral Committee an Award of Merit to a Kniphofia from Mr. Bennett-Poë.

In the afternoon there were upwards of forty new Fellows elected to the privileges of the Society; and a paper on "The Blue Nymphæas," by Mr. James Hudson, V.M.H., was read by Mr. A. Dean. This related in detail the methods of cultivation which have been afforded these plants in the garden of Mr. Leopold de Rothschild, Gunnersbury House, Acton, where their requirements have been studied fully, and their cultivation practised with marked success.

Floral Committee.

Present: W. Marshall, Esq. (Chairman); and Messrs. C. T. Druery, H. B. May, R. Dean, G. Nicholson, G. Reuthe, C. R. Fielder, Chas. Dixon, W. Howe, J. A. Nix, Chas. Jeffries, R. C. Notcutt, R. W. Wallace, E. H. Jenkins, W. J. James, C. Blick, and Geo. Paul.

A pretty though small collection of alpine plants was shown by Mr. A. R. Upton, The Guildford Hardy Plant Nursery, Millmead, Guildford. Iris alata was in bloom, also Saxifraga Burseriana major, Pulmonaria rosea, Galanthus Elwesii, Erica mediterranea, &c.; and there were nice pieces of Veronica saliciornioides, V. cupressoides, Saxifraga longifolia, S. valdeosis &c.

Messrs. R. Wallace & Co., Kilnfield Gardens, Colchester, showed the following Irises in bloom:—I. Tauri, I. histrioides, I. Histrio; also Adonis amurensis (from the open), and excellent specimens of Galanthus Whittalli.

Messrs. Barr & Sons, King Street, Covent Garden, London, W.C., exhibited forced Narcissus, also many varieties of Helleborus, and fine pans of Galanthus, Elwesii, Cyclamen Coum, Iris persica var. Tauri, &c. (Bronze Flora Medal).

Mr. H. Whateley, The Nurseries, Kenilworth, again showed blooms of the new white Chrysanthemum H. Whateley.

Three very fine seedling Hippeastrums were shown from the gardens of Lord Rothschild, Tring Park (gr., Mr. E. Hill). These were Rufus, a self coloured scarlet; Prince of Orange, a curiously mottled variety in which shades of scarlet and pink were combined; Edeokop, a flower with brilliant scarlet margin and white centre. Each plant bore four large flowers.

Mr. Jas. E. Lowe, Shrewley Nursery, Warwick, showed Chrysanthemum Warwick Beauty, a rose-purple sport from Princess Victoria; Mr. Ed. Lowe, a white sport from Framfield Pink; and Princess Beatrice, a blush sport from the same variety. Winter Cheer is another sport from Framfield Pink, and the richest coloured of them all.

A red and bronze coloured decorative Chrysanthemum named Christmas Glory, was shown by Mr. W. H. Dyer, Mitchett Nursery, Frimley, Surrey. It is a capital colour for so late a season.

Messrs. Hugh Low & Co., Bush Hill Park Nurseries, London, N., showed a group of double-flowered varieties of Rhododendron (Azalea) indicum, also forced Lilacs and other plants; Epacris, Acacia longifolia magnifica, Lilies of the Valley, Toxicophlœa spectabilis, and choice stove and greenhouse plants (Silver Banksian Medal).

Messrs. H. Cannell & Sons, Swanley, Kent, made a very large display with single-flowered varieties of Primula sinensis, the plants furnishing one side and a half of one of the long tables. Most of the plants were in 5-inch pots, and had just expanded their first flowers.

Some of the principal varieties were Pink Queen, Cannell's White, H. Cannell (bright crimson), Swanley White, Pink Perfection, of much deeper colour than Pink Queen; Swanley Blue; The Sirdar, with very large flowers of rich rosy-carmine colour; Eynsford White; Swanley Giant, rosy-purple colour; Sparkler, intense crimson. Many of the "pyramidalis" varieties were very pretty, as Triumph, rosy-purple; alba plena, Miss Irene, Red Rover, Mrs. H. Cannell, white; Lady E. Dyke, &c. (Silver Flora Medal).

Awards.

AWARD OF MERIT.

Kniphofia (Tritoma) longicollis.—A pure yellow-flowered variety, shown by J. T. BENNETT-POE, Esq., Holmewood, Cheshunt (gr., Mr. Downes).

Orchid Committee.

Present: Harry J. Veitch, Esq. (in the chair); and Messrs. Jas. O'Brien (Hon. Sec.), de B. Crawshay, R. B. White, F. A. Rehder, H. Ballantine, J. Douglas, E. Hill, J. Cypher, W. A. Bilney, W. H. Young, W. Boxall, H. A. Tracy, W. H. White, J. W. Potter, and H. Little.

There was a small show of Orchids, Messrs. SANDER & SONS, of St. Albans, securing the only Silver Medal awarded. Their group contained good Phaius × Norman, P. × Marthæ, and a new bronze and rose form of P. grandifolius, Lælio-Cattleya × novissima, a new hybrid between L. anceps and C. Gaskelliana; Cypripedium × barbato-Rothschildianum, a distinct hybrid of dark colour and good form; a very dark variety of C. × Tautzianum, C. × Lord Derby, and other hybrid Cypripediums; Lælio-Cattleyas, &c., and the very fine new Zygopetalum × Sanderi (see Awards).

The Right Hon. Lord ROTHSCHILD, Tring Park (gr., Mr. E. Hill), showed cut spikes of Phalænopsis Schilleriana and P. Stuartiana, the former having twelve branches and eighty-eight flowers, and the latter thirty-eight flowers, both from plants which have been many years in the collection (Cultural Commendation).

J. COLMAN, Esq., Gatton Park (gr., Mr. W. P. Bound), showed three plants of Dendrobium × Wiganianum, the variety called "Gatton Park" having finely-formed flowers, cream-white, tinged with lilac.

FRANCIS WELLESLEY, Esq., Westfield, Woking (gr., Mr. Gilbert), sent Cypripedium × Miss Alice Wallace, C. × Miss Edith O'Reilley, and C. × Euryades Gilberti, all good flowers; also a fine Cattleya Percivaliana.

NORMAN C. COOKSON, Esq., Oakwood, Wylam (gr., Mr. H. J. Chapman), sent a spike of Odontoglossum × leochristyense "Oakwood variety," very dark in colour, and finely marked. Flower very pale yellow, nearly covered with rich purplish brown blotches.

J. BRADSHAW, Esq., Southgate (gr., Mr. Whitelegge), again showed his beautiful large blush-white Lycaste Skinneri "Enchantress," which exhibited the peculiarity of having formed twin pseudo-bulbs from one growth; L. S. Lady Gladys, a much smaller light form; L. S. alba, with two flowers on a spike; also the new Odontoglossum × Bradshawiæ, mentioned in the list of Awards.

J. T. BENNETT-POE, Esq., Cheshunt (gr., Mr. Downes), showed Ipsea speciosa superba, with three spikes of fine yellow flowers (Cultural Commendation); and Odontoglossum Edwardi.

Messrs. HUGH LOW & Co., Bush Hill Park, staged a group in which were Cattleya Trianæi Lowiæ, a large blush-white, with orange disc; C. T. Cleopatra, and C. T. Atalanta, both fine distinct flowers; a remarkably large and richly coloured C. Percivaliana, several Cypripedium niveum, C. × Lawrenceo-Charlesworthi, fine well-flowered Lælia anceps Sanderiana, and the pretty Cynorchis Lowii.

J. FORSTER ALCOCK, Esq., sent a form of Cypripedium insigne near to Bohnhoffiauum.

Awards.

FIRST-CLASS CERTIFICATE.

Zygopetalum × *Sanderi* (Perrenondi × Mackaii), from Messrs. SANDER & SONS, St. Albans.—A very fine hybrid, and a great improvement on Z. Perrenondi, which it resembles in some respects. Inflorescence stout, upright; flowers wax-like, and fragrant. Sepals and petals apple-green, heavily blotched with blackish-purple. Lip large and expanded in front, the basal and central part bearing velvety lines of purple, merging into the glowing rosy-purple colour of the front portion. The white ground colour shows through at the base of the lip, and the blending of the colours is very fine.

Odontoglossum × *Bradshawiæ* (Harryanum × Andersonianum), from J. BRADSHAW, Esq., The Grange, Southgate (gr., Mr. Whitelegge). A very handsome new hybrid, of equal beauty with the best O. × crispo-Harryanum, but with the colours arranged almost exactly as in O. × Andersonianum. Sepals and petals very pale yellow, the inner halves beautifully marked with purple, the petals showing a white basal area, surrounded by purplish spots as in O. × Andersonianum. Lip large, white, spotted with purple on the basal half, and with a yellow crest.

AWARD OF MERIT.

Cypripedium × *J. Wilson Potter* (Harrisianum superbum × Charlesworthi?), from J. WILSON POTTER, Esq., Elmwood, Park Hill Road, Croydon (gr., Mr. W. H. Young).—A beautifully-formed flower, with all the parts broad and well rounded, the dorsal sepal being especially fine. The whole flower is of a warm purplish-rose tint, the veining being the darker, and the margin of the dorsal sepal pure white. Both in form and colour there are few hybrid Cypripedes to compare with this pretty novelty. The Orchid Committee considered the plant probably of the parentage given above, although it bears very slight resemblance to C. × Bingleyense (Harrisianum × Charlesworthi).

Fruit and Vegetable Committee.

Present: Geo. Bunyard, Esq., in the Chair; and Messrs. H. Balderson, W. Bates, Geo. Woodward, H. Eslings, S. Mortimer, A. Dean, H. J. Wright, H. Markham, C. G. A. Nix, J. Willard, F. Q. Lane, O. Thomas, A. H. Pearson, H. Somers Rivers, W. Poupart, and J. Jaques.

Mr. GEO. WOODWARD, Barham Court Estate Gardens, Maidstone, showed some excellent fruits of the valuable late Pear, Passe Crassane, which Mr. Woodward describes as the very best Pear for so late a date. His fruits were above medium-size, short, with great circumference, and possessing very rich flavour. The variety has been already awarded the Society's First-class Certificate (Cultural Commendation).

Messrs. SUTTON & SONS, Reading, again showed specimens of their Superb Early White Broccoli, which becomes ready for table as early as the month of January.

Messrs. T. RIVERS & SON, Sawbridgeworth, made an interesting exhibit of ripe Oranges, showing about a score of varieties. These were called by names the appropriateness of which was not apparent, as Sustain, Bittencourt, Dulcissima, White Achilles, Egg, Botelha, Silver, Brown's; also more distinct ones, and better-known varieties, as Jaffa, thin-skinned St. Michael's Maltese Blood, the Myrtle-leaved variety of Citrus aurantium, Tangierine, the Grape-fruit, and White Lemon (Citrus Limonum) (Silver Knightian Medal).

WEYBRIDGE HORTICULTURAL AND GARDENERS'.

JANUARY 13.—Mr. R. Dean gave a lecture before the members of this society, in the Public Hall, on the "Florists' Tulip," illustrating the same by means of coloured diagrams. There was a good attendance of members, who seemed much interested in what was to them a novel subject.

Dealing briefly with the history of the Tulip, which it is believed was introduced to Western Europe about the middle of the sixteenth century, it was mentioned that Conrad Gesner, after whom it was named, first saw the Tulip in 1559, in a garden at Augsberg. It was in 1600 that the first roots were imported from Vienna to England. Some cultural notes, and a description of a Cheshire Tulip show, with some amusing reminiscences, brought the lecture to the close.

A hearty vote of thanks was passed to Mr. Dean, and a wish expressed that it would not be long before he again visited Weybridge as a lecturer.

LINNEAN: General Meeting.

JANUARY 15.—FRANK CRISP, Esq., Treasurer and V.-P., in the chair.

The meeting having been made special for the consideration of certain proposals, as announced from the chair on December 18 last, and communicated to the Fellows by circular letter of December 31, the Rev. T. R. R. STEBBING, F.R.S., moved:—"That this meeting, approving of the alterations in the constitution of the Linnean Society of London, as shown in the printed statement circulated, hereby authorises the Council to take the necessary steps to obtain a supplementary Charter embodying the said alterations, and thereafter to prepare revised bye-laws in accordance with the provisions of the new Charter." This was seconded by Dr. J. REYNOLDS GREEN.

The first alteration, adding the words "without distinction of sex" to the existing paragraph on p. 5 of the Charter as printed, was put from the chair, and the result of the ballot was declared as follows:—In favour, 54; not in favour, 17; and the motion was thereupon declared to be carried.

The motion in favour of the adoption of the remaining alterations, as shown in the printed statement in the hands of the Fellows, was then put, the votes being:—In favour, 43; not in favour, 3. Thereupon the Chairman declared the remaining alterations carried.

CARDIFF AND COUNTY HORTICULTURAL.

JANUARY 19.—Mr. A. M. Bailey presided over the fourteenth annual general meeting of this Society on the above date, a large number of members and friends being in attendance. The financial statement for the past year was read and unanimously adopted, and showed a balance of £125 3*s.* 2*d.* in hand. The date of the next show is fixed for July 22 and 23. The Rt. Hon. Lord Windsor, was elected President for this year; Dr. De Vere Hunt, Chairman; Mr. Alec. W. Morris, Vice-chairman; and Mr. H. Gillet was re-elected Secretary.

There will be an exhibition of honey; and also of paintings and photography, of horticultural subjects only.

CROYDON AND DISTRICT HORTICULTURAL MUTUAL IMPROVEMENT.

JANUARY 20.—The first meeting in the New Year was held at the Sunflower Temperance Hotel, George Street, on the above date, when the Chairman, Mr. W. J. Simpson, introduced Mr. J. Deans, who read an interesting paper on "Nature's Seed-sowing."

The lecturer, in his opening remarks, referred to the well-known authorities on the subject, such as Darwin, Lubbock, &c., and their theories of the many ways which Nature has of distributing the seeds of plant life over the earth, attributing the methods of dispersing the seeds to four, viz., by water, wind, birds, and animals, and explaining the methods of each in detail.

A discussion by the members followed the reading of the paper.

The next meeting will be on February 3, when Mr. Thos. Bunyard will take for his lecture the subject of "Garden Root Crops."

REDHILL, REIGATE AND DISTRICT GARDENERS' MUTUAL IMPROVEMENT.

JANUARY 20.—The fortnightly meeting of this Association was held at Mutton's Hotel, Reigate, on the above date, Mr. Bound in the Chair. After the usual business and election of new members, the names and winners of the Society's Certificates were awarded. The lecturer on this occasion was Mr. McLeod, gr. at Dover House, Roehampton, who gave a discourse upon "Carnations." A discussion followed the reading of the paper. *Jno. W. B.*

DEVON AND EXETER GARDENERS'.

JANUARY 21.—The opening meeting of the spring session was held at the Guildhall, Exeter, on the above date, the subject to occupy the members being "A Demonstration of the Various Methods of Preparing Cuttings." Mr. Luscombe, general foreman at Messrs. Veitch's Nurseries, occupied the chair. Mr. S. Radley opened the discussion with a short paper on the advantages of a practical knowledge of the best methods of preparing cuttings of various kinds of plants. Examples were given of the manner of preparing leaf-cuttings, and of those cuttings on which a bud had to be retained. Cuttings of Chrysanthemums, Carnations, Pelargoniums, Azaleas, Heaths, Laurels, and other subjects, were prepared by the senior members present, and the reasons given for a preference for this or the other method being adopted by the operator.

A more valuable demonstration has not been given before the society, and evidence of its appreciation was shown by the very large attendance of members.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

JANUARY 22.—There was a very small meeting on this date, and only a few plants were placed before the Committee.

S. GRATRIX, Esq., Whalley Range (gr., Mr. Cypher), exhibited Cypripedium × Hindeanum (C. Godefroyæ × C. insigne var. Harefield Hall var.), a beautiful hybrid, showing its parentage plainly (see fig. 26, p. 53, in last week's number). It is a fine, handsome flower of good substance, and ranks among the best hybrids of C. insigne (First-class Certificate).

Cypripedium × "Samuel Gratrix No. II." was also shown by the same grower. It is a pretty flower, and was granted an Award of Merit. This fine Cypripedium is much in the way of a fine form of C. ×

Leeanum, but with a magnificent dorsal sepal (Award of Merit).

JOHN COWAN & Co. staged a fine group of Lycastes, principally varieties of L. Skinneri; one or two varieties being worthy of notice (a Bronze Medal was awarded for the group).

Mrs. ARDERN, Stockport, exhibited a fine form of Odontoglossum crispo-Harryanum, Cypripedium × Thompsonianum, and Cypripedium × microchilum (Vote of Thanks). *P. W.*

CHESTER PAXTON.

THE opening meeting of the present session was held in the lecture theatre of the Grosvenor Museum on Saturday, when the President of the Society, Captain MacGillycuddy, lectured before a large and appreciative audience. Taking as his subject, "Some National Flowers," Captain MacGillycuddy, in his introductory remarks, said that flowers had been adopted as national emblems from very early times. Flowers were also identified with families, such as the Violet with Bonaparte, and the Primrose, which had a political significance. They were also associated with days, as the Snowdrop, sometimes called the Purification flower, and the Fair Maid of February; the Crocus, called St. Valentine's flower; and the Daisy, the Marguerite, because it appeared about St. Margaret's Day.

Turning to the nations, the lecturer commenced with Japan, which had for its national flower the Chrysanthemum, so called from its being the "flower of gold." The Emperor of Japan had one particular Chrysanthemum which was 10 feet high, and 15 feet long, having attained the proportions of a forest tree. It was trained to represent a Chinese junk, and had 4 000 individual blooms. The Empress had a flower of her own, namely, the Cherry-blossom. Germany had adopted as her national flower the blue Cornflower, which was the favourite flower of one of the German Emperors. France at war had chosen the Lily, the "Fleur-de-Lys." It was extremely interesting to Englishmen, because up to the time of William III. it was borne on the arms of England, in memory of the time when the King of England was the King of France. Switzerland had the Edelweiss; the United States of America had selected a beautiful stately flower called the "Golden Rod." Turning next to the great British family, the first country he mentioned was Egypt, the wonderful land of the "Lotus," which was a most beautiful flower. India had the Palm as its national plant; Canada had chosen the Maple, which in the autumn of the year looked beautiful in its red and golden glory; Australia had still to find a national flower. Wales had adopted the Leek; why she had done so he had been unable to discover. Scotland was represented by the Thistle; the Shamrock, Trifolium repens, was the national plant of Ireland. The connection between England and the Rose was very simple.

Mr. N. F. Barnes moved a vote of thanks to the lecturer, and threw out the suggestion that an appropriate national flower for South Africa would be the Orchid [!], and the motion was carried amid hearty applause. An entertaining discussion was afterwards taken part in by the chairman, the lecturer, and Mr. G. P. Miln (Hon. Sec.).

LIVERPOOL HORTICULTURAL.

ON Saturday evening, Jan. 24, at the "Bear's Paw," Lord Street, the 16th annual dinner and social evening was held, and presided over by Geo. Gordon, Esq., V.M.H. There were about 120 present, which included all the leading horticulturists of the city and suburbs.

The principal toasts of the evening were the "King, Queen, and Royal Family," and "Liverpool Horticultural Association." In submitting the toast of the above Association, Mr. Gordon remarked on the perseverance and doggedness of societies in general, and how they had fallen to a very low ebb, and yet by the persistent efforts of a few persons they now held a prominent position in the horticultural world; as by the holding of their exhibitions, meetings, and discussions, a great amount of enthusiasm was circulated freely amongst the gardening fraternity and general public. He acknowledged that such societies as the Liverpool society had done a great amount of good, and yet doubted whether they had done all that might be accomplished; and to be successful in this sphere of work, they should be knit together by a bond of unity. He also mentioned the mischief that smaller societies in suburban districts sometimes occasion, the influence and support which is accorded them being detrimental to the parent society, and hoped that Liverpool was not troubled in this respect. Mr. Foster (Chairman of the Society), in responding, said they had several of these minor societies around Liverpool, and that if these were to amalgamate, Liverpool could hold exhibitions second to none in the Kingdom, and hoped that in future they would rally round the parent society.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.

REPORT OF THE COMMITTEE FOR THE YEAR 1902.

THE committee have the pleasure to submit their annual report and statement of accounts, as audited, for the year 1902. They are thankful to be able again to congratulate the members and subscribers of the Institution on its satisfactory condition, and the continued progress it has made, as evidenced by the increased benefits they have been able to dispense to those who through misfortune, declining years, and other causes, have been forced to seek its aid.

At the commencement of the year 190 persons—103 men and 87 widows—were receiving £20 and £16 a year respectively, entailing an annual liability of £3,452. During the year seventeen of that number died—seven men and ten widows. Three of the men left widows, whose circumstances, after careful investigation, proved to be of such a nature as to warrant their being placed on the funds for the widow's pension of £16 a year, in accordance with the powers conferred on the committee under Rule III., 13, thus leaving at the close of the year 176 persons in receipt of permanent aid. The committee propose to increase this number by recommending for election this day fifteen candidates from a list of forty-six applicants, and also to ask the subscribers to confirm their action, graciously approved by their President, H.R.H. the Prince of Wales, in placing on the funds without election all those of the unsuccessful candidates—eleven in number—at the last election, *who had previously been subscribers to the Institution*, to commemorate the Coronation of their Majesties the King and Queen, patrons of the Institution, and as a thank-offering for the recovery of the King from His Majesty's recent severe illness. The total number of pensioners, therefore, on the funds will be 202, twelve more than on the corresponding date last year, and the largest number at any period in the history of the Institution. Whilst fully cognisant of the increased liability thus incurred, the Committee feel they will have the practical sympathy and support of every friend and well-wisher of the charity in their forward policy of assisting more of the unfortunate people whose cases plead with such pathetic urgency, and they strongly appeal to all their friends not to relax their efforts on behalf of this old and well tried work, which for sixty-four years has done so much for disabled and decayed horticulturists, or their widows, in their time of need.

The Committee are glad to be able to report that the anniversary festival dinner, which was held in May last, under the presidency of His Grace the Duke of Marlborough, K.G., proved most successful; and they desire to place on record their very grateful thanks to His Grace for his able and convincing advocacy of the claims of the Institution, which brought such a substantial addition to its funds. The Committee also express most gladly their indebtedness to the stewards, collectors, donors of flowers, the horticultural Press, and to other helpers, whose kind services and contributions were sincerely appreciated. They likewise gratefully acknowledge the services of the honorary secretaries of the several auxiliaries, which still continue to prove valuable adjuncts to the Institution.

During the year the following amounts have been received:—Reading and District Auxiliary (hon. sec., Mr. H. G. Cox), £117; Worcester Auxiliary (hon. sec., Mr. Percy G. White), £110; Bristol & Bath Auxiliary (hon. sec., Mr. G. Harris), £79; Devon and Exeter Auxiliary (hon. sec., Mr. W. Mackay), £33; and Wolverhampton Auxiliary (hon. sec., Mr. R. Lowe), £20.

The Committee have pleasure in reporting that in consequence of a large public meeting and concert at Liverpool, which was attended by the treasurer and secretary, as a deputation, an auxiliary has been inaugurated in that city, which gives promise of being very successful, and likely, under the able honorary secretaryship of Mr. Waterman, to render substantial assistance to the Institution.

To the gentlemen named above, and to other friends throughout the country who have helped forward the work, the Committee tender their best thanks.

The "Victorian Era Fund" and the "Good Samaritan Fund" are still a source of incalculable benefit.

From the first named fund £104 has been distributed amongst the unsuccessful candidates at the last election, who had been subscribers, and £120 has been given from the latter Fund to the remaining unsuccessful candidates, who were not subscribers, and to other applicants as temporary help in their distress and need. This latter Fund has been particularly useful in enabling the Committee to assist cases of a very pressing nature, to which, had it not been for this Fund, they must necessarily have had to turn a deaf ear. As the interest alone of the Fund is available—unless special donations are given unconditionally—the Committee's resources are limited, and they therefore again commend it to those who have the power to increase its usefulness.

With regard to the new rules which were adopted at the special meeting in January, 1902, the Committee are hopeful that they will prove satisfactory in their working, and to the advantage of the Institution. On the whole, general approval has been expressed with the alterations, which were inevitable under the circumstances. A suggestion which has been made from several quarters to increase the number of votes at elections to annual subscribers of twenty years' standing and upwards is receiving the careful consideration of the Committee.

Unfortunately, the committee have to deplore the loss by death of many valued friends and supporters during the past year. Amongst others who have thus passed away may be mentioned G. F. Wilson, Esq., of Weybridge, a vice-president; Mr. E. W. Cathie, of Simpson's, an old subscriber; and T. F. Peacock, Esq., of Gray's Inn, who for many years had acted as honorary solicitor to the Institution, and whose services on many occasions will be gratefully remembered.

They are glad to be able to state that W. A. Bilney, Esq., of Fir Grange, Weybridge, and Temple Chambers, Temple Avenue, has kindly consented to take the place of Mr. Peacock, and to help the charity by acting as its honorary solicitor.

In conclusion, the committee most earnestly ask for renewed effort on behalf of this national horticultural charity. After to-day's election, there will be thirty-one applicants left on the list who are appealing for aid, and of this number several are totally blind. To help them an increased income is needed, and whilst being thankful beyond measure for the generous support accorded to them in their work in the past, the committee plead most earnestly for further aid to enable them to extend the benefits of the charity to those who are so much in need of them.

H. J. VEITCH, Chairman.
GEO. J. INGRAM, Secretary.

[The above report was presented on the occasion of the election of pensioners, on Thursday, January 22, 1903, reported in our last week's number. ED.]

(*For Balance Sheet, see p.* xv.)

THE BRIGHTON AND SUSSEX HORTICULTURAL.

THE Annual General Meeting of this Society was held in the Imperial Hotel, Brighton, on Thursday, the 15th inst., when Mr. T. Billing, a Vice-President, presided over a large attendance of members. The President Alderman J. Colman, J.P., wrote regretting his inability to attend, and expressing a wish to present a Silver Cup as a prize in a Carnation competition this year.

When the balance-sheet was submitted, a considerable increase in the receipts and a substantial reduction in the expenses was noted, last year closing with a credit balance of £268 7*s.* 11*d.*

The shows for the present year will be held on April 21-22, August 25-26, and November 3-4.

Obituary.

GEORGE RAWLINGS. — This veteran cultivator, exhibitor, and raiser of Dahlias died on the 17th inst. at his residence, Pen-y-Van, Whitebrook, Monmouth, in his eighty-third year, and was buried in Llandogo Churchyard by the side of his wife, whom he outlived seven years. One of his sons, Mr. William Rawlings, was with him at the time of his death.

It is not until 1851 that I can find any mention of Mr. Rawlings. At that time he appeared to be in business as a florist in Bethnal Green, then a semi-country district. He was one of the original members of the National Floricultural Society, and was in all probability, with the exception of Mr. William Paul, the only remaining one of the band of 207 members when the society was formed in 1851. In that year he came before the public as a raiser of Dahlias, and at the meeting of the National Floricultural Society on Aug. 21, he obtained a label of commendation for Dahlia Dr. Frampton, a pale ground flower edged with purple, which was said at the time to be a variety of considerable promise, and which at the following meeting of the Society was advanced to a First-class Certificate of Merit. It obtained other certificates that year. With it Mr. Rawlings exhibited Sir F. Thesiger, a lilac self; Louisa Glenny, deep yellow; Defiance, blush-white; and Rose of England, rose-pink. Dr. Frampton and Sir F. Thesiger both became highly popular varieties, the former especially. At the outset of his career as a raiser, Mr. Rawlings set a high ideal before him, and he followed it to the end, as can be seen in the high position attained in the present day by his latter-

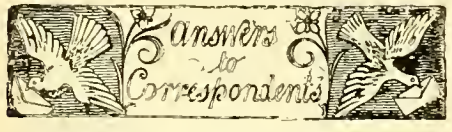
day seedlings. Lilac King, one of Mr. Rawlings' seedlings, obtained a First-class Certificate in 1852.

The growth of London in the direction of Bethnal Green, and the erection of factories, gradually absorbed the available land suitable for nursery purposes, and in course of time drove Mr. Rawlings to Romford, and here he carried on a successful business as a Dahlia specialist, and raised a large number of varieties, several of which occupy a high place among the most popular exhibition flowers. Mention may be made of Arthur Ocock, Clara, George Gordon, George Rawlings, Harrison Weir, Harry Turner, John Bennett, J. T. West, Mr. G. Harris, Mr. Glasscock, Mrs. Glasscock, Mrs. Shirley Hibberd, Queen of the Belgians, R. T. Rawlings, Shirley Hibberd, T. J. Saltmarsh, Thos. S. Ware, William Dodds, and William Rawlings. All of these possess the best qualities of form, petal and centre; and a few of them took a high position in Mr. E. Mawley's Dahlia audit of this year. R. T. Rawlings is one of the very best show Dahlias in cultivation. In his day, Mr. G. Rawlings raised a large number of seedlings. His commencement and his close as a raiser were alike glorious. His name appears as a subscriber to the funds of the National Dahlia Society in the annual report just issued. Mr. Rawlings left Romford some years ago, leaving his business to the care of his sons, and lived in retirement at Whitebrook up to the day of his death. *R. D.*

LAW NOTES.

FAILURE TO SUPPLY PELARGONIUM CUTTINGS ACCORDING TO AGREEMENT.

At the Lincoln County Court on Wednesday, the 21st inst., Geo. Taylor, Bracebridge Low Fields, market gardener, sued F. M. Marks, Littlehampton, Sussex, for £13, for return of money, and for damages caused through defendant failing to deliver Pelargoniums within a certain time. Mr. Epton was for the plaintiff, and explained that the plaintiff ordered 5,000 Jacoby Pelargoniums, and sent a cheque for £5, together with 13*s.* 6*d.* which he owed for samples. Defendant wrote acknowledging the receipt of the cheque, and stating that the Pelargonium cuttings would be sent in the course of a day or two. The cuttings were not supplied. Plaintiff said he estimated the damages at from £15 to £20. His Honour gave judgment for the plaintiff for £13.



*** EDITOR AND PUBLISHER.—Our correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all communications relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication, or referring to the literary department, and all plants to be named, should be directed to the EDITOR. The two departments, publishing and editorial, are quite distinct, and much unnecessary delay and confusion arise when letters are misdirected.

BLACK CURRANT: *D. B.* Yes; certainly.

BONE SUPERPHOSPHATE: *P. G. W.* Is an enduring dressing for grass-land, but not so quick in its action as some other manures. It is quite safe, and may be used without the basic slag if you wish to do so. The latter is a source of phosphoric acid, an almost indispensable ingredient in soils.

CEMETERY SUPERINTENDENT: *X.* We know of no such book.

CENTAUREA NIGRA, WHITE VAR.: *Horthorn Loon.* Centaurea nigra (Knapweed), a white flowered variety is sometimes found growing wild, but we are in doubt as to its constancy.

CLIMBERS FOR BACK WALL OF STOVE TO FLOWER, IF FLOWERING, FROM OCTOBER TO APRIL: *X.* Argyreia splendens, Jasminum Sambac, Combretum racemosum, Bignonia cherere, Begonia nitida, Euphorbia jacquiniæflora, Ipomœa Horsfalliæ, Passiflora racemosa. At the cooler part, Luculia gratissima, and Plumbago capensis. Evergreens for leafage only, Philodendron laceratum, P. Simsii, and Monstera deliciosa.

COLOUR OF THE MEN'S SHIRTS AT KEW: (!) *Horthorn Loon.* A bluish-grey.

COMMUNICATION: *H. Mitcham.* The meeting having occurred so long ago, we must decline to publish the report of it, more especially in the crowded state of our columns at the present time.

CRICKETS, TO CATCH: *A. G.* An answer was given to an enquirer in our last issue, p. 64, which exactly fits your case.

CYPRIPEDIUM × DEYOPE: *J. F. A.* The name was that under which it was shown, and one that was unquestioned by the Committee. The flower did not resemble C. × Bingleyense, and reputed to be from the same parents, viz., Harrisianum superbum and Charlesworthi.

DEODAR: *W. C. Leach.* The article appeared in our issue for January 30, 1897, p. 82.

DWARFED JAPANESE TREE BOUGHT AT AN AUCTION SALE: *A Constant Reader.* The tree may be hardy in this country, or it may be rather tender and need winter protection. You should ascertain its English botanical name and let us know, and we would then tell you what is the right way of proceeding. Annual slight top-dressings of mild manure mixed with stiff loam should be afforded yearly, first removing as much of the old soil as will admit of this being done. Keep it moderately moist at the root till growth begins. Stop all run-away shoots, and afford open air treatment in the summer.

EMPLOYMENT AT KEW: *H. K.* You must in the first instance make your wishes known to Mr. W. Watson, the Curator.

GARDENING BOOKS FOR S. AFRICA: *C. A. P.* South Africa is a big country, with a great variety of climates, altitude, &c. We would advise the young gardener to take out standard works, such as the *Dictionary of Gardening*, published by Upcott Gill, 170, Strand, W.C.; the *Fruit Manual*, by the late Dr. Hogg, published at the office of the *Journal of Horticulture*; *Villa Gardening*, by Hobday, published by Macmillan & Co., London; the *Orchid Manual*, published by Messrs. Williams & Son, Victoria Nurseries, Upper Holloway, N.; Kemp on *How to Lay Out a Garden*, published by Messrs. Bradbury, Agnew & Co., 10, Bouverie Street, Fleet Street, London, E.C., if it can still be obtained.

GOOSEBERRIES: *New Reader.* Excellent varieties are Green Walnut or Langley Green; Crown Bob or Warrington, reds; Whitesmith, white; Keepsake or Bright Venus, yellows. These are chosen for good flavour.

INFLUENCE OF THE MOON ON THE WEATHER: *X.* We are so gorged with matter that we cannot find room for your obliging communication, with which we entirely agree; but popular errors are an unconscionable long time dying.

MODEL OF A GARDEN: *C. C.* If you do not make a copy of an existing Italian flower garden, you must rely on your imagination in the creation of the model; but if we may judge by the questions you put to us, you are unlikely to take honours in the competition. Messrs. Cannell & Sons, Swanley, Kent, would furnish plans on application.

NAMES OF PLANTS: *Correspondents not answered in this issue are requested to be so good as to consult the following number.*—*A. F.* Apparently a variety of *N. pseudo-Narcissus Telamonius plenus.*—*H. S. M.* Euphorbia jacquiniæflora.—*R. S.* should not address the Publisher on such a matter, it has nothing to do with advertisements, or the sale or purchase of the paper; 1, next week; 2, Cupressus Lawsoniana; 3, variety of Thuya orientalis; 4, Asclepias curassavica; 5, Diplazium pubescens; 6, Melia Azedarach.—*W. B.* 1, Abies brachyphylla; 2, Abies grandis; 3, Tsuga canadensis; 4, Thuya occidentalis, var.; 5, Thuya occidentalis, var.; 6, Juniperus communis, var. It is a risky proceeding to name Conifers without their cones, but we do our best.—*M. O. R.* 1, Cupressus (next week); 2, Thuya dolabrata; 3, T. gigantea = Lobbi of gardens; 4, Cupressus, we cannot tell which without the cones; 5 and 6, Thuya gigantea.—*J. S.* Seed vessels of Araujia albens.—*Kelway & Sons.* Unable to name with certainty; send when in flower.

PALM-LEAF: *T. Fletcher.* The dark linear lines are a species of scale insect, which may be destroyed with petroleum emulsion, applied with a soft brush or bit of sponge.

PARSNIPS DISEASED: *Amateur.* Kindly send some roots for our inspection, as we are unable to afford an opinion unless this be done.

PÆONIES: *H. B.* The herbaceous species are propagated by division, one or two buds being left on each piece of root, as is done with Rhubarb. This is usually performed in February, just previous to growth taking place. The roots may also be grafted (wedge or cleft) with other varieties, this operation being performed in pots, in mild heat, under glass. No Pæony that has been much disturbed will produce flowers for three years afterwards. Shrubby Pæonies are usually grafted on stocks of the Moutan Pæony, or seedlings of it, the operation being likewise carried out under glass in the spring; almost any ordinary method is suitable. Pæony-seeds may be sown when ripe in the autumn, and treated cool—not sown out-of-doors. Make use of sandy loam and peat only.

SEEDLESS GRAPES: *Enquirer.* There is one variety, the Black Monukka, which is generally destitute of seeds. Attempts have been made to cross this with others, but with no advantage. The dried Sultana Grapes and the so-called Currants have no seeds. The proportion of people who die from appendicitis from such a cause is infinitesimally small, as compared with the numbers who eat pudding.

SEEDLING ZONAL PELARGONIUMS: *T. Knight.* The flowers sent being, as you say, seedlings, do not in all likelihood quite resemble those of the parent plants. They are fine, large blooms of good tints, and you may give them any names you like.

SIZES OF ENGLISH FLOWER-POTS: *G. de B.* Thimbles 2 inches in diameter, and 2 inches in depth; thumbs, 2½ by 2½ inches; sixties, 3 by 3½ inches deep; forty-eights, 4½ by 5 inches deep; thirty-twos, 6 by 6 inches deep; twenty-fours, 8½ by 8 inches deep; sixteens, 9½ by 9 inches deep; twelves, 11½ by 10 inches deep; eights, 12 by 12 inches deep; sixes, 13 by 12 inches deep; fours, 15 by 13 inches deep; twos, 18 by 14 inches deep.

TRICHINIUM MANGLESII: *H. J.* The plant may be in the possession of Mr. W. Thompson of Ipswich.

WINTER FLOWERS IN SUNNY CLIMES.

SHELTERED by its protecting range of mountains, forming a barrier against the icy blasts and inhospitable snows of the north, and fertilised by an abundant and enriching sunshine, the favoured villages of the Riviera bring forth their annual harvest of colour and fragrance. That natural forcing ground, Grasse, I suppose may be reckoned the chiefest among these southern French flower regions, with its bountiful supplies of sweet-scented Violets, its multi-coloured Anemones, and its delicate Tea Roses, but each of the above and many other blooms may be found not only in spots especially cultivated for such, but in wellnigh every garden-plot and terrace-walk throughout the length and breadth of that narrow but comprehensive strip familiarly known as "The Riviera." With the exquisite surroundings of the many featured Monte Carlo as its centre, the whole of this region may be said to abound with flowers all the winter through, from the humble little Pansy and the beauties aforenamed, to the luxuriant and gorgeous Bougainvilleas and the feathery Acacia.

In mid ocean between Europe and Africa, and within a days' voyage of France, there exists another beauty spot in the form of the romantic Island of Corsica, or rather and more particularly its chiefest pearl, the peerless semi-tropical Ajaccio. Here, at any rate, all seems peace, from the still and transparent bays looking like motionless lagoons, and the glorious Orange-trees which meet the gaze at every point, to the *dolce far niente* and picturesque appearance of the native with his patois of Italian and the dark tint of his Berber or Arab blood plainly betraying his origin. Here too, may be seen many beautiful specimens of the Acacia in fullest bloom, like a mazy cloud of brimstone, barely stirring in the delicate touch of the light air. Fine large trees, for the most part revelling in their sympathetic bed of decomposed granite, they form a grand and becoming ornament among beauties of other attractive charms. In one lovely spot that I well remember on the hill slopes surrounding a beautiful white château, the dainty Neapolitan Violet was largely produced, and doubtless exported to our and other colder climes; as also the Narcissus, of which I saw several large stretches, and embracing some three or four different varieties.

Perhaps more striking still in many ways is the seductive display afforded on the further shore of the Mediterranean in sunny Moorish Algiers. Exquisitely displayed in terraced walks at varying levels, the white villas seem for the most part clad as it were with a transparent mantle of veiled green, interspersed with some rich or bright toned colour, and adorned at their base and flanks with masses of brilliancy harmoniously blending their shades into one perfect vista and dream of delight. Very fine indeed is the aspect presented by many dwellings from the blood-coloured flower-leaf of the showy Bougainvilleas. The Roses here are of quite bewildering shades and varieties, and enjoy greater immunities from the occasional wintry touches which their sisters on the near shore now and again have to contend against.

Much earlier, indeed in mid-winter, but in an almost tropic region, to wit, on the plain of the Jordan, I have plucked in plenty the vivid scarlet Anemone with which the sandy sward of this erstwhile fertile district is sometimes strewn, especially if the "former rain" has been plenteous in its supplies. The flora upon the mountains of the wilderness of Judæa is also very beautiful and varied, but necessarily somewhat later than that found in the depressed flat and heated stretch between tiny Jericho of the present day, and the mystic lifeless Dead Sea.

And here I must begin to turn my steps and attention northwards once more, though still under (to us, at any rate) southern skies. Parts about Naples and other auspicious districts in Italy and Sicily produce amongst other flowers prodigious supplies of the Parma and Neapolitan Violet. Those conversant with Rome and Florence will readily recall certain nooks and points of vantage at street corners and bridges where the somewhat plaintive cry of "Violetti, Violetti," "Dolce Rose," is a very familiar one. Truly do these welcome harbingers of spring bring much consolation and hope to the passer-by in the somewhat sombre winter streets, even of "la bella Italia;" for the idea that the sun is ever spreading her radiance over the land is a sadly erroneous one. Rome Florence, and even Naples can on occasion out-Herod Herod for cold and damp dreariness combined.

In closing, I cannot refrain from putting in a claim for notice to a more northern but yet very delightful domain; that at the entrance to the peaceful Rhone valley, and on the lower slopes and valleys above Montreux, and the further end of the lake of Geneva. Here, though of course rather later, but while the winter months are still upon us, many grateful blooms break forth in the open, wild, and entirely uncultivated ground. Thus the increasing warmth of the sun brings through and unfolds the elegant Crocus, yellow, white, or mauve; and even where snows have possessed the surface of the upland meadow or hillside, hardly has it melted before the little welcome bulb appears in bloom. Close following upon it in patches may now and again be found a long-stalked, pure white flower of a kin with our homely Snowdrop, but with several "drops," if I remember aright, upon one stem. Companions in plenty by the end of February and early March appear in the shape of gorgeous displays of Daffodil, Fritillaria, the exquisite blue Gentian, and the seductive little Hepatica, of the same colour but of a deeper hue. The wooded parts are carpeted, indeed, with the latter, both blue, white, and pink; while roaming whether through the yet sleeping vineyards, as also on the hill-slopes, the Gentian, of several sizes and shapes, rejoices the eye and heart alike. Dainty little Pansies about the same time spring up among the Olive-trees, as if seeking for a fair share of attention to their modest charms. The climax perhaps is reached when the Narcissi unfold their fragrance, and mingle their beauties in whole fields of flower among the fast-growing grasses, as they advance in sweetness and stature towards the early-matured spring crop of these mountain valleys. *J. A. Carnegie-Cheales.*

NEW OR NOTEWORTHY PLANTS.

TWO NEW PLANTS FROM CHINA.

Mr. E. H. Wilson, who has collected so largely in China for Messrs. James Veitch & Sons, recently brought specimens to Kew of two curious plants, of which the firm have living examples. As he remarked, one looks like a Hydrangea with alternate leaves; and the other he regarded as a Honeysuckle, though it presents some distinct deviations from the many morphological variations displayed by the numerous species of the genus Lonicera. It is a shrub having opposite, simple leaves, very similar to those of some species of that genus; and also resembling those of the smaller kinds of Philadelphus, except that they are not rough. But the peculiarities are in the structure of the flower and fruit. The small flowers are borne in clusters at the ends of short, lateral branchlets, and they are almost always in pairs, with the ovaries of the pairs consolidated or confluent. The ripe fruit, as well as its exceedingly slender stalk, is thickly beset with long, brown, spreading bristles, or thick hairs, and crowned by two calyces, the whole being about a third of an inch long. A fully-developed fruit shows in cross section two three-celled, semi-circular components, which are completely consolidated, so that the section looks like that of a six-celled fruit. But the two calyces at the top proclaim its true character. These little calyces

consist of a very slender tubular portion, surmounted by five equally slender spreading lobes. The tube is thickly clothed with spreading hairs, as long as itself. The body of the fruit also comprises two or three (perhaps sometimes four) relatively thick ribs of corky tissue, which seem to be transformed, adnate bracteoles, as they terminate in free tips, not much thicker than the bristles of the fruit. From this structure there is no doubt that the shrub in question is—

KOLKWITZIA AMABILIS,*

or a closely-allied species, for it does not agree in several particulars with Gräbner's description. Whether we have to deal here with a genus distinct from Lonicera is questionable; but I think it will prove deserving of generic rank, though not altogether on the grounds advanced by the author, who states that its twin flowers are not on the same level, one ovary being attached laterally to the top of the other. I find that when the two are perfectly developed, they are on the same level; but the fruit is usually imperfect, two out of each set of three cells being undeveloped, and sometimes one whole set of three, and two of the other set, are suppressed. The corolla, I may add, is unknown, but I should guess from the size of the calyx it must be a very small body, and it, together with the stamens, may afford further characters of generic value. Mr. Wilson procured this shrub from the mountains of Hupeh, at an elevation of 10,000 feet, so there is no doubt of its hardiness, should it prove sufficiently ornamental to establish itself in our gardens.

* Engler's *Bot. Jahrbücher*, xxix., p. 583.

The other plant is a new species of—

CARDIANDRA,

which I will call C. sinensis.* Siebold and Zuccarini founded the genus (*Flora Japonica*, i., p. 119, tt. 65, 66) on a Japanese species, C. alternifolia, which was in cultivation in 1866, and is figured in Regel's *Gartenflora*, t. 486. It is too early to say anything about their value as ornamental plants at present, but the new species looks like a plant that will improve under cultivation. They are perennial herbs, having creeping rhizomes, much like those of the Solomon's Seal, throwing up a single stem at the end each year, with, in old plants, a crowd of sockets of previous years' stems behind them. Briefly, they are herbaceous Hydrangeas, with alternate leaves and numerous stamens; and the larger, sterile flowers of C. sinensis in the circumference of the inflorescence, differ from those of C. alternifolia, in consisting of two heart-shaped sepals, combined or free from each other at the base. The name, Cardiandra, was given in reference to what I believe to be a mistaken view of the shape of the anthers, and I may add, that the petals are strongly imbricated, not valvate, as described by the authors of the genus. Kew possesses specimens of Cardiandra sinensis from the Ningpo Mountains, collected by the Rev. E. Faber in 1888, and Mr. E. H. Wilson's specimens, n. 2426, from Western Hupeh, which were collected in 1901. *W. Botting Hemsley.*

* C. *sinensis*, Hemsl., species nova; *C. alternifoliæ* simillima, differt imprimis forma calycis florum sterilium. Herba perennis, more Polygonati multiflori rhizomatosa, caulibus erectis simplicibus, 1—2-pedalibus. Folia alterna, bifaria, petiolata, papyracea vel fere membranacea, ovato-lanceolata vel oblongo-lanceolata, cum petiolo 4—6 poll. longa, argute serrata, dentibus setulosis, acute acuminata, basi cuneata, utrinque præcipue secus venas parce strigillosa, interdum ferruginea. Flores difformes, in corymbum compositum terminalem pedunculatum dispositi, graciliter pedicellati, bracteis bracteolisque parvis (angustissimis vel fere setiformibus. Corymbus 3—4 poll. diametro. Flores steriles exteriores, ½—1 poll. diametro, pauci, interdum nulli; calycis lobi 2, inæquales, cordato-rotundati, basi connati vel liberi. Flores fertiles circiter 3½ lin. diametro; calycis dentes minutissimi, rotundati, persistentes; petala valde imbricata, orbicularia, concava, circiter 1½ lin. lata; stamina circiter 20; capsula glabra, subglobosa, circiter 1 lin. diametro, imperfecte trilocularis stylis 3 coronata, polysperma.

FIG. 35.—ODONTOGLOSSUM × BRADSHAWLE.

ODONTOGLOSSUM × BRADSHAWIÆ.

THIS handsome hybrid, shown in fig. 35, was awarded a First-class Certificate at the meeting of the Royal Horticultural Society on January 27. It was shown by J. Bradshaw, Esq., The Grange, Southgate (gr., Mr. Whitelegge), and is a hybrid from O. Harryanum and O. Andersonianum. The flowers were described in our last issue as being of equal beauty with the best O. × crispo-Harryanum, but with the colours arranged almost exactly as in O. × Andersonianum. The sepals and petals are very pale yellow, the inner halves beautifully marked with purple; the petals showing a white basal area surrounded by purplish spots, as in O. × Andersonianum. The lip is large, white, and spotted with purple on the basal half, and having a yellow crest.

BULB GARDEN.

THE FORCING OF DAFFODILS.

WHILE the early forcing of Daffodils offers no difficulties to the large market-grower and the best informed of gardeners, there are others who are not successful with these bulbs under artificial conditions of culture. The lack of success can frequently be traced to experimental tactics. Albeit, the bulbs themselves, or the source of supply, are invariably blamed for this, when, as a matter of fact, it may be readily discovered by the unsuccessful cultivator himself. It is due to the manner in which the work has been done. Upon one occasion my opinion was asked concerning a batch of bulbs in a hot propagating-house. Going to view them, to my surprise I found the boxes and pots containing an admirable lot of Narcissus Horsfieldi stood upon the bare boards or slabs that covered the pipes. This was the work of an excellent gardener, but the forcing of Daffodils baffled him. On making enquiry, I found some advice had been given by one who was supposed to know how to force these bulbs in the Channel Islands, and I further learnt that this valuable lot of bulbs had been brought into this great heat, and following the advice given, they were at once consigned to the bottom-heat bed. The lot having been set fully three weeks, and the owner thinking it time that with such heat at disposal a start should be made, communicated with the writer. The whole lot was ruined, so far as early flowers were concerned. In another instance a large lot was in August or September planted in the side beds under glass, the houses having had an early summer crop of Cucumbers; in this case the bulbs had been planted nearly as deep as when planted in the open, and the beds being on the level of the path, the bulbs were naturally below this line. At this level the bulbs were unaffected by the house temperature, which at most was only that of a cool greenhouse. But because an early start was made, it was argued that they were bound to come early. It is very remarkable, too, that in these very opposite instances very little water had been afforded to the bulbs, and at the end of the year in the second case the outgrowth from the bulb was less than in the

case of others in the open ground planted some weeks later. But the fact that a glass roof kept away all the rainfall, which during the rooting period of the bulbs is often considerable, had been entirely overlooked. In the end, much of the top soil was removed, so that the bulbs might receive more warmth from the air. The crop was very late, and the flowers very indifferent, also a large number refused to expand. Many other failures could be enumerated from causes widely different to the foregoing, but these will suffice.

In the forcing of Daffodils a liberal supply of moisture is an absolutely essential item. It is only necessary to point to the improvement of the flowers of the Daffodils when placed in water a few hours to recognise the importance that moisture is to them. Next to soil moisture, a damp or constant humidity is very desirable. Under ordinary culture in pots and boxes, a thorough soaking of the soil should take place twice a week. From the time the foliage is half-grown, and until the scape is fully grown, the supply of water may be increased one-third. From the moment of the scape attaining its full height, to the bursting of the bud, a vigorous application from the syringe is an urgent necessity. One day of arid condition of the air at this juncture may ruin a crop of perfectly-grown plants in a few hours. This is especially true where the plants are in pits, or in small, low, much-confined houses. The same thing is less likely to ensue in lofty structures. In Nature and in the open garden, rain, wind, the rustle or friction of bud with leafage, is of untold good in breaking open the bud, or assisting thereto. A very dry, arid state of the air, or that excessive wetting of overheated pipes, if retained in the house, and which latter seem to find favour with the young and indiscreet, are both responsible for much so-called blindness. Daffodils will not be steamed into flower, but in a temperature of 50° to 60° may be developed to perfection. *E. Jenkins, Hampton Hill.*

CYPRIPEDIUM × J. WILSON POTTER.

The striking hybrid Cypripede, illustrated in fig. 36, was thought by the Orchid Committee to be from a cross between C. Harrisianum superbum and C. × Charlesworthi, although it bears a slight resemblance to C. × Bingleyense (Harrisianum × Charlesworthi). It is a beautifully formed flower, with all the parts broad and well rounded, the dorsal sepal being especially fine. The whole flower is of a warm purplish-rose tint, the veining being the darker, and the margin of the dorsal sepal pure white. Both in form and colour there are few Cypripedes to compare with this pretty novelty, which was awarded the Royal Horticultural Society's Award of Merit, when shown on January 27 by J. Wilson Potter, Esq., Elmwood, Park Hill Road, Croydon (gr., Mr. W. H. Young).

Fig. 36.—CYPRIPEDIUM × J. WILSON POTTER.

CULTURAL MEMORANDA.

LOBELIA CARDINALIS AND OTHERS

of the perennial section, may be increased by division, or raised from seed. When raised from seed, I much prefer to sow the seed early in the new year, so as to allow plenty of time for the young seedlings to make nice plants before putting them out; and have found the seed to germinate more regularly in a temperature of 55° to 60° in the beginning of the year, to that of a higher temperature later in the season. In all cases of raising plants from seed, and especially that of which takes several days to germinate, sweet fresh soil should be employed, and water sparingly supplied for some time; otherwise the soil may become sour, and fatal to young seedlings, &c. The varieties of cardinalis will be found exceptionally useful for the herbaceous borders; and when planted in masses, or intermixed with other suitable plants, have a very imposing effect. *H. Markham, gr., Wrotham Park.*

Early Broad Beans.

Most persons like Broad Beans in early summer, a season not abundantly supplied with choice vegetables; and if the Beans are gathered whilst the seeds are tender and easy of digestion, the piquancy of their flavour is much relished. Of the Early Mazagan, the one variety which English gardeners usually grow, there are several strains, varying in the height of the haulm and in earliness of podding. The pods are slightly flattened, and larger than a large horse or field Bean. The seeds are grey, and in this respect are not so nice-looking as the small green July Bean, which is also somewhat later. The Dwarf Fan, or Cluster, which bears erect pods in twos and threes, the seeds quadrangular, thick, and bulging; Beck's Green Gem Bean is a capital early variety, with small, dark green seeds to the number of four in a pod. This and the Dwarf Fan can be readily forced in the same manner as Peas in frames. These dwarf Broad Beans are useful catch crops, or for intermediate cropping, as being of short growth, the plants do not throw shade on adjoining crops.

These Beans should be gathered for consumption when fully grown and young, and before the eye has become black. When taken at an earlier stage they have a bitter taste. *F. M.*

Antirrhinums.

These may be considered hardy, but on more than one occasion have I failed to winter young plants raised from seed sown in the open in July and August. But when sown at that time, taken up and planted in shallow boxes, and then stood in a somewhat dry airy position under glass, and where damp and frost is partly excluded, these plants make very useful stuff for planting out early in spring. There are a goodly number of useful varieties, both in regard to colour and height, which if sown during the present month in a little warmth, and duly attended to as regards water, pricking off into other boxes or small pots, and properly hardened prior to transferring them to the beds or borders where they are intended to flower, that will be found exceptionally useful where these flowers are appreciated, and make a brilliant display till late in the autumn. *H. M.*

GARDENING UNDER GLASS.*

(Continued from p. 50)

AIR.—"The respiration of plants does not differ either in its method, or in its object and significance, from that of animals." *Kerner.*

From the moment when germination commences in the seed till the death of the plant, air is necessary to its life. When the supply of air is insufficient or impure, the plant suffers. Breathing goes on day and night, and, as with animals, it is the free oxygen of the atmosphere that is necessary to the plant's existence. Aquatic plants obtain their supply of oxygen from that absorbed by the water, as fishes do. Respiration is most active whilst growth is vigorous. Kerner likens it to a machine which requires more fuel the greater the results required from it. If fuel is wanting or not present in sufficient quantity the machine stops, or does not perform as much work as it should be capable of doing. It is exactly the same in living plants. If the respiratory materials are absent, respiration is discontinued, and the plant dies.

We are told that a root can never have too much air, but often has too little. In the open air the supply of fresh air to plants presents no difficulty, but under glass it is different. Usually ventilation is considered only in relation to temperature. If the air inside a house is too warm, either from sun-heat or the hot-water pipes, the ventilators are opened; but the supply of fresh air to the plants is generally overlooked. It must, however, be evident from what has already been stated that this is wrong. The effects on the health of plants of atmospheric impurities may be seen in the houses at Kew after a severe fog. It is not the vapour of the fog that does the mischief, but the impurities held in suspension in it. A few hours of yellow fog are sufficient to cause the leaves of many plants to wither and fall off, and to blast the flowers and buds wholesale. Cultivators who have had no experience near London are apt to belittle our efforts here. Many gardeners have come to Kew direct from a garden where they grew certain plants exceptionally well, but have failed to repeat their successes here. Generally, their failure has been due to the impurities of the atmosphere at Kew, with which they had not reckoned. It is certain that the purer the air inside our plant-houses, the healthier the plants will be.

The best methods for affording a continuous supply of fresh air to plants in houses and frames are simple, and easily applied. There need not be much if any loss of heat. Generally, the air is let in through passages beneath the hot-water pipes.

If I can succeed in convincing you that plants must have fresh air at all times, you will easily find means for providing it. I said in my last paper that it is in the manipulation of ventilators, blinds, heating apparatus, and watering-pots that the careful cultivator obtains success. All the appliances may be of the most approved kinds, but if carelessness in these essentials is permitted, failure must be the result. Generally, a plant-house should be ventilated on precisely the same lines as a man's house, avoiding rushes of air, sudden changes, and draughts; at the same time admitting sufficient to maintain buoyancy and freshness.

LIGHT.

"The first thing in the morning, when the first ray of sunshine falls upon a plant, the 'protoplasts' begin to work in their little laboratories, decomposing carbonic acid, and producing from it sugar, starch, and other similar compounds; and it is not till the sun sets that this work is suspended, and the influx of carbon-dioxide stopped till the following morning" *Kerner.*

The influence of heat, air, and water on growth and health is very much the same in the case of plants as of animals. Light, however, is of even more importance to plants than to animals. Light is the life of plants; without it they are unable to form growing material from the food supplied by the roots and leaves; moreover, they may be said to lose flesh in consequence of the exhalation of carbon-dioxide and aqueous vapour when light is absent. Deciduous plants, and those with tubers, bulbs, or fleshy roots, will live for a considerable time in darkness when they are more or less dormant; directly, however, they begin to grow and form new leaves, they must have light. If they grow and form leaves in the dark they do it by the aid of the reserve material stored up in them, and therefore may be said to be living on their own fat.

When the light is feeble very little work of the nature of growth can be done; the work increasing with the light until the maximum is reached.

Plants vary in their capability to endure light. For some, direct sunlight is injurious; whilst others enjoy the fiercest glare, and between these extremes there are many gradations. The nature of the plant must be understood before we can decide the amount of sunshine that is good for it. The growth of plants in the open air and exposed to full sunshine is always much more satisfactory than that made in houses more or less shaded.

Given good glass, the right kind of ventilation, and a due regard to temperature, the plants we grow in houses would generally grow better and be more satisfactory in every way if less shading were used. As I have said, we must not overlook the nature of the plant, its condition with respect to age and health, and the purpose for which it is intended. The supply of water to the roots would necessarily require to be in accord with the other conditions, and of course the temperature would have to be watched. No conditions could be worse for plants generally than those afforded by a draughty house, the pots all exposed to the drying influence of hot, dry air, and the sun beating down on the leaves. Many houses are so badly constructed that it is next to impossible to keep any plants in them healthy. When designing our plant-houses, we do not pay sufficient attention to the principles of light, air, and heat, in their relation to plant-growth. I would repeat that every plant should be provided with all the light that its nature will enable it to bear. Plants are asking for it when their leaves turn from the shade to the light. Shading is too often resorted to, to save labour, and not to benefit the plant; with the blinds down practically all day, the plants require less attention than they would do if the blinds were up. The quality of the glass used for the roofs of plant-houses should be of the best—that is, it should be quite clear, and free from flaws or knots, otherwise much harm may be done by burning. *W. Watson.*

(To be continued.)

* Paper read before the Kew Mutual Improvement Society, January 5, 1903, by Mr. W. Watson, Curator.

CHINESE CONIFERS.

KETELEERIA DAVIDIANA.*—The first species of this genus was that originally made known by Fortune. It was at one time considered a true Abies, or Silver Fir; but the description by Professor Pirotta of the male flowers, which were produced on the famous tree in the nurseries of Signor Rovelli at Pallanza, coupled with anatomical data furnished by Bertrand and Van Tieghem, supply ample evidence of the correctness of Carrière's opinion, that the genus Keteleeria, in which he proposed to include Fortune's tree, is a valid one. Mr. Kent, in *Veitch's Manual*, ed. 2 (1900), p. 487, associates this species with the Douglas Fir in a proposed new genus Abietia; but the arrangement of the male flowers, the dehiscence of the anthers, the nature of the pollen, and the position of the cone, are all different from what obtains in the Douglas Fir.

The leaf-structure is slightly different in Keteleeria from that of Abies and Pseudotsuga, and more so from that of Picea or Tsuga. The structure of the leaf in K. Davidiana is remarkable for a group of large, colourless cells near the angles of the leaf, which probably afford storage for water.†

The male flowers of Keteleeria, first described by Pirotta in *Bull. Soc. Tosc. di Orticultura* (1887), p. 263, are in umbels, quite unlike the solitary arrangement in Abies and Picea or Pseudotsuga; and it is very remarkable that a similar arrangement occurs in Cunninghamia, in Pseudolarix, and in Ginkgo—all Chinese or Japanese genera.

For some time K. Fortunei was the only species known, but the researches of Henry, Delavay, the Abbé David, and others, have brought to light at least two, and perhaps more, species, one of which, K. Davidiana, of Beissner, we illustrate (p. 85) from specimens sent home by Mr. E. H. Wilson to Messrs. Veitch's nurseries at Coombe Wood. K. Fortunei is tender in this country, but K. Davidiana, coming as it does from the mountains of western and central China, where it was discovered in the first instance by the Abbé David in the mountains of Szechuen, may prove more robust.

K. Davidiana differs from K. Fortunei in its leaves, which are obtuse, and grooved on the upper surface, so that the prominent midrib is concealed. In K. Fortunei the leaves are acutely pointed, not grooved on the upper surface, but with the midrib very prominent on both surfaces. The cones are larger, narrower, and more elongate, more cylindric in form than in K. Fortunei, and with the edges of the scales rolled back so as to show the tip of the wing of the seed. The cone-scales, both in this species and in K. Fortunei, do not always fall away completely from the branch as they do in Silver Firs, but the cone detaches itself above the base, leaving a few of the basal scales remaining on the thickened branch, much as happens frequently in Pinus

* KETELEERIA DAVIDIANA, Beissner, *Handbuch der Nadelholzkunde* (1891), p. 424, f. 117; Masters, "Genera of Taxaceæ and Coniferæ," in *Journ. Linn. Soc.* (1892), xxx., p. 33, where other bibliographical references are given.
=*Abies Davidiana*, Franchet, in *Nouv. Archiv. du Museum* (1884), t. 113; Masters, in *Gardeners' Chronicle* (April 9, 1897).
Pseudotsuga Davidiana, Bertrand, in *Ann. Sc. Nat.*, 1874, xx., p. 87.

† See Mast. in *Gard. Chron.*, April 9, 1887; and Van Tieghem in *Bull. Soc. Bot. France*, 1891, p. 412.

ponderosa. The individual scales do not fall away so completely from the central axis as those of the Silver Firs (Abies) do.

The germination of K. Davidiana, which I had the opportunity of observing at Kew in 1889, resembles that of some species of Podocarpus in the circumstance that the embryo plant has but two cotyledons. The resemblance of the adult leaves of K. Fortunei to those of Podocarpus has already attracted attention.

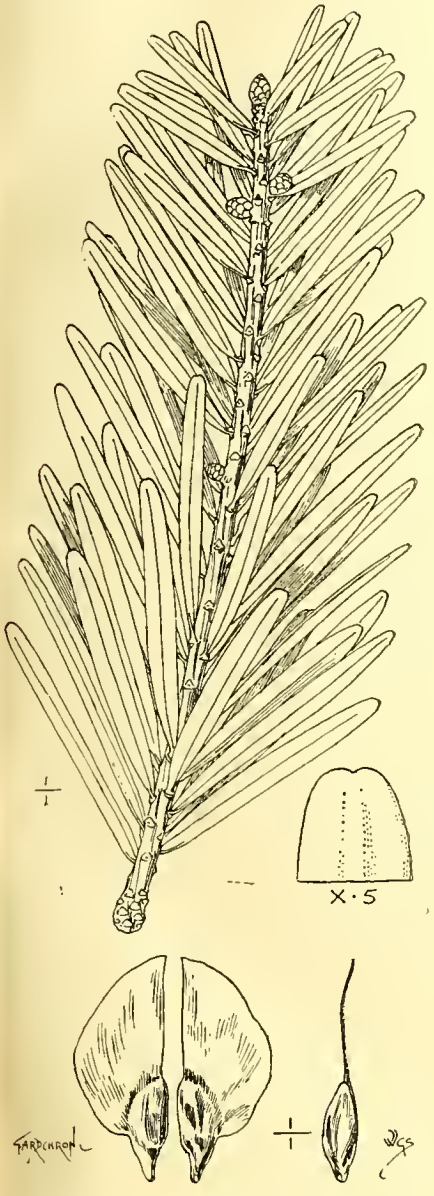

FIG. 37.—FOLIAGE AND SEEDS OF KETELEERIA DAVIDIANA.

The original tree of K. Fortunei was found in the vicinity of a Chinese temple near Foo-Chow, a circumstance which led the writer to infer that the tree might have been introduced there, as at that time the tree had not been discovered in a wild state. But Mr. F. B. Forbes obligingly pointed out in a letter addressed to me, that the very fact that any given tree is found growing around a temple is looked upon as the strongest proof that it belongs to the indigenous vegetation which the Chinese have been busied for ages in destroying for fuel and house-building (see Hance in *Journal of Botany*, 1870 & 1878, p. 7), reserving often for religious or superstitious reasons those that grow in the vicinity of their temples. The fact that some of these trees, e.g., Cryptomerias in Japan are in avenues, shows that they were designedly planted and may not necessarily have been indigenous to the particular district in which the temples stand.

FIG. 38.—KETELEERIA DAVIDIANA, A CHINESE CONIFER: CONE AND FOLIAGE OF REAL SIZE. COLLECTED BY MR. E. H. WILSON.

Since Fortune's time, K. Fortunei has been found by Dr. Hance, and later on by Mr. C. Maries, who found it in great numbers on the coast ranges of Fokien. See Kent in *Veitch's Manual*, ed. 2, p. 486.

There is no information at present forthcoming as to the relative value of the timber of the several species of Keteleeria, but as to their handsome appearance we have the warm testimony of Fortune. *M. T. M.*

PREPARING FOR TRANSPLANTATION.

"SLOW and sure," is a safe motto for those to follow who attempt the transplantation of trees and shrubs of a large size, or, even of a dubious character for well-doing after that operation. For centuries the barbarous expedient was adopted of cutting back tops to equalise the roots destroyed in removing trees from one place to another, and perhaps the practice is not yet quite extinct. It was, I know, practised by the late Mr. Wills, and was in his younger days advocated by him. Details of these old-fashioned methods are, however, of little interest. Suffice it to say, that about a century ago the then Lord Fitzhardinge made a break from principles then

current, and successfully initiated the system of cutting-in the roots to a reasonable distance from the bole, meanwhile allowing the subjects operated on to remain two or three years to recover before transportation was finally effected. Robert Monteath, at one time in the service of George the Fourth, was an early convert to the system, but he courted failure to some extent by removing his subjects too soon after surgical operations. From the same cause, the elder McNab had several failures with the trees and shrubs which were transferred from the old to the new Botanic Gardens, Edinburgh, in 1822. But as a whole, that very bold proceeding exercised a vast influence for good on the gardening community of the period.

For my own part I have never known a judicious application of the principle to fail, and have repeatedly seen its value exemplified. The most striking example of the difference resulting consequent on the carrying out of this very simple expedient, occurred in the thinning of a group of very large and handsome "Golden Queen" Hollies. Some were prepared by root pruning two years previously to removal, and were shifted successfully, without exhibiting any after bad effects. Then it was thought that a further depletion of the plants would be an improvement, and the removal was made at once without any preparation, with complete failure as the result. The money loss alone in this instance, if the plants could have been replaced, would have been considerable; but their value was, as in the case of all fine examples of this nature, beyond price. Not long ago some Quercus Ilex, that had been lined-in closely together as little plants ten years previously, were wanted to complete some planting. The roots of the several plants were run through and through each other, and as the case is with evergreen Oaks always, there were no fibrous roots that could be secured close to the stems. As time was important, a trench was taken out along each side the line of trees and within a foot of the stems, all the roots being severed in the process, and then those pushing downwards were cut across. Once new roots had pushed freely, these were also cut close back, and immediately new growth had recommenced the trees wanted were transplanted, and quite safely. I have an Arbutus to remove that could not be transplanted successfully without cutting the roots well back. Two plants are growing rather close together; both were large specimens in 1880, when they were cut to the ground by the severe frost of that winter, so that they are practically trees of over twenty years growth with roots that have never been checked. To transplant either without first preparing the roots, would require more labour, and almost certainly the plant would not recover, whereas the treatment it will receive previous to attempting its removal, will ensure the tree looking as well as ever in a short time subsequent to removal. These are instances such as may be expected to occur in the experience of most, when the need of great care is absolutely necessary to ensure success. But, root-cutting is of, if not equal importance, at least of sufficient importance to establish it as a part of routine management whenever shrubs or trees that have been several years in the same position require to be transplanted.

The labour and care involved in preparation varies considerably, according to circumstances. For instance, a deciduous tree, such, for example, as a Crab or a Thorn that had been transplanted ten or twelve years previously, will be sufficiently treated by cutting at a distance of 2 feet from the stem and as deeply as possible all the roots that a sharp spade pressed down with the foot will reach. The same treatment will be suitable to Hollies, Portugal Laurels, or other evergreens that do not require a large ball. Manipulated at any time from now till May, these will be in perfect condition to remove in October, each with a nice ball of fibrous roots that will begin operations at once upon the soil of their new surroundings.

Larger specimens that require a ball of suitable proportions necessarily call for a greater preparation, and this work most often can be overtaken at the present season with little leakage of labour power, because weather unsuitable for garden labour presents no drawback for this. There are only a few points connected with these that need recapitulating. Perhaps the initial step with most people would be to mark off a circular space for the trench. The round, however, in this case is much less convenient than the square. A four-sided ball is easier to handle, and where it is necessary to apply boards in which to box the roots, the square is the only form possible. Whether the four sides can be cut at the one time depends (1) on the size of the subject, and (2) on the condition of the roots. It is in any case more proper to reduce the ball to the lowest safe proportions, than to make it so large as to be unwieldy. If it is considered to the advantage of the plant to prepare the ball on every side, the spade, which should be kept sharp in order to cut clean, must be used to cut the roots while they are still firmly held in the soil before taking out the trench. Any thick roots will be best cut with a pair of French branch-pruners, or if not too numerous may be allowed to remain for the present. Eighteen to 21 inches is sufficiently deep for a ball; but it is not necessary to cut quite through the bottom, though a portion certainly ought to be cut. In the case of subjects about which there is any dubiety, better cut two opposite sides and part of the bottom, rather than run any risk. The remaining portion may be cut in autumn, or any time convenient during the dull season, and the greatest care be taken to form the sides perfectly square. When the mass of soil to be moved is deemed larger than with the means at command can be managed successfully, the two last sides to be cut may be made a little nearer to the stem; even three inches make a palpable difference, and no bad effects will, as a rule, be felt by the tree. When the earth is returned to the trench, it can hardly be rammed too hard in. It would be a mistake to add any better material to the old, because while the whole proceedings are conducted on the principle of producing the life-providing feeders of the plant in a contracted space, we want these feeders to be of as "hardy" a nature as the soil will produce. *B.*

The Week's Work.

PLANTS UNDER GLASS.

By J. MAYNE, Gardener to the Hon. MARK ROLLE, Bicton, Budleigh Salterton, Devonshire.

Stove Climbers require to be thinned annually, or growth becomes weak and flowers few. The shoots of Stephanotis floribunda, Dipladenia, Ipomœa, and Clerodendron Balfourianum, should be shortened back to well ripened wood. The last-named species when planted out is seldom devoid of flower, but being a strong grower the knife must be freely used once a year. Rondeletias should have the weakest wood cut out, and the strongest shoots shortened a little; while Allamandas and Bougainvilleas should be cut back to within a few buds of last year's pruning—indeed, the Bougainvillea is best treated similar to the Vine, i.e., spurring back close to the leading growths. The colour of the bracts is far more intense when the plant is grown in an intermediate or warm greenhouse than in the stove. Train the growths fairly near to the glass roof, and afford but little shade at any period of the year. After pruning the plants, keep them fairly dry at the root until growth starts afresh, when those in pots may be partially shaken out and repotted, and those planted in borders may be top-dressed after removing a little of the surface-soil. A compost of equal parts of fibrous loam and peat, with finely-broken charcoal, and some coarse silver or clean river sand, will suit all the species mentioned above.

Codiæums (*Crotons*).—Any unsightly or leggy plants should have their tops removed, cutting them close under to a leaf. The cuttings may be used for obtaining young stock, and if grown with single stems they make excellent plants for the decoration of the dinner-table. The cuttings, after preparation, need not be more than 3 inches in length. Insert them in thumb-pots, and keep them close to the side of the pots; use a sandy soil, and after applying water to the cuttings, place them in a propagating-box having a bottom-heat of 75° to 80°, the temperature of the house being 65° to 70°.

Cordylines (*Dracænas*).—The tops may also be removed from Dracænas that are become shabby, and afterwards rooted in small pots or in water, or cut the stem into pieces about an inch long, and place them in pans of sand; afford a good bottom-heat, but do not keep them too moist before the buds are well advanced. November is the best time to do this, but if the work was omitted then, it may be done now. D. gracilis and D. Goldieana are best propagated from side-shoots taken off with a "heel," such as start away from the main stem after it has been stopped.

Anthuriums.—The flowering section may now be repotted, first shaking away the old soil, and cutting off any dead roots. Leggy plants may have the rootstock shortened, but the surface or aërial roots should be preserved. Let the pots or pans be well drained, filling them about one-third with washed crocks. The compost should consist of two parts peat, lumpy and fibrous, and one-third fibrous loam; also coarse pieces of charcoal, and plenty of silver-sand. Keep the crown of the plant a little above the rim of the pot, and work the soil down among the roots with the fingers, making it moderately firm, and finishing off with a layer of fresh sphagnum-moss. Syringe the plants twice daily, and then little or no water at the root will be necessary for some few weeks. Afford them a light position in a temperature of about 60° at night, with a rise of 5° or 10° during the day.

THE ORCHID HOUSES.

By H. ALEXANDER, Orchid Cultivator to Capt. G. L. HOLFORD, Westonbirt, Tetbury.

Leaf-soil.—Orchid cultivators are not agreed respecting the use of leaves as a potting compost, and some having given it a trial, have discarded it entirely, and others, on the contrary, are well satisfied with the results obtained. In any case, a gardener should use it tentatively, making small experiments and noting results. I have made use of leaf-soil here for a year and a half, and so far I am satisfied with the growth and flowering of the plants. In a few instances, leaf-soil unmixed with other ingredients has been employed, and fresh sphagnum to cover it. It is, however, where a certain amount of chopped peat and sphagnum, with a good sprinkling of broken crocks and silver-sand has been added, that the results have been most satisfactory. It is difficult for the cultivator, when leaf-soil is alone employed, to decide when and how to apply water. The more porous materials permit water to pass away quickly, provided the drainage is abundant and in good order; whereas with leaf-soil, water does not pass off so quickly as is the case with the ordinary compost of peat and sphagnum, and the pots filled to three-quarters of their depth with crocks; consequently it should not be afforded so often. I would advise those cultivators of Orchids who reside in or near large cities, and in smoky localities, to use peat, &c., in the potting composts, so as to make them more porous, and in larger quantity than that given in this Calendar for each class of plants.

Cypripediums.—Some plants of this genus which flower in autumn and winter will stand in need of repotting, and among the first to receive attention will be C. insigne and varieties; C. Arthurianum, C. A. pulchellum, C. Leeanum, and the crosses of the above-named species. The same kind of treatment applies to all, for being of vigorous growth, and needing plenty of water at the root when the pots are filled with roots, pots of

a fair size, provided with perfect drainage, should be employed. A layer of clean crocks, not less than 1 inch deep, is sufficient, and over that another of sphagnum, in order to prevent the drainage from becoming choked. Our Cypripediums are placed rather lower than the rims of the pots, and the compost used in the potting consists of one-third good turfy loam, one-third lumpy peat, and one-third of equal parts of leaf-soil and sphagnum, together with some clean sharp sand and small crocks. When repotting a specimen plant in an 8 or 10-inch pot, let the material be very coarse; then the plant will not need to be repotted for three years, provided water is applied with care till such time as the new roots completely permeate the soil. The appearance of a newly-potted plant is improved if some heads of live sphagnum be pricked in all over the surface. In the case of choice or valuable varieties, one plant of each should be broken up each year to furnish duplicate plants, if this be considered necessary. The true characteristics of a Cypripedium are not observable till the plant has reached specimen size, and the flowers have come of the fullest size. The species and varieties named above succeed in the cooler part of an intermediate-house, and for the sake of convenience, in a group or groups together.

THE KITCHEN GARDEN.

By JOHN FLEMING, Gardener to Sir C. PIGOTT, Bart., Wexham Park, Slough.

Peas.—Make a sowing of the early, round-seeded Peas on a south border or some warm sheltered position, on land suitably trenched and manured. No kitchen-garden crops are more commonly injured than Peas by being thickly sown, more especially the taller-growing varieties. The early sowings should be put in rather thicker than is necessary later on, owing to the failure of some of the seeds to germinate, and the ravages of rats, mice, birds, &c. A good rule to observe in drawing the drills is to have the between-space exceed the height of the plants by not less than 1 foot, and to draw them in the direction of north and south. The drill should be flat, and 6 ins. in width, and of a depth of 2½ to 3 ins. Before the seeds are sown, damp and roll them in red-lead powder. Some gardeners immerse the seeds in petroleum for about twenty minutes. Having sown the seeds, closed the drills, and made the ground tidy, let a number of traps be set for mice, which are sure to be troublesome. The Peas sown last month under glass for planting outside should be kept sturdy by affording air night and day when there is no frost, and water applied before the soil gets very dry.

Broad Beans.—Make a sowing of Longpod and Green Windsor to succeed the earlier sowing. Long-pod Beans for earliness, the Green Windsor for its good flavour. Let the seeds be dibbled-in at 2 inches deep and 6 inches apart in double rows drawn at 2 feet apart. The Beans raised under glass require the same kind of treatment as that bestowed on Peas.

Potatos on Hotbeds.—As soon as these are through the soil let the haulm be earthed up, and if the quantity of soil does not suffice for the purpose, some suitably prepared light soil that has been made as warm as that of the beds should be employed, carrying out the work during the middle hours of the day. Plant succession crops on hotbeds made up of tree-leaves and stable-litter. Radish seed may be sown between the rows, the roots being ready for use before the Potato haulm requires to be moulded up. When the proper conveniences are not at command for forcing Potatos, skeleton frames, spare lights from garden frames, or garden mats, may be made of use for raising a crop of Potatos. Choose a warm position, wheel on to the ground light turfy sandy soil, to the depth of 6 or 9 inches, and well mix together with the staple, and when levelled and made firm, plant it with the sets which have been put to sprout in cutting boxes or on shelves, breaking off all the sprouts excepting the three strongest; plant in rows 15 ins. apart, 12 ins. from set to set, and 6 ins. deep. If the soil in which the earliest Potatos are growing in pots is found on examination to be dry, afford tepid water in quantity sufficient to moisten the whole body of soil, but do not apply water in excess.

Turnips.—The crop of bulbs from seed sown at this date on a slight hotbed, or even in cold frames, will be ready for use in about twelve weeks. If the hotbed treatment be afforded, be careful to avoid a bottom-heat higher than 75°, or top-heat higher than 60°. Place light soil to the depth of 12 inches in the frame; after the materials have settled and the strong heat has passed off, make firm and level, and sow thinly in drills drawn at 9 inches apart. The bed of soil should not be more than 8 inches from the glass at the first, and if it sink much, the frame must be lowered. Keep the air moist, apply ventilation in fine weather, and sprinkle the frames when they are closed in the afternoon. Sutton's White Gem and Carter's Early Forcing are excellent varieties that mature quickly, and are of superior quality. Early Milan is likewise useful as a forcing Turnip, but is less quick in growth and good in quality than those.

FRUITS UNDER GLASS.

By T. H. C.

Figs.—The earliest trees in pots will now be forming their foliage, and the young embryo Figs will be getting larger. If the heat from the plunging material is declining, let more be added from the fermenting heap. Apply tepid water, with which a small quantity of weak liquid-manure or other fertiliser may be mixed, to the roots. In fine, bright weather syringe the trees at the least once daily, and otherwise maintain the air of the house in a moist condition, and slightly increase the temperature.

Orchard-house.—This structure contains the more hardy fruit trees planted out or grown in pots, and the fruit produced usually attains to a high degree of perfection. If heated, so much the better, not so much for assisting the ripening of the fruits, as to help in ripening the shoots of Peaches, Figs, &c., in a season like that of last year. If not already done, let no time be lost in getting all pruning and cleansing finished, and thoroughly cleanse the house according to the directions previously given in these columns. Trees planted in the borders, if they are in a good fruiting condition, should have the surface-soil removed down to the roots, replacing it with turfy loam, to which may be added a small quantity of bonemeal and lime-rubble, and apply a mulch of decayed stable-manure. Young trees which have made vigorous growth and shown no signs of fruiting, should have their roots pruned. This is an operation that is more properly carried out at the fall of the leaf than at this season, but rather than lose another season let half the mass of roots be pruned forthwith, and the remainder at some future time. Do not top-dress such trees, excepting with charred garden refuse, which may be lightly pointed in, and other means adopted to cause the roots to grow near to the surface.

Trees in Pots.—Remove the surface soil from amongst the roots with a pointed stick, and afford a top-dressing of rich compost, at the same time see that the drainage is in good order. The orchard-house being in readiness for starting should be placed under quite natural conditions, employing fire-heat only to exclude frost, and in dull weather when the trees are in flower to maintain a buoyant atmosphere. When the flowers expand, distribute the pollen with a rabbit's-tail, or sharply tap the branches, or syringing the trees at midday. The two latter methods are often resorted to where large numbers of trees are grown, but they are faulty, inasmuch as the beneficial effects of cross fertilisation are not so surely brought about. Where hive bees abound, they largely assist in this function, and should be kept in every large garden.

THE HARDY FRUIT GARDEN.

By CHAS. PAOE, Gardener to J. B. FORTESCUE, Esq., Dropmore, Maidenhead.

The Morello Cherry.—If the work of pruning and nailing of the Morello Cherry trees was not carried out in the autumn, let advantage be taken of mild days to carry it out forthwith. If any of the trees were infested with black aphides last year, loosen the branches from the wall, fasten them loosely together in bundles, and syringe them with some approved sort of insecticide, then proceed with the nailing. If disbudding was properly attended to last June, but little pruning will be required. Shoots which carried fruits last summer, and which were disbudded of all the shoots but one at the base of each, may be removed; and those which were pinched at the points, so as to induce the formation of fruit-spurs, shortened, leaving two or three buds. Young shoots may, in some instances, be fastened to the bare main branches. Let the young wood be laid-in evenly and regularly at about 4 ins. apart. When the nailing or tying is finished, remove the surface-soil, if much trampled upon, to the depth of 2 or 3 inches, and replace it with fresh soil, to which finely-broken mortar-rubble may be added.

Trees to be Grafted.—Apple and Pear-trees which are to be grafted this year should be headed back early this month; and in the case of orchard standards, from three to five of the best-placed branches should be retained, of about 18 inches in length, which will allow of 6 inches being removed from each at the time of grafting. The rest of the branches should be cut back to within 3 inches of the trunk, care being taken to smooth the cut surface with the pruning-chisel. If the branches removed are of a large size, a cut should first be made on the under-side with the billhook or axe, to prevent the wood or bark splitting off when cut with the saw. Grafted trees of last spring should have the grafts made secure against the wind by tying them to stakes fastened on to the branches.

Miscellaneous.—Take advantage of fine weather to expedite all planting and pruning operations, as severe weather may yet put a stop to operations of this kind for a time.

THE FLOWER GARDEN.

By J. C. TALLACK, Gardener to E. MILLER MUNDY, Esq., Shipley Hall, Derby.

Bedding Plants.—Autumn-struck zonal Pelargoniums may now be shaken out of the soil in which they have been growing, and be either potted singly or boxed in fresh soil, i.e., loam, leaf-mould, and sand. The more convenient method where suitable accommodation exists is to pot them singly or in pairs, and afford a temperature of about 50°. In some gardens, fruit-forcing houses destitute of stages are utilised, and in these it is better to put the plants into boxes. The chief danger from doing this is the check given the plants when planted out; but I have observed that if an inch layer of rough Mushroom-bed materials, or some partly decayed tree-leaves be used for covering the bottom of the boxes instead of crocks, each plant can be readily cut out with a compact ball of soil and manure attached thereto, and no more check inflicted than when a plant is turned out of a pot. After potting or boxing, syringe the foliage lightly once or twice a day, but afford no more water before root activity begins, and a month later begin to harden off by degrees.

Dahlias.—If the stock of roots of any variety is not sufficiently numerous, put some old roots into boxes, cover with leaf-soil, and place on a gentle hotbed to produce shoots, any of which may be cut or broken off close at the base when about 3 inches high, inserted singly in sandy soil in 60's, and plunged in bottom-heat of 75° to 80°.

Verbenas, Alternantheras, and other Bedding Plants, which were started into growth a few weeks ago, will have shoots fit for making cuttings which may be struck and rooted as quickly as possible, so as to yield cuttings in their turn. These tops, the earliest cuttings, should be valued, as they are not liable to become stunted or diseased. It is astonishing how quickly a big batch of Lobelia speciosa can be worked up in this manner.

Seeds.—The hot-bed made up for raising East Lothian Stocks, &c., being now ready, sprinkle slaked lime over its surface and rake it in, in order to prevent loss of plants by damping off. Into this frame may be placed pots and pans and boxes containing seeds of Antirrhinum and Pentstemon. But for the fact that one cannot depend on getting Pentstemon from seed true to colour, this would be an ideal method of propagation.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the Publisher.

Letters for Publication, *as well as specimens and plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Illustrations.—*The Editor will thankfully receive and select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.*

Local News.—*Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY, FEB. 7—Société Française d'Hort. de Londres meeting.

MONDAY, FEB. 9—Surveyors' Institute meeting; United Hort. Ben. and Prov. Soc. Com. meeting.

TUESDAY, FEB. 10—Royal Hort. Soc. Coms. meet; also Ann. Meeting of Fellows.

FRIDAY, FEB. 13—Roy. Gardeners' Orphan Fund, Ann. Meet. at Cannon Street Hotel.

SATURDAY, FEB. 14—Royal Botanic Soc. meeting.

SALES FOR THE WEEK.

MONDAY, FEBRUARY 9—
Herbaceous Plants and Bulbs, Lilies, Gladioli, &c., at Protheroe & Morris' Rooms.

WEDNESDAY, FEBRUARY 11—
Roses, Liliums, Begonias, Carnations, &c., at Protheroe & Morris' Rooms.—Roses, Shrubs, Lilies, &c., at Stevens' Rooms, at 12 30.

FRIDAY, FEBRUARY 13—
Standard, Dwarf, and Climbing Roses, Spiræas, Davallias, &c., at Protheroe & Morris' Rooms.—Imported and Established Orchids, at Protheroe & Morris' Rooms.—Specimen plant of Cypripedium Morganiæ at 2 P.M.

(For further particulars see our Advertisement columns.)

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick —39·1.

ACTUAL TEMPERATURES:—
LONDON.—*February* 4 (6 P.M.): Max. 50°; Min. 46°. *February* 5 (Noon): Dull, moist: 56°.
PROVINCES.—*February* 4 (6 P.M.): Max. 50°, W. Ireland; Min. 42°, N.E. Scotland.

"The Hall."

THE report of the Council of the Royal Horticultural Society to be presented, together with the statement of accounts, to the annual meeting on Tuesday, February 10, at 3 P.M., has been circulated among the Fellows. It is a very satisfactory document, and one that reflects great credit on the officials of the Society. It consists of twenty-five paragraphs, all of which at any other time would demand attention. At present, the main interest centres in the Hall.

What has the Council done to carry out the all but unanimous and strongly expressed wishes of the Fellows? What progress has been made towards the accumulation of the necessary funds? When may we look for the realisation of our hopes? Some answer to these questions may be found in the report. After diving into ancient history and narrating what took place in April, 1900, with reference to the proposal to purchase land at South Darenth for the purpose of a garden to replace Chiswick, the report goes on to say:—

"After considerable discussion a resolution was carried 'that the proposed site is not the best means of celebrating the Centenary of the Society,' and in supporting this resolution Mr. H. J. ELWES, F.R.S., unconditionally offered £1,000, if a New Hall were substituted for a New Garden as the celebration of the Society's Centenary. Mr. A. W. SUTTON, V.M.H., and Mr. N. N. SHERWOOD, V.M.H., also offered £1,000 each, and Baron SCHRÖDER a day or two afterwards offered £5,000 if a New Hall were adopted.

"After this Meeting the Council felt bound to carry out the manifest desire of the Fellows to build a permanent home for the Society as the Celebration of the Centenary, and a Committee was appointed to enquire into the possibility of securing a suitable site within the means of the Society.

"Relying on the already promised subscriptions, and the enthusiastic reception with which the appointment of the Committee had been hailed, the Council reported to a Special General Meeting, held on March 21, 1902, that a suitable site had been found in Vincent Square, Westminster. The utmost enthusiasm for the Hall prevailed at this meeting, which was attended by nearly 300 Fellows; 'the principle of building a New Hall' was 'accepted,' and the Council were authorised to take the necessary steps to enable the building to be opened in the year 1904,' a resolution embodying these words being carried with only three dissentients.

"The Council at once took 'the necessary steps to enable the building to be opened in 1904,' on the completion of the one hundredth year of the Society's existence. The site in Vincent Square was secured by Baron SCHRÖDER, on behalf of the Society, and after careful consideration, Mr. EDWIN STUBBS was requested to draw up plans for the buildings in accordance with instructions given by the Council. A subscription list has been opened, to which H.M. the KING and H.R.H. the PRINCE OF WALES, have been graciously pleased to subscribe, their subscriptions being accompanied by letters of full approval and encouragement. The sum subscribed up to the date of this Report going to press is £22,000, which the Council cannot but regard as a promising commencement. The total estimated cost of the New Hall and Offices is £40,000, inclusive of furniture and equipment. While the Council gratefully acknowledge on behalf of the Fellows the response they have already received to their appeal, they feel confident that there are very many Fellows, amateur and professional, who will desire to recognise the great and continuous advantages they receive from the Society, by liberally supporting the New Hall Fund.

"The Council are aware that the plans and elevation they have placed before the Fellows have been criticised. They desire to point out that they have purposely restricted expenditure on external ornamentation, in order to provide satisfactory internal accommodation; and that the architect has to comply with the restrictions and limitations necessary to meet the requirements of the ground landlords, the County Council, and other authorities.

"The Council desire to assure the Fellows that the provision of a New Garden has by no means been lost sight of. The Society's lawyers are in correspondence with those of the Duke of DEVONSHIRE, and negotiations for the surrender of the Chiswick lease are in progress, and they hope that these, when completed, will materially facilitate the acquisition of the New Garden."

So stands the matter. The site has, through the public spirit of Baron SCHRÖDER, been obtained, and cleared ready for building. The amount already promised is £22,000. In addition to this there is a surplus fund, which was destined from the beginning to be used for purposes of the Hall, and which might well be utilised to form part of the endowment to cover the ground-rent, and enhanced expenses of maintenance. The Society is now so financially strong, that its surplus on the year's working amounts to over £2,000. Surely never at any period was the Society so powerful, either in funds or in the number of Fellows. Surely, therefore, never was there a more favourable opportunity for realising the general desire of the Fellows for the creation of a home for the Society, which shall also be the headquarters of British horticulture. The iron is glowing hot; let us strike and strike again while it remains so. The plans submitted do not meet with universal approval—what plans would? Many of the objections raised to them can be met if sufficient funds be forthcoming. In the meantime, while by no means overlooking the æsthetic side of the matter, we are bound to place suitability to its purpose before appearances, and to remember that it is to general convenience and adequacy of the internal arrangements that we have to look rather than to an imposing façade.

His Majesty the KING and the Prince of WALES have shown their sympathy in the work in the most practical manner, several gentlemen, in addition to Baron Sir HENRY SCHRÖDER, have contributed substantial aid. Now it is for the Fellows in general to do their part. The nursery trade which derives, and ever since the establishment of the Society has derived, such benefits from it, should certainly be very largely and munificently represented on the subscription lists.

The horticultural societies throughout the kingdom should contribute according to their means. The special societies should feel it particularly incumbent on them to help in the good work, as some of them have already done.

All those who derive their living from horticulture should feel that they owe a duty to the profession which gives them bread, and contribute accordingly.

Lastly, the thousands of garden-lovers, the tens of thousands of those who delight in flowers and value the pleasure they afford and the lessons they teach, should tender their assistance.

The more large sums that are subscribed, the better; but these are not the only requirements. We want the mites of the masses also, and, for our own parts, we shall be happy to forward to the proper quarter any sums that may be entrusted to us, and to acknowledge their receipt in these columns. The urgency has become so great, and matters have progressed so far, that a Hall we must have. We may trust the horticulturists of the Empire to prove practically that which they have already asserted in words, that the best means of celebrating the centenary of the Royal Horticultural Society is by the erection of a properly constructed and duly endowed home.

KEW.—Signs of approaching spring were apparent even so early as the 30th ult. Hellebores, Hepaticas, Winter Aconites, and other early-flowering plants were in full bloom. Rhododendron Nobleanum × was expanding its flowers in the Rhododendron dell, and the very beautiful Prunus Davidiana was covered with its pinkish-white blossoms. Perhaps at no season of the year does the Bamboo-garden look to better advantage. The fresh green foliage is stirred by every passing breeze, and the pliant shoots bend before each gust with a grace and elegance that induces the belief that they enjoy the movement. As to the rock-garden, illustrated in our Supplement, go when one may, one is sure to find something of beauty and interest. The large foliage in the foreground is that of a Rodgersia.

ROYAL GARDENERS' ORPHAN FUND.—We would call the attention of our readers to the fact already announced, that the Annual Meeting of this charity will be held on Friday next, at Cannon Street Hotel, London, E.C., at 4 P.M. It is most gratifying to learn that the Committee propose to place upon the funds all of the twenty-four children applying for relief, by resolution. We hope that next year the support given the fund will be so liberal that a similar course will be possible. There is a proposal to amend the rules, so that the Committee may in exceptional cases have power to help the children until they are sixteen years of age, or two years beyond the time limited.

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the Committees will take place on Tuesday next, February 10, in the Drill Hall, Buckingham Gate, S.W. The annual general meeting of the Fellows of the Society will also be held in the Drill Hall at 3 P.M., on the same date. At a general meeting held on Tuesday, Jan. 27, forty-eight new Fellows were elected, amongst them being the Countess FITZWILLIAM, and Baron de TEISSIER, making a total of 138 elected since the beginning of the present year.

"THE BOTANICAL MAGAZINE" for February contains coloured figures and descriptions of the following plants:—

Sanseviera grandis, J. D. Hooker, tab. 7877.—A supposed native of tropical Africa, but introduced into Cuba in the hope that the fibre it contains, which is of extraordinary strength, might be turned to commercial account. The plant is growing in the temperate-house at Kew, and has a tuft of broad, obovate, oblong, acute leaves 3 to 4 feet long, 6 inches wide, pale green, with transverse stripes of a deeper colour, and a central stalked raceme some 3 feet high of numerous regular, erect, funnel-shaped, greenish flowers, each about 2 inches long, the linear perianth-segments as long or longer than the narrow tube. As an ornamental plant, it has high claims on the attention of gardeners, and its cultivation would seem to present no difficulty.

Impatiens Balfouri, J. D. Hooker, tab. 7878.—A very pretty Himalayan Balsam, with lanceolate leaves and rosy-pink flowers. Royal Botanic Garden, Edinburgh.

Acidanthera candida, Rendle, tab. 7879.—An Iridaceous plant, native of east tropical Africa, with lovely symmetrical white flowers. It was imported by J. T. BENNETT-POË, Esq.

Astilbe Davidii, Henry, tab. 7880.—A very beautiful Spiræa-like plant, described and figured in these columns by Mr. HENRY. It was introduced to Messrs. VEITCH's establishment by their collector, Mr. E. H. WILSON.

Rhododendron brachycarpum, D. Don, tab. 7881.—A species which forms vast tracts in the mountains of northern and central Japan above the line of forests. The flowers are white, flushed with pink, the upper lobes of the corolla spotted. It flowered in June, 1902, in the arboretum at Kew. The glabrescence of the leaves and the colour of the flowers are variable.

"GARDEN FANTASIES."—Mr. and Mrs. ALBERT STEVENS have on view at the Leicester Gallery, Leicester Square, a collection of water-colour drawings, to which we desire to call the attention of our readers.

SCOTTISH HORTICULTURAL ASSOCIATION.—The first meeting for the session of the Scottish Association was held on Tuesday evening, the 3rd inst., at 5, St. Andrew Square, Edinburgh. The President, Mr. J. W. McHATTIE, occupied the chair, and there was a crowded attendance. We hope next week to be enabled to publish a part the President's address.

THE SURVEYORS' INSTITUTION.—The next ordinary general meeting will be held in the Lecture Hall of the Institution on Monday, February 9, 1903, when a paper will be read by Mr. WILLIAM WOODWARD (Fellow), entitled "Some of the Difficulties which Present Themselves to the Architect and Surveyor Practising in London." The annual dinner of the Institution will be held at the Empire Hall, Trocadero Restaurant, Piccadilly Circus, on Friday, Feb. 20, 1903, at 7 o'clock precisely.

SOCIETY FOR THE PROTECTION OF BIRDS.—The annual general meeting of the above Society, of which Her Grace the Duchess of PORTLAND is the President, will take place on Tuesday, February 10, 1903, at the Westminster Palace Hotel, Victoria Street, London, S.W. His Grace the Duke of BEDFORD will take the chair at 3 P.M.

HONG-KONG.—We learn that Mr. FORD, the Director of the Botanic Garden, has resigned his appointment after a lengthened term of service, and that Mr. S. T. DUNN, from the herbarium staff of the Royal Gardens, Kew, has been appointed in his stead.

ROYAL BOTANIC SOCIETY.—A laboratory has, we read with gratification, been opened in the gardens of the Royal Botanic Society at Regent's Park, in which classes for instruction in botany and horticultural chemistry are held three days a week. Mr. E. J. SCHWARTZ, Demonstrator in Botany at King's College, has been appointed director, and he has now completed arrangements for the reception of pupils. The laboratory has been erected and equipped under the ægis of the Technical Education Board, and there is ground for hope that it may form the nucleus of a more ambitious botanic institute in connection with the Royal Botanic Society.

GARDENS AT RAILWAY STATIONS.—The directors of the Great Eastern Railway Company have decided to improve the appearance of some of their country railway stations by laying out pieces of waste ground at the back of platforms as gardens and shrubberies. The directors have appointed a gardener, whose duty it is to suggest where these improvements can be made, and superintend the carrying out of the work.

VILLA THURET.—We have received a copy of the *Catalogue des Graines*, or catalogue of seeds, offered for exchange by the Director of the Villa Thuret, at Antibes, so long under the management of our venerated friend, CHARLES NAUDIN, and now under the direction of M. GEORGES POIRAULT, to whom applications for exchanges should be made before March 1.

MR. W. A. COOK.—We regret to learn that Mr. COOK, who for several years was head gardener at Compton Bassett, and so recently as last year appointed to a similar post at Erlestoke Park, Wilts, has, through the death of SIMON WATSON-TAYLOR, Esq., to relinquish his charge. We hope so good a gardener will not long remain disengaged.

ASCOTT, LEIGHTON BUZZARD.—On the occasion of the festivities following the coming of age of Mr. LIONEL DE ROTHSCHILD, which continued for more than a fortnight, balls playing an important part, the floral display was very extensive, and uncommonly rich and effective. This display was concentrated in a temporary pavilion 200 feet in length and 70 feet wide, which had been erected on the cricket-ground, and this the various gardeners at Gunnersbury Park, Gunnersbury House, and Ascott, had done their utmost to make worthy of the auspicious event. Among the material that contributed to the show, we may mention Forget-me-not and Yellow Tulips (blue and yellow), the Rosebery colours; pink and pale yellow Roses, with foliage of Galax aphylla, &c. Palms and tall Dracænas were used as a background to beds and lines of smaller Dracænas, Codiæums, Lilacs, Euphorbias, Begonias, and standard zonal Pelargoniums, arranged in the aforesaid pavilion. It was the boast of the able gardeners to the various members of the family, Messrs. J. HUDSON, G. REYNOLDS, and J. JENNINGS, who carried out the decorations, that nothing was employed but what had been grown and supplied by them.

VISIT OF THE KING AND QUEEN TO WYCOMBE.—On the occasion of Their Majesties visit to Earl and Countess CARRINGTON at Daws Hill Lodge, High Wycombe, on January 29, there were several memorial trees planted. The KING and QUEEN planted two Cedars of Lebanon in the flower garden, on the south front of the residence, and Countess CARRINGTON planted a Plane-tree. Their Majesties were greatly interested in the alterations and improvements that have been carried out under the superintendence of Mr. G. T. MILES, sen., Lord CARRINGTON's steward. Subsequently the QUEEN, through Lady CARRINGTON, expressed her desire to present to Mr. MILES the spade which had been used in the planting of the trees. The spade, which was supplied by Mr. R. C. R. POTTER of Wycombe, had a specially polished blade and handle, and it is Earl CARRINGTON's intention to have a suitable inscription engraved on the implement.

"DIE VEREDELUNGEN VON OBSTBÄUMEN UND FRUCHTGEHÖLZEN," Von Ph. HELD, Stuttgart (WILLIAMS & NORGATE) ("The Improvement of Fruit-trees and Bushes").—We mention this work for the sake of calling attention to the very numerous coloured illustrations, showing the methods of grafting, budding, pruning, as well as of the destructive insects most frequently met with on fruit trees. The figures are excellent, and should find a place in technical schools to facilitate practical work.

"OUR POULTRY."—The seventh part of Mr. HARRISON WEIR's exhaustive work on poultry (HUTCHINSON & Co.) has been published. It deals with the game-cock, is finely illustrated, and contains much curious matter, interesting not only to poultry-fanciers, but to naturalists generally, and to those interested in "sport"!

"THE GARDENING WORLD" in its new guise has greatly improved its appearance. As to its contents they were always good, and they are so now.

"INDIAN PLANTING AND GARDENING."—This is an old friend with a transmuted title—"Planting" and especially the cultivation of Tea—now take the first place, and gardening is relegated to the second half of the paper, but as its interests seem to be as well cared for as before, Indian gardeners have no cause for complaint.

JARDIN DES PLANTES.—Prof. COSTANTIN, the newly appointed Director of the garden attached to the "museum" of Paris, has issued a lengthy catalogue of seeds collected in the garden in 1902 and available for exchange. Applications should be made to the Director (Service de la Culture), Rue Cuvier 57, Paris.

"THE GARDENING YEAR BOOK."—Messrs. COLLINGRIDGE, of 148, Aldersgate St., have published the forty-fifth yearly issue of this little book, also known as the *Garden Oracle*. It is full of useful practical hints, a list of new plants of the past year, an enumeration of the principal public parks and gardens throughout the country, from which by the way we miss mention of the Radnor Park at Folkestone, and much information of a miscellaneous character. When we say it is prepared by the editor of the *Gardeners' Magazine*, we have said all that need be said in the way of commendation.

TREES AND SHRUBS.—Under this title, Prof. SARGENT is bringing out what may be termed an appendix to his famous "Silva." It consists of a series of illustrations of new or little known ligneous plants growing in the Arnold Arboreum, of which he is the director. The drawings are by Mr. FAXON, and in size are somewhat smaller than those in the Silva. A full description of each tree is given by the author. Numerous new or little known species of Cratægus are illustrated in the first number. The publication can be had of HOUGHTON, MIFFLIN & Co., Boston, through WILLIAMS & NORGATE, Henrietta Street, Covent Garden.

SIR WILLIAM HOOKER.—Those interested in the history of Kew, and the career of its first director, will read with avidity the sketch of the life and labours of Sir WILLIAM JACKSON HOOKER, contributed to the January number of the *Annals of Botany*, by his son and immediate successor, Sir JOSEPH HOOKER. Only a comparatively few of the present generation can have personal knowledge of the details concerning the history of the Royal Gardens when in 1841 they were taken over by Sir WILLIAM HOOKER. Those few will be delighted to have their remembrances freshened by this charming piece of biography. Others familiar with the existing establishment will read with great interest the account of the steady evolution of the institution under the guidance of successive directors. We are all proud of Kew, and this memoir will increase that feeling, and enhance our admiration at the unceasing labours and the consummate ability of those by whom it has been brought to its present condition. The sketch of Sir WILLIAM's life in Glasgow as Professor and Director of the Botanic Garden is also particularly interesting, and shows how wise was the choice of such a man to organise and direct the national botanical establishment. In Glasgow were laid the foundations of that correspondence with merchants and botanists abroad and in the colonies, which afterwards bore fruit in the Kew museums, and in that attention to economic botany which has resulted in such great benefits to our colonies. At Glasgow, too, the herbarium and library were gradually accumulated till they have become unrivalled. There also was found the artist, WALTER FITCH, whose aid and talent rendered possible the production of the prodigious number of illustrated works which emanated either from Glasgow or from Kew. We have not space to dwell at greater length on the career of Sir WILLIAM HOOKER; we can only end, as we began, by saying that this sympathetic biographical note will be read with avidity.

MOSQUITO BANE.—In a recent number of *Nature*, Mr. SHIPLEY called attention to the influence of the leaves of Ocimum viride in banishing mosquitos. Following up this subject, Mr. PERCY GROOM narrates how his house at Whampoa was comparatively free from the invasion of these insects, a circumstance which he attributes to the presence of a line of Papaw-trees which intervened between his house and the river. Other houses in the same island were more or less infested with these insects. Once, after a typhoon had blown down two of the trees, and left a gap, the number of mosquitos in the house increased. Mr. GROOM further states that he never saw an insect on these trees, though he frequently examined them, and observed flies and other insects upon the Bamboos and Bananas near by. As the Papaw has usually unisexual flowers, and is in fact generally dicecious, it becomes interesting to know by what means fertilisation is effected.

GOOSEBERRY DISEASE.—In the *Journal of Botany* for January, is published in full a paper by Miss A. LORRAIN SMITH, which was read before the British Association, at Belfast. The bushes for an area of about two acres were found to be dying off. On examination the mischief appeared to be confined to the base of the stem immediately above and below the ground level, where the bark was split and broken. Numbers of hard black lumps, or "sclerotia" were found in the cracks associated with threads of Botrytis, the "conidial" form of Sclerotinia. These fungus threads were traced through the stem and into the roots. Portions of the bark and stem were placed in a damp chamber with the result that a plentiful growth of Botrytis took place, as well as of sclerotia. A Peziza also grew from one of the sclerotia which was duly examined and measured. Some of the soil was obtained in which were planted Potatos, Beans, and Lettuces, all plants that had suffered from sclerotium disease. On the Lettuce, Botrytis cinerea made its appearance, but the other two plants remained healthy. This Botrytis is very common on decaying tissues, and begin by feeding on the decaying tissue, after which they become truly parasitic and feed on the living healthy cells. The hyphæ or fungus threads secrete oxalic acid, a poison, which kills the cells, and the fungus then lives on the dead tissue. The conidial spores of the Gooseberry fungus were cultivated in a mixture of gelatin and plum decoction, and produced a copious growth of spawn "mycelium" with "organs of attachment." Incidentally Miss SMITH describes the growth of the spores of the Pæony fungus which also bore conidial threads and sclerotia. We should fear there is no hope for the Gooseberry grower, except the destruction of the diseased plants, and the culture of the bushes in some other spot.

THE EVOLUTION OF SPECIES.—The article which Dr. A. R. WALLACE contributes to *Black and White* of January 17 on his relations with DARWIN in connection with the theory of natural selection, is, says *Nature*, from which we quote what follows, "a historical document of great scientific interest. Dr. WALLACE was introduced to DARWIN in the insect-room of the British Museum in 1854. While living in Borneo in 1854, Dr. WALLACE wrote a paper 'On the Law which has Regulated the Introduction of New Species,' which was published in the *Annals of Natural History* in the following year. Hearing that DARWIN was preparing some work on varieties and species, Dr. WALLACE sent him a copy of his paper, and received a long letter in reply, but no hint was given by DARWIN of his having arrived at the theory of natural selection. DARWIN had, however, actually written out a sketch of his theory in 1842, and in 1844 this sketch was enlarged to 230 folio pages, giving a complete presentation of the arguments afterwards set forth in the *Origin of Species*. Dr. WALLACE arrived at the idea of the 'survival of the fittest' as the operating cause in evolution in 1858, and immediately sent the outlines of this theory to DARWIN, who brought the communication before Sir C. LYELL and Sir JOSEPH HOOKER, and urged that it should be printed at once. Upon their advice, however, DARWIN consented to let an extract from his sketch of 1844 be presented to the Linnean Society with Dr. WALLACE's paper on July 1, 1858." In conclusion, Dr. WALLACE says, "The one great result which I claim for my paper of 1858 is, that it compelled DARWIN to write and publish his *Origin of Species* without further delay."

"THE FLORA OF THE EAST RIDING OF YORKSHIRE," including a physiographical sketch, by JAS. FRASER ROBINSON; to which is added a List of the Mosses of the Riding, by J. J. MARSHALL. (London: A. BROWN & SONS, Ltd., 5, Farringdon Avenue, E.C., and at Hull and York.)—Mr. ROBINSON tells us that no former flora of the East Riding has been published, so that his book supplies a distinct want. It is the result of seventeen years' study and observation on the part of the author, and of other members of the Hull Scientific and Field Naturalists' Club, and many authorities have been consulted with a view to rendering the information as correct as possible. "The district treated of includes chalk-wolds, sandy plains, glacial mounds of clay and gravel, alluvial and marshy flats, an estuary, and a sea-board. Around the docks at Hull are certain waste grounds, upon which large numbers of interesting aliens flourish. Of the ninety-eight Orders of British plants, no fewer than ninety-one are represented in the Riding. Without the mosses, the flora includes 1,035 species, and full particulars of each are given, viz., scientific and common names, dates of flowering, whether native, alien, &c.; general remarks on distribution, habits, localities, authorities for records, &c." From this quotation from the programme, readers will know what to expect from this book. After an introductory chapter and one on the physiography of the East Riding, comes the "Flora," arranged according to the London Catalogue; and, lastly, the list of mosses and Hepatics, and their habitats. An index is appended, and a map showing the flora and also the botanical divisions into which, for the sake of reference, the Riding has been separated. Much careful labour has gone into the book, and we commend it to all readers in general, and intelligent Yorkshire folk in particular.

UNIVERSITY EDUCATION IN BRITAIN.—Our contemporary, *Nature*, for January 1, contains an article on the above subject, from which we take the following paragraphs. The topic is one in which everybody should feel an interest, and which cannot be too widely and wisely discussed. President Sir OLIVER LODGE has prepared a pamphlet entitled *Survey of the Sciences*, which forms an appendix to a paper on University Development, and it is from this that the statements quoted are obtained:—"Our eleven universities are competing with 134 State and privately endowed in the United States, and twenty-two State-endowed in Germany. English private endowment is much less than 10 per cent. of the American endowment, and the German State gives to one university alone more than the British Government allows to all the universities and university colleges in England, Ireland, Scotland, and Wales put together. These are the conditions which regulate the production of brain-power in the United States, Germany, and Britain respectively, so far as universities are concerned—conditions which Sir OLIVER LODGE proposes to face as manfully as he may." In his recent paper on the Survey of the Sciences, he thus reports upon botany in connection with the University of Birmingham. He says that "botany is studied with us partly for its own sake as a department of natural history, allied to horticulture and gardening generally, and also from the point of view of vegetable physiology. This science is the foundation of much of agriculture, of forestry, of materia medica, of timber and plant diseases, the fermentation industries, and of many human diseases. It is allied on its morphological side with palæontology; on its physiological side it is largely dependent on physics and chemistry. At the present time it is not taught as a separate subject in the medical curriculum at Birmingham, but admittedly only because the course is so crowded that something had to give way." The same article from which these paragraphs are taken also mentions the scale upon which certain American colleges are endowed, and quotes the following from the Trust Deed with which Mr. CARNEGIE has endowed a research Institution at Washington with ten million dollars; it is considered to be an "altogether admirable statement of 'aims':—

"To promote original research, paying great attention thereto, as one of the most important of all departments.

"To discover the exceptional man in every department of study, whenever and wherever found, inside and outside of schools, and to enable him to make the work for which he seems specially designed his life-work.

"To ensure the prompt publication and distribution of the results of scientific investigation, a field considered highly important. The chief purpose of the founder being to secure, if possible, for the United States of America leadership in the domain of discovery, and the utilisation of new forces for the benefit of man."

TOMATOS.—In Bulletin No. 81 (November, 1902) of the University of Illinois Agricultural Experiment Station, is an essay by Mr. ALVIN C. BEALE, upon forcing Tomatos, from which we quote the following summary :—

"By checking the plants it is possible to secure fruit in fifty days from benching. Pollen is not discharged during cloudy weather, and advantage must be taken of short periods of sunshine to pollinate by hand. Since the product is most valuable it will pay the grower to pollinate by hand regularly between December 1 and March 1. The advantages are, a larger number of fruits set, with larger and uniform fruits. A careful selection of varieties for the mid-winter crop is requisite for the greatest success. Those varieties developed under forcing-house conditions, like Best-of-All and Lorillard, give the best results. Eclipse gave the largest yields both for the winter and spring crops of 1902. It is not quite so early as Best-of-All, but it produced the smoothest and most solid fruits. The yield of Yellow Prince was decidedly inferior to that of Combination grown under similar conditions. Plants trained to single stems gave a much greater yield per square foot of bench than those trained to three stems, the yield of the former being one and one-fifth pounds against four-fifths of a pound for the latter. The average yield for the season, 1901-02, including both the winter and spring crop, was from 2 to nearly 2½ pounds per square foot of bench, or from 7 to almost 9 pounds per stem."

FRUIT FROM THE CAPE.—The authorities of the Union Castle R.M. Steamship Co. inform us of the arrival of the *Walmer Castle* with sixteen boxes of Apricots, fifteen of Peaches, and four of Pine-apples; the *Scot*, with 389 boxes of Plums, fifteen of Peaches, and sixteen of Apricots; the *Briton*, with 939 boxes of Plums, and eight of Peaches.

PUBLICATIONS RECEIVED.—*New Zealand Department of Agriculture: Tenth Annual Report*, 1902. Deals largely with reports on live stock and dairying, and with notes on New Zealand Hemp, by C. J. Fulton, and from the various experimental stations. Much work has been done in the horticultural and biological sections with various crops, of many of which illustrative plates are given; there are useful notes on weeds (Senecio Jacobeus and Picres echioides), and upon experiments with Vines and other fruits, together with reports on exports.

A BRANCHING PSEUDO-BULB.

FORKING or branching in the pseudo-bulbs of Orchids is by no means of common occurrence, on which account we give an illustration (fig. 39) of a plant exhibited before the Royal Horticultural Society on January 27 by J. Bradshaw, Esq., Southgate (gr., Mr. Whitelegge), which showed this peculiarity. The growth started, we are informed, in the ordinary manner, but speedily divided into two branches, which became of equal size. Why this should have occurred we do not know—possibly from some injury at a very early stage of growth.

ENQUIRY.

TROPICAL HERBARIUM SPECIMENS.—M. Buysman, Middelburg, Holland, is desirous of obtaining herbarium specimens of tropical plants.

APPLE-GROWING FOR PROFIT.*

(*Concluded from p. 69.*)

THE MARKETING OF FRUIT.—On all sides complaints are being made about the indifferent way in which home-grown Apples are sent to the market. In 1895 Mr. George Monro, of Covent Garden, stated that Apples and Pears were worse packed than they were twenty years ago. But above everything, it is the want of grading which is felt. American Apples are well packed, and carefully graded, hence buyers know exactly what they are getting, and buy readily. Much of the home-grown fruit is sent to market loosely packed, in packages of varying capacity, and ungraded, simply as taken from the trees; large and small Apples mixed, or not infrequently packed so that large Apples are on the top and small Apples underneath. This absence of system has been ruinous to the trade in home-grown Apples. English and Irish growers of repute who pack securely in uniform packages, boxes or barrels of known capacity, as the case may be, and who carefully grade their fruit into firsts, seconds, and even thirds, have no difficulty in disposing of it at really good prices. A study must be made of the particular market to which consignments are sent—a study of the most suitable package to use, and the capacity of that package; a study of the varieties most in demand, for there is a difference in the Dublin, Glasgow, Liverpool and London markets; and if these points are attended to fruit will sell well.

Growers for market will find it much to their advantage to use with first quality fruit a cheap, non-returnable package, which will be sold with the fruit, as the barrels in which American Apples are imported are sold. Grocers and retail dealers are more inclined to purchase fruit in such packages, as they are saved all further trouble, and the fruit can be sold direct out of the boxes or cases, without having to be unpacked.

* Paper read at the Fruit Conference, Cork, on October 17, 1902, by Mr. F. W. Moore, A.L.S.

FIG. 39.—LYCASTE SKINNERI WITH BRANCHED PSEUDO-BULBS.

SYSTEM OF STORING FRUIT.

The method of storing Apples also requires consideration. An elaborate, expensively-built fruit store is unnecessary. Apples keep best in a cool store, which is not too dry, but which must be ventilated, and from which the light can be excluded. An old stable or store, with brick or concrete floor, is an excellent place, and if lined with ½-inch planks, such frost as we get in Ireland will do very little harm. Good broad shelves made of strips of wood, with small spaces between them, the shelves 12 inches apart, can be put up very cheaply. The smaller and firmer fruit can be placed several layers deep on the floor. The large Apples should be placed in single layers on the shelves. Do not use straw or hay in storing. In case of frost, keep doors and windows closed, and do not open the store for some days after a thaw. A little frost will not injure Apples if they are allowed to thaw slowly, and are kept from sudden changes. If kept in a bright or dry room Apples shrivel quickly, and get unattractive. They must not be put too near the roof, nor must they be allowed to touch the outer walls. A store with a wooden roof inside slates, or with a loft or packing-room over it, is best, and provided ventilation can be secured Apples can be stored underground.

When orchards are in full bearing they require additional attention. The trees must be fed both with stable manure and artificial manure, to secure the best results. An excellent plan is to dress one year with stable manure, the succeeding year with chemical manure, and the third year to give a dressing of fresh lime over the surface, reverting to stable manure the fourth year. Both ground and trees must be kept clean by constantly keeping weeds down; and each winter very lightly forking over the surface under the trees, not going deep enough to touch the roots. The trees can be kept clean and healthy by spraying. Spraying should be done in spring, before the buds open. Bordeaux Mixture makes a good spray, and an excellent mixture can be prepared by

dissolving 1 lb. crude soda, 1 lb. caustic potash, ¾ lb. agricultural treacle, in 8 to 10 gallons of water; this will suffice for twenty fair-sized trees, if carefully used. In conclusion, I may remark that larger growers almost unanimously state, and market statistics prove, that a higher price is now given for good Apples than twenty-five years ago. *F. W. Moore.*

HOME CORRESPONDENCE.

BEGONIA GLOIRE DE LORRAINE UNDER COOL CONDITIONS.—Being very much interested in the cultivation of Begonia Gloire de Lorraine and its sports, I should like to tell you of a houseful of them which I saw in the Rev. R. G. Buxton's garden, Sutton Hall, Sutton-on-the-Hill, Derby (gr., A. Shambrook), grown entirely under cool treatment. I have never observed any to equal them for size and sturdiness of habit, and for such a beautiful tint of foliage, which is not to be obtained with a warm, moist treatment, although I had myself always grown them in a warm and moist house, and had large plants. For the future I shall certainly afford this plant cool treatment; and from what I saw at Sutton Hall, I should be more inclined to say that cool treatment indicates the way to complete success. I think this corroborates the statement of "H. W. W.," given in the last volume of the *Gardeners' Chronicle*,, p. 451, and also Mr. Divers' statement, that with care and a carefully selected position, they might be grown outside in the summer. *C. L. Branson, gr., Coleshill Park, Birmingham.*

FRENCH PRUNES.—It was recently stated on editorial authority in the French *Journal le Jardin*, that besides importations from California, more than two hundred thousand tons of Prunes (two hundred and forty million kilos.) are annually imported into France from the principality of Servia alone, and sold as "Prunes d'Agen." This would be about twenty thousand large railway truck loads, and seems a very large order, but I looked in vain in subsequent numbers for any correction of the statement. *C. W. D., Malpas.*

IPOMŒA RUBRO CŒRULEA.—Sometimes called Morning Glory, which name is a very appropriate one, for it is in the morning when the beautiful blue of this charming creeper, with its funnel or bell-shaped flowers, are so much appreciated. Yet how seldom one sees or even hears of it being cultivated! This can in no way be attributed to the difficulty experienced in its cultivation. Here it is the general practice to have a fairly constant supply of flowers for at least three months in the year, and at a season when flowers of this colour are but seldom to be seen, and variety is one of the greatest charms of a garden. It is our usual practice to commence gathering the flowers of this plant about November 1. In fact, it was a special request to have the breakfast-table decorated with this flower on November 5, and in this there is little or no difficulty, breakfast and luncheon-tables, being with but few exceptions, decorated during November, December, and January, at which season the Ipomœa has many admirers. To accomplish this, the seed should be sown early in June, in small 60-sized pots, in an intermediate-house, never allowing the plants to become potbound before repotting them, finishing with 8 or 10-inch pots, when they should be placed in their flowering quarter and allowed to run; and with little attention, perhaps, in directing them over the space which it is intended they should occupy, which should be near the glass in a house with a minimum warmth of 60°. Red-spider is the only enemy, but with a fairly moist atmosphere, and avoiding dryness at the root, little difficulty is experienced. Where accommodation can be provided, planting-out is a sure and satisfactory practice to be adopted. Rich loam, with the addition of leaf-mould and some manure from a spent Mushroom-bed, or the like, with due attention to watering, is all that will be found necessary. *William Fyfe, Lockinge Gardens, Wantage.*

PHEASANTS IN THE GARDEN. (Reply to Enquiry).—Living in a district where pheasants are reared in large numbers, I have found them to be real pests in the garden. They are more troublesome in the autumn and winter months, and especially during prolonged frosts, when green food is difficult to obtain outside of a garden. These birds are very partial to Brussels Sprouts, young Cabbages, Parsley, Carnation-grass, and will also tear up bulbs and the corms of Anemones. As pheasants do not willingly fly down into confined spaces, but run about the garden in search of suitable food, I have had wire-netting 3 feet high, and supported with stakes, placed round the vegetable quarters and beds where pheasants are likely to be troublesome; and as the birds are unable to run in and out as they like, this has been the means of my preventing losses in vegetables and flowers in gardens where formerly nothing could be saved. *J. H. Cumming, Grantully, N.B.*

GRAND YORKSHIRE GALA, 1903.—I expect by this time that all who are exhibitors or in other ways interested in the above Institution, will have received the prize-schedule for this year. It is to be hoped that the committee may have a more successful year than was the past one. What with preparations for the then hoped-for coronation of the King, and the wretched weather, they had a severe loss. As will be noticed, the time fixed for this year's gala is somewhat later than has been the case for some few years past. I think the committee are wise in choosing the dates, June 24, 25, 26; and it must be an advantage to the majority of exhibitors, whether in the plant, fruit, or vegetable classes. Several old familiar classes are struck out this time. I allude to the ones for specimen Azaleas and Cape Heaths, and the one for six specimen Fuchsias, and fifteen show Pelargoniums. The competition in these classes has been but slight in recent years, since some of the older exhibitors gave up exhibiting. No doubt, the great glare of colour annually seen in the Pelargonium-tent was a great attraction to many of the visitors; still, with, we may hope, the better educated taste of the general public, no one can blame the committee for the step taken. Smaller classes and prizes are retained, and there is no diminution in the classes for zonals, single and double-flowered, and Ivy-leaved varieties. In the place of the class for six specimen Fuchsias, a new one is offered for a group of Fuchsias arranged for effect with Ferns, &c. This must be a decided improvement in general effect, assuming that fair competition is shown. While skill was required to grow and flower at the right time the big specimen Fuchsias so often seen at York, it must be admitted there was a great sameness in them from year to year; latterly they have scarcely been worth the money offered in prizes. Amongst the newer classes may be mentioned an additional prize in the collection of pot-Roses, prizes for twenty-four and twelve bunches of garden Roses, for eighteen bunches of herbaceous Pæonies in variety, and for twelve bunches of Sweet Peas, distinct, arranged in vasea or glasses. In the bouquet classes new prizes are offered for a shower-bouquet of Roses, and sprays for ladies and gentlemen, six of each. The prizes offered for fruit and vegetables are practically the same as in previous years. It would be difficult at that season of the year to improve upon this portion of the schedule. Mr. Fred Arey, Davygate, has succeeded Mr. C. W. Simmons as secretary to the Gala committee. *H. J. C.*

NEW CHRYSANTHEMUMS.—Growers who may now be thinking of purchasing a few of the large number of novelties offered by various trade growers must find the task of selection no easy one, especially so when their only guide is the trade lists; but those who have been fortunate enough to see any of the varieties at the shows will be less bewildered in making a choice. It is, however, for the larger number of growers that the following are submitted for consideration, based upon notes made at several exhibitions; and in describing this selection, the usual tedious redundancy of catalogues will be sacrificed to brevity. Experts are agreed that the best of the year is the variety known as Miss Mildred Ware, said to be a seedling from Madame Carnot and Lady Hanham; the build of the blossoms resembles the first-named, whilst in colour it is similar to the latter. These two merits will be ample to illustrate this variety for the consideration of growers of large blooms. The limited number that we possess of good crimson shades of full size will this year be increased by the addition of the variety George Penford, a warm crimson with a bright yellow reverse, of full size and pleasing formation; the florets droop and curl in a graceful manner. Lord Hopetoun, an Australian variety, is also of a crimson colour, and as shown in the autumn, promises to be seen in good form next season. The inclusion of yet another crimson is justified by the generally acknowledged absence of colour upon exhibition tables. Thus, Wilfred H. Godfrey, can be commended as possessing the essential merits of size and colour, being a rich crimson with a golden reverse. All growers well know the variety Lord Ludlow, so that to say succinctly, Donald McLeod is an improvement of that splendid Chrysanthemum, is sufficient to convey a clear impression of what this last-named is like. In Edith Smith we have a blossom of a creamy-white shade. The refined appearance of well finished Madame Carnot blossoms is characteristic of this variety as seen on one or two occasions at the shows. Two varieties of a yellow shade were consistently good; one named F. S. Vallis, raised on the Continent, is put forward as an improved G. J. Warren. The comparison is apt, and provided it is of more certainty in development than the Carnot family, should become a general favourite. The other is known as the Hon. Mrs. A. Acland, exceedingly meritorious at the October shows; its florets are a good length, and build up a full size bloom of deep rich yellow. Where early blooms are required this should be noted. One of the most rare and pleasing shades of colour is a true pink, and admirable blooms are remembered of the Countess of Harrowby, the prettiest pink of recent years; it is large enough for any exhibition, and of prepossessing appearance. All the foregoing are Japanese. Of new incurveds of conspicuous merit, a variety named The King was noted as of satisfactory build and distinct colour, and has already been shown successfully. Pantia Ralli bids fair to gain the full number of points at shows; its colour is bronzy-buff, with petals of good substance. The frequent appearance of the variety Mrs. Henry J. Jones warrants the popularity of its yellow flushed red sport, Mildred Lyne, and possessing the well known traits of the former excepting colour needs no further remark. Two other important sports may be mentioned: Cheltoni, a yellow sport from Miss Nellie Pockett; and H. J. Gillingham, a yellow sport from Western King. *H.*

ELASTIC THREADS IN EUCALYPTUS. — I was so much interested with the nature and behaviour of a leaf of Eucalyptus citriodora, which I picked yesterday, that I send you the specimen I dealt with, which I have mounted on the paper. When I broke the leaf, which was about 3 inches long, across the midrib, I found that there was an attachment, as of a thread or filament, at each of the outside edges of the leaf. On drawing apart the two broken pieces of the leaf, these two threads still held on, and I slowly drew them out, when, besides stretching out like a thread of indiarubber, they gradually separated or unravelled from the edges of the leaf, both at the stalk end and at the tip of the leaf. The threads were so elastic that I drew them out to the length of 6¾ and 7¼ inches respectively before they broke, and they then curled up like a piece of indiarubber cord when the strain is taken off, and they now, after twenty-four hours, retain their elasticity. "*Rus in Urbe.*" [The Eucalypts, like most of the Myrtaceæ, have an "intra marginal" vein running round the leaf, just within the margin. It is this vein which has been broken across, and the fibres stretched out. In Musas, Nepenthes, and other plants, a similar occurrence is constant, but we never saw it in Eucalypts before. ED.]

CAMPANULA LATIFOLIA.—On p. 100 of the September, 1902, *Quarterly Journal of the Royal Horticultural Society*, I observe, and ask to be allowed to correct, what I think is an error concerning the native distribution of C. latifolia, Lin. It is there stated to be "a British hedge plant, very plentiful in Sussex." I have never seen C. latifolia growing really wild in the South of

England. The large Campanula common in the south in hedges and thickets is C. Trachelium, Lin. This is common as far north as Cheshire and Shropshire, but in Derbyshire begins to be replaced by C. latifolia, which extends northwards into Scotland, frequenting woods rather than hedges. *C. Wolley Dod, Edge Hall, Malpas.*

CRICKETS.—In reference to your correspondent "A. G." in the *Gardeners' Chronicle* of January 24 concerning crickets in hot-houses, I would advise him to use "Steiner's Vermin Paste." Some months ago we were much troubled here with crickets and cockroaches. Since using Steiner's paste we have been quite free. It should be placed near their haunts, in pieces rolled up to the size of a Pea. The insects may be found dead in scores underneath stages, &c. *George Hall, Melchet Court Gardens, Romsey.*

THE ROYAL GARDENERS' ORPHAN FUND.—The subscribers to this very popular Fund will not this year enjoy the customary excitement of being invited to vote for candidates for election on the Fund. That no fewer than twenty-four orphan children should be nominated, and that the committee should find themselves in a position to place all on the Fund at once, is not only to establish a record in the Fund's operations, but also to do an act which should make every subscriber's heart to rejoice. Probably next year it may be needful to revert to the customary election. It is now, in any case, most satisfactory to learn that the Fund has so far prospered as to enable this great act of generosity to be thus accomplished. True, under the existing and perhaps rather too iron-bound regulation that compels all children to go off the Fund when the age of fourteen is reached, some of the new candidates can enjoy the benefits of the Fund but a very brief time. That does materially reduce the demand that otherwise would by this considerable election be made on the Fund; but cases now and then occur which from their undoubtedly painful nature invite more extended assistance. That the committee should have power to grant even up to the age of sixteen at least, especially where orphans are afflicted with some distressing ailment, seems desirable; whilst few subscribers would complain could the present age limit be extended to fifteen years in all cases. Necessarily, when cases call for special treatment, the fullest confidence should be reposed in the committee, all the members of which body desire to manage the Fund at once in the most economical yet most beneficent way. It is difficult to avoid feeling deeply, in reading over the descriptions of the various candidates, to find how many good fathers have died so comparatively young. A knowledge of this fact should help to arouse in the minds of the young gardener-fathers of to-day a more appreciative sense of the great value the Fund is to the gardening community. *A. D.*

ROYAL HORTICULTURAL SOCIETY. — I learn from the annual report just received that the Society has, in addition (I presume) to the £22,000 said to have been subscribed for the new Exhibition Hall, a balance of over £16,000, invested and on deposit; say, £38,000 in all. As the estimated cost of the new building is £40,000, we seem to be within measurable distance of having it if the £16,000 is to be so employed. Perhaps at the annual meeting on the 10th inst., some Fellow will ask if this is so, and if not, why not? *X.*

—— It was not my intention to occupy your space again under the above heading, but the anonymous letter by an old Kewite seems to call for some notice. Surely this correspondent is not voicing the opinions of the promoters of this National Institution, when he seeks to limit freedom and thought by suggesting "earning the right to criticise by the liberality of their contributions." The idea of earning the right to criticise a scheme in its inception by the "liberality of their contributions" is quite new, and only leads to the conclusion that those who have contributed most liberally have the most right to criticise, a position quite untenable considering that the greater part of the proposed expenditure has yet to be provided. The first step should have been to awaken the interest of all the Fellows, by taking them into the confidence of the promoters. An exhibition of competitive designs should have been held, and the opinions of the Fellows upon their merits invited. In this way the best result would have been attained. To secure "liberality of contributions," something must be presented which commends itself to the judgment of those most interested. So far the scheme does not appear to have aroused interest, not to mention liberality, and the design which accompanies it represents rather an ungainly site for the present purposes, and no provision appears to have been contemplated for future additions to meet the growing requirements of horticulture. I have taken a deep interest in this question, and given much thought to it, and would have willingly contributed £25 towards a prize for the best design, in which the fine arts and perhaps music had a place, in addition to adequate accommodation for floral and fruit exhibitions, and space allotted for the equally important vegetable section. A light gallery running round the interior of the hall would have a good effect, and here the vegetables, &c., might be exhibited. The walls of the building, both gallery and ground floor, would then be hung with pictures, which would greatly enhance the appearance of the hall, and harmonise with the floral surroundings. An annual exhibition of pictures rejected at the Academy would be very attractive, and such an exhibition would be sure to command success, and assist in providing funds for the maintenance of the hall, and a certain revenue from the letting portions of the building for meetings of various kinds and also concerts. I think these various interests should not have been overlooked. *James L. Wood, F.R.H.S.* [Our correspondent has evidently not seen the notice-boards displayed on the Vincent Square site, or he would see that to some extent his wishes have been anticipated. Ed.]

NEW INVENTIONS.

THE PRIAULX PATENT TROUGH.

In figs. 40 and 41 are illustrated a new trough invented for the cultivation of Tomatos, Melons, Cucumbers, Beans, &c. It will be seen that the trough is made in pieces, which measure 18 ins. long by 9 ins. wide and 6 ins. deep, inside measurements. Two pieces, therefore, form a length of trough 18 ins. long by 18 ins. wide, and 6 ins. deep, as represented in fig. 41. It is obvious that the trough may be continued to any length desired, and terminated then by special corner pieces, which have one end closed. It may be made deeper by placing the pieces so that the 6-inch width is on the ground, and the 9-inch width as a wall. Such a trough is recommended for a double row of Tomatos or Beans; but another size suitable for a single row of Tomatos is made, the pieces of which measure 18 ins. long by 5 ins. wide, by 6 ins. deep. By these pieces a trough may be constructed measuring either 10 ins. wide by 6 ins. deep, or 12 ins. wide by 5 ins. deep.

In fig. 40 another description of trough is shown, in which the pieces are made in such a manner that the trough may be built over the hot-water pipe. This is recommended for crops requiring bottom-heat.

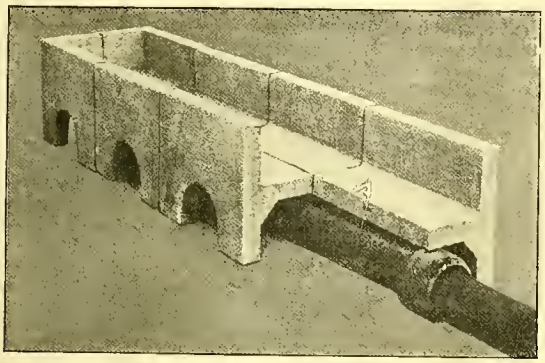

Fig. 40.—The Priaulx trough placed over a hot-water pipe.

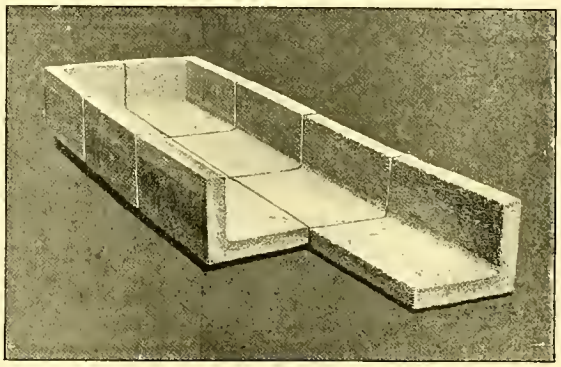

Fig. 41.—The Priaulx trough placed on the ground.

The pieces for both types are said to be made of materials into which Portland-cement and shingle enter largely. The trough is described as being absolutely porous, which means that the material not only absorbs water, but allows water to pass through it readily; it will not hold water. The inventor, Mr. W. N. Priaulx, a market grower in Guernsey, claims that owing to this porous quality, the trough is a more healthy receptacle for crops than pots, and the material will not rot or break, as boxes do.

The invention was introduced prominently to the market growers in Guernsey last year, and we are informed that already several miles of the trough are now in use in that island. Market growers in the south and elsewhere will soon discover whether the system is worthy of wide adoption, and is better than pots, boxes, wooden troughs, or raised borders. By its use it follows that the roots of the plants are kept quite under the control of the cultivator, and in cases of early forcing this is a great advantage, as compared with the case of plants growing in the soil of the house. It may be added that the trough can be placed directly upon the soil, and no drainage material of any description is needed. The patentees are the Priaulx Patent Trough Co., Ltd., St. Martin's, Guernsey.

TREES AND SHRUBS.

GARRYA ELLIPTICA.

It may not be generally known that Garrya elliptica grows well in limestone soils, or those of the basaltic formation, which are usually very warm, owing to their being well-drained naturally. In these the roots penetrate to a great depth, and nothing ever hurts the plants. For forming thick, impenetrable hedges, they are the equal of the Holly; and if space allows, such hedges may be allowed to extend to 4 feet in thickness and 8 to 10 feet in height. The plant bears cutting with the shears like Holly, and its flowering is not injured thereby.

ORCHID NOTES AND GLEANINGS.

DICTIONNAIRE ICONOGRAPHIQUE DES ORCHIDÉES.

Part No. 50 of this useful work by M. Alfred Cogniaux, with excellent coloured illustrations from drawings made by M. A. Goossens, contains:—

Bulbophyllum Dearei.—A showy Philippine and Bornean species, closely allied to B. Lobbii, and of the Sarcopodium section. Flowers yellow with reddish markings, the labellum and lateral sepals bearing purple markings on a white ground.

Cattleya Luddemanniana var. Stanleyi.—A very beautiful white flower with yellow centre to the lip, the front of which is beautifully marbled with purplish-rose. It is a white form of the plant often called in gardens C. speciosissima. Imported and flowered by Messrs. Stanley, Ashton & Co., of Southgate, and named after a member of that firm. First-class Certificate, Royal Horticultural Society, September 21, 1902.

Cattleya × flavescens.—A pretty hybrid, raised by M. Maron of Brunoy, France, between C. Trianæi and C. luteola. Flowers whitish, tinged with yellow; disc of lip orange colour, front purplish-rose.

Cirrhopetalum Mastersianum. — A remarkable species introduced some years ago by Messrs. Linden from the Dutch Indies, and named in honour of Dr. Maxwell T. Masters, F.R.S., Editor of the *Gardeners' Chronicle*. Flowers conspicuous, produced in umbels, yellow, showily marked with dark red.

Cypripedium × Syrinx.—Raised by Reginald Young, Esq., of Liverpool (gr., Mr. Poyntz), between C. tonsum and C. × Youngianum. Upper sepal white, striped with green and purple; petals greenish, tinged with rose, and bearing scattered purple spots; lip tinged with pale tawny lilac; staminode yellowish, veined with green.

Dendrobium chrysotoxum suavissimum.—The well known yellow flowered form with purplish disc to the lip. Generally known in gardens as D. suavissimum, Rchb. f.

Lælia autumno × cinnabarina.—A singular cross between Lælia autumnalis and L. cinnabarina, but which in form and colour closely adheres to L. autumnalis. The hybrid was first raised by Messrs. Charlesworth & Co. of Heaton, Bradford, and the flowers figured came from the collection of Sir Trevor Lawrence, Bart.

Lælia × juvenilis var. Fournieri. — Raised originally by the late M. Alfred Bleu of Paris, between L. pumila and L. Perrini, and in this case the Lælia pumila præstans was the variety used with L. Perrini in its production. Sepals and petals purplish-rose; tube of the lip whitish, disc yellow, front purple of various shades.

Maxillaria rufescens.—A very old inhabitant of our gardens, and frequently imported from British Guiana and Trinidad. Flowers yellow with red spots on the lip. Of the class "botanical."

Odontoglossum crispum var. Leonie.—Flowers white, tinged with purple, and bearing rose-purple blotches. Named after Madame Leonie Closson, and flowered with M. Jules Closson (etablissement Jacob-Makoy), of Liège, Brussels.

Selenipedium Schlimii.—The chief ancestor of the very large race of hybrids of the S. × Sedeni class, and still far more beautiful than any of its descendants. Flowers white, with dark rose markings on the lip and petals. Staminode yellow, with two dark red marks in front.

Stanhopea graveolens.—Sepals and petals yellow, the petals spotted with red. Base of the lip orange, marked with red-brown; front portion white, with purple spots.

Trigonidium Egertonianum. — A very singular member of a small genus, with Maxillaria-like growth and habit, the solitary flowers borne on long stalks, calling to mind one of the smaller Irids. The three outer segments, or sepals, which form the showy part of the flowers, are brownish-yellow, tinged with purple, and changing to white towards the bases on the interior, the small purplish petals appearing in the centre.

The *Chronique Orchidéenne*, which accompanies the illustrations and descriptions, contains useful information; and an article on Disa grandiflora, by M. O. Ballif.

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

January 27.—*Present:* Mr. A. Michael, F.R.S., in the Chair; Messrs. Hooper, Baker, Odell, Saunders, Worsdell, Worsley; Drs. Cooke and Rendle; Prof. A. H. Church, Revs. H. Ellacombe, W. Wilks, and G. Henslow (Hon. Sec.).

Peas attacked by Grubs.—Mr. Saunders gave the following report upon the specimens brought by Mr. Baker to the last meeting:—"I have examined a considerable number of the damaged Peas exhibited at the last meeting of the Scientific Committee, and I cannot say definitely by what insect they have been injured. The weevil (Bruchus pisi) certainly is not the culprit. Many of them appear to me to have been attacked by the "Pea-moth" (Grapholitha pisana), but I cannot find any trace of the insect; but that is not to be wondered at, as the moth lays her eggs on the pods when they are quite young, whence the little caterpillars make their way into the pods and feed on the Peas. When full grown they fall to the ground, and become chrysalides in the soil. A few of the Peas were attacked by mites, which were feeding on them in considerable numbers; and it is possible that they were the sole cause of the mischief. But I think not, or I should have found them in a larger proportion of the Peas. The mites, no doubt, only attacked the Peas after they had been placed in store, and any receptacle in which they were placed should be thoroughly cleansed; scalding is perhaps the most satisfactory method, if it be practicable. If any Peas attacked by mites were sown, no harm would be done. Some I examined would not have germinated, but the pest would not spread in the ground. If the Peas were injured by the caterpillars I have mentioned, it would be well, if not too late, to bury the top 3 inches of soil on which they grew as deeply as possible, so as to prevent the moths from leaving the chrysalides later on. The mites had appeared, no doubt, after harvesting."

Weevilled Peas.—Mr. A. Sutton sent specimens for comparison with those brought by Mr. Baker, in which the hole was quite irregular in shape, whereas it is perfectly circular if caused by the weevil:—"In further reply to your letter of the 13th inst., I now send you three samples of weevilled Peas, as a comparison between these and the maggoty seeds you sent me, which may be of interest to yourself, and possibly also to the Committee on Tuesday. Sample No. 1 are English grown early round Peas of harvest 1901, with a few of harvest 1900. Both these seasons were exceptionally hot and dry, and it is only in such seasons that we find English grown Peas at all weevilled. Broad Beans, on the other hand, are much more often attacked by these insects than Peas, but in such a wet, cold summer as the last, the damage is very slight indeed. In 1900 and 1901 a large quantity of Beans were badly weevilled. Sample No. 2 is a sample of "wrinkled" Peas "Champion of England" Canadian grown, of harvest 1900. These you will find also show the distinct clean circular opening made by the weevil in its escape from the seed. As I said in my last letter, I never recollect seeing a sample of English grown wrinkled Peas weevilled. No. 3 is a sample of French Sugar Peas also weevilled, and you will find the dead insects inside some of these seeds. These are of harvest 1901."

Sclerotium on Lilium flower-stalks.—Dr. Cooke reported on the specimen submitted at the last meeting by Mr. Holmes, having a black Sclerotium on the flower-stalks of Lilium candidum:—"In so far as a Sclerotium can be determined, this appears to be the same as one which is common on the stems of Heracleum and other Umbelliferæ, and which I think was called in olden time Sclerotium durum, when it was also recognised (see *Handbook*, p. 601) as the origin of the mould Botrytis, or Polyactis cinerea. Berkeley described a mould on Lily-stems as Ovularia elliptica, for which I afterwards suggested Botrytis elliptica. Marshall Ward, in hi paper on Lily disease, seems to have made acquaintance with the same mould, which he simply calls Botrytis. Massee recently, in *Journ. R. H. S.*, figures the mould under the name of Botrytis cinerea. Possibly there is only one mould, and that one the old Botrytis cinerea. But now, in latter days, this mould is regarded as the conidial stage of a Peziza, under the name of Sclerotinia Fuckeliana, and perhaps some others; at any rate, the little black Sclerotium, the mould, and the Peziza, are regarded as phases or conditions of one and the same fungus."

Dead Horse-Chestnut Trees.—Dr. Cooke also communicated the following report:—"Since the last meeting of Committee I have been consulted as to the death of some old Horse-Chestnut-trees in Greenwich Park; which has been caused, it is confidently affirmed, by a fungus which appears externally on the bark—and internally, in a plentiful mycelium, between the bark and wood. The species credited with this destruction is Stereum purpureum, although, so far as I am aware, neither Hartig nor any other of the German authorities on the parasites of forest-trees have mentioned this species as suspected of causing disease or death. It is generally recognised that the yellow Stereum hirsutum, which is so common on all dead wood as a saprophyte, is capable also of becoming parasite, and entering by wounds in the bark, causes destruction of living trees. Hence it is not so improbable that Stereum purpureum may also be capable of becoming a parasite. Another phase of this subject is interesting: Not long since it was brought to the notice of this Committee that a paper had been published which contended that this same fungus was the cause of 'silver-leaf' in stone fruit-trees."

Araucaria Bidwilli Cone.—Mr. F. Bull, Southport, sent a cone of this tree. The tree is about 40 feet in height. Dr. Masters observes that it fruited at Kew in 1873 (see *Gardeners' Chronicle*, 1873, p. 561, fig. 73). As the tree requires a great deal of space, it is not likely that there are many specimens outside botanic gardens. The seeds are eaten by the natives of Australia.

Campanula rotundifolia, diseased.—Mr. Worsdell exhibited specimens in which the flower-buds were attacked by Cecidomyia campanulæ, and presented a swollen appearance.

Pelargonium stipules, Use of.—Mr. Davidson, Fanners, Wickham Bishops, Essex, described an experience indicating a special use of these organs:—"Some time ago I was struck with the 'nursing' properties of the stipules of Pelargonia, which, when grown cold in winter, lose their leaves. If, for the sake of tidiness, the withered stipules are also removed, the buds are very slow to break in spring; but if the stipules are left on, the buds break much more readily, a fact which I found to be due to their holding moisture, and thus softening the skin. Darwin has observed that stipules sometimes serve to hold water."

Club-root in Cruciferæ.—In reply to a question as to remedies, Mr. Massee wrote as follows:—"The germs are hungered out, if the soil is kept free from cruciferous plants—cultivated and wild—for four years; their exit being hastened by the use of lime. As it would be at least inconvenient to cease growing 'greens' for such an extended period, the following plan might be adopted: As much quicklime as is compatible with the healthy growth of Turnips, Sprouts, &c., should be intimately mixed with the soil to the depth of 6 in. to 8 in. Just now is the time for this, as the germs will soon begin to be on the run. If gaslime is used, a layer about 1 inch thick, sprinked on the surface should remain for four weeks, and then be pointed into the upper 6 inches of soil. No planting should be attempted until after the gaslime has been on the soil for at least six weeks. The great bulk of plants are inoculated when quite seedlings, and those that escape for the first six weeks of their existence do not, as a rule, become diseased when planted in infected soil." Mr. Baker added some interesting remarks upon his experience. He said that a badly infected soil should have all cruciferous plants rigidly excluded for four years; and Shepherd's Purse, which is very liable to be attacked, should be entirely weeded out. The fungus could not cross a narrow path, but could easily be transmitted by garden instruments, or by the boots of the workmen. Superphosphates were rather favourable to the growth of the fungus, whereas basic slag was less so. Mr. Worsley had found gaslime to have been quite effective.

Ismene calathina, bulb germinating.—Mr. Worsley observed that in the germination of the seeds of this plant, before any leaf-growth takes place, it forms a

bulb and continually loses moisture, so that its weight diminishes from that of the seed to the amount of 75 per cent.; so that while ten seeds weigh 10 oz., it requires forty-four of the small bulblets to weigh that amount. Besides water, it is known that all seeds lose weight, as carbon is lost in respiration, which generates energy required for vital processes displayed in growth.

ROCHDALE CHRYSANTHEMUM.

JANUARY 21.—The annual meeting of members of the Rochdale and District Chrysanthemum Society was held at the Provident Hall on the above date. There was a large attendance, and the proceedings were prolonged and, at times, lively. In the absence of the chairman (Mr. James Goodwin), Mr. W. Brookes was voted to the chair.

After expressing gratification at the large attendance at the exhibition, the report went on to say that the loss on the 1901 show had been more than made good by the result of last year's exhibition. The income amounted to £224 0*s.* 7½*d.*, including balance and special prize-money. Subscriptions obtained last year totalled £93 16*s.* After paying expenses and prize-money there was left a balance to the good of £74 5*s.* 7*d.* The chairman submitted the balance-sheet, and on his proposition, seconded by Mr. Rouse, the report and accounts were passed.

The following officers were then unanimously elected: Chairman, Mr. Thomas Driver; Secretary, Mr. J. Edwards; and Treasurer, Mr. J. Glenister. Seven representatives of professional gardeners and two of amateurs had to be elected on the committee. The following gentlemen were appointed:—Messrs. W. Brookes, G. Horsman, M. Greenwood, E. Hubbard, J. Gresty, G. Goodwin, and E. Polly (professionals); and G. H. Rouse and A. Chadwick (amateurs).

READING & DISTRICT GARDENERS' MUTUAL IMPROVEMENT.

JANUARY 26.—On the foregoing date nearly 200 members of the above Association paid a visit to the new range of glasshouses recently erected for Messrs. Sutton & Sons, to inspect the fine collection of Primulas raised by the firm.

In the evening the ordinary fortnightly meeting was held in the Club Room, and Mr. W. Barnes, gr., Bearwood, the vice-chairman, presided. Much disappointment was felt that through illness the newly-elected chairman, Mr. J. T. Powell, was unable to give his lecture, "The Making of Sprays and Buttonholes;" but fortunately, Mr. J. Gibson, of Danesfield Gardens, and Mr. G. Stanton, of Park Place Gardens, kindly gave instead, "Winter Tomatos," and "Hardy Winter Berried Plants" respectively.

The only exhibit consisted of eight dishes of Sutton's Winter Beauty Tomato, exhibited by Mr. Gibson. Nine new members were elected.

BINFIELD (BERKS) AND DISTRICT HORTICULTURAL.

JANUARY 27.—The annual meeting of this Association was held on the above date, Mr. Bungay in the chair. The balance-sheet showed a satisfactory account of the finances of the Association. During the past year the library had been augmented by the addition of some good standard works.

The retiring Chairman (Mr. Bungay) was strongly urged to continue in office, but declined, as he considered a fresh one should be elected each year. Mr. Mason was then proposed and elected, with Mr. Woodman as Vice-Chairman. Mr. Paine was re-elected as Secretary.

BRISTOL & DISTRICT GARDENERS' MUTUAL IMPROVEMENT.

JANUARY 29.—The subject for discussion at the meeting of the Association, at St. John's Rooms on the above date, was "The Renovation of Aged Fruit-trees," by Mr. Neve, of the Reading Mutual Improvement Association. Full instructions as to the best method of improving the condition of such trees, instructions that were based on his own experience, he himself having now trees of eighty years of age which at one time were unfruitful, and are now in excellent bearing. He laid great stress upon inducing roots to come to the surface by means of top-dressings of farmyard manure, a heavy application of water and liquid-manure, and pointing over the ground lightly with a digging-fork. Pruning was a most important factor in the renovation of aged trees, and it should be very carefully done, removing weak shoots, and regulating the branches so as to let sun enter the head. Insects that infest fruit-trees were dealt with, and methods of destruction and prevention afforded. Mr. Binfield, Old Sneyd Park Gardens, occupied the Chair.

BECKENHAM HORTICULTURAL.

JANUARY 30.—On Friday, at the Church House, Mr. George Clinging gave an instructive lecture on Pears. Councillor Crease occupied the chair. He could not, he said, understand why Pears—so delicious when stewed—were not more generally appreciated, considering they could be bought so cheaply when in season. He always admired the French Pears as put on the market. English cultivators failed from lack of method in packing and grading; they also kept their fruit too long—buyers found it bruised and rotting.

The room was crowded, and a free discussion followed.

CHESTER PAXTON.

"How to improve our Exhibitions," was the subject down for discussion at the usual fortnightly meeting held on Saturday, Jan. 31. The Hon. Sec., Mr. G. P. Miln, in introducing this, gave a short epitome of the educational work of the Society, and traced the progress of its exhibitions from the time when they were first instituted in the Museum some sixteen years ago. Although they were at that time of a non-competitive character, they nevertheless were very successful, and served a good purpose in promoting the culture of hardy fruits throughout Cheshire and north Wales. He pointed out that after a few years they outgrew the available space at the Museum, the Town Hall having since been granted for this purpose. The popularity which the Society had attained was, he contended, largely due to the beautiful exhibits of Chrysanthemums which had been so much admired at the exhibitions of late years. The table decorations exhibited by ladies had also, he said, contributed to this popularity, as well as the classes for Grapes, bottled fruits, &c. Mr. Miln pleaded for greater attention to be given to the classes for single and naturally-grown Chrysanthemums, and strongly advised entirely doing away with the old fashioned Chrysanthemum boxes in favour of vases, in which the blooms can be seen to much better advantage. In conclusion, he also strongly urged the claims of hardy fruit, and hoped these would never be neglected at the expense of the other classes. An interesting and profitable discussion followed, in which the Chairman (Mr. N. F. Barnes, gr., Eaton Hall), and others took part. Several additional prizes and improvements were suggested, which the Committee promised to take into consideration when compiling the schedule of prizes for the next exhibition. The meeting closed with the customary vote of thanks.

LIVERPOOL HORTICULTURAL ASSOCIATION.

THE twenty-fourth annual general meeting of the above was held on Saturday last, Jan. 31, at the Secretary's office, Victoria Street, Mr. T. Foster, Chairman, of the Association presiding over a numerous attendance. The subscription list is the chief source of income by which the work of the Association is carried on. This year it amounts to £331 11*s.* 6*d.*, a capital result when one considers the numerous small shows in the suburban districts. The loss on the spring show was £120 0*s.* 1*d.*, on the autumn show of £104 16*s.* 4*d.*, and the balance in hand is about £253.

The retiring members were re-elected without opposition, the Chairman speaking in glowing terms of the Committee's work during the past year. Votes of thanks were passed to the chief officers, donors of special prizes, and not the least to Messrs. Ellis & Ranson, who have been instrumental in collecting subscriptions from the more remote districts. Sums of three and two guineas were voted respectively to the Gardeners' Royal Benevolent Institution, and the Royal Gardeners' Orphan Fund. *Orchid.*

NATIONAL CHRYSANTHEMUM.

FEBRUARY 2.—The annual meeting of this Society was held on Monday last, at the Albert Hotel, Buckingham Gate, Westminster, about sixty persons being present. In the absence of Sir Albert Rollitt, M.P., through illness, the chair was taken by Mr. Thos. Bevan, chairman of the Executive Committee.

The Secretary (Mr. R. Dean) read the lengthy minutes of the proceedings at the last general meeting, which were adopted.

EXTRACTS FROM THE REPORT OF THE EXECUTIVE COMMITTEE.

"It is under circumstances of peculiar interest, as they affect the future of the Society, that your committee make their annual report on this occasion. The long connection of the Society with the Royal Aquarium and Summer and Winter Garden Society, Ltd., has come to a termination through the sale of the building. For twenty-six years the Society's exhibitions have been held in the Aquarium. It was in November, 1877, that the Society, then known as the Borough of Hackney Chrysanthemum Society, commenced to hold its shows at Westminster, and the financial assistance secured by a donation to the Prize Fund operated to create increased interest in the work of the Society; a growth of membership followed, and eventually resulted in the change of the title of the Society to that of the National Chrysanthemum Society.

"Your committee have made an arrangement with the Crystal Palace Company to hold three exhibitions at Sydenham in 1903, namely, on October 6 and 7, two days; on November 10, 11, and 12, three days; and on December 8 and 9, two days; the sum of £200 to be given towards the prize schedules of the three shows.

"Though the altered circumstances of the Society will necessitate some revision of the schedule of prizes, your committee hope that by the institution of members' entrance fees, and the new regulations affecting miscellaneous exhibits—to maintain the high character of the Society's shows.

"The arrangements with the Crystal Palace Company are for one year only.

"During the past season the Floral Committee awarded sixteen First-class Certificates of Merit and eight Commendations.

"The present number of societies in affiliation is 130. The present number of members on the books is 645, viz., 77 Fellows and 569 ordinary members, in addition to the foreign list.

"The financial position of the Society is satisfactory, the balance in hand at the bank, as shown by the statement, is £68 9*s.* 6*d.* The Reserve Fund has been added to in the year by one donation of 10*s.* 6*d.*, and the interest on the deposit £1 16*s.* 7*d.* The total amount in the bank is £112 10*s.*"

The report of the Executive Committee, together with the balance-sheet, were taken as read, and on the proposition of Mr. Ballantyne, were adopted. Several points were raised upon matters mentioned in this report. Mr. Newell asked if the agreement with the Crystal Palace Company had been signed, and said that so far they had been unable to obtain the signature of the Crystal Palace Company. The secretary replied that he had written for the draft, but it had not yet been sent to him. Mr. D. B. Crane raised the question of holding three shows this year, and stated that it was proposed to offer £150 in prizes, and only £200 of this would be contributed by the Crystal Palace Company. He asked for an estimate of the receipts and expenditure for the year, but the matter was permitted to drop. One of the auditors (Mr. Tagg) strongly recommended the Society to concentrate their efforts in one large exhibition rather than three small ones. The Society's reduced income rendered this change very desirable. In answer to another question as to arrears due to the Society, the secretary said that of £78 19*s.* 6*d.* there had been received to date the sum of £33 11*s.*

ALTERATION OF RULES.

Two non-contentious amendments moved by the Secretary were passed unanimously. One of these referred to the appointment of delegates by affiliated societies, and the other will prevent the waste of time caused by the Floral Committee having to convene a special meeting after election to choose a Chairman for their own body. This will now be the preliminary business of the first ordinary meeting.

The third alteration was decidedly not acceptable to some present. It was moved by Mr. R. Kenyon to insert as an addition to Rule XIV. after the words "Executive Committee for approval," "No member of any Committee of the Society shall be eligible for nomination as a judge at any of the Society's exhibitions." Mr. Kenyon disclaimed any other motive for proposing this amendment than the best interests of the Society. It was not in the least degree designed against the *ex officio* officers.

A very animated debate followed, in which some feeling was manifested. The speakers included Messrs. Foster, Newell, Howe, Witty, McKerchar, Moorman, Langdon, Bevan, Simpson, Pearson, and several country members. The voting was by show of hands, and the tellers were Messrs. Taylor and McKerchar, who declared the amendment carried by 25 votes to 18.

ELECTION OF OFFICERS.

The President, Sir A. K. Rollit, M.P., having written that he would be unable to accept the position again, the names of several gentlemen were nominated, and the Secretary was authorised to communicate with them.

Mr. J. W. Moorman was re-elected with acclamation to the post of Treasurer, but in view of the amendment to Rule XIV which had been adopted, Mr. Moorman was unable to accept any active share in the Society's management, at any rate for a time. He did not object to the principle of the amendment, but complained that the agitation in favour of this was not what it should have been. Eventually Mr. Taylor was elected Treasurer, Mr. T. Bevan was re-elected Chairman of the Executive Committee, and Mr. Witty Vice-Chairman.

The re-election of the Foreign Corresponding Secretary (Mr. Harman Payne) and that of the General Secretary (Mr. R. Dean) was carried unanimously.

The following gentlemen were elected, or re-elected, members of the Executive Committee: Messrs. Newell, Lyne, Ingamells, Blick, Reeve, Hawes, J. Jones, Tapper,

Milsom, Windibank, E. Jones, English, Want, Smith, and Shearn.

On the recommendation of the Executive Committee the honorary Fellowship of the Society was conferred on the President of the French Chrysanthemum Society; and upon the proposition of Mr. B. Wynne, a hearty vote of thanks was passed to Mr. Moorman for services rendered to the Society. The opinion was general that the Executive Committee will subsequently recommend that a Honorary Fellowship be also conferred upon him. New members were elected, and the meeting terminated after sitting about three hours.

NATIONAL DAHLIA.

WE have received from Mr. P. W. Tulloch, Sterndale, New Church Road, Hove, the report of the above Society for 1902, together with the prize schedule for 1903. Compared with the report for 1901, issued ten months ago, the changes are as follows: the name of the Earl of Ilchester is added to the list of patrons; and that of Miss Willmott, V.M.H., to the list of patronesses. Mr. F. W. Sharpe has resigned his position as vice president, and Mr. J. F. Hudson, M.A., has been elected a vice-president in his place. Mr. Hudson thus retires from the position of hon. secretary, which he has so ably filled during the past six years, and Mr. P. W. Tulloch has been elected hon. secretary in his place. Mr. E. T. Cook has been elected to the vacant seat on the committee, caused by Mr. Tulloch's appointment. Compared with the date of issue of the last report, the membership show an increase of over 11 per cent., and the prize schedule for 1903 has been improved by the addition of four new prize trophies, as already notified. It may be added that negotiations are in progress for the holding a special exhibition of Dahlias by this Society at Manchester in September next.

A meeting of the Committee will be held in the room of the Horticultural Club, Hotel Windsor, Victoria Street, on Tuesday, February 10, at 12 o'clock (noon).

NOTICES OF BOOKS.

THE AMATÉUR'S GREENHOUSE. By T. W. Sanders.

THIS little book, the work of an experienced cultivator and a most diligent teacher, has been published by Messrs. W. H. & L. Collingridge. It deals with the construction, heating, and management of greenhouses, and the cultivation of the plants collected within them. After about 100 pages devoted to generalities, special instruction is given as to the nature and requirements of "popular greenhouse" plants, the names of which are arranged alphabetically. Botanical details are almost entirely omitted—not even the natural orders of the several genera being mentioned, and there is no monthly calendar of operations, although this is to a considerable extent to be gleaned by the reader himself from the sections on greenhouse management.

The plants are sometimes ranged under their popular names, e.g., Snowdrop, but the genus Galanthus is not entered separately. In other cases a different plan is followed; thus under the generic name "Solanum," the popular names "Jerusalem Cherry, Star Capsicum, and Jasmine nightshade" are given. To which, if to any, of the 900 species of Solanum do these names apply? To this question we may add another—does anybody make use of these so-called popular names at all? We have no intention to disparage the book by calling attention to these details; on the contrary, we heartily recommend it to the notice of the amateur, and remind the expert that he also may derive many valuable hints from this very serviceable little treatise.

AMERICAN HORTICULTURAL MANUAL. Part I. By J. L. Budd, assisted by N. S. Hansen. (New York: John Wiley & Sons; London: Chapman & Hall.)

THIS is an excellent work for the student, and will be handy for reference by the expert. It deals with "the leading principles and practices connected with the propagation, culture, and improvement of fruits, nuts, ornamental trees, shrubs, and plants in the United States, and Canada."

"In the days when gardening was a mere art, the operator was told what to do and how to do it. At this time the student is required to know not only how to perform a given work, but to give the reasons for doing it in a certain way in order to reach given results. In agricultural college work, at institutes, and at horticultural meetings, the discussion of practical details is now associated with the underlying principles that often border on science."

These extracts will suffice to show the general scope of the work, and as an illustration of the method pursued, we may advert to the chapters on seeds and seed-growth. In them are summarised the nature of the seed, seed-variation, seed-collection, seed-saving, stratification, and other details connected with the form and growth of the embryo plant from the seed, and the cultural details relating to the germination and the raising of seedling plants. Stems, roots, leaves, flowers, are treated in like manner; while special chapters are devoted to fruit trees, spraying, lawn and park trees, ornamental shrubs, bulbs, flowers, kitchen-garden plants, and irrigation. Systematic pomology is to be treated of in a second volume. Though intended mainly for transatlantic use, it will be found very serviceable on this side of the Atlantic also. This is a book which would be a most useful occupant of any gardener's book-shelf.

Obituary.

L. G. KING.—We much regret to have to announce the death of Mr. L. G. King, of the firm of Messrs. John K. King & Sons, of Coggeshall, Essex, and Reading, Berks, who passed away peacefully at Matlock on January 30 last, at the early age of thirty-five years. The deceased gentleman took an active and practical interest in the business; he was much esteemed in the neighbourhood of Coggeshall, where he resided, and was highly respected on Mark Lane and other markets by all who had business transactions with him. Great sympathy has been shown to his widow and other relations, as the family of the Kings are held in high esteem throughout East Anglia.

WILLIAM WILDER.—This old servant of the Turners died at Slough on the 28th ult., aged sixty-four, after a service of many years at the Royal Nursery. Going there when a lad after leaving school as an assistant in the seed shop, he ultimately became head shopman, and was at all times a painstaking and industrious servant, well-known and highly respected in the neighbourhood. He was a member of the church choir for the space of forty-four years.

ANSWERS TO CORRESPONDENTS.

BLACK INK FOR WRITING ON ZINC LABELS: *S. V.* The *Horticulturist's Rule-Book* gives the following receipt:—Verdigris, 1 oz.; Sal ammoniac, 1 oz.; lamp-black, ½ oz.; rain-water ½ pint. Mix in an earthernware mortar or jar, and put in a bottle. To be shaken before use, and a quill-pen to be used, on a clean surface.

CŒLOGYNE CRISTATA: *W. J. M.* The young growths might fail in the manner shown if watered overhead late in the day, and the temperature fell very low during the night, or from injudicious watering with liquid manure.

COPY IN FINE CONDITION OF KEMP'S "HOW TO LAY OUT A GARDEN": *S. G.* You should advertise the book in our columns.

CORRECTION: In the description of the water-wheel, *re* article on garden pumps in our last issue, fig. 33 was that of an "overshot," not an "undershot" wheel, as there described.

CYPRIPEDIUM FAIRRIEANUM: *C. L.* We believe it has been found that this species will cross with other species, but not with its own varieties.

CYPRIPEDIUM INSIGNE SANDERI: *C. L.* Yes, it is quite true that this beautiful variety comes true from seed. At least, we know that it has done so in Mr. Norman Cookson's garden.

GALVANISED WIRE NETTING TO EXCLUDE THE SMALLEST BIRDS: *F. S.* A $\frac{1}{10}$-inch mesh would do this. To exclude birds of all kinds from a fruit garden at all seasons has its drawbacks in the increase of insect pests above and below ground. We would rather protect the fruit when in season, and remove the nets for the rest of the year.

JAPANESE ARTICHOKES: *J. B.* Stachys Sieboldi, sometimes called by the French name, Crosnes.

MARKET FLOWERS: *F. B.* Our weekly market report will afford you a good idea of the kinds to cultivate for profit, and the prices obtained in London. The tastes of the buyer in London, as well as in your town, have to be studied in the matter of bunching, packing, &c.

NAMES OF PLANTS: *Correspondents not answered in this issue are requested to be so good as to consult the following number.*—*M. O. R.* 1, Cupressus macrocarpa; 4, Juniperus virginiana.—*W. B.* 1, Abies brachyphylla; 2, A. grandis; 4 and 5, Thuya occidentalis var.; 6, Juniperus sinensis var. squamata.—*R. S.* 1, Juniperus chinensis.—*G. R.* 1, Davallia Mooreana; 2, Platycerium alcicorne; 3, Asparagus procumbens; 4, Davallia pentaphylla; 5, Panicum plicatum; 6, Cheilanthes elegans.—*W. M.* 1, Davallia dissecta; 2, Asplenium nidus (Bird's-nest Fern); 3, probably Phœnix canariensis; 4, Chamædorea graminifolia; 5, Dracæna Reginæ; 6, Dracæna ornata; 7, Dracæna rubra.—*W. P., Northampton.* Dendrobium × chrysodiscus (Ainsworthi × Findlayanum).—*A. Y. O.* Narcissum maximus.—*J. W.* Nuttallia cerasiformis.—*H. C. C.* 1, Polypodium nigrescens; 2, Davallia canariensis; 3, Adiantum Waltoni; 4, Adiantum cuneatum; 5, Adiantum capillus-veneris variety; 6, Lastrea setigera cristata; 7, Davallia solida.—*G. B.* Streptosolen Jamesoni.—*W. W., N.B.* The spotted leaf is Richardia Elliottiana, and the plain leaf Richardia Pentlaudi; there seems to be no botanical difference, but in gardens they are distinguished as above.—*C. H.* Thunbergia erecta, more commonly known in gardens as Meyenia erecta.—*Veritas.* Cattleya Trianæ, and Phaius maculatus.—*W. O., Devizes.* Panax Victoriæ.—*H. J. G.* 1, Euonymus radicans, variegated form; 2, Pittosporum Tobira; 3, not recognised; 4, Choisya ternata; 5, Phillyrea angustifolia; 6, Pernettya mucronata.

NUMBER OF SQUARE YARDS IN AN ACRE OF LAND: *An Old Reader.* The number is 4,840, and treble that number if the turf be cut into strips of 1 yard long and 1 foot wide.

ORCHID SEED: *Miss Gould.* 1, The seed appears to be imperfect; 2, The seed seems perfect, but we have not yet examined microscopically.

ROSARIAN'S ADDRESS: *Hortus.* It is unknown to us.

ROYAL WARRANT: *E.* If you have supplied the King's establishment you can obtain what you require by making application to the Board of Green Cloth, Buckingham Palace.

WIREWORM: *F. W. S.* These are difficult to destroy, except by applying gas-lime as a top-dressing, and permitting no plant to occupy the land for a year or longer. Short of this radical remedy, you can intercrop with Lettuce sown thickly, or you can make holes with a dibber and insert the roots of Carrots, for which the wireworm has much partiality; these should be drawn out once or twice a week, and the creatures brushed off into a pailful of quicklime or scalding water.

SWALLOWFIELD PARK, READING.

(*See Supplementary Illustration, and fig.* 44, *p.* 101.)

THE first thing that strikes the visitor to Swallowfield is the wonderful individuality of the place. Within 5 or 6 miles is Reading, busy and bustling with 20th century life, and yet, barely out of sight of its many chimneys, here is a garden which carries one back to those "good old times" when life, if stirring, was scarcely so strenuous as now. The marvellously fine trees in the grounds, the superb hedges of Box and Yew, that have probably not their equal in the country, not less than the gloomy cloister and quadrangle of the mansion itself, all teem with memories of the past.

Swallowfield Park has passed through a very chequered career; but it has contrived to bring into our own day much of its own individuality and that of its owners—it is essentially a place with a history.

In the Domesday-survey, Berkshire is divided into twenty-two hundreds, and about 200 manors, some forty-six of the latter being vested in the Crown. We find that in the hundred of "Cereledone," or Charlton, was placed "Soanesfelt," or "Swalfelle," now Swallowfield. Of considerable value in Saxon times, the Manor of Swalfelle fell to the lot of William FitzOsbern, the Lord of Breteuil, a faithful "dapifer" or steward of that sturdy raider William the Conqueror. The "dapifer" seems to have been greater at winning manors than his descendants were at keeping them, for the fortunes of the St. Johns, Despencers, De La Beches, and Beaumys were all linked up with those of Swallowfield, as it came to be called. Then we read of William Backhouse, the Rosicrucian, who died there in 1662, when the estate passed to his daughter, Dame Fflower Backhouse. This lady, at her third marriage, espoused Henry Hyde, Viscount Cornbury, the son of the famous Earl of Clarendon.

Contrary to report, no part of Lord Clarendon's *History of the Revolution* was written at Swallowfield, and there is also no truth in the rumour that Queen Anne was born there. It is quite correct, however, that Princess, afterwards Queen Anne, was a frequent visitor. John Evelyn, too, has much to say of Swallowfield. One of the entries in his *Diary* reads:—"This house is after the antient building of honourable geutlemen's houses . . . but the gardens and waters are as elegant as 'tis possible to make a flat by art and industrie." He writes, too, of "innumerable timber trees," of "an orchard of 1000 Golden and other Pippins," and of "walks and groves of Elms, Limes, and other trees."

Thomas, better known as "Diamond" Pitt, the ancestor of the celebrated Earl of Chatham, bought the estate in 1719, and so Swallowfield became mixed up with the Pitt Diamond. A bridge over the Blackwater in the park, built by him, still remains. To jump to the year 1820, we find Swallowfield coming by purchase to Sir Henry Russell, and it has remained in the hands of the Russell family till the present day.

Swallowfield Park now comprises about 2,400 acres, all of it rather flat and low-lying, seeing that it is here that the Loddon and Blackwater meet. The energies of these rivers in the past have bequeathed a special legacy in the shape of a very gravelly soil, which, enriched as it is with alluvial matter, suits many a fine tree to perfection. The pleasure-grounds are full of stately specimens. Few estates can boast of finer Oak timber—clean, handsome trunks with spreading heads everywhere abound. Curiously enough, the Turkey Oak (Quercus cerris) does not thrive. For a few years it grows apace; then, if two or three dry seasons come, it fades and dies. The Cork Oak (Q. suber), on the other hand, is suited exactly. One fine specimen is pointed out with pride as being the best in England, and when the size of the trunk and the spreading limbs, with the general healthiness of the subject, is taken into consideration, other Cork Oaks must look to their laurels. Elm has not been largely planted, yet there are some good trees. Of Conifers, one of the most notable examples is Pseudotsuga Douglasii, which, despite that reprehensible habit of snapping off its leaders, is of good height and feathered well to the ground; Pinus sylvestris does well, and there are several fine specimens of Cedrus Libani. Planes and American Hickories abound. Immediately in front of the south side of the mansion is a fine Catalpa bignonioides, which flowers freely and well each year.

The flower-garden proper is not very large; it seems to merge insensibly into pleasure-ground, with the charming Loddon and its characteristic scenery in the background. Once the Loddon is crossed, the lover of the natural may revel in the woods, where, at the time of my visit, the Snowdrops in their thousands were peeping from under the Hazel-stools to greet a more than usually mild February. Later will come the Bluebells all, like the Snowdrops, planted by Nature in one of her lavish moods.

Back to the house again by one of the numerous winding sylvan walks! We catch a glimpse o the last remains of the canal at its junction with the Loddon; formerly this canal ran close by the house. There it was that my Lord Clarendon used to fish; but the canal was filled up years ago, and the rustic bridges that once spanned it, no longer needed, have gone, like the fish.

The illustration which forms the Supplement for this week shows the principal part of the flower-garden proper, opening from the south front of the house. Bounded on two sides by a grassy bank, the beds themselves, as the illustration shows, are cut in the grass. At the time of my visit these were filled with Wallflowers and bulbs in variety, eked out with small decorative shrubs, amongst which the Golden Privet showed up strongly. Later on the visitor will be charmed with the taste displayed in the arrangement of the summer occupants of this flower-garden, but he or she will probably turn with even more pleasure to the shady nooks and the umbrageous walks that lead to the river.

The mansion itself is "quadrangular in plan, enclosing what was originally a complete cloister." Some of the arches have been filled in, but enough of them are left to demonstrate the old-world character of the structure, which is very solidly built.

There are nearly 6 acres of kitchen-garden, 4 acres being within walls. As the site has been a garden for many years, and many clever gardeners have at various times had charge, the soil has been developed to a high state of fertility. Showy gardening is not favoured, but of good fruit and vegetables there are plenty. In one respect, at least, the kitchen-garden at Swallowfield is unique, viz., in the artistic gateway by which admittance is gained. Itself a superb example of Italian art, this arch (which is shown in the second illustration, fig. 44, p. 101) at one time held a more pretentious position, for it spanned the entrance to the corridor leading to the great quadrangle. As the result of some "improvements," as they were then styled, it was taken from the corridor and set up to guard the entrance to the garden. More, the splendid carving was hidden beneath a wealth of trailing Ivy, and it is only recently, and owing to the initiative of Mr. Cole, the gardener, that this art treasure has been unveiled. The picture shows the panels of Ivy that remain, one on each side of the gate. The wall into which this archway is built is covered with thriving specimens of Magnolia grandiflera, which flowers with remarkable profusion each year. It is to be regretted that the photographer did not include in the picture a glimpse of the double row of Irish Yews, which lead from the great quadrangle to the archway; but he has given us a sight in the garden beyond of that fine Yew hedge, which recalls the times of John Evelyn of *Diary* fame. This hedge, which runs right across the vegetable garden from east to west, and bisects it, has a width of nearly 10 feet, and a height of about 9 feet. It is continuous, save at the points where the gravel walks, of which there are several, run through. It appears that this Yew-hedge was one of John Evelyn's great ideas, and, from all accounts, Swallowfield owes more than one of its present features to the same source.

Hardy fruit is particularly well done; the trees everywhere show signs of being in good hands. The Peach-wall displays Peaches in the height of condition, and the Plums could scarcely be more freely set with buds. The great feature of the hardy fruit is, however, supplied by what may be called a pergola of Pears. Imagine a continuous arch of single cordon Pears, with a span of between 6 and 7 feet, running for a

length of 94 yards, every tree healthy, vigorous, and well set with fruit-buds, and you will have an idea of what the Swallowfield Pear-pergola is like. In a good year many hundredweights of fruit are picked from this arch alone, the favourite varieties being Williams', Doyenné du Comice, Beurré Diel, and Marie Louise.

The glass department is extensive. Figs, Vines, and Peaches, are grown in great quantities in a large range of lean-to's, which run right across the kitchen garden at its northern end. The fruit-houses are flanked on each side by a span-roofed plant-house, where the usual collection of stove and greenhouse plants are accommodated. There is a number of other plant-houses, pits, and frames scattered about, all heated by two Trentham boilers in the stokehole at the back of the vineries. About 1,000 Strawberries are forced, and Royal Sovereign is the favourite. The inevitable Chrysanthemums are not forgotten, some thousand plants being grown.

Upon the day of my visit, Mr. Cole, the gardener, completed his tenth year of service at Swallowfield, and during that time he has seen not a few changes. Still, the changes in the appearance of the gardens and grounds themselves have all been in the right direction—indeed, it would be better to speak of them as "restorations." Than Lady Russell, the mother of the present baronet, few ladies are more keenly alive to the desirability of not allowing the new to swamp the old. Her ladyship's recently published book, *Swallowfield and its Owners*, to which I am indebted for much of the information here given, voices the same veneration for the past, and as long as she has a voice in the guiding of the destinies of the estate, these time-honoured features will be preserved. *A. S. G.*

OPUNTIA CANTABRIGIENSIS.*

THIS is a very fine plant, but I can find no single character which, embodied in a name, would serve to distinguish it from others; and I may therefore perhaps be pardoned for naming it as above. The name is justifiable from the fact that for many years the plant has been a feature of the Cambridge Botanic Garden—is, in fact, nowhere else so fine to this date, and from the circumstance of its wide distribution from Cambridge. It flowered first in 1900, and until that time was supposed to be O. Engelmanni, but a comparison with description immediately showed this to be wrong. At Kew the plant was at first supposed to be O. pseudo-Luna (see *Gardeners' Chronicle*, July 28, 1900, p. 64); but that species, like the true O. Engelmanni, has yellow spines; and by the courtesy of the Director, Sir William T. Thiselton-Dyer, K.C.M.G., a further examination was permitted in July of last year. He informed me that it did not appear to be typical O. Engelmanni, but that it might be a form of the variety cyclodes. A distinguishing name was thus necessary, and since, for practical purposes, it is quite distinct, I may safely pass over the difficult question of true systematic position, which can hardly be dealt with under the circumstances at present. My finest specimen is now 12 feet wide, 6 feet from front to back, and nearly 4 feet high. It was raised from cuttings taken from an older specimen in 1895, and it flowered with the original in 1900. The older specimen had been undisturbed for twelve years before it flowered, but hot summers apparently affected both specimens in the same way. At first only few flowers were produced, but the number on each specimen has increased each year from the first.

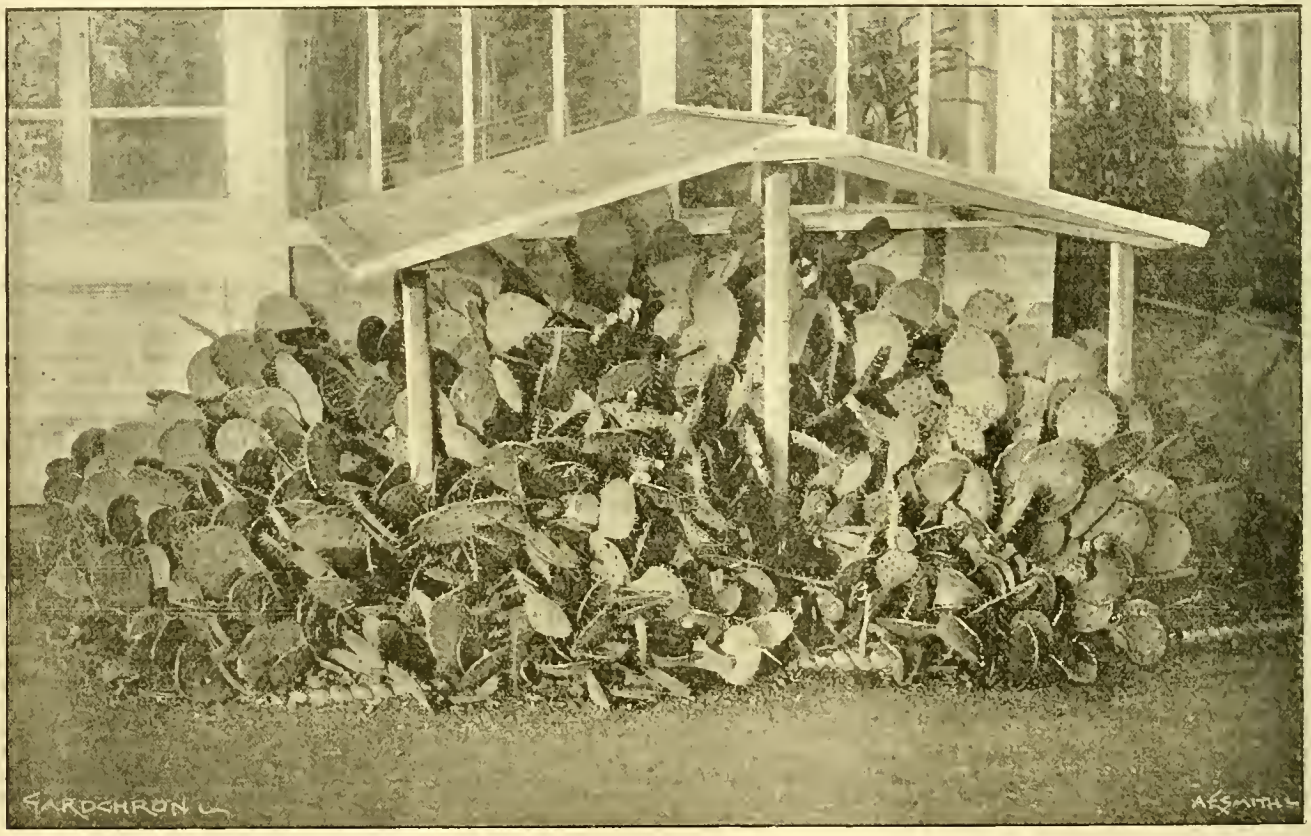

FIG. 42.—OPUNTIA CANTABRIGIENSIS IN THE BOTANIC GARDEN, CAMBRIDGE.

* *Opuntia cantabrigiensis.*—Decumbens, articulis late obovatis compressis, 16—24 cm. long, 12—17 cm. latis leviter glaucescentibus; pulvillis remotis setosis et armatis, aculeis 1—3 erectis, albidis 1—2 cm. long; floribus 1—7 ad articulum, flavis vel fulvo-flavis circa 9—14 cm. diam.; ovario late obconico, pulvillis setosis sub calyce armatis; sepalis circa 10 crassis deltoideis; petalis circa 20 obovato orbiculatis apiculatis; stigmatibus 10 viridibus in capitulum globosum sulcatum dispositis; bacca ovoidea 4 cm. long, rubra leviter glaucescente pulvillis brunneis; seminibus 3 mm. latis marginatis.

Planta robusta ad 1·20 m. alt.

O. Engelmanni var.? cyclodes, E. et B. affinis, sed articulis distincte obovatis.

Opuntia Engelmanni, *Gard. Chron.*, 1901, vol. xxx., p. 409, fig. 123, non O. Engelmanni, Salm., a qua differt imprimis spinis albidis nec non ovario obconico. Patria ignota. In *Hort. Cantab.*, per multos annos culta. *R. I. L.*

The accompanying illustration (fig. 42) shows the winter protection by means of small lights overhead. This species is hardy enough to stand all but the most exceptionally severe winters without protection, but it is conceivable that during a very wet winter the overgrown centre might rot—and moreover, fine specimens are worth extra care. The form of protection here illustrated is very convenient for more tender kinds, because it is easy to hang mats around, and to cover all over in case of necessity. The majority of the outdoor Opuntias are protected from wet by similar lights, but leaning against the walls and raised in front. With the protection illustrated, the true Opuntia monacantha has grown well, and flowered for several years past; a still more tender kind has also grown magnificently, but in these cases mats have been hung over and around when sharp frost might be expected. *R. Irwin Lynch, Botanic Garden, Cambridge.*

REVERSION IN ODONTOGLOSSUMS.

There are some enthusiasts who regard Orchids as having been specially created by Nature, and endowed by her with fixed characteristics; and there are some Odontoglossum specialists who believe their favourite genus to be *the one* where only that fixity of character and constancy of peculiarity is to be found.

Nature has decreed it otherwise, and though it may be almost heresy to say so, the hybridist will ere long prove that the two sections of collectors above mentioned have not fully grasped the inviolability of Nature's universal law, whereby she forbids confusion beyond certain limits, laid down so rigidly that we are powerless to overstep them. That law is "reversion."

In Orchidology there is at present no more absorbing topic than hybridity; for almost everyone is attempting to solve the difficulty. The results when continued for a few generations (of plants) will prove beyond a doubt that Orchids are only one of Nature's many ordinary vegetable creations, and are no more specialised than any other order of plants.

Down to the present time, very few have been able to raise and bloom Odontoglossums, and from the paucity of evidence, it may be thought that reversion will not enter into conflict with them.

I suppose that M. Charles Vuylsteke has raised and flowered more hybrids than anyone, and his results prove reversion in so decided a manner that it scarcely seems to need further elucidation; but the stronger and more diffused the evidence, the better the proof. He crossed a heavily-spotted O. Pescatorei with a still more heavily-blotched O. crispum (O. c. Franz Masereel), and produced as a result many absolutely unspotted hybrids, a few spotted forms, a still smaller number being finely blotched. Nature here at the outset begins to hold her children back.

M. Vuylsteke has not yet bloomed an O. crispum raised from the intercrossing of the spotted forms, nor one from a spotted form fecundated by an unspotted one.

I have always contended that any yellowing or spotting of the white of O. crispum and O. Pescatorei is the remains or result of hybridity, and M. Vuylsteke's results strengthen that contention, for the heavy markings of both parent plants are largely annihilated in the progeny. If they were the characters of species they would unite and produce a great majority of heavily marked hybrids, but being the result of hybridity they are nullified by "reversion."

An occasional "sport" seems to contradict this theory, but a stray case does not alter the general principle.

Prepotency is germane to this matter, and has lately been exemplified in O. waltoniense (figured in *Gardeners' Chronicle*, January 24, 1903, p. 51), raised upon a fine white unspotted crispum from a very heavily marked O. polyxanthum. The result, in the first plant to bloom, is a deep yellow flower, with one small spot in one sepal only, and a small transverse blotch (small compared to the heavy brown lip of polyxanthum) in each lip of the three blooms it bore.

We shall not have to wait very long for the results of raising seedlings from blotched forms of O. crispum. If these all come true, it will prove that a crispum can be white or blotched; but if they vary greatly and produce many unspotted forms, it will prove that a blotched crispum is a hybrid made by Nature, for some, perhaps a special, purpose.

Of course, anyone will admit that these blotched forms have seeded in their own habitat, yet there are no two in cultivation that are identical. Were they members of a true species the reverse would obtain, and there would be many alike.

Further proof lies in the fact that where one blotched form blooms from an importation, another does not appear like it. If they came true, it would only be reasonable to find many more in the same batch. That such is not the case, is the continual experience of all of us. *de B. Crawshay, February 4, 1903.*

ARAUCARIA IMBRICATA.

The specimen of Araucaria shown in fig. 43, though not amongst the very largest in this country, is one of the best specimens in the locality of Warminster, Wiltshire, and is certainly well grown and shapely. Its height is 44 feet, and the spread of branches 6 feet from the ground is 28 feet 6 inches. At the same distance from the ground the stem measures 5 feet 6 inches in circumference. Mr. H. Theodore Cookson, Sturford Mead, in whose garden the tree forms a feature of considerable attraction, kindly informs us that the age of the specimen is not known with certainty, but the impression exists that it was planted from forty-five to fifty years ago. The tree appears in vigorous health. Nine tiers of branches have been lopped off from the base.

Fig. 43.—Araucaria imbricata.

In the gardens of H. T. Cookson, Esq., Sturford Mead, Warminster. Height of tree, 44 feet; spread, 28 feet.

NEW OR NOTEWORTHY PLANTS.

MASDEVALLIA BURFORDIENSIS.

The flowering of a second plant of this fine Masdevallia by the Hon. Walter Rothschild, M.P., serves to establish the right of the Masdevallia burfordiensis for which Sir Trevor Lawrence, Bart., was accorded a Botanical Certificate at the Royal Horticultural Society, November 6, 1900, to its rank as a distinct species. M. burfordiensis is of the section "Coriaceæ," and nearest to M. angulata, Rchb. f., but differs from that species in its shorter leaves, longer and broader flowers, which have the greater part of their surface of a rich claret-purple colour, and in some other particulars. Leaves spatulate, coriaceous, and with a slightly roughened surface. Scape inclined forward, about 2 inches in length, and with generally two bracts; green, spotted with purple. Flowers large, and wax-like in texture. Tube of the perianth about three-quarters of an inch wide, and the same in depth; gibbous beneath. Free portion forming the sepals gradually diminishing, and continued into yellowish tails, the whole about 2 inches in length. Exterior of perianth whitish, with the spaces between the veining

heavily tinged with purple, the face being densely spotted and tinged with claret-purple, the lower portion also furnished with short violet-coloured papillæ. Petals spatulate, whitish, striped with rose-purple, the under side of the column being similarly coloured; blade of lip ligulate, channelled in the middle, and densely spotted and tinged with rose-purple. Flowers apple-scented. Both M. angulata and M. burfordiensis were collected by Consul F. C. Lehmann, who stated that they were from different localities, and called attention to the difference in their flowers. *J. O'B.*

CHINESE MAPLES.

(*Concluded from p.* 63.)

SPECIES WITH TRILOBED LEAVES.

9. *Acer Francheti*, Pax.—Hupeh. Now in cultivation in Coombe Wood. This is a shrub about 12 feet high. The leaves are trilobed, the lobes being triangular, with sharp remote serrations. It is a handsome species, and is near to the Himalayan A. villosum, Wall. The fruit is very large.

10. *Acer tenellum*, Pax.—Szechwan. In cultivation in Coombe Wood. This is a beautiful species, and is bound to become a favourite for planting. The leaves recall those of the Aspen; they are very thin in texture, and borne on long petioles; they shake with the slightest breeze. It is a shrub about 12 feet high. The leaves are small, trilobed, or in part undivided and wholly entire; they are cordate at the base. A figure of this species is given in Hooker's *Icones Plantarum*, t. 1,897.

11. *Acer Schœnermarkia*, Pax.—This is a Yunnan species, my No. 10,497. The leaves are tri-lobed, but as the tree is not in cultivation, I need not here give any more details.

12. *Acer, sp. nova* (?), collected by Mr. Wilson in Hupeh, and now in cultivation at Coombe Wood. This has trifid leaves and a racemose inflorescence. It seems to be quite distinct from A. trifidum, H. et A.

13. *Acer sp. nova* (?), collected by Mr. Wilson in Hupeh, and in cultivation at Coombe Wood. This has trifid leaves and a corymbose inflorescence.

SPECIES WITH FIVE-LOBED LEAVES.

14. *A. sinense*, Pax. This has 5-lobed cordate leaves, sharply serrulate towards the apex. It was found by me in Hupeh, but Mr. Wilson did not find ripe fruit, so it is not in cultivation at Coombe Wood.

15. *A. Campbelli*, Hk. f., an East Himalayan species. It is very close to the last, but differs in the caudate leaves, green on both sides, and 7-lobed leaves also occur in it. It was found by me in Yunnan, my No. 10,495.

16. *A. erosum*, Pax; Hupeh. In cultivation at Coombe Wood. This is the Chinese representative of the Japanese A. rufinerve, S. et Z. It is a shrub with cordate 5-lobed leaves. The margin of the leaves is irregularly serrato-dentate, the teeth being cuspidate.

17. *Acer Maximowiczii*, Pax; Hupeh. This is a 5-lobed species; the median lobe is very long. All the lobes are acuminate with doubly-serrated margins.

18. *Acer Oliverianum*, Pax; Hupeh. This is a 5-lobed species; the lobes are triangular in outline, with sharply serrulate margins. This is a very pretty species, and I do not know if Mr. Wilson obtained it, or if it is in cultivation at Coombe Wood.

19. *Acer laetum*, C. A. Mey., *var. cultratum*, Pax. Hupeh and Yunnan (my numbers 5347, 10872).—This is in cultivation at Coombe Wood. The leaves are five-lobed, truncate at the base, and with entire margins; it is a tree very graceful in habit.

SPECIES WITH FIVE TO SEVEN-LOBED LEAVES.

Acer palmatum, Thunb.—This common and variable Japanese species has hitherto not been found in China. Mr. Wilson met with it in the mountains of Hupeh, and plants from fruits collected by him are now growing at Coombe Wood.

21. *Acer sp.*, Hupeh; in collection at Coombe Wood.—This is intermediate between A. japonicum, Thunb., and A. circumlobatum, Maxim., and will doubtless be found to be a new and distinct species.

SPECIES WITH TRIFOLIOLATE LEAVES.

This is a remarkable section. The discovery in one Mid-China mountain range, of no great extent, some fifty miles long, of three new and distinct species, quite different from the three species of the same section occurring in Japan, is quite in accordance with my views of the extraordinary richness of the Chinese flora.

22. *Acer Henryi*, Pax; Hupeh, and neighbouring part of Szechwan.—In cultivation at Coombe Wood. This is a shrub or small tree. It has three entire leaflets, mounted on moderately long petiolules, and the inflorescence is spicate. In the Japanese A. cissifolium, Koch, the leaflets are deutate, and the inflorescence is racemose.

23. *Acer sutchuense*, Franchet. — The leaflets are lanceolate with serrate teeth. This is a beautiful species, occurring in Szechwan, close to the Hupeh border. Mr. Wilson apparently did not find any specimens of this tree.

24. *A. griseum*, Franchet.—This is the Chinese representative of the Japanese A. nikoense, Maxim., and occurs in the mountain range north of Ichang in the high forests. It is in cultivation at Coombe Wood, and is a most remarkable tree, attaining large dimensions. The bark is reddish, peeling off like a Birch; the leaves are very large, measuring 8 inches long by 9 inches wide, exclusive of the petiole; the leaflets have large teeth towards the apex. Their upper surface is glabrous and opaque. The under surface of the leaves and petiolules, &c., are densely pubescent.

The above list by no means exhausts the Chinese Maples; other species occur in the north of China and in the coast provinces, and I only had an opportunity of seeing part of Mr. Wilson's dried specimens—the lot collected by him in his first year at Ichang. *Augustine Henry.*

THE SEED TRADE, AND TREE SEEDS.

So far as foreign advices have come to hand respecting the yield of tree seeds, it would appear that, as in the cases of those of vegetables and flowers, there is a variable yield. Such a subject as Pinus sylvestris (Scotch Fir) yielded everywhere a short crop, and cones are scarce, and procurable at high prices only. In order to extract the seeds from the cones of scaly-fruited Coniferæ, such as the Scotch Fir, they have to be exposed to the heat of the sun, or dried on kilns by artificial means, until they are fully open, and the seed-grains are then thrashed out. Picea excelsa, Norway Spruce, shows in some of the seed-producing countries an average yield; and Larix europæa (Larch), in the forests of Germany and in the Tyrol, has yielded a small quantity of seed only. Pinus Strobus (Weymouth Pine) has given a satisfactory crop; that of P. austriaca (Austrian Pine) is a very poor one. The same may be said of Abies pectinata (the Silver Fir), though the yield is rather better of the two. It is the custom of the German collectors of the seed-cones of the foregoing to set up machinery, by means of which the seeds are extracted, with all the necessary precautions, and with as little deterioration as possible of their germinating qualities.

In some instances, deciduous tree seeds show short crops, the best yield coming from long distances. Quercus pedunculata, the common and the scarlet Oak, Q. rubra, have in some countries yielded good crops, but they appear to vary in bulk; the American Red Oak has yielded quite a small crop of seeds; the Black Oak, Q. robur, has a better result. It would appear that on the whole the foreign dealers have a good supply of Acorns. Acer platanoides, the Norway Maple, and A. pseudo-platanus (Sycamore), each show a medium crop of seeds; but there is quite a small yield of Alnus glutinosus (Alder) and A. incana, the white smooth Alder. There are good stocks of Betula alba (Birch), Carpinus betulus (Hornbeam), and Cratægus oxyacantha, the Whitethorn. Of Fraxinus excelsior (common Ash) there is a poor crop; Robinia pseudo-Acacia, a medium crop; the large-leaved and the small-leaved Limes have yielded very sparingly, and the same remark applies to Cytisus scoparius (Broom) and Ulex europæus (Furze). A fair amount of seed of the common Elm (Ulmus campestris) has been harvested. The common Broom is sown for coverts, from 15 lb. to 20 lb. per acre being used; it is occasionally sown for sheep-walks, for the purpose of affording the animals a supply of winter food, and though the sheep eat it, it has been thought, from its excessive bitterness of taste, and the diuretic qualities ascribed to it, that they take it rather in the way of medicine than for actual nourishment. Furze is also sown on sheep-walks, to the extent of 20 lb. to 30 lb. per acre; it is said the sheep thrive well on it during severe and snowy weather, while it forms an excellent covert, and when properly trimmed a dense sheltering hedge. *Pisum.*

ORCHID NOTES AND GLEANINGS.

ONCIDIUM WARSCEWICZII.

A PLANT of this very distinct, showy, and rare species is now in flower in the collection of R. I. Measures, Esq., Cambridge Lodge, Camberwell. The raceme has eight rich yellow flowers, each furnished with a long glumaceous bract, the singularly elongated labellum having reddish markings on each side of the middle portion. It is a native of Veragua and Costa Rica, and is found at an altitude of 8000 to 10,000 feet, and consequently it is most successfully cultivated in a cool house. It is sometimes met with in gardens under the name of O. bifrons.

ANGRÆCUM SESQUIPEDALE.

A singular abnormally constructed flower of this large species is sent by E. Roberts, Esq., F.R.A.S., Park Lodge, Eltham. It represents a star with four long segments, the petals being horizontally and the sepals (the two lateral joined) perpendicularly extended 7 inches from tip to tip. The flower appears to be spurless, but examination discloses the fact that the spur has been incorporated in the ovary. The labellum is reduced to an inconspicuous two-lobed blade, pressed so close to the face of the column as to appear part of it. The pollinia are perfect, and the whole flower irregular, though it be well developed.

CYPRIPEDIUM × ARGUS.

Under this name a beautiful cross-bred Cypripedium, with some of the features of the finely coloured C. × Lathamianum splendens, is sent by G. W. Law-Schofield, Esq., New Hall Hey, Rawtenstall, Manchester (gr., Mr. Shill). The upper sepal measures 2 inches; it is rich rose-purple, with yellowish base, white margin, and broad purple central band. Petals and lip similar to those of a large dark-coloured C. villosum, the upper halves of the petals being dark reddish-purple, and the lower halves yellowish tinged with purple. Lip also yellow tinged with purple.

NOTES FROM ISLEWORTH.

The Summer of 1902.—A sunless summer, and generally disappointing. The lawns and grass-walks were the chief glory of the past year, and never of late years have they kept so continuously green and beautiful. In the immediate vicinity of the house it is a great mistake to rely too much upon flowering plants for effect. The emerald-green of British lawns, and the dark sombre shades of our Conifers, form in themselves the best and most lasting harmony. By judicious use of deciduous trees, coloured either in spring or autumn, various Acers, Bamboos, &c., splendid colour effects can be produced.

The past season was one in which most exotics refused to flower well outside; Cannas were particularly disappointing. The flowering in the open of various exotic bulbs (usually grown under glass), which is made a feature in this garden, also proved a disappointment, especially the various Crinums, only Moorei and Powelli flowering well. Lycoris squamigera produced about a hundred flowering scapes, but the flowers were mostly poor, and lacked the vigour of previous years. Amaryllis also flowered sparingly, and Brunsvigias not at all.

Outside Bulbs.

Gladiolus, hort. "princeps."—I regard this as the finest Gladiolus ever introduced; it is, indeed, *facile princeps* in the genus, and should have the best place in every garden. It is also a first-class "cut" flower.

Tulips.—Among new or little-grown species, I was specially pleased with—

T. Mauriana, a splendid large late red, with pure yellow base.

T. Kolpakouskiana, after the type of Greigii, but a different shape.

T. armena, after the type of oculis solis; very variable in size.

T. Eichleri, the finest Tulip I have ever seen, which should be given the best place in every garden. Some forms are not so fine as others.

T. Lownii, a minute Violet-scented flower.

T. Billetiana, should be largely-grown; it lasts a long time in beauty, and changes from greenish-gold to canary-yellow with red markings.

T. triphylla aurea and T. Biebersteiniana are also worth growing.

Narcissus, hort. "King Alfred," as shown at the Royal Horticultural Society, marks an advance on anything yet seen in this genus. It promises to become a splendid garden plant when the time comes that it can be used for this purpose.

Inside Bulbs.

Hymenocallis macrostephana.—This fine hybrid is neither so well known nor so well grown as it deserves to be. Some gardeners condemn it as difficult to flower; this is not so if proper treatment is given. It retains the sun-loving character of one of its parents (Calathina), and should be placed in full sun directly the foliage is sufficiently toughened to stand it. In such positions, minimums of 55° to 60° are sufficient; manure-water should be given, but only sufficient to prevent the foliage flagging. Under this treatment, every full-sized bulb will flower at least once a year. Remember that this bulb is evergreen. For private greenhouses, it is undoubtedly the best in its class. The recently raised hybrid "Daphne" is the best form of the speciosa × Calathina hybrids yet raised, and is superior to the older hybrids.

Hymenocallis concinna.—I described this new Mexican species in the *Gard. Chron.* last June.

Crinum Wimbushi, C. Samueli.—These two new Crinums from Central Africa are in alliance with C. pauciflorum. I described them from my garden, for the first time, in *Gardeners' Chronicle*, Oct. 25, 1902. *A. Worsley.*

(To be continued.)

THE ROSARY.

ROSES OF RECENT INTRODUCTION.

Perhaps the most notable Rose that has been recently introduced is a pure white Hybrid Perpetual, a great improvement in form and colour on Merveille de Lyons. This variety has received from its eminent raiser the name of Frau Karl Druschki, and was introduced by P. Lambert in 1900. I have been informed that it was the result of a cross between Caroline Testout and Merveille de Lyons, and there can be no question that it has already proved itself worthy of such a distinguished parentage, combining as it does the finest attributes of both. It opens with the facility of Caroline Testout, while on the other hand it is much superior in colour and form to Merveille de Lyons; the latter of which, I may add parenthetically, was, at the period of its first appearance in this country, considerably over-estimated. Now that it has been so manifestly transcended by a Rose of greater purity derived from its vigorous self, it will take a secondary position, its proper place. It had, in any instance, already been surpassed by a much more valuable Rose for the garden, perhaps the grandest of all varieties for impressive effect, viz., Margaret Dickson.

Another remarkable Rose, introduced contemporaneously with Frau Karl Druschki, is Soleil d'Or (Pernet Ducher, 1900), which, though very much darker in colour, owing to its apricot or Nasturtium-red shading, very much resembles the beautiful Persian Yellow. I saw it at Waltham Cross for the first time two years ago; subsequently at the great Temple Show, where it was splendidly exhibited by that veteran rosarian, Mr. William Paul, and greatly admired. Other comparatively recent continental introductions of great promise are Madame Charles Monnier, a highly artistic hybrid Tea; Madame Jean Dupuy

Fig. 44.—Entrance to flower garden, Swallowfield Park, Berks. (see p. 97.)

(Photographed by F. Mason Good.)

Préfet Montiel, and Souvenir de Pierre Notting, which are likely to prove important acquisitions.

Recent British Roses have emanated for the most part from Newtownards in Ireland, Cheshunt, and Waltham Cross; Colchester and Oxford also contributing conspicuously. Perhaps the finest of Mr. William Paul's creations of late years have been Boadicea, which I had in splendid flower during last summer and autumn. Its colour is delicate peach, exquisitely tinted with pink and tenderest violet; Fortuna, apricot, with a suffusion of buff; Salmonea, and Morning Glow, which well sustain the reputation of the firm over which he presides.

From the famous nurseries of the Messrs. Dickson, at Newtownards, near Belfast, have come of late, Alice Lindsell, and Mildred Grant, which, like so many of their celebrated predecessors, have won the Gold Medal of the National Rose Society; Duchess of Portland, which has achieved the same distinction, and Lady Moyra Beauclerk, all of these being precious additions to the race of Hybrid Teas. Rosslyn, a somewhat older variety, introduced by them in 1900, rosy-flesh in colour, and splendidly effective, is a derivative from that uniquely lustrous Rose, much more beautiful than any of her descendants, Susanne-Marie Rodocanachi.

The latest productions of Mr. George Paul, the famous Cheshunt rosarian, have been Una and The Lion; hybrid Briars of a very fascinating character; Atro-purpurea, crimson in colour, deeply shaded with maroon, an extremely interesting hybrid Rugosa; and Lady Battersea, a richly hued addition to the Hybrid Teas.

Mr. Prince of Oxford, has given us Bellefleur, a single decorative variety of great interest, with a climbing tendency (which should be encouraged by cultivators), and perpetual in habit; also Marie Corelli, a pale salmon-pink sport from Susanne-Marie Rodocanachi; and therefore having Rosslyn as a beautiful sister Rose.

A pure pink form of Turner's Crimson Rambler should be regarded by rosarians as a charming possession, of this nature is the new Rose entitled Queen Alexandra, raised and introduced by the Messrs. Veitch of Chelsea.

To Mr. Frank Cant of Colchester, we are indebted for Lady Roberts, which owes its finest characteristics to Anna Olivier, though regarded as an improved version of that exquisite Rose; while the new varieties, also natives of Colchester, which bear the honoured names of Mr. and Mrs. Ben Cant, have gained the highest distinctions which the National Rose Society has the power to bestow. *David R. Williamson.*

GARDENING UNDER GLASS.*

(*Concluded from p. 84.*)

HEAT.—The temperature of the air and soil surrounding plants has an important influence on their growth and health. There is a minimum temperature at which each and every plant is brought to a state of absolute rest. For plants of temperate regions this minimum may be said, in general terms, to be at or a little above the freezing-point; for those of tropical regions it is some degrees higher. Under certain conditions, and when properly prepared, plants will support a comparatively low temperature for a considerable time without suffering, and even exposure for a short time to a very low temperature may not be fatal, the injury depending very much upon the proportion of water which the plant contains.

A variety of conditions may affect the power which a plant has of enduring exposure to extreme temperatures. Age exerts an important influence, the younger the plant the more sensitive it is. The conditions under which the plant has been grown must also be taken into consideration. Some plants are much more elastic in their adaptability to temperatures than others. For example, many plants cannot be forced; in other words, they will not develop leaves and flowers under the stimulus of a higher temperature than that which is normal to them. On the other hand, there are plants which respond readily to a high temperature. This adaptability is not peculiar to the plants of any order or genus, or even to the forms of a species. For instance, only a few of the many varieties of Azalea indica, of Camellia japonica, of Rhododendrons, and of Tulips, will bear forcing. The same is also true of various fruits, for instance, Grapes, Strawberries, &c. The same peculiarities occur with respect to the degree of cold that plants will support.

A plant has been likened to a steam-engine in its relation to heat. When the tension of the steam is slight, the machine is barely able to overcome the friction of its own parts, and under such circumstances can do little or no work. As the tension of the steam is increased the work increases also, until the point is reached when the maximum amount of work is done; beyond this the parts of the machine become strained, and a break-down may result. In the case of the plant, there is a point in the temperature barely sufficient to induce growth. With increasing heat there is a corresponding increase of growth, until a point is reached when the best growth is made; beyond this point the growth may indeed be quicker, but it is weak and lacking in stability.

There is a close correlation between heat and light in their effects on the growth of plants, expressed by the horticultural axiom: the brighter the light, the higher the temperature of the air may be. In sunny summer weather it is not difficult to balance these conditions, but we are afraid to make as much use of the sun in our glass-house gardening as we might do with advantage. We recognise the beneficial influence on growth of bright sunlight out-of-doors, but the same plants if by any chance placed under glass would be regularly shaded. If less shading were used in summer for plants under glass we should get sturdier growth, and better flowers and fruits than we do. The growth of the plants in the Succulent-house at Kew is a proof of this. That house is never shaded, consequently in summer when the sun is powerful the temperature of the air is high; and yet the plants grow and flower most satisfactorily. There is, of course, a limit with regard to temperature beyond which we must not go, but too often we fall short of that limit.

When the atmosphere in a plant-house is kept dry, a comparatively low temperature will suffice to maintain the plants in health during the winter. This is in many ways an advantage. Plants kept in these conditions are better able to withstand any sudden fall in temperature, consequent on a severe frost or the break-down of the heating apparatus; they also rest better, and will stand with greater vigour when the growing season again arrives. *W. Watson.*

* Paper read before the Kew Mutual Improvement Society, January 5, 1903, by Mr. W. Watson, Curator.

The Week's Work.

THE ORCHID HOUSES.

By H. ALEXANDER, Orchid Cultivator to Capt. G. L. HOLFORD, Westonbirt, Tetbury.

Cypripediums.—The varieties C. Charlesworthi and Spicerianum, when repotted, should be put into the same sort of compost as that advised in our last week's Calendar, keeping them a little above rather than below the rim of the pot. The first-named variety is injured by water at all seasons if given in excess, while the second will take plenty of water at the roots in the summer months. Plants that have been recently repotted should have the sides of the pots, and the staging or bed on which they are standing, frequently damped during the daytime, and the leaves moistened in sunny weather.

Seedlings.—If the raising of seedlings is carried on, there will be little plants at this season in need of pricking off. The operation if done forthwith will enable the plants to get established before the summer arrives. Seedlings of last year standing singly in small pots, if well rooted, may be afforded a slight shift, the plants growing apace after arriving at a certain age. The first pots employed should be either 1½ or 2 inches in diameter, and the potting compost consist of equal parts of peat and leaf-soil, and finely chopped living sphagnum being placed on the surface. Do not make the compost very compact. After this potting, a small quantity of loam may be added to the compost, and a more porous compost used till the plants come of flowering size, when a more substantial compost should be employed.

Sowing the Seed.—Seed which has ripened during the present winter may be sown on pots containing plants newly potted, affording the compost abundance of water a day before sowing. Much care must be exercised for some time after in affording water, till such time as the seed gets embedded in the compost; and the water should be allowed to soak in gradually, and occasionally the pots may be dipped in a vessel of water to half their depth, which will moisten the compost at the bottom of the pot. Seedlings often appear in the second year after sowing and even later, and the cultivator must have patience.

THE FLOWER GARDEN.

By J. C. TALLACK, Gardener to E. MILLER MUNDY, Esq., Shipley Hall, Derby.

Anemones and Ranunculus. — Prepare beds, lines, or stations, for clumps by digging in rotten cow-dung or other mild manure, and set the former about 2 inches deep, and the Anemones 1 inch deeper. Both will root very readily if surrounded with sand or road-grit.

Alstrœmeria, Eucomis punctata, &c., may safely be planted now. The former frequently dies out in gardens after a hard winter, owing to the roots getting in the course of time too near to the surface. To obviate this loss, transplant the tubers once in three years, and bury them 7 inches deep. Eucomis punctata is quite hardy when the bulbs are set deep. It is seldom seen excepting as a pot plant, but in this condition is not nearly so fine as when growing in the open ground. Hyacinthus candicans bulbs must be planted early in order to get strong spikes, and it is an excellent plant either for massing by itself, or for planting in groups among herbaceous plants.

Borders of Herbaceous Perennials.—At the time of writing the weather is in every respect suitable for carrying out planting operations. Plants too, are getting very forward, so that unless the weather again becomes frosty, it will be advisable to push on with all dividing and replanting of plants that have been established for more than two years. Plants which form tufts are the better in the nature of things for division, and for being replanted at intervals of three years. In doing this, only the outer portions of the tufts should be used, securing those with the greatest possible number of roots, with very little of the old woody stems and roots. Most herbaceous perennials need much nutriment in the soil in which they will have to grow for the time named, and it should be in at the least two layers of well decayed stock-yard manure, and the soil trenched. The deep digging will stand the plant in good

service in times of great heat and drought. The scheme for replanting should receive much thought, in order that the plants are of suitable heights for the positions they will have to occupy, and the colours harmonise or contrast in a pleasing manner if these are displayed at the same time of year. In the matter of spring and early summer flowering plants, I prefer to have them in beds and borders by themselves, and to assign other borders to those which flower in summer and autumn. When planted in mixture, irrespective of seasons of flowering, the vacant spaces caused by the departure of the spring-flowering bulbs, Pæonies and the like, are sure to result in a certain amount of disappointment, and the case is only partially met by sowing quick-growing annuals, which scarcely ever seem to be in keeping with their neighbours.

New Varieties of Hardy Plants.—There are now many improved forms of certain herbaceous perennials, a fact that the gardener should not overlook when re-arranging his borders, and at the same time he should not discard old favourites till the newer ones have been tested. One observes, for instance, at horticultural shows, collections of Asters (Michaelmas Daisies) containing improved forms as regards that portion of the plant cut for show, but which when reproduced at home one finds at times some inherent defects in the plants, which robs one of the inclination to increase their number at the expense of others that are as good or better. Where strong established clumps of Hellebores grow and flower satisfactorily, do not disturb them, neither herbaceous Pæonies, and a few other plants that are the better for being let alone. The Doronicums, Heleniums, Chrysanthemums, and others of a rambling or rampant growth, belong to another class, and are the better for being dug up and divided into small pieces annually.

THE HARDY FRUIT GARDEN.

By Chas. Page, Gardeoer to J. B. Fortescue, Esq., Dropmore, Maidenhead.

The Spraying of Fruit-trees.—This work should be undertaken forthwith, as the blossom buds of Pears are commencing to swell. There are several alkali washes in use which are excellent for the purpose if used according to the directions sold with them, and an ordinary spraying syringe may be employed in distributing the wash over pyramids and espaliers; but for standard trees the garden engine is the better appliance, or, failing that, Stone's pneumatic spray-pump. The gardener who distributes the alkali wash should provide himself with india-rubber gloves, as the wash burns the hands, also the clothing. Spraying should be carried out in every garden where hardy fruit is grown, and if this were done annually the Codlin-moth and aphis would work much less harm to our fruit crops.

Strawberries.—Take advantage of dry days to clean up the Strawberry-beds and quarters. It will suffice to use the Dutch-hoe for stirring the land if the soil was lightly dug with a nearly worn out diggiug-fork in the autumn. Young plants set out last autumn must not have the crowns buried in the soil. Alpine varieties, if the seed was sown early last month, will now be above ground, and should be kept near the glass in a warm pit, and he afforded a small amount of ventilation on mild days, so afforded as not to chill the plants.

Hints on work in general.—The buds of Peaches and Apricots are developing fast in this part, rendering it necessary to finish quickly all nailing or tying. These johs finished, syringe the trees with diluted quassia extract. In the case of fruiting trees and bushes, the soil should be lightly turned in, burying all weeds and rubbish, and receive a dressing of fresh loam, pounded mortar-rubble, and plaster, &c., a 6-inch potful of bone-meal being added to each wheelbarrow load. Stake all newly planted trees, putting a simple loop round the stem, and stake with a bolster of moss, cloth, &c., between the bark and the latter. See that every rotten stake is replaced with a new one, and remove from the soil the decayed ends, these being apt to breed fungus, injurious to the roots of the trees. Collect all prunings and dislodged bark from the fruit borders and plantations, and burn them forthwith, so as to minimise the chances of infestation by pests of various sorts.

THE KITCHEN GARDEN.

By John Flemino, Gardener to Sir C. Pigott, Bart., Wexham Park, Slough.

Carrots, &c.—A sowing may now be made on a south border in gardens located on warm soils. Rub the seeds together with silver-sand between the palms, and sow in shallow drills drawn a foot apart, and if the seed be of 1902 harvest sow thinly. Before closing the drills, sprinkle the ground thickly with finely-sifted wood-ashes. Make sowings in cold frames for succession. Excellent varieties are Sutton's Scarlet Intermediate, Veitch's Scarlet Model, and Carter's Early Long Forcing. Sow Turnip-seed on a similar patch of ground, and as the birds are partial to the seeds in the early months whilst other food is scarce, protect the bed by stretching fish-nets over it at a short distance above the surface.

Lettuce.—The plants raised from recent sowings should be pricked off before they get drawn, and placed on slight hot-beds made of tree-leaves, keeping the boxes or pans near to the glass. Make a sowing in a cold frame or on a south border in quantity in accordance with probable requirements. Golden Queen and Harbinger are valuable early Cabbage varieties; Dwarf Perfection should be grown by all those who require a good early Cos variety. If the autumn-sown Lettuces standing in cold frames are likely to be consumed before the spring-sown ones are fit for consumption, replace them with plants from the open beds, planting them in frames standing on a hotbed having top-heat of 55°, and bottom-heat of 70°.

Cabbages.—Sow seeds in pans or boxes, and place in a warm frame or forcing-house, keeping them when the seed germinates close to the glass. The plants raised last month should be pricked off into cold frames, and those that were pricked out last autumn should have the soil between them stirred. Apply water with care, and do not let the plants get crowded together.

Brussels Sprouts.—Another sowing should now be made under glass for succession. Afford a treatment similar to that recommended for the Cabbage.

FRUITS UNDER GLASS.

By T. H. C.

Strawberries.—When the flowers are set, a mean temperature of 65° should be maintained in the Strawberry-house. Keep the plants close to the roof-glass, and syringe them twice a day, particularly the underside of the foliage, which will greatly help in keeping red-spider in check. At every application of water let much diluted liquid-manure be used, and now and then as a change some approved sort of artificial fertiliser. Ventilate upon every favourable occasion, but guard against cold currents of air. Damp down frequently in fine weather, and otherwise provide a moist atmosphere. Succession plants in flower should be fertilised daily, and be afforded a temperature of 50° to 55°. Keep up a succession by placing fresh batches of plants in the starting-pits at fortnightly intervals, the quantity being determined by the demand.

Pot Vines.—If started in November, the flowers of pot Vines will have set, and in some instances the bunches and berries will have been thinned. The crop of bunches should be commensurate with the condition of the plant; a strong cane will bring to perfection a dozen bunches of Black Hamburgh and Foster's Seedling, which are excellent varieties for early crops, and half-a-dozen is a sufficient number for canes to carry that are less strong. Commence to thin early, and in the case of the Black Hamburgh do little more than to remove imperfect berries this time. The bunches of Foster's Seedling will probably have more berries, and should therefore be thinned moro severely. In both cases the size of the matured berry must be borne in mind. Stop all lateral shoots, and keep the foliage clean. Red-spider is often troublesome among early Vines, and the infested leaves must be cleansed with soapy water and a piece of sponge as soon as this pest is observed. The roots being confined to pots, regular applications of manure in some form is necessary. Drainings of the bullock or cowsheds, or sheep or deer droppings steeped in water may he applied alternately. Such manure as Thomson's Vine or Le Fruitier sprinkled over the surface soil and carried down to the roots with tepid water, are of service. Maintain a temperature at night of 65° in fine weather, and by day one of 10° higher. Ventilate upon every favourable opportunity, and close early in the afternoon, allowing the warmth to rise to 80° or 85°. Syringe and damp all walls, paths, and other surfaces.

Succession Vineries.—Fertilise Vines in flower daily at mid-day, and when the air is dry affording ventilation if it be advisable. Tie down lateral shoots slightly, bringing them down to the wires by degrees, and not all on one day, otherwise they are apt to snap off.

The Muscat Vinery.—Muscat of Alexandria and the varieties of it require slightly more heat than other Vines, more particularly when flowering. Vines started early last month should be disbudded, leaving one bearing shoot to each spur, which should be stopped at one or two points beyond the bunch, according to the quantity of space between the main rods and between the spurs. Before the Vines flower, the border should be tested, and if the soil is found to be approaching dryness, apply water mixed with liquid-manure, and sprinkle an artificial manure over the surface. A night temperature of 65° at present, with a rise of 5° to 10° at the flowering stage, and a day temperature of 75° now, and rising 10° to 15° more when in flower, more or less according to the weather, will be suitable. Admit air with a rising temperature early in the forenoons on fine, bright days, this being a very important point during the setting period. Maintain a dry atmosphere to aid in the proper distribution of the pollen.

Grape Room.—Make a weekly examination of Grapes in bottles, and remove those that are decaying. Make sure that the bottom part of the lateral is in contact with the water, otherwise shrivelling of the berries will take place. Maintain a uniform temperature of 45°.

PLANTS UNDER GLASS.

By J. Mayne, Gardener to the Hon. Mark Rolle, Bicton, Budleigh Salterton, Devonshire.

Stove Plants.—February being the best month in which to repot the general stock, an examination should be made of each plant as to whether more space at the root is required to maintain it in a healthy growing state for another season, or whether a top-dressing will suffice after removing a little of the surface soil. In any case, satisfy yourself that there exists perfect drainage. See that clean pots, peat, loam, and leaf-soil are prepared for use, and warmed to the temperature of the house before repotting is commenced. Avoid too large a shift; pots from 2 to 3 inches larger than those the plants are removed from usually suffice for the healthiest specimens; and should there be any plants not thriving satisfactorily, and it is necessary to retain them, most of the old soil should be shaken away or removed with a pointed stick, and such plants may be put into smaller pots, and afforded a gentle bottom-heat for a few weeks. For most stove plants a compost of about equal parts of fibrous loam and peat, and one-quarter of the whole of half-decayed leaf-soil, a little charcoal broken to the size of marbles, and sufficient river or coarse silver-sand to keep the whole porous, will be found suitable. Ixoras, Marantas, and Dipladenias thrive better in a greater proportion of peat, and they enjoy a brisk bottom-heat; but both can be grown and flowered well without bottom-heat. Those plants that show signs of new growth should be the first to take in hand, carefully removing the surface soil and crocks with a pointed stick. Place some rough leaf-soil, moss, or turfy compost upon the drainage material in the new pots, then work down the soil evenly around the ball of roots, making it firm with a potting-stick as filling-in proceeds. Reserve 1 inch space at the top for holding water, but the latter must be afforded with much care for some few weeks after this operation; and it is better to afford rather too little than too much. As the days lengthen and the sun gains more power, a slightly higher temperature may be afforded, viz., 63° to 68° at night according to the weather, rising to 75° or 80° with sun heat during the day. Admit air cautiously for the present, and spray the plants overhead with the syringe not later than 2 P.M

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the Publisher.

Letters for Publication, *as well as specimens and plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Illustrations.—*The Editor will thankfully receive and select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.*

Local News.—*Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return the unused communications or illustrations, unless by special arrangement.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.*

APPOINTMENTS FOR THE ENSUING WEEK.

THURSDAY, FEB. 19—Linnean Society meeting.
FRIDAY, FEB. 20—Surveyors' Inst., Ann. Dinner.

SALES FOR THE WEEK.

MONDAY and FRIDAY NEXT—
Perennials, Herbaceous Plants, Roses, Fruit Trees, &c., at Protheroe & Morris' Rooms, at 12.
TUESDAY, FEBRUARY 17—
Clearance Sale of Nursery Stock at The Nurseries, Shaw House, Melbourne, near Derby, by order of Messrs. J. Salsbury & Son, by Protheroe & Morris, at 11.30.
WEDNESDAY, FEBRUARY 18—
Azaleas, Rhododendrons, Palms, Roses, Herbaceous Plants, &c., by Protheroe & Morris, at 12—Roses. Rhododendrons, Japanese Lilies, &c., at Stevens' Rooms, at 12.30.
FRIDAY, FEBRUARY 20—
Imported and Established Orchids at Protheroe & Morris' Rooms, at 12.30.
(For further particulars see our Advertisement columns.)

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick —39·2°.

ACTUAL TEMPERATURES:—
LONDON.—*February* 11 (6 P.M.): Max. 53°; Min. 46°.
February 12 (Noon): fine; 52°.
PROVINCES.—*February* 11 (6 P.M.): Max. 50°, S.E. England; Min. 43°, N.E. Scotland.

The Royal Horticultural Society.

THE annual meeting of the Royal Horticultural Society on Tuesday last passed off, on the whole, very quietly. If the enthusiasm which characterised some previous meetings as to the erection of a suitable Hall was not so pronounced, it was, at least, obvious that no change had come over the minds of the Fellows, but rather that noisy enthusiasm had given place to fixed determination, which is a much more desirable quality. The criticisms on the design of the Hall were appropriately met by the President, who pointed out that similar criticisms were always forthcoming in the case of proposed new buildings. Philistinism at least knows what it wants, while æstheticism is apt to waste its energies on what is not practical. Suitability to purpose is more important than elegance of design; but there is really no need why the building should be ugly, and there is no reason whatever why the proportions of the building should not be such as to satisfy the artcritic and the requirements of those who have to use the building.

Of Mr. ELWES' criticisms, in so far as they were personal to himself, we have nothing to say; but as regards an amalgamation with the Royal Botanic which he suggested, we must say that the proposal is most distasteful. The Gardens in Regent's Park, indeed, are beautiful, and well suited for their purpose; but the methods pursued by the Society of late years have not been such as to commend themselves to horticulturists, still less to botanists. Moreover, the Gardens are not easy of access, and the Society is, we believe, deeply in debt. These are good reasons why the Royal Horticultural Society, which has higher aims, and has successfully carried them out, should hesitate to enter into any entangling alliance with the sister society.

That the Government has been unjust in utterly ignoring the Royal Horticultural Society, and over-benevolent to the Royal Botanic Society, which has done next to nothing to justify the concessions made to it, shows that either the Government knows nothing or does not realise what the Royal Horticultural Society has done. This, which would be matter of astonishment in a foreign country, is not surprising here, where we look askance on Government assistance—and look with much greater favour on individual enterprise in all cases where that is possible. We could not have a better example of Government bungling than that which is afforded by the treatment of the Royal Horticultural Society and of the Royal Botanic Society respectively.

As to the question of a new garden, Mr. ELWES raised the point whether the Society has the power to take action in that matter without a renewed consultation with the Fellows. Whether this be so or not, it is clear that the whole energies of the Society should, for the present, be concentrated on the erection of the Hall. When that is an accomplished fact, it will be time enough to consider the question of a new garden. We have a garden at present, and we are not obliged to quit it for many years to come. Surely it is best to remain as we are at Chiswick, at least till the new Hall, which is a much more urgent affair, is erected and endowed. That done, it will be time enough to consider the question of a new garden, and to entertain some proposals less preposterous than those which were put forth some few years since. We do not think the Council have the legal right to bargain away the Society's property at Chiswick without communicating with the Fellows; or if they have the right, we do not think it would be at all expedient for them to exercise it.

A dead set seems to have been made in certain quarters against Chiswick in defiance of all tradition and sentiment. The thin end of the wedge has been inserted, and every desire seems to exist to drive it home. The abandonment of Chiswick may sooner or later become inevitable; for our own part, we hope it may be later rather than sooner. There is no reason why, even at Chiswick, a scientific experimental garden should not be established, which would be more conducive to the good of horticulture, than the delusive trials now carried on there. But we are wandering from the urgency of the moment, which is the provision of a proper home for the Society. At present all our efforts should be concentrated on that, and all other matters should be postponed till that is accomplished.

A HARDY, RUBBER-YIELDING TREE.—Eucommia ulmoides was figured and described by Prof. D. OLIVER in HOOKER'S *Icones Plantarum*, tt. 1950 (1891), 2361 (1895), from specimens collected in the Province of Hupeh, China, by Dr. HENRY. It forms a tree 20 to 30 feet high, with a branch-system resembling that of the common Hazel, the deciduous leaves resembling those of the Elm; the flowers small, and unattractive; and the fruit in clusters, samaroid, winged, about an inch long, ¼ inch wide, each containing a single oblong seed. The genus is related to Trochodendron, Cercidiphyllum, and more distantly to Hamamelis. A plant of it was presented to Kew in November, 1897, by M. MAURICE DE VILMORIN, and in the space of four years it has grown from a small plant a foot high to a sturdy bush 7 feet high, and 6 feet through. It has stood the frost of that period in the open air without any protection, and appears to be quite as hardy as the Witch-Hazel. Cuttings of the branches root readily, and large branches of it may be successfully layered. This plant has a special interest from its caoutchouc-yielding property, as will be seen from the following note. "Tu-chung" (Eucommia ulmoides) is a native of Central China, where, according to Dr. HENRY, it is cultivated in the districts of Chang-yang and Patung, in Hupeh, N. lat. 35°; it is also, according to FAROÈS, cultivated in about the same latitude in eastern Sze-chuen, in the district of Tchen-keow-tin. A singular feature about this plant is the extraordinary abundance of an elastic gum in all the younger tissues, especially in the bark, the leaves, and petioles. Any of these snapped across when dry, and the parts drawn asunder, exhibit the silvery sheen of innumerable threads of this gum. The bark itself (to which, according to Dr. HENRY, tonic, invigorating, and other properties are ascribed) is a most valuable medicine with the Chinese, selling at 4s. to 8s. per lb. Further, the leaves are eaten when young, and the fruit is astringent. The merits of the Tu-chung as a caoutchouc-producing plant are entirely unknown; it is, however, deserving of notice. It would be likely to thrive in semi-tropical countries, such as Algeria and Florida, and in the mountainous parts of Southern India and the West Indies; it might also survive the winters of southern Europe (Morris, 1898). Messrs. VILMORIN, ANDRIEUX & Co., Paris, who offer young plants of the Eucommia, give the following particulars in their *Catalogue des Graines d'Orangerie, et de Serre pour* 1903:—"M. J. DYNOWSKI, the eminent Director of the Colonial Garden at Vincennes, has called attention to this tree, which contains in all its parts a notable quantity of gutta-percha of good quality. Unlike all other caoutchouc-yielding trees which are confined to the tropics, the Eucommia may be cultivated with success in a temperate climate. We have a plant which has stood for five years in the open air without protection, which has not suffered in the least, although the thermometer has fallen to —8° Cent. (17° Fahr.), and we believe it will support a temperature still lower than this." Plantations of this tree are being formed in France. There is good reason for believing that it would be worth while to plant it in the warmer parts of the British Islands as a probable source of rubber, and also for its medicinal properties. The Kew plant is in a border near the Economic-house (No. 12). *W. W., Kew.*

LINNEAN SOCIETY.—On the occasion of the meeting to be held on Thursday evening, Feb. 19, 1903, at 8 P.M., the following papers will be read:—1. "Electric Pulsation in Desmodium gyrans," by Prof. J. C. BOSE; 2. "Ceratapis Latania: a Remarkable Aphid," by Miss ALICE L. EMBLETON; 3. "Specialisation of Parasitism in the Erysiphaceæ," by Mr. S. E. SALMON, F.L.S.

BANANAS.—Messrs. ELDERS & FYFFES inform us that, in round figures, the consumption of Bananas during the past two years—i.e., since Mr. CHAMBERLAIN'S effort to aid Jamaica—has risen from 1½ million to 3½ million bunches per annum, which speaks eloquently for the growing popularity of this fruit.

SPRING CLEANING.—Gardeners, as well as other people, experience the necessity for this proceeding, on which account we may be excused for calling attention to the most expeditious and satisfactory method of carpet-cleaning we have ever witnessed. One day last week, seated calmly in the Editorial chair, we were startled by seeing what looked like a fire-hose raised in front of the window at which we were sitting, whilst in the street below was a red vehicle which might readily have been mistaken, for the moment, for a fire-engine. On investigation, the apparent fire-engine turned out to be an exhaust-pump, worked by steam, causing a vacuum in the hose-pipe. To one end of this pipe was attached a flattened nozzle with a horizontal slit. This nozzle was passed lightly over the carpets and over the chairs, curtains, &c., with the result that the dirt and dust—no inconsiderable quantities in Wellington Street, were sucked up through the nozzle into the pipe, and discharged into a receptacle in the vehicle below without a particle escaping into the room. A glass tube inserted into the pipe in its course enabled one to see the dust as it whirled its way from the room to the receptacle below. A strange sight it was! how many bacteria there might have been mixed with the dust cannot be stated. Enough to say, that in the course of an hour, two small offices were to all appearances thoroughly cleansed, without carpet or any article of furniture being moved from its place—think of that, housekeepers! Oh, that the managers of the District Railway would adopt the system, and substitute this speedy and efficient method for the perfunctory and wholly inadequate measures they now employ in cleaning (?) their carriages. Our readers may be assured that this is not a "puff," but a plain statement of experience, and that the work was accomplished by the Vacuum Cleaner Company, of 25, Victoria Street, Westminster, to whom we recommend our readers to apply for a prospectus.

GILBERT NABONNAND.—We regret to have to announce the death at Mandelieu, Alpes Maritimes, in his seventy-sixth year, of this distinguished rosarian. He graduated with GUILLOT of Lyons, and in 1861 he founded a nursery at Golfe Juan, where he cultivated a large number of the exotics which thrive in that climate, but is best known here by his culture of Roses. Among the Roses sent out by him are Bardon Job, Paul Nabonnand, Papa Gontier, and many others.

GARDEN AND FARM PRODUCE BY RAILWAY.—From the traffic superintendent of the Great Eastern Rail. Co., we learn that the number of farm produce boxes forwarded by passenger-train during the past half-year was 71,500; whilst during the same period for 1901 the company conveyed about 65,000—a difference of about 6,500 boxes; and a fair indication of the success attending the scheme.

BLUE HYDRANGEAS. — It appears from a communication of M. ANDRÉ to the *Revue Horticole*, that a certain soil near Angers, consisting of sand and humus, is made use of for the production of blue Hydrangeas with more or less success. The soil has been analysed and found to be chiefly silicious in its nature, but very rich in humus and organic matter, including nitrogen and with a fair proportion of phosphoric acid and iron. Potash and lime are in very small proportions, so that it is recommended to grow the plants in soil destitute of lime.

HONOURS TO HORTICULTURISTS.—From the *Revue Horticole* we learn that M. VIALA, the author of a valuable book on the diseases of the Vine, has been promoted to the grade of Officer of the Legion of Honour. M. DEBRIL and M. OPOIX, of the Luxemburg Garden, have been nominated Chevaliers. M. CROZY, of Hyères, has been appointed Commander of the "Merite Agricole." M. DANIEL, well known for his experiments in grafting, and many other gentlemen not so well known in this country, have been included among the Chevaliers of that Order.

MR. W. BROWNE, after thirty years' service, is retiring on a Civil Service pension from the superintendentship of the Royal Central Parks, London.

STOCK-TAKING: JANUARY.—The Trade and Navigation Returns for the month of January open with an enormous amount of alterations and additions—so numerous, indeed, as to preclude further notice; it is to be hoped they may prove helpful to those whom they concern. The imports for the month have decreased in value by £3,915,833—being £46,226,515, against £50,142,348 for the same period of 1902. The import of flour, grain, &c., decreased by £1,766,113—other dutiable articles by £1,835,815; these and other items including cocoa, £57,499; refined sugar, &c., £1,218,186: unrefined do., £343,344; tea, £355,822. The following items are from the new summary table:—

IMPORTS.	1902.	1903.	Difference.
	£	£	£
Total value ...	50,142,348	46,228,515	−3,915,833
Articles of food and drink—duty free	9,010,031	9,136,016	+125,982
Articles of food & drink—dutiable	11,911,172	8,309,244	−3,601,928
Raw materials and articles mainly unmanufactured	17,850,950	17,070,440	−780,510

We may note, on the subject of timber imports, that for January they amounted to £886,900, against £1,024,253 for the same month in 1902, or a decrease of £137,353. Fruit, roots, and vegetables next claim our attention, and the following table is culled from the figures in Section I. of the Returns:—

IMPORTS.	1902.	1903.	Difference.
Fruits, raw:—	Cwt.	Cwt.	Cwt.
Apples	186,989	297,893	+110,904
Apricots and Peaches	16	8	−8
Bananas... bunches	157,053	170,132	+13,079

"Minus" has certainly won this time; the popular demand seems to have fallen off, in sympathy with unfavourable crop returns. But colonial fruit is now on the seas for our market, and Cape Pears, &c., are to be seen on some stands. The—

EXPORTS

continue to show an increase in value and in variety. The values for the past month foot up at some £24,903,636, against £24,269,174 — an increase of £634,462. It is pleasant to have even a small increase to record in the face of the many sinister rumours afloat.

THE MIDLAND CARNATION AND PICOTEE SOCIETY. — The twelfth annual Report of this Society has just been published, and includes a very complete record of the exhibits at the exhibition in August last. It is proposed to hold the next show in the Botanical Gardens, Edgbaston, about the end of July, or early in August. The schedule of prizes offered is a liberal one, amounting to about £150.

ROYAL BOTANIC GARDEN.—An evening entertainment and concert was recently held in the Royal Botanic Garden, Regent's Park, as a reunion of past and present members of the Society's gardening school. Tea was provided in the classroom, and at its close the tables were cleared, and a capital programme of vocal and instrumental music followed, arranged in two parts, with Mr. E. F. HAWES in the chair. During an interval of the concert, and in suitable terms, Mr. F. J. WINSTONE, on behalf of the students, presented Mr. HAWES with a massive silver cruet set, as a mark of appreciation by the students of the excellent manner in which the work at the school had been conducted during the past year Mr. H. D. STREATFEILD was then presented with a silver-mounted letter-case, after which the concert was resumed and carried on to its close. This is the fifth occasion on which the work of Mr. HAWES has been publicly acknowledged by the various classes of students under his charge at the Royal Botanic Garden school.

—— The Secretary of the Royal Botanic Society informs us that Messrs. BARR & SONS have decided to hold their usual exhibition in the Gardens, from June 29 to July 6.

HOME CORRESPONDENCE.

PHEASANTS IN GARDENS.—In the *Gardeners' Chronicle* for January 27, "Enquirer" asked for directions to prevent pheasants from up-rooting and eating bulbs, &c. Sow "black sulphur" all over the beds, &c.; light sulphur will do, but black is stronger, and less conspicuous. Or water with diluted paraffin, using ½ pint of paraffin in 3 gallons of water. But this method needs to be applied more often than sulphur. *Wm. Lewis, East Sutton Park Gardens, Maidstone.*

—— We have lost thousands of Tulip-bulbs here from the pheasants, and the remedy is not simple. Where pheasants are permitted to make their home in the grounds near the house, they can at no time be depended on to abstain from eating bulbs—Tulips being only one kind—old as well as newly planted bulbs at any season of the year. I have had plants in flower destroyed as well as dormant bulbs. It is, too, a curious fact that pheasants will abstain from Tulips for several years and then suddenly begin to feed on them. They even exhibit a partiality for particular sorts, and some birds develop a stronger liking for the bulbs than others. On this account it was once suggested to kill those addicted to the vice, but that, of course, could not be entertained. Such a nasty preventive as common petroleum poured in such excess on the ground as to kill the bulbs has failed to check the birds. Latterly when planting Tulips and Crocuses, of which they are exceedingly fond, I have planted bulbs and corms at least 10 inches below the surface, and that, so far, has proved too deep for their intelligence. Deep planting, moreover, is a certain deterrent to the ravages of mice, but I cannot say it is equally so to rats. *B.*

—— When pheasants are allowed to acquire a taste for Tulip-bulbs, it is a difficult matter to stop them with anything short of getting the keeper to shoot them at the proper season. Of course, if the damage is being done in the close time, as it mostly is, there is nothing for it but to put wire-netting around the beds, and cover with strong herring or fruit-netting. If in a flower-garden near the mansion, a lot of netting round the beds does not improve the appearance of things, and it is sometimes

advisable to plant Tulips only where they can be protected, without the netting making an eyesore. Here we find pheasants troublesome in the kitchen-garden, with Brussels Sprouts, Broccoli, young Cabbages, Carnations, Aldboro' Anemones, &c.; but the last three or four winters I have found it a sufficient protection to surround the plots or beds with wire-netting 2½ to 3 feet high. Pheasants are stupid in some things; they may be seen to run round the netting, but are chary of flying into the enclosures. Of course, when the men are about, the pheasants have to move on to their own quarters, for, if encouraged to make a sanctuary of the garden, they are sure to cause loss of some one or other of the crops. Some of the plantations of Cabbages and Cauliflowers made in spring are rather large, and I run a line or two of wire-netting down the inside of the enclosure so as to prevent them flying into the larger open spaces. Tulips may sometimes be grown for a number of years without disturbance by pheasants; but if any of the bulbs are left about at lifting time, or laid-in with insufficient covering, some bird of an enquiring turn of mind is sure to find them out, and when another visit is paid it is always in company of other pheasants—then the mischief is done, as they will then search for Tulips, although they may have to dig for them with their beaks to a depth of 4 or 5 inches. *D. M.*

ROYAL GARDENERS' ORPHAN FUND.—Non-subscribing gardeners who may happen to notice in the gardening press that twenty-four candidates are to be elected this year without the trouble of seeking votes, must not think that the funds of the charity are so much better than they were, that their support is not needed, as the reason for this number being put on the fund is that twenty have to retire in 1903, which makes only four fresh candidates for this year; but in 1904 there will only be three retiring, so if there are many candidates for election next year, funds will be much needed. Looking over the annual report for the last year it is surprising to note the indifference of gardeners to this useful fund. How thankful we as a class should feel towards all who subscribe so handsomely to it, i.e., employers of gardeners, nurserymen, and many who live near gardeners and appreciate them as a class. Out of 1600 subscribers only about 300 are gardeners, or 1 to 5, which, I think, is not very creditable to our much-lauded fraternity. Approximately speaking, there are 7,000 head gardeners in the United Kingdom, of whom about 300 support this Fund, leaving 6,700 who are, as we may infer, indifferent to its claims on their pockets. As a test of this indifference, the Committee might this year send out 6,000 collecting cards, stating that they wished all to have an opportunity to give a little in appreciation of the blessings of peace and the recovery of our King, who appreciates a good gardener and a garden. If 5,000 gardeners would start this year with subscriptions of 5s. each, this would, when invested, support two candidates for ever. I need not say that 5,000 or 6,000 collecting cards should bring in a sum of £2,000 at least. Of course, Mr. Wynne would require help to address the above cards. *Jas. Hamilton, Duns, N.B.*

AGAVE AMERICANA.—I was much interested with the supplementary illustration in the *Gardeners' Chroniele*, January 31, and the article on the Agave in Britain. I have observed some good specimens of the Agave in the Scilly Isles, but I was of the opinion they were much too tender for planting out near London. There are two fair specimens planted in a garden near Farnham Station, which up to the present look well, although 17° of frost have been experienced. I shall note their appearance later on, for if they survive I shall try them in different positions in the gardens here. *W. J. P., gr., Frensham, Farnham.*

COLEUS THYRSOIDEUS.—The popularity of this beautiful winter-flowering greenhouse plant has resulted in diverse stories as to its origin. A correspondent asks if it is true that a nurseryman obtained it by crossing a blue Salvia with a Coleus [!]; another supposes that it is a sport from a coloured-leaved Coleus (C. Blumei var.). Whilst the breeder is nowadays doing much for the garden, Nature, unassisted except by the collector, must still be credited with some beautiful recent additions to garden plants, and among them I think this Coleus is one of the most valuable. Its history is as follows: In 1897 Mr. Alexander Whyte, F.L.S., when collecting in British Central Africa, found "a showy blue Labiate" growing in damp situations at 6,000 ft. elevation on the Nyika Plateau, east of the northern extremity of Lake Nyassa. He collected specimens, which were forwarded to Kew, and from them a few seeds were obtained. Shortly afterwards Mr. Mahon, at that time Assistant in the Botanical Department at Zomba, in British Central Africa, sent seeds of the Coleus to Kew, recommending it as a likely garden plant. From these two sources the original stock of plants as obtained at Kew, where they flowered in February, 1898. Plants were then liberally distributed to nurserymen and others. In 1899 the Kew treatment for this Coleus was published in the gardening papers, from which the following extract may be helpful to beginners: "Last summer the plants were grown in a greenhouse, where they formed bushes 2 feet high and wide. This year some plants raised from spring-struck cuttings are thriving planted out in a sunny border, the intention being to lift them and plant them in pots in the autumn." *W. Watson, Kew.*

—— With reference to this species I can endorse all that which Mr. Wadds has written in its favour in this journal, having grown a good batch of the plants last season from seed. The long spikes of vivid blue flowers reminding one of a good variety of Delphinium, make it a great acquisition for conservatory decoration, showing well when grouped together. Our plants were placed in a cool conservatory on December 15, and they are even at this date in fair condition. The longest flower-spikes on our plants are produced by those which are growing in 8-inch pots. When in full growth and showing bloom, I afford the plants manure-water. *H. Stark, Bournemouth.*

DAHLIAS.—Under this heading Mr. Tallack, p. 87, advises the propagation by cuttings of the varieties of which the stock-roots are not sufficient. I understand from this that if there are enough stock-roots they should be let alone, which is decidedly unadvisable, as except in very few cases it repays the gardener for his extra trouble to obtain young plants yearly. I shall not deal with the advantage of the system, this having been done on several occasions. Any further information from Mr. Tallack would be welcomed, as we cannot get too much of it, if it be on sound principles. *C. D. Z.*

STRAWBERRY PLANTS.—If possible, the land to be planted with forced plants, should have been well trenched and liberally manured some weeks previously, light loose soil rarely producing an abundant crop of fruit. I rarely use for forming beds the very early forced plants, except a few of the Vicomtesse for producing a second crop of fruit, but plants which have been only moderately forced and are fairly clean, and these usually fruit satisfactorily. I never care to keep the plants in the pots any longer than is really necessary to harden them off. Plants are sometimes very much injured by being kept in the pots long after having come out of the forcing-houses, and my practice is to stand the pots in any moderately cold place to slightly harden them, and then plant them out, loosening the roots and affording plenty of water before and after planting. If the land has been recently dug, plant low down and make very firm. *H. Markham, Wrotham Park, Barnet.*

SCOTTISH HORTICULTURAL ASSOCIATION.—The membership of the Association is so widespread that it seems hardly fair to debar any of its Scottish members, at least, from competing for any of its prizes, unless these have been specially given with the restrictions annexed. It is desirable to encourage the culture of the Chrysanthemum in and around Edinburgh, but the whole of the members of the Association are, as a body, responsible for the show, and its funds are liable for any deficiency which might occur. No one who knows anything of the Committee of the association will suppose for a moment that they desire "to bring grist to their own mill," but a good many will feel that they have been led into a mistake with the best of intentions. The matter is now beyond recall, but the Committee might well consider whether it would not be preferable another time to open this class to members resident in Scotland, if a restriction is required at all. *Another Country Member.*

WHAT IS A "PACKET"?—What is a "packet" of Sweet Peas, or any other seed? I have sent to one firm, who are advertising Sweet Peas, and find of one variety the packet contains twenty seeds, and of another fifteen, and of another only ten, although each is charged 1s. Take Tomatos again. I see some advertise 200 seeds for 3*d.*, while others charge 1s. to 2s. 6*d.* per packet, and do not give many over 100 seeds. I think it would be much more satisfactory to buyers if advertisers would state the number or the weight of seeds in a packet; or where the same-priced packets vary so much in quantity, would it not be much more satisfactory to buyers, and more honourable, if advertisers would mention that the number of seeds varies, according to circumstances? then purchasers would know better how many to buy. *Seedsman.*

THE FIRST DAFFODIL.—On Sunday, Feb. 8, we had a Daffodil fully in flower in the open. The position is exposed to the sun and wind, is 500 feet above sea-level, and six miles west of Birmingham. This is the earliest date a Daffodil has ever bloomed here. The variety is either N. minimus or nanus; it appears to be between the two, and is a stray plant which has come among some imported (collected) bulbs. *Jno. Pope, The Ericas, King's Norton.*

Obituary.

GEORGE UNDERDOWN.—A familiar figure has passed away with the demise of Mr. George Underdown, who was for nearly forty years head gardener and forester to the Right Hon. Sir John Kennaway, of Escot, East Devon. He took an especial interest in the management and culture of fruit trees, orchards in particular, which have been sadly neglected in Devonshire. As a judge of horticultural exhibits he was in much request, and was a member of the Devon and Exeter Horticultural Society's Committee. A most genial man, a faithful and valued servant, he will not only be greatly missed by his employers, but by a number of friends, who showed by their presence at the graveside on Monday, February 2, the respect in which he was held. He was sixty-four years of age, and has left a large family.

B. JOHNSON.—We learn with regret of the death on the 8th inst. of Mr. B. Johnson, for upwards of forty years head gardener at Swakeleys, Uxbridge, Middlesex, after a very short illness. He was greatly respected by all in and around the district, and enjoyed a high reputation among the gardening fraternity. He leaves a widow, who is at the time of writing seriously ill, and a grown-up family.

JAMES GLAISHER.—In his ninety-fourth year, the career of James Glaisher, the ardent meteorologist, the intrepid aëronaut, the zealous Chairman of the Palestine Exploration Fund, was brought to a close. He died on the 7th inst. at Croydon, and was buried at Shirley on the following Wednesday. Most readers are aware of his labours as a meteorologist. Observations and computations in the observatory did not satisfy him; he must extend his researches into the higher reaches of the atmosphere. To this end he made repeated ascents, but that on Sept 5, 1862, was the most remarkable. On that occasion, he and Mr. Coxwell ascended to a height of seven miles; a temperature below zero was experienced at an altitude of 5 miles, but above this the cold became so intense that Mr. Glaisher was no longer able to read his instruments, and became unconscious. His companion, Mr. Coxwell, was only in a slightly less degree incapaci-

tated; his hands were frostbitten, but he contrived to seize a rope with his teeth. The valve was thus opened, the gas escaped, and the balloon speedily descended into warmer regions, till it ultimately reached the ground near Ludlow. For many years Mr. Glaisher contributed the weather-table to the columns of this Journal, and his records and observations were in some respects more serviceable to our readers than those now published by the Meteorological Office. It was Mr. Glaisher also who, as a member of the Scientific Committee, collated and rendered available for comparison the meteorological observations made at Chiswick by the late Robert Thompson, for forty-three years of which weekly use is made in our columns, and in our annual Almanac. These records were printed in the *Journal of the Royal Horticultural Society* in South Kensington times, when much was done under unfavourable circumstances, to foster the interests of horticulture. These tables form one of the most complete records of the kind in existence, only comparable, we believe, with the Greenwich records.

ROBERT MACKELLAR.—We have much regret in announcing the death on January 28 of Mr. MacKellar, for very many years head gardener at Abney Hall, near Cheadle, Staffordshire. Deceased was a good gardener, and was widely respected. He has corresponded with this Journal frequently during the past quarter of a century.

FIG. 45.—LOURYA CAMPANULATA, AWARDED A BOTANICAL CERTIFICATE ON TUESDAY LAST. (SEE P. 108.)

SOCIETIES.

ROYAL HORTICULTURAL.

FEBRUARY 10.—There was a very nice display at the fortnightly meeting of the Committees of this Society on Tuesday last, in the Drill Hall, Buckingham Gate, Westminster. Sufficient Orchids were forthcoming to furnish one of the long central tables, in addition to a number of novelties that were arranged upon the usual cross table. The awards to novelties included two First-class Certificates and four Awards of Merit. An Odontoglossum from NORMAN C. COOKSON, Esq., excited the greatest interest, and was admired by everyone.

The FLORAL COMMITTEE recommended but one award to a novelty, namely, a First-class Certificate to a new alpine species of Saxifraga from Albania. The groups before this Committee included Palms, various ornamental-foliaged plants, Chinese Primulas, Cyclamens, hardy flowers, &c.

No novelty gained an award from the FRUIT AND VEGETABLE COMMITTEE, but there were two excellent collections of Apples staged, one from J. B. FORTESCUE, Esq., Dropmore, and another from Messrs. GEO. BUNYARD & Co., Maidstone.

The annual general meeting of Fellows was held at o'clock in the canteen, which was packed to the uttermost extent. At this meeting there were elected seventy-eight new Fellows to the privileges of the Society. The attendance at the Hall throughout the day was unusually large, and most of the members of the various Committees were present.

Floral Committee.

Present: Geo. Bunyard, Esq. (in the Chair); and Messrs. J. Cheal, Geo. Woodward, W. Bates, S. Mortimer, A. Dean, W. Pope, W. Fyfe, H. J. Wright, H. Markham, Geo. Kelf, G. T. Miles, F. Q. Lane, G. H. Maycock, G. Norman, A. H. Pearson, W. Poupart, and J. Willard.

Messrs. W. BULL & SONS, 535, King's Road, Chelsea, exhibited a group of Palms in which a considerable number of species were represented. We noticed Phœnix hybrida = P. dactylifera × farinifera, P. senegalensis, Calamus flagellum, Latania Commersoni, Chrysalidocarpus (Areca) lutescens, Thrinax parviflora, Cocos Weddelliana, Livistona chinensis, Wallichia densiflora, Cocos plumosus, Pritchardia pacifica, Thrinax radiata, Ptychosperma Macarthuri, Pinanga maculata, Livistona Woodfordi, L. Wigani (Silver-gilt Banksian Medal).

Mr. H. B. MAY, Dyson's Road Nursery, Upper Edmonton, London, N., staged a group of plants, in which Adiantum tenerum Farleyense was conspicuous, as well as other good Ferns, including Polypodium Mayii; also choice varieties of Codiæums, as Alexander II., a broad-leaved variety of bright colour; Warreni, Countess, ruberrimus, &c.; Davallia tenuifolia Veitchi, Aralia Chabrieri, and Hydrangea japonica variegata. Cordyline (Dracæna) His Majesty is a bright-coloured plant of nice habit, and the variety Edmontoniensis has narrower leaves of rather deeper colour (Silver Flora Medal).

Messrs. THOS. S. WARE, Ltd., Hale Farm Nurseries, Feltham, London, exhibited quite a bright bank of hardy plants in flower in pots. There were many varieties of Narcissus, and in addition Dielytra spectabilis, Hyacinthus azureus, Muscari botryoides, &c.; Hepatica triloba in variety, Iris histrioides, I. sindjarensis, &c.; Snowdrops, Crocuses, Cyclamen Coum album, &c. (Silver-gilt Banksian Medal).

Mr. JOHN RUSSELL, Richmond Nurseries, Surrey, exhibited a group of shrubs in pots, and these were interspersed with forced flowering shrubs. Amongst these latter were large plants of Daphne Mezereon and Prunus triloba. The shrubs included tree Ivies, Hollies, young Conifers, Cotoneaster microphylla, Aucubas, Eurya, Berberis Beali, &c. (Silver Flora Medal).

Messrs. JAS. VEITCH & SONS, Ltd., Royal Exotic Nurseries, King's Road, Chelsea, again exhibited a number of fine plants of the new flowering Coleus, C. thyrsoideus, in full flower; also a group of strong flowering plants of Primula × Kewensis, a hybrid from P. floribunda and P. verticillata, see fig. 63 in *Gard. Chron.*, March 31, 1900. For general purposes it is similar to P. floribunda, but has a much stronger habit, and produces its yellow flowers in great profusion. Flowers were also shown of a good strain of Chinese Primula (Silver Flora Medal).

Messrs. H. CANNELL & SONS, Swanley, Kent, made a display of Primula sinensis varieties, and showed some varieties of the stellata type in good condition. One of the best of these was named Fashion, and had a profusion of good-sized flowers of rich pink colour, with a white eye; The Queen and Cannell's White are also good varieties of the same section. Amongst the florist's or older strain were Eynsford White and Eynsford Purple, My Favourite (pink), alba lutea, Pink Queen, Swanley Blue, H. Cannell, &c. (Silver Banksian Medal).

Carnations were again exhibited by Messrs. W. CUTBUSH & SONS, Highgate, London, who had fine cut flowers of new and choice varieties they have shown previously, including the excellent Mrs. S. J. Brookes, white; Mrs. T. W. Lawson; Sir Hector MacDouald, pink; and Viscount Kitchener, white, with scarlet markings.

Mr. J. R. BOX, Croydon, exhibited a small group of Cinerarias, and some fine plants about 3 feet high of Begonia Gloire de Sceaux. The large rich pink-coloured flowers of this variety, and the dark, metallic-looking foliage, make it exceedingly decorative.

Three seedling varieties of Hippeastrum were shown by Mr. E. Hill, from Lord ROTHSCHILD'S garden at Tring Park, Tring. They were not without merit, but failed to secure a distinctive Award.

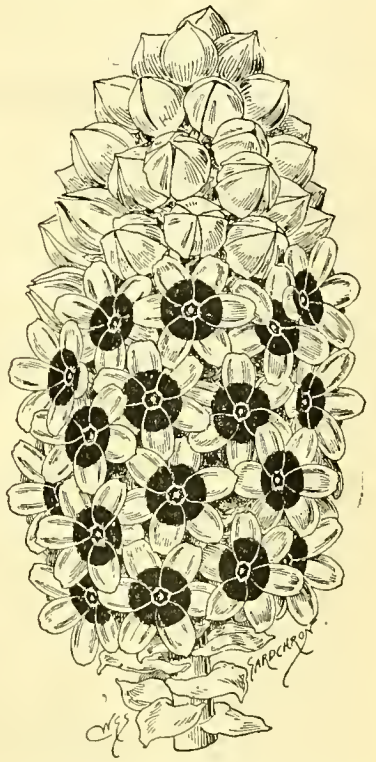

FIG. 46.—INFLORESCENCE OF LOURYA CAMPANULATA. (SEE P. 108.)
(Flowers snow-white, with a purplish centre.)

Messrs. R. WALLACE & Co., Kilnfield Gardens, Colchester, exhibited a small collection of early-flowering alpines—bulbous and other, in nice bloom generally. There were among them Iris Tauri, I. histrioides, and I. stylosa speciosa; a panful of Hepaticas, including the single-flowered white variety, Adonis amurensis, Muscari azureum, Anemone blanda, Primula megasæfolia, Colchicum libanoticum, &c.

Lord JERSEY, Osterley Park, Isleworth (gr., Mr. F. Hawkes), showed a gay looking group of Cyclamens in variety, having Euphorbia Jacquiniæflora, as cut shoots in bloom, and pyramidal plants in the background of Begonia Gloire de Sceaux (Vote of Thanks).

Messrs. SUTTON & SONS, Reading, showed some forty plants of their new Imperial Strain of Cinerarias, consisting of large-flowered corymbs, and in some instances of fairly refined forms and new tints in so far as light blue and pinks are concerned. As regards the individual flowers, we may expect to find in the course of time considerable improvement, but in stature, size of corymb, and general vigour, nothing would seem to be called for (Vote of Thanks).

Messrs. HUGH LOW & Co., Bush Hill Park, London, N., made a pleasing exhibit of forced plants, including

Indian Azaleas, Simon Marner, double flowered, pink; Deutsche Perle, the old Vervaeniana, and Professor Wolters; Toxicophlœa spectabilis, Lilac in variety; and Genistas, Cyclamens, Lily of the Valley, Funkia subcordata, Epacris, mixed with dwarf-growing species of Ferns forming the setting, and a few Palms the background to the group.

Messrs. BARR & SON, 11, 12, and 13, King Street, Covent Garden, exhibited a small collection of hardy flowering subjects, including Helleborus guttatus sub-punctatus, antiquorum roseum, H. Olympicus, flower white and green; H. niger, with a faint pink flush on the petals that is not common; Galanthus Elwesii, prettily in bloom; Cyclamen Coum album, C. C. rubrum, Narcissus cyclamineus major, and Snowdrops set in a bed of moss. There were forming part of the exhibit a plant of Daphne Mezereum album, a branch of Forsythia suspensa in bloom, tufts of Erica carnea, Tazetta Narcissus, the bulbs closely packed together in shallow bowls, &c.

Mr. JOHN MAY, Gordon Nursery, St. Margarets, Twickenham, showed Cyclamen grandiflorum in white, crimson, rose, pink, rosy-purple, and other shades of colour, the flowers being mostly of large size, and thrown up well above the leaves. The plants were admirably grown and flowered (Silver-gilt Banksian Medal).

Awards.

Lourya campanulata (figs. 45, 46).—A nice plant of this curious Hæmadoraceous genus, from Cochin-China was shown by Mr. LEOPOLD DE ROTHSCHILD, Gunnersbury House, Acton (gr., J. Hudson). In general appearance, the plant resembles an Aspidistra, but the flowers although produced at the base like those of Aspidistra, are larger and more showy, the inflorescence being also more elongated. The fruit is a blue berry, and being produced in considerable clusters is very effective (Botanical Certificate).

Saxifraga Grisebachii.—This pretty little alpine species, newly imported from Albania, was shown by Mr. G. REUTHE, Wensleydale, Hanworth Road, Feltham, and by Messrs. R. VEITCH & SONS, Exeter. The plants are very dwarf, and the flowering growths apparently about 3½ inches high. These growths and the bracts are very hairy, and reddish-purple in colour. The tiny flowers have red petals (First-class Certificate).

Orchid Committee.

Present: Harry J. Veitch, Esq., in the Chair; and Messrs. Jas. O'Brien (Hon. Sec.), Norman C. Cookson, de B. Crawshay, H. Ballantine, W. Cobb, W. A. Bilney, E. Hill, Francis Wellesley, H. T. Pitt, J. W. Potter, H. A. Tracy, H. J. Chapman, A. A. McBean, T. W. Bond, M. Gleeson, J. W. Odell, W. Boxall, W. H. Young, W. H. White, F. J. Thorne, F. W. Ashton, H. Little, and J. G. Fowler.

There was a very fine show of Orchids, an unusually large number of groups being staged, and over fifty subjects entered to go before the Committee. But among all the beautiful things shown, the phenomenal blotched Odontoglossum crispum Cooksoniæ, shown by NORMAN C. COOKSON, Esq., formed the centre of attraction. It was generally conceded by experts that it was without exception the finest Odontoglossum of its class ever shown. The Committee awarded it a First-class Certificate (see Awards) (fig. 47).

Sir TREVOR LAWRENCE, Bart., Burford (gr., Mr. W. H. White), staged a fine group, that consisted largely of the fine hybrid Dendrobiums raised at Burford. Among he many fine plants heavily laden with flowers were Dendrobium × Juno, D. Wiganiæ and its fine yellow variety xanthocheilum, D. × xanthocentrum pallens, D. × Cybele, D. × Curtisii, D. × Hebe, Sophro Lælia × Psyche, the yellow Sophronitis Rossiteriana, Lælio-Cattleya × Adolphus, L.-C. Mrs. Gratrix, and other showy kinds; and some botanical Orchids grown into charming specimens (Silver Flora Medal).

Captain G. L. HOLFORD, Westonbirt (gr., Mr. H. Alexander), showed a group of rare and well grown Orchids, including the handsome Odontoglossum × loochristiense "Lady Victoria Grenfell," which had previously secured an award; Lælio-Cattleya × Afterglow, a fine bright yellow flower, with many on a spike; L.-C. × Doris; Miltonia × Bleuana grandiflora, very large, and nearly white; Lycaste × Mary Gratrix, with seven fine ruby-tinted flowers; Selenipedium × Schroderæ candidulum, Odontoglossum × Adrianæ, and O. × Wilckeanum, both fine (Silver Flora Medal).

H. T. PITT, Esq., Rosslyn, Stamford Hill (gr., Mr. Thurgood), showed a fine group of Odontoglossums, backed by seven fine plants of Oncidium splendidum. The group included Dendrobium atro-violaceum, D. pallens, Epidendrum × Endresio-Wallisii, Lycastes, Cœlogynes, fine forms and others; besides the singular-looking Bulbophyllum rufinum, and B. Pittianum. Of the Cypripediums, C. × Ajax and C. × Stanley James Pitt were new, distinct and good; Cattleya Trianæ, Phalænopsis, and Vandas were represented (Silver Flora Medal).

J. COLMAN, Esq., Gatton Park (gr., Mr. W. P. Bound), had an effective group, principally of white forms of Lælia anceps and hybrid Dendrobiums. Among the former were noted the rare L. a. Waddoniensis, and of the latter D. × Ainsworthi Colmani was the best, its fine flowers being heavily tinted with purple, and the labellum with dark claret colour. Masdevallia × Courtauldiana, M. tovarensis, and various Cypripediums were also good (Silver Flora Medal).

Messrs. SANDER & SONS, St. Albans, secured the premier award for groups, viz., a Silver-gilt Flora Medal for a good display of fine subjects. There were three very fine forms of Odontoglossum × Wilckeanum, named respectively Fascinator, Illuminator, and Rex, the last-named taking the fancy of the Orchid Committee most, and securing an award. Among the Cypripediums were the new C. × Illustre (Lathamianum × nitens, Sanders' variety), a very handsome flower, with a fine white dorsal sepal, having a broad chocolate-purple band; C. × Ilione (Lynchianum × insigne Harefield), very distinct. At the ends of the group a number of fine forms of Phaius × Norman, P. × Marthæ, and other hybrids, and a profusely-flowered Pleurothallis Roezlii, with many racemes of flowers, were displayed.

Messrs. J. VEITCH & SONS, Chelsea, S.W., showed a group of hybrid Cypripediums, &c., including some fine forms of C. × Hera, Euryades, C. × Leonidas, C. × Lathamianum, C. × Actæus, hybrid Lælio-Cattleyas, Dendrobiums, &c. (Silver Flora Medal).

Messrs. HUGH LOW & Co., Bush Hill Park, staged a group of Dendrobiums, Odontoglossums, Cypripediums, &c. C. × Olivia was finely represented, also C. × orphanum and C. × Euryades (Silver Flora Medal).

FRANCIS WELLESLEY, Esq., Westfield, Woking (gr., Mr. Gilbert), showed his fine Lælio-Cattleya × Wellsiana magnifica (see Awards), Cattleya chocoensis, Westfield variety, a very pretty white-petalled flower, and a good Cypripedium × Hera Euryades.

NORMAN C. COOKSON, Esq., Wylam, showed Phaio-Calanthe × Ruby; and a hybrid Calanthe, flowering in eleven months from the sowing.

F. A. REHDER, Esq. (gr., Mr. Norris), sent Cypripedium × Ianthe superbum, and a neatly formed cross, named C. × Tia, whose flower is between it and C. exul.

Messrs. CHARLESWORTH & Co., Heaton, Bradford, showed Cattleya × Enid (Mossiæ × Warscewiczii), intermediate between the parents; Cypripedium × Hera Madeline, with a very handsome dorsal sepal; Miltonia Endresii, Cattleya Trianæ delicata, the fine yellow and brown Odontoglossum × Harryanum triumphans, Lælio-Cattleya × Sunray, L.-C. × luminosa, Miltonia × Bleuana grandiflora, &c.

M. LOUIS FOURNIER, Marseilles (gr., Mr. Cleverley), sent a flower of fine form of L.-C. × luminosa.

Sir F. WIGAN, Bart. (gr., Mr. W. H. Young), showed Cypripedium × Eira (Chamberlainianum × concolor).

Messrs. STANLEY, ASHTON & Co., Southgate, showed Odontoglossum × Ruckero-triumphans, a pretty hybrid with a yellow ground and reddish-brown markings.

W. M. APPLETON, Esq., Weston-super-Mare, sent Cypripedium × Lady Roberts and Cattleya × Trianæ, Appleton's variety. Mr. H. WHATELEY, Kenilworth, showed hybrid Cypripediums. Mr. ALEX. WRIGHT, Reading, showed Cypripedium × Mrs. A. W. Sutton.

DE B. CRAWSHAY, Esq., Rosefield, Sevenoaks, showed a fine plant in flower of Odontoglossum triumphans, grown in a clear glass pot for two years, its fine root development being visible and very interesting.

Mr. JAS. DOUGLAS showed varieties of Lælia anceps. Sir WILLIAM MARRIOTT (gr., Mr. Denny), sent a good spike of Dendrobium spectabile.

Awards.

FIRST-CLASS CERTIFICATES.

Odontoglossum crispum Cooksoniæ (see fig. 47), from NORMAN C. COOKSON, Esq. (gr., Mr. H. J. Chapman). The finest blotched Odontoglossum yet seen, and a model flower in every respect. Flower (one of six) of a thick substance, four inches across, and each petal 1¾ inch wide. All the segments were fringed, and heavily tinged with purple at the back. The face of the flower presents a small pure white area round the column, and the margins of each segment are white tinged in places with purple, the remaining two thirds of the flower are taken up by large purplish-red blotches, the larger being surrounded by smaller blotches, but divided only from the larger ones by thin lines of the white ground colour. It is impossible to imagine an improvement on this extraordinarily beautiful Odontoglossum.

Dendrobium × *Wiganiæ xanthocheilum*, from Sir TREVOR LAWRENCE, Bart, Burford (gr., Mr. W. H. White). A remarkable and beautiful departure from the ordinary forms. Flowers bright yellow, the lip having a maroon disc.

AWARDS OF MERIT.

Odontoglossum × *loochristyense, Lord Howick*, from Captain G. L. HOLFORD (gr., Mr. Alexander).—A very pretty and distinct form, with bright yellow sepals and petals, each bearing one or two large brown blotches, the petals having a white base; lip white, with brown blotches and yellow crest.

Lælio-Cattleya × *Wellsiana magnifica* (L. purpurata × C. Trianæi), from FRANCIS WELLESLEY, Esq. (gr., Mr. Gilbert).—A very showy hybrid, with large flowers, the sepals and petals of which are delicately veined and tinged with purple; front of lip dark ruby-purple, disc tinged with yellow, and bearing fine dark lines.

Cypripedium × *Minos Young's variety* (Spicerianum × Arthurianum), from R. BRIGGS-BURY, Esq., Bank House, Accrington (gr., Mr. Wilkinson).—Dorsal sepal circular, white, with a greenish base, and showy markings of dotted purple lines. The rest of the flower is yellow, tinged with brownish-purple; a very handsome hybrid.

Odontoglossum × *Wilckeanum Rex*, from Messrs. SANDER & SONS.—Flowers cream-white, the petals blotched with red-brown in oval rings, the sepals more heavily marked with transverse bars of red-brown. Lip white, with reddish-brown spots and yellow crest. The fine plant made a handsome object, bearing sixteen flowers on the spike.

CULTURAL COMMENDATION.

To Mr. W. H. White, gr. to Sir TREVOR LAWRENCE, Bart., for a large panful of Epidendrum polybulbon, finely flowered; and a similar specimen of its variety, luteo-album.

To Mr. Alexander, gr. to Captain HOLFORD, for Lycaste × Mary Gratrix, with seven flowers.

BOTANICAL CERTIFICATE.

Bulbophyllum suavissimum, from Sir TREVOR LAWRENCE, Bart. (gr., Mr. W. H. White).—A gem of a botanical Orchid, with eighteen spikes of small, yellowish, fragrant flowers.

Fruit and Vegetable Committee.

Present: W. Marshall, Esq. (chairman); and Messrs. Geo. Nicholson, R. Dean, Jno Green, Amos Perry, J. F. McLeod, Jas. Hudson, J. Jennings, G. Reuthe, W. Howe, C. R. Fielder, Chas. Dixon, C. J. Salter, W. Bain, Chas Jeffries, Herbert J. Cutbush, R. W. Wallace, W. Cuthbertson, R. Wilson Ker, W. P. Thomson, E. H. Jenkins, W. J. James, H. Turner, and Geo. Paul.

A collection of thirty-six dishes of Apples, shown by J. B. FORTESCUE, Esq., Dropmore, Maidenhead (gr. Mr. C. Page) was rewarded by an award of a Silver Banksian Medal. There were fine specimens of King of the Pippins, Annie Elizabeth, Duchesse de Bordeaux Blenheim Orange, and Cox's Orange Pippin, &c.

Messrs. GEO. BUNYARD & Co., Royal Nurseries, Maidstone, showed a remarkable collection of 100 dishes of Apples and a few stewing Pears. The collection included the very best varieties in commerce, and nearly all of them were first-rate examples, of large size and high colour. Some of the most noteworthy were Vicar of Beighton, Wealthy, Cox's Orange, Blenheim Pippin, Beauty of Kent, an excellent Apple, possessing fine flavour at the present season, a good grower, and free cropper; King of Tomkin's County, Bow Hill, similar to large fruits of King of the Pippins, one of its parents; Warner's King, Bess Pool, Royal Jubilee, a good-looking Apple, possessing much merit; Lord Burghley, Gascoigne's Scarlet Seedling, Newton Wonder, Washington, &c. (Hogg Medal).

Messrs. SUTTON & SONS, Reading, showed examples of Sutton's Hardy Sprouting Kale, the stems being abundantly clothed throughout their length with close sprouting growths.

Annual Meeting.

The annual general meeting of this Society was held at the Drill Hall, Buckingham Gate, Westminster, on Tuesday last. Sir TREVOR LAWRENCE, Bart., presided over a large assemblage of the Fellows.

The Secretary (Rev. W. WILKS), having read the notice convening the meeting, and the minutes of the previous annual meeting, the President announced that seventy-eight new members had been that day nominated. These were duly elected.

Mr. ALEX. DEAN next proposed a vote of thanks to the retiring members of the Council: Mr. J. T. Ben-

nett-Poë, V.M.H., Mr. Wm. Marshall, and the Rev. H. A. Berners. He bore testimony to the valuable services rendered by those gentlemen.

Mr. Geo. Paul seconded. He was sure the Society would miss the members, but he was glad that Mr. Marshall had been re-elected, and that he would resume for the fifteenth year the Chairmanship of the Floral Committee. The motion having been carried—

The Secretary announced that the following gentlemen had been duly nominated to fill the vacancies upon the Council:—The Right Hon. Lord Redesdale, The Hon. John Boscawen, Mr. William Marshall. The following had been nominated for election as Vice-Presidents:—The Right Hon. Joseph Chamberlain, M.P.: The Right Hon. The Earl of Ducie, The Right Hon. Lord Rothschild, Sir Frederick Wigan, Bart; Sir John T. D. Llewelyn, Bart. The following had been nominated for election as officers:—Sir Trevor Lawrence, Bart., V.M.H., President; J. Gurney Fowler, Esq., Treasurer; Rev. W. Wilks, M.A., Secretary; Alfred C. Harper, Esq., Auditor.

The President said that as no other nomination had been received, there was no occasion under the New Charter to issue a balloting sheet.

The Report.

The President said the next business was to move the adoption of the report. He did this with very great pleasure, because he thought there must be very few people connected with the Society who could fail to feel that the Society had not only entered on an era of prosperity, but that there appeared to be every probability that the era of prosperity would continue. Last year the number of new Fellows elected, between 1,100 and 1,200, was the largest number that had ever been elected in one year, and already this year they had, including those mentioned that day, 212 new Fellows. He thought there was reason to hope that this, the hundredth year of the existence of the Society, would show an accretion of new Fellows exceeding those of any previous year. All interested in horticulture heartily wished that this might be so. His recollection went back to his own very early days, when Chiswick was at the height of its success and prosperity. Chiswick became the resort of the fashion of the metropolis, and he had always thought, and he believed it was the experience of most people, that these institutions and societies, as well as other matters, which were taken up by people of fashion were generally let down quite as readily as they were taken up. He thought with regard to their Society they had every reason to hope that this might not be so. Since they had left South Kensington the condition of the Society had greatly improved, until they were now within measureable distance of having 7,000 members enrolled on the books of the Society. He did not think that there was another society in the least degree claiming to be a scientific society that numbered so many members; and he attributed that, not to the efforts of the Council, for that he did not do, but to the fact that the Society had acted steadily in the promotion of the art and science of horticulture, by which it had gathered round it a very large number of those who were interested in the science of horticulture. It was impossible to attend the fortnightly shows without seeing that the people who attended were not merely a fashionable crowd. Of course, they saw many smart toilettes, and they also saw remarkably nice-looking members of the gentler section of the British race. They would be very sorry not to see them; but, on the whole, it was quite evident to anyone who observed, that the majority of those who attended did so as a matter of business, on account of their great interest in the promotion of horticulture—people who wished to see how they could improve their own gardens, and add to the horticultural treasures which they already possessed. It should not be forgotten that their work formed one of the important industries of the kingdom. They not only derived great pleasure from their English gardens, but they also derived a large portion of their food from the plants and vegetables cultivated in this country. As to that point, he would allude to the show of fruit and vegetables to take place at Chiswick in the autumn, and from which he hoped forgreat results, not only as to the production of vegetables, but as to the perhaps more important branch of the question, the cooking of vegetables—an art which was rather neglected in this country.

In going through the report, it was not necessary to say very much. The second paragraph contained a reference to legal expenses. The total sum was not large—only £61. There was always a tendency in regard to a place like Chiswick to an increase in the cost. He did not say that because it was Chiswick; but there was always a tendency on the part of a garden belonging to a society like theirs to increase in cost. The cost of labour had increased, and owing to increase of membership, there was a growing increase in the cost entailed by the distribution of plants; and latterly there had been a decrease in the result of the sales of produce, owing to unsatisfactory climatic conditions.

Going on to paragraph 6, they had had during the past year the great advantage of having had a very important and successful subsidiary show—subsidiary to the great Temple Show—in the grounds of their friend, Lord Ilchester, a member of Council. He was sure they would allow him to express the thanks of the Society to Lord Ilchester for the kindness and generosity with which he had placed his grounds at their disposal. They had every reason to believe that the show at Holland House would have been a financial success, owing to the great attractiveness of the place, and it was now felt that, but for the greatly lamented illness of the King, that would have been the case. The Society made a small loss, but Lord Ilchester had been kind enough to again place his grounds at their disposal this year, and he had no doubt they would have a very successful show.

Referring to paragraph 7, he thought it was very satisfactory that the subsidiary horticultural societies had shown their attachment to the parent Society. It was evidence of the good feeling which existed between these societies and the parent Society, and it was always the pleasure of the latter to promote their interests.

With regard to Paragraph 9, it was necessary to leave the Crystal Palace, because it was felt that vegetables should be represented at the shows, but the Crystal Palace authorities had set their faces against that. He was not specially a grower of vegetables, but he took a deep interest in them, and he could not forget that at the last Chiswick show, when they had a beautiful display from Her late Majesty's gardens at Frogmore, his own gardener, in his small way, showed one hundred different varieties of vegetables and other culinary products of excellent quality. He hoped the Fellows would help the Society in this important matter. The Council did not like to unnecessarily beg from the Fellows, but any financial support they could give to the Prize Fund for fruit and vegetables would be very thankfully received.

"The Journal."

Not wishing to take up their time, he would pass to paragraph 17, which referred to one of the most important features of the Society. It was perfectly impossible, he believed, to speak too highly of the admirable way in which their Secretary conducted the *Journal* of the Society. It was a *Journal* of which any Society might be proud, and it was gratifying to know that during the last two or three years, in addition to other evidence from abroad, they had had applications from foreign Societies to exchange publications. That showed perfectly clearly to those who could read between the lines, the important place occupied by their *Journal*, and they should not forget that this was mainly, almost entirely, owing to the labours of their Secretary. Perhaps most gentleman would think he was speaking too strongly, but he would say that if the Secretary could not do a thing himself, he was always able to put his finger on the right man to do the work. Of course, the *Journal* was an expensive item. It cost now about £1,800, and it could hardly be anticipated that this cost would be reduced, but he was quite sure that no Fellow of the Society grudged the cost of the *Journal*.

Paragraph 19, as to the numerical growth of the Society, was very satisfactory; and from the next paragraph, it would be seen that already 118 country Societies had availed themselves of the opportunity to affiliate themselves with the parent Society under the scheme put forward a year or so ago. That he considered showed their unmistakable appreciation of the efforts of the parent Society to help them in various ways.

The Hall.

Coming next to paragraph 21 (relating to the new Hall), he said that up to the present, so far as he could perceive, the views of the meeting had been entirely in accordance with the opinions he had expressed, and he did not himself see why they should not be so till the close of the meeting. The position as to the new hall in regard to which important steps had been taken to realise the desires expressed at the last general meeting, was this:—They had had offered to them by their friends, as a free gift, without conditions and without control, a sum of nearly £23,000, that would help them very largely to achieve the object of the Society—the

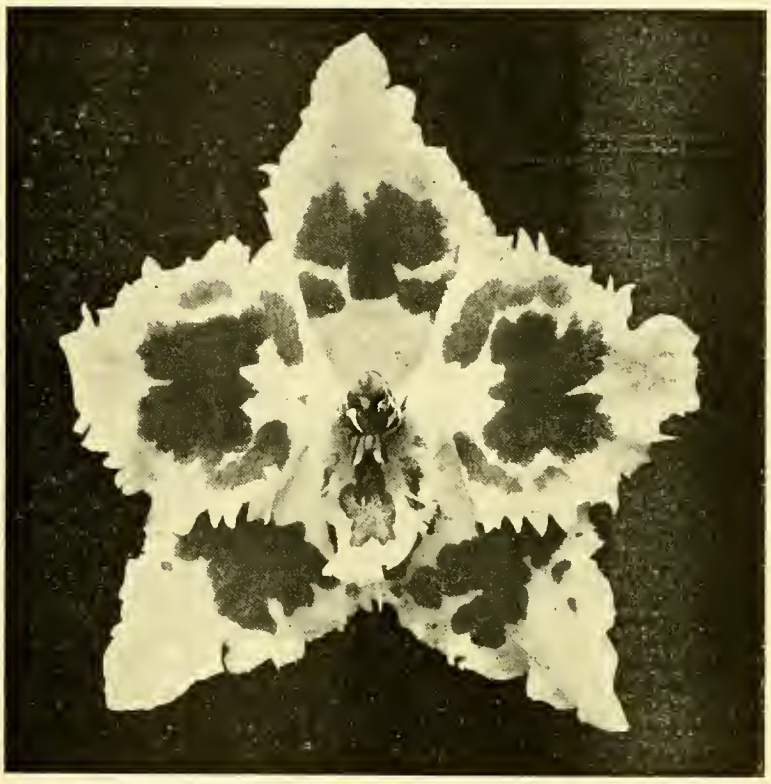

Fig. 47.—Odontoglossum crispum Cooksoniæ, awarded a first-class certificate on Tuesday last. (see p. 108.)

provision of a proper place to display the plants and flowers sent up to the Society's shows. It was quite impossible for anyone to walk through that Drill Hall, where they had got a very excellent show that day, without seeing that it was a place in no way suited for the exhibition of plants and flowers; and he confessed that he was not at all surprised when the Society, by an overwhelming majority, and with only three dissentients in a very full meeting, decided in favour of obtaining a new Hall. As to the designs, of course a great many criticisms had been received in connection with the project, and after a long experience he never anticipated anything else. He had seen the same thing in connection with other buildings. He did not suppose any building in the world had been more adversely criticised than the Houses of Parliament; and almost the same could be said of the new Foreign Office, which was built by one of the most eminent architects of the age, Sir Gilbert Scott. Then they would recollect that there was a perfect outcry against the decorations of St. Paul's Cathedral, which were designed by Sir William Richmond. Then they had seen a great deal of correspondence about the new Vauxhall bridge, which had been described as a deplorably inartistic and disgraceful affair. He was sorry to say that he was not an architectural expert at all. Of course, he liked a thing to look well, but he liked it to be convenient and useful for the purpose for which it was required. If they succeeded in getting that, he was afraid the critics must allow the Council to confess that it might possibly be ugly. He did not know, not being a judge; but he knew what he admired, and he also knew that what many people admired he did not. He had been asked to admire a magnificent building close by—he meant the Saracenic Roman Catholic Cathedral, but a more hideous and inappropriate building he never saw. In matters of architectural tastes they could not, of course, all agree. He would, therefore, hope that the Society would adhere to the decision they arrived at last year, and support the proposed Hall.

With regard to the office staff. Owing to the increase of the Fellows of the Society, and the increased correspondence and general work of the office, the Council appointed last year the Rev. Eyre Kidson as Assistant Secretary. The arrangement was that Mr. Kidson should give two or three days a week to assist in office work, but it had been found that this was not sufficient. The Council had therefore terminated the arrangement with Mr. Kidson, for whose courtesy, attention, and zeal for the welfare of the Society he was anxious on the part of the Council and the Fellows of the Society to express hearty recognition and warm thanks. The Council had decided to make a permanent addition to the staff.

THANKS TO EXHIBITORS, COMMITTEES, &c.

There was only one other matter. He desired to say that it was impossible to express too strongly the thanks they owed to the exhibitors—both amateur and professional—in all parts of the kingdom for their support. It should not be forgotten that they did not all live near London, and that they sent their productions long distances and at very considerable risk to their plants. They also owed a great debt to the scientific and practical gentlemen who wrote valuable papers for their meetings; those papers were published in the *Journal*, and supplied information which it would be difficult to get from any other source.

With regard to the gentlemen who served upon the committees, they, like the plants that the Society exhibited, came from all parts of the kingdom. They gave their valuable time and services to the Society. The Society would be nowhere without their help.

THE STAFF.

The Secretary had gathered round him an excellent staff, but he was bound to say that their Secretary did the lion's share of the work. It was impossible to exaggerate the valuable services of Mr. Wilks, and he wished to pay a tribute to the way in which the staff, when called upon, seconded their Secretary.

He was obliged for the way in which they had listened to him, and if he could answer any questions, it would give him very great pleasure to do so.

THE DISCUSSION.

Mr. ARTHUR SUTTON seconded the motion. Reference, he said, had been made to the new Hall. He would like to say that although the site was not all that could be desired, it was the best possible site the Council could find; and although the buildings might not be all they could wish for, they were planned with the object of affording the greatest possible facilities to the exhibitors, and the offices were the most commodious that could be made on the site in question. He hoped it would be believed that the Council had done their utmost to carry out the wishes of the Fellows; and that, although in the first instance the Council considered a garden more desirable for the Society, they had adopted the views of the Fellows, and had put their shoulders to the wheel, and had brought the Hall scheme practically to a completion. The work of carrying out the designs was a mere nothing. They could not have found a better architect, for he had gone into the details most thoroughly. The Council placed the utmost confidence in him, and felt sure that he would carry out the work in the best possible way. He was certain their President would answer any question with satisfaction to as large a majority that day as was the majority last year in favour of the scheme.

MR. ELWES' CRITICISMS.

Mr. H. J. ELWES regretted that he had to criticise the report, especially in respect of paragraph 21, dealing with the question of the Hall. In one section of that paragraph he believed a challenge had been thrown down to him by the statement that he "unconditionally" offered £1000 towards the new Hall. It would be remembered that, after the controversy, those present at the last meeting who favoured a hall as against a garden, were challenged as to how the money was to be found. He, rising on the spur of the moment, and without previous consideration, offered to find—whether the word was "find," or "give," he could not say—£1000; but in a subsequent letter to the President, he expressed the conditions under which he intended the offer to be made. That being so, he thought the word "unconditionally" must have been inserted in the report with an object, and if he did not rise to call attention to it, he would not be fair to himself nor anyone else. The paragraph which contained the objectionable word was as follows:—

"After considerable discussion a resolution was carried, 'that the proposed site [for a garden] is not the best means of celebrating the Centenary of the Society,' and in supporting this resolution, Mr. H. J ELWES, F.R.S., unconditionally offered £1,000 if a New Hall were substituted for a New Garden as the celebration of the Society's Centenary. Mr. A. W. SUTTON, V.M.H., and Mr. N. N. SHERWOOD, V.M.H., also offered £1,000 each, and Baron SCHRÖDER a day or two afterwards offered £5,000 if a New Hall were adopted."

He ventured to suggest that that paragraph was completely stultified by the following paragraph:—"The Council desire to assure the Fellows that the provision of a New Garden has by no means been lost sight of. The Society's lawyers are in correspondence with those of the Duke of Devonshire, and negociations for the surrender of the Chiswick lease are in progress, and they hope that these, when completed, will materially facilitate the acquisition of the New Garden." It was evident that the Council, who agreed that a hall should be substituted for a garden, were now taking steps preparatory to the acquisition of a garden, and were trying to do two things at once instead of doing one thing at a time. It did not matter two straws whether they called a garden or a Hall a celebration. The question was which did they want first, and did they need a Hall which should be built in such a way that it should meet the requirements, not of the present only, but for a long future period? He had for a long time felt doubts as to whether the Building Committee had had a free hand. But after what Mr. Sutton had said and Mr. Shea had written in *The Garden*, and after statements by Mr. Godman, he ventured to think they had not. The same thing had occurred when he was a member of the Council. Before proceeding to buy a site, the Council should have endeavoured to have acquired a possible site by other means than by the purchase of land. He did not know whether the Government had been approached on the subject; but considering the fact that the Government had made grants to the Botanic Society, and having regard to the fact that many years ago the Royal Horticultural Society had unexhausted improvements representing £30,000 confiscated by the Exhibition Commissioners without any return. Having regard also to the fact that an influential member of the Government, Mr. Chamberlain, was a Vice-President of the Society, the first step the Council should have taken was to have ascertained if it was impossible to secure favourable consideration in the circumstances in which they found themselves. If that had been found impossible, there was another course open to them. In the report of the meeting, published in the *Gardeners' Chronicle* of February 15, 1902, he read the following remarks made during a speech by Sir Trevor Lawrence:

"I daresay some of you have seen in the newspapers some paragraphs associating the name of this Society with the Royal Botanic Society. We received most courteous letter from that Society, suggesting that they should place their gardens at the disposal of this Society. Unfortunately, this Society had already made all its arrangements, not only for the present year, but I may say for practically a considerable time to come, and we were unable to meet the advances which were made to us."

Had he been present at that meeting he would have wanted to know why; because it seemed to him that the Royal Botanic Society was a kindred Society to their own. He did not say that they should amalgamate with that Society, but they might make some arrangements by which the very beautiful grounds of the Botanic Society might be used for the purposes for which the Royal Horticultural Society were building a hall; and it would enable them to get rid of the difficulties of the Temple Show, and at the same time enable them, notwithstanding the generosity of Lord Ilchester, to hold such shows as only that Society could hold. Whether the matter had been discussed with the Botanic Society he did not know; but he thought that was a way by which they might have got a great deal of what they wanted without buying this Vincent Square site.

A FELLOW: The last special general meeting settled that question.

Mr. ELWES replied that Mr. Shea had stated that the site was not brought forward before the Council.

The PRESIDENT: At a meeting held on March 21 last year, the question of the site was brought forward, and the site was practically unanimously adopted by the meeting. I confess I think that if Mr. Elwes is not out of order, he is straying very near. (A voice: "Free discussion").

Mr. ELWES said he did not know whether the meeting wished to hear him; but Mr. Sutton distinctly stated in conversation, and afterwards confirmed the statement, that the question of the site was practically decided before it came to the Building Committee or the Council.

Mr. SUTTON explained that Mr. Elwes must have misunderstood him. What he said was, that when he joined the Building Committee he found the plans prepared, but that there was full opportunity for considering them, and he was delighted to support the plans.

The PRESIDENT: It was brought before the general meeting and, practically, unanimously adopted. You cannot get behind that.

Mr. ELWES said he did not desire to throw stones at the Council, but he maintained that the thing had not been thoroughly examined. They were told that £22,000 had been promised. They were told, in the first place, that it would cost £25,000. Now it was to be £40,000, and they could not be sure that it would not cost £50,000. Did the Council consider they had a sufficient mandate for them to allow the accumulated (Reserve) fund to be dumped down for such a purpose? Did the Fellows of that Society desire their money to be spent in that way? All these were matters requiring consideration. He knew for a fact that many prominent members of that Society had declined to subscribe to the Building Fund until they were satisfied that the money would be properly safeguarded. What was the position? They had got 6,000 members; and from £20,000 to £22,000 had been subscribed by a very small number of them.

He would be delighted to see a new garden, but he would like to know whether the Council had given the slightest thought as to how the two schemes could be financed together. What would be the fate of the hall if at some future time a new Council came in and the Society got into debt? Difficulties would arise. They could not sell the garden, they could sell the hall, and the hall would go! The people who had subscribed the money would then be at the mercy of ten times the number of those who had not found the money. But supposing the hall were built, would it suit the future requirements of the Society should its numbers be quadrupled? To say as Mr. SUTTON said, that the hall was the best that could be obtained under the circumstances, was certainly damning it with faint praise. He thought if they could get nothing better they should stay their hand, and the Council should take the Fellows into their confidence.

MR. ELWES' AMENDMENT.

He would move as an amendment: "That a Committee be appointed by the subscribers to confer with the Council as to the Hall and as to the proposal to surrender Chiswick, and that no contract be entered into until their report has been presented to a general meeting of the Society."

Surgeon Major INCE seconded, and Mr. GODMAN briefly supported the amendment.

The PRESIDENT, in reply, said whatever conditions Mr. Elwes had in his mind when he promised the

£1,000, they were not expressed. As to the site, nothing was settled until it was definitely settled at the last general meeting on March 21. A great deal had been said about the Royal Botanic Society. He had had frequent conferences with members of the Botanic Society, and he found that any amalgamation would be financially impossible. The Botanic was deeply in debt. He was sorry that it should be so, but that was the case; whereas the position of the Royal Horticultural Society, notwithstanding what had been said with regard to its finances, was totally different. They had a surplus on the working last year of £2,500, and they had already an accumulated surplus of £16,500. There was another thing. He did not wish to say anything against the Botanic Society or any other Society; but the Botanic Society had taken to methods of raising money which were different to those followed by the Royal Horticultural Society. They had taken to clubs, bazaars, and dances, and things of that sort—useful and amusing, no doubt, in their way; but they were not horticulture, and the very worst thing the Royal Horticultural Society could possibly do would be to associate themselves with the Botanic. Mr. Elwes seemed to think that the Council had forgotten that there was a Government in this country. He could assure Mr. Elwes that he was quite mistaken. He (the President) had been in conference with Lord Esher, and he could assure them that he never had a greater damper spread over his views. That applied to a portion of Hyde Park, or of any other park. He had discussed the matter not only with Lord Esher, but with Col. Wheatley and Major Hussey, and the Council came to the conclusion that it was impossible to get any portion of the parks to be placed at their disposal. He could assure the meeting that that matter had been carefully and exhaustively considered. Then Mr. Elwes went on to speak of a hypothetical future. He (the President) was content with the difficulties of the present, which, no doubt, Mr. Elwes had no desire to increase. What might be the case when the Society, which now numbered 6000 members, had quadrupled, he could not undertake to say, but he supposed that Mr. Elwes did not suggest that they should now provide for a society of 24,000 members! The requirements of the Society had been carefully thought out. The whole matter had been gone into. The elevation of the building had been altered completely once, and in smaller details several times. One of the proposals was that the offices should be on the ground floor, and that the whole of the remainder should be one vast glass hall. Apart from the question as to whether the ground landlord and the London County Council would have agreed to anything of the sort, it would have been perfectly impossible, because there would have been no light from behind, and the back part of the hall would have been merely a cellarage. The Council had to provide for offices, committee rooms, library, and other requirements, and he hoped the Fellows would find that as much as possible had been made of the site. Mr. Elwes seemed to think that that condemned the scheme. Where in this great metropolis could they get a large area without paying a great sum? They had to get the best area they could with the sum which appeared to be within their reach. He considered that the amendment amounted to a vote of no confidence in the Council, and he called upon the Fellows to show, by as near an approach to unanimity as possible, that they repudiated the idea that the Council had forfeited their confidence.

Mr. ELWES asked if the Council withdrew the word "unconditionally" from the report.

The PRESIDENT: You confirmed your offer.

Mr. ELWES: In that case, why did you write to me on the subject twelve months afterwards?

The PRESIDENT: Anything I may have said in my letter did not alter your original offer. I am afraid it is a casuistical view, beyond my intelligence.

The PRESIDENT then added that the solicitors had stated that £5000 might be obtained for the surrender of the Chiswick lease, and that would make the financial position of the Society very much stronger. They would then have an accumulated surplus of close upon £22,000. As to using the whole of the accumulated funds for the construction of the new Hall, if the Council considered they would require the authority of the Fellows—and in his opinion they would require it—they would ask the Fellows for their authority. There was nothing behind that remark in his mind.

Mr. ELWES: Do the Council consider they have the right to surrender Chiswick without appealing to the members?

The PRESIDENT: If the Council considered it desirable to surrender the Chiswick lease—and they already hold the opinion that it is desirable, unless the bye-laws say they are obliged to appeal to the Fellows, I think they would consider themselves entitled to do so

Mr. ELWES: Without an appeal [to the Fellows]?

The PRESIDENT: Yes, without an appeal.

LOSS OF THE AMENDMENT.

The AMENDMENT was then put, when it was lost by an overwhelming majority, only nine voting for it.

Mr. ALEX. DEAN: Is it proposed to get rid of Chiswick before a new garden is obtained?

The PRESIDENT: The position is this. We must first resign the lease, and the arrangement is that we shall be given a year after that resignation to provide ourselves with a new garden.

Mr. GEO. PAUL: And the Council would, of course, endeavour to provide a new garden?

The PRESIDENT: Yes. A Committee is already appointed, and enquiries are already being made.

The report was then adopted.

On the motion of the Rev. G. H. Engleheart, seconded by Mr. C. T. Druery, a hearty vote of thanks was accorded to the President, and the proceedings ended.

THE WEATHER.

Remarks.—The weather during the greater part of the week has been dull, with bright sunshine at intervals.

GENERAL OBSERVATIONS.

THE FOLLOWING SUMMARY RECORD of the weather throughout the British Islands, for the week ending Feb. 7, is furnished from the Meteorological Office:—

"The *weather* during this period has differed greatly in the various parts of the kingdom. Over the western and extreme northern districts rain was very frequent; it was not, however, heavy, as a rule, until the end of the period, when falls of more than an inch, composed of rain and sleet, were very common in Scotland. Over the greater part of England the weather, although mostly cloudy, was generally dry.

"The *temperature* was above the mean, the excess ranging from 1° in the Channel Islands to 4° or 5° in most other districts. The highest of the maxima were recorded on Saturday, when they varied from 57° in Ireland, S., and 56° in several other districts, to 55° in Scotland, N. and England, S. and E. The lowest of the minima, registered during the earlier days of the week, varied from 27° in England, N.E. and E., to 32° over Ireland, and to 36° in the Channel Islands.

"The *rainfall* was much more than the mean in Scotland, N., considerably more in Scotland, W., and rather more in Scotland, E. and Ireland, N., while in England, N.W., the mean was just equalled. In all other districts there was a deficit, the fall over eastern and central England being scarcely appreciable. The total fall for the week was 4·38 inches at Fort William, 4·30 inches at Glencarron, and 3·37 inches at Laudale.

"The *bright sunshine* exceeded the normal in England, E., and was just equal to it in England, N.W., but was deficient in all other districts. The percentage of the possible amount of duration, ranged from 27 in England, E., and the Channel Islands, to 10 in Scotland, W., and to 6 in Scotland, N., and Ireland, N.

THE WEATHER IN WEST HERTS.

THE present term of unseasonably warm weather has now lasted three weeks. Two days in the past week were exceptionally warm, both during the daytime and at night. In fact the lowest temperatures on the two nights were several degrees higher than would have been seasonable in the warmest part of the day. The ground has now become very warm, the readings being 5° warmer at 2 feet deep, and as much as 9° warmer at 1 foot deep than their respective averages for the month. The rainfall has been too light to affect the passage of rainwater through the percolation gauges, indeed, no measurable quantity has come through either of them for the last five days. Four days of the week were altogether sunless, and one other nearly so. Taking the remaining two days together, the sun shone for altogether ten hours. The winds have been as a rule high, and have come exclusively from some southerly or westerly point. On the 7th, the highest mean velocity recorded in any one hour, was 16 miles, and on the following day 18 miles. The air has on the whole continued rather dry for the time of year. Crocus Imperati came first in to flower in my garden on the 6th, which is three days later than the average for the previous nine years, and a selected patch of double Snowdrops was first in blossom on the same day, or two days earlier than its average date of first flowering in the preceding sixteen years. *E. M., Berkhamsted February* 10, 1903.

MARKETS.

COVENT GARDEN, February 12.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Thursday, by the kindness of several of the principal salesmen, who revise the list, and who are responsible for the quotations. It must be remembered that these quotatioos do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the supply in the market, and the demand, and they may fluctnate, not only from day to day, but often several times in one day. ED.]

Oats	20 3	16 11	— 3 4

TRADE NOTICE.

MR. A. LL. GWILLIM has started in business at Cambria Nursery, Eltham, Kent, as a Begonia and seed grower, after being some years with Messrs. J. Peed & Son, of West Norwood.

ANSWERS TO CORRESPONDENTS.

*** *Owing to the pressure on our space we are compelled to postpone the publication of many communications.*

ADDRESS WANTED: *H. P.* If the writer of a brief note on "The Lot of Gardeners," which appeared in our issue of December 20 last, p. 464, will forward his full name and address, we will send him a letter we have received from the Curator of the Botanic Garden, Grahamstown, South Africa.

ARUM MACULATUM: *A. S.* Pot the tubers in early autumn, or as soon as obtainable, and keep them cool, and the soil moderately moist till growth begins, when more water will be necessary.

ASH FOR MAKING WALKING-STICKS: *Ash Plant.* Seedlings are mostly employed. The seed may be sown this month in drills on good ground deeply dug, the drills being drawn at a foot apart; sowing thinly, or one or two year old seedlings may be purchased from the nurserymen, and bedded out in lines at 1 foot apart, and 6 inches in the lines. Beyond stirring the soil with a hoe and killing weeds, nothing more is needed. The site of the beds should be open and free from the shade of trees. Where large, thick sticks are wanted, it might be necessary to transplant and let them stand two or three years in the new bed. Ash is tougher when grown on cool soils and grown slowly, that is, not hurried on by the use of manurial top-dressings.

BEGONIA GLOIRE DE LORRAINE: *A. Stamford.* If you will turn to our issue for December 20, 1902, p. 451, you will find the information you desire.

BOOKS. *T. S. S.* We can recommend the following works: *Fertilizers, their Character, Composition, and Suggestions as to their Use for Different Crops*, by Prof. Voorkees, price 4s. 6d. (Macmillan & Co., London); *A Treatise on Manures*, by Dr. A. B. Griffiths, price 4s. 6d. (Whittaker & Co., Paternoster Square); and *Manures for the Garden*, by Dr. A. B. Griffiths, price 1s. 6d. (Messrs. Collingridge & Co., London). —*H. A.* There does not exist any modern work on table decorations in the English language. That of Miss Anne Hassard has been long out of print, but it may be met with at the old book shops.—*Hortus. Alpine Plants*, "A Practical Method for Growing the Rarer and More Difficult Alpine Flowers," by W. A. Clark, illustrated; published by Upcott Gill, 170, Strand, London, E.C.

CARNATION FOLIAGE DISEASED: *Mac, and T. W.* The "grass" is attacked by a fungus, Helminthosporium echinulatum, which no remedy will cure without at the same time killing the plant, as it is internal. Carefully dig out the entire plant, and burn it forthwith. Grow your Carnations on a new site.

COOL ORCHIDS: *W. North, Bow.* The subject, to do it justice, could not be treated of in this column. We would advise you to read Mr. Frederick Boyle's book, entitled *The Culture of Greenhouse Orchids*, published by Chapman & Hall, London.

DICTIONNAIRE ICONOGRAPHIQUE DES ORCHIDÉES: *R. J.* The language employed is French. The work is published at 24, Rue Quinaux, Schaerbeek, Brussels. Business letters should be sent to M. Goossens, No. 68, Rue Walkiers, Auderghem, Brussels.

EUCHARIS BULBS: *T. W.* The bulbs sent are very slightly affected by the bulb-mite, and if a good method of cultivation be followed, and no severe drying-off is practised, the pest will probably die out, or have no injurious effects on the plant.

EVERGREEN SCREEN AND WIND-BREAK: *Wm. B. Welch.* Approximate heights, five years after planting 3 ft. high plants, in good soil:—English Yew, 6 ft.; Holly, 5 ft.; Euonymus, 7 ft.; Evergreen Oak, 5 ft.; Pinaster, 8 to 10 ft.; Monterey Cypress, 8 ft.; Lawson's Cypress, 8 ft. The more exposed the site, the slower the growth.

HORTICULTURAL HALL: *J. W. M.* Your suggestion has been forwarded to the proper quarter.

IRRITATION SET UP BY THE HAIRS ON THE LEAVES OF PRIMULA OBCONICA: *F. S.* If the irritation be left to itself it will subside. Goulard-water might be used if it be very severe.

LAND UNDER TREES: *J. J. J.* Get good old turf off heavy land, then manure and dig the ground before it is laid; make level and firm by trampling and rolling, then lay the turf neatly and beat to a level, firm surface. This may be done between the present time and the end of next month, but not when the turves are in a frozen state. If it get rather bare in a year or two, sow fine grass seeds and Clover (Trifolium minus), and afford a dressing of loam and wood-ashes.

LEASE OF MARKET GARDEN LAND: *Plums.* We think that you should get your lease drawn up anew; but before doing anything, obtain legal advice.

NAMES OF FRUITS: *J. Broodia.* Apple Cornish Mother.

NAMES OF PLANTS: *Correspondents not answered in this issue are requested to be so good as to consult the following number.*—*A. S.* Cattleya Trianæ delicata. The flowers are not pure white. They are imperfectly developed, and probably when better grown they will have still more colour.—*L. S. R.* 1, Gymnogramma chrysophylla; 2, Asplenium Belangeri; 3, Hæmanthus natalensis.—*V. T., N. Wales.* 1, Zephyranthes carinata; 2, Cyrtanthus McKenniæ; 3, Cyrtanthus lutescens.—*Foreman.* 1, Pleurothallis rubens; 2, Bulbophyllum auricomum; 3, Bulbophyllum saurocephalum.—*J. H.* 1, Cœlogyne graminifolia; 2, Odontoglossum Rossii, with unusually coloured petals.—*Veritas.* Cattleya Trianæi.—*J. T.* 1, Not recognised; 2, Stachys lanata.—*G. T. W.* 1, a variety of Yucca aloifolia; 2, Cestrum fasciculatum; 6, Diplacus glutinosus; for the rest, send better specimens.—*Enquirer.* 1, Anthericum lineare variegatum; 2, Coronilla glauca. —*Weekly Reader.* Eriostemon intermedius.

RICHARDIA IN A TANK OF WATER: *Hortus.* The water may top the pot by 2 to 3 inches, or even a less depth.

ROOTS OF PEACH TREES AND VINES: *A. S.* The roots of the Peach, that is, of the stock, some sort of Wilding Plum, are covered with adventitious buds, which would eventually develop into suckers. Some sorts of Plum-stocks are capable of producing many such buds, and we can suggest no remedies other than pruning off the suckers quite close to the roots when they appear above the soil. The Vine-roots showed no trace of eelworms, but they were poor specimens, and insufficient for the purpose.

SITUATION AS GARDENER IN SOUTH AFRICA: *W. B.* The proper course is to advertise in home and South African journals; or, provided you have as much money as will keep you from want for six months, to go out, and obtain an idea of the conditions of employment, and take any kind of job for a time.

SOCIETIES: *W. S.* Royal Jersey Horticultural Society, Sec., E. Salway, Dorking Avenue, Brighton Road, St. Heliers; Société Française de Londres, Mr. G. Schneider, 17, Ifield Road, West Brompton, London, S.W.

TULIPS FLOWERING BADLY: *Tulipa.* Without seeing some of the affected plants, the soil, &c., and the treatment being more fully described, we are unable to say what has arrested development. Were the bulbs well rooted before forcing began, or has the bottom-heat been so high that the roots have suffered?

BELMONT CASTLE.

IN the vicinity of the Grampian Hills, and about a mile from Alyth Junction, on the Aberdeen and Edinburgh Caledonian Railway, stands the palatial Scottish residence of Sir Henry Campbell-Bannerman, Bart. The estate although not extensive, contains tracts of land, judging from tree growth and farm crops, as good as any to be found in the Howe of Strathmore. Belmont Castle is within a short distance of such notable places as Glamis Castle, Hallyburton House, Aurtherstone House, and several other estates including the land forming the southern boundary of Perthshire, and the northern boundary of Forfarshire. The strath on which the Castle stands is perfectly flat, and from its walls a prospect of varied scenery is obtained for miles around. The history of the Castle dates from the Reformation in the sixteenth century, when it was known as Kirkhill Castle, and when it was the seat of the bishops of Dunkeld. At the time of the Rebellion in 1745, the proprietor at the time being a follower of Prince Charles, lost the estate, which was confiscated by the Crown. The Castle was afterwards sold to Lord Privy Seal McKenzie, who had it rebuilt and enlarged in 1752 (still, however, preserving the oldest portion), the work being executed from designs by Adams', the famous architects of Edinburgh. The estate afterwards became, through marriage, the property of Lord Wharncliff. With the exception of the oldest portion, which is fireproof, the building was in 1885 burned to the ground. In this ruinous condition the Castle and estate was bought by the present proprietor, who at once commenced the erection of the handsome building, the frontage of which is shown in the illustration (fig. 48, p. 114), presenting the southern aspect. Only a small part of the original Castle now remains, and this includes the clock tower, the walls of which are 7 feet thick, and the rooms arched over with stone. The style of architecture is Scottish baronial, after Holyrood and Falkland Palaces, which are now about the only examples of this style remaining in Scotland.

As it now stands, the Castle is very different from the original, the entrance being changed from the north to the south side. The stables and outbuildings, instead of being close to the mansion, stand some two or three hundred yards distant, and they are completely shut out from view by ornamental trees and shrubs. These changes demanded a re-arrangement of the grounds, and the two approaches which, after passing through thickly-wooded portions of the demesne, enter the park on the west and south sides, but instead of striking almost a direct line through it as formerly, a regular sweep of the southern boundary is made, with the Castle continuously visible from every point.

In places of any antiquity there are usually to be found trees of great size and age, and this is the case at Belmont, as may be observed from the view (fig. 49, p. 115) taken of a walk leading from the garden to the approach, where there are growing many famous Beeches, with straight clean trunks, 50 feet in height. Throughout the policies, old stately trees of various species meet the eye at every turn, and close to one of the approaches there is a specimen Tsuga Mertensiana, the Albert Fir, about 60 feet in height, a most symmetrical plant, and thought to be one of the best in the country. There is no Pinetum, properly so-called, but Conifers form an important feature, every species and variety capable of enduring the climate having been planted during the last ten years, and all of these trees are in robust health. Nor should mention be omitted of the winter garden at the west side of the castle, which is laid out in the French style with gravel walks edged with turf and the beds with Ivy. The beds, which are varied in form, are closely planted with a unique collection of dwarf Conifers, and all the most rare shrubs adapted for the purpose.

The kitchen garden, which is in the form of a shield, is about 4 acres in extent within the walls, and is situated about 400 yards from the Castle, from which it is screened by tall Beech trees and a judicious arrangement of Conifers, beds of Rhododendron, and other ornamental foliage and flowering shrubs. A select collection of fruit trees has been planted, including most of the new varieties of Apples, which latter are on trial. Under no conditions could the test be better undertaken than under the management of Mr. Dingwall. The following is a list of varieties which succeed at Belmont, and one which should be of good service for intending planters in that part of Scotland.

Kitchen Apples.—Lord Grosvenor, Duchess of Oldenburg, Early Julien, Pott's, East Lothian, Bramley's and Ecklinville Seedlings, Bismarck, Grenadier, Golden Spire, James Welsh, Loddington, Lady Henniker, Small's Admirable, Lord Derby, Ringer, Warner's King, Atalanta, The Queen, and Northern Greening.

Dessert Varieties of Apples which bear well and ripen their fruit in the district are Early Harvest, Red Juneating, Lady Sudeley, Kerry Pippin, Worcester Pearmain, Allanbank, King of the Pippins, James Grieve, Gascoigne's Scarlet, Allan's Everlasting, Jenny Sinclair, and Fearn's Pippin. Most of the varieties named are grafted on the broad-leaved Paradise stock, and they are trained as half-standards, with open crowns. With the exception of a cankered branch here and there, the trees are in the finest condition.

The Pear is not largely grown in the bush form, but the evidence of good crops was abundant on wall trees. The cultivation of wall fruit is a specialty at Belmont, and besides the enclosing walls of the garden, which are well furnished with trees, there is an old brick wall, 200 yards long, extending across the middle of the garden, filled from end to end with trees of the Peach, Plum, Apricot, and Cherry. This wall, which is 15 feet in height, and 25 inches thick, was built in 1768, and can be warmed throughout by means of smoke-flues. The use of heated walls was common in the north before the erection of glass structures, and on them Apricots more especially were very successfully cultivated.

The principal kinds and varieties of fruits grown on the open wall are: Peaches, Waterloo, Hale's Early, Royal George, Noblesse, and Alexander; Apricots, Large Early, Moor Park, Hemskirk, and Peach; Plums, Oullin's Golden Gage, Green Gage, Prince Englebert, Denyer's Victoria, Pond's Seedling, Jefferson, Kirk's, Diamond, White and Red Magnum Bonum, and Archduke; Cherries, Early Rivers, May Duke, Black Eagle, Bigarreau Napoleon, Tartarian, Florence, Fraser's Bigarreau, and Late Duke. These are the varieties specially grown on the old wall referred to. The visitor will be struck by the fruitful condition of the trees on this wall, which make little wood, but bear fruit heavily year after year; even the Washington Plum, usually a shy bearer, carrying as heavy a crop as any other. The explanation given is, that when the border which slopes to the south was prepared, a large quantity of lime and plaster rubbish from the ruins of the castle was incorporated in the soil, which is a yellow loam on a fine red "till." The virtues of lime, even in this form, for the culture of stone fruit is not sufficiently recognised by some gardeners, who afford all kinds of fruit-trees the same kind of soil.

One of the ranges of vineries and Peach-houses is of the same age as the fruit wall referred to, and the houses will apparently stand for fifty years longer. Another range, also for fruit and stove and greenhouse plants, was erected seven years ago, and everything contained therein bears the stamp of cleanliness and high cultivation. The whole place bears evidence of liberality without ostentatious display, everything plain and substantial, while the remodelling of the grounds by Mr. Dingwall bears testimony to the fact that successful landscape gardeners, like "painters and poets," are "born not made." I must reserve a description of the hot-house department, bush fruit, and Strawberries, for a future occasion. *W. W., late of Tarvit, N.B.*

NEW OR NOTEWORTHY PLANTS.

STANHOPEA LANGLASSIANA, COGN.

IN giving the names and elevation of the localities in which the above species grows, in the *Gardeners' Chronicle* of December 14, 1901, p. 424, and also of January 18, 1902, p. 38, there have occurred several errors which, I think, ought to be corrected. Such errors often propagate themselves for generations, and grow in proportion of their age to such an extent that it becomes extremely difficult to distinguish the correct from the incorrect. Instances of this fact could be cited by hundreds.

There is no such locality as Altaquezo, which would mean a high cheese; nor is there any river

called Cuaiquer; and last, not least, Altaquer is neither situated on the small river called Rio Cuaiquer, nor on a big one of this nomination, and much less at an elevation of 1700 m. above the level of the sea.

The river in question belongs to the great and complicated hydrographic system of Rio Mira, and bears a number of different names according to the locality through which it takes its course. It is no small river, but a mountain torrent, conducting an enormous body of water into the Mira. Being formed out of two mountain torrents, the Rio Guavo, which takes its origin on the volcanic mountains El Guálcala and El Azufral, and the river Chucunés, which descends from the lofty volcano De Cumbal; it is first called Rio de San Pablo until the Quebrada Imbi joins it from the right. From here downwards it bears the name Rio de Cuaiquer for a considerable distance until its junction with the Rio de Mayasquer, and from there down to the confluence with Rio Mira, Rio Guiza.

FIG. 48.—BELMONT CASTLE, PERTHSHIRE, THE RESIDENCE OF SIR H. CAMPBELL-BANNERMAN, M.P. (SEE P. 113.)

The district is characterised by a number of similiar appellations of localities, such as Guataqner, Pipulquer, Pususquer, Guaiquer, Altaquer, Mayasquer, &c., the significance of which appears to be at present quite obscure. The altitude of the region assigned to the spontaneous growing of this Stanhopea is also quite incorrect. Besides that, Altaquer is only situated at an elevation of just about 1,000 m. above the sea, no species of Stanhopea in any part of Central or Andesian America, so far as my knowledge goes, grows spontaneously up to elevations of 1,700 m. above the sea-level, the maximum average being 1,500 m. with trifling plus or minus. In a cultivated state a few species, S. grandiflora (H. B. K.), Rchb. fil., S. connata (Kl.), S. Lehmanni (Kranzl.), and two more undescribed species, thrive tolerably well up to 1,800 m., and even higher, but in these elevations they flower very seldom. Cultural trials made here with species of Stanhopea from all regions have proved that all grow best and flower freely and constantly at an elevation of 1,000 m., to which nearer the equator corresponds an annual average temperature of 22° to 23° Cent., the extremes of maximum and minimum ranging between 16° and 30° Cent.

Stanhopea Langlassiana grows on trees and rocks in damp woods near Cuyambi, Altaquer, Guesbi, &c., in the district of the Rio de Cuaiquer, on the western declivities of the Andes of Tuquerres; and also at Naranjo, on the Rio Dagua, on the western Andes of Cali, from 400 to 1,200 m. above the sea, in the localities of which it has been observed since 1878. It is not a common species. In my herbarium it bears the No. 10,040. *F. C. Lehmann, Popayan.*

ABOUT MUSHROOMS.

A GLANCE at the market reports in the *Gardeners' Chronicle* for a number of weeks past will point to the fact that the prices for Mushrooms have been quite abnormal, averaging something like 1s. 8*d.* per lb., a figure which is much higher than is usual at this time of year. For this, many reasons have been offered, the main one being the preceding cold wet spring and early summer which destroyed all chances of an abundant wild crop in the autumn. If this opinion be the correct one, then I venture to think that growers for market have, to some extent at least, shown a want of foresight in not having been prepared for the contingency; and by laying down beds in good time, not only securing an ample supply of the favourite esculent for the public, but materially increasing the profits of their own establishments.

It has been frequently noted that when an abundant crop of wild Mushrooms is in evidence in the autumn, the preceding spring and summer have been invariably dry and warm. The lessons of Nature, however, in this respect would appear to be lost sight of to a remarkable degree by our growers for market, by whom one would suppose they would be taken to heart with avidity as absolutely infallible.

Whilst holding with the opinion that the scarcity of the wild crop has considerably influenced the ruling prices for Mushrooms during this autumn, I am far from thinking that other causes have not contributed to the high rates. Ever and anon we hear of growers, large and small, relinquishing the work on account of crop failures, and the remark expressed that "Mushroom growing is far too much of a lottery for us to continue it longer." Certainly, the cultivation of the Mushroom differs in many respects from that of almost any other horticultural product, and it appears to me that there are only a very few who can say with confidence, after they have finished spawning and casing a bed, that a good crop will follow. That Mushroom-growing can be reduced to such a certainty I verily believe, but I am equally confident that the methods to be employed for its realisation are understood only by the few. Rules may be laid down for the cultivation of most of our garden products, and successfully followed by men of absolutely no practical experience whatever, but this I do not think holds good with regard to the cultivation of the Mushroom. To be a successful grower, the man must find out for himself by long experience all the difficulties attending this branch of horticulture, and the various occult natural causes of failure and success. Except on a few points, I do not think that the reading of books devoted to the subject can help him much. They may, it is true, encourage him to make a beginning, and his first endeavour may be successful to an extraordinary degree, whilst succeeding efforts may prove disastrous, till such time as the grower has found out by dint of experience, and, it may be, heavy cost, the art of production by reducing to a minimum the chances of failure.

As I have already stated, there are some few points in Mushroom cultivation which the beginner may accept with advantage to himself from writers on the subject; but in this paper I will only allude to one, but that it is a cardinal one, and one that has been but too lightly touched upon even by our best writers on the art of Mushroom cultivation, I am equally convinced. I allude to the absolute necessity of refraining from attempting to grow Mushrooms too often on the same ground or in the same building.

It may be difficult to offer a reason for the failure of crops when the same ground or building is used for several consecutive years for attempted Mushroom production, but that the "sickening" of the positions under such circumstances takes place with disastrous consequences no one can deny. After brilliant successes, the railway tunnel at Edinburgh had to be abandoned, at least for a time, and one frequently is informed by growers of the fact that they cannot produce such crops of Mushrooms now as they used to do when they began the cultivation some years ago, the reason for which they cannot imagine, but in nine cases out of every ten is the one, in my belief, given above.

Poultry farmers were quick to perceive and act upon the fact that pure conditions of life were absolutely necessary for the profitable production of healthy birds and an abundant supply of eggs, hence the introduction of the practice of shifting the pens in a meadow at stated periods from one position to another before the "sickening" of the old one, and consequent appearance of disease. The good results of this plan are apparent everywhere. The Mushroom-grower, I fear, has been slow to follow in this line, greatly to his disadvantage; he has been too frequently content to struggle on in the vain pursuit of success on positions thoroughly contaminated by previous culture, with the inevitable results of partial or total failure.

It appears that as in the animal, so in the vegetable kingdom, all domesticated organisms should have the advantage of the purest conditions of life, and that all plants artificially cultivated should be scrupulously afforded the same conditions. My ideal method for the artificial cultivation of the Mushroom is something like the following:—Procure, if possible, a meadow clear of all the contaminating influences of a large town, and begin work on it by laying down the required number of beds for the season on one side of the field, and when another batch is wanted, use the opposite side, and so on, until the ground is worked all over.

By this means, a supply of the purest soil will be available on the spot, and by the time the land is thus worked all over, that first operated upon will be in readiness for another lot of beds. Should the following system be carried out, viz., when the first beds are exhausted, remove every particle of spent manure from the ground, then dig or trench without the addition of any kind of manure whatever, and crop with any kind of vegetable that would be likely to pay till such time as it is required again for the Mushroom-beds, when it will be rested and purified. By this system of working, I do not see why a virgin pasture should not be utilised by the Mushroom grower for an unlimited time with a minimum risk of failure. *J. Lowrie.*

ORCHID NOTES AND GLEANINGS.

CALANTHE VEITCHI.

It appears that this beautiful winter-flowering Orchid will succeed in soil of different natures, though had I good turfy loam, I should discard peat and add a small quantity of partly decayed leaf-soil, with a sprinkling of coarse river sand, pounded brickbats, or charcoal. Equally good results are achieved when potsherds are employed in lieu of brickdust. Mr. Fulford attributes his success partly to the fact of his pseudo-bulbs not being "too large;" on the contrary, I have always held, and found, that the larger the pseudo-bulbs the finer the spikes. As regards not hurrying the plants into flowering, at Bicton, the pseudo-bulbs when potted are placed in the Melon-house, where the night temperature never goes under 70° at night, and rises to 85°, and often 90° in the height of summer, and this sort of treatment, with full ventilation, meets the requirements of the plants.

Some flower-spikes sent to the editor in the Christmas week were as fine as any that we have observed. Diluted drainings from the cow-stalls, applied as soon as the pots become packed with roots, say, twice or so weekly, are of much service; and when the flower-spikes are pushing upwards, a layer of cowdung, an inch in thickness, may be laid on the soil. I have found no ill effects from using a little Peruvian guano as imported, squeezed up in the water and given to the plants once a week. The flowers retain their colour and last longer if, as soon as a score or so of flowers are open upon a spike, the plant is removed to a light dry house, having a night temperature of 60°, though no harm will accrue should it fall to 55° during severe weather. After passing out of flower expose the pseudo-bulbs to sunlight, and do not store them under other plants—as is often done. *J. Mayne, Bicton.*

SLEEPING SICKNESS AND ITS CAUSE.

A paragraph recently appeared in the daily press that a Dr. Hans Ziemann had been making investigations into the cause of "sleeping sickness," and had arrived at the conclusion that it was due to chronic intoxication with a poisonous material ingested with food, and that Manioc or Cassada is the food which fulfils these conditions. It is further said that "the author, in support of his belief, that this disease is an intoxication, and not due to a specific organism, gives it as a fact that in the blood of persons suffering from sleeping sickness there is no exciter of disease that can be cultured by the usual methods, so as to be made to develop further." In relation to this matter, as is well known, the Manioc, or Cassada, or Cassava plant (Manihot utilissima) belongs to the poisonous family, Euphorbiaceæ, and the juice owes its toxic properties to the presence of hydrocyanic acid (prussic acid). The application of heat, however, destroys the poison, so that the boiled juice becomes a thick black fluid, valued in cookery, and in the preparation of many table sauces; and the starch, after repeated washings, is finally dried on hot-plates, and becomes the tapioca of commerce, any remaining poison being completely dispelled by the heat in drying.

In connection with the Cassava plant, and as indirectly associated with Dr. Ziemann's opinion, a curious and interesting statement recently appeared in the *Agricultural News* of the West Indies, taken from the *Geographical Journal* for September last, giving an account of a journey up the Caura affluent of the Orinoco, where the Cassava-plant is much grown, from which cakes and a drink known as Yaraqué is prepared. The following account is given of its preparation:—

"Yaraqué is known under different names all over Guiana. Ordinarily, it is prepared only in sufficient quantities every three or four days to meet the requirements of the household. Banana-leaves are placed on the ground in the corner of the hut, and upon these leaves the Cassava, thoroughly damped with water, is spread in layers. On each layer a powder of sage-green colour is sprinkled. This powder is called Yaraquéro, and is prepared from the leaves of a plant of the same name (Trema micrantha). The preparation of this powder is simple. The leaves having been dried on the large slab used for baking Cassava, an operation which does not take long, are then reduced to powder by rubbing between the hands. This powder is kept in well-stoppered gourds, as there is a minute red ant which is very fond of it, and will find it out wherever it may be hidden. The mass of damp Cassava and Yaraquéro is then covered with Banana-leaves, and allowed to ferment. At the end of two or three days the mass becomes slightly sour. In this state it is either eaten or drunk mixed with water and cane-juice. If allowed to ferment for more than three days it becomes intoxicating. Large quantities of Yaraqué are consumed during the dances, which form part of almost every celebration among the Indians. On these occasions the stuff is prepared on a big scale, generally in dug-outs." *John R. Jackson, Claremont, Lympstone, Devon.*

NURSERY NOTES.

MESSRS. JAS. CARTER & CO.

In these days of cheap glass there are very few gardens devoid of a greenhouse, and for this reason the demand for decorative plants of a tender nature is almost universal. Amongst such plants the position accorded to the Chinese Primrose is an important one; it is cultivated in nearly every garden, and its many varieties meet with general appreciation. Gardeners have difficulty in selecting a plant that is more effective in a vase than a well-grown Primula, and it is as useful for the dining or sitting-room as for the conservatory or greenhouse. Though essentially decorative as a plant, the blooms of some of the varieties, when cut, last a considerable time in water, and are effectively used in cut flower arrangements. Particularly charming in this way are those of the Stellata section, and the semi-double flowers.

Fig. 49.—view in the gardens at belmont castle, perthshire. (see p. 113.)

In order to supply the large quantity of Primula seeds necessary every year, certain of the large seed firms spend an immense amount of care upon the cultivation of plants exclusively for ripening seeds, and in these collections is practised the cross-fertilisation and selection that cause the improvements and developments in the strains from year to year. A few days ago we were invited to the Forest Hill Nurseries of Messrs. Jas. Carter & Co. to see a display of upwards of one thousand plants, most of which are in full flower at the present time. Being cultivated expressly for seeding, the plants are not large specimens, but bloom in pots about 5 inches in diameter. The seeds are sown in July, and the first flowers open about the last week in January. There are numerous varieties, and these differ from each other mainly in the colour of the flowers, but occasionally in form of foliage only, or even in the colour of the leaf petioles. The most charming of all the singles is Princess May, a rich but soft pink colour, about 2 inches across each flower, which has beautifully wavy margins, and is much fimbriated. The flowers have unusual substance as well as size, the variety is more

robust in growth, and the foliage is Palm-shaped or plain. Crimson King is known in all gardens for its rich deep colour. Rose Queen is less handsome than Princess May, judged by the individual flower, but it produces a greater abundance of bloom, being more free in habit. Old Elaine is pure white, and there are now two improved strains of this, one with white petioles, and the other with dark petioles, but having larger flowers than these of the old strain; Elaine may be had with Fern-like foliage or plain. There are Holborn Magenta, H. Blue, and H. Scarlet, the flowers of the last-named being of very bright red colour, but they need to be shaded from the sun's rays, even in February; Carmine has good-sized flowers, and the colour is attractive. Venus is a type that is less popular than others; the flowers are white with splashes of red colour, and the type may be obtained with plain and Fern-like foliage. Vermilion is an effective variety of the high-colour section, but is quite distinct from the Crimson King or Holborn Scarlet. Another variety is known as Salmon, and is reddish-salmon in colour; Ruby is a richly coloured variety, with a white ring around the disc, and in the colour upon the margin are tiny white spots. The "frilling" has the appearance of ruby-coloured flakes one upon the other. Holborn Queen is a fine white variety with blush of pink colour, and the foliage is Fern-like.

The newest of the singles are Edward VII. and Holborn Coral. Edward VII. is a pure white variety, one of the parents being Bouquet, which has a foliaceous calyx, and is extra strong in growth, but failing to produce seeds, is useful only in cross-fertilisation; the flowers of the cross are large, of much substance, and heavily frilled. Holborn Coral is a very recent cross from Salmon × Hercules; in colour the flowers are pleasing coral-pink, and very attractive. In Hercules the flowers are rich carmine, and they are larger, and possess greater substance than some of the others.

The double-flowered section include Carmine Empress; Snowflake, white, with blush; Aurora, pink; Lilac Queen, scarlet; Princess of Wales, white, with rare splash of red colour, &c. The largest double flowers are of salmon colour, and the habit good.

In other houses we saw collections of Cinerarias just beginning to show the flower-buds, and a collection of herbaceous Calceolarias that Messrs. Carter generally exhibit well at the Temple Show.

A house devoted to imported Davallias, or Fern "balls," and another containing an importation of dwarfed plants from Japan, seem to indicate that a good business is being done in these fanciful specialties.

NOTES FROM ISLEWORTH.

(*Continued from p.* 101.)

Hippeastrum, hort. "*Mrs. R. S. Holford*" (shown by Capt. Holford at the Royal Horticultural Society), seems a new break in the garden section. The flowers are white selfs, greenish-white below. They are rather small, and three or four are carried to the scape. It is the only really white Hippeastrum I have ever seen, excepting solandriflorum in some of its forms.

Hippeastrum, hort. "*Cristovit.*"—The effect of re-introducing vittatum blood to our red selfs has produced most brilliant orange-scarlet forms with white star.

Hippeastrum, hort., from gardens at Port Elizabeth.—From this source I received one of the early hybrids, dating back to the early days of last century in all probability. It was an Equestre form, with a very clearly defined white star.

Urceocharis Clibrani ×; Mast.—This is new to my collection; it grows and flowers freely with Eucharis.

Hymenocallis speciosa angustifolia.—A very stiff narrow-leaved form. The flowers are quite as fine as the type, and the foliage is in much less compass—a good point in a stove plant.

Phædranassa chloracea.—The type has markedly glaucous leaves, but a variety called "obtusa" has not this peculiarity. The inflorescence is identical.

Eurycles.—The genus requires revision; some species have been founded on inconstant characters. I flowered this year some very fine forms distinct from any yet described.

Brunsvigia Cooperi and B. gigantea. — Some years ago I received an importation direct from S. Africa of about fifty (or more) bulbs of a species of Brunsvigia which I took to be B. Cooperi. I flowered about forty different bulbs, and on one occasion had a dozen out together; and I also obtained mature fruits therefrom, so that I had an opportunity, not always presented to botanists, of describing this species in a comprehensive way.

Unfortunately, so many descriptions of rare bulbs are founded upon one dried specimen or drawing in some museum. Putting on one side the errors that may originate from such work, it is obvious that the result cannot be the description of a species, but simply of an individual, which may or may not be typical. After a time, perhaps, other individual plants are presented for examination, and thus, at one time and another, the first description gets gradually expanded and altered until what was crude, restricted, and incomplete, becomes at last a good specific description. This is, at least, the process that should go on in herbariums.

I found B. Cooperi to carry from ten to twenty-eight flowers to the umbel, with an average of nineteen flowers; leaves four to six, prostrate, lingulate, deciduous, minutely granulate upon the surface, and with scabrous edges; the stamens equal in length to the perianth limb.

Bearing in mind that cultivated bulbs generally carry more flowers than when in a wild state, I was satisfied of the identity of this species with the B. Cooperi described by Mr. Baker, and figured in *Refug. Bot.* 330. The nearest allied species is B. gigantea; this has from twenty to thirty flowers to the umbel, four spreading leaves, and rather exserted stamens.

Here we have two specific names with scarcely more than varietal differences in their descriptions. A very slight expansion would include them both in one species.

Miscellaneous Notes.

Platanus acerifolia variegata (= P. a. Suttneri?).—This is the finest variegated tree introduced into our gardens since Acer Negundo, if it does not indeed surpass it in beauty. It appears to be a variegated form of the London Plane, and the variegation is most bold and beautiful.

Ipomœa rubro cœrulea.—Well worth growing in every warm house. The flowers are of an intense azure blue, becoming flushed and striped with red before they fade.

Arctotis grandis (silvery white), *aspera* (white), *and Leichtlini* (yellow).—All do well outside, and flower all the summer. Grandis is the most beautiful and the most useful for vases, but the other two are not to be despised.

Tropæolums.—It is very doubtful if T. Lobbianum and T. major can be specifically distinguished, but at least they may be considered as typical of two distinct garden sections of Tropæolums. Last year I mentioned that I had obtained crosses between climbing T. Lobbianum and dwarf major. All these turned out to be good garden climbers, carrying a great profusion of flowers, and one of them has become far the largest climbing Tropæolum I have ever seen, making many shoots 60 feet long in a few months growth (under glass).

The great value of *Azalea sinensis* (garden section) for large beds in parks and lawns, has not yet been fully appreciated. Such varieties as Anthony Koster, Gloria Mundi (a fiery golden with small flowers), and many others, are subjects of great delight in June, and possess the whole air with Honeysuckle perfume. There is a great future for this section.

Pelargoniums.—Among purples I have seen nothing to compare with "Royal Purple," a dark blazing colour with large substantial single flowers in a fine truss. This kind is also a good seed-bearer. "Achievement," said to be a cross between the Fancy and the Zonal sections, bids fair to be a useful decorative kind. It is a pinkish-red self, single flowered, and stiffly erect.

Among *Cannas* several good new forms with orange-coloured flowers were raised last year in this garden, and the older section represented by Paul Bert and Senateur Montifore have been superseded.

Among *Cinerarias*, two new colour-breaks have occurred here. "Noël," a Christmas flowering form, is a light pink self, with dark blue seed disc; and another form, in white and red is marked like the "Paragon" Dahlias.

Comparative Hardihood.

Not Hardy.—Chlidanthus Ehrenbergii (stood the winter unharmed, but failed in summer), Cypella gracilis, Gloxinia tubiflora (syn. Achimenes tubiflora), Sparaxis, garden forms; Nerines, all kinds and species tried, including those said to be hardy; Zephyranthes, all kinds except the small-growing candida; Cyrtanthus angustifolius, said to be hardy by Herbert; Hæmanthus coarctatus, &c., and Herbertia pulchella.

On May 13, 1° of air frost cut down the foliage of Sprekelias, Lachenalias, and Ornithegalum lacteum, and injured all Acers and Platanus, especially Acer reticulatum. The foliage of Habranthus advenum was uninjured.

On November 20, 5° of air frost cut down all Crinums and Cinerarias in the open, and injured Arctotis and Tulbaghia. The foliage of Brunsvigias and Pennisetum Ruppelianum was uninjured.

Hardy.—Brodiæa aurea (five years), B. Sellowiana (five years). The flower-buds will stand 23° without harm, and the foliage 20°; sparrows eat the flowers. Moræa spathacea [Dietes bicolor?] (seven years), Cypella platensis (two years).

Hardy at base of heated wall in the open.—Hæmanthus carneus, flowers early in August, and carrying seed.

Hardy at base of unheated wall in the open.—Scilla peruviana. *A. Worsley.*

(*To be continued.*)

CHINESE CONIFERS.

Picea neoveitchii,* *Mast., sp. n.*—Desirous of attaching the name of Messrs. Veitch to one of the novelties among the Conifers introduced from China, through their enterprise and encourage-

* *Picea neoveitchii, Mast., sp. n.*—"Arbor 25 ped.;" ramis glabris pallide fulvis, nitentibus; foliis 15 mill. long, linearibus arcuatis apiculatis tetragonis utrinque stomatiferis; gemmis ovoideis, squamis oblongis, coriaceis subcastaneis glabris; flor. masc. haud visis; strobilis pendulis oblongo-cylindratis parum curvatis, utrinque, ad extremos parum angustatis; squamis subcoriaceis flavo-brunneis superne transversim oblongis seu suborbicularibus, apice vix productis, integris trulliformibus; seminibus obovoideis alis membranaceis oblique obovato-oblongis dimidio brevioribus. In *China Occident.*, W. Hupeh, ad alt. 5,500 ped.; Coll. Wilson, n. 2601.

ment, by Mr. E. H. Wilson, we encountered a difficulty. That difficulty arose from the fact that although Abies Veitchii is now generally recognised, yet both in books and in gardens it is still not unfrequently called Picea Veitchii. To propose another Picea Veitchii would have been quite within our rights, but as it would in all probability be productive of much confusion, we decided to modify the name and adopt the designation at the head of this article. If it serves its purpose as a distinguishing label, that is all that is required. We apply it to a Spruce

FIG. 50.—PICEA NEOVEITCHII: CONE OF REAL SIZE; COLOUR PALE YELLOWISH-BROWN.

Fir collected by Mr. Wilson (n. 2601) in Western Hupeh. It is evidently a handsome species, with the usual rough sulcate branches, which are shining, and of a yellowish-brown or fawn colour. The leaves are about 15 mill. long, four-sided, linear, curved, with a cartilaginous point, and stomatiferous on all sides. The leaf-structure is essentially the same as in other species of Picea, but the submarginal resin canals have no strengthening cells (stereome) around them. The leaf-buds are broadly ovoid, with leathery, chestnut-brown, glabrous scales. The pendulous cones are 13 to 14 cent. long, 7 to 8 cent. lat., oblong, cylindric, slightly curved, and narrowed at both extremities. Cone-scales slightly leathery, yellowish-brown, oblong or suborbicular, entire scoop-like at the apex. Seeds 25 mill. long, including the wing, obovoid, surmounted by an obliquely, obovate-oblong, membranous wing, exceeding in length the seed itself. In the dried state the scales of the cone are widely separated, and their scoop-like appearance is then very conspicuous. When the cone is soaked in water, as was done before the photograph was taken (fig. 50), the original form of the living cone is restored.

In the shape of the cone and scales the species resembles the Himalayan Picea Morinda, but the foliage is quite different, and the same remark applies to the Japanese Picea polita. Mr. Wilson tells me that he saw but one tree, from which he gathered cones, "it was about 30 feet high, very symmetrical in shape, and was growing on the top of a well-nigh inaccessible cliff in Western Hupeh, at an altitude of about 5,500 feet." *Maxwell T. Masters.*

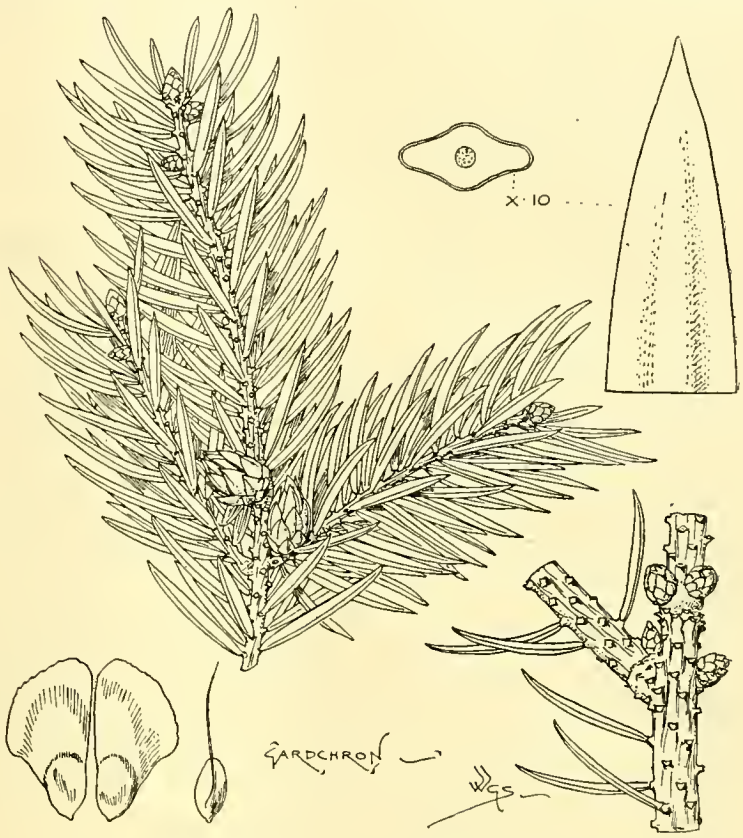

FIG. 51.—PICEA NEOVEITCHII.

A new Chinese Spruce Fir collected by Mr E. H. Wilson, n. 2601. The drawing shows a shoot with foliage, a portion of a branch with the projecting pegs; the apex of the leaf magnified; a cross section of the leaf, and the seeds.

NOTICES OF BOOKS.

FLORA SIMLENSIS: A Handbook of the Flowering Plants of Simla and its neighbourhood, by the late Colonel Sir Henry Collett, K.C.B., F.L.S.; with an introduction by W. Botting Hemsley, F.R.S., F.L.S., Keeper of the Herbarium and Library, Royal Botanic Gardens, Kew; and 200 illustrations in the text, drawn by Miss M. Smith, artist at the Herbarium, Kew. (London: W. Thacker & Co. Calcutta: Thacker & Spink. 8vo, 652 pp.)

IT has long been a matter of regret that it is so difficult, from the absence of an easy handbook, for residents in any part of the Himalaya to acquire even the most rudimentary scientific information about the numerous and interesting plants which grow around them. Royle's unequal, and on the whole unsatisfactory, folio on the *Botany of the Western Himalaya*, besides being rare and costly, affords very little help to anybody who wants to identify a wild plant which may have attracted his attention during a ramble on the hillsides near Simla. For the Eastern Himalaya, Mr. Gamble provided, twenty years ago or thereabouts, a list of the more important trees and shrubs found near Darjeeling; but Mr. Gamble's work is only a list, and from it the smaller shrubs and all herbaceous plants are excluded. The publication of the late Sir Henry Collett's *Flora Simlensis* removes this disability from the country around the summer capital of India. And henceforth no intelligent resident in, or visitor to Simla can plead, in extenuation of his ignorance of the plants of its neighbourhood, the want of a plain and simple book from which a knowledge of them can easily be obtained. Colonel Collett was quartered at Simla for four years, during which he devoted himself, with characteristic enthusiasm, to collecting the plants of the surrounding country. The area over which he worked (and of which a map is given in this book) measures about 55 miles from east to west, and about 35 miles from north to south. It includes a country varying in elevation from 2,000 to 10,000 feet, and may be taken as thoroughly characteristic of much larger areas of the Himalaya, extending both eastwards and westwards. Collett's identifications were made as he worked by means of Hooker's *Flora of British India*. Not having had any training in systematic botany in early life, he found himself rather overwhelmed by the extent of that monumental and admirable work, dealing as it does with the flora of the whole Indian Empire, from the Himalaya to Singapore. But Collett was the last man in the world to be discouraged by a difficulty; and the results he arrived at in the matter of naming his collections, proved that he had the instinct of a true botanist. Knowing, however, full well from his long experience of Anglo-Indian society, that the desire for informa-

tion about natural objects in general burns in the breasts of the majority of its members with but a feeble and flickering flame, he determined to put into the hands of its next generation a book, the scope of which is best described in the opening sentence of his preface to the present volume.

"It has been my endeavour," writes the author, "to produce a book which shall supply to residents at Simla interested in botany, and acquainted with the rudiments of that science, the means of identifying the trees, shrubs, and herbs they see in their walks about the station roads and along paths, in the neighbouring valleys, or on excursions" beyond these limits. This endeavour has been carried out most admirably, and the result is a local flora of quite an unique type. About 1,300 species are described in it, and 200 of these are illustrated by figures prepared from drawings made by Miss M. Smith, of the Kew Herbarium. These drawings are interspersed in the text; they resemble those given in Bentham's *British Flora*, and are remarkable alike for their artistic spirit and their botanical accuracy. They cannot fail to afford great help to novices in the use of a *Flora*. The descriptions, both generic and specific, are terse and graphic; and excellent keys are provided for all the Natural Families, and for every genus which contains more than a single species. An interesting feature in the book is the etymological account which is given of every generic name.

The text is preceded by an introduction written by Mr. Hemsley, in which are given a brief but excellent account of the phyto-topography of the area treated of, an analysis of the constituents of its flora, together with an outline of the botanical classification followed in the book (that of Bentham and Hooker), and a full glossary of terms. The preface is from Collett's own pen, and it is immediately followed by a graceful "In Memoriam" notice written by Sir William Thiselton-Dyer, in which is embodied a letter from Lord Roberts, giving a brief account of Collett's career as a soldier.

At the conclusion of his service at Simla, where the collections which form the basis of his book were made, Colonel Collett commanded a brigade in the Burmese war, which culminated in the deposition of King Thebaw and the annexation of Upper Burma. During that campaign he collected vigorously, and brought back with him specimens of about 700 species, many of which were new to science. An account of these, prepared in collaboration with Mr. Hemsley, keeper of the Kew Herbarium, was published in the *Journal of the Linnean Society*. Collett subsequently commanded brigades on two widely different frontiers of India, namely, the North-Eastern, with headquarters in the Khasia Hills, in the midst of the richest botanical regions in India; and the North-Western, with headquarters at Peshawar, in the midst of a comparatively poor flora. His experience as a field botanist was therefore wide and varied. His high sense of duty induced Collett, on account of his deafness, to retire from active service at the very time when his friends considered a higher command than he had ever held seemed to be within his grasp. After his retirement, Collett settled in London, and he devoted the remaining years of his all-too-short life to the elaboration of this *Flora of Simla*. The collections on which he chiefly worked where those which he had brought from India; for these he was free to dissect as he pleased. But he also freely consulted the fine suites of Himalayan plants in the Kew Herbarium, and it was in that herbarium that his Flora was prepared. For years his slender, active figure was almost daily to be seen hovering about the cabinets, while his bright, cheery manner endeared him to al the workers under the same roof. Collett had practically finished the manuscript of his Flora, and he had seen one or two of the earlier sheets of it in proof when he had a slight paralytic stroke, which proved to be the first signal of the breaking down of his powers. During the succeeding portion of his life, Collett was more or less of an invalid, and the task of editing his Flora and of passing it through the press was put into the very competent hands of Mr. Hemsley, by whom it was published about a year after the author's decease.

Collett's death was a loss to the science of systematic botany in England, which in its present depressed condition could ill spare so keen a follower. It was an irreparable loss to those who had the privilege of his friendship, or even of his acquaintance, for in him were united in singularly happy proportions the chivalry of a soldier of the old school, the mental alertness of a man of science of the present day, the shrewdness of a man of affairs, and the sweetness, courtesy, and grace of a true English gentleman—

"His bones are dust,
His good sword rust,
His soul is with the saints, we trust."

G. King.

The Week's Work.

THE FLOWER GARDEN.

By J. C. TALLACK, Gardener to E. MILLER MUNDY, Esq., Shipley Hall, Derby.

Lawns.—Daisies and other weeds will need every effort at this season to extirpate them, the work being carried on till mowing begins. The best method of doing this is to use the hand-weeding fork, which takes out the root, and leaves very few traces that the first shower or week of mild weather does not efface. The work should be done systematically, taking a narrow strip and marking it off with a line, and so on, over the entire surface; and the roller should be used after every heavy shower.

Ground-work. — This should be expedited, especially where heavy operations are involved. If turfing has to be done on land that has been manured, it will be advisable to remove some of the soil and replace it with other that more nearly approaches the staplo which underlies the lawn. Where it is advisable to make a grass-edged walk narrower, let the turf be raised and drawn forward into the new position, and fill in the gap so made behind the strip with new turf.

Conifers.—Conifers are mostly gross feeders, and never look so happy as when a mild form of manure is applied annually. The present is a suitable season for affording a mulch of decayed manure, in bad cases removing a thin layer of the soil, and replacing it with richer material. Where this is done, it has great influence on the new growth.

Hydrangea paniculata.—A group of this fine hardy shrub has a bold effect on turf, especially if there is a background of evergreens. In order to obtain good heads of bloom, the plants should be pruned severely down to buds near their base, and the resultant shoots reduced in number to not more than half a dozen per plant, as the fewer the shoots the larger the flower-heads.

Bulb Garden.—Stir the soil in beds of Tulips, Hyacinths, and the like, while there is yet room to work an implement among them. If for tidiness sake a mulching of cocoanut-fibre is considered necessary, it should be applied after the soil is stirred. Cutting winds injure the leaves of Tulips, &c., and if shelter can be applied it will be an advantage.

Begonias.—Tubers lifted in the autumn should now be placed in boxes on a small quantity of soil, and be half covered with the same, which should contain a large proportion of leaf-mould. Start under cool treatment, and grow them cool all the time they are under glass. The stock of plants may be increased by dividing tubers which show numerous buds. The cut surfaces of these divisions should be sprinkled with quicklime or flowers-of-sulphur, and be allowed to get dry before boxing them. Seedlings may be pricked off into boxes, and grown on in warmth. It is not advisable to single out these seedlings at this stage, as this will be better done at the next shift. For the present prick them off in small colonies.

THE KITCHEN GARDEN.

By JOHN FLEMING, Gardener to Sir C. PIGOTT, Bart., Wexham Park, Slough.

Cauliflowers.—Autumn-raised plants should be afforded air freely, and not be allowed to suffer lack of water at the root, or buttoning will follow. If they are crowded, lift every other plant with a trowel, and plant them under handlights or in cold frames at 6 or 8 inches apart; afford water to settle the soil, and keep close for a few days. Plants not large enough to be handled easily should be pricked out into pans or boxes, and placed in a frame made up for the purpose, with a not too rich, light soil. Ventilate abundantly on every fine day, and cover the lights with mats when frost threatens. A successional sowing may now be made, choosing such varieties as First Crop, Early Forcing, or Defiance. In order to secure later crops, small sowings should be made of Magnum Bonum, Walcheren, and Autumn Giant, and of the Self-protecting Broccoli.

The Parsnip.—A sowing of Parsnip-seeds may be made on soil that is light and dry, which was trenched in the autumn. The land should be levelled, and the surface made of as fine a tilth as possible. If the seed be new, sow thinly in drills 1½ inch in depth drawn 18 inches apart, covering lightly, and finishing off neatly with a wooden rake. In the north, and in cold districts and heavy soils, sowing may generally be deferred till the beginning of next month.

Shallots.—Plant forthwith on manured, trenched land, top-dressing it with road-grit and wood-ashes; setting the bulbs in shallow drills drawn at 1 foot apart, and 9 inches apart in the drills. Press the bulbs down with the finger-and-thumb sufficiently deep to keep them in position, and cover to the extent of three-quarters of their depth.

Garlic may be similarly planted, just covering the bulbs.

Seakale.—If this vegetable be grown at home for affording roots for early forcing, the "thongs" which have been reserved to serve as sets should now be cut into 6-inch lengths, the upper end being cut level, and the lower end slanting; then tie them in bundles of twenty, and stand them upright in some fine soil, the tops just being covered, and place in a garden-frame, where they will soon form buds. They may then be planted when a callus has formed at the root-end. Continue to place crowns in the Mushroom-house or other warm, dark place.

Capsicums and Chillies.—Sow seeds for raising plants for early fruiting, and place the pans or seed-pots in a hotbed, potting off the seedlings singly when they have got large enough to be handled; and later bring them into 6 or 7-inch pots. Keep them stocky by placing them within a short distance of the glass in a pit or forcing-house having a warmth of 60° to 70°.

Mint and Tarragon.—These roots should be lifted in the required quantity, and placed, the former in boxes, and the latter in pots, using a light, finely sifted soil for covering the roots. Apply water to settle the soil, and introduce them in batches to gentle warmth. See that the roots do not lack water, or growth will be stunted; and afford air, in order to keep the growth stocky.

Celery.—If Celery be required early in the autumn, sow seed of White Gem or some other early variety in pans, in light porous soil, sowing thinly if the seed is new, and place on mild bottom heat in a frame having a top-heat of 60°. Celery should never suffer lack of water at the root, or it will soon run to seed; and of these early sowings it may be said that the plants should never be checked in their growth.

Parsley.—Sow the seed thinly in boxes under glass in a gentle warmth. Gradually harden off the seedlings, and plant out in deep, rich soil in April, at one foot apart. Seed sown in the open at this date germinates slowly, and will not give such good return as that sown under glass.

THE HARDY FRUIT GARDEN.

By Chas. Page, Gardener to J. B. Fortescue, Esq., Dropmore, Maidenhead.

American Blight.—Apple-trees affected with this troublesome pest should have a lather of Gishurst Compound-soap rubbed into all chinks of the bark, &c., with a stiff painter's brush, or in lieu thereof petroleum emulsion may be employed. All dead bark should be removed from the affected spurs and branches before applying the remedy.

Protecting the blossoms of Apricots.—The Apricot is beginning to expand its blossoms in the south, consequently protective measures should be forthwith taken to ward off frost, showers of hail and snow; and for this purpose a double thickness of fishing-net is excellent, as it obstructs the light but very little. Stout poles of Larch or Spruce-Fir should be driven into the border at a distance of 4 feet from the base of the wall, and their tops pushed up tightly under the coping; the fishing-nets can then be tied to the top and bottom of each pole, which should be placed at 5 feet apart. In the event of severe frost appearing imminent, tiffany should be placed over the nets, and made secure.

The Blackberry, &c.—This fruit should be grown on strained wire fences, or on wooden palings facing south. The method of cultivation is that pursued with the Raspberry, the wood that fruited last summer being removed in the autumn, or at the present season; the shoots cut back to a well ripened part, and then be fastened to a wire-fence or to stakes. The soil about the stools should be lightly pointed over, and a mulch of short manure applied.

Rubus laciniatus, &c.—The Parsley-leaved Blackberry is an excellent hardy species. Wilson Junior bears fine fruit of a pleasant flavour; R. phœnicolasius, the Japanese Wineberry, is very good eating as a preserve, and the foliage and stems are ornamental.

The Fruit-Room.—The remainder of the Apple-crop should be examined once a week, and any fruit showing the least sign of decay removed. Of the culinary varieties, Wellingtons, Norfolk Beaufin, and Gloria Mundi are keeping well this year; and that fine old Apple, Sturmer Pippin, is now at its best.

FRUITS UNDER GLASS.

By T. H. C.

Pine-apples.—This is a good time to put into their fruiting-pots the plants that are well rooted, choosing for Queen Pines pots of 10 inches in diameter, and for Smooth Cayenne and other robust-growing Pines, pots of 11 and 12 inches. Do not pot any Pine plant unless the soil is in a dry state, as then, for a few days after the potting, a syringing twice daily will afford all the moisture necessary. The potting soil should consist of light turfy loam, torn to pieces by hand; to each wheel-barrowful of which a 7-inch potful of bone-meal and rather more of charcoal-nuts may be added. If the loam is retentive, add as much mortar-rubble as will make it porous. All soils used in potting should be made warm. Use a rammer in potting; but do not injure the leaves. Afford the plants bottom-heat of 85° and top-heat of 60° to 65°. Keep close for a week, and syringe twice a day, damping the walls and the surface of the bed. Plants that exhibit signs of fruiting by an enlargement of the central rosette, should be afforded warm liquid-manure or other fertiliser whenever moisture at the root is needed. If there are plants which, although growing strongly, show no signs of fruit, let water be withheld till they do show them. The bottom-heat need not exceed 85°, nor the top-heat 65° by night, and 10° higher by day, affording air when the weather permits.

The Early Peach and Nectarine-house.—The fruits are swelling rapidly, and may in cases where the general state of the plants seems to call for it be afforded mild liquid-manure, if not any has been applied since the trees were started. No certain rule can be laid down as to when water may be applied to fruit-tree borders, so much depending upon the character and depth of the situation. Shallow borders, or those consisting of porous light loam, need a small quantity at a time and frequently, whereas retentive soils do not need so much water, nor such frequent applications. In any case, water should be applied before the soil gets really dry, and then in sufficient quantity to thoroughly moisten the entire mass of soil, and no more, and not as is sometimes done, to wash much of the goodness out of it by excessive applications. Disbudding and thinning the fruit will now be partially carried out, the best placed being left on the upper sides of the branches, and small or deformed fruits removed. If time permit, when the shoots are about 4 inches in length, tie them in at the base to the bearing wood, which will facilitate the final tying in, and is a point to be observed in the proper training of Peach trees. Pinch the points out of very strong shoots, or cut them back to basal laterals. A night temperature of 55° to 60° may now be maintained, and one of 10° higher during the day; ventilating freely when the weather permits, starting early in the day with a small amount, gradually increasing it, closing the house in the afternoon or earlier in the day, and syringing the foliage and damping down. Ply the syringe in the early morning, and in other ways keep the air of the house moist.

Succession Houses.—Attend to the disbudding, fertilising of the flowers, and to other details as advised for the early house. Houses containing trees from which fruit is looked for in the months of July and August should now be closed. The buds of trees in succession houses are in a forward condition, and if the fruit is not wanted till late in the season, let as much air as possible be afforded night and day, closing the ventilators only in the event of frosty weather occurring.

THE ORCHID HOUSES.

By H. Alexander, Orchid Cultivator to Capt. G. L. Holford, Westonbirt, Tetbury.

Shading.—Shading will soon be wanted on the roofs of the various houses, especially in the south. The various sorts of shading employed should be put into proper working order. Those houses which should be the first to be furnished with shading are such as contain Cypripediums, Phalænopsis, Odontoglossums, Masdevallias, Miltonias, and others having leaves of a soft texture. At Westonbirt the blinds are of tiffany, a special white kind being used on many of the houses, and another of a lighter texture on houses containing Dendrobium Phalænopsis Schroderiana, Vanda teres, Thunias, Lælia anceps, and for other plants which are not injured by slightly modified sunshine. These are fixed on runners placed 9 ins. from the glass, so that a free passage of air passes between the blinds and the glass. Doubled blinds should be used on houses in which shade-loving plants are cultivated, especially if the aspect is southerly; these should be fitted so as to be worked separately, using the double shade only when the days are very bright and the sun's rays scorching.

Lælia anceps.—Mexican Lælias that have short pseudo-bulbs have ceased to flower, and should now be transferred to the intermediate-house to be rested in full sunshine, with sufficient water applied at the roots as will keep the pseudo-bulbs plump, and the roots in a healthy state. Lælias of this section usually produce a cluster of roots from the last-made pseudo-bulbs soon after flowering, and the white varieties do this much earlier as a rule than the coloured ones; and when this cluster of roots is remarked, repotting or surfacing may receive attention, but on no account should the plants be repotted unless the compost has deteriorated greatly. When repotting must be performed, let the whole of the compost be shaken from the plants, and the dead roots removed, as well as the pseudo-bulbs that are no longer of any use to the plant, and repot in well-drained, shallow pans or baskets. A suitable compost for Lælias consists of equal parts of turfy peat and rough loam, a small quantity of chopped-up sphagnum, and a heavy sprinkling of small crocks and silver-sand. The surface may be finished off with clean, chopped sphagnum and peat-fibre, mixed together. Plants that have been repotted may be placed on a stage for a time, sprayed overhead daily till such time as new roots penetrate the compost, afterwards suspending them in a lighter position, and affording water sparingly. A sodden condition of the potting materials must not occur, or the new roots will decay as soon as they enter the compost.

PLANTS UNDER GLASS.

By J. Mayne, Gardener to the Hon. Mark Rolle, Bicton, Budleigh Salterton, Devonshire.

Cannas.—A stock may soon be worked up, as every bud with a few roots attached will quickly make a plant if given a bottom heat of 60°, and a temperature of about the same degree. The soil should be rich and porous, containing a good proportion of well rotted dung. Cannas are easily raised from seeds, which should be sown now in a bottom heat of 70° to 80°, soaking the seeds in warm water for a day or so previously.

Coleus.—Take an early batch of cuttings and insert them singly in small pots containing sandy soil, and place in the propagating box as advised recently for Crotons. Avoid too much moisture, and leave on a very little air during the night.

Gloriosa superba.—The tubers of this interesting stove climber should now be shaken out of the old soil, and be repotted in 10 or 12-inch pots, which should be three-parts filled with peat and loam in equal quantities, and a fair amount of sand; put three tubers into each pot, and as the plants require much water when making quick growth and flowering, let the drainage be made perfect. The tubers start away much better if a little bottom-heat be afforded, but no water should be applied until growth appears above the soil.

Caladiums.—A part of the stock may now be introduced into a warmer structure. Shake them out, and repot as soon as it can be seen the roots are active, examining each tuber, and if decay has set in, scrape the affected parts with a knife and rub it with powdered lime. Loam, half-decayed leaf-soil, with a little peat, and fresh horse-droppings passed through a ¼-inch sieve, silver-sand, and a small quantity of charcoal, make an excellent compost for Caladiums. Plunge the pots in bottom-heat, and afford but little water until growth is active, giving them the full benefit of the sun for some weeks yet.

Sowing Seeds.—The following should now be sown in heat, treating the tuberous Begonias, hybrid Gesneras, and Streptocarpus as advised for Gloxinias in a previous calendar; Richardia Elliottiana, Grevillea robusta, and a pinch of Torenia Fournieri and T. Bailloni for early flowering.

Hanging Baskets.—Asparagus Sprengeri and A. deflexus are plants that look well in baskets, and when growing thus some attention should now be given the plants. If a basket has to be replanted, line it with moss and fill it round the plant with lumpy loam and peat. Davallia bullata, and other Davallias, are excellent Ferns for baskets.

Bouvardias.—The shoots may be pruned to prominent buds and placed near the glass in a house having a temperature of about 60°, syringing them once or twice daily, but affording no water at the roots for a few weeks. When the plants break, shake off the spent soil, remove a few of the stronger roots from the more robust plants, and place the pieces in sandy soil in mild bottom-heat to form roots, and soon afterwards nice little plants will grow, which must be potted off. Another way is to shorten the shoots less, and afford a moist heat of 65°, when plenty of cuttings will be forthcoming, but I prefer root cuttings, as they are sooner out of hand, and usually make more bushy plants, by reason of their throwing up strong suckers from the roots. Aged plants should be placed in smaller pots in equal parts of loam and leaf-soil, with plenty of sand, put in the same position as first mentioned, and be often syringed, but not afforded much moisture at the root.

General Remarks.—Eranthemum pulchellum, Plumbago rosea, Begonia Gloire de Lorraine, Centropogon Lucyanus, Coleus thyrsoideus, Justicias, and Reinwardtias that are past their best, may be cut back to within a few inches of the last stopping, and be placed near the glass in a temperature of 60°, when later on nice, sturdy cuttings will be forthcoming. Libonias, Coronilla glauca, and Solanum capsicastrum require to be rooted early. Place them in a bell-glass or hand-light in the same temperature.

EDITORIAL NOTICES.

ADVERTISEMENTS *should be sent to the Publisher.*

Letters for Publication, *as well as specimens and plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Illustrations.—*The Editor will thankfully receive and select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.*

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY, FEB. 23—Surveyors' Institute meeting.

TUESDAY, FEB. 24—Royal Horticultural Society's Committee's Meeting.

WEDNESDAY, FEB. 25—Royal Botanic Society meet.

THURSDAY, FEB. 26—Irish Gardeners' Assoc. meet.

SALES FOR THE WEEK.

MONDAY and FRIDAY NEXT—
Herbaceous Plants, Perennials, Liliums, Rose and Fruit Trees. &c. at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.

MONDAY, FEBRUARY 23—
Large quantities of Dwarf Roses, Conifers, Ornamental Flowering Shrubs, &c., by Messrs. Johnson, Dymond & Son, at their City Auction Rooms, 38 and 39, Gracechurch Street, E.C., at 12.

WEDNESDAY, FEBRUARY 25—
Azaleas, Rhododendrons, Palms, Rose Trees, Liliums, &c., at 67 and 68 Cheapside, E.C., by Protheroe & Morris, at 12.—Orchids, Lilies, Roses, Gladiolus, &c., at Stevens' Rooms, at 12 30.

THURSDAY, FEBRUARY 26—
Nursery Stock, Greenhouse, Horses, &c., at the Nursery, Grove Park, Lee, S.E., by order of Mr. G. Hind, by Protheroe & Morris, at 12.

FRIDAY, FEBRUARY 27—
Orchids in variety, at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12 30.

(For further particulars see our Advertisement columns.)

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick —40·1°.

ACTUAL TEMPERATURES:—
LONDON.—*February* 18 (6 P.M.): Max. 50°; Min. 35°.
February 19 (Noon): fine, cool; 52°.
PROVINCES.—*February* 18 (6 P.M.): Max. 50°, W. Ireland; Min. 40°, E. England.

Sale of Poisons.

WE learn from the *Times* that the Departmental Committee appointed by the Lord President of the Council to consider the question as to the sale of poisons, has issued its Report. We have not ourselves, at the time of writing, seen the report, but we understand that the Committee express the opinion that poisonous preparations used in agriculture and horticulture, or for sanitary purposes, should be sold only by licensed persons, and subject to regulations to be made by the Privy Council.

The Pharmaceutical Society, under existing regulations, is compelled by the terms of the Pharmacy Act to proceed against unauthorised vendors of certain poisonous compounds, such as sheep-dip and weed-killers; and these regulations, which are objected to by other dealers as establishing a monopoly, are also considered by the Committee as unduly onerous.

Certain regulations in Parts I. and II. of Schedule A are suggested, of which the most important relates to the regulation of the traffic in arsenic and its preparations. The Committee also suggests a third sub-division under the schedule, in which are placed preparations of (1) arsenic, (2) tobacco, or the alkaloids of tobacco, and (3) carbolic acid, or its homologues, exclusively for use in connection with agriculture or horticulture, or in the case of carbolic acid for sanitation as well. Mr. A. CROSS, in an interesting supplementary report, advocates allowing greater latitude in the sale of poisonous substances for manufacturing uses, which is developing continually.

That some such regulations are required in the public interest, can hardly be doubted. Whilst no druggist can legally sell certain poisons or compounds containing poison for medicinal purposes in small quantities without complying with various formalities intended for the protection of the public, it was a common practice, till lately, for corn-dealers, ironmongers, seedsmen, and others, to sell similar articles intended for manufacturing or agricultural purposes, without any such formalities. We have ourselves purchased weed-killers and fumigating materials containing enough poison to prove fatal to large numbers of people without any restriction or enquiry whatever, and in some cases without any indication on the package as to the dangerous nature of the contents. The question whether the sale of such substances should be monopolised by one set of licensed dealers is altogether secondary to the principal issue, and is one which need not be discussed here. The main point is to secure that all reasonable precautions should be taken in the sale of such deadly substances by whomsoever distributed.

Against deliberate wickedness or dense stupidity, no regulations can wholly avail, but, at least, they can be so contrived as to prevent any facilities being offered for carrying out nefarious practices, and to place obstacles in the way of preventable accidents.

ROYAL HORTICULTURAL SOCIETY. — The next meeting of the Fruit and Floral Committees of the Royal Horticultural Society will be held on Tuesday, February 24, in the Drill Hall, Buckingham Gate, Westminster, 1 to 4 P.M. A lecture "On the use of Ether and Chloroform in the Forcing of Shrubs" will be given by M. EMILE LEMOINE.—At a general meeting of the Society, held on Tuesday, February 10, eighty-two new Fellows were elected, amongst them being the Duke of Leeds, Viscountess Morpeth, Sir William Vincent, Bart., Sir Gilbert Greenall, Bart., Sir Harold Pelly, Bart., Lady Brownlow, Lady Evelyn Cotterell, and Lady Evelyn James, making a total of 220 elected since the beginning of the present year.

—— EXAMINATION IN HORTICULTURE.—The Society's annual examination in the principles and practice of horticulture will be held on Wednesday, April 22, 1903. Full particulars may be obtained by sending a stamped and directed envelope to the Society's offices, 117, Queen Victoria Street, London, S.W. The questions set at all the previous examinations are now published, price 1s., complete.

—— FRUIT AND VEGETABLE SHOW, CHISWICK, SEPT. 29, 30; OCT. 1, 1903.—A desire has been expressed in several quarters that some idea of the vegetable schedule should be put forth at once. We are accordingly authorised to say that it will include classes for (*a*) single dishes of all sorts of vegetables; (*b*) collection of vegetables (trade only) 100 square feet; do. (amateurs), 50 square feet; do. (amateurs), 24 square feet; collection of Pumpkins and Gourds (open), 50 square feet; collection of 18 vars. of Potatos (trade); do., 12 vars do. (amateurs). (*c*) 3 dishes of Peas, distinct (amateurs); 6 dishes of Round Potatos (amateurs); 6 do. Kidney Potatos (amateurs); 3 do., Kidney Potatos (amateurs); 3 do. Round Potatos (amateurs); 4 dishes of Tomatos, distinct (amateurs); 2 do., Tomatos, do.; 9 vars. salad plants in basket (amateurs)

THE SURVEYORS' INSTITUTION.—The next ordinary general meeting will be held in the Lecture Hall of the Institution, on Monday, February 23, 1903, when a paper will be read by Mr. HENRY LOVEGROVE (Fellow), entitled "Regulations for Protection from Fire." The chair will be taken at 8 o'clock.

HORTICULTURAL CLUB.—The flowers which decorated the tables on the occasion of the annual dinner on Tuesday, February 10, were chiefly sent by Messrs. J. VEITCH & SONS, of Chelsea, who also kindly arranged them. Messrs. SANDER & SONS sent a boxful of choice Orchids for the same purpose.

—— It is desired that applications for membership be received at least ten days before each Committee meeting, which is held on the second Tuesday in the month (the day of the fortnightly display of the Royal Horticultural Society). Application for membership must be made to the Secretary, Hotel Windsor, Victoria Street, London.

MRS. FREDERICK AMES.—The death of this lady is announced as having occurred at Boston, U.S.A., on January 20. Her establishment at North Easton, Mass., is one of the finest in the States, and specially remarkable for its collection of Orchids.

MR. A. D. WEBSTER.—This gentleman has been appointed Superintendent of Regent's Park and Primrose Hill. We hardly know whether he is to be congratulated or not on leaving so interesting a place as Greenwich Park, of which he has lately given us a history; but, at least, we can wish him every success in his new position.

THE HORTICULTURAL HALL.—We are pleased to find that among the donors to the fund in consequence of the appeal in our columns is an eminent foreign horticulturist, who sends a cheque for £5 as a token of his great respect for what the Society has done for horticulture at large, but desires that his name be not mentioned. We are glad also to see that not only the Veitch Memorial Trustees, but also the committee of the Horticultural Club, have made donations to the fund, and we trust that their example may be followed by the local and special societies generally. We could hardly have expected that our foreign friends would have contributed to the fund, but it is incumbent on all our "home-grown" horticulturists to assist in the good work according to their means.

WILLOWS.—A case recently tried in Edinburgh is interesting as showing the practical importance of a knowledge of species such as is now often thought to be of merely academic interest. On Saturday, January 31, 1903, Lord KYLLACHY gave judgment in an action by a firm of Willow growers and exporters, Antwerp, against certain chemical manufacturers, Edinburgh, in which they claimed payment of £238 12*s.* as the price of 75 tons of "red scorse" Willow peelings, which they supplied to the defenders under contract. The defenders refused payment on the ground that the cargo was not conformable to contract. Lord KYLLACHY in disposing of the case said: I have found this to be a difficult and perplexing case. So far as appearances went, I saw no reason to prefer the witnesses on the one side to witnesses on the other. It is, I think, according to the weight of evidence—(1) That what is known commercially as rood or red Willow coincides with what is known botanically as Salix fragilis. (2) That the only other Willows grown commercially in Belgium, or, so far as appears, elsewhere, are Weda (or Salix viminalis), and Rens (or Salix triandra), and that these two Willows do not contain salicin, and are not only botanically but commercially distinct from rood or red Willows, or Salix fragilis. (3) That the cargo in question contained not less than 10 per

cent.—and probably from 15 to 20 per cent.—of Weda (Salix viminalis), or, at all events, Weda and Rens (i.e., Salix triandra). (4) That as regards the suggestion that the admixture consisted partly of Salix purpurea or Salix rubra, which latter is described as a hybrid between Salix purpurea and Salix viminalis, it is sufficiently proved that these Willows, although containing salicin, are not known in commerce as falling within the description of rood or red Willow, and indeed are not known in commerce at all; and further, that it is not proved that the admixture complained of did in fact consist to any appreciable extent of Salix purpurea or Salix rubra. *Pharmaceutical Journal.*

KEW.—The following plant-lists and guides are on sale at the Royal Botanic Gardens, Kew. Those who require them sent by post should be careful to enclose the amount of the postage as well as the cost of the book:—

Key Plan and Index to the Royal Botanic Gardens, Kew. Fifth edition, 1900.

Official Guide to the Museums of Economic Botany. No. 2: "Monocotyledons and Cryptogams." 1894.

Official Guide to the Museums of Economic Botany. No. 3: "Timbers." Second edition, revised and augmented.

Official Guide to the North Gallery. Fifth edition, revised and augmented. 1892.

Hand-list of Trees and Shrubs grown in Arboretum (excluding Coniferæ). Second edition, 1902. Part II. (first edition): "Gamopetalæ to Monocotyledons." 1896.

Hand-list of Ferns and Fern Allies cultivated in the Royal Gardens. 1895.

Hand-list of Herbaceous Plants cultivated in the Royal Gardens. Second edition, 1902.

Hand-list of Orchids cultivated in the Royal Gardens. 1896.

Hand-list of Tender Monocotyledons cultivated in the Royal Gardens. 1897.

Hand-list of Orchids and Tender Monocotyledons, in one volume, cloth boards.

Hand-list of Tender Dicotyledons cultivated in the Royal Gardens. 1899.

Mycologic Flora of the Royal Gardens, Kew. 1897.

The prices are very low; the precise amount in each case can be obtained from Mr. W. WATSON, Curator, Royal Botanic Gardens, Kew.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.—The annual general meeting of this Society will be held at the Caledonian Hotel, Adelphi Terrace, on Monday, March 9, at 8 P.M. Mr. JOHN GREEN, of Dereham, Norfolk, has kindly consented to preside.

SIR WILLIAM HOOKER.—In a recent number, p. 90, we referred to a most interesting "sketch" by Sir JOSEPH HOOKER of the life and labours of his father, Sir WILLIAM HOOKER. This we rightly characterised as a charming piece of biography, but, by an oversight, we spoke of the sketch as an "account of the steady evolution of the Institution [Royal Botanic Gardens, Kew], under the guidance of successive directors." As the memoir in question refers exclusively to the work accomplished or initiated by the first director, our words convey a false impression, which we are desirous to correct. The article in question contains much in relation to the early history of Kew which is not generally known, and many details that have not previously been published, for which reasons we may take an early opportunity of again adverting to it.

ROYAL GARDENERS' ORPHAN FUND.—At the meeting of the supporters of this charity, reported on p. 125, it transpired that whilst many previous subscribers had forgotten to send their usual subscriptions, some one at Surbiton had forwarded to the secretary a P.O. for 5s., along with a voting-paper, but omitted to enclose a note of his name and address. The committee will be glad to learn who was the sender, that the amount may be properly entered in the books.

PUBLICATIONS RECEIVED. — *Proceedings of the Academy of Natural Sciences of Philadelphia,* volume liv., part 2; May to September, 1902. Contains: Two Fungous Diseases of the White Cedar, by J. W Harshberger; and other scientific papers and reports.—From the U.S. Department of Agriculture, Bureau of Soils: *Field Operations of the Bureau of Soils,* 1901. Third Report by Milton Whitney, Chief, and his assistants. The thoroughness with which such works of investigation as are herechronicled are undertaken by the Department is witnessed by the bulky tomes before us. The land has been divided into areas, and elaborate reports are published as a result of soil surveys over these several districts. The extent of country examined involves wide geological differences, and these are well brought out in both letterpress and illustrations. In a separate cover the maps of the counties are enclosed in a form handy for reference, and these also are prepared with a care that must make them of great value to all who have to study the important subject with which they deal.—*Proceedings of the Agri-Horticultural Society of Madras,* January to March, 1902.—*The Agricultural Journal of the Cape of Good Hope,* January, 1903. Contents: Agricultural Education in Cape Colony, Potato Disease (both these articles are illustrated), A Farmer and his Soil, &c.—*Agricultural News,* Barbados, January 31. Contains: Notes on Sugar Cane, Mangosteens, Grape Culture in British Guiana, &c.—*Santo Domingo: The Queen of the Antilles,* by Prof. J. W. Harshberger, University of Pennsylvania. "The Island possesses undoubted resources, mineral and agricultural, which ought to be developed. . . . The gardens of the people bespeak the general decay. . . . Unquestionably the course of events will lead to the annexation of the Island to the United States."—*Additional Observations on the Strand Flora of New Jersey,* by J. W. Harshberger. An interesting account of waterside plants. — *Bulletin from the Laboratories of Natural History of the State University of Iowa.* Contents: The Coleoptera of Colorado, by H. F. Wickham; Descriptions of American Uredineæ, IV., J. C. Arthur and E. W. D. Holway.

BELVOIR CASTLE.

[SUPPLEMENTARY ILLUSTRATION]

"Belvoir, neighbour to the sky,
That with light doth deck its brows—
Belvoir! Art's masterpiece, and Nature's pride."
Harleian Miscellany, 1679.

BELVOIR CASTLE, the seat of his Grace the Duke of Rutland, K.G., is situated in the N.E. corner of Leicestershire, close on the borders of Lincolnshire, and is 8 miles W. of Grantham; it occupies the summit of a sharp, conical hill, which is 200 feet above the land immediately adjacent, and 443 feet above sea-level. The name is pronounced Beever, and is spelt in eighteen different ways in the old deeds and manuscripts. It is derived from the beautiful prospect of the surrounding counties which may be seen from its windows and terraces. Peck, in his MSS. dated 1727, justifies the appellation by a list of 173 parishes in the counties of Nottingham, Leicester, and Lincoln which can be seen. On clear days, Lincoln Cathedral is plainly visible, although it is 27 miles to the N.N.E.

Several castles have occupied this site and disappeared; the oldest part remaining is inside one of the towers, and dates back to the early part of the 16th century; the present building was commenced in 1801. From its commanding position, this site was probably occupied many years before the Norman Conquest, but no records of such occupation are known to exist; some authorities, including Camden, have asserted that it is the ancient site "Margidunum" of Antoninus.

The first castle of which any record exists was built by Robert de Todeni, who came over from Normandy as standard-bearer to William the Conqueror; he also built a priory at the foot of the hill, where he was buried in 1088. The present noble owner is a descendant of this brave old Norman, but the name has changed through the property descending to daughters at various times. Nothing remains now connected with any gardens that existed previous to 1680; some of the old MSS. (of which there is a very large and choice collection) contain various references to vineyards, gardens, and things connected with them. Robert de Todeni gave a tenth of all his vineyards to the priory at Belvoir, and gardens are also mentioned in this charter of endowment: William de Albini III., one of the succeeding owners, who died in 1236, gave "to God, and the Church of St. Mary of Belvoir, and to the monks there . . . the Thorns and other trees growing in my Warren of Belvoir . . . saving to me and my heirs the hares, pheasants, and partridges."

The following interesting items occur in the old Castle accounts:—

	£	s.	d.
1659. The kitchen garden and gardens above ye hils.			
Feb. 4. For 36 Cherry-trees bought at Harlaxton	01	03	04
For 6 more Cherry-trees, at 7*d.* a tree	00	03	06
June 9. To ye French gardner for a gallon of sugar pease and 30 hartichocke plants	00	03	08
1663. Dec. 10. John Hoult, his bill for trees (vidz.), 40 Plum-trees and 40 Cherry-trees	02	14	00
April 17. For ye carriage of 23 Poplar bills out of Derbyshire to Belvoire...	00	6	00
1646-7. Paid to Thomas Milner, my Lord's gardner, his wages beinge in arrere att the takeinge of the Castle* ...	03	06	08
Ite pd. to Ropesley men for 22,000 of quicksetts†	03	00	00
Dec. 24. Eleven laborers that did help to get plants, at 8*d.* p. diem ...	00	06	08

The elevated position which gives the Castle such a commanding appearance for many miles, also contributes largely to the scenery of the flower gardens which adorn the hillsides, and enables many tender shrubs and plants to be grown successfully which are only found in milder climates. The soil is chiefly a strong, deep clay, belonging to the middle lias formation, a layer of a few feet in depth on the top of the hills consists of a sandy loam resting on ironstone, but no stone whatever is found after piercing this layer, nothing but heavy clay to an unknown depth. Rhododendrons and other peat-loving plants thrive here without any admixture of peat, and the Oaks and other timber trees are some of the finest in the kingdom.

The illustration represents a portion of the "Castle" flower-garden; this is surrounded on the N.E. and W. by a thick belt of shrubs, which give protection from cold winds, and the beds can thus be raised above the surface more than usual; a finer effect is secured in this way than could possibly be obtained on the flat system. The pale foliage in the distance is a bold mass of Abutilon Thompsoni, surrounded by Salvia patens, Iresine Herbsti, white variegated Pelargonium Princess Alexandra, and Alternanthera amœna. On the left, in the foreground, tall Ivy-leaved Pelargoniums Jacques Caillot (purple), and tall plants of Swainsonia galegifolia alba, are dotted on a carpet of Artemisia Stelleriana, and surrounded by Iresine Herbsti, golden Pelargonium Verona, Viola Blue Bell, and Echeveria; on the right, in the foreground, is seen a mass of rose-coloured Begonias, surrounded by Veronica Andersoniana variegata, Iresine Lindeni, Golden Feather, and Echeveria; this bed had a centre plant of Dracæna indivisa. In the centre of this garden (on the right of the picture) is a fine specimen of Magnolia umbrella, and behind it a large copper Beech-tree. The tall trees on the left are large specimens of Quercus Ilex, which form an excellent shelter from the north winds. *W. H. Divers.*

(To be continued.)

* The Castle withstood a long siege in the Civil Wars, but had to surrender to the Parliamentary Forces on February 3, 1646.

† Whitethorn plants for hedges.

EARLY SPRING FLOWERS AT EXETER.

A WEEK of summer-like weather, both as regards temperature and sunshine, indnced me on February 11 to see what indications of spring were manifesting themselves out-of-doors in a Devon nursery, so being in the ancient city of Exeter, which may be correctly described as the central axis of the county from which railways and most other things radiate, it was an easy and agreeable occupation to spend an hour or two in the nurseries of Messrs. Robert Veitch & Son, the results of which, at this early period of spring, may be of some interest to the readers of the *Gardeners' Chronicle.*

Of course, my first interest was in what was to be found in flower in the open, and it goes without saying that Crocuses and Snowdrops were much in evidence, but the broad belt of yellow Crocus a foot or more wide along the edge of one of the garden walks reflecting the bright sunshine, was brilliantly visible from distant parts of the nursery. Here also were clumps of Christmas Roses, with abundance of flowers of the pure white and purple forms. Amongst Saxifragas we noticed the white flowers of Saxifraga oppositifolia major; but the new S. Grisebachi (fig. 53), was very striking in the sunlight, the crimson tops of the flower-spikes passing into pale pink below, being well seen above the foliage. Large masses of the double Arabis alpina were showing flower well, as was also Potentilla alchemilloides, and the pretty little Triteleia uniflora.

Amongst flowering shrubs may be mentioned the following:—Rhododendron Nobleanum, with numerous large trusses of deep rose-coloured flowers, a most refreshing sight at this early period; Prunus Pissardi, Exochorda grandiflora, Corylopsis spicata, and Hamamelis arborea, with its curiously twisted yellow flowers.

In a cool house we noticed some very compactly grown plants in pots of Rhododendron davuricum Early Gem, all of which were in full flower, notwithstanding they had been lifted from the open at Exminster Nursery only the day before. Of other plants under glass worth mentioning were the following:—Berberis congestiflora var. Hakeoides; Camellia reticulata, the fine red flowers of which are extremely showy. Though this plant is under glass at Exeter, it grows well, forming large bushes and flowering freely out-of-doors in Cornwall. A single pure white Camellia, called Devonia, was finely in flower in the same house. Daphne indica var. rubra was also a prominent object, as well as a group of the delicate Primula floribunda var. Isabellina, each plant of which was crowded with the pretty pale yellow flowers. Amongst other Primulas were P. stellata Giant White, P. obconica grandiflora, with pinkish-white flowers. Speaking of this species reminds me that, in answer to a question, I was informed that this species has never produced any ill-effects upon those engaged in handling the plants at the Exeter Nursery. Grevillea alpina, a Proteaceous plant with singularly twisted flowers, white tinged with pink, was also well in flower. A good healthy stock of the lovely Transvaal Marguerite (Dimorphotheca Eckloni), though not actually in flower, was full of buds ready to expand, as was also Arctotis aspera. The delightfully fragrant Boronia was also full of buds, but not sufficiently forward to emit its odour. On the other hand, several species of Acacia were attractive, not only for their flowers, but also for their fragrance. In the Orchid-house the presence of a flowering plant of Dendrobium heterocarpum aureum was manifest by the delightful scent which filled the house.

To come to more general things, which however lent brightness at this period of the year, Cinerarias, Carnations, Begonias, and such like, were fully represented. *J. R. J.*

THE CODLIN-MOTH.

DURING the past few years, more stringent measures have been taken than hitherto to annihilate this dreaded pest (fig. 52) of the orchard and fruit garden; and there is still room for continued effort, if one may judge from the state of many orchards, and of the fruit sent to market. From the present date till early in the month of March is the best time to spray the trees, while the buds are dormant, using the caustic alkali wash so frequently mentioned in these pages. This wash not only destroys the eggs of many kinds of insects that hibernate under the rough bark of the trees, but it destroys moss and lichens, which infest trees in damp localities.

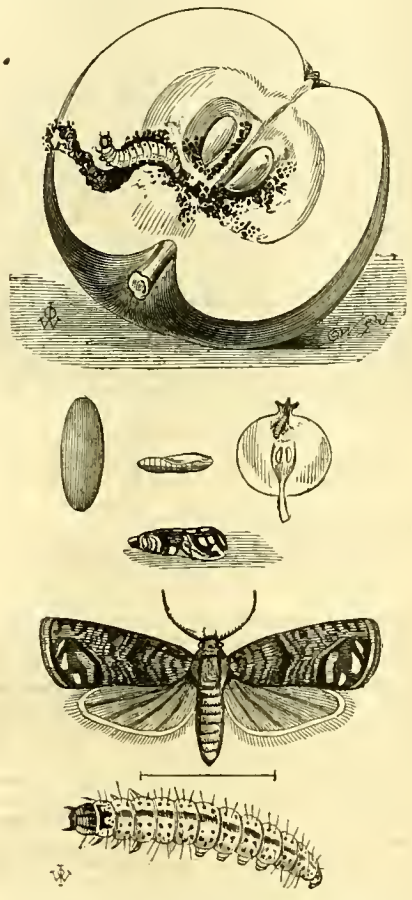

FIG. 52.—THE CODLIN-MOTH: CARPOCAPSA POMONELLA. Caterpillar highly magnified; perfect insect; cocoon, and chrysalis in two stages.

It is estimated that every moth lays about 250 eggs, which in a favourable season turn into caterpillars, that eventually find an entrance to the fruits, which fall to the ground long before they are of full size, with the result that quite half, if not a larger proportion of a crop is spoilt. Now, if this wholesale destruction of fruit can with a little extra perseverance be lessened, surely the fruit-growers of this country would be lacking in their duty if they did not use every means to stamp out this pest. There are several useful sprayers on the market to suit all kinds of customers, and I have found the wash sent out by Messrs. Campbell, of Manchester, to be what they claim for it; it is sent out in canisters sufficient to make 50 and 100 gallons respectively, and is moderate in price.

And while touching upon this subject, it would be well to consider whether our American friends do all they can to mitigate this evil, as I have it on good authority that the codlin-moth is very prevalent in that country, and that large numbers of this maggot are annually imported into this country with their fruit during the autumn months; and if such is the case, there is not the least doubt that when the barrels are opened, these maggots crawl out, and doubtless are carried into the country orchards and gardens by salesmen's empties.

[When the seeds are eaten the fruit falls to the earth, the maggot crawls out, and ascends the tree, gnaws a little bark away, and in the recess it has made, becomes a chrysalis almost immediately. ED.]

I am of opinion, could we but rid our orchards and fruit trees in general of the many pests, such as the Apple-blossom weevil, bark-louse, mussel-scale, codling-moth maggot, Apple-sucker, red-spider, moss, lichen, &c., we could grow as good, if not superior, fruit, to that sent from the other side of the Atlantic, and in quantity enough to meet the demand in this country. But to effect this, we must spare no effort to eradicate these many enemies, which can only be done by paying strict attention to the annual winter washing of fruit trees, and again after the fruits are set, gathering up all early dropped fruit, and burying it, or giving it to the farm-stock, and early in October placing grease-bands around the stems of the orchard trees in order to catch the winter-moth; and an annual dressing of quicklime and soot applied to the ground, especially to orchards under grass. Perhaps some of our leading market growers or salesmen could throw some light upon the importation of the codlin-moth maggot from abroad; if so, I feel sure it would be both interesting and instructive. *J. Mayne.*

CULTURAL MEMORANDA.

ALLAMANDA HENDERSONI.

THIS old-fashioned stove climbing plant holds its own against all new comers. It is a strong grower and free-flowerer, producing its large trumpet-shaped pale yellow flowers in regular succession all through the summer and autumn months. Plants grown on, and shifted into 12-inch or 15-inch pots in due time, and trained over a trellis fixed under the roof-glass at about 15 inches therefrom, will cover a good space of same within a few years from the cutting stage. The somewhat stiff woody shoots should be trained thinly over the trellis, from which the young flowering shoots should be allowed to depend. The plant is also admirably adapted for furnishing pillars and wall-trellises in stoves. So popular and effective is the Allamanda, that one or two varieties trained to balloon-shaped trellises are generally included in collections of stove and greenhouse flowering plants, six of each, staged at leading provincial shows. Cuttings, say three inches long, taken off with a little of the matured wood ("a heel") attached, and inserted round the edge of 3-inch pots (previously crocked and filled to the rim with some of the mixture indicated, but finer, and surfaced with sand) and watered, will soon root if plunged to the rims in a box containing three or four inches deep of dry sawdust, and sufficiently deep to admit of a square of glass being placed thereon without touching the cuttings. The box should be placed on the front stages over the hot-water pipes, or on a shelf in the stove, hot-water pit, or anywhere in heat, potting off the little plants into the same sized pots when well rooted, returning them to a similar position, affording water, and shifting them into larger pots before the roots become matted, they will in due time attain to large dimensions.

IMANTOPHYLLUM MINIATUM.

This old favourite inmate of the stove or warmer greenhouse still holds its own against new comers, the large heads of delicate reddish-orange flowers being very telling in effect during

the spring and early summer months. The compost that the plants succeed best in consists of three parts fibrous loam and one of peat, with a liberal dash of sand and small charcoal added, this being well mixed before being used. The pots should be well crocked, the potsherds being covered with a little moss, or a few half-rotted leaves, to insure good drainage. In repotting the plants, be careful not to over-pot them. On the contrary, stuff them into pots in which there is a clear space of say 1 in. between the ball of earth and roots, and the edge of the pots, so as to admit of the compost being rammed moderately firm round the roots in potting, prior to which the ball of earth and roots should be pricked round with a pointed stick, in order to liberate the roots to some extent, the better to enable them to lay hold of the new mould. Water so as to settle the soil about the roots, afterwards applying it sparingly until the roots have pushed into the rooting medium; after which the supplies of water at the roots must be more frequent, always giving sufficient to moisten the ball of earth and roots. When the flower-spikes appear, occasional applications of weak liquid-manure will greatly assist in the production of fine spikes of large flowers.

POLEMONIUM HIMALAICUM.

This hardy perennial border plant is well worthy of cultivation in every garden, no matter however small; the large branching spikes of lovely sky-blue flowers render it a charming and most desirable garden plant. It is, like the two or three other species of "Jacob's Ladder," of very easy cultivation, doing well in any good garden soil; but the best results are obtained from plants set in a deep, rich, well-drained, sandy loam. The plant is increased by seed and division of the roots, and flowers from May to August. *H. W. W.*

SAXIFRAGA GRISEBACHII.*

THIS remarkable species (fig. 53) received a First-class Certificate from the Royal Horticultural Society at the last meeting, viz., Feb. 10. Not only is it a novelty, but it was collected in quite a new district, having been found at between 4,000 feet and 5,000 feet altitude in Albania and Macedonia. In the dormant stage, the plant is not unlike a small-growing S. longifolia, that is, as regards the largest rosettes; while in others, it partakes of the characters S. calyciflora (media), and particularly in the form and clustering character of the rosettes. Among the chief points of interest and beauty is the purplish-crimson colour of the miniature blossoms. From quite an early stage a purplish-red tint is visible in the inflorescence, even before it emerges from the crustaceous rosette. The peduncles are about 4 inches long, purplish in colour, and densely hirsute, the points now and again tinged with the same colour as the stems. The paniculate inflorescence is somewhat crowded at the apex, and freely furnished with short, bluntish, oblong, decidedly green-tipped leaves, which also render it distinct. The species will in all probability submit to the usual cultural conditions of the members of the genus, and when fully established will prove more free-flowering than those near approaches to it have done to the present time. *E. Jenkins, Hampton Hill.*

ENQUIRY.

FRUIT ROOM.—Will some of our experienced gardening friends kindly afford "Subscriber" some facts in connection with the erection of a fruit-room, or rather of a store for Apples and Pears, he being about to have a room made, and is told by a gentleman that Apples and Pears keep best set singly on stone slabs in a dark cellar with very little light and ventilation.

* *Saxifraga Grisebachii*, Degen and Dörfler, in *Denkschrift d. Kais. Acad. d. Wissenschaft*, Wien, lxiv. (1897), p. 721, tab. II., f. 3.

HOME CORRESPONDENCE.

DAHLIAS. — Your correspondent "C. D. Z.," criticises my notes regarding Dahlias. I have no wish to enter into any controversy on the matter, but am prepared to assert that the replanting of stock roots is, in many cases an advantage, especially when the plants are used for effect and not so much for the production of show flowers. Stock roots produce the earliest flowers, and I have never yet experienced a summer that was long enough to put an end to the flowering season of a Dahlia. This is always left for the frost to do. I might also give instances where it is a distinct advantage to the quality of the flowers to grow them from stock roots, and will mention two, viz., Mrs. Peart and Marguerite Bruant. Stock roots split up, allowed to start slowly in cold frames, and planted out as soon as the weather is suitable, give very little trouble. Work under glass in spring is generally superabundant, and there are very few private gardeners who are prepared to add to their labours by raising a few hundred Dahlias from cuttings at that busy period, and to afford them the after-attention they need, to make good plants for planting out in May. We certainly often hear of the advantages to be gained by using absolutely young plants, but we very seldom indeed see them. In order to mitigate the pressure of work in the spring, my practice is to take cuttings in summer and to winter them in small pots, and let them start away under cool treatment in the spring. Had "C. D. Z." the patience to wait, this would have been outlined in due season, and he, certainly, does not want personal information, for he writes with authority. *J. C. Tallack.*

AGAVE AMERICANA. — I gather from "W. J. P.'s" note, p. 106, that he is under the impression that the flowering Agaves, which formed the subject of the supplementary illustration on Jan. 21, are permanently planted in the open ground. The wording of a portion of the accompanying article certainly rather favoured that supposition, but the quotation from the superintendent's letter shows that this is not so, but that they are afforded glass protection during the winter. Mr. Moorman writes:—"The two plants grew in a house 12 feet in height, and the glass had to be broken so as to allow them to develop," i.e., to allow the flower-stems formed under glass shelter to ascend. Later on, when the weather became more genial, they were evidently removed from the glass structure, and placed in the position in which they are seen in the photograph, where they perfected their flower-stems. I imagine that leaving these Victoria Park Agaves unprotected in the open through the winter would assuredly put an end to their existence. It is a different matter in the genial climate of the south-west, where the other photograph was taken. There Agaves may be planted out from 6-inch pots, and left year after year without attention or protection, until at length a flower-stem is thrown up and the plant blossoms and dies. Agaves that reach a great size do not, however, invariably flower. The finest specimen I have ever seen either in England or abroad, was growing in a Torquay garden, but died last year without having flowered. The dimensions of this Agave were, height of tip of tallest leaf from the ground, 11 feet; girth of plant, 41 feet; length of longest leaf, 8 ft. 11 ins.; breadth of leaf, 19 inches. A few years ago a splendid specimen of the variegated form of Agave americana growing at Kingswear,

FIG. 53.—SAXIFRAGA GRISEBACHII.
Awarded First-Class Certificate at the last Meeting of the Royal Horticultural Society.

South Devon, about a couple of hundred yards from the one illustrated on p. 69, flowered. A little earlier a fine example growing beneath the rock-walk, Torquay, in a portion of that town's public gardens, blossomed; and I have seen two in flower near Berry Head, the western promontory of Torbay. But as "W. J. P." writes, they are to be viewed to best advantage in the Isles of Scilly, where I have noted a group of several flowering simultaneously. *S. W. F., South Devon.*

ROYAL GARDENERS' ORPHAN FUND.—If it is decided to send out collecting cards, I am at present at liberty, being on the look-out for a situation as head gardener, and if about a dozen others similarly volunteered, each undertaking to address 600 or 700 envelopes, the work would readily be accomplished. I would suggest that the addresses be taken from the *Horticultural Directory* for the present year, and that one or more counties, according to size, be allotted to each correspondent. It may be also worthy of note, that there are many children now receiving the benefits of the Institution whose fathers were "single-handed" gardeners, or gardeners in small places, and the names of whom do not appear in the *Directory*. An effort should be made to reach this very numerous class; and as a means of bringing the claims of the Institution before them, I would suggest that suitable literature should be sent to the secretaries of local flower shows, to be distributed at their annual exhibitions. I enclose P.O. for 2s. 6d. as a small donation to the fund. *R. Cubbon, 4, Fern Bank, Victoria Road, Hale, Cheshire.*

AN EARLY SEASON.—An event, such as the opening of the flowers on pyramidal Pear-trees out-of-doors at such an early date as Feb. 12, is almost, I think, unprecedented. Here, the Pear-trees have been for some days quite white with bloom partly open, and several varieties have their cymes fully exposed; and on two trees —Duchesse d'Angoulême and Princess—several fully developed blossoms are visible. In 1902, the first Pear-tree to open its flowers was a Duchesse d'Angoulême, but that was two months later, i.e., April 16; even then the majority of the young fruits were destroyed by subsequent frosts and cold rain, therefore what sort of a fruit-crop may we anticipate this year if sharp frosts should occur during the next six weeks? *Geo. Woodgate, gr., Rolleston Hall, Burton-on-Trent.*

[From Sevenoaks we lately received Strawberry-runners of the variety Monarch, in full bloom. ED.]

WINTER WALLFLOWER, SUTTON'S EARLIEST OF ALL.—With the exception of a few days in January, we have been able to cut Wallflowers continuously since the early part of November, and no protection has been afforded, beyond planting them on a south border. At the time of writing (Feb. 6), the border presents a wealth of flower. I have grown this variety for five years, and it has never failed to produce flowers freely during. If protection is given during severe weather, the supply would be constant. The seed should be sown about the first week in June, and in the middle of July the seedlings pricked out into a nursery bed, allowing six inches between them each way, to enable the plants to make sturdy growth. When they are established, stopping should be carried out. Make the final planting on a dry sunny border, not later than the end of September. *W. P. Bound, Gatton Park Gardens, Reigate.*

THE FORCING OF DAFFODILS. — I fully endorse all that your correspondent, Mr. E. Jenkins, says regarding the forcing of Daffodils on p. 82 in the issue of the *Gardeners' Chronicle* of the 7th inst.; but there are two or three other points that might be added. The lack of success might be traced both to the want of timely preparation, and to the non-observance of the laws of Nature under which these bulbs thrive outside. In order to have the old double-flowered variety Van Zion (Telamonius plenus) in perfect flower during the latter part of December and in January, it is essential that the bulbs be strong, and potted-up or boxed during the preceding July or August, so as to allow a long period for the formation of roots. The bulbs must be placed in heat by easy stages, that is by gradually encouraging the growth till the bulbs are finally transferred to the higher temperature; and even at that time the scape must be well out of the bulb, and it should proceed at an even rate of growth with the foliage. If the foliage is seen to be outstripping the scape, the bulbs are then not in a condition to respond to warmth in a desirable manner, and the foliage will continue to lengthen and the scape remain behind to shrivel up or the flowers to open in a deformed state. If attention to this matter receives timely thought, and the temperature is lowered a little, and air is afforded at the apex of the house or pit, the prevention of an entire loss will be the result. As the different species of Daffodils vary in behaviour when brought into heat, I advise that a few bulbs should be tried, till one is thoroughly versed in the peculiarities of individual varieties. Although the common English Daffodil grows rapidly in its native habitat outside, bringing them into flower artificially very early is somewhat difficult to the uninitiated cultivator. As I pen these few notes, the Daffodils in the plantations are about 3 inches high, and full of flower-buds. *W. Sharpe.*

COLONIAL NOTES.

THE BLUE COLOUR IN HYDRANGEAS.

MR. A. C. BARTLETT'S letter in the *Gardeners Chronicle* of October 11 is in some measure informing, but I think that he and others may easily discover that the temperature and degree of air and moisture in the soil determine the nature of the food imbibed by the roots, and consequently the quality of the sap made available to the flowers. Flowers opening in a rising temperature do not receive sap of the same chemical nature as those which advance in a falling temperature.

The Hydrangea flowers often appear over a considerable length of time, and it may be noted that spring flowers are rarely blue, excepting when they come very early, or are subjected to a return of cold weather, which chills, and excludes air from the soil. Late autumn flowers are frequently blue, and they rarely escape this colour where two or three frosts or continuous rains prevail. Where blue, white, and pink flowers occur at the same time, it may be seen that the wood is of unequal vitality, and also that the roots supplying the respective parts are working in soil differently endowed as to light, heat, and air.

The effect of light in producing colour must always depend on the nature of the sap as it is prepared by the root and leaf. Where leaves are shaded, the roots are generally shaded also; hence, imperfect feeding and debilitated sap, which must of necessity produce a new or exceptional colour in the local flower. The Hydrangea is hyper-sensitive to change of temperature. *C. B. L., Melbourne, Victoria.*

JAMAICA.

In the *Bulletin of the Botanical Department*, Jamaica, for December, 1902, Mr. W. Fawcett mentions that alterations are to be made in the scope and title of this publication. The first number of it was issued in April, 1887, three months after the arrival of Mr. Fawcett as Director of the Department. He now writes that:—"The Botanical Department, or, according to its official title, the Department of Public Gardens and Plantations, has always been concerned with the agricultural development of the Colony, and the bulletin has been an index, or outward sign, of the kind of work that is being carried on. Fifty numbers of the old folio series appeared at irregular intervals to December, 1893, and in January, 1894, a new octavo series was commenced, which has been published once a month ever since. It has been decided now to adopt it as the organ of the Department of Agriculture, which was established by His Excellency the Governor last year with the Honourable the Colonial Secretary as Chairman. With the wider outlook, and to mark that attention will not be confined to the planting side of Agriculture, it has been thought well to alter the name, and it will henceforth be known as the *Bulletin of the Department of Agriculture, Jamaica.*"

MELBOURNE.

NOTES FROM THE BOTANIC GARDENS.—During the past few weeks (December) there has been a perfect blaze of colour in our Botanic Gardens. This was due not alone to the herbaceous or annual border flowers, or even to the Roses (of which we have at least six hundred kinds distributed about the grounds), but also to the flowering trees and shrubs. Visitors from the neighbouring states have expressed their astonishment at the marvellous effects and glorious splendour of large Sterculias (notably S. acerifolia or Flame-tree); the Erythrinas or coral trees—all scarlet or crimson; the masses of orange-coloured Grevillea robusta; the canary-yellow of the huge bushes of Cassia lævigata; the heavenly blue of Jacaranda; the royal purple of the Bougainvilleas; the fleshy-pink of those magnificent trees of South Africa—Dais cotinifolia, and the so-called Cape Chestnut, Calodendron capense. Nothing need be said of the Mesembryanthemums, for they have been seen by everyone who has walked or driven along the Alexandra drive. By the way, we have a novelty here in the way of Pentstemons, P. heterophylla, the flowers of which are cœrulean blue, set on fairly long spikes, and when propagated and massed in borders or beds, it will no doubt become a very popular plant. The Swainsonas are not cultivated in private gardens so much as they deserve. Here there are at least a dozen varieties of S. galegifolia in shades of maroon, purple, pink, crimson, and there is also a pure white variety. *W. R. Guilfoyle, The Garden Gazette.*

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

FEB. 10.—*Present:* Dr. M. T. Masters (in the chair); Messrs. Baker, Fraser, Odell, Michael, Bowles, Worsdell, Sir John D. Llewelyn; Drs. Cooke and Rendle; Revs. W. Wilks, Engleheart, and G. Henslow (hon. sec.).

Eelworms.—A grower sent a communication relating to eelworm in Cucumber-houses, and stated that:—"Twelve houses, each 200 ft. by 20 ft., used for growing Cucumbers and Tomatos, have become infested with eelworm. It is not convenient to either change the crop grown, or to allow a long period of idleness." Mr. Odell reported on this case as follows: "To prevent recurrence of this pest, drastic measures must be taken to destroy the eggs of the eelworm (Tylenchus); merely dressing the bed with lime and soot will not be effective. (1) The whole of the brickwork inside the house should be scrubbed with a hard brush and strong soda water, afterwards lime-washing the same. (2) All barrows, baskets, and other tools used to take out the old soil should be treated as infectious, and thoroughly cleansed. (3) The soil used for refilling the beds should be as fresh as possible; soil standing or stacked near the houses should not be used. (4) Avoid stable or farmyard manure for a time if possible; use artificial manure instead. It should be remembered that organic manures are frequently a source of infection, as the nematodes can pass uninjured through the intestines of an animal fed on infected fodder. The leaflet of the Board of Agriculture on the knot-disease caused by eelworms advises that the interior of the house should be washed with carbolic acid one part, and water eight parts. This I should think would be more effective than the strong soda solution recommended."

Grubs in soil.—Specimens were sent by Miss M. C. Edlmann, Hawkwood, Chislehurst, upon which Mr. SAUNDERS reports as follows:—"The grubs (so-called) proved to be of two kinds; those which were most numerous had unfortunately become chrysalides, so that it is impossible to name them with any certainty. I believe that they belong to the family Bibionidæ, the same family to which the very common flies, the 'St.

Mark's' flies, belong; they are so named because they are often found flying about in large numbers on or about St. Mark's day (April 25). They are in a perfectly harmless condition now, but as grubs they feed on the roots of plants, and are the cause of much injury to them. There were two specimens of the 'galley-worm,' Polydesmus complanatus, one of the Myriapods nearly allied to the Julidæ, which are most destructive creatures. Insecticides have little or no effect on them, but they may be trapped by burying small slices of Turnips, Mangolds, or Carrots just below the surface of the soil near the plants they are attacking. A small wooden skewer should be stuck into each, so as to show where they are buried; these traps should be examined every morning."

Bulbs with dying roots.—Dr. VOELCKER inquired on behalf of a lady who found that bulbs of Roman Hyacinths, Freesias, and Daffodils, after being potted and placed in a greenhouse, were apparently growing well, but the roots had decayed. Mr. WILKS observed that this was due to the bulbs not having been allowed to make roots in ashes for a month previously; so that the shoots were living at the expense of the bulb only, not having sufficient roots for a supply, the latter were starved.

Cattleya, Rapid Flowering.—Mr. ODELL called attention to the very short time in which a plant exhibited at a shew had taken to flower, for it was sown only eleven months ago.

Hybrid Calanthes and the Mendel Theory.—Dr. MASTERS showed purple and white flowers received from Mr. Chapman, who wrote as follows: "The hybrid Calanthes, C. Sibyl (pure white) and C. Oakwood Ruby (the deepest coloured variety in cultivation), were both obtained from the same pod of seed, the original cross being between C. Veitchi and C. rubro-oculata. From selections of the best varieties derived from this batch of seedlings and intercrossing amongst themselves, and continuing the inbreeding for four or five generations at Oakwood, these remarkable results were obtained. This is interesting at the present moment, seeing that Mendel's *Laws of Inheritance* have been placed so prominently before the members of the Scientific Committee of the Royal Horticultural Society. It certainly goes to prove that, instead of reversion to the original crossing by the process of inbreeding, the result has produced and placed before us the widest possible variations from the original cross, and from each other; showing that Mendel's *Laws* cannot be applied [universally] in the way some of our specialists have indicated. It may be interesting also to state what effect inbreeding has had upon the constitution of these plants. It is impossible to describe the diminished size of the bulbs while the general constitution of both varieties is exceedingly delicate. C. Oakwood Ruby I consider the most difficult subject to cultivate among the whole genus Calanthe. I regard it as one of the most difficult Orchids I have ever had to deal with. I hope, before the season is over, to place before the Committee other results of inbreeding of Orchids, which, I think, will go far to prove the inapplicability of Mendel's Laws to Orchids."

Chinese Primrose, Ivy leaved.—Dr. MASTERS showed drawings of this variety taken in 1887, the leaves being lobed like those of an Ivy, and the flowers being remarkable for having only four petals and abortive organs. It appears to be precisely the same now, not having advanced at all.

Cypripedium synanthic.—He also showed drawings of the flower of Cypripedium villosum received from the *Horticole Coloniale*, having six stamens and two stigmae, the sepals being multiplied. The appearances were due to the fusion of two or three flowers into one.

ROYAL GARDENERS' ORPHAN FUND.

ANNUAL MEETING.

FEBRUARY 13.—The supporters of this excellent Fund assembled at the annual general meeting on the above date at Cannon Street Hotel, E.C., but the attendance, as usual, was not large. The chair was taken by Mr. H. B. May, Chairman of the Executive Committee.

REPORT OF THE EXECUTIVE COMMITTEE.

"The presentation of their fifteenth annual report enables the Executive Committee to again offer their congratulations to the supporters of the Fund on its continued prosperity, as although, unhappily, there has been an appreciable falling off in the regular annual subscriptions, the total receipts for the year (exclusive of legacies) show a gratifying increase of £110 1*s.* 7*d.* over the record of the previous year.

"Grateful acknowledgment is made of the receipt of a legacy of £250 from the trustees of the will of the late Mr. Alfred H. Smee, one of the founders, as also one of the original trustees of the Fund; and of a legacy of £100 from the executors of the widow of Mr. John Wills, who, in the early days of the Fund, was a member of the Committee, and until his death was incessantly active in promoting its best interests.

"The Committee, with much regret, record the death of two of the Vice-Presidents, Mr. E. J. Beale, of the firm of Messrs. James Carter & Co., and Mr. William Bull. Mr. Beale was one of the first to assist in the establishment of the Fund in 1887, and it will be within the recollection of many of the subscribers that it was in his office that practical shape was first given to the movement.

"The number of orphans who have been elected to receive the benefits of the Fund during the past fourteen years is 155, and the total amount expended in allowances during the same period is £10 937 7*s.* 6*d.* The number of children receiving the full benefit of the Fund is seventy-three, and during the year compassionate allowances have been made under Rule XIV. to fifteen of the candidates waiting for election.

"With reference to the election this day, the committee believe that they are but carrying out the wishes of all the subscribers in recommending that the whole of the candidates (24 in number) be elected without a ballot, in commemoration of the Coronation of His Majesty King Edward VII., and his most gracious Consort, Queen Alexandra, the patroness of the Fund.

"The committee again most cordially acknowledge the valuable assistance rendered to the Fund by local secretaries and associations of gardeners and others in the districts of Altrincham, Bournemouth, Bradford, Bristol, Chesterfield, Chislehurst, Reading, Rugby, Sheffield, Wimbledon, &c., by means of concerts, and the sale of flowers at exhibitions, on behalf of the charity, and they earnestly hope that during the present year the gardening communities in other districts may be prompted to follow so good an example.

"The committee have much pleasure in recording the fact that on the occasion of the Coronation of His Majesty King Edward VII., and of Her Majesty Queen Alexandra, Mr. John Pinches, of Camberwell, very kindly presented a handsome Coronation Medal to all the children on the Fund. The committee thank him most cordially for his generous gift.

"With keen regret, the committee have to announce the retirement, through pressure of other engagements, of Mr. J. B Stevenson, the local secretary for the Bournemouth district, and who, for the past twelve years, has, at his own cost, most admirably discharged the duties of his office. In the name of the subscribers, and on their own behalf, the committee tender to Mr. Stevenson most grateful thanks for his valuable services.

"The annual festival held at the Hotel Cecil on May 8, under the genial presidency of Leopold de Rothschild, Esq., was of the most successful character, and the Committee most heartily desire to thank all who assisted them in bringing about such a happy result. The Chairman's whole-hearted appeal on behalf of the Fund met with a most generous response, the subscription list amounting to £387 1*s.* 6*d.*, or an increase of £38 14*s.* 5*d.* over the previous year's list. Very cordially indeed do the Committee acknowledge their indebtedness to Mr. Leopold de Rothschild for his great kindness, and it affords them the greatest pleasure in recommending that he be this day elected a Vice-President.

"The supporters of the Fund will doubtless be as gratified to know, as the Committee are to make the announcement, that the Right Hon. the Earl Carrington has most kindly promised to preside at the next festival, which has been fixed to take place at the Hotel Cecil on Tuesday, May 5. The Committee feel sure that they will not appeal in vain for the support of all lovers of horticulture and friends of the Charity, in their efforts to still further enhance the popularity of the festival.

"Several cases having come before the Committee in which, owing to exceptional circumstances, they have been satisfied that it would have been greatly to the advantage of the children concerned if the benefit of the full allowance of 5*s.* per week could have been given for a somewhat longer period than is now fixed by the rules, invite the subscribers to-day to consider and, if approved, to adopt such an alteration in Rule XIII. as will enable them in future to deal with such cases in the manner which they may consider will be most conducive to the welfare of the children under the special circumstances of each particular case.

"The alteration proposed is to add the words printed in italics in the following sentences in Rule XIII., commencing in line 6:—'No child shall receive annual support after having attained the age of fourteen years, *but the Committee may, at their discretion, in exceptional circumstances, continue the usual allowance for a further period not exceeding two years. Further,* the Executive Committee, at their discretion, shall have power to grant a sum not exceeding £10 towards apprenticing or otherwise promoting the start in life of any orphan on whose behalf application shall have been made to the Committee.'

"The members of the Committee who retire by rotation are Messrs. W. Bates, H. J. Jones, H. B. May, J. W. Moorman, W. Nutting, G. Reynolds, A. W. G. Weeks, and J. H. Witty; and Messrs. Bates, Jones, May, Moorman, Nutting, Reynolds, and Witty, being eligible, offer themselves for re election. Mr. G. Caselton, Garden Superintendent, Crystal Palace, is nominated for election to the seat rendered vacant by the retirement of Mr. Weeks.

"The Committee most heartily congratulate Mr. Sherwood on his restoration to health, thank him most sincerely for his continued efforts in promoting the welfare of the Fund, and have great pleasure in again nominating him for re-election as Treasurer.

"The best thanks of the Committee are also due, and are hereby tendered, to Mr. M. Rowan and Mr. P. R. Barr, for their valued services most cheerfully rendered as Auditors. Mr. Barr is the retiring Auditor, and is nominated for re-election."

STATEMENT OF ACCOUNTS.

The principal sources of receipts in 1902, were as follows:—Annual Dinner, £187 1*s.* 6*d.*; Subscriptions, £272 16*s.* 4*d.*; from local Secretaries, £50 6*s.* 6*d.*; Donations, £220 17*s.* 7*d*; from local Secretaries, £19 0*s.* 8*d.*; legacies from Mr. A. H. Smee and Mrs. Jno. Wills, £350; Emma Sherwood Memorial, £13; Dividends on Stock and Interest on Deposit, £309 5*s.* 4*d*; other items, £17 19*s.* 10*d.* Total (including balance of £728 15*s.* 9*d.* from last account), £2,699 3*s.* 6*d.* On the expenditure side, a sum of £1,006 was distributed among Orphans; £73 15*s.* as Grants in Aid; and £13 by the Emma Sherwood Memorial, making a total of £1,092 15*s.* Other expenses were: Annual Dinner, £172 15*s.* 7*d.*; Secretary's Salary, £100; Printing and Posting list to Subscribers, £36 10*s.* 5*d.*; various other items show an expenditure of £98 5*s.* 2*d.* There are balances at Bank on deposit and in hand of £1,198 17*s.* 4*d.*, making a total of £2,699 3*s.* 6*d.*

PROCEEDINGS.

In proposing the adoption of the report and balance sheet, the Chairman said that the increase in the receipts was chiefly due to donations. It was most desirable that there should be more annual subscribers, and that previous supporters of the Fund should not withhold their subscriptions because there was no election on that occasion. An interesting letter was read from Mr. Geo. Stanton, Park Place Gardens, Henley-on-Thames, relating that in the past seven years the Orphan Fund box in the garden bothy had been the means of obtaining a sum of over £12. The gardener on duty there each Sunday passes the box around for pennies, and Mr. Stanton has never heard of a refusal on a single occasion. This practice might be adopted with good results in other gardens. In reference to the candidates for election, the Chairman said that the committee had thought well to advise that all of them should be elected that day by resolution. This was but following the example of the Gardeners' Royal Benevolent Institution, which had placed upon its funds the whole of the unsuccessful candidates last year who were subscribers, to mark the Coronation.

Dr. M. T. Masters, F.R.S., in seconding the adoption of the report, especially congratulated the committee upon the proposal to alter the rules, in order that discretionary powers might be given the committee to assist necessitous children for a period of two years beyond the present time limit. He hoped the meeting would sanction that change unanimously.

On the proposition of Mr. A. Dean, seconded by Mr. W. Cutbush, Mr. Leopold de Rothschild was elected a Vice-President of the Fund. Mr. N. N. Sherwood was then unanimously re-elected Treasurer, on the proposition of Mr. Bates, seconded by Mr. Roupell.

Mr. Rudolph Barr was re-elected Auditer, and the *personnel* of the Committee was amended as suggested in the report above. Mr. A. W. G. Weeks, who has retired from the Committee, was elected a Vice President.

Mr. Brian Wynne was unanimously re elected Secretary at a salary of £100 a year, the Chairman making appreciative reference to the manner in which Mr. Wynne discharges the duties of his office.

CHILDREN ELECTED TO THE FUND.

Sir J. T. D. Llewelyn, proposed the election by resolution of the twenty-four candidates whose names were before the meeting, and remarked that although there would then be 97 orphans upon the Fund, he believed they would be quite justified in doing this gracious act. This was carried unanimously.

ALTERATION OF RULE.

The alteration of Rule XIII., in the manner suggested in the report, was then proposed by the Chairman, who gave some very practical reasons for the change, and

Sir J. T. D. Llewelyn seconded this. In doing so most heartily, he appealed for a wider, broader basis of support for the Fund, as would be the case were there more annual subscribers. At present, the receipts from the annual dinner were excessively disproportionate to the receipts from annual subscriptions. The alteration to the rule was carried unanimously.

THE FRIENDLY DINNER.

Mr. Harry J. Veitch presided in the evening at the friendly dinner of the Committee and friends, the Vice-chairs being taken by Messrs. J. F. McLeod and Brian Wynne. Mr. Veitch was reminiscent, and said that he well remembered going to ask the late Sir Julian Goldsmid to become their first President, and that benevolent gentleman replying:—"Yes, I am already president of thirty-nine societies; I suppose another will not kill me." Since then, said Mr. Veitch, their distributions to orphans and the investments amounted to the sum of £21,000, being an average of about £1,350 per year. But there was a falling off in annual subscriptions, when there should be a gain. He had that day read a letter in the *Gardeners' Chronicle* upon that subject. Mr. Veitch concluded by making an earnest appeal for a greater measure of support from those who can afford to help, even in the least degree, reminding those present of the words. "Inasmuch as ye have done it unto one of the least of these, my brethren, ye have done it unto me."

LINNEAN.

PROFESSOR S. H. VINES, F.R.S., President, in the Chair.

Referring to an exhibition on December 4, 1902, by Rev. John Gerard, of a monstrous form of Geum rivale, Mr. B. Daydon Jackson exhibited specimens in further illustration of median prolification, from the herbarium of Sir James Edward Smith, and the British collection in the possession of the Society. He also stated that the prolified form was mentioned by C. Merrett, in his *Pinax*, 1667, p. 22, as occurring "at Brearcliff, in a wood of Mr. Brearcliff, below his house"; and by John Ray, in his *Synopsis*, 1690, p. 89, as "Caryophyllatam flore amplo purpureo quadruplici aut quintuplici serie petalorum observavit D. Lawson prope Strickland magnum in Com. Westmorland." This locality is mentioned by J. Petiver in his *English Plants*, tab. 40, fig. 4, in 1711, when figuring the plant as "Childing Avens." Later authors, as Relhan in his *Flora Cantabrigiensis*, 1785, p. 200; ed. 3, 1820, p. 207; and Withering's *Arrangement*, ed. 2, 1787, p. 538; ed. 3, 1796, vol. ii., p. 478, refer to this form; the latter author also states that "when cultivated in a dry soil, the flowers are apt to become double or proliferous," *op. cit.* p. 478 [see Masters, *Vegetable Teratology*, p. 122].

Mr. C. H. Wright, A.L.S., on behalf of Sir W. T. Thiselton-Dyer, K.C.M.G., exhibited amphicarpic fruit in specimens of (1) Cardamine chenopodifolia, Pers.; (2) Trifolium polymorphum, Poir.; and (3) Vicia amphicarpa, Dorth.

Mr. H. E. H. Smedley, F.L.S., exhibited twelve wax models of longitudinal and transverse sections of the following seeds:—Stephanospermum akenioides, Pachytesta from the French Permo-Carboniferous Formation, Lagenostoma from the English Coal-Measures, with the recent Torreya and Zamia, in illustration of Professor Oliver's paper.

Prof. F. W. Oliver, D.Sc., read a paper "On Stephanospermum, Brongniart, a genus of fossil Gymnospermous seeds," which was illustrated by lantern-slides, drawings on the blackboard, and the models prepared by Mr. Smedley. The communication was restricted to a consideration of two seeds from the Stephanian of Grande Croix, respectively Stephanospermum akenioides, Brongn., and a new seed which the author proposes to name S. caryoides. Special attention was drawn to the pollen-grains found in the pollen-chambers of these two seeds, which were described at length, and a few grains of unknown pollen were shown to occur occasionally. The complexity of these seeds as compared with those of recent Cycads and other Gymnosperms was pointed out, and a hypothetic scheme was shown to demonstrate a possible transition from one type to the other.

SCOTTISH HORTICULTURAL ASSOCIATION.

WE offer our readers a few extracts from Mr. McHattie's address, given at the first meeting for the session of the above body of gardeners on the 3rd inst., at No. 5, St. Andrew Square Edinburgh:—

"Undoubtedly during the past fifty years great economic improvements have taken place in our methods for the production of fruits, flowers, and vegetables. The study of fruit culture requires the utmost attention of the gardener. Soil, situation, pruning, propagation, selection of suitable sorts, diseases, and feeding, all require to be thoroughly understood and mastered before anything like success can be expected.

"The pomological world is much indebted to Knight, Braddick, Rivers, and Hogg, for their unwearied efforts to raise fruits suitable to grow in our native land. Out of season, and in season, there is a greater demand growing for fruit. With the aid of glass and ingenuity, we have so to speak improved our climate, and where possible, we endeavour to be equal to the great demand for these wholesome productions.

"I do not intend to say anything in regard to the kitchen garden, further than to draw your attention to the importance of studying the management and the nature of different soils for their improvement. A change of crops is founded on acknowledged facts that each sort of plant draws a nourishment peculiar to itself, therefore the young gardener should know the more important constituents of vegetables, if he is to hold his own.

"The ever-increasing demand for choice plants and flowers has quite revolutionised our methods. Efficiency and economy in production are, to my mind, the most powerful considerations, and should be practised and improved on by every opportunity.

LANDSCAPE GARDENING.

"There is less improvement in this branch of gardening than many seem to suppose. Why is this so? Because there is no fellowship with Nature. There is too much presumption and bad taste, founded upon ignorance of what a true garden ought to be. I do not intend to condemn one style or praise another. Much depends on the scenery of the district, the site of the estate, and the climate. Refinement and good taste are clearly apparent in the charming old gardens scattered over the length and breadth of our land.

"I feel certain the present generation of gardeners have more ample material at their disposal in hardy trees, shrubs, plants, roots, and bulbs, for the embellishment of the gardens, than had our forefathers. And I appeal to our young friends here to master this important subject.

"The gardener's prospects are distinctly good in all branches. In the onward march of progress you find the gardener in the front rank:—

'Let us then be up and doing
With a heart for any fate;
Still achieving, still pursuing,
Learn to labour and to wait.'

"Great is the effect of the discoveries of modern science and horticultural practice. Much of this advancement has been brought about by numbers of distinguished gardeners, and by the efforts of associations like this. Not by the fostering care of Parliament, although I hope to see the day when the science of Horticulture is taught in our public schools. No matter what are the surroundings, Nature will always continue to retain a strong claim on the affections of mankind.

"Gardeners have in the past by intelligence, forethought, and persistent industry, left us much material for our edification. To the young men here I would say make yourself acquainted with the gardening of the world, form some definite aim, and see that you carry it out. What has been said of the British gardener is true, viz., that he is the best. See you to it, that by your broad knowledge of your profession and general affairs, this high reputation is maintained, no matter what the difficulties are.

"It must be remembered that most employers are clear headed, well educated business people, and in nineteen cases out of twenty only a good all-round man will please them for any length of time.

"There is nothing for which self-knowledge is more indispensable in practical life than to enable a man to steer a straight course between two extremes, and to discern clearly the boundary line between right and wrong.

"It admits of no question that the first duty of everyone is to endeavour to raise himself above the level of daily cares, and plant himself in a position where he can face the present, and look forward to the future. The man who fails in this is himself a failure; while the man who by his industry and energy supports his home in comfort and respectability, according to his station in life, although fortune may not have placed him in a position of responsibility, yet he has tasted the truest pleasure of mortal existence. A brain trained to respond to the calls of duty soon does so with ease, just as the muscles of the blacksmith's arm, or of the legs of the racehorse, acquire strength and vigour by persistent exercise. Never permit brain or limb to become weakened by self-indulgence. Take the simplest case of a young journeyman gardener, with health, and a knowledge of his trade, or even without the latter, with good thews and sinews, he is the most free and independent of mortals, particularly on one condition, that he has saved, say £12. Then he is a free agent in disposing of his labour, without which he cannot move from place to place. He must accept the wages offered or starve. Gentlemen, is it not peculiarly important for the young to set about correctiug bad habits, and forming good ones, while the faculties are fresh, and the brain supple?

"And I am proud of the position we have held for so many years in matters horticultural. I need not point out that by improving the article in fitness of things we raise its market value."

REDHILL AND REIGATE DISTRICT GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.

FEBRUARY 3.—This Society held its fortnightly meeting at the Public Hall, Redhill, on the above date, the President, J. Coleman, Esq., J.P., D.C., in the Chair.

The Chairman introduced the lecturer, Mr. Kromer, of Roraima Nursery, West Croydon, to give his lecture, "An Orchid Collector's Travels through British Guiana to Brazil."

Mr. Kromer ably dealt with his subject, which was illustrated by lantern-slides. A brief history of Cattleya Lawrenceana was given, and during his travels he mentioned a great many different species of Orchids that were to be found growing—now some were found on the margin of dense forest, and even these were not to be found a few yards inside these forests, showing clearly they require light and air; others growing on rocks beside waterfalls. The lecturer gave an interesting account of his travels up the Massaruni River, and then the ascent of the Roraima mountain, some 8,000 ft. above the level of the sea.

CROYDON AND DISTRICT HORTICULTURAL MUTUAL IMPROVEMENT.

FEBRUARY 3.—An instructive lecture was given on "Peaches" by Mr. Alderman on the above date, which touched on all the most essential points in the cultivation of Peaches. The lecture was most interesting, and was attentively followed by those present. The next paper will be one on the subject of 'Garden Root Crops," by Mr. T. Bunyard, on Tuesday, February 17.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

FEBRUARY 5.—There was on this occasion a good display of plants. S. GRATRIX, Esq., showed a small, but choice collection of plants including Dendrobium × Apollo var. alba, in good form, which has previously been certificated here; Odontoglossum crispum var. "West Point," received an Award of Merit. It is one of the symmetrical, large circular type, destitute of markings; Odontoglossum × Harro-crispum "West Point var.," was not sufficiently developed for the Committee to adjudicate upon it, the plant will, however, be shown again; Cypripedium × Rex, a flower of gigantic proportions and believed to be a cross between C. Harrisianum and C. villosum, received an Award of Merit. The group was awarded a Bronze Medal.

Mrs. GRATRIX exhibited a nice plant of Lælio-Cattleya × luminosa.

Messrs. T. SANDER & SONS, St. Albans, received an Award of Merit for Lælio-Cattleya × Bletchleyensis var. excellens, a fine bold flower having a very richly coloured lip.

Mr. W. HOLMES, Timperley, received an Award of Merit for Cattleya Trianæ var. "Our Queen," a flower of very good form with fine petals and sepals, and a richly coloured lip.

Mr. JOHN ROBSON, Altrincham, sent two Odontoglossums, a good form of O. Adrianæ and O. Harryanocrispum.

A. J. KEELING & SONS, Westgate Hill, near Bradford staged Cypripedium × Pollettianum and C. × Charlesianum.

JAS. CYPHER & SONS, Cheltenham, staged a nice bright group of plants consisting of various good Dendrobes, D. × Leechianum var. giganteum and D. × Ainsworthi, Cypher's var., receiving Awards of Merit. Some well flowered plants of Sophronitis grandiflora, were also in this group (Silver Medal).

Mrs. R. TUNSTILL, Burnley, received a First-class Certificate for a magnificent hybrid Cypripedium called C. × Priam, whose parents are C. insigne var. Chantini × C. Niobe var. superba. It is a handsome addition to our garden hybrids, and is said to be a unique plant.

JOHN COWAN & Co., staged a group of Lycaste Skinneri, in which were several distinct and interesting forms (Bronze Medal). Stanhopea Amesiana, received a First-class Certificate.

O. O. WRIGLEY, Esq., received a Silver Medal for a good group of Cypripediums.

Messrs. CHARLESWORTH & Co., Bradford, received a Bronze Medal for a small group of choice plants. Cattleya × Adonis, a handsome cross between C. Mossiæ × C. gigas the flower showing the characteristics of the two parents (First-class Certificate). Cypripedium × resplendens (Cleopatra × Lawrenceana) received an Award of Merit. *P. W.*

CARDIFF AND DISTRICT CHRYSANTHEMUM.

FEBRUARY 6.—On the foregoing date a large number of members and friends of this Society met at the Grand Hotel, Cardiff, to receive the report and statement of accounts for the working of the Society for the

past twelve months. The chair was occupied by Mr. Councillor J. W. Courtis. The accounts show a small deficit, which was accounted for by the bad weather on each of the two days the show was held; notwithstanding this, there is every prospect of the Society still flourishing, as it was announced by a gentleman present that he had been able to provide three Challenge Cups for competition—one of 10 guineas for the open classes, one of 5 guineas for the amateur section, and one of 5 guineas for the cottagers, who, as a rule, show some marvellous exhibits.

The next show will be held on November 4 and 5. The usual vote of thanks terminated a very pleasant meeting.

CHELTENHAM MARKET GARDENERS.

FEBRUARY 6.—The first annual dinner of the members of the Cheltenham Market Gardeners' Association was held at the Lamb Hotel, Cheltenham, on the above date, and it proved a most successful gathering. The chair was occupied by the Mayor (Col. Rogers). Mr. Bence had the honour of proposing the toast of the evening: "Success to the Cheltenham Market Gardeners' Association."

SOUTHAMPTON ROYAL HORTICULTURAL.

FEBRUARY 6.—There was a good attendance of members of the Royal Horticultural Society of Southampton at the meeting which was held on the above date in the Mayor's Parlour in the Municipal Offices. The Mayor (Councillor H. I. Sanders) presided.

Councillor Blakeway moved the adoption of the report, a summary of which has appeared, and the balance-sheet, urging that as Southampton progressed, the Society should also go ahead, and he made a strong appeal to get another 100 subscribers, which would improve the financial position of the Society, and relieve the Council of anxiety, while it would enable them to make their annual shows, as described by judges, second to none in England.

READING & DISTRICT GARDENERS' MUTUAL IMPROVEMENT.

FEBRUARY 9.—The fortnightly meeting of the above was held in the Club Room on the foregoing date, Mr J. T. Powell presiding over a large attendance of members. The subject for the evening was "Melon Culture: Right and Wrong Methods," and was introduced by Mr. W. Iggulden, of Frome.

The exhibits included some flowers of Rhododendron Veitchi, by Mr. A. F. Bailey, gr. at Leopold House, Reading. Eight new members were elected.

THE HORTICULTURAL CLUB.

FEBRUARY 10.—The annual meeting of the members of this Club was held at the Hotel Windsor on the above date, under the presidency of Sir J. T. D. Llewelyn, Bart.

The report of the committee showed that the Club had made very substantial progress during the year, no fewer than fifty-four new members having been elected, demonstrating that the policy of reducing the subscription to a guinea had borne good fruits in the direction of numerical strength, while the names of the newly elected members demonstrated equally clearly that the status of the Club was fully maintained. Allusion was made to the valuable papers and interesting exhibits which had been read and given by Mr. Arderne on "Cape Gardening," and Mr. Stevens in the direction of splendid photography; and it was abundantly obvious that the Club's claim to be not only the recognised social centre of the horticultural cult, but also an active contributor to horticultural progress, was fully substantiated. Financially the Club maintains its footing, despite the reduced subscription, the new membership, even in the first year, having practically restored the equilibrium of income and expenditure.

After the business meeting, a dinner was held, at which some eighty members and guests attended, including a good number of ladies, though not so many as the Club would have liked to have seen. A capital programme, vocal and recitative, arranged by Mr. E. T. Cook, the secretary of the Club, was interspersed with the usual loyal and appropriate toasts.

Sir John T. D. Llewelyn, who presided at the dinner, in proposing the toast of the Club, pointed out with great force the value of such a cult to business men, who there found precisely the recreation, at once natural, elevating, and inexhaustible, which was best adapted to fill their leisure and distract their minds from the arduous strain of business worries.

Among the visitors was Mr. H. E. V. Pickstone, from the Cape, where he formerly had the control of Mr. Cecil Rhodes' fruit enterprises; and the Club is to be congratulated on the fact that this gentleman has kindly consented to give a paper on "Commercial Fruit-growing in South Africa" at the March meeting of the Club, which will undoubtedly lead to another numerous assemblage of the members, and an interesting and instructive discussion. The Club in this way is doing good and sterling work, and it is greatly to be hoped, in the interest of horticulture, that its recent rapid progress will be well maintained in the future, since the really nominal subscription is so well repaid by the character of its reunions.

THE NATIONAL DAHLIA.

FEBRUARY 10.—A largely attended meeting of the Committee of this Society was held in the rooms of the Horticultural Club on the above date, Mr. E. Mawley presiding. The first business was the selection of patterns of cups or vases which, under Mr. Tulloch's active labours have been provided for competition at the Society's annual show at the Drill Hall, in September next. Some handsome samples were sent for inspection. The committee then dealt with the important question as to the holding of a provincial show at Manchester in the autumn, and letters from that town were read. The Botanical Society, which is desirous of holding an autumn Fruit and Dahlia Show, offered a good sum as prize-money for Dahlias; and from other sources £10 were promised. The committee, in a whip round, promised another £10, and as the value of the prizes offered would be £51 10s., it is hoped that some Manchester people will find the rest. The show is to be held as that of the National Dahlia Society, the committee furnishing the schedule and the judges, whilst the Botanical Society will undertake the advertising. A desire was expressed that the show take place on September 11 and 12, if suitable locally. Dahlias now, besides having two special exhibitions allotted them in London, are catered largely for at all the leading autumn provincial shows, but the Manchester show will be the first provincial show yet held under the auspices of the National Dahlia Society. The chairman strongly urged the members of the trade present to send good garden varieties of Cactus Dahlias to Chiswick for the trial there this year. It was important that the lover of these garden flowers should be catered for as much as the exhibition grower. Mr. A. Dean said his customary prize at the show of 10s. 6d. would this year be offered for the best decorative variety of the Cactus section grown at Chiswick, the prize to be awarded by the committee of inspection.

EALING HORTICULTURAL.

FEBRUARY 13.—At the annual meeting of this Society, a somewhat lugubrious report was presented by the Committee, which went to show that on the occasion of the annual exhibition in July last, which was held at Gunnersbury Park, the weather was very wet, and the loss great, not only sweeping away the balance in hand, but compelling them to enter upon another year with a serious deficit. It was resolved that the committee should take means to bring the claims of the Society before the inhabitants, who have greatly increased during the past few years. The annual exhibition was fixed for July 8, and will take place in the Walpole Public Park, which is near the centre of the town. The committee will determine as to whether a Chrysanthemum show shall also be held. Mr. Leopold de Rothschild was re-elected president.

NATIONAL CHRYSANTHEMUM.

FEBRUARY 16.—The newly-elected executive committee met at the Albert Hotel, Victoria Street, S.W., on the above date. The Secretary called attention to the fact that Mr. H. E. English, who was elected a member of the executive committee at the recent annual meeting was not a member of the Society according to the rules, though a delegate from an affiliated society. Mr. English was declared disqualified, and the highest on the poll of the unsuccessful candidates declared duly elected, namely, Mr. S. B. Linford. A letter was read from Mr. C. E. Shea accepting the post of President, in the place of Sir A. K. Rollit, M.P., resigned. A letter from Messrs. Mackenzie & Moncur, horticultural engineers, London and Edinburgh, was read, offering plate to the value of £10 as a special prize at the November show of the society, which was accepted.

The Secretary presented an interim financial statement showing a balance in hand of £37 8s. 8d., with but a few small outstanding liabilities. It was resolved that the payment to the Secretary for his services in 1903 should be the same as last year.

An offer was accepted from the authorities of Essex Hall, Strand, for three meetings of the Floral Committee to be held there in 1903, viz., on September 21, October 26, and November 23. Meetings will also be held at the Crystal Palace on the first days of the October, November, and December shows. The annual outing was fixed for Monday, July 13, probably to Park Place, Henley-on-Thames.

Of the six outgoing members of the Floral Committee, Messrs. Brookes, Davis, Seabrook, and Turk were re-elected, with the addition of Messrs. C. Black and J. C. Riding. The schedule revision and finance sub-committees were re-elected, with slight modifications; also the classification committee, and the board of arbitration was extended to include the whole of the executive committee.

Considerable discussion took place on the financial condition of the Society, and its ability to carry out three exhibitions at the Crystal Palace. Eventually a resolution was passed to the effect that the finance committee bring up to the next meeting of the executive committee an estimate of the probable income and expenditure for the present year. Five new members were elected.

CHINA.

SHANGHAI.

ONE of the first things Mr. Arthur [Superintendent of the Public Gardens, Shanghai, and an old Kewite], did was to study the nature of indigenous trees in order to find out which are best adapted for foliage trees. The best of the lot was the Pterocarya stenoptera, or Ash, as it is often mistakenly called, and after that the Stillingia sebifera, or Tallow-tree, the Sophora, Melia japonica, and the Ginkgo biloba. The Sterculia was largely used as a shade tree, being mistaken by many for a Plane-tree, but owing to the softness of the wood it is not a suitable tree to plant. All the Planes now growing here have been imported from Europe, or raised from the seed of the imported trees, and luckily proves to be one of the best of trees for shade. The hardy Pterocarya is also a favourite, and how useful it is for the purpose required is practically demonstrated in Range Road, which has recently been planted with it, and already the saplings have developed into sturdy well-grown shade trees. The Ginkgo biloba is another that has proved well worthy of special cultivation. The seeds, after careful preparation, are sown in the nurseries, and obtain a height of about 6 or 8 inches the first year. These seedlings are planted out in beds in the second year a foot apart, and their growth is rapid, so that they are sturdy saplings when again transplanted the third year. Greater space is allowed each sapling during this third year, and pruning is resorted to, which improves the appearance and sturdy growth of the now tall saplings, which are ready when the third year is passed for transference to the roads, and in a very short time they form handsome and useful shade trees.

There are certain indigenous trees that are also being cultivated in large quantities to give variety to the roads, as they all form good shade trees, and these are the Tallow-tree, Stillingia sebifera; the only variety of Elm to be found in this part of China, Ulmus parvifolia, the Sophora, and the Acacia, and the results have proved very satisfactory, so that Mr. Arthur has not only a reserve of shade trees to draw upon ample in quantity, but he can supply a great and pleasing variety.

Mr. Arthur is making experiments with the culture of many species of Japanese trees and shrubs for roads and gardens. A very handsome Japanese tree that is receiving Mr. Arthur's attention is the Paulownia imperialis. This tree is largely cultivated in Japan, because its wood is excellent for making native wooden clogs; but it also forms a very handsome shade tree, and is beautiful in the early summer, when its handsome lilac-coloured racemes are in bloom. Other Japanese shade trees that repay attention in cultivation are the Maple (Acer varieties), Flowering Cherry (Prunus, pseudo-cerasus), Melia japonica, Magnolia speciosa, and varieties of the Oak and Chestnut.

Some very interesting experiments are also being made with well known trees from England, and in the municipal nurseries can now be seen saplings of various sorts. Experience will prove which are best adapted to this climate, so that when use is actually made of them it will be with a reasonable prospect of a good result.

Mr. Arthur has also gone in extensively for the cultivation of ornamental shrubs with a view to improve the appearence of our gardens, cemeteries, &c.; and as a large variety can be easily obtained in Japan, Mr. Arthur has lost no time in experimenting with a view to a survival of the fittest, and therefore there are in the municipal nurseries already a large stock of foliage and

flowering shrubs, prominently amongst which may be seen Lagerstroemia, Camellia, Spiræa japonica, Hydrangea, Ilex latifolium, Juniper, Taxus, Hibiscus, Maple, and many of the handsome variegated Conifers for which Japan is celebrated. There also may be found the indigenous Privet, Ligustrum lucidum, used for hedges; and the Citrus, or wild Lemon, which forms such useful and handsome hedges in Japan. *The N. C. Herald and S. C. and C. Gazette.*

Obituary.

J. HENRY BYVOET. — We learn with great regret of the death on the 15th inst., of this gentleman, at Overveen, near Haarlem. Mr. Byvoet, who died at the age of 70, was the head of the firm of the Gebroeder Byvoet, and was held in the highest respect and esteem by his friends and acquaintances in this country.

CHARLES PENNY. — We regret to have to announce the death, on the 12th inst., of this gentleman, in his seventy-seventh year. He was for some time in the employ of Mr. A. Gibbs, Regent's Park, and was subsequently entrusted with the management of the gardens of the then Prince of Wales at Sandringham. Mr. Penny will be remembered as one of the first to propose in our columns the formation of the Gardeners' Orphan Fund, in commemoration of the first jubilee of her late Majesty Queen Victoria.

TRADE NOTICE.

WE are informed by Mr. A. A. Fabius, Redlands Nursery, Emsworth, Hants, that he has taken into partnership Mr. F. W. Miller, and the firm will in future be known as the Redlands Nursery Company.

ANSWERS TO CORRESPONDENTS.

APPLE SHOOTS: *H. Barclay.* A bad case of canker. Cut out the affected parts, or remove entirely cankered fruit-spurs and the worst affected shoots. If the knife be used, cut down to live healthy tissue and cover with grafting clay or thin sheet lead. If the trees are young, replant them on to a well-drained piece of land, keeping the roots near the surface, and prevent them getting deep by placing a bed of coal-ashes stamped firmly, or concrete about 5 feet square under each tree at 2 feet below the surface of the land.

BLACK SPOTS ON CUCUMBER-LEAVES: *F. W. M.* The appearance remarked on the leaves are the spores of a species of Pilobolus, a dung fungus, which are emitted with some degree of force from the spore cases, but do no harm.

BOOKS: *Manual on the Cultivation of Pansies.*—*R. B.* Mr. House, Coombe Nurseries, Westbury-on-Trym, Bristol, publishes one. The different varieties may be obtained of any nurseryman dealing in hardy plants.—*A. H. and others.* A correspondent kindly informs us that a book dealing with *Table Decorations*, by W. Lowe, is published by Messrs. Chapman & Hall, Ltd., London. The price of the book we do not know.

CHRYSANTHEMUMS: *Novice.* The varieties you mention should afford good results if cultivated as you describe.

CINERARIA PLANTS DYING OFF: *Puzzled.* There are neither insects nor fungus on the specimen sent, and its death is doubtless brought about by some error in cultivation—perhaps affording very cold water, or pouring water always against the stem.

CORRECTION: The names of the members attending the Floral and the Fruit Committees respectively, were accidentally transposed in our last issue.

CUCUMBER-RAISING: *Market Grower.* The general practice is to sow the seeds in moderately moist soil, making the soil firm beneath the seeds, but loose above them, and to afford no water at that time. It is the danger of the seed rotting which induces the gardener to afford no water till germination has taken place. That is under hotbed treatment; still, seeing that success attends the contrary practice in your case, and the seed-boxes stand over hot-water pipes, you have no necessity to alter your practice. To prevent drawing, it is necessary in the early winter and spring, when sunlight is not abundant, and the admission of fresh air is attended with difficulty, to keep the plants near the glass, whether the plants are raised and grown in hotbeds or over hot-water pipes; and soon after germination, to place them on shelves, hanging or other, placed within a foot of the glass in a warm house. Doubtless plants raised in warmth of 65° answer the purpose, but progress would be greater if bottom-heat of 80° and top-heat of 70° were applied, and the plants kept therein till they have reached a height of 12 to 15 inches. If intended to fruit on the surface of a bed of soil, the plants should be stopped at the first pair of rough leaves, not otherwise.

DOUBLE-SPATHED RICHARDIA: *A. M., Scone Palace.* A very common condition in the white species, and there is no reason why it should not become so in the yellow ones, when they have been longer in cultivation. As yours is a seedling plant of Richardia Elliottiana, it will be interesting to see if the habit is constant.

EMIGRATING GARDENER: *T. H.* In consideration of the delicate health of your wife, South Australia, Tasmania, or New Zealand are the better colonies. They are rich in promise for market gardening, fruit-growing, dairying, and sheep-farming; and employment is well remunerated if the emigrant is competent to carry out in a workmanlike manner that which he undertakes to do. You might with advantage advertise in the columns of this or colonial journals.

GRAFTING THE CHERRY ON AN OLIVE: *J. N.* We do not believe that success would attend the attempt.

GRUB: *H. Barclay.* The insect does no harm to living roots, &c., but subsists on decaying matter.

JOURNEYMAN GARDENER LIVING IN A BOTHY: *C. B.* In the absence of any agreement the gardener is in law, assumed to be a domestic, and before he can quit his employment, except in the case of gross dereliction of duty, he must give or receive a month's notice.

MANURES FOR THE TOMATO PLANT: *W. J. D.* We intend to publish an article upon the subject in an early issue of the *Gardeners' Chronicle.*

NAMES OF FRUIT: *S. S. S.* 1, Hambling's Seedling; 2, Royal Russet; 3, not recognised; 4, forward to the Fruit Committee of R. H. S. next year; 5, very nice appearance and good flavour. It would be wise to forward this also to the Committee; 6, Claygate Pearmain.

NAMES OF PLANTS: *Correspondents not answered in this issue are requested to be so good as to consult the following number.*—*Devon.* 1, Pseudotsuga Douglasii; 2, Sequoia sempervirens; 3, Retinospora squarrosa; 4, perhaps Hypericum, send when in flower; 5, Ribes fuchsioides; 6, Polygonum complexum.—*Land.* 1, Carex paludosa; 2, Myriophyllum spicatum; 3, Radiola Millegrana; 4, Filago germanica; 5, Spergula arventis.—*J. W. R.* Thank you for the fine specimens you send. We believe the cones are as follows: 1, Pinus Montezumæ; 2, 4, 6, forms of P. ponderosa; 3 and 5, P. Jeffreyi. All these species are extremely variable.—*W. H. S.* The cut may be intended to represent some species of Galium, but your question is apparently not of a horticultural character.—*J. S. B.* 1, Iris histrioides; 2, Rhododendron, an early-flowering variety, perhaps "Early Gem;" 3, Hedera Rœgneriana; 4, H. helix var. conglomerata; 5, Piptanthus nepalensis; 6, Rhododendron hirsutun.—*Reader.* Cornus mas, Cornelian Cherry.—*G. H. S.* Petasites fragrans, white variety.—*H. T.* 1, Berberis Mahonia; 2, Berberis Darwini; 3, Berberis Wallichi; 4, Berberis stenophylla, a hybrid; 5, Berberis buxifolia; 6, Berberis Bealei.—*J. P. Croydon.* Cœlogyne lactea.—*H. H.* Cypripedium insigne, and Clivia miniata, often called Imantophyllum miniatum. It is a Natal plant, and will grow well in the dwelling house, conservatory, or greenhouse.—*A. Y. L.* Odontoglossum odoratum.—*T. T.* 1, Adiantum cuneatum grandiceps; 2, Adiantum cuneatum Pacottii; 3, Adiantum Waltoni diffusum; 4, Adiantum cuneatum variety; 5, Adiantum cuneatum; 6, Adiantum capillus-veneris; 7, Adiantum pubescens.—*B. G.* 1, Anthericum lineare variegatum; 2, Ophiopogon Jaburan variegatum; 3, Eranthemum variegatum; 4, Streptosolen Jamesoni; 5, Sparmannia africana; 6, Peperomia arifolia; 7, Lithospermum prostratum.

PALM-LEAVES DESTROYED: *H. J.* and *A. H.* The application of XL-All has been of too great a strength. There are no traces of insects, and no fungus is present.

PRUNUS MYROBALANA AND "QUICK": *Reader.* The growth of the former is the more robust, but less dense, until repeatedly pruned with the shears, than "Quick" (Whitethorn). It forms a safer fence against horned etock.

ROYAL GARDENERS' ORPHAN FUND: *F. B., Ipswich.* The sum of 6s. has been forwarded to the secretary.

SULPHATE OF AMMONIA AS A MANURE FOR A LAWN, ORCHARD TREES, VEGETABLES, VINES, &c.: *J. H.* Good ammonic sulphate will contain about 20 per cent. of nitrogen, and its action upon plants is immediate if the soil is moist. A suitable quantity for farm crops is from 2½ cwt. to 3 cwt. per acre. It would, therefore, be a useful top dressing for lawns if applied at the end of March in small quantities, and four or five times during the season of growth, and to leafy vegetables, Runner Beans, salads, Leeks, Celery; but less so to Potatos and Jerusalem Artichokes. For fruit-trees and Vines it would be less suitable than nitrate of potash and superphosphate.

TAR-DRESSING FOR MEALY-BUG ON VINES: *Grower.* Mix to the consistency of thick paint, cowdung one-fourth, clay two-fourths, and lime one-fourth, with water, in a bucket of ordinary size, then mix with some hot water half-a-pint of gastar till it is quite liquefied, and add this to the contents of the bucket. Tar has a tendency to float, so that it is very necessary to keep the whole mass well agitated whilst applying the dressing to the Vines. The buds of the Vines must be quite closed, or it will do harm.

THE SHADDOCK (C. DECUMANA): *C. H. W.* The fruit of C. decumana has been known as the Shaddock because the fruit was discovered in China about 200 years ago by Captain Shaddock, and carried by him to the West Indies. The fruits occasionally weigh as much as 20 lb., and are then called Pompoleons; it is only the small fruits that are generally seen in English markets, where they are sometimes called "Forbidden Fruit." The Shaddock needs similar cultivation to that afforded Orange-trees; but it is seldom grown in English gardens.

THUIA OBTUSA: *A Constant Reader.* Cool greenhouse treatment in the winter and summer, or if you have space, and the plant is in a pot, stand it out-of-doors in the summer months. All, or nearly all, pruning should consist of pinching the points of the shoots during growth, and finishing in time to allow a slight growth to be made before winter. The instructions given at p. 80 still hold good.

GLASGOW BOTANIC GARDEN: PAST AND PRESENT.

THE Glasgow Botanic Garden has had a somewhat chequered career, and although it has been utilised more or less for two centuries for teaching purposes, it is only within the last few years that anything like a condition of comparative stability has been attained with regard to the collections in the various departments.

The original garden, adjoining the old College in the High Street, was, according to Sir Walter Scott, "laid out in the Dutch taste, with clipped hedges and statues." It was here that Sir Walter laid the scene in which Rob Roy interrupted the combat between Rashleigh and Francis Osbaldistone. The garden, however, has an historical significance, chiefly from the fact that it was here that Dr. (afterwards Sir William) Hooker devoted the early part of his career, and to whom the garden is indebted for a great portion of its early success.

There seems to have been very little interest taken in botany in Glasgow previous to the eighteenth century. The *University Records* show that the science, conjoined with anatomy, was taught in the old College as far back as the year 1718.

In 1717, the Provost of the city disposed of a portion of the north side of the "Doohill" to the Glasgow College for the purpose of forming a garden; but it is certain that a piece of ground, set apart as a botanic garden, for the cultivation of plants illustrative of botany, existed prior to this date.

A few years later, viz., September 29, 1720, there is a minute in the "Records" to the effect that, "A motion in favour of Mr. Andrew Graham that there should be granted to him a diploma creating him a Doctor of Medicine, he having studied for a long time, and particularly that he had studied botany in this University."

It would seem from the following that the College authorities deemed it prudent to exercise a strict supervision over those entitled to admission to the garden :—

> "THE COLLEGE, GLASGOW, Feb. 13, 1721.
>
> "The Faculty, considering that the keys of the Garden-door are now renewed, and that, conform to a former order, none but Masters have got any of them, it may be convenient that the sons of noblemen who are scholars have the use of said keys, with a certain restriction, do therefore allow the said sons of noblemen a key to the Great Garden and Physic Garden, providing the said privileged person, upon receiving the said key from the Principal, promise to allow no other the use of said key, and at the end of every session to re-deliver said key to the Principal."

No detailed account of the old physic garden or of its contents remain. Owing, doubtless, to the rapid extension of manufactories and other buildings in the vicinity of the College at the beginning of the last century, the site of this garden became anything but favourable to the cultivation of plants.

In 1817, Mr. Thomas Hopkirk, of Dalbeth, a distinguished local botanist, with the co-operation of the University and several prominent citizens, succeeded in establishing a public botanic garden at Sandyford, then on the outskirts of the city.

The combination of botany and anatomy was found to be unsuitable, and a separate lectureship was instituted in 1818, Dr. Robert Graham being the first occupant of the Regius Chair. This gentleman took an active part in the formation of the new garden, and gave several courses of lectures within its grounds. In 1820 he was succeeded by Dr., afterwards Sir William Hooker. Owing partly to the energy of the latter, as well as his influence with Glasgow merchants and shippers, contributions began to arrive rapidly from all parts of the world. The number of living species in the garden in 1820 was about 9,000; in 1825 the number had increased to 12,000, while from this time onwards the stock kept steadily increasing.

In 1841 Sir William Hooker, having been appointed Director of the Royal Gardens, Kew, resigned the Glasgow chair, and was succeeded in the same year by Professor J. H. Balfour. About this period it became evident, owing to the rapid extension of the city, that another site must be selected, and in 1841 the garden was again removed westwards to the picturesque situation which it now occupies on the banks of the river Kelvin.

The successive occupants of the chair of botany (Prof. G. Walker-Arnott, appointed 1845; and Prof. Alexander Dickson, appointed 1868), had many financial difficulties to contend with during their respective periods as directors. But that the time from 1841 to 1879 was not quite barren of results is proved by the fact that many new species, including Dracæna Goldieana, Aristolochia Goldicana, and Strophanthus Bullenianus, Mast. (all figured in the *Gardeners' Chronicle*), and others not previously described, were sent to the garden during this period by the late Rev. Mr. Goldie, and other enthusiastic collectors.

The ground originally occupied by the botanic garden consisted of 21 acres, but since the acquisition by the corporation recently of part of the Montgomery Estate, north of the Kelvin, the extent has been increased to 40 acres. The new addition, however, is of the nature of a public park, and is separated from the garden proper by the river Kelvin.

In 1871, Mr. John Kibble, of Coulport, Lochlong, a retired Glasgow merchant, presented to the garden his very beautiful conservatory, which was removed from Lochlong and re-erected on a more extensive scale in the garden by Messrs. James Boyd and Sons, the famous horticultural builders of Paisley. It is constructed entirely of glass and iron. The façade is 150 feet in length, and consists of entrance hall 50 feet wide, terminated on each side by transepts 50 by 28 ft.; while a pond, mainly used for half-hardy aquatic plants, occupies the centre immediately within the entrance door. The "main hall" is 471 feet circumference, the roof being supported by iron pillars connected by spandrils. It was in this building the opening meeting of the British Association took place in 1876. Here also Benjamin Disraeli and William Ewart Gladstone delivered their addresses as Lord Rectors of Glasgow University. It was subsequently turned into a winter-garden. The centre under the dome is completely occupied by a unique and varied collection of, mostly, arborescent Ferns. Conspicuous amongst them are large specimens of Cyathea insignis, C. dealbata, C. medullaris, Dicksonia Smithii, D. Schiedei, D. Barommetz, Marattia cicutæfolia, M. Cooperi, &c., Podocarpus vitiensis, P. chilina, Agathis australis, A. obtusa, Araucaria Rulei, Phyllocladus trichomanoides, and other interesting coniferous plants are successfully cultivated here.

If the fifteen years, ending 1840, were notable in the history of the Glasgow garden, the six years ending 1885, were equally so. Prof. Bayley Balfour was appointed to the Glasgow Chair in 1879, and during his tenure of office the general aspect of the garden was completely changed. It was during his directorship that the Kibble Conservatory, previously used as a concert hall, was transformed into a winter-garden. He also succeeded in procuring funds for the erection of the splendid Teak-wood range of conservatories, so sadly needed at the time; and the herbaceous ground, then under the old Linnæan system, was remodelled and re-arranged in accordance with Bentham & Hooker's *Genera Plantarum* under his supervision. In the carrying out of these important changes, Prof. Balfour had the assistance of Mr. Robert Bullen, the late and estimable Curator. Prof. Balfour left the Glasgow garden splendidly equipped on his appointment to Oxford, and he was succeeded in 1885 by Prof. F. O. Bower, the present occupant of the Regius Chair.

Though inferior in size to Kew, Dublin, or Edinburgh, the Glasgow garden is not proportionately inferior in interest and value. Certain portions of the collection will bear comparison with the best. It is in the open air department that the weak spot is to be found. This weakness is certainly caused by the smoke-contaminated atmosphere, rendering impossible the establishment of a good representative shrubbery or arboretum. Most Conifers refuse to grow at all; others, as Pinus austriaca, P. Strobus, P. sylvestris, and Taxus baccata, have a begrimed appearance; while all deciduous trees suffer more or less. Notwithstanding these drawbacks, every recognised branch of out-door botanic gardening is adequately represented at Glasgow, including the herbaceous ground, rock-garden, bog-garden, and water-garden.

C. Sherry.

ORCHID NOTES AND GLEANINGS.

CYPRIPEDIUM × J. BARTELS.

A FINE flower of this showy, though rather narrowly-constructed cross between C. callosum and C. Boxalli is sent by Mr. H. C. Corlett, gr. to Holbrook Gaskell, Esq., Woolton Wood, Liverpool, who has raised it from seed. The large, reflexed-edged dorsal sepal is blackish-purple, changing to bright dark rose colour as it approaches the white margin. The petals and lip are yellowish, the former being tinged with purple on the upper half, and the latter similarly tinged on the face. It was first shown by Messrs. Sander & Sons at the Royal Horticultural Society, November, 1894. The flower is specially interesting, for it is identical with two sent a little time ago by M. Otto Beyrodt of Marienfelde, Berlin, which were said to have been taken from plants received with a batch of freshly imported C. callosum.

BULBOPHYLLUM OCCULTUM.

A fine specimen of this singular Mauritian species is in flower in the collection of H. T. Pitt, Esq., Rosslyn, Stamford Hill (gr., Mr. Thurgood). The plant has stout flower-spikes, bearing triangular racemes of flowers almost hidden by large imbricating bracts, giving to the inflorescence the appearance of a head of corn. The bracts are arranged in three rows, with the rather pretty whitish, purple-stained flowers just peeping out from beneath them. Bulbophyllum rufinum and a few other singular "botanical" Orchids are in bloom; also, in addition to a good display of the showier species, among which the Odontoglossums are especially vigorous.

CYPRIPEDIUM × PRIAM.

The fine results to be obtained by intercrossing the crosses of Cypripedium Fairieanum, was well demonstrated in the beautiful C. × Minos, Young's variety, for which R. Briggs-Bury, Esq., secured an Award of Merit, at the Royal Horticultural Society's meeting, on February 10; and now, an equally good example is sent by Mrs. Tunstill, Monkholme, Brierfield, Burnley (gr., Mr. W. Balmforth), the flower being of C. × Priam (Niobe × insigne Chantini). It was raised by Messrs. Jas. Veitch & Sons, who obtained a First-class Certificate for it when shown at the meeting on November 20, 1900, and it is said that only this one appeared. It was purchased by the late Robert Tunstill, and secured a First-class Certificate at Manchester, on February 5. It is a fine companion to C. × Minos, Young's variety, its large white dorsal sepal being beautifully marked with bright purple. The petals and lip have a yellow ground colour, finely marked with bronzy-purple.

CYPRIPEDIUM × JUNO.

Although this extremely pretty cross between C. Fairieanum and C. callosum was awarded a First-class Certificate when shown by its raiser, Drewett O. Drewett, Esq., at the Royal Horticultural Society's meeting on February 9, 1892, it is still a rare plant, seldom seen in flower. In the collection of Francis Wellesley, Esq., Westfield, Woking (gr., Mr. Gilbert), a special feature is made of all the C. Fairieanum crosses, both direct and secondary, and at the present time some of them are in bloom; but the flower of C. × Juno—two on a scape—has a fine dorsal sepal, flushed and lined with carmine-rose, and veined with purple, making it most attractive. The petals and lip are tinged and marked with a dark purplish tint, and the entire flower is very distinct, notwithstanding that a large number of hybrids have already flowered. Of these crosses, C. × Baron Schroder and C. × Minos, Young's var., are regarded as two of the showiest.

CYPRIPEDIUM × MINNIE.

By an error in the record of the parentage, this distinct hybrid was given an Award of Merit on January 17 as C. × Samuel Gratrix var. Miunie. The fact, afterwards disclosed, that it did not resemble C. × Samuel Gratrix, caused the committee to alter the name to C. × Minnie (parentage unrecorded). It was shown by its possessor, Francis Wellesley, Esq., Westfield, Woking (gr., Mr. Gilbert). It is a fine flower, with a large pure white dorsal sepal, the lower two-thirds of which possesses evenly-distributed lines of rose-purple spots. The lip and petals are yellow, tinged and veined with dark purple. A large number of varieties of C. × Euryades, C. × Leonidas, and others of the same section, are now in bloom in Mr. Wellesley's collection, but among them there is none that indicates the parentage of C. × Minnie. *J. O'B.*

NURSERY NOTES.

MESSRS. V. N. GAUNTLETT AND CO., REDRUTH.

WHEN in Cornwall, during the month of January, I paid a visit to Messrs. V. N. Gauntlett & Co.'s nursery at Redruth, and, though the season of the year was far from being a favourable one to view open-air plants in any portion of England, I saw enough to assure me that during the spring and summer months a walk round the grounds would prove a treat to any lover of the rarer flowering shrubs. The genial atmospheric conditions which exist in Cornwall render that county particularly adapted for the growth in the open air of subjects whose culture is not possible except under glass shelter, throughout the greater part of England. The owners of good gardens being aware of that fact, and being, fortunately, for the most part, enthusiastic gardeners themselves, one is able, in making a tour of Cornish gardens, to see many rare and beautiful greenhouse shrubs and plants enjoying perfect health in the open grounds. Messrs. Gauntlett have especially laid themselves out to supply the wants of those who are desirous of attempting the culture of rare and tender shrubs in the open, and their collection is an interesting and varied one. Their assortment of Bamboo embraces sixty-three species, some of which, such as Arundinaria nobilis and Phyllostachys mitis, are difficult to obtain true to name. Of the rarer species of Rhododendrons, Falconeri, Griffithianum (better known as Aucklandi), Thompsoni, barbatum, argenteum (grande), and others, are well represented, large plants in tubs being available for such as wish for immediate effect. Of the general collection of shrubs, the following were noteworthy: Andromeda (Zenobia) cassinæfolia, A. nitida, Asimina triloba, Banksia quercifolia, and others, the climbing Berchemia racemosa variegata, Buddleia Colvillei, B. insignis, B. japonica, and B. variabilis; Clerodendron trichotomum, of which there are several fine examples in the south-west, the yellow-flowered, sharply-thorned Cæsalpinia japonica; the queen of Camellias, C. reticulata; Corokia buddleoides, Crinodendron Hookeri (Tricuspidaria hexapetala), Caryopteris Mastacanthus, and its white variety; Carpenteria californica, a common shrub in the south of Devon and Cornwall; Daphniphyllum glaucescens, a specimen of which in the neighbourhood of Penzance has attained a height of 12 feet, and a spread of 22 feet; Desfontainea spinosa, D. Hookeri; the ivory-blossomed Drimys Winteri, Edwardsia (Sophora) grandiflora, E. microphylla, the brilliant-flowered Embothrium coccineum, whose vermilion bloom-clusters glow in many a Cornish garden in the spring of the year; the Persimmon (Diospyros Kaki), the Canadian Mayflower (Epigæa repens), of which there was a large stock; the noble Eryngium pandanifolium, a splendid plant for the wild garden, throwing up flower-stems 10 feet and more in height; Euonymus fimbriatus, whose young crimson leaves look like flowers in the spring.

Of Eucalypti there are about thirty species, together with Escallonia langleyensis, Fremontia californica, a handsome yellow-flowered shrub, of which there are some good specimens in the south-west; the white-flowered Illicium religiosum, and I. floridanum, with maroon blossoms; the pretty Indigofera floribunda alba, Lagerstrœmia indica, Laurus camphora, L. glandulosa, L. regalis, Lycium barbarum [? sinense] variegatum, an ornamental climbing shrub; Olearia (Aster) argophylla, with musk-scented leaves; O. insignis, O. macrodonta, O. nitida, O. nummulifolia, Olive-tree, Parrotia persica, a little-known shrub producing brilliant autumnal effect; Paulownia imperialis, Pernettya ciliaris, Philesia buxifolia, bearing Lapageria-like flowers; Phormiums in variety, many species of Pittosporum, including P. Ralphsii; Photinia arbutifolia, Pueraria japonica, a vigorous climber bearing rosy-purple flowers; Romneya Coulteri, the Fuchsia-flowered Currant (Ribes speciosum), several Senecios, Solanum crispum, Spiræa japonica coccinea, a new variety introduced by Messrs. Gauntlett from Japan; Magnolias of many species, Stephanandra Tanakei, Tetranthera californica, a rare evergreen shrub bearing white flowers; Trochodendron aralioides, Veronica Gauntletti, a shrubby species producing orange-red flower-spikes; Viburnum Awafuki, a Japanese species bearing a profusion of white flowers; and Zelkova Kaki.

Messrs. Gauntlett grow a large collection of the best of the Water-Lilies, and of the Japanese Iris Kæmpferi, or lævigata, they have some 10,000. On the day I was at Redruth, large cases of Tree-Pæonies from Japan were being unpacked. In one of the houses I saw three pots of Mutisia decurrens, a rare climber now almost unobtainable. *S. W. F.*

PEAS IN 1902.

AT no time during the last ten years have my Pea crops been so good as they were during 1902; and while my success may be partially attributed to the use of manure, a large proportion must be set down to the heavy rainfall of the year, the quantity of rain registered being 30·01 inches.

There is no lack of variety among dwarf-growing early Peas, but for the first crop I put my trust in Chelsea Gem, for although it has not the true Marrowfat flavour, as have some of the newer dwarf Peas, it turns-in quickly, and is a heavy cropper; and the first Peas tasted in the season, even if they are not Marrowfats, are always much appreciated.

Sutton's Green Gem carried some very fine pods, filled with Peas of good flavour. This variety will grow from 9 to 12 inches in height. Many may not agree with me, but I think 1 foot is quite short enough for these broad-podded early Peas, for when less than this the pods are too near the ground.

Veitch's Seedling is another fine early round Pea, growing about 18 inches in height, of good flavour, and heavy cropping properties. Veitch's Acme, growing about 3 feet in height, is an abundant cropper that I shall continue to grow. A fine-flavoured early Pea from the same firm is their Earliest Marrow, which I have grown for several years; it still holds the same place among the early marrows, and is an abundant bearer.

Of the early, large-podded marrow Peas, Thomas Laxton is unexcelled, and when sown at the same time as the earliest marrows, Early Giant or Gradus, it comes in more than a week earlier. The pods are large, closely set with large Peas of good flavour; it is a good Pea to grow for

clearing off quickly, much superior to Gradus. The last-named Pea I grew for three years, and only had it good once in that period of time; I have now discarded it. I think, if my memory serves me aright, there were two strains of this sent out, and now that it is re-selected it may prove more satisfactory.

Sutton's Ideal, sent out in 1901, did remarkably well. It grows about 3ft. in height, and produces a profusion of dark, green-coloured pods, and the Peas are of good flavour. Duke of Albany is a well-known Pea that succeeds in these gardens, and is an indispensable taller growing variety. A Pea in very much the same way as the last-named, but a few inches taller, which might be described as an improved Duke of Albany, is Laxton's Alderman. In regard to cropping I had nothing to equal it last year. This and Duke of Albany were grown side by side, in lines about 12 ft. apart, for comparison, and both were dressed with artificial manure, Alderman receiving basic slag and the other superphosphate of lime; both rows had kainit and nitrate of soda in addition, but whether the heavy crop was due to the use of basic slag I cannot say. Certainly, the results justified the use of artificials, including nitrate of soda, which last was applied when the haulm was about 18 inches high. The dressings of kainit and superphosphates were forked into the land previously to sowing the seed. For comparison, a row of Thomas Laxton was dressed with nitrate of soda only, applied when the plants were 18 inches high, but with apparently no benefit to the crop. One, if not the largest, of the broad-podded Peas is Eckford's Ideal, a Pea that reaches a height of 5 feet, which is a good second early variety. I have grown it for the last four years, and it has always been good, or if it have a fault it is in being rather tall for a second early Pea.

Glory of Devon, sent out by Messrs. Veitch, of Exeter, is a magnificent maincrop Marrowfat Pea, of which Veitch's Perfection may be one of the parents; but it is a hardier and more vigorous grower. Masterpiece proved a good cropper, and grows to about 3 feet in height. Criterion is now well known; and the newer Chelsonian is also a tall-growing Pea, of good flavour. Hertford Success is rightly named, if the term is applied to its cropping, for it quite came up to the standard of some varieties that apparently crop so heavily when grown on paper. Edwin Beckett and Weston Maincrop were, through an oversight, sown later than I intended; this, however, did not alter the quality of the produce. Weston Maincrop, offered by Messrs. Cutbush, is a tall-growing Pea, which I hope to test again. With Edwin Beckett one need not hesitate, for among all the varieties I cultivated, this possessed the finest flavour in a season generally good for Peas. Autocrat maintained its place as an excellent maincrop or late Pea. Dwarf Mammoth was likewise good as a late cropper; as was Best-of-All, which is an equally good variety for either a showery or dry season, it being likewise a continuous bearer. Ne Plus Ultra was good, as usual; and Lord Roberts, a Pea with haulm of moderate height, was a promising variety.

In the cultivation of Peas my former practice was to manure and trench the land intended for Peas, and there is something to be said in its favour if one could foretell the kind of weather. I now trench and manure the ground generally as for other crops, while before sowing I have applied various artificial manures with very good effects, and I have made use of nitrate of soda, superphosphate of lime and potash, with satisfactory effects sometimes, but not always.

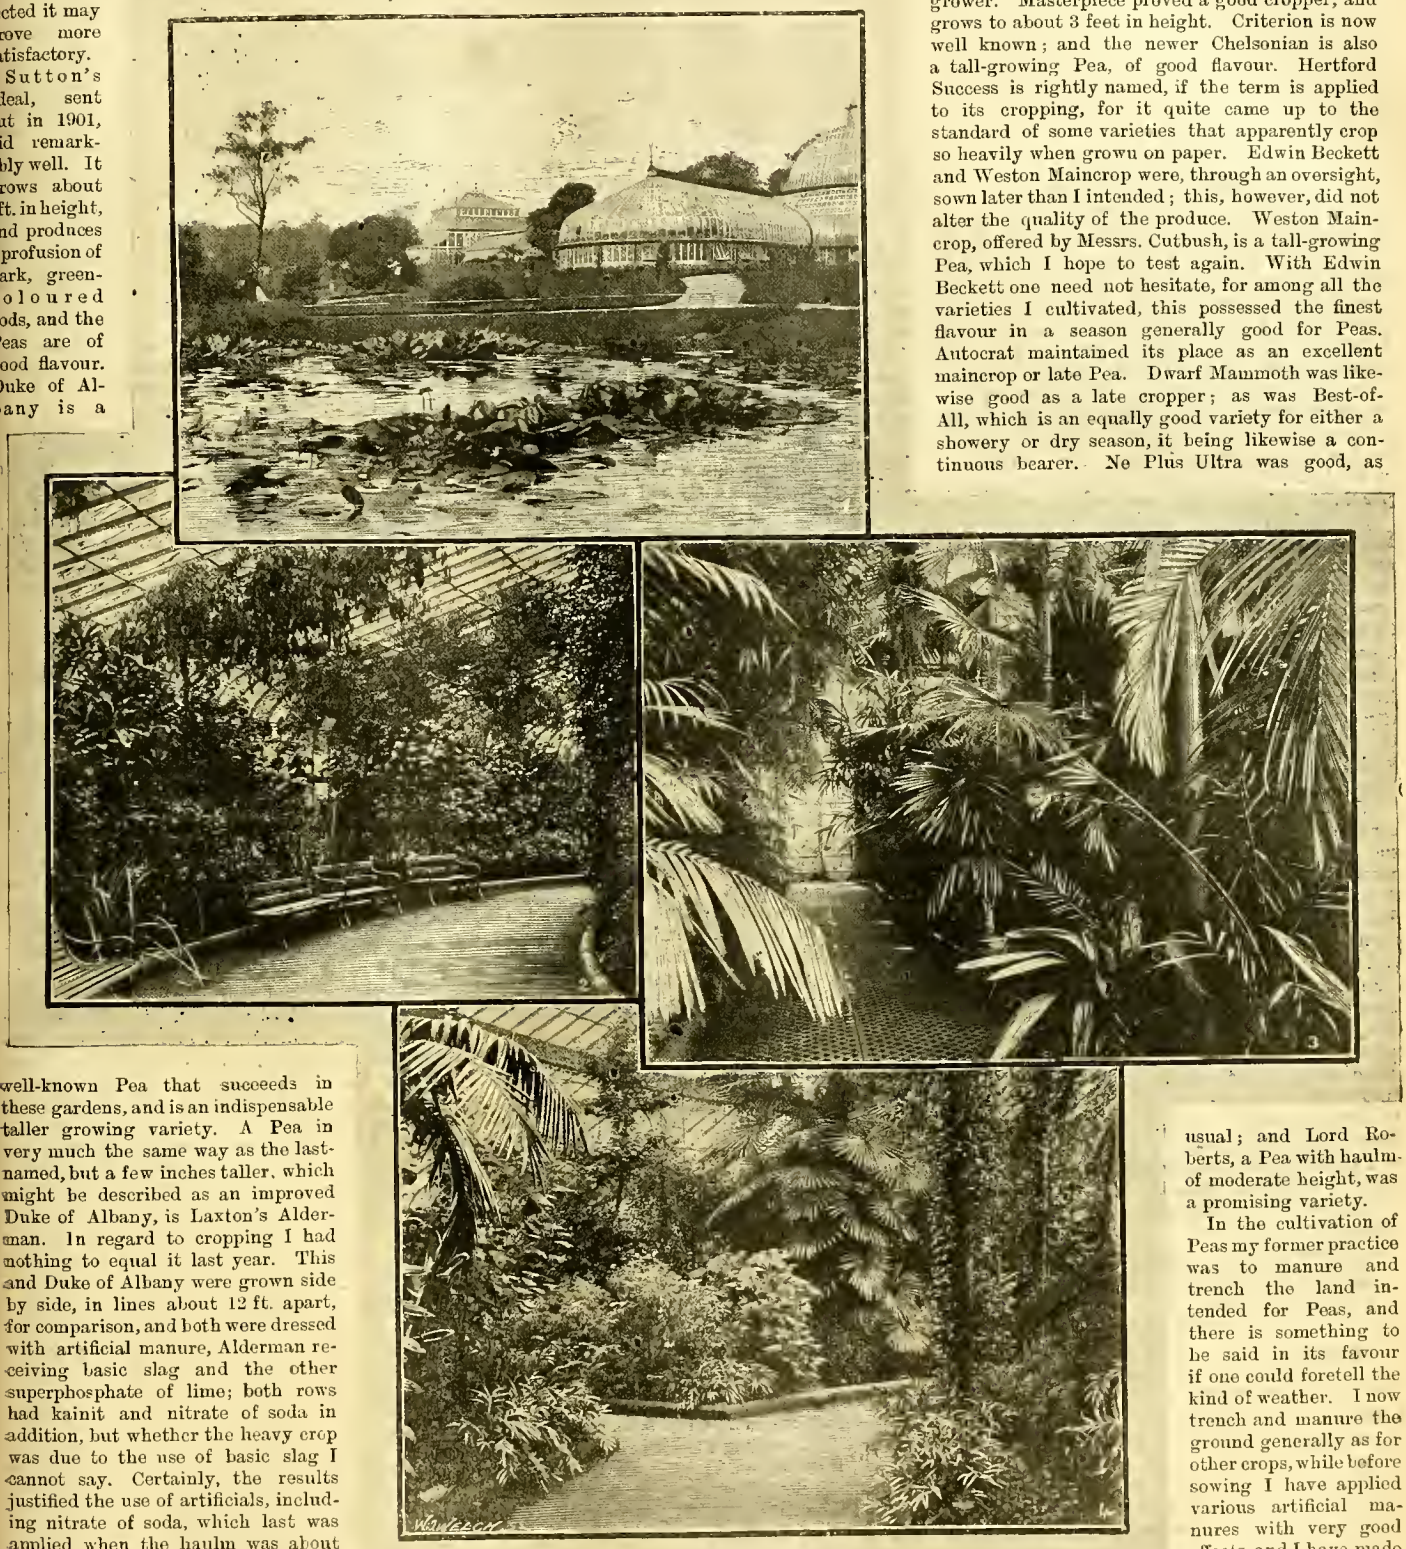

Fig 54.—Glasgow Botanic Garden.

No. 1.—Lily Pond and Bog Garden.
No. 2.—Outer Circle, Winter Garden.
No. 3.—Interior of Palm-house, centre passage.
No. 4.—Inner Circle, Winter Garden.

(see p. 129)

One's failures often point the way to success, and in the use of these manures it seems best to apply them at different stages of growth, some of them being slow in action. With basic slag the nature of the soil has to be considered, and it is better to apply it in the winter. Although the Leguminosæ absorb their nitrogen from the air, the application of nitrate to the land does benefit the plants, perhaps more so in early and midseason than later. From my own observations there must be ample moisture in the soil either by natural or artificial means, or the results of the nitrate dressing is not always satisfactory. *T. H. Slade, Poltimore, Exeter.*

THE TOMATO.

THE extensive use of the Tomato as an article of food has caused many enquiries to be made as to its nutritive value, and also as to the best methods of culture. In the United States, the Tomato has become such an important crop that, according to a recent estimate, there are canned from 3,000,000 to 4,000,000 cases of this fruit annually, each case containing two dozen cans.

In the United Kingdom, in addition to the enormous quantities of Tomatos which are grown for market, there are imported each year from foreign sources about 370 tons, which are valued at £791,339; that is, about 19*s.* per cwt., or 2*d.* per lb.

The food substance present in Tomatos in the largest amount is sugar; while the organic acids are the main substances which give individuality or character to the fruit. In tables of chemical analysis, Tomatos are given as containing from 92 to 95 per cent. of water, about one-half of 1 per cent. of ash, 1 per cent. of protein or flesh-forming matter, and about 5 per cent. of carbohydrates or heat-giving substances. The quantity of sugar which constitutes the main part of the carbo-hydrates is very variable in different varieties, but it may be said to average about 3½ per cent.

When the Tomato is to be used for food, care should be taken to retain all the juice, as the nutritive properties are present largely in soluble form, and any diminution of the amount of juice entails a corresponding loss of nutrients. For the same reason, the freshness of the fruit should not be impaired, as the acid salts quickly undergo chemical change.

In order to understand the manurial requirements of the Tomato, a study of the chemical composition of both fruit, bine, and roots becomes necessary. The following table will serve to guide us in this respect, though the amounts and proportions of plant-food removed from the soil by any crop cannot be taken as absolute indications of the requirements, inasmuch as the soil may furnish more of one constituent than another, and the plant may have the power of acquiring certain of its constituents more readily than others.

Table showing the four most important chemical constituents in Tomato fruit, the Tomato-bine and roots, each separately, and also an average for the whole plant. One ton of each contains:—

Description.	Nitrogen.	Phosphoric acid.	Potash.	Lime.
	lb.	lb.	lb.	lb.
In fruit	3·2	1·0	5·4	2·0
In bines (green) ...	6·4	1·4	10·0	6·7
In roots	5·4	0·2	7·6	12·0
In whole plant ...	5·0	0·9	7·7	6·9

The impression is very prevalent among growers that the Tomato does not require heavy manuring. This is true, if the fruit only is to be considered; but experiments show that the Tomato is a plant which quickly and profitably responds to the use of fertilisers, and that the maturity and yield are very largely influenced by the method of manuring. It must also be acknowledged that unless the plants are properly nourished they cannot yield a satisfactory crop of fruit. The foregoing analysis shows that the element nitrogen constitutes a very important factor in the growth of both bines and roots. If the plant is to produce abundant fruit, the bines and roots must be well fed with a nitrogenous food in order to keep up the vegetative power of the plant, and enable it to bring its fruit to perfection. Then, again, potash is a most essential ingredient in fruit, bines, and roots. The function of potash is to keep the bines healthy, to tone down the otherwise too stimulating effect of the nitrogen supply; it also exercises a very important part in the formation of the fruit acids. Lime, also, is an essential element, more especially in the growth and vigour of the root; it tends to render the other constituents more available, and helps on the maturation of the fruit. The Tomato plant is dependent throughout its whole life upon a proper proportion of phosphoric acid.

Although the figures of the table do not point to this as being an important item in its manurial requirements, yet we know from experience that phosphoric acid is absolutely essential, not as an element of which a fertile soil is generally deficient, but as an agent for promoting to a remarkable degree the early and vigorous development of the young plant, and carrying it rapidly over those stages, any delay in which is attended with great injury, and often with the destruction of the whole plant.

Phosphoric acid, then, in combination with nitrogen and potash, causes a much-enhanced development of the underground collective apparatus of the Tomato-plant, especially of lateral and fibrous root, distributing a complete network around the plant, and throwing innumerable feeding-mouths to the surface of the soil. We believe that if Tomato-culture is to be a success, the aim of the grower should be, not to increase unduly the above-ground organs of food-collection (the leaves), but rather the underground fibrous roots. These will assist in the blooming operation, and in the due development and colouring of the fruit.

The following table gives an illustration of the amount of selected chemical constituents required in the growth of 1 ton weight of the whole Tomato crop, and of the amounts of such food provided by half a ton of average farmyard manure:—

In 1 ton of Tomato plant (fruit, bines, and roots), and in half a ton of Farmyard Manure.

Description.	Nitrogen.	Phosphoric acid.	Potash.	Lime.
	lb.	lb.	lb.	lb.
In 1 ton, whole plant	5·0	0·9	7·7	6·9
In half-ton farmyard manure	5·5	4·0	6·0	8·0
Manure more (+) or less (—) than plant requirements ...	+0·5	+3·1	—1·7	+1·1

From these results it is seen that half-a-ton of average farmyard manure will yield half-a-pound (0·5) more nitrogen than is taken up by one ton of Tomato plants, comprising fruit, bines, and roots, each in equal proportions. The dung will also yield rather more than 3 lb. of phosphoric acid, and 1 lb. of lime in excess of the requirements of these plants. But the potash is deficient by about 1¾ lb., thus more of this element is required than is provided by the dung. This is quite consistent with experimental evidence.

For rapidly growing Tomato-plants the amount of available potash is not sufficient in ordinary farmyard manure, therefore if healthy, vigorous growth and fruit production is to be maintained, an artificial supply of soluble potash is advisable. Besides, it must be remembered that farmyard manure is very slow in its action, and requires some solvent, such as lime or potash, to render its properties more quickly assimilable. In the use of farmyard manure for Tomatos, excessive quantities should be avoided, for the reason that it encourages an undue development of stem and foliage rather than of fruit. The slowness of its action will also tend to lengthen out the life of the plant and retard ripening.

In manuring the Tomato, it should be the aim to furnish a sufficiency of nitrogen to give the necessary growth, but inasmuch as we have seen from the foregoing analysis that the Tomato belongs to the potash-consuming class of plants, any manurial mixture should be particularly rich in this element. Lime and phosphoric acid must by no means be overlooked. For a late crop of Tomatos, manures that have proved of the most service are those which contain a relatively smaller amount of nitrogen than is required for early crops, with a richer percentage in the ingredients phosphoric acid and potash.

The following formulas are recommended: one part of nitrate of soda, two parts of desiccated blood, four parts of superphosphate or bone-manure, and three parts of kainit; or one part nitrate of potash, two parts of guano or desiccated blood, and two parts of superphosphate or bone-manure. The soil compost having been properly prepared at the start, these manures may be applied as soon as the first fruits are set. They may be dissolved, and applied at the rate of half-an-ounce in a gallon of water given once a week, or the same quantity sprinkled over a square yard of soil. *J. J. Willis, Harpenden.*

PEARS OF RECENT INTRODUCTION.

THE Pear fruits early when grown as a cordon, and those who wish to grow some of the varieties recently brought into notice would do well to grow them as such, so as to put their qualities to a test. If not found satisfactory on walls and espaliers, the loss of time and space is not great. Both kinds of stocks should be employed, as by that means the gardener is enabled to ascertain which best suits his land and climate. Some of the new Pears are of foreign origin, and sometimes the trees have been grown abroad, and on other stocks than those we employ.

One of the good new Pears is Michaelmas Nelis, which might be termed an early autumn; Doyenné du Comice, which some may regard as a high commendation, but it is one that is deserved, the fruit being of delicious flavour, although of middle or small size. It is earlier than Fondante d'Automne in coming into use, if the land is well drained. Michaelmas Nelis, if grown on the Quince, is very free and a regular bearer, and quite young trees fruit freely.

Another very fine introduction as regards cropping is Marguerite Marillat, a large fruit, very prolific, fine in appearance as a cordon, and early in 1901 at Syon the fruits were ripe at the end of the month of August, but last year they were later. The tree will thrive where Doyenné du Comice fails; the flesh is sweet, and the flavour distinct and aromatic. The habit of growth is upright, and the variety succeeds on the Quince stock, and is equally fitted for a cordon, pyramid, or espalier. The fruits being large, unfits the variety for an orchard standard. Conference, one of the late Mr. Rivers' seedlings, is a valuable Pear, that has been some years in commerce, and is hardy, and a good cropper. The fruit is distinct, long, pyriform, the skin of a dark green tint, with much russet; the flesh melting and juicy. The tree grows well in almost any kind of soil; it is in season in late October. A favourite among the new Pears is Dr. Jules Guyot, an early September fruit, not unlike a Williams' Bon Chrétien, a compact grower on the Quince

stock; and to catch it at its best the fruit should be taken early from the tree, or gathered a short time before they are fully ripe. The tree is a free cropper, and the fruit handsome.

Doubtless the late ripening new Pears are more desirable than those ripening in the autumn. Of these, President Barrabé, of French origin, will doubtless become a favourite variety. The fruit is of middle size, very fine quality, and ripens in midwinter and later, according to locality and methods of storage. The tree is a close grower, and makes a fine pyramid on the Quince stock and very hardy; flesh rich and melting. Another French Pear is Le Lectier, a cross between Williams' Bon Chrétien and the Bergamotte Fortunée. The fruit large and of pleasing form; rind mottled green; flesh melting, juicy, and of fine flavour. At Syon the tree crops freely, and is of a free, erect habit; the fruits keep till March. So far the best crops have been obtained from cordons. Another modern Pear is St. Edmund's, a fine looking nice fruit, coming into use earlier than the last named, small but good; one of Messrs. Rivers' raising. It is not unlike President Barrabé in regard to size and quality. A valuable late Pear is the Duchesse de Bordeaux,

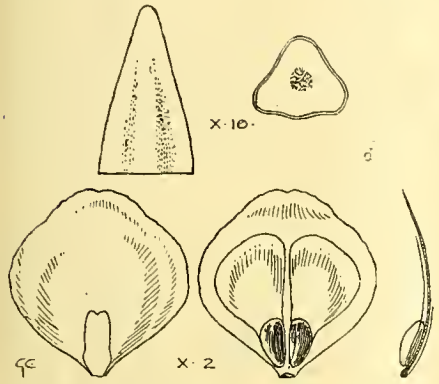

FIG. 55.—PICEA WILSONI.

Apex of leaf; cross-section of leaf; bract and cone-scale from the back; inner surface of cone-scale showing the two-winged seeds; section through bract, scale, and seed.

but to do it justice it needs a warm wall, a rich root-run, and well drained soil; it is a close grower, and with us is best on the Quince stock. The fruit is not large, but the tree is a great bearer, fruits much russeted, and its season is January to March. The flesh is rich and juicy. A few years ago the variety received a First-class Certificate as a valuable late variety. The above varieties I consider the best of the more recently introduced Pears. *G. Wythes.*

CHINESE CONIFERS.

PICEA WILSONI,* *Mast.*, sp. n.—This is a heretofore undescribed Spruce-Fir, collected at Fang, in Hupeh, by Mr. E. H. Wilson, for Messrs. Veitch & Sons.

Its appearance cannot fairly be judged by the illustration (fig. 56), which represents a herbarium specimen from which most of the leaves have fallen, thereby permitting the rugged bark to be seen. It is evidently a fine tree, concerning whose qualities as a timber-producer we have yet everything to learn. The branches are glabrous, of a pale grey colour, the leaves linear-oblong, acute, curved, four-sided, with stomata on all sides; the oblong-cylindric cones do not exceed 2 inches in length, the bracts are linear-oblong, retuse, less than half the length of the roundish ovoid entire scale, whose upper border is eventually recurved. The seeds are provided with a hatchet-shaped wing.

The distinguishing characteristics of this Spruce are to be found in the small-sized cones, the ovoid or roundish entire scales with recurved margin, and the linear oblong bract. It is allied to P. Alcockiana, but may be distinguished by the characteristics just mentioned. *Maxwell T. Masters.*

* *Picea Wilsoni*, Mast., sp. nov.—Arbor 40-70 ped., dense ramosa, ramis pallide griseis pulvinis lageniformibus crebre notatis; gemmis ovoideo-subglobosis, perulis suborbicularibus vel oblongis coriaceis castaneis imbricatis vestitis; foliis 1 cent. long, arcuatis linearibus acutis quadrilateralibus, stomatibus utrinque instructis, juvenilibus pilosulis; amentis masculis haud visis; strobilis aggregatis pendulis stipitulatis, 4-5 cent. long, 3 cent. lat., oblongo-cylindratis subacutis; bracteis lineari-oblongis obtusis squamis plus quam dimidio minoribus; squamis, coriaceis ferrugineis suborbicularibus integris vel erosis basi late cuneatis, margine superne demum revolutis; seminibus obovoideis ala oblique obovata duplo-triplove longiore superatis. Fang, in prov. Hupeh. Coll. E. Wilson, n. 1897!

TREES AND SHRUBS.

VIBURNUM TINUS AND OTHER PLANTS.

The note in the *Gardeners' Chronicle* of the 24th ult., p. 60, by Mr. J. Murray of Sopley Park, Christchurch, applies equally to the growth of Laurustinus in this part of Devon. It is not only very abundantly planted as bushes, but it is plentifully used as hedges. Under the former condition it, of course, flowers most freely, as it is not subjected to such close and constant clipping. In front of this house which faces south, is a small bush about 6 feet high which has been covered with the flowering corymbs since early in December, and at the present time the flowers are fully expanded. Separating the front garden from the road is a hedge about 6 feet high, composed partly of Laurustinus and Bay Laurel. Though this hedge was clipped several times during last summer, the Laurus-

FIG. 56.—PICEA WILSONI: SHOWING BRANCHES, FOLIAGE, AND CONES (REAL SIZE).

tinus is now in full flower though not so thickly as the bush. We have experienced some severe frosts, but they have had no effect whatever either on the Viburnum or the Bay Laurel. In some gardens about Exeter some of the varieties of V. Tinus make noble shrubs, growing up to 10 or 15 feet high, and quite as free flowering as the type. As a hedge plant, as Mr. Murray suggests, in situations where it is not affected by frost, no better plant can be used than Viburnum Tinus. While on the subject of hedges, I may perhaps say that in a garden facing the sea at Exmouth, in a very elevated position, looking across to Dawlish, is a fine evenly-clipped hedge of Furze (Ulex europæus), topping a high fence along the public path. This hedge last season formed a striking line of golden yellow, especially when lit up by the sun. It is now partially in flower. Another hedge which, though somewhat less striking on account of colour, is nevertheless noteworthy, is to be seen on the road bounding Powderham, the estate of the Earl of Devon, from Starcross to Kenton. In this case the plant used is the Snowberry (Symphoricarpus racemosus), the plants overhanging a wall of moderate height, and when the plants are in full fruit in late autumn and early winter, the white berries are very striking.
John R. Jackson, Claremont, Lympstone, Devon.

The Week's Work.

PLANTS UNDER GLASS.

By J. MAYNE, Gardener to the Hon. MARK ROLLE, Bicton, Budleigh Salterton, Devonshire.

The Fern-house.—The plants have now begun to grow, which is a reminder that dividing and repotting may soon be undertaken. It is occasionally necessary to divide Adiantums, especially A. cuneatum, and in carrying out this operation, the middle portion should be discarded. The remaining pieces should be denuded of soil with a pointed stick, and no larger pot should be made use of than is really necessary for the well-being of the plant. Such divided plants should be grown apart from the rest, and great attention should be given them in the matter of affording water at the root, which will be but little until growth has become general. Adiantum Farleyense is a variety requiring considerable care in handling, and the less disturbance of the roots, the better. This variety does well when suspended from the roof of the fernery, where more water has, however, to be afforded it than is the case when it is stood on the stage. Turfy loam and leaf-mould, sand, and a small quantity of finely-broken charcoal, will grow most species of Ferns. If the loam be heavy, peat to the extent of one-half should be used. Let the old fronds be removed gradually, as fast as new ones push up. Keep the plants, especially small sporelings, well up to the light. A night temperature of 55° to 60°, with a rise of 5° to 10° by day, will be suitable for some time to come.

The Palm-house.—Though Palms may not need repotting every year, a survey should be made of the plants as to which require repotting. It is surprising for how long a period young Palms will keep in good condition when assisted with manure-water. Cocos Weddelliana is one of the handsomest Palms for indoor decoration, and should be grown at the warmest part of the house. Kentias too are likewise very useful in the same way, and, like Cocos Weddelliana, they may be grown in small pots. A soil similar to that employed in potting Ferns is suitable for Palms, excepting that less peat may be used if the loam be good. Thoroughly good drainage is essential. Palms grow readily from seed placed in a brisk bottom-heat, and it is best to sow the seeds in the spring. Most of the varieties are the better for stove treatment, and thrive better when the degree of warmth does not fall below 55°. A temperature of 60° to 65° from now onwards, with plenty of aërial moisture, is called for.

Humeas.—Plants in 5½ or 6½-inch pots should be transferred to others having a diameter of 8½ and 9½ inches respectively. Use a compost of good fibrous loam and leaf-soil, with a small quantity of decayed manure, pounded charcoal, and coarse sand. Great judgment is required in applying water to the root, Humeas being very soon injured if afforded too much. Stand the plants in a coolhouse or pit where there is plenty of light, and safety from frost. Should aphides appear in the centre growths, destroy them by fumigation.

Azaleas that are passing out of flower should be afforded a temperature of 55° to 60°. Syringe the plants early in the morning, and again at about 2 P.M. Should any of the plants require repotting, the work is best done before much new growth is made. Turn out the plants, remove the crocks, and pick away with a pointed stick a little of the old soil. Avoid giving the plants too large a shift, as pots a couple of inches larger than those from which they have been taken are usually suitable. Use a compost consisting of three-parts fibrous peat, and one-part good loam and leaf-soil, with plenty of coarse silver-sand. Make the soil very firm, and ram it around the sides of the pot with a potting-stick; apply water with care for some weeks. In removing the old flowers or seed-pods, be sure the young growths are not pulled out as well; and plants not requiring more space at the root, should have a sprinkling of Standen's or Clay's manure once a week while growth is being made, and be well watered in. A good stock of that valuable white variety, Deutsche Perle, should be found in every garden, the plants remaining in beauty longer than any other variety with which I am acquainted. Those required for blooming during May and early June must be kept as cool as possible, avoiding too wet or too dry a state at the root, the Azalea quickly resenting either extremes.

Begonias.—The tuberous-rooted or summer flowering varieties should be started in a temperature of 55°, shaking away all the old soil if this be not already done, placing the tubers in shallow boxes of sifted leaf-soil or Cocoanut-fibre, lightly syringing the same once or twice daily, and potting up singly as soon as a couple of inches of growth have been made, using three parts loam to one of leaf-soil not too much decayed; and plenty of sand to keep it porous, placing the plants in a light position to keep the growth sturdy.

THE ORCHID HOUSES.

By H. ALEXANDER, Orchid Cultivator to Capt. G. L. HOLFORD, Westonbirt, Tetbury.

Zygopetalum Mackayi and Z. crinitum are two very useful species for flowering in winter, especially where flowers are in demand for cutting. The plants may be cultivated easily, provided they are afforded a light position in the intermediate-house and supplied with an abundance of water at the roots when they are actively making growth. The species are greatly checked in growth by root disturbance, and repotting should only be done in cases where the material has become sour or decayed. The present time is a suitable season for doing such kind of work. Let the pots be clean, and well provided with material for drainage. The compost should be similar to that advised for Cypripediums in a recent calendar, being careful to include plenty of sand and finely-broken crocks. Newly-potted plants will need to be afforded extra shade, and very carefully supplied with water until such time as the roots obtain a good hold of the compost.

Platyclinis glumacea.—The young growths of this spring-flowering species are making considerable progress, and the plants will need liberal supplies of water at the root. A position near to the glass at the cooler end of the East Indian-house is the most suitable place for this plant during the growing season. When repotting is necessary, it should be done immediately after the plants have flowered, using for this purpose a compost consisting of equal parts fibrous-peat and good leaf-soil, with a little chopped sphagnum-moss, and sufficient sand and broken crocks to render the whole very porous. Well-drained pans of moderate depth and of sufficient size to allow of the plants making two further seasons' growth are the most suitable receptacles. Let the surface of the compost remain a little below the rim of the pot, and afford water sparingly for some time following this operation. Subsequently the plants will need an abundance of water, but when the small pseudo-bulbs have attained to their full size, the supply should be again lessened, and the plants be removed to the Cattleya-house for their resting period.

THE FLOWER GARDEN.

By J. C. TALLACK, Gardener to E. MILLER MUNDY, Esq., Shipley Hall, Derby.

Hollyhocks.—If raised from seed this plant is less liable to diseases than when raised from cuttings, and I find that many even of the double-flowered varieties come absolutely true to colour, so that the seedlings may be used with confidence in any colour scheme of planting. If seeds were sown last summer, the plants may be set out forthwith in mild weather. The finest flower-spikes are produced by plants set out at this date. Furnish abundance of manure, and let the soil be deeply dug.

Carnations.—Layers potted in the autumn of last year, which have been wintered in frames, may now be planted out where they are intended to flower, planting firmly; and if the soil is in a fairly dry condition, trample the beds lightly, and afterwards stir the surface with a Dutch-hoe. I only put Carnations into pots for wintering in exceptional cases, better general results being obtained by planting in the open in the month of October. If sparrows injure the "grass," stretch black thread low down over the plants.

Violas may now be lifted from the cold frames and planted. Autumn planting is the best for the Viola, but as it is rarely convenient at that season it has to be postponed till the present season. Violas are excellent for forming a carpet under Tea Roses when due regard is had to the proper blending of colour, as the slight shade the Rose bushes afford, and the good soil in which the Roses grow, suit them.

Pentstemons.—Pentstemons raised from cuttings should be planted early, so that they may get established before warm, dry weather sets in; some of the cuttings may not be more than callused, but this does not matter, as roots will soon form, if they be made firm in the ground.

Lobelia cardinalis.—Old clumps if put into mild warmth as advised a few weeks ago, will be now ready for division. Each crown should be split or cut off with roots attached if possible, and be replanted in boxes of sweet, light soil, far enough apart to enable them to remain in the boxes until planting times arrives. For the present keep them in warmth, and do not attempt to harden them off until they are making roots freely.

Sowing seeds.—Among seeds which may be sown in heat at this date are Lantanas, pretty plants for warm soils; Salvia patens, and Verbenas, not forgetting the old and useful V. venosa; and Pyrethrum aurenm (Golden Feather) for edging purposes in formal arrangements.

The Rockery.—In the rockery there will probably be some choice morsels of alpines beginning to grow, which slugs will soon make short work of if allowed to get at them. Bran placed on pieces of slate makes an excellent trap. At night the slugs may be found feeding on the bran, and by day they will be found hidden under the slates. In any case, provide a sufficient number of such traps, so that the vermin may not have far to travel in reaching one or other.

FRUITS UNDER GLASS.

By T. H. C.

Tomatos. — These plants are now growing strongly, and must be afforded water very carefully, keeping the soil on the dry side till a good set is secured, and afterwards, if growing in a limited space, they may be afforded abundance of water and artificial stimulants. If the plants are grown as cordons, pinch out side shoots, and tie in the leaders as growth extends, being careful to tie loosely, so as to allow for the increase in girth of the stems. Pot-on succession plants, or those for planting in odd corners, &c. Sow seeds for raising plants for an early autumn crop. Plants now in fruit should have their flowers fertilised daily, and if laterals are encouraged to keep up the supply, stop them at a joint beyond

a truss. A modorately dry atmosphere with constant ventilation, more or less according to the state of the weather, and a night temperature of 55° to 60°, should be afforded.

Figs.—Excepting where extension of growth is desired, the points of the shoots may be stopped at the fifth or sixth leaf, which will induce a second crop of fruits to form at the base of the leaf-stalks, and also assist the swelling of the present crop of fruit. This crop, if very abundant, should be thinned so as to enable the remaining fruits to come to perfection. Early pot-trees or those planted in confined spaces should be afforded water freely, and liquid-manure and other fertilisers applied frequently. The leaves should be syringed morning and afternoon in fine weather, and the paths and other surfaces damped. The night temperature may now be raised to 60°, and that of the day to 70° or 75°. Ventilate freely when the weather allows, and afford a small amount of air early in the morning. Early forced Figs suffer a good deal from infestation by red-spider, but this pest may be kept in check by the forcible use of the syringe and clean water.

Melons.—In an earlier calendar it was advised that early Melons should be grown in 12 to 14-in. pots, well-drained, and filled firmly to within 3 inches of the rim with rich turfy loam, to which charred refuse and mortar-rubble are added. These pots should be plunged in a bottom-heat of 80° to 85°, and close to the glass. The plants should not stand closer than 2 feet apart. If the compost is moist at the time of planting, no water should be afforded till some days afterwards. Lightly syringe the plants morning and afternoon in fine weather, and maintain a moist atmosphere in the house. Shade from bright sunshine till the plants are established. Remove all laterals until the bine reaches the trellis, and remove the point of the leading shoot at 18 inches from the top of the house, so as to induce the formation of side shoots. Three fruits per plant are a sufficient number for a crop. Remove gradually all shoots that would interfere with the full development of the principal leaves. If the Melons are to be planted in borders, proceed as for Cucumbers, and for the first crop close planting and the restriction of the root run are advisable, especially in low houses. After this date plant direct from the small pots in which the plants were raised Apply air whenever the weather is mild, so as to induce a short-jointed and sturdy growth. A night temperature of 65° to 70° is desirable, but in very cold weather the lower figure should be preferred. The day temperature of the Melon-house may be of 10° to 15° higher, in accordance with the weather.

THE KITCHEN GARDEN.

By JOHN FLEMING, Gardener to Sir C. PIGOTT, Bart., Wexham Park, Slough.

Hints on Work in General.—Let all decaying leaves be removed from the stems of Kales, Brussels Sprouts, &c., and also the remains of other crops. Roots of Turnips, Parsnips, &c., that were left in the ground should be taken up and stored in fine coal-ashes or sand, in banks or conical heaps, tops outwards. Manure, dig, and trench vacant plots, choosing frosty mornings for wheeling purposes; and making deposits of road-scrapings, charred refuse, and soot, to be used as top-dressings to the land. Let land which will be sown next month be lightly dug. Use the Dutch-hoe among autumn-sown Onions. Well air Parsley plants growing in cold frames whenever there is no frost.

Herbs.—Perennial sweet herbs, to be successfully grown, should be replanted every third or fourth year. Spearmint being much required in the kitchen, and an easy plant to grow, should be transplanted every third year, otherwise the stems get wiry and the leaves small, and the plants will often die right out; and if this be not performed, a dressing of sifted leaf-soil and spent Mushroom-bed dung, applied at this date, will maintain the plants in vigour. Tarragon, Chives, pot Marjoram, and Lemon Thyme, should be likewise transplanted. Sorrel should be divided annually into small clumps, and planted in rows 18 ins. apart, allowing a foot between the clumps. The soil should be well enriched and deeply dug. The large-leaved or French Sorrel is the best. Sorrel forms a good inner edging to paths. A part of the herb-border may be reserved for perennial and annual pot herbs that will be sown next month.

Onions.—A long season of growth is necessary to ensure fine bulbs; therefore the first opportunity should be taken when the land is in a dry, workable condition to sow the seed, the ground being previously lightly dug with a fork and levelled, and then dressed with soot and salt sufficient to colour the ground. Let this dressing be pointed in 2 or 3 ins. deep, then rake the land with wooden rakes. Light soils should be trodden down very firmly, and heavy ones pressed with a wooden roller. The drills should be drawn of half an inch in depth, and at 1 foot apart. Sow the seed evenly, and apply a dressing of sifted wood-ashes, having previously filled-in the drills with the feet. This finished, trample the land in the opposite direction, and again apply wooden rakes to make all tidy and neat. Gardeners having heavy retentive land to deal with, should avoid as far as possible much trampling, and omit the final raking. Onions raised under glass last month will be ready for being pricked off into boxes filled with turfy loam two-fourths, leaf-soil one-fourth, and one-fourth dried horse-droppings and coarse-sand or road-grit. This compost should be sifted through a ¼-inch meshed sieve, be made warm, and used in a moderately dry condition. The plants should be lifted with a pointed stick, and pricked out at 3 inches apart each way, and made firm. Apply tepid water after planting, and keep near the glass in a house having a warmth of 50° or 55°. Syringe twice daily, and shade from strong sunshine; sufficient air being applied as will keep the plants sturdy, but guarding against cold draughts. After re-establishment, afford all the light possible, and air in increasing quantities, till planted in April.

Leeks sown under glass should have the same kind of treatment as Onions, but dibbling in the seedlings deeper.

Vegetable-Marrows.—If early fruits are desired, a sowing should now be made. Sow the seeds singly in large 60's, placing them in moderate heat and shifting into 6-inch pots before they get pot-bound, and planting on slight hot-beds made up in heated pits. The plants will fruit in the month of May, if they are not grown in too high a temperature. Sutton's Perfection and Moore's Vegetable Cream are excellent varieties for forcing.

THE HARDY FRUIT GARDEN.

By CHAS. PAOE, Gardener to J. B. FORTESCUE, Esq., Dropmore, Maidenhead.

The Fig.—The protecting materials may now be removed from the trees, and the pruning and nailing finished forthwith. If disbudding and stopping was attended to during the summer, the shoots will be well ripened, and these may be laid in at about 1 foot apart, a great mistake being made if these are crowded together. Pruning and nailing finished, afford the border a top-dressing of fresh loamy soil and mortar-rubble broken small.

Vines on Walls, Pergolas, &c.—Let these plants be pruned without loss of time, and in the case of barren rods, a young shoot should be selected near the bottom, and trained in to take its place another season. If red-spider infested the leaves last summer, paint the canes with a mixture of soft-soap and flowers-of-sulphur, and enough clay to give it consistency. Royal Muscadine, Sweetwater, and Millar's Burgundy are excellent varieties of the Vine for outdoor cultivation.

Hints on Work in General.—Any wall Pear, Plum, and Cherry-trees that were transplanted last autumn may now have the mulch over the roots removed, and the soil lightly dug with a fork, an operation that will admit warmth and air to the roots. Some varieties of the Pear form fruit-buds at the ends of the shoots that are required for the extension of the trees, and such must be rubbed off, or the shoot cut back to a wood-bud. On the 18th of this month 9° of frost were noted at 7 A.M., and the more forward buds of the Jargonelle on standard trees are blackened, but Apricot-trees that were protected by triple fish-nets have not suffered. Ground on which Strawberries will be planted in March should be kept clean with the hoe, and a good tilth obtained in readiness for planting.

THE APIARY.

By EXPERT.

Cheap Bee Hives.—A good deal has been written in reference to bee-keeping for profit. To obtain this object one must not indulge in expensive hives, nor purchase all sorts of new inventions that are placed on the market. These things are all very well for those persons who, regardless of expense, keep bees for a hobby, not otherwise. The first thing necessary is a good safe hive of standard size, this must be the first object, not only of having all hives the same as regards the inner dimensions, but as regards selling them if necessary. A good and easy plan for those who may be about to commence bee-keeping, and who wish to make their own hives, is to purchase a few of Tate's sugar boxes, and knock away one side and nail it on to the top, this will bring the box to 17 inches wide inside instead of 14 inches, and afford plenty of room to put in the extra sides. The inside measurements should be as follows: 14½ inches wide, which will allow ¼ of an inch each side of the frames, which will be 14 inches wide. A greater space than this should not be allowed, or the bees will be almost certain to build combs from the frames to the side of the hive, which will be found very inconvenient. The depth should be 9 inches, this will allow ½ an inch for the bees to crawl on the floor board without being crushed, as the frames are 8½ inches deep. The dummy board should be made to fit into the back of the hive as securely as possible, to prevent the bees getting through either at the sides or bottom, or in honey-time the bees will be building combs at the back, instead of working in the sections or shallow frames. The section crate should be made to hold twenty-one, 1 lb. sections, and if this does not quite cover the whole of the frames, place pieces of brown paper or carpet to allow the bees to have access only by way of the crate. Before commencing hive-making, a modern bar framed hive should be obtained for a pattern if possible. The cost of such a hive as described should not be more than 2s. 6d.; this with two boxes, costing 1s., will be enough to make the inside section-crate, &c.; French wire nails, 6d.; paint, &c., 1s. Anyone with a little ingenuity and a taste for carpentry, can soon make a very creditable hive at a small cost.

General Hints.—After the spell of frost we had, it will be advisable to place on each hive a cake of candy, but without disturbing the bees. The same applies to straw skeps when possible; and each skep should be uncovered to ascertain if mice have got inside, and if this is the case, put a queen-excluder zinc over each entrance.

CAPE COLONY FOR THE SETTLER.—As this publication announces in the sub-title that it gives an "Account of Cape Colony's Urban and Rural Industries, their probable Future Development and Extension," we need not further describe the scope of the book. The author is Mr. BURTON, editor of the *Transvaal Agricultural Magazine*, and the volume is issued by order of the Government of the Cape Colony, so that the information given may be trusted. There are chapters upon the Flora of the Cape, of which a very short, but as far as it goes, an excellent account is given; Native Labour, Cape Farmers, Fruit, Wheat, and Lucerne culture, Irrigation, and kindred topics. Accounts of the "divisions" into which the colony is divided form a feature of the book. The whole matter is arranged for easy reference, with plenty of illustrations, statistics, and maps. The publishers of the volume are Messrs. P. S. KING & SON, of Orchard House, Westminster.

TASMANIAN APPLE TRADE. — From the officials of the Orient Royal Mail Steam Navigation Company, we learn that the first steamer bringing fruit from Hobart in the coming season will be the *Omrah*, leaving that port on Feb. 14, followed by the *India*, the *Ormuz*, *Oceana*, *Orizaba*, *Australia*, *Oroya*, *Victoria*, *Orestes*, *China*, and the *Oruba*, of the P. and O. and Orient Pacific lines, at intervals of a week thereafter. There will probably be also some four or five steamers of other lines during the period in question, but their dates of departure are at present uncertain.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the Publisher.

Letters for Publication, *as well as specimens and plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Illustrations.—*The Editor will thankfully receive and select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.*

APPOINTMENTS FOR MARCH.

THURSDAY, MAR. 5—Linnean Society Meeting.

SATURDAY, MAR. 7—Société Française d'Horticulture de Londres Meeting. Surveyors' Institution (Junior) Meeting.

TUESDAY, MAR. 10—Royal Horticultural Society's Committees Meeting, lecture on "Natural Selection *v.* Adaptation."

SATURDAY, MAR. 14—Royal Botanic Society's Meeting.

THURSDAY, MAR. 19—Linnean Society's Meeting.

MONDAY, MAR. 23—Surveyors' Institution Meeting.

TUESDAY, MAR. 24—Royal Horticultural Society's Committees Meeting (Hyacinth and Tulip Show), lecture on "Photomicography."

WEDNESDAY, MAR. 25—Lady Day. Royal Botanic Society's Meeting. Liverpool Horticultural Association, Bulb and Plant Exhibition.

THURSDAY, MAR. 26—Royal Agricultural and Horticultural Society of Jersey, Show of Bulbs. Irish Gardeners' Association Meeting.

SALES FOR THE WEEK.

MONDAY and FRIDAY NEXT—
Herbaceous Plants, Roses, Azaleas, Liliums, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12 30

TUESDAY, MARCH 3—
Palms, Bays, Liliums, Flowering and Ornamental Plants, at Pollexfen's, Pilgrim Street, Ludgate Hill, E.C., at 12.30.

WEDNESDAY, MARCH 4—
Azaleas, Rhododendrons, Palms, Roses, Herbaceous Plants, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12 30.—Consignment of 837 cases of Liliums, &c., from Japan, at 67 and 68, Cheapside, by Protheroe & Morris, at 5.—Imported Japanese Iris, Lilies, and Fern Balls; also Azaleas, Roses, &c., at Stevens' Rooms, at 12 30.

THURSDAY, MARCH 5—
Palms, Bays, Liliums, Flowering and Ornamental Plants, at Pollexfen's, Pilgrim Street, Ludgate Hill, E.C., at 12.30.

FRIDAY, MARCH 6—
Orchids in variety, at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12 30.

(For further particulars see our Advertisement columns.)

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick —41°.

ACTUAL TEMPERATURES:—
LONDON.—*February* 25 (6 P.M.): Max. 54°; Min. 43°. *February* 26 (Noon): rainy; 45°.
PROVINCES.—*February* 25 (6 P.M.): Max. 50°, Scilly; Min. 41°, N.E. Scotland.

Sale of Poisons.

We are now in a position to give further details concerning the recommendations of the Committee appointed to consider the question of the Sale of Poisons, which we alluded to last week. We extract such portions of the report as are specially pertinent to horticulture:—

"Your Committee found it impossible to consider and recommend a re-arrangement of the Poisons Schedule without taking into account, first, the effect of the restrictive sections of the Pharmacy Act, 1868, upon certain trades and industries; and, second, the changes which have taken place, especially in agriculture and horticulture, since the passage of the said Act.

Your Committee had their attention forcibly drawn to the great increase in the use of poisons in agriculture and horticulture since the passing of the Pharmacy Act, 1868. Sheep-dips, usually containing strong poisons, have come into universal use, and must be considered indispensable to the modern sheep-farmer. Five-and-thirty years ago, the killing of weeds, of parasitical insects, and of fungoid growths upon growing crops, by means of poisonous substances, was rarely if ever practised, but such poisonous substances are now to be reckoned among the regular auxiliaries of agriculture and horticulture.

It was not possible for those responsible for the Pharmacy Act, 1868, to foresee the degree in which these industries should come to depend upon the use of poisonous materials; nor is it credible that, had they done so, they would have enacted anything calculated either to interfere with farmers and gardeners obtaining them conveniently, or to enhance their price by creating anything in the nature of a monopoly.

Your Committee, therefore, feeling convinced that the industries of agriculture and horticulture cannot be conducted effectively on modern principles without the extensive use of poisonous materials, felt it incumbent upon them, before proceeding to suggest re-arrangement of the Poisons Schedule, to ascertain whether either or both of the above-mentioned undesirable conditions had been caused by the provisions of the Pharmacy Act, and if so, whether relaxation could be conceded without undue risk to human life.

PROSECUTION OF UNREGISTERED SELLERS OF POISON.

Under the law as it stands, certain poisons and poisonous compounds (other than liquid carbolic acid for sheepwash or other agricultural or horticultural purpose) cannot be legally retailed except by a registered chemist and druggist, and the Pharmaceutical Society is charged, under the 15th Section of the Act, with the duty of proceeding against unauthorised vendors.

The administration of this section has been characterised by considerable uncertainty and irregularity, arising, your Committee believes, out of the inadequate means at the disposal of the Society, which has no staff of inspectors, nor other regular machinery for detecting the sale of poisons by unregistered persons.

It follows from this that the effect of the 749 prosecutions undertaken during the six years 1896-1901 by the Pharmaceutical Society, and of the numerous cases in which penalties were exacted without prosecution, has been very unequally felt; for while the law has been enforced in some districts, it has been wholly inoperative in others.

Your Committee are of opinion that the obligation laid upon the Pharmaceutical Society by the 15th Section of the Act is unduly onerous, seeing that even the limited extent to which they have taken action under it has involved them in a net loss of £700 a year beyond the sums received as penalties, which are due to be dealt with as the Treasury may direct, but which the Society has been allowed to retain.

INCONVENIENCE TO FARMERS AND GARDENERS.

Inconvenience has been experienced by farmers and gardeners owing to the restriction of the sale of poisonous material to registered chemists and druggists in such districts where there is no such qualified tradesman within easy reach. Your Committee are convinced that the inconvenience would have amounted to a very serious interference with legitimate industry had the provisions of the 15th Section been universally put in effect. For example, in the Highlands and islands of Scotland, where sheep-farming is the principal business of agriculture, farmers are sometimes upwards of 50 miles distant from the nearest registered chemist and druggist, and the sale of sheep-dips is regularly carried on by ironmongers and other traders, in contravention of the statute.

A nurseryman and florist in Kent [Mr. CANNELL] gave evidence as to the extreme inconvenience caused to cultivators when, owing to the successful prosecution of a firm of seedsmen, the sale of weed-killers and insecticides was discontinued by nurserymen. He alleged that in horticulture there are numerous small cultivators and amateurs who would use these materials if they could get them, to the advantage of their greenhouses and gardens; but that chemists and druggists do not know what to recommend, whereas the nurserymen have knowledge of the proper remedies, and ought to be in a position to supply them.

CONVEYANCE OF ARSENIC AND ARSENICAL COMPOUNDS.

In the course of their enquiry the Committee had their attention drawn to the manner in which arsenic, intended for industrial purposes, is conveyed. Mr. Lytle, a manufacturing chemist, making sheep-dips and weed-killers, stated that he received arsenic by rail or by ship, and he added: 'We often receive the casks of arsenic with the contents running out on to the cart.' He stated that a small lot, say a 4-ton lot, would come by train, and that arsenic not only might be, but was, distributed about the goods station. He stated that although the railway companies have regulations as to the handling of dangerous things, they are not acted upon, and cited the Crieff case as evidence of the fact.

Asked if the barrels coming to him were marked 'Poison,' he answered: 'Some of them, not all; sometimes they are marked "Arsenic" with a small stencil; in other cases they have the word "Poison."' But he added: 'It is the exception they are so marked; in fact, the only time that I recollect their being marked "Poison" is when we have bought foreign arsenic.' Mr. Lytle stated that foreign arsenic was packed in casks enclosed in a second cask, which, in his opinion, tended to make the carriage 'absolutely safe,' but that such is never done in the case of English goods. The witness stated that instances had been brought to his knowledge where unfortunate results had followed from the careless way in which arsenic is handled in the wholesale way. There was, he stated, a very general evasion by traders of the 17th Section of the Pharmacy Act. Arsenical residue from oil-of-vitriol works—sulphide of arsenic, for example—was sent away to be treated, and any packages were thought good enough to hold it.

Your Committee are of opinion that the conveyance of arsenic, and substances containing large quantities of arsenic, under such lax observance of precaution is a source of danger to the public.

RECOMMENDATIONS.

Your Committee consider that it would be going beyond their reference to suggest changes in the administration of the 15th Section of the Pharmacy Act; they are of opinion, however, that preparations for use in connection with agriculture, horticulture, or sanitation, might be placed in a third part of the Schedule, to be sold only by licensed persons, and subject to regulations to be made by the Privy Council.

Your Committee further recommend that the traffic in arsenic should be regulated either by an amendment of the Arsenic Act, 1851, or by more stringent enforcement of the provisions of the 17th Section of the Pharmacy Act, 1868.

Your Committee beg to submit the following suggested alterations in Schedule A:—

PART III.

Preparations containing arsenic exclusively for use in connection with agriculture or horticulture, and contained in a closed vessel or receptacle, distinctly labelled with the word 'Poison,' the name and address of the seller, and a notice of the agricultural or horticultural purpose for which the preparation has been made.

Preparations of Tobacco, or the alkaloids of Tobacco, exclusively for use in connection with agriculture or horticulture, and contained in a closed vessel or receptacle, distinctly labelled with the word 'Poison,' the name and address of the seller, and a notice of the agricultural or horticultural purpose for which the preparation has been made.

Preparations of carbolic acid, or its homologues, for use as sheep-wash, or for any other purpose in connection with agriculture, horticulture, or sanitation, and contained in a closed vessel, distinctly labelled with the word 'Poison,' the name and address of the seller, and a notice of the special purposes for which the preparations are intended."

ROYAL HORTICULTURAL SOCIETY.—*Alteration in Rules for Judging.*—Everyone possessing a copy of the Rules is requested to make the following alterations:—Page 14, line 4, should in future read thus: "Muscat of Alexandria or other Muscat Grapes, 11." And the word "other" should be inserted before "Black Grapes." By order of the Council. *W. Wilks, Secretary.*

"THE JOURNAL OF THE ROYAL HORTICULTURAL SOCIETY."—The part for December, 1902, reached us recently, and we can only repeat the encomiums we have already passed on former parts. Dr. Cooke's article on "Pests of the Flower Garden" is so useful that we may hope it will be issued as a separate book. The Earl of Annesley contributes an article on the "Ornamental Trees and Shrubs at Castlewellan," with several beautiful illustrations. Professor Potter deals with a disease of Carnations, due to the growth of Septoria Dianthi. Then follows a report of the Rose show and conference, both of which were in themselves full of interest, but sadly interfered with by the illness of the King, which it will be remembered was made known on the afternoon of the first day of the show. Mr. Baker contributes descriptions and illustrations of two new Roses from the S.W. United States, R. minutifolia and R. stellata, both near allies of R. spinosissima. Miss Anne Dorrance has an article on "Rose Forcing in America," which may be commended to the notice of our market growers. M. Maurice de Vilmorin describes numerous Asiatic Roses which he has in cultivation. M. Viviand-Morel treats of hybrid Roses; Miss Jekyll deals with garden Roses, a subject taken up also by Mr. William Paul. Chinese Roses (species) form the subject of some remarks by Mr. G. Nicholson; M. Viviand-Morel has an article on the "Methods of Striking Roses." The sensitiveness of cultivated Roses to changes of weather finds an able exponent in Mr. Ed. Mawley. As an illustration of a perfectly hardy Rose, Mr. Mawley cites Bennett's seedling. Rev. J. Pemberton, Mr. A. Dickson, and Mr. O. G. Orpen, descant upon the hybrid Tea Rose; Mr. George Paul upon exhibition Roses, and Mr. G. Mount on Rose culture under glass; lastly, Tea Roses form the subject of a communication from Mr. Frank Cant. After this enumeration there can be no question as to the success of the Rose Conference. The Malta Botanic Garden is described by Dr. Debono; and Professor Henslow contributes some remarks on the flora of that island. Mr. A. Gaut contributes a valuable report on hardy fruits grown in Yorkshire; whilst the Gooseberry mildew (Sphærotheca) finds an exponent in Mr. Ernest Salmon. Some of Professor Henslow's lectures on various subjects to the Chiswick students are reported. Then follows a very important communication from Captain Hurst on the application of Mendel's principles to Orchid hybrids. "For all practical purposes," concludes Capt. Hurst, "Mendel's principles may be safely accepted as a working formula for the hybridist in general and the Orchidist in particular." Fruit trees in pots form the subject of a communication to the Horticultural Club by Mr. T. Alfred Rivers; and horticulture in Egypt is treated by Mr. Lionel Saunders. The remainder of the part is taken up with reports on the trials at Chiswick, including Tomatos, Asters, Phloxes. The short abstracts from current literature are becoming increasingly useful.

FORESTRY. — In the House of Commons, February 18, Sir CHARLES DILKE asked the President of the Board of Agriculture, if it is intended to take any steps to carry out the Report of the Departmental Committee on Forestry before the House of Commons has the opportunity of expressing an opinion as to the suitability of the centres recommended, to which the following reply was made by Mr. HANBURY: "The evidence has not yet been printed, and I am therefore not in a position to decide as to the urgency of any particular recommendation. But I will, of course, take care that the Right honourable baronet, or others interested, have a proper opportunity of expressing their views."

LINNEAN SOCIETY.—On the occasion of the evening meeting, to be held on Thursday, March 5, 1903, at 8 P.M., the following papers will be read: 1. On some points in the Visceral Anatomy of the Characinidæ, by Mr. W. S. ROWNTREE, F.L.S. 2. On the Anatomy of the Pig-footed Bandicoot, Chæropus castanotis, by Mr. F. G. PARSONS, F.L.S. 3. Further notes on Lemurs, by Dr. ELLIOT SMITH.

THE NATIONAL HORTICULTURAL HALL: AN OFFER.—Mr. ROBERT SYDENHAM, of Birmingham, offers a contribution of £50 towards the building fund, providing twenty nurserymen or seedsmen will give the same amount; replies should be sent to G. J. INGRAM, Secretary of the Appeal Committee, Royal Horticultural Society, 117, Victoria Street, London, S.W.

—— The Drapers' Company have contributed £105 towards the building fund. The trustees of the Williams' Memorial Fund at their recent meeting agreed to contribute £10 to the fund being raised to secure the erection of a Hall and offices for the Royal Horticultural Society. Mr. MAYNE, of Bicton Gardens, sends us, for the same purpose, 10*s.* 6*d.*, which has been transmitted to the proper quarter.

—— COLLECTING FOR NEW HALL. Will other gardeners follow the excellent example of Mr. GEO. BOND, of High Ashurst Gardens, Dorking, who has collected £4 in aid of the building fund?

DR. PRIOR.—Dr. R. C. A. PRIOR, of 48, York Terrace, Regent's Park, and Halse House, near Taunton, Somerset, who died on December 5 last, left estate of the gross value of £110,781 3*s.* 7*d.*, and of the net value of £108,781 3*s.* 7*d.* He bequeathed £100 to the Linnean Society; and his herbarium to the Directors for the time being of Kew Gardens, and the executors may expend £50 in carrying out this bequest.

COTTAGE GARDENS AND AMATEUR GARDENERS. — The Dean of Rochester sends the following note:—"We have so many societies in this neighbourhood [Rochester], for the extension of cottage gardens and the encouragement of amateur gardeners; so much has been done by our Kent County Council to confer the advantages of horticulture upon the working classes by the appointment of experts, to supervise, to give lectures and practical instruction, to establish exhibitions, to reward success; and the happy results of these beneficent endeavours have been so often seen in a closer attachment to home life, in escapes from temptations and evil habits to healthful and useful employment, in the variety and increase of wholesome food, in that admiration of the beautiful, which purifies the mind and exalts it to look 'through Nature up to Nature's God.' All these considerations assure me that a large number of your readers will read with interest of a new and generous attempt to evoke enthusiasm, ambition, and experience among these cottage and amateur gardeners. In addition to the local shows, at which individuals compete with each other, Lady ALGERNON GORDON LENNOX proposes an exhibition, on the Bank Holiday in August next, at Broughton Castle, Banbury, for societies or groups of villages, each society or group to select from its members a collection of hardy flowers, fruit, and vegetables, grown by cottage gardeners and amateurs only. The Lennox Challenge Cup value 50 guineas, will be awarded to the winner of the first prize, to be held for one year, and retained after three successive years of victory. The Royal Horticultural Society will present four of their Banksian Medals, and £30 will be given in money. The exhibition is restricted to gardeners dwelling in Northamptonshire, Oxfordshire, and Warwickshire, but we may hope that this example will be followed in other counties by those who enjoy, and would impart to others, the happiness of a garden." *S. Reynolds Hole.*

THE COUNTESS OF SPENCER SWEET PEA.—A Midland seed merchant writes:—"There seems to be an impression abroad that this pretty variety, which was certificated in 1901, is likely to be lost on account of the seed failing to ripen properly last year. The crop was certainly disappointing, and was so small that it was impossible to quote it this year; but having secured from the original raiser a fair quantity of seeds, which have long since been sent to his seed-raiser on the Continent, he hopes to have a sufficient quantity to meet all reasonable demands for the variety next year."

THE NATIONAL AMATEUR GARDENERS' ASSOCIATION.—We have received from the Secretary of this Association, founded in 1890, the Syllabus for 1903, and the report and balance-sheet for 1902. From this we learn that the Association is making progress slowly. The balance-sheet submitted shows a slight improvement on that of last year, but there is still a balance on the wrong side. Monthly exhibitions are held, and prizes awarded. The next meeting will be held on March 3, when Mr. J. CHEAL, of Crawley, will give a lecture anent his rambles in the U.S.A. and Canada, with lantern-slide illustrations. The Secretary is Mr. A. J. FOSTER, 57, St. Donatt's Road, New Cross, London, S.E.

THE OPEN-AIR TREATMENT OF THE AILING.—There are upwards of half a hundred open-air sanatoria in this country for those who can well afford to pay for the treatment, but for the poorer class of patient little provision has been made. To meet the pressing need, a Working Sanatorium Colony has been inaugurated by Drs. CHARLES REINHARDT and FRANK FOWLER at Ipsden, near Wallingford. Patients who are not too ill to do some outdoor work, and who can pay a small sum, or for whom a subscription can be raised, are received at the Subscription Sanatorium, Ipsden, Wallingford (Mr. E. SMITH, Secretary), and they not only have the opportunity of being restored to health by the open-air treatment, but they are at the same time enabled to fit themselves for an open-air life by learning such occupations as poultry and pheasant rearing, and suitable forms of agriculture and horticulture. Women patients, whose state of health is considered suitable, also engage in outdoor pursuits at the discretion of the Resident Physician.

VALUE OF A HERBARIUM.—In a recent issue we quoted from *Botanizing*, Prof. W. W. BAILEY's practical book for field botantists, an extract on the usefulness of botanic gardens. The following appreciation of a herbarium, from the pen of the same author, forms an interesting supplement:—"But let us consider a little more closely the uses of a herbarium, and of a botanic garden. In regard to the former, it is to be said that much of the systematist's work is of necessity upon dried plants. These he soaks in warm water, which in a measure restores the contours, and softens the tissues so that they can be examined. A botanist could not by any chance visit all countries, or even every part of his own, but in the herbarium he can have all or a large part of the plants of any given region exposed in their natural sequence, or what science at the time considers such. Plants even of one family or genus are not all simultaneously in flower or fruit, but in the herbarium all parts can be thus viewed. The natural affinities and geographical and alti-

tudinal distribution can be learned in no other way, though closet work must need supplement more direct field observation. Again, the herbarium is a cyclopædia of ultimate appeal. To it the student in doubt may appeal as to an authority. At least, he will ascertain what the best investigators have thought. Hence a fine public herbarium is something to be amassed and cherished. A botanic garden is almost equally important. Therein plants should be arranged as nearly as possible by their natural affinities, well and clearly labelled, so that all may learn them. Many horticultural experiments can here be tried. Moreover, the garden should, like that of Kew, be a centre of dissemination both of knowledge and useful products. It should at all times be open to the public, and hence become a park of most delightful and varied usefulness."

"THE NATURAL HISTORY OF PLANTS."—The re-issue of this important periodical (BLACKIE & Co.) has now reached the 8th part. It was originally written by Prof. KERNER, of Vienna, and the English edition has been prepared by Prof. F. OLIVER. It is nicely got up, and beautifully illustrated, and is so complete and "up-to-date" that it should form part of every garden library.

"THE GARDEN GAZETTE."—We congratulate our Melbourne friends on the success of their enterprise in providing the colony of Victoria with a high-class and well got up Journal. Our contemporary may be supposed to know its own business, but we in Europe should welcome some signs of the development of Australian horticulture proper, by which we do not mean a mere repetition of what is done in Europe or America, but the culture and improvement of native Australian plants, which would afford so much greater novelty and interest. We are glad to see the names of Mr. GUILFOYLE and Mr. POCKETT, in the new Gazette.

APPLE "PRINCE BISMARCK."—This Apple, Mr. CHARLES DRAPER states, in the *Garden Gazette* of Melbourne, is of Colonial origin, having in fact, been raised near Maryborough, Victoria. The facts are these:—Some years ago, some fine specimens of a new seedling Apple were sent to the Royal Horticultural Society (Victoria) for classing and naming, and were highly approved of by the fruit judges, Messrs. DRAPER & HARBISON, who named the new variety "Prince Bismarck." This first exhibit was sent in by Mr. CLARKSON, of Maryborough. A curious coincidence now occurred in the naming of this Apple. At the next meeting of the Society, another claimant came forward with still finer specimens of this Apple, exhibiting fruit that Mr. DRAPER declares were the largest Apples that he ever saw in all his lengthy experience as a fruit grower. These were exhibited by the raiser, and were from the original tree in his orchard, and curiously enough he was a German, an orchardist of Smoky-gully, Maryborough, whose name Mr. DRAPER does not recollect. So quite unwittingly the Apple was most aptly named "Prince Bismarck," under which name it has been propagated and distributed ever since. This variety was the result of a cross between Emperor Alexander and Stone Pippin, and is a fine cooking variety, retaining the high colour and handsome appearance of "Emperor Alexander" and the firm flesh of "Stone Pippin." It is an early and heavy cropper.

FRUIT NOTES FROM TASMANIA.—The following is extracted from a communication by the Secretary for Agriculture, Tasmania, under date December 23, 1902, to a correspondent of this journal:—"Whilst it can hardly be expected that the same enormous yield per acre that was obtained this past season will recur next year, yet the steady advance that has been made in the direction of planting out fresh areas during th past few years will help to keep up a large yield in the aggregate, and thus act as a set-off against the probable light yield in those full-bearing orchards which carried such heavy crops last season. Generally speaking, the present prospects of this immense industry are excellent; each season sees a distinct advance made by orchardists recognising the efficacy of the various sprays recommended by the Department, and their more widespread application. The adoption of the 'Peacock' (10 by 15 by 20 inches) fruit-case, which now carries all the fruit to England, and almost all fruit grown in Tasmania to the large markets on the mainland (Sydney, Brisbane, &c.), has proved a great saving to growers in this State. Not only does it require less timber to make, but it is easier to handle, easier for the grower to fill when picking, and can be stowed away in greater number to the ton on board ship. In a recent article of the *Canadian Horticulturist*, the Dominion representative in London recognised that Tasmania was to the fore in the style of package and its general get up. The number of different shipping companies at present competing for the carriage of Tasmanian Apples to London and elsewhere in the Old Country is all in the interests of the fruit-grower, as it means improved methods of carriage, and more care exercised over the fruit whilst on board ship, with the general tendency to still further reduce the freight."

—— From recently-issued statistics, we learn that the total area in acres under Apples is 8,396; Pears, 730; Apricots, 530; Plums, 508; Cherries, 211; Peaches, 121; Raspberries, 886; Gooseberries, 461; Strawberries, 91; Currants, 531. As to the yield last year, Apples gave 843,348 bushels, Pears yielded 50,212 bushels, whilst other fruit gave 65,129 bushels.

THE NATIONAL ROSE SHOW.—We are requested by the President of this flourishing Society to publish the subjoined note, which we commend most heartily to the notice of rosarians of all degrees:—"The National Rose Society has greatly added to the beauty and interest of its later exhibitions by awarding prizes to 'garden or decorative Roses,' of which a 'selection of the fittest,' is included in their admirable official catalogue. The committee is most anxious to increase the attractions of the show, and to improve the arrangement of the flowers; and it might be helpful if some of those critics who are most severe in their denunciation of the present methods, would kindly make a few practical and possible suggestions as to the future. We all desire more diversity, more graceful adaptations, more room and less heat in the tents, and outside of them the surroundings of a spacious garden, with umbrageous trees, comfortable seats, and charming grottoes; but at present we are in the unhappy condition of 'Little Bopeep, and don't know where to find them.' As for the cruel suggestion of a two days' show, which, with its faded petals and *pot pourri*, intensified by a few 'renovations,' would represent the decline and fall of Queen Rosa's empire. I should anticipate that the visitor to such a dismal display would

> Feel like one, who treads alone
> Some banquet-hall deserted,
> Whose guests are fled, whose Roses dead.

Or like MARIUS weeping over the ruins of Carthage, or some enthusiastic bedder-out in his garden after a hailstorm! Better to bear the ills we have, and try to overcome them, than fly to others which we know not of. Sufficient unto the day is the evil thereof. *S. Reynolds Hole, President of the National Rose Society, The Deanery, Rochester, February* 21, 1903."

MR. GEORGE STANTON, who has, with his many other duties, had charge of the gardens at Park Place for the last thirty-two years, is giving up the management of the gardens in order to devote all his time to the farms and estate. He is succeeded in the gardens by Mr. T. J. POWELL, who has been under Mr. STANTON as foreman for many years.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—The Earl of WARWICK will preside at the sixty-fourth anniversary festival dinner in aid of the funds at the Hôtel Métropole on June 24 next. The Secretary, G. J. INGRAM, 175, Victoria Street, London, S.W., will be glad to receive the names of those willing to act as stewards, or to in any way assist to make the gathering a success.

BACTERIA AND OTHER MICRO-ORGANISMS AND MINERAL MANURES.—To encourage investigations into the increase of fertility in soils by the action of bacteria and other micro-organisms, under the influence of mineral manures, with special reference to manuring with basic slag, the Berlin Association of THOMAS's Phosphate Works has instituted a competition, with prizes amounting to a total of £1,950. Scientific essays and experiments conducted by practical farmers will be admissible in the competition. The competition is to be open to all, without regard to nationality. Competitors are requested to send in their essays, written in German, to the address of the Association, Berlin, S.W., Hafenplatz 4, not later than February 1, 1906.

AN AUTOMOBILE LAUNCH.—Count ZEPPELIN, the inventor of the first navigable airship, has completed another invention. It consists of an "automobile launch," which possesses the peculiarity of having its propellers in the air. According to the inventor, the launch will be of the greatest use in tropical lakes and rivers encumbered with aquatic plants, which, obstructing the screw, render an ordinary steam launch useless. This novel launch is extremely light, has a draught of only 10 inches, and it skims the water at a rate varying from 14 to 16 miles an hour.

BOTANICAL CONGRESS AT VIENNA.—A congress will be held in Vienna from June 12 to 18, 1905. The list of committees has been already circulated, from which we find that Dr. RICHARD VON WETTSTEIN and Dr. JULES WIESNER are to be the presidents. Dr. ED. HACKEL and Dr. HANS MOLISCH, of Pragne, vice-presidents; and Dr. ALEXANDER ZAHLBRUCKNER, curator of the botanical section of the natural history museum, Vienna, general secretary. A large number of Austrian botanists comprise the general committee, and sub-committees are appointed in the various sections—1, finance; 2, festivities; 3, exhibitions; 4, excursions; 5, nomenclature. All correspondence should be addressed to the secretary, Dr. A. ZAHLBRUCKNER, Vienna, I. Burgring 7.

THE PREVENTION OF CORRUPTION.—Earl GREY asked the Lord Chancellor whether it was the intention of His Majesty's Government to reintroduce, at an early date, with the view of its becoming law before the end of the current Session, the Prevention of Corrnption Bill. He said that last year he sat on a departmental committee of the War Office on canteen contracts; and the evidence taken in the course of that inquiry disclosed a state of things so grave that he held it would be a scandal if any delay were allowed to occur before their Lordships' House took the necessary action to make this form of corruption a criminal offence. He was convinced that the practice of accepting and offering secret commissions was nothing short of a canker attaching itself to the vitals of our commerce. He had been requested by the great body of co-operators, who, as their Lordships were aware, numbered 7,000,000 of the population, to ask the noble and learned Earl what were the intentions of the Government with respect to this subject.

and to express a hope that the Government would in the interest of honest trading endeavour to secure the passage of a Bill through Parliament. The Lord Chancellor said he had himself received since last year ample proof of the extraordinary development of the system of corruption by what were delicately called commissions, but which were, in truth, bribes to people to betray their duties to their employers. But whether the facts collected and published have not to some extent increased it, he did not say; but he could not help thinking that a great many people had learned for the first time from them how easy it was by pressure on others to insist on commissions. The fact, undoubtedly, was that the system had grown extensively, and he agreed that it demanded the attention claimed for it. So far as he was concerned, he was happy to say that he held in his hand a Bill which, as soon as the other business, of the House was disposed of, he proposed to ask their Lordships to read a first time. In the congested state of the House of Commons business, there was no doubt that there was great difficulty in getting on with a Bill of a character that was neutral, although it was most important socially. He would do his best to push the Bill through the House, and would do what he could to advance the prospect of its becoming law, because nobody felt more strongly than he the enormous importance of this question. The Lord Chancellor then presented a Bill for the Prevention of Corruption, which was read a first time.

New Cycads from the Congo. — M. de Wildeman has recently published an enumeration of the plants collected on the Congo by M. E. Laurent of Gembloux, among which we find a new Encephalartos, E. Lemarinellianus (after Capt. Lemarinell). M. Gentil has forwarded to Laeken living specimens, so that we may expect fuller details shortly.

Xanthosoma × Caladium.—M. Dybowski, of the Nogent Colonial Garden, recently showed before the French Horticultural Society, a fine set of new hybrids obtained by crossing Xanthosoma sagittifolium and Caladium pictum. The crossing was effected in Reunion, and the bulbs were forwarded to M. Dybowski when they were the size of small Hazel-nuts. Placed in the Colonial Garden they grew well, and it is hoped that they may prove sufficiently hardy to pass the cold season out-of-doors in a sheltered spot, as do Begonias. The plants are like Xanthosoma as to foliage, but the leaves have white-yellowish, or red spots like those of Caladium. They are not specially fine, but do not fall in winter. M. Dybowski hopes to make them a starting point from which to obtain a race of richly coloured plants.

Horticultural Congress in Paris. — A Horticultural Conference will be held in Paris on May 22 next in the rooms of the Société Nationale d'Horticulture de France, 84, Rue de Grenelle. The following questions are offered for discussion:—1. Methods of training and pruning Peaches previously to forcing them; 2. Cold storage appliances and their uses and effects; 3. Influence of fertilisers on the ripening and preservation of fruit; 4. Horticultural monograph dealing with one genus of plants; 5. Selection of seed with a view to originate or create varieties; 6. The method of growing the same crop continuously in one place; 7. Which are the best insecticides and fungicides? Mention the constituents of those recommended; 8. What is the best substitute for stable-manure for vegetables? 9. How may cold storage be made to assist in forcing plants by causing them to develop prematurely, or by retarding their development; 10. Is a horticultural museum of use, and how can it best be started? 11. What are the best methods of sowing, raising, and improving Orchids? 12. On the practical utility of leaf-mould in the cultivation of various Orchids; 13. How may nurserymen protect their own interests in regard to new varieties of their own raising? 14. Is it better to sow freshly gathered or stored seeds? Give reasons for either course as adopted for different plants. Contributions should be written in French, and forwarded to the office of the Society before March 19.

Publications Received. — *Agricultural Bulletin of the Straits and Federated Malay States*, December, 1902. Contents: Coffee and other products in Zanzibar; Cultivation of Orchids for Amateurs, by C. Curtis; Funtumia elastica, by H. N. Ridley, &c.—*The Transvaal Agricultural Journal.* Issued by the Agricultural Department; edited by A. Burton. Vol. i., No. 2, January. Contents: Rural Notes, Fruit Growing Districts, &c. A valuable publication for all interested in the Colony and its development.—*Guide to Hope Gardens, Kingston.* By Mr. W. Jekyll. A handy account of well-known gardens in which much good work is done. It is trustworthy, being published under the authority of the Governor of Jamaica, and pictures and letterpress are alike pleasing. Mr. W. Fawcett is the Director of Public Gardens and Plantations in the district.—*Transactions of the English Arboricultural Society*, vol. v., Part 2. Compiled by John Davidson, Secretary and Treasurer. This contains reports of meetings, articles on French forests and forestry, and on various other suitable subjects.—*Annual Report of the Jamaica Board of Agriculture and Department of Public Gardens and Plantations*, 1901-1902. A satisfactory record of work and progress, though in some stations a wet season proved a great hindrance.

ÆSCULUS INDICA.

The Indian Horse-Chestnut seems to have been first introduced from the Himalayas to England about the year 1851. Seeds were sent home by Colonel Bunbury to his brother at Mildenhall in Suffolk, and a tree raised from them flowered there in July, 1858. I do not know of any big specimens of it anywhere in this country now, although the one that flowered at Mildenhall forty-five years ago ought, by this time, to be a big tree if it is living—but I fear it is no longer in existence. Possibly the species is not hardy enough to survive the severer winters of the midland and eastern counties, but it ought, nevertheless, to be perfectly at home in the south and south-west of England and Ireland. In sheltered places at Kew it has succeeded very well during the last seven or eight years, and has flowered a few times. The Supplementary Illustration was made from a branch of a young tree that flowered there last year. Æ. indica is quite distinct from all other cultivated Horse-Chestnuts. Its foliage is very striking, for there are sometimes as many as nine leaflets to a leaf, the largest of them being 12 inches long, and 3 or 4 inches wide. They are spreading, as in the common Horse-Chestnut, of a rich dark green, and serrated; the leaf-stalks (as well as the young wood) are tinged with a Rhubarb-like red. The flowers are borne on an erect terminal raceme 8 to 10 inches long, the petals being white, the two upper ones with a red and yellow blotch at the base, and the two lateral ones flushed with pale rose. The long stamens add much to the character and beauty of the raceme. It does not blossom until June and July, when the common Horse-Chestnut and several of its allies are past, and this adds to its value. It is a native of Nepal and other parts of northern India, where it is found at elevations up to 10,000 feet; it is also a native of Afghanistan. There it rivals the common Horse-Chestnut in stature and bulk, growing as it does 70 feet high, and having a trunk 10 feet in circumference. It appears to be worth a serious effort to introduce in quantity. Like our common species, its seeds lose their vitality soon if kept dry. They should be gathered and sent off as soon as ripe, and packed in fairly moist soil, so that if they commence to germinate on the journey there is a sufficient supply of moisture to keep them alive till suitable conditions can be given. Of some scores of seeds received in ordinary paper packets in recent years at Kew, not one has germinated. *W. J. Bean.*

HOME CORRESPONDENCE.

A fruit room.—To "Subscriber," who is seeking information regarding the erection of a fruit-room, I may say that last year in these gardens I had built what is proving an excellent fruit-room at a—comparatively speaking—very small cost. It is a lean-to building facing west, the height at the back is about 11 feet, the front 7 feet, length 15 feet, and the width 8 feet. Material used, sides and ends of feather-edged boards outside, and match-boarding inside, the 3 or 4 inch space between these boardings, from the floor to the roof being filled with dry sawdust. The roof is also of match-boarding inside, with flooring boards above that, then felt, and pantiles, these being much cooler in summer and warmer in winter than slates. The footings of the building are of concrete, and come up about 18 inches above the ground-level. The floor consists of about 7 inches of concrete, rendered smooth with about 1 inch of cement and sand. Although we have had 14° of frost, such a building has not gone below freezing point, so that I have not needed to heat it, as I have only Apples and Pears; but it is very likely if Grapes had to be stored, a somewhat higher temperature would be required. The stages for the fruit are at the sides and ends, and they are 18 inches wide, made of battens planed on the top-side, and the upper edges bevelled. "Orr's patent fruit trays" are excellent for economising space in the fruit-room, and if made use of there is really no need of stages at all. I may add, that I have two small shutter-ventilators in the back, and a small window with shutters in the front, and the room is kept dark. The fruit keeps fresh and plump. *W. H. Robbins, Chislehurst, Kent.*

—— I would advise "Subscriber" to obtain from Messrs. J. Veitch & Sons, or Messrs. Bunyard & Co., their photographs and instructions for constructing fruit-rooms and houses. I built one lately on the plan these experienced nurserymen recommend, and find it very satisfactory. The walls are built of brick, and are hollow. I used bricks on edge, with the moulded face outwards, which gives an original and ornamental effect; the inside wall is built with the smooth face of the bricks inwards. The two walls are bonded together with headers at intervals, which makes the wall very strong; and the air-space between the two walls, of about 4 inches, secures an even temperature. The roof is boarded, and well thatched. The floor is of earth sunk about 2 feet below the surface of the ground; and ventilation is provided above and below by hit-and-miss iron ventilators, protected by sheets of perforated zinc. There are two doors, a solid one outside, the inside one having panels of perforated zinc, which can be provided with shutters if necessary. I shall have much pleasure in showing "Subscriber" the house if he will take the trouble to come here. *A. G. Sandeman, Presdales, Ware, Herts.*

Calanthe Veitchii.—I was much pleased with Mr. Mayne's remarks in last week's issue on Calanthe Veitchii. I notice that Mr. Mayne places his pseudo-bulbs, when potted, in a Melon-house. I think it would have been more instructive had Mr. Mayne described his Melon-house, if a lean-to, three-quarter, or a span-roofed house. I presume they are grown on the back shelf if a lean-to house or three-quarter span, or on shelves near the roof if a span-roofed house. I may say that I am not now an advocate for growing Calanthe Veitchii on shelves near the glass. We grow at Dawpool seventy plants of this beautiful Orchid, and more would be grown if space allowed. The pseudo-bulbs are potted about the first week in March, singly in 5 and 6 inch pots, the pots being filled with clean crocks to the depth of 2 inches, and the compost of which use is made consists of good turfy loam and cow-dung, a small quantity of charcoal, and a sprinkling of Orport Gravel. After potting, the pots are stood on inverted 6-inch pots on the centre bed of gravel in a lean-to stove, where they remain till the plants require a drier atmosphere, that is when a score or so of flowers have opened; a house is then chosen where a suitable temperature and atmosphere can be

maintained. When the spikes are fully developed they are removed to the conservatory, and arranged on the side stages interspersed with Ferns, so as to hide the pots and pseudo-bulbs; and a very fine feature they present, until such times as they are cut for house decoration. The pseudo-bulbs are then stood in a suitable place fully exposed to sun-light, until the potting season comes round. Many of the pseudo-bulbs throw up two good flower-spikes. During the season of growth various liquid-manures are afforded; and when the flower-spikes are well up, say 5 in. high, a top-dressing of loam and cow-dung is applied. *R. Horne, Dawpool, Cheshire.*

LABELLING FRUIT TREES.—Another easy mode of labelling fruit trees, in addition to those methods described by Mr. Page in the Calendar of the Hardy Fruit Garden for January 17, is that of stencilling the names on cast-iron or zinc labels, which have previously received two coats of white-lead paint. Indian-ink is the best to employ for the purpose, and if the paint is perfectly dry, the name, whatever it may be, will stand out quite clear and legible on the surface of the label, and if varnished afterwards it will last for years. A handy man can stencil a great many labels in a day after a little practice. Brass stencils of various sizes and types of letters can be obtained through a good ironmonger, and the Indian-ink can be procured at any stationery depôt, where drawing materials are kept in stock. *A. W.*

THE GOOSEBERRY.—Much has been written lately in the *Gardeners' Chronicle* about Gooseberries, and a summary of the whole matter may not be out of place at this date. There is no comparison possible between this fruit and say Pines, Melons, Grapes, Peaches, Nectarines, Apples, and Pears. Most gardeners like to display as many dishes of fruit as is possible with the means at their command, and the Gooseberry is not despised. It is almost the first out-of-doors fruit to be sought after for culinary purposes, and makes a fine preserve. We cannot expect to get the full flavour of this fruit when it is grown on a north aspect, but it certainly can be kept till late in the year, as may also Red Currants and other fruits. If a Gooseberry-bush is properly pruned, that is by leaving the shoots long and thinning them, and nipping off the points of the young wood, there would be fewer failures of crop. The more buds the pruner leaves, the better for the birds. With the barbarous practice of spur-pruning Gooseberry and Currant bushes, that is, shortening all the young shoots to two or three buds at the base, we cannot expect to get good crops of fruit. When, however, the bushes are grown against a trellis, fence, or wall, the only method that can be adopted to keep them in bounds is by spur-pruning. The Gooseberry succeeds to a greater degree in the north than in the south, the plant being adverse to much warmth. At Castle Eden we seldom miss a good crop of fruit. *W. Fulford.*

COOLING'S MATCHLESS BROCCOLI.—This is an excellent variety to grow for early spring cutting. It is self-protecting, has a pure white curd, large and close, and the plant is compact in growth, and perfectly hardy. It comes into use soon after Snow's Winter White. Planted alongside the latter variety, it proved itself to be the hardier of the two. Where I lived in Cornwall, Snow's Winter White was always grown to succeed Veitch's Self-Protecting, an arrangement which answered admirably. I have tried the same thing here (Cambridgeshire) three years in succession with very disappointing results, quite 80 per cent. of Snow's being killed by frost before they were ready for lifting and storing in a frame. For the future I shall grow more of Cooling's Matchless, and less of Snow's. The soil here is very heavy. *W. J. Snell, Cambridgeshire.*

PLANT BREEDING.—Having read with interest the various articles on the above subject appearing in the *Gardeners' Chronicle*, I have come to the conclusion that it would be better if writers would be more clear in their utterances on this subject, which would be more especially so to those who are not well versed in hybridisation, for example, the use of the terms "cross-breeding" and "hybridism," which by some of your correspondents are used as having two distinct meanings, when they are really synonymous, a state of matters which is rather confusing to beginners. Before starting to cross the flowers of one plant with pollen taken from another, it is essential to know to which genus they belong to, and whether they are self-pollinating or the cross-pollinating. I think one example of each of these two classes will suffice to explain my meaning. A common example of the self-pollinating plants is the Wallflower. Wallflowers are rarely cross-pollinated by insects, but come true from seed, yet they are easily pollinated by human agency. A common example of the cross-pollinating plants is the Antirrhinum, which will readily take on the pollen carried by insects from one flower to another. These two examples can be readily tested by sowing some seed of Wallflower which will invariably come true to the parent, and sowing some seed of Antirrhinums which it will be seen are all crosses from the parent. By these two examples it is necessary to ascertain whether the flowers we are going to cross will take on the pollen carried by insects, and if so we must isolate them, or take precautions that no other pollen, other than that which we put on, reaches the stigma of the flowers we are pollinating; otherwise we shall not know whether we or the insects have the credit for the crosses. If these precautions are taken, we shall then be better able to judge whether the natural crosses, or the crosses by carefully chosen flowers, produce the best results. I might dwell further on the methods of crossing, but I fear to trespass too much on your space. *A. McL. May.* [Cross-breeding is a general and comprehensive term; hybridisation a special application to the crossing of species only. ED.]

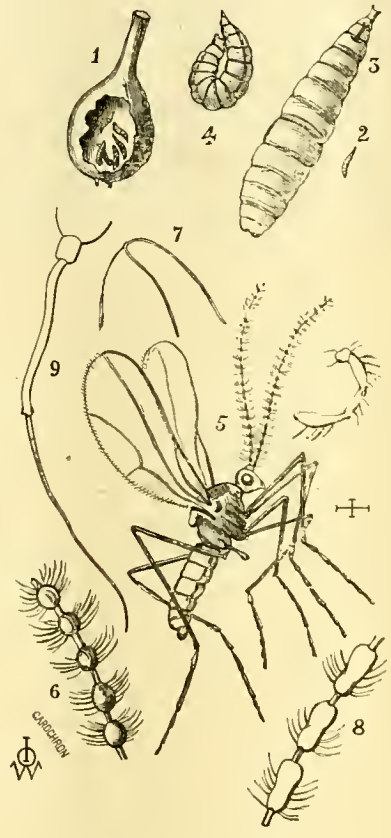

FIG. 57.—THE PEAR MIDGE.
1.—Young fruit with grubs.
2.—Grub, real size.
3.—Ditto magnified.
4.—Chrysalis.
5.—Perfect insect magnified.
6, 7, 8.—Details of structure.

PHEASANTS AND FLOWERS.—In the recent correspondence on this subject, I have not seen any mention of what I have found to be the best protection. I plant all bulbs too deep—say 8 in. to a foot—for pheasants or mice to reach them, and find they flower quite as well, though they do not increase so fast when flowering begins. I have for many years watered Crocuses, Dogtooth Violets, Anemones, Fritillarias, &c., with a strong infusion of quassia—an ounce of chips boiled in a gallon of water. A 2-gallon water-pot, with a very fine rose, will water many thousand flowers. It is better to apply it when the flowers are shut up, so as not to wet their inside. If this is used as soon as the first flowers show, pheasants will try them and reject them, and afterwards leave them alone. I observe that in the latest number of the Royal Agricultural Society's *Journal*, 2 ozs. of quassia-chips to a gallon of water is recommended as an insecticide. Perhaps this strength is even more effective against slugs, green-fly, and other pests, and would do no harm to flowers, but I warn gardeners not to try it for the Gooseberry-caterpillar. I once did so almost before the Gooseberries were past flowering, and the Gooseberries were so bitter as to be useless to the very end of the season. *C. Wolley Dod, Edge Hall, Malpas.*

ENTRIES AT THE ROYAL HORTICULTURAL SOCIETY.—As Honorary Secretary of the Orchid Committee of the Royal Horticultural Society, I am asked to impress upon exhibitors the necessity for observing the Society's rule that all plants intended to go before the Committee should be entered at the table before 11.30; and further, to ask them to assist by entering such plants at the earliest possible moment, either by sending the entries beforehand by post, or by handing them in immediately after they reach the Hall. Unfortunately, it has again become the common practice for exhibitors to leisurely stage their exhibits, and afterwards fill in the entry papers, so that just before 11.30 a number of entries are on hand which have to be copied into two books, and the exhibitors' cards to be filled in before noon, when the Committee meet. Much confusion is caused in this way, for at such a meeting as the last it is impossible to deal with the entries properly in the time. *James O'Brien.*

THE PEAR MIDGE.

(DIPLOSIS PYRIVORA.)

(FIG. 57.)

DURING the last few seasons the Pear gnat-midge has been very prevalent in gardens, and where it abounds steps should be forthwith taken to eradicate the pest, for when once it is allowed to spread, much vexation and disappointment is felt, hence the reason of drawing attention to the fact now. Where it was prevalent last season, much might have been done during the winter to stay its progress; and at the present time, if the affected trees of last season are now sprayed with petroleum emulsion once or twice before the flowering period, I believe an attack would be averted, as the insect pierces the flower-bud just before it expands, but probably this fact would escape the notice of an ordinary observer till the fruits began to drop. Now, by spraying the trees at this date with the emulsion or other insecticide, much good would be done; and on trees infested last year, this should certainly be carried out. I had several Pear trees badly infested last season, but I collected all the small fruits that fell and burnt them, and put quicklime on the soil beneath the trees during the autumn and winter. The ground was dug as deeply as it could be without causing injury to the roots.

The weaker trees seemed to be those mostly infested, and the worst were Marie Louise, Ne Plus Meuris, Doyenné Bossouch, and Jargonelle, which were all weak-growing trees, but now they are in robust health. Doubtless, some of our fruit pests are imported from abroad, as some Oranges indicated when examined some time ago. These were covered with a small scale insect in a living state; they resembled our ordinary oyster-scale (Mytilaspis pomorum), found on the Apple-tree bark, which gardeners do not regard as injurious—a mistaken idea. *W. A. Cook.*

SOCIETIES.

ROYAL HORTICULTURAL.

FEBRUARY 24.—The Drill Hall, Buckingham Gate, Westminster, was very full of exhibits on the occasion of the ordinary fortnightly meeting of the Committees on Tuesday last. Orchids were particularly numerous, and there were some very choice novelties among them.

The ORCHID COMMITTEE sat for an unusually long time, and recommended awards, including two First-class Certificates and six Awards of Merit.

There were many groups of plants and flowers before the FLORAL COMMITTEE, but few novelties were submitted, and of these only one (a new variety of Iris from Miss WILLMOTT) was granted an award; but seventeen medals were awarded by this Committee, which is an unusually large number. A brilliant group of mollis Rhododendrons, shown by Messrs. R. & G. CUTHBERT, was probably the finest exhibit of these plants ever displayed in the Hall in the month of February, and reminded us of the magnificent collections of Rhododendrons that may be anticipated at the Quinquennial Exhibition that will shortly take place at Ghent.

The FRUIT AND VEGETABLE COMMITTEE had little to do, the exhibits consisting mainly of a collection of Apples from Mr. TAYLER of Hampton; a collection of preserved fruits from America; and some very fine Asparagus from the Duke of NORTHUMBERLAND'S garden at Syon House.

In the afternoon, the *personnel* of the Society was strengthened by the election of 100 new Fellows; and a lecture upon "The Use of Ether and Chloroform in the Forcing of Shrubs," by M. EMILE LEMOINE, was translated and read by the Secretary, the Rev. W. WILKS, M.A. The attendance throughout the day was inconveniently large.

Floral Committee.

Present: W. Marshall, Esq. (Chairman); and Messrs. Chas. T. Druery, H. B. May, Geo. Nicholson, R. Dean, Jno. Green, A. Perry, J. F. McLeod, Jno. Jennings, J. A. Nix, Jas. Hudson, W. Howe, G. Reuthe, C. R. Fielder, Chas. Dixon, C. J. Salter, Chas. Jeffries, H. J. Cutbush, R. M. W. Wallace, C. E. Pearson, Chas. E. Shea, W. P. Thomson, E. H. Jenkins, M. J. James, Chas. Blick, Geo. Paul, Harry Turner, and W. G. Baker.

Messrs. PAUL & SON, The Old Nurseries, Cheshunt, N., exhibited some large plants in 9-inch and 10-inch pots of Erica lusitanica (Codonodes), a tall-growing species, with tiny white flowers, longer than broad; also a few plants of the brightly-coloured Carnation, "America;" and a collection of forced Lilacs, amongst which we noticed the following varieties:—Mme. Abel Chatenay, double white; Countess H. de Choiseul, also double white, the individual flowers of larger size; Marie Lagraye, large single white; alba grandiflora, and Alphonse Lavallée, a double flower of the palest lilac colour, &c. The pretty new Polyantha Rose Lcuchtstern, pink with white centre, was shown in flower.

An unusual feature of these meetings was a large collection of Crocuses in pots, shown by Messrs. W. CUTBUSH & SON, Highgate, London, and Barnet, Herts. There were about 100 7-inch pots, and many of them contained nearly a dozen bulbs, sixteen varieties being represented. The white flowers included Grand Concurrent, Caroline Chisholm, Mont Blanc, and King of the Whites, the last-named variety being the best in habit of growth and effect. One of the very best of the deep purple-coloured varieties is named Baron Von Brunow, but it is resembled by King of the Blues, Albion Blue, purpurea grandiflora, Thackeray, &c. Othello is rather smaller in the flower, but richer in colour; Garibaldi is a pale striped variety, and Albion Striped and La Majestueuse are others of the same type.

Messrs. H. CANNELL & SONS, Swanley, Kent, made a large exhibit of Cyclamens, remarkable for the profuse show of flowers. Varieties were numerous, and included all the colours obtainable. The "Papilio" section was well represented (Silver Flora Medal).

A group of plants of Begonia Gloire de Sceaux, from W. M. CAZALET, Esq., Fairlawn, Tonbridge (gr., Mr. F. Cubberley), were remarkable specimens, some 4 feet high or more, strongly grown, and flowering abundantly (Silver Flora Medal).

Mr. JNO. R. BOX, West Wickham and Croydon, exhibited a group of Chinese Primulas, including florists' varieties, and some of the "pyramidalis" strain.

Lord ALDENHAM, Aldenham House, Elstree (gr., Mr. E. Beckett), made a delightful exhibit of Thyrsacanthus rutilans, showing about thirty plants; these had apparently been cultivated moderately cool, and were of sturdy habit. The inflorescences were numerous, and many of them 2½ feet or more long. It was a fine group, and represented good cultivation. A good group of Cyclamens was also exhibited from the same noted garden (Silver-gilt Flora Medal).

Messrs. R. & G. CUTHBERT, Southgate Nurseries, Middlesex, created the gayest effect by showing a great mass of hardy Rhododendrons (Azaleas), forced into bloom; they formed a bank of bloom on the table running along by the side of the wall, and occupied three-quarters of its length. The sloping bank of white, yellow, bronze, and red colour was relieved by the presence of a few light Palms and Acers, also by the inclusion of a few standard Rhododendrons, 4 ft. high or so, that bore masses of bloom above that formed by the dwarf plants. Many of the varieties were seedlings, but we noticed amongst others the following, all of which were exceedingly effective:—Comte de Quincy, yellow; President Carnot, also yellow, but more nearly approaching the tint of an apricot; Baron Edmond Latherlane, pale red; Comte de Gomer, clear vinous red, distinct and good; Anthony Koster, the unrivalled yellow variety, thoroughly well known; Purity, creamy-white, upper petal shaded yellow; lutea major, resembling Anthony Koster, but deeper in colour, and rather smaller in size; Ebenezer Pycke and Comte de Papadopoli, two of the reddish varieties shown, the latter being the better of them; Anna, pink and bronze colour; Prince Hendrick, very light yellow; R. Koster, Peter Koster, &c; a row of about thirty plants of the new variety Ramona, of the "rustica" section, staged at the last Temple Show, gave the group an attractive margin (Silver-gilt Flora Medal).

Mr. H. B. MAY, Dyson's Road Nursery, Upper Edmonton, exhibited some of the earlier flowering Clematises of the C. lanuginosa type, that flower upon short sprays from the old wood. Some of the varieties were Miss Bateman, pure white, very free; Nellie Moser, the new pink one, having deeper coloured stripes in the flower; Mrs. Crawshay, pale mauve colour, exceedingly large; Lord Wolseley, bluish purple, with reddish-brown bands; Fair Rosamond, white; also several very nice plants of the very free flowering C. indivisa lobata. These Clematises were subjected to very slight warmth about Christmas time, and not "forced" to any extent. The flowering plants appeared above a groundwork of choice Ferns (Silver Banksian Medal).

Messrs. JAS. VEITCH & SONS, Royal Exotic Nurseries, King's Road, Chelsea, exhibited plants in bloom of Daphne Fioniana, also Shortia galacifolia, the curious Chinese Shrub, Loropetalum chinense, with white thread-like flowers, figured in *Gardeners' Chronicle*, Feb. 3, 1883; some handsome seedling Clivias (Imantophyllum), and a group of plants of the hybrid Primula, from P. floribunda × P. verticillata, known as P. × Kewensis (Silver-gilt Banksian Medal).

Mr. ROBERT SYDENHAM, Birmingham, showed plants growing in a preparation known as Moss fibre, which is used in vases and requires no drainage material. The Narcissus and Daffodils shown had developed perfectly, and for ladies or amateurs especially, the fibre may be recommended in place of soil, as it is more cleanly.

Mrs. SOPHIA MILLER, 1, Campden Hill Road, Kensington, exhibited a collection of coloured drawings, some of them being of considerable size. The subjects particularly well presented were Tree-Pæonies, wild Roses, Foxgloves, and other well known garden flowers.

Messrs. HUGH LOW & Co., Bush Hill Park Nurseries, Herts, exhibited an effective group of forced shrubs and other plants. There were Viburnum Opulis (rather green in colour), varieties of Azalea indica and A. mollis, Staphylea colchica, Magnolia conspicua, Souvenir de Louis Späth, and other varieties of Lilac; Acacias cordata and Drummondi, &c. (Silver Banksian Medal).

A few nice plants of Thyrsacanthus rutilans were shown by Mrs. JOHNSTONE, Bignor Park, Pulborough (gr., Mr. E. Wickens), also some strongly-grown plants of Richardia grandiflora, &c.

Mr. GEO. MOUNT, of the Rose Nurseries, Canterbury, staged some very lovely Rose blooms, among which the varieties Mrs. Jno. Laing and Mrs. W. J. Grant were conspicuously good (Silver Banksian Medal).

A very nice double white Chinese Primula, named Southern Star, was shown by Mr. J. WEBSTER, South Street, Chichester.

Mrs. W. H. BURNS, North Mymms Park, Hatfield (gr., Mr. C. R. Fielder), exhibited some fine Violet blooms, which had been forced in the beds over which frames had been placed. There were La France, Luxonne, and De Parma (double).

Her Grace ADELINE DUCHESS OF BEDFORD, Woodside, exhibited a collection of fine Helleborus flowers in variety (Bronze Flora Medal).

Mr. G. REUTHE, Hardy Plant Nursery, Keston, Kent, exhibited a collection of hardy plants, including I. Tauri, and others of this section; also the new Saxifraga Grisebachi, &c. (Silver Banksian Medal).

Messrs. GEO. JACKMAN & SONS, Woking, exhibited Anemone pulsatilla alba, Iris sindjarensis, I. lumosa, and Erodium Pelargonifolium, a species from the Taurus Mountains, 3,000 feet above sea level, bearing extraordinary superficial resemblance to a Pelargonium. A number of other plants were included in the collection (Silver Banksian Medal).

Messrs. B. S. WILLIAMS & SON, Victoria and Paradise Nurseries, Upper Holloway, N., exhibited numerous flowers of forced Tulips, representing the choicest varieties for this purpose. Also a few Narcissus and Lachenalias.

Messrs. WALLACE & Co., Kilnfield Gardens, Colchester, had a collection of hardy plants in flower, such as Hepaticas, Anemone blanda, Iris histrioides, and the variety known as Major, &c. (Silver Banksian Medal).

Mr. THOS. S. WARE (1902), Ltd., Feltham, Middlesex, exhibited a group of forced Daffodils, and a number of hardy plants in flower, including species of Saxifraga, Cyclamen, Primula, and Iris, and a fine plant of Primula denticulata alba, under the name grandiflora (Silver Banksian Medal).

From Mr. K. DROST, Kew Nursery, Richmond, Surrey, came a small group of Azalea mollis in variety, and some bushes of well flowered white Lilac, furnished with foliage. The group had an edging of Funkia ovata variegata, very suitable for its contrast with the bright tints of the Azaleas (Bronze Flora Medal).

The usual group of flowers in season was shown by Messrs. BARR & SONS, King Street, Covent Garden. We remarked among other subjects plants of Chionodoxa sardensis, deep blue, and very pretty; a panful of Iris reticulata, Narcissus Harbinger, the bloom having a yellow corona, and a paler perianth; it is small and early. Helleborus in variety, Anemone-Rose de Nice, a number of Saxifrages bedded out; Primula obconica kermesina, of a nice bright tint; Hepaticas, Cyclamens, a large-flowered variety of Saxifraga Burseriana, Gerbera Jamesoni from seed, Chionodoxa gigantea, said to be a seedling form, flowers of a light blue tint, passing into white at the centre.

Mr. JOHN ODELL, florist and market-gardener, Colham Green, Hillingdon, showed Primula sinensis Duchess of Fife, of a pale pink tint, having a good truss and pips, and compactly growing foliage; besides these was an excellent exhibit of Cyclamens in all shades of colour, dwarf, well grown and flowered Silver-gilt Banksian Medal).

Mr. JOHN RUSSELL, Richmond Nurseries, Richmond, Surrey, showed largely in a group placed on the floor near the end entrance to the Hall, forced plants of Spiræa confusa, Wistaria sinensis, Cerasus Watereri, Prunus sinensis, &c.; a bright line of colour being contributed by Azalea mollis in variety. There were plants of Staphylea colchica very well flowered, Lilac Souvenir de Louis Späth, and L. Marie Lagraye, very dwarf and floriferous (Silver Flora Medal).

We remarked some samples of the "Charteras" Seedling Protector. This simple invention consists of two arched pieces of wire, crossing one another transversely, which are fastened together at the top. At intervals along these hoops holes are punched, through which black thread is run. This forms a cage which can be readily placed over the plant or seeds it is desired to protect, the legs being pushed a few inches into the soil. Birds attacking the plants do not notice the black thread, touch it unknowingly, and are at once startled away.

AWARD OF MERIT.

Iris persica variety.—Miss WILLMOTT, Warley Place, Great Warley, Essex, exhibited a variety of I. persica, obtained from a cross between this species and the variety purpurea. The flowers were 2½ inches high, purple, with darker purple blotch on lip; throat white, with a yellow line through it (Award of Merit).

Orchid Committee.

Present: Harry J. Veitch, Esq. (in the chair); and Messrs. Jas. O'Brien (hon. sec.), de B. Crawshay, R. B. White, F. A. Rehder, F. Wellesley, J. Douglas, E. Hill, F. W. Ashton, A. A. McBean, H. J. Chapman, J. W. Potter, M. Gleeson, J. W. Odell, W. H. White, W. H. Young, J. Charlesworth, H. Little, H. A. Tracey, W. Boxall, and J. Gurney Fowler.

There was a very large display of Orchids, Dendrobiums predominating, some fourteen groups being staged, and about fifty entries were placed before the

Committee. The exhibits were so numerous, that only the more notable subjects can be enumerated.

H. T. PITT, Esq., Rosslyn, Stamford Hill (gr., Mr. Thurgood), had the largest group, and received a Silver-gilt Flora Medal. In his group a large specimen of the fine Cattleya Trianæ "Our King" was an effective object. Of the Dendrobiums, D. nobile, Pitt's variety, was likewise noteworthy, as well as D. n. Ballianum, D. n. nobilius, and other forms. Among the hybrids, Dendrobium × pallens, D. × Apollo grandiflorum, D. × Owenianum, and other hybrids, were noted; and there was a fine selection of Odontoglossums, Cypripediums, Epidendrum × Endresio-Wallisii varieties, &c.

Messrs. J. CYPHER & SONS, Cheltenham, were awarded a Silver-gilt Flora Medal for an extensive group of very well grown and profusely flowered Dendrobiums, the forms of D. nobile and the crosses of it in almost bewildering numbers. A few of the finer ones were D. × Apollo grandiflorum, and D. × A. album; D. × Virgil, D. × Rubens grandiflorum, D. × Schneiderianum, D. × Ellerianum, D. nobile rotundiflorum, and about a dozen other distinct forms; Cypripediums, Sophronitis, Masdevallias, &c.

Captain G. L. HOLFORD, Westonbirt, Tetbury, exhibited some rare species, in which the very beautiful Odontoglossum × Adrianæ "Lady Evelyn Grey," a large, white flower, in shape very near to O. crispum, and evenly spotted with purple, was one of the finest; Lælio-Cattleya × Warnhamensis, Westonbirt variety, with orange-yellow coloured flowers and ruby lip, was a great improvement; Dendrobium × Wiganianum xanthocheilum, a grand plant of D. primulinum, with about one hundred flowers; Cattleya × Enid, and Cypripedium × Captain Holford were observed (Silver Banksian Medal).

Sir TREVOR LAWRENCE, Bart., Burford (gr., Mr. W. H. White), showed a pretty group of Burford hybrid Dendrobiums, including varieties of D. × melanodiscus, Rainbow, Juno, Dido, &c.; a good Cattleya Trianæ Backhousiana, two plants of Spiranthes colorata maculata, &c., were noted (Silver Banksian Medal).

NORMAN C. COOKSON, Esq., Oakwood, Wylam-on-Tyne (gr., Mr. H. J. Chapman), secured a Silver Banksian Medal for a small but select group, in the centre of which was a very remarkable specimen of Phaius tuberculosus (simulans) in robust health, and furnished with five robust flower-spikes (Cultural Commendation); Cypripedium × Helen, Oakwood variety, with yellowish flowers spotted with purple; a pretty white Dendrobium nobile, having a pale lavender-rose coloured disc; two remarkable Dendrobiums obtained by crossing D. nobile burfordiense and D. n. Cooksoni the one being handsomely striped with purple, resembling an improvement on D. n. jaspideum (Lindenia), and the other having elongated lower sepals marked like the lip; Phaius × Clive (see Awards), and P. × Norman, and a fine specimen of the best large-flowered Odontoglossum crispum with a strong spike, bearing thirteen magnificent flowers, all of which were equally well developed.

R. G. THWAITES, Esq., Streatham (gr., Mr. J. M. Black), was awarded a Silver Flora Medal for a fine group containing a very large number of Dendrobiums. The number of varieties in this group was remarkable, and even the smallest plants were finely flowered. In addition to the best forms of D. nobile, D. × splendidissimum, and their crosses, there were some pretty varieties that one rarely meets with, such as D. × Isis (moniliforme × hercoglossum), good flowers of D. × Venus, &c. There were noted besides these, good examples of D. nobile album, Sophronitis, &c.

Messrs. JAS. VEITCH & SONS, Chelsea, showed a select group of principally crosses, including the handsome Cypripedium × Euryades var. guttatum, the new deep scarlet-coloured Epidendrum × Delphi (pristes, Rchb. f. × O'Brienianum), varieties of C. × Leonidas, Lælio-Cattleya × Pallas, Lælia × Mrs. Gratrix, &c. (Silver Banksian Medal).

FRANK A. REHDER, Esq., Gipsy Hill (gr., Mr. Norris), was awarded a Silver Banksian Medal for a very good selection of Dendrobiums and other Orchids. Among the forms of D. nobile, two good specimens of the best variety of D. nobile album were noted; also D. × pallens, D. × Magda, &c.

Messrs. SANDER & SONS, St. Albans, secured a Silver Flora Medal for a good group. Among the Cypripediums C. × Beechense was Sander's variety, a large flower of great merit, having beautiful markings; C. × Annie Measures, and C. villosum "Golden King," were good, and the varieties of Phaius, Dendrobiums, &c., were effective.

Messrs. J. & A. A. MCBEAN, of Cooksbridge, secured a Silver Flora Medal for a group consisting chiefly of Odontoglossums. The best was the spotted O. crispum "Grace Ruby" (see Awards), although other specially good forms were observed, and notably a large and richly coloured variety of O. × Ruckerianum; likewise some bright Epi-phronitis × Veitchi, Sophronitis grandiflora, Cymbidium eburneum, Dendrobiums, &c.

Messrs. CHARLESWORTH & CO., Heaton, Bradford, were awarded a Silver Banksian Medal for a select group, in the centre of which was a magnificent, broad-petalled, heavily blotched Odontoglossum crispum; besides O. luteo-purpureum Vuylstekeanum, Lælio-Cattleya × luminosa, L.-C. × Digbyano-Mendeli, the finely coloured Cattleya Trianæ Beyrodtii, Odontoglossum × Rolfeæ, Cypripedium × Leysenianum, C. × Laurebel, Cœlogyne sparsa, &c.

Mrs. HAYWOOD, Woodhatch Lodge, Reigate (gr., Mr. C. J. Salter), staged a group of finely-flowered crosses of Dendrobium, three of which secured Awards (see Awards).

DE B. CRAWSHAY, Esq., showed a small group with two varieties of white Lælia anceps Hollidayana, the large-flowered Odontoglossum Rossii "Lionel Crawshay," and the very beautiful Odontoglossum crispum aureum Rosefieldiense, which had previously secured a First-class Certificate (Silver Banksian Medal).

Messrs. HUGH LOW & Co. showed a good group, in which were fine forms of Cattleya Trianæ, C. T. Mrs. T. Miller Crook, being a beautiful lavender-tinted flower, with delicate rosy-lilac lip. The Dendrobiums included D. Jamesianum, D. crassinode, D. Boxalli, D. Wardianum, D. aureum, D. aggregatum, &c.; and Lycaste × Cappei, and other showy things were staged (Silver Banksian Medal).

FRANCIS WELLESLEY, Esq., Westfield, Woking (gr., Mr. Gilbert), showed Cypripedium × Angelus superbus, C. insigne Gilberti, Lælio-Cattleya × Charlesworthi "Westfield variety," and L.-C. × Gottoiana "Mrs. Douglas."

J. BRADSHAW, Esq., Southgate (gr., Mr. Whitelegge), showed Cattleya Trianæ Fairy Queen, C. T. cœrulea, Lælio-Cattleya Hon. Mrs. Astor var. Yellow Prince, and Lycaste Skinneri Beauty.

HENRY LITTLE, Esq., Baronshalt, Twickenham (gr., Mr. Howard), showed Lælio-Cattleya × Captain Percy Scott, pretty and fragrant.

Messrs. STANLEY, ASHTON & Co., Southgate, sent Odontoglossum × Wilckeanum Southgatense, and a very dark form of O. × loochristyense.

Messrs. D DOWELL & SON, horticultural sundriesmen, Ravenscourt Avenue, Hammersmith, showed a good selection of pots suitable for Orchids, from the tiny first seedling pot upwards; also potting material, &c.

Awards.

FIRST CLASS CERTIFICATE.

Zygopetalum crinitum cæruleum, from Messrs. CHARLESWORTH & Co., Heaton, Bradford.—One of the handsomest Zygopetalums of its class, either imported or hybrid, and infinitely superior to the original form, which bore that name. Sepals and petals emerald-green, barred with brown. Lip large, broad, and flat; pure white, with fringed lines of a bright violet colour.

Odontoglossum crispum Grace Ruby, from Messrs. J. and A. A. MCBEAN, Cooksbridge.—Flowers large, and of the best form, white, evenly spotted with purple spots; petals fringed.

AWARDS OF MERIT.

Dendrobium × *Ophir* (signatum × aureum), from Capt. G. L. HOLFORD (gr., Mr. Alexander).—Flowers formed like those of a large D. aureum; cowslip yellow. A very distinct hybrid.

Dendrobium × *melanodiscus Sunray* (Findlayanum × Ainsworthi, Woodhatch var.), from Mrs. HAYWOOD (gr., Mr. C. J. Salter).—Sepals and petals white, tipped with rose. Disc of lip maroon, with yellow band.

Dendrobium × *Salteri* (splendidissum grandiflorum × Findlayanum), from Mrs. HAYWOOD (gr., Mr. C. J. Salter).—A very pretty hybrid, with flowers bearing some resemblance to D. × Sibyl, and of the same bright rose tint, with white bases to the segments. Disc of the lip orange, with claret base.

Dendrobium × *splendidissimum*, *var.* "*Mrs. Haywood*," from Mrs. HAYWOOD.—A very large flower, heavily marked with purplish-lilac, and with a maroon-purple disc to the lip.

Phaius × *Clive* (Norman × tuberculosus), from NORMAN C. COOKSON, Esq. (gr., Mr. H. J. Chapman).—This is a fine P. × Norman, with the expanded lip of P. tuberculosus. Sepals and petals light yellow, with a slight rose tint on the surface; base of the lip broad, and heavily blotched with chocolate-purple; front whitish, blotched with a deep rose tint, and crest yellow.

Dendrobium × *Wiganianum album* (nobile album × Hildebrandi), from R. G. THWAITES, Esq., Streatham (gr., Mr. J. M. Black).—A clear white hybrid, most nearly approaching D. Hildebrandi in shape.

Fruit and Vegetable Committee.

Present: Geo. Bunyard, Esq., Chairman; and Messrs. Jos. Cheal, H. Balderson, W. Bates, S. Mortimer, Alex. Dean, E. Beckett, H. J. Wright, G. Kelf, J. Jaques, H. Somers Rivers, R. Parker, G. Reynolds, F. Q. Lane, G. Wythes, W. Poupart, Jas. Gibson, and O. Thomas.

Mr. GEO. WYTHES, exhibited from the Duke of Northumberland's garden, Syon House, Brentford, a bundle of forced Asparagus from an open bed, the forcing material used having been tree leaves. The growths were exceedingly sturdy and big, and were awarded a Cultural Commendation.

Miss C. E. MARTIN, Willow Brook, Auburn, New York, U.S.A., showed a considerable quantity of preserved fruits in patent stoppered bottles. Some of them were preserved in syrup containing a small quantity of spirit, as the "Brandy Peaches," &c. Others were similar to the French fruits preserved in syrup, and further samples were jam made from Strawberries, Blackberries, Tomatos, &c. Generally, the preserves were considered too sweet for the English taste (Vote of Thanks).

Mr. W. TAYLER, Osborne Nursery, Hampton, Middlesex, showed a small collection of excellent Apples in a first-class state of preservation. Among them Lane's Prince Albert, Annie Elizabeth, a superior sample, Bismarck, Gascoigne's Scarlet, Ribston Pippin, Cox's Pomona, Dutch Mignonne, Newton Wonder, Northern Spy, Pine Golden Pippin; and of Pears, Chaumontel, Catillac and Uvedale's St. Germain (Silver Banksian Medal).

The Lecture.

THE USE OF ETHER AND CHLOROFORM IN THE FORCING OF SHRUBS.

At the afternoon meeting, a considerable audience had the pleasure of hearing a paper on the use of "Ether and Chloroform in the Forcing of Shrubs," written by M. Emile Lemoine, and translated from the French by the Rev. W. Wilks, M.A., Secretary, who also read the paper. M. Lemoine commenced by referring to the original experiment that Claude Bernard made with ether and chloroform in order to prove that the protoplasm of vegetables is essentially the same as that in animals. Both are affected similarly by anæsthetics. The sensitive plant when subjected to the fumes of ether, became insensible, and would no longer droop, when touched, as it did before, but, when removed from the influence of the anæsthetic, the shoots and leaves slowly regained their normal sensitiveness.

In 1890, Dr. Johannsen, professor of vegetable physiology at Copenhagen, commenced experiments with a view to ascertaining the effect of ether in respect to forcing the plants into flower; and on November 17, 1893, Dr. Johannsen showed for the first time, before the Academy of Sciences, at Copenhagen, a Lilac that had been forced by means of etherisation. The Professor had noticed that if a tree lost its leaves in summer, the buds upon that tree would occasionally, open in the autumn, although similar buds upon trees that retained their leaves were ripening and going to rest. This led to the statement of a theory in which the repose or resting period in trees was divided into three stages:—(1) the initial stage, when the development that has been going on is diminishing; (2) complete rest, when the development has ceased; (3) final period, during which development is in process of recommencing—the rest now being made compulsory by the conditions of air and temperature to which the plant is exposed. In the case of the Lilac, the first stage occurs naturally in August and September, complete rest is reached at the end of October, and the final stage commences at the end of December. It was only after the final stage of rest had commenced that shrubs could be forced into flower satisfactorily. Dr. Johannsen found that these processes could be forwarded materially by the use of ether, which has a similar result upon the plants to that which follows if the leaves are removed early, as remarked above, namely, the development of abnormal and precocious growth. By etherisation, the third stage may be reached by the beginning of October, or three months earlier than under normal conditions.

Proceeding to describe the process of etherisation, the lecturer said the plants should be put into a box that can be hermetically sealed, in dry sand, and the interior of

the box, as well as the plants themselves, should be dry, so that they will not absorb the ether. The temperature of the air in the box should be 62° to 66° Fahr., but the higher the temperature, the less quantity of ether is required. Under the lid of the box there should be a small bottle, into which the ether may be poured through the lid. It is important that the ether should be applied from the top, because being heavier than the atmosphere, it falls to the bottom by gravitation. The operation should be done during the daytime, and no light, or even a cigar, must be permitted to be brought near to the box, because ether fumes are exceedingly inflammable, and when mixed with air become dangerously explosive. The quantity of ether required is approximately about 300 grammes weight for every 100 cubic mètres of air, and the plants may be subjected to the treatment for a period of 48 hours. It may be advantageous to repeat the process with the same plants after a few days. Pure sulphuric ether was used, which boils at 95° Fahr. The plants are removed to a cool house, and the forcing process afterwards is simple. Plants of Lilac Charles X., etherised early in August by Dr. Johannsen, were in full flower in the middle of September.

M. Lemoine proceeded to say that the German florists subsequently took an interest in the subject, and one of them from Hamburg went to Copenhagen, and studied Dr. Johannsen's experiments there. It had been admitted by these florists that the great firms would be obliged to use ether for early forcing, especially so as the economy of fuel in forcing etherised plants covers the cost of etherisation itself, and also because Lilacs may be forced into bloom in eighteen days after removal to a warm atmosphere. One of the principal firms in Hamburg had proved (1) That etherised Lilacs force most rapidly; (2) Some varieties that are known to be difficult of forcing may be forced after etherisation as successfully as the variety Charles X.; (3) That some Lilacs not specially prepared for forcing had been lifted from the open, etherised, and subsequently forced with capital results.

M. Lemoine described experiments that had been made in France last year with chloroform as well as ether; and although it is probable that chloroform may be used in some cases in place of ether, the results were not altogether satisfactory or conclusive. They, however, appeared to show that the amount of chloroform which was used was excessive, and that its influence is of much greater degree than that of ether, probably to the extent of three parts in four.

Reference was next made to the results obtained by Mr. Jannech, a nurseryman at Dersingham, Norfolk whose experiences have been "quite beyond anticipations." It is obvious that the importance of the vapour of ether in relation to the forcing of shrubs is only applicable to very early forcing, that is, at a season previous to Christmas, for after the commencement of January, when the plants have reached the third stage of rest described by Dr. Johannsen, forcing by ordinary means may be done successfully. M. Lemoine, after again urging the importance of making the ether chamber air-tight, and of doing the operation during daylight, in the absence of any artificial light whatever, proceeded to discuss the probable reasons for the effect upon plants, that it is now known ether is capable of exercising. It was certain that the vital powers of the plants became latent under its influence, and repose or rest became deeper. It is also known by the cultivator that the deeper the rest to which a plant is driven, the more quickly may the vital powers be brought again into life, under proper conditions.

It had been said that ether acted as an anæsthetic and abolished sensation; also that it acted in a similar manner to frost. It seemed pretty certain that ether, like frost, was capable of expelling water from the tissues of plants, and it might be asked if the effect of ether or chloroform upon a plant was due to their drying power? Such an effect would be similar to that which follows extreme cold or great drought, and everyone knows that an alpine plant hidden away by a covering of snow, springs into growth, and flowers in an amazingly short space of time after exposure to the sunlight. If the ether acted as a stimulant in removing the water from the plants, then it was just possible that the same results might be obtained from the use of less dangerous materials, as chloride of potassium, or quicklime.

[In connection with the above notes of M. Lemoine's lecture, we may direct the attention of our readers to an article in the *Gardeners' Chronicle* on March 1, 1902, in which the results of experiments conducted by M. Franz Ledien, of the Dresden Botanic Garden, are fully described, and where practical information is given to cultivators who desire to etherise Viburnums, Azaleas, Deutzias, Lilies of the Valley, Hyacinths, Prunus, &c. See also *Gardeners' Chronicle*, November 22, 1902, p. 379, where reference is made to Lilacs that were etherised and forced in the nursery of Mr. Harms, of Hamburg, and where we appealed to our own market-gardeners to adopt, or at least try, this system. Also *Gardeners' Chronicle*, December 20, 1902, where attention is drawn to a pamphlet upon the subject by Mr. Albert Maumene (Paris: Rue de Grenelle, 84 bis); and *Gardeners' Chronicle*, December 27, 1902, p. 475, where the satisfactory experiences of an American florist may afford useful hints in the actual work of etherisation. ED.]

DEVON AND EXETER GARDENERS' ASSOCIATION.

FEBRUARY 4.—The paper read at the meeting of this Association on the foregoing date was by Mr. R. Hodder, gr. at Ponsonby, Torquay, the subject being entitled "A Stroll in the Garden."

In a pleasant, gossipy style, the lecturer imparted much interesting information, bearing on the literary as well as the practical side of English gardening. He strongly advocated every house in the country, however small, having its little garden, for the average Englishman loves a garden. *A. H.*

BRISTOL AND DISTRICT MUTUAL IMPROVEMENT ASSOCIATION.

THE fortnightly meeting of this association was held at St. John's Rooms, Redland, on Thursday evening, Mr. E. Binfield, Old Sneyd Park, occupying the chair. The subject of the discourse for the evening was "Melons and Cucumbers," introduced by Mr. Collier of the Cardiff Gardeners' Association. The lecturer detailed the best methods for cultivation, including time for sowing the seed, training, stopping, tying, and general treatment. He also described the insect pests and diseases to which the plants are liable, and the means for their eradication and prevention. Soils and composts also received his attention, and were fully explained. A good discussion followed Mr. Collier's lecture. *H. K.*

SHROPSHIRE HORTICULTURAL

FEBRUARY 11.—The annual meeting in connection with the Shropshire Horticultural Society, was held at Shrewsbury, on the above date. The Mayor of Shrewsbury (Mr. H. H. Southam) presided, and among those also present were:—Mr. E. C. Peele (chairman of Committee), Major-General the Hon. W. H. Herbert, the Rev. W. Leeke, Colonel Robinson, Messrs. Adnitt & Naunton (joint Hon. Secs.), Mr. James Vine (Treasurer).

The report of the Committee stated that the show last year was favoured with splendid weather on the two days in August, and the result was a record attendance of visitors, as evidenced by the fact that the total receipts from all sources amounted to the large sum of £5,001 15s. 5d., being £254 19s. 4d. in excess of the previous year, which up to that date was the Society's largest income, viz., £4,746 16s. 1d. It has long been the ambition of the Committee that the Society's total returns should reach £5,000, and therefore it is with a degree of pride that the success attending the twenty-eighth show has placed them in a position to announce that such a sum has at last been realised.

Mr. Vine presented the statement of accounts, which showed that the profit on the summer show was £873 18s., while the total profit for the year amounted to upwards of £1,000, compared with £827 10s. 3d. the previous year. During the past year the Society voted from their funds several large sums, including £300 for the laying-out of the Abbey Public Gardens. They also expended £184 8s. 7d. in the improvement of the river banks in the vicinity of the Quarry, making the total which the Society have expended for this one purpose £1,500. Since 1878 the Society have voted to various deserving objects no less than £6,953.

On the proposition of Mr. E. C. Peele, seconded by Mr. Salt, Lord Forester was elected President of the Society for the ensuing year.

Mr. W. Thorn (superintendent of the Joint Railway Companies) said it would probably interest those present to learn that, apart from ordinary trains, on the occasion of the last show there were between fifty and sixty specials, comprising 869 coaches, no fewer than five miles of rails being required to stable these coaches during the day. He would like to disabuse their minds of the idea that when the new station was completed the difficulties of the railway companies would be at an end. So far-reaching was the popularity of the Shrewsbury floral fête, that the Honorary Secretaries were always anxious to increase the number of excursions and tap new ground; and last year between 3,000 and 4,000 people were brought from a new district.

REDHILL, REIGATE, & DISTRICT GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.

FEBRUARY 17.—This Society held its fortnightly meeting at Mutton's Hotel on the above date, Mr. BOUND being in the chair. Ten new members were elected. The chairman introduced Mr. Duncan, of South Park, Reigate, who gave a lecture on "Insect Pests of the Garden." The lecture was well illustrated with lantern slides.

WYLAM AND DISTRICT MUTUAL IMPROVEMENT.

FEBRUARY 19.—The fortnightly meeting of the above Society was held in the Institute, Wylam, on the above date, presided over by Mr. H. J. Chapman (the Chairman). A paper was read by Mr. Paxton, of Prudhoe Hall Gardens, in which the various methods of propagation, cultivation of Dahlias, both for show and cut flower purposes, and of storing and preserving the tubers were discussed.

At the next meeting, March 5, Mr. N. C. Cookson, of Oakwood, has promised to exhibit his Orchid paintings, and Mr. Chapman will give a lantern-illustrated lecture on Cypripediums.

GLOUCESTERSHIRE ROSE.

THE annual meeting of this Society was held in Gloucester last week. The Treasurer had to report a deficit on the year's working of £9 12s. 6d; while the members had to deplore the resignation of the Hon. Secretaries, the Rev. Thomas Holbrow (who has removed from the neighbourhood to Corbridge-on-Tyne), and Mr. T. A. Washbourn; but the services of both these gentlemen, who have done so much for the Society, will be retained on the Committee. Owing to the unpropitious weather experienced on the show days for the past few years, a suggestion was made that the exhibition should be held in one of the large assembly halls in the city; but that the next exhibition be held in the Spa Cricket Field as usual. The resolution was carried.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

FEBRUARY 19.—There was a capital display of plants on the above date, the room being well filled.

Messrs. J. CYPHER & SONS had a group of plants to which a Silver Medal was awarded, that consisted chiefly of fine varieties of Dendrobiums, the best being D. × Apollo var. magnifica, a flower of good size and substance (Award of Merit); D. nobile var. rotundiflora, a good form (also received an Award of Merit); Cattleya Trianæ var. "Arle Court" was also submitted to the committee. Dendrobium × Cybele var. nobilior, and D. × Ellerianum, a natural hybrid, with a large proportion of D. heterocarpum in its composition, were also noticeable, as were also some plants of Odontoglossum Roezlii.

W. THOMPSON, Esq., Stone (gr., Mr. Stevens), staged a small group, consisting principally of Odontoglossums; and a nice form of Odontoglossum × Harryano-crispum var. roscum was given an Award of Merit. There was a very good specimen of O. Pescatorei, with eight flower-spikes, and a probable aggregate of about four hundred flowers. A large and well spotted form of O. Pescatorei, O. × aspersum, O. × Wilckeanum, and O. × Adrianæ var. Starlight, were also found in this group, which was awarded a Bronze Medal.

Messrs. A. J. KEELING & SONS, Westgate Hill, near Bradford, exhibited Cypripedium × M. de Curte Keeling's var.

STANLEY, ASHTON & Co., Southgate, displayed a choice collection of cut flowers, all Odontoglossums (the rules of the Society forbid the exhibition of cut flowers except when severe weather prevails). A Vote of Thanks was awarded. In the collection O. × Wilckeanum var. Southgatense stood out prominently from the others.

E. O. SCHNEIDER, Esq., Whalley Range (gr., Mr. Hunt), staged a few well-grown Dendrobiums, a fine piece of D. nobile receiving a Cultural Certificate; and there was shown a well-flowered plant of D. × Schneiderianum.

S. GRATRIX, Esq., Whalley Range (gr., Mr. Cypher), exhibited Lælio Cattleya × Jeanette, a cross between L.-C. × Gettoiana × Cattleya labiata var. Jeanette. This plant produces an intensely dark crimson-purple bloom, the labellum being of a deeper tint. An unanimous First-class Certificate was voted to this plant. From the same collection Odontoglossum crispum var. "Gipsy Queen" received an Award of Merit. The flowers are very chaste and well formed, with a large dark blotch on each sepal.

R. LE DOUX, Esq., West Derby (gr., Mr. Davenport), received an Award of Merit for Masdevallia × Rustoni, a cross between M. ignea × M. racemosa var. Crossii.

JOHN COWAN & CO., LTD., Gateacre, received a Bronze Medal for a group of plants, amongst which were some pretty crosses of Odontoglossum, and a distinct form of Dendrobium Wardianum, called aureum, the flower distinct, and possessed segments of a bronze tint. The committee desired to see it at a later stage of its flowering.

J. LEEMANN, Esq., Heaton Mersey (gr., Mr. Edge)' sent four very choice Odontoglossums. The four were of such excellence that possibly full justice was not done to all of them. O. crispum var. "Marie" was voted a First class Certificate; it is a fine, round flower, and very evenly marked with small spots. O. crispum var. Mrs. Peeters, considered by some who saw it to be the best of the quartet, was voted an Award of Merit; this flower is of the bluish lilac type, and the colour which suffuses the entire flower is rather more prominent at the back than at the front; the petals reflex towards the points, and possibly this fact detracted somewhat from the character of the flower. If the Committee erred in this case, it was on the ungenerous side. O. crispum var. Francoise, another good spotted form, received an Award of Merit. O. crispum var. Ella was also shown. A Silver Medal was voted for the collection.

W. DUCKWORTH, Esq., Flixton (gr., Mr. Tindall), staged a bright-looking group of Dendrobiums, consisting of about thirty distinct forms of hybrids and species. A Silver Medal was awarded.

Mr. A. A. PEETERS, Brussels, exhibited a few good crosses of Cypripediums, two forms of C. × aureum being worthy of note. A Bronze Medal was awarded.

Mr. J. ROBSON, Altrincham, received a Silver Medal for a group of plants; some good Odontoglossums and Cattleya Trianæ being prominent therein. Awards of Merit were voted to Odontoglossum crispum var. compactum and Cypripedium × Euryades, Robson's var.

Messrs. SANDER & SONS, St. Albans, staged a choice group of Orchids, for which a Silver Medal was awarded. Several fine plants in different varieties of Phaius × Marthæ, were worthy of note; P. × M. var. aurea, P. M. var. superba, P. × Normani var. striata, and P. Normani var. nigrum, were all plants worthy of a place in any good collection; Odontoglossum × Wilckeanum var. Fascinator, was a fine form.

Mr. S. ALLEN, Sale, staged a collection of Dendrobium Wardianum, Cœlogyne cristata, Cypripedium villosum, &c., and was voted a Bronze Medal. *P. W.*

CHESTER PAXTON.

FEBRUARY 21.—A meeting was held in the Grosvenor Museum on the above date, Mr. Wynn in the Chair, when Mr. J. Taylor, of Colwyn Bay, gave a lecture on "The Out-door Culture of the Vine." In the course of his remarks, Mr. Taylor said there were many localities in Cheshire and North Wales where Vines could be profitably cultivated out-of-doors, provided they were planted on a south or south-west aspect, on good loamy land with a dry subsoil, and proper cultural attention afforded them. Apart from the utilitarian aspect of Vine culture out-of-doors, Mr. Taylor said it was of a much more ornamental character than many plants at present seen on garden and cottage walls, and he advised his hearers very strongly to give it a trial, if only on a small scale. An interesting discussion followed.

GLOUCESTERSHIRE ROOT, FRUIT, AND CHRYSANTHEMUM.

THE annual meeting of this Society was held in Gloucester on Saturday, when a favourable report was submitted to the members. Mr. W. Priday was re-elected chairman, as he has been for very many years in succession.

The balance in hand (£4) 3*s.* 6*d*) is the largest in the Society's records. The Secretary, Mr. Sydney S. Starr, was re-elected, and announced that as the result of negotiations, Messrs. Webb & Sons, and Messrs. Sutton & Sons were again offering all their old prizes, free from the restrictions which prevented their acceptance last year. These prizes represented something like £35.

The Society are offering in the Chrysanthemum and other classes some £10 more in prizes, and a number of additional Awards are offered this year by local firms and private persons. November 9 was fixed for holding this year's exhibition.

ANSWERS TO CORRESPONDENTS.

BLISTER ON PEACH-LEAVES: *W. B. S.* We do not know of any means by which this disease of the Peach can with certainty be prevented from attacking the foliage. De Bary (see the *Gardeners' Chronicle* for July 31, 1875) in an article on this minute fungus, Ascomyces deformans, by W. G. Smith, is quoted as describing and figuring it "as living in an early stage inside the leaf among the cells, and at length only emerging to perfect itself on the exterior." This seemed to Mr. W. G. Smith only reasonable. Probably sulphide of potassium (liver-of-sulphur) applied at the rate of ½-oz. in one gallon of water as soon as the leaves unfold, would destroy the spores that have alighted on them, and another application after the fungus manifests itself on the leaves would destroy it. But the only apparently efficient means of overcoming the pest is to remove every affected leaf, and forthwith destroy by fire.

BOOKS: *F. Hansen.* A manual on *Peaches and Nectarines Indoors and Under Glass*, by the late D. T. Fish, price 1*s.*, is published by Mr. Upcott Gill, 170, Strand, London, W.C.

CATTLEYA-LEAF DAMAGED: *E. D.* It is not a fungus which has caused the damage to the leaf. You state that the leaf was from an imported plant, and it is most likely that the cellular tissues got damaged in transit, or became so dried up that only part of them could be re-established when the plant was started into growth; the consequence was, that the surface of the leaf decayed in patches, which became confluent where the damage was greatest. Sometimes leaves will go in that way when the plants are so placed that the direct heat from the hot-water pipe gets to them; in such cases it is the tissues which decay, and the damage is not begun either by fungus or insects.

COAL-ASHES IN POTTING SOIL, &c.: *Pinkie.* A small quantity would render the stiff loam porous, and the better able to part with its moisture and admit the air. Sift it in a ¼-inch meshed sieve before mixing it with the soil. We cannot tell you by what insect the eggs sent were deposited.

CORRECTION: *Cypripedium* × *Angus.* This showy hybrid, mentioned in the *Gardeners' Chronicle*, Feb. 14, p. 100, was printed C. × Argus, in error.

CUCUMBER DISEASE: *Constant Reader.* The material sent is not sufficient.

HYBRIDISING AND CROSSING ORCHIDS: *H. W. J.* We know of no work dealing exclusively with this subject. F. W. Burbidge, in his book, *The Propagation and Improvement of Cultivated Plants* (W. Blackwood & Sons, Edinburgh and London, 1876), gives a good deal of useful information about the matter.

NAMES OF FRUITS. We have had the misfortune to get the Apples from our three correspondents, *J. C.*, *J. S. Upex*, and *A. B.*, mixed. Doubtless they will readily recognize them by description given. The large Apple with orange cheek is Harvey's Wiltshire Defiance. The green specimen is Duke of Devonshire. The small yellowish-brown russety Apple is Ashmead's Kernel.—*C. W. Strickland.* 1, Newtown Pippin; 2, Bedfordshire Foundling.

NAMES OF PLANTS: *Correspondents not answered in this issue are requested to be so good as to consult the following number.*—*R. C., Stanmore.* R. Nobleanum.—*E. D.* Odontoglossum maculatum. The bulbs and leaves are longer and more upright than those of Odontoglossum Rossii, and of a lighter green. You could easily separate the species by those tests.—*A. Urquhart.* Rhododendron dauricum. —*M. P. E.* 1, Abies Lowiana; 2, Pittosporum tenuifolium; 3, Abies amabilis; 4, Buxus balearica; 5, Thuya occidentalis; 6, Cupressus, we cannot tell without the cones.—*Constant Reader, Bath.* 1, Pulmonaria officinalis, white form; 2, Equisetum hyemale; 3, Atriplex Halimus.—*W. C., Kylemore.* 1, Pinus; 2, Pinus; 3, Picea polita, Japan; 4, Retinospora plumosa of gardens; 5, Cupressus; 6, Picea ajanensis; 1, 2, and 5, we will compare with our specimens, and let you know next week if possible.—*F. B.* 1, Onychium japonicum; 2, Davallia canariensis; 3, Adiantum Waltoni.—*H. B. P.* An old Camellia of the Colvillei section.—*Orchids, Surrey.* 1, 2, and 3, varieties of Cattleya Trianæ; 3, is very fine in colour; 4, Dendrobium Wardianum; 5, Dendrobium primulinum; 6, Cœlogyne flaccida.—*D. V.* 1, Odontoglossum Pescatorei; 2, Odontoglossum blandum; 3, Odontoglossum nævium; 4, O. tripudians; 5, Odontoglossum nebulosum; 6, Odontoglossum Andersonianum. — *A. J.* 1, Cypripedium insigne; 2, Dendrobium nobile, of good colour; 3, Odontoglossum pulchellum majus. The Crotons, or Codiæums, are imperfect specimens, but 4 is probably C. variegatus; 5, C. interruptus; 6, C. pictus. —*S. W., Bristol.* 1, Asparagus decumbens; 2, Lachenalia Nelsoni; 3, Odontoglossum Lindleyanum; Oncidium Cebolleta; 5, Begonia argyrostigma; 6, Abutilon Savitzii.—*H. T., Newbury.* 1, Euonymus japonicus aureo-marginatus; 2, E. latifolius argenteus; 3, Escallonia macrantha; 4, Euonymus radicans variegatus; 5, E. japonicus; 6, Jasminum nudiflorum.—*Sussex.* 1, Browallia speciosa; 2, Adonis autumnalis.—*Mrs. E. H.* Staphylea colchica.

NOTICE TO QUIT SERVICE: *J. H.* As has often been stated recently in these columns, in the absence of an agreement to the contrary, the length of time is four weeks for each party. To the second question the answer is No.

NURSERY MANAGER: *Enquirer.* If you have a written agreement, it might be of use in a court of law; otherwise you have no redress. Usually a month's notice is required on either side, but cannot be insisted upon.

PRICES OF MUSHROOMS IN THE LONDON MARKETS: Some of our correspondents have drawn our attention to an article by Mr. Lowrie in last week's issue of the *Gard. Chron.*, and inform us that the selling price of Mushrooms is now much nearer 8*d.* than 1*s.* 8*d.* per lb. It is right to say that Mr. Lowrie's quotation referred to the average prices in October and November last, the publication of his article having been unavoidably delayed.

QUALIFICATION OF A COUNTY COUNCIL HORTICULTURAL LECTURER: *Moorpark.* A good knowledge of plain gardening, with a knowledge of how to do a thing, and specially to be able to give the reason why; more especially in fruit and vegetable culture. An intimate acquaintance with the more common garden foes, both fungous and insectivorous, and methods to be adopted for their extirpation. Power of exposition by word and diagram on the blackboard, or magic-lantern; and in simple language "understandable of the people." Ability to act as a judge at shows, and in garden competitions. Ability to show novices how to handle and work in the most efficient manner with any kind of tool or simple machine; and to show the various methods of grafting, inarching, budding, root pruning, and making cuttings. To show how properly to clip, slash and plash hedges, and to plant various kinds of hedge plants, and how to "set in" trees for felling. The treatment of Osiers, &c. How best to grow room and window plants; how to pack fruit and vegetables for market, including sorting and grading. Indeed, it is not easy to tell you what subjects you should not be acquainted with, so multifarous are the matters coming withing the purview of a horticultural lecturer.

RAISING CEDAR OF LEBANON: *E. Brunl.* Obtain new seed, and sow in October in pans filled with sandy loam sifted finely and underlaid with nodules of loam capable of passing through a sieve having a ½-inch mesh, putting in as much as will form a 1 inch layer. Place the pans in a cold pit, and afford water when the soil has become dryish. The plants will appear above ground late in spring, and the pans must then be brought up to the light, so as not to allow the plants to become drawn in the least degree, affording plenty of air, and giving full exposure as the season advances. The plants may be pricked out in beds in the second year, and only as they become furnished with a few true needles.

VIOLET, A SPORT FROM V. PRIMAVERA: *E. Bland.* It is too large, to our thinking, for a "modest Violet;" in that respect resembling the variety Susanne.

VIOLET ROOTS DYING OFF: *J. Lawe.* The foliage is attacked by the fungus called Cercospora Violæ. Pick off badly-affected leaves, and spray with dilute Bordeaux Mixture or with potassium sulphide. Excessive moisture favours the growth and spread of the parasite. *G. M.*

WATER-LILIES: *E. H.* If tubs be not employed, mounds of loamy soil, equal to two or three wheelbarrow loads, may be placed in the pond in which the plants may be planted. If the tops of the mounds are about 2 feet from the water-level, less rather than more, the plants will succeed. It is well to cover the mounds with a 1-inch layer of very coarse gravel, so as to keep the soil compact and in position.

THE TULIP DISEASE.

THE garden Tulip is not, as a rule, subject to either fungoid or insect pests, but it has long been recognised that there is one disease of a fungoid nature which may wipe out or seriously cripple even an extensive collection.

Readers of the old florists' magazines will remember the discussions which raged in the fifties over the destruction of Headley's and Hepworth's Tulips—whether it was due to frost or to want of drainage; while as late as the Tulip Conference, held at the Botanic Gardens in 1897, there were many Tulip growers, including Herr Krelage, who could speak of the damage wrought within their own experience. As a rule, however, the destruction has been sporadic and temporary; the foliage and the bloom were lost, but the bulb, weakened indeed, survived for another season. The disease appears to make a beginning above-ground where hail or frost, followed by sunshine, gets hold of the foliage; dead brown patches appear, which increase until the whole of the upper growth becomes a dried-up papery mass, and even the bulb itself may be invaded. At times a more dangerous form appears, when the bulb, after planting, is attacked, and perishes without throwing up a shoot at all and it is this latter form of the disease which appears to have been on the increase of late—so much so, that some of the famous Tulip grounds in Holland have become infected and incapable of carrying Tulips. The disease has now been made the subject of a thorough investigation by Dr. J. Ritzema Bos, the well-known Professor of Economic Zoology at Wageningen, who has published an account of his researches in the current issues of the *Centralblatt für Bakteriologie* (ii., 10, 18).

According to Dr. Ritzema Bos, the disease is due to a parasitic fungus, Botrytis parasitica (Cavara), and though known for twenty years or more, it is only within the last decade that it has assumed serious dimensions and begun to affect the bulb industry. Two forms of infection seem to exist, one proceeding from the ground, the other from the air.

In the former case, the young shoot is attacked just as it is pushing from the bulb in late autumn, the tip is first affected, and the disease spreads downwards, consuming the whole shoot, so that no growth appears above-ground. The scales of the bulb are generally attacked, but even at the time the bulb should be blooming the plate and the roots are often still healthy, though they afterwards die. This agrees with what Tulip fanciers in this country have previously observed. Thus we find as early as 1854 Mr. W. Parkinson, of Derby, then a well-known florist, writing, "I have searched the roots over and over again, when I have perceived them turn black or begin to flag, and invariably found grown one or two inches of fine white fibre and root, as healthy as possible to be, and yet a sort of mildew or canker has killed the stem just above the bulb." The offsets which form may become infected also, and often survive, but remain very small, because of the absence of growth above-ground.

In Holland the disease is found to occur in patches in the Tulip fields, and these patches, known as "kwade plakken," do not shift, but gradually increase in size from year to year. It should be remembered that for a long time the land has been cropped on a sort of rotation of first Tulips, then other bulbs, such as Hyacinths, Iris, or Narcissi, then Potatos or Peas, after which Tulips come round again. Though Tulips suffer the most, other bulbs are also attacked, particularly Spanish Iris. That the soil gets infected is to be seen by the recurrence of the disease on the same spot. One very striking case was seen of a new field becoming infected only in places adjoining gaps in the hedge, which separated it from an adjoining diseased field. Clearly the infection had been carried in the soil adhering to the boots of the workmen trampling through the gaps.

When the infection is air borne, the appearances are similar to those already described. In late spring, perhaps after the leaf and bud have developed normally, brown spots appear on the leaf, which grow and become confluent, until the whole is flaccid. If the stem is affected, the bud or bloom falls over; if only the leaf, the bloom becomes correspondingly weakened. In dry weather the diseased parts become thin and white, and almost transparent, through the destruction of tissue. This form of the disease was very common last season (1902) after the severe frost of May 14, when 9° or 10° of frost followed rain, and was succeeded by bright sunshine the next morning. Though the Tulips were blooming in the south of England they died off with great rapidity, and generally an attack of Botrytis was to be seen just where the petals sprang from the stem; in my own case, I was not able to bring a single pod of seed to maturity from this cause. Similar appearances are to be noticed with Iris, Gladiolus, and Hyacinths, and the disease is always more severe in forcing-houses and damp places generally.

On examining the diseased parts, a number of fungi are generally to be seen, mostly common saprophytic forms; but one, characterised by the formation of dark olive-brown conidia, was always present, which turned out to have been previously described under the name of Botrytis parasitica (for description *vide* the current *Journal of the Royal Horticultural Society*, 27, 389). Dr. Ritzema Bos has demonstrated that this species causes the disease by sowing some of the conidia on a Tulip-leaf, and keeping it in a damp place. After three days, yellow spots appeared on the leaf, they soon became visible on both sides, enlarged, and eventually destroyed the leaf with all the characteristic symptoms described before. The fungus also assumes a resting stage in the shape of dark brown or black "sclerotia," bodies like flattened shot varying in size from one-twentieth to one-eighth of an inch, which are found abundantly between the scales of the dead bulbs. Where the disease has been prevalent, the soil was found to be full of these sclerotia, especially where the old dead bulbs had been left in the ground. In these sclerotia lies the real source of the permanent infection of the land with the disease, for after lying dormant in the soil they will start again into activity, most probably in autumn when the ground is warm and moist, and the young hyphæ ranging the earth for food find their way into the growing tip of the Tulip-shoot, and begin the work of destruction.

The question that is of the most practical importance is whether the disease is likely to be carried on in the bulbs; whether, in fact, there is any danger of introducing the disease into our gardens by the importation of bulbs from infected districts, as some parts of Holland undoubtedly are. In the case of Tulips, it is highly improbable that the disease will be thus transmitted by the bulbs, for the Tulip is strictly an annual bulb, formed entirely afresh each year. Moreover, the offsets of diseased bulbs which might be infected, even if they survive, are extremely unlikely to grow to marketable size, because of the destruction of the leaf and all the upper growth.

Hence, a full-grown Tulip-bulb is pretty sure to be free from infection. The case is, however, different with Hyacinths, the bulb of which requires more than one year to grow to marketable size, and which may become more or less infected in their outer scales, yet are large enough to be saleable, and even able to bloom.

Thus, Hyacinth-bulbs from an infected district may become a source of danger, for after blooming, perhaps weakly, they leave behind sclerotia of the Botrytis in the ground, ready to seize upon Tulips or other bulbs planted in the same place in the

following year. It is important, therefore, if an importation of Hyacinths are found to bloom in a weakly fashion, and show the characteristic signs of the disease in the presence of olive-brown patches on the stem, that the ground should be rested for some time from Tulips and other kindred bulbs, and particularly that the diseased bulbs should all be dug up and burnt. But in view of the widespread dissemination of the conidia in the air, and it must be remembered that the disease is always thus springing up, as it were, spontaneously in England when conditions are favourable to its development, it is not likely that soil infection will play any large part in ordinary gardens in this country. The grower of bulbs for market will however be wise, if he finds the disease, to grow some other crop than bulbs on that piece of land for a year or two, just as the fancier with a large collection ought to change his soil after an attack. Furthermore, as a preventive, Tulip-growers ought to be sure that their soil is properly provided with lime; it has been repeatedly noticed that the disease makes little headway on soils rich in lime, but is always at its worst on sour soils, and on those light alluvial lands which have been deprived of almost all their lime by washing. In Holland, liming and resting the land from bulbs for a time has proved the best means of curing the infected spots, and in a small way the use of lime or mortar-rubbish, or best of all basic slag, which also invigorates the Tulip by the phosphoric acid it contains in addition to free lime, have proved effective in maintaining healthy Tulip-beds in this country. *A. D. H.*

NEW OR NOTEWORTHY PLANTS.

LYCASTE EISGRUBENSIS ×, *Kränzlin.*

In size and foliage this new hybrid (L. Skinneri, Lindl., ♂ × L. lasioglossa, Rchb. f.) agrees in every respect with the parent plants. The flower-stalks are rather long, clothed with two or three distant sheaths; the bract is nearly identical with the sheath, and shorter than the ovary. The dorsal sepal is narrow, oblong-lanceolate, acute; the lateral ones oblong, acute, and produced into a short blunt point afterwards at the inferior margin. The colour is a dirty reddish-purple inside, and green outside, except at the margin where the red is slightly suffused with green. The lateral sepals have, near the base on the innerside, the peculiar cobweb hairs of Lycaste lasioglossa, and in size and colour they are directly intermediate between both parents. The petals are smaller than the sepals, but not so reduced in size as they are in L. lasioglossa; they are elliptical, oblong, blunt, whitish, and suffused with pale rose, a little darker to the base. The lip is in shape, circumference, and hairiness, nearly the same as in Lycaste lasioglossa, but the colour is more in the way of a rather dirty variety of Lycaste Skinneri. The column is whitish at the top, and dark purple coloured at the base. After all, the plant is as intermediate between the parent plants as a hybrid can be. The plant is surely a natural hybrid, and was imported by Messrs. Sander & Sons, St. Albans, among a lot of true Lycaste Skinneri. I received fresh material from Prof. Zimmermann, Eisgrub, Moravia, superintendent of Prince Liechtenstein's rich Orchid collection. Prof. Zimmermann informed me that he had received two specimens of this plant direct from Messrs. Sander & Sons. *F. Kränzlin, Berlin.*

NURSERY NOTES.

JAMES VEITCH & SONS AT FELTHAM.

Those who have seen the alterations at the Royal Exotic Nurseries in the King's Road, Chelsea, that have resulted in the loss of part of the land there, and of several of the well-known plant-houses, will undoubtedly be interested by a visit to the new nursery at Feltham, in Middlesex. The present writer having been to Feltham but ten days ago, speaks thus confidently, knowing that his experience there must, in some measure at least, be that of other gardeners who may subsequently avail themselves of the same privilege. The visitor will not be at Feltham long before he is satisfied that compensation on a very liberal scale indeed, has been provided here for the losses at Chelsea; whilst the means that

FIG. 58.—HYBRID BEGONIA AT FELTHAM.
Showing growths from axils of leaves, and formation of tuber at base of stem.

exist for subsequent development are of the most ample character. The firm was well advised when it purchased, some four or more years ago, the freehold of the site of 50 acres the nurseries now occupy. Situated about ten minutes' walk from the railway-station, the surroundings are perfectly rural, and although the London builder is a most daring and pushful variety of the species, under ordinary circumstances it will be many years before the locality can become so populated as to cause atmospheric conditions unsuited to perfect vegetative life and growth.

GLASS-HOUSES RESTORE BALANCE.

The work of building plant-houses, though relaxed, is not completed; several others will be added to those at present in use before a halt is made. The work, so far as it has gone, has been to balance the loss of glass at Chelsea, and of land and glass at the Southfields nursery, a branch which will very soon be only of historical importance. And incidentally, provision has been made at Feltham for just those plants that had shown a lack of appreciation for the conditions at Chelsea. Palms and Ferns, and many stove foliage plants, are not quite so fond of the country as other species, and they accordingly, with their clever grower, Mr. Tivey, remain at Chelsea; but the beautiful and valuable winter-flowering Begonias, that are excellent additions to the list of winter-flowering plants, the tuberous-rooted Begonias, the Hippeastrums, the greenhouse Rhododendrons, the Streptocarpuses, Gloxinias, Cinerarias, and many other species that for years have been cultivated and developed under the immediate care of Mr. John Heal, V.M.H., and that certainly thrive best in a clear atmosphere, are now at Feltham; together with hosts of soft-wooded plants, as Chrysanthemums, Fuchsias, Pelargoniums, Carnations, Cannas, Dahlias, Bouvardias, &c., that are Mr. Weeks' especial care, and the pot Vines under the management of Mr. Williams. All these, and many other species of plants will now be cultivated at Feltham.

The houses that have been built for the purpose are of the best description. They are generally about 100 feet long and 12 feet wide, have span roofs, and are built with a view to affording a maximum amount of light and a minimum of draught. The exceptions include the ideal Carnation-house, which is 100 feet long and 18½ feet wide, in two divisions; the Rhododendron-house, which is actually the one from Chelsea, and has been removed here; and the four vineries and orchard-house, which are 120 feet long and 23 feet 6 inches wide, and are each divided into two divisions.

In addition to the houses, which number nearly a score, there are plenty of useful frames suitable for the cultivation of dwarf-growing plants, the raising of seedlings, &c. By a glance at fig. 61, p. 149, the reader may obtain a good idea of the range of plant-houses and frames, as viewed from the top of one of the three windmills that have been provided for pumping water, &c. It was after two unsuccessful attempts from other "points of view" that the photographer was compelled to drag his apparatus to so hazardous a position.

It must be pointed out that the houses and frames shown in the photograph do not include the five excellent and spacious vineries and orchard-house, which form a block unto themselves some little distance away, and are faced by a long row of convenient garden buildings. No further reference to the vineries need be made at this time, except that already some of the young "eyes" are being rooted; they will soon be making their early growth in turves, and finally fill the grand central beds in these houses, that are now filled with sawdust, into which the pots will be plunged. One of the houses is used in some measure for raising a stock of Fig-trees, another division for the cultivation of Oranges in pots, and the fifth house is entirely devoted to the cultivation of fruit-trees in pots for furnishing orchard-houses. There are also two frames which are supplemental to the vineries, and each is 110 feet long and 6 feet wide.

The Lapagerias now grow at Feltham just as they did at Chelsea, for like the snails they have taken their house with them, and the growths are pegged over the sandy-looking surface of soil, for layering, just as we have seen them so often. Reverting for a moment to the Carnation-house, which is provided with a central and side stages, we remarked in this structure a capital collection of winter-flowering varieties, and some very strongly-grown layers of the variety Souvenir de la Malmaison. The plants of Coleus thyrsoideus we have seen at the Drill Hall in bloom are now in the Chrysanthemum-house, and the rest of their flowers will be encouraged to develop seeds.

A CULTURAL NOTE.

Having reason to believe that the average gardener finds some difficulty in the cultivation of Messrs. Veitch's new hybrid Begonias that flower during winter, it may be interesting to relate the

conditions to which the plants are at present subjected, and also the exact state of the plants themselves. For this purpose a photograph (see fig. 58) was taken of a typical specimen in a rather small 6-inch pot. It must be borne in mind that in this section the cultivator has got not merely a tuberous-rooted plant, or a fibrous-rooted one, but both. These hybrids from B. socotrana and the tuberous-rooted section have the characteristics of both species; and whilst they should not be subjected to the same degree of drying-off as the tuberous-rooted varieties, they distinctly resent the presence of much moisture about the roots after the flowering stage.

At the present time Messrs. Veitch's plants are in a span-roofed house, which is kept at about the temperature of a warm greenhouse, and abundance of air is afforded when the conditions out-of-doors will allow. The roots are kept moderately dry, being afforded water once a week or so, according to the weather. The photograph will give an exact representation of a plant ten days ago. It will be noticed that the leaves are still upon the plant, and are healthy (one has been purposely removed to afford a better view); also that from the axils of the leaves there are pushing young growths, and that at the base of the stem, where the soil has been rubbed away, there is in course of development a small tuber. The culture at the present time is directed to getting the tuber to swell properly and to mature fully, for which purpose it is necessary to keep the leaves healthy and green as long as practicable. Presently the young growths when large enough will be removed from the axils of the leaves, and used as cuttings for the increase of stock, and at the beginning of the month of June the plants will be cut down to about 2 inches from the base. Let the treatment afforded the plants at the present time be one that will slowly (to use a garden term) ripen the plants.

The house devoted to the Streptocarpuses is just now a picture of healthy growing plants that promise to make a magnificent display at the end of May. They represent the strains known as Veitch's Hybrids and S. achimeniflora; this latter strain originated by the crossing of S. polyanthus and Veitch's Hybrids together. Seeds are sown in January, and the young seedlings are planted out in the houses, and some of the most precocious of them commence to flower in September; but these flowers are removed, and in February the plants are put into 4-inch and 5-inch pots. Streptocarpuses may be had in bloom during ten months out of twelve. Some gardeners complain that the seeds do not germinate freely, but at Feltham the pots in which seeds had been sown were as fully furnished as if they had been used for testing lawn grass-seeds. It is evident they are capable of germinating when the conditions are right. Messrs. Veitch's experienced grower, Mr. Heal, sows the seeds in pots in January, in a temperature of 60° to 65°, and the seeds being small, they are not covered at all. It is again a question, in the consideration of which we must take into notice the water-can. The seeds must not be over watered. If the soil becomes sour the seeds will perish. Nor must the soil be allowed to get quite dry; it is the happy medium alone that will induce success.

One large house contains Hippeastrums, something like 6,000 plants, if we remember rightly. They are plunged, and are just commencing growth. The seeds are sown soon after ripening, about July, and last year's seedlings have now three or four slender leaves to each.

Primula × Kewensis (fig. 59), the hybrid from P. floribunda and P. verticillata, is one of the best of new winter flowering plants. Messrs. Veitch have something like 500 or 600 plants. The inflorescences rise boldly from the base 12 or 15 inches high, and require no staking. A photograph (fig. 60, p. 149) was taken of the plants, and this will suffice to show that they produce a large quantity of flowers. The colour is rich yellow, and each individual flower is nearly an inch across.

The new rock plant, Corydalis thalictrifolia (figured in *Gard. Chron.*, Oct. 18, 1902, p. 289, and Supplement), and other new Chinese plants, occupy the greater part of a frame 100 ft. long, by 6 ft. wide. Of the bright flowering Kalanchoe flammea (see fig. 26 in *Gard. Chron.*, July 15, 1899) there is quite a large batch of plants, some about ¾ foot high, but the species K. Kirki, which is scarcely so good a garden plant, is 2½ feet high, and is already coming into flower; also a new hybrid between these two species that has never yet bloomed.

The span-pits, which together have a length of about 250 feet, and are 9 feet 6 inches wide, contain Boronias, Camellias, and general greenhouse plants, and frames extending for 280 feet are used for all kinds of bedding plants, border Carnations, and similar species. There is also a propagating-house for the same class of plants, 100 feet long by 11 feet wide, in two divisions.

Fig. 59.—Primula × Kewensis = P. floribunda × P. verticillata: flowers yellow.

Out-of-Doors.

It will be obvious to the reader that the glass-houses and nursery buildings having been erected on a piece of land 50 acres in extent, there

remains quite five-sixths of the land for the cultivation of out-of-door crops. Of this about 6 acres are used for trials of flower and vegetable seeds; and in connection with Mr. Dawkin's seed department there is also a house 60 feet long and 12 feet 6 inches wide, in three divisions, for the trial of choicer seeds.

Beyond this there are acres of fruit-trees and of young forest-trees, and a walk through the principal grass-covered roads with Mr. Middlebrook, the manager, showed that the very most is being made of the excellent opportunities the ground affords. The operations that were being carried out at the moment included the transplanting of promising Apple-trees, two years old, which are now given spaces of 2½ by 3 ft., where they will have an opportunity to make well balanced trees; 3,000 will be so transplanted every year. Stone-fruit trees make the best of roots upon this soil, and many of these being lifted at the time, impressed the writer by the numerous and fibrous roots they possessed. Extra care is taken with the standard Peach-trees. The stocks are the ordinary Mussel stock, but they are budded just above the surface with a selected and superior "Mussel" for forming a straight, smooth stem, and are then budded with the Peach at the height required. This also prevents much swelling taking place at the point of union. Standard Cherries, 7 feet high, had made excellent stems, and there is an immense number of young Pear-trees, about 8,000 being budded each year; 6,000 Raspberries are cultivated every year, and altogether 100,000 fruit-tree stocks are handled every season. But refraining from remarking in detail upon this department at the present time, this note may close with a reference to the stock of healthy young Yew-trees, which is unusually large.

ACÆNAS.

THE Acænas, or New Zealand Burs, as they are frequently called, are little plants whose usefulness has not as yet been properly recognised in gardens. There are a few growers of alpines who cultivate a small number of species, but, as a rule, only some two or three of these valuable and pretty little plants are to be met with even in large collections of such flowers. It is unfortunate that this is the case, as there are many plants far more largely cultivated which might be dispensed with to make room for these New Zealand Burs. It may be said, by the way, that this "popular" name is unfortunate, as several of the species are not from New Zealand alone, but from other parts of Australasia; while a considerable number of species hail from the south and south-west of the American continent. However, the name of New Zealand Bur will die hard, and is perhaps quite good enough for those who persist in confining themselves to "popular" names, even when such a simple scientific one of Acæna is available. This is derived from akaina, a thorn, from the presence of the spines on the calyx or fruit.

Generally speaking, almost all of the introduced species appear to be hardy in most gardens in Great Britain, although one would expect from the native habitats of some that they would be tender. They either show more adaptability than other plants, or are widely spread in their native habitats, and our stocks have come from colder latitudes, for such as A. ovina, which is said to grow in New South Wales, appears to be hardy enough in Scotland.

They are among the most accommodating of our garden plants, thriving happily in either sun or shade; and some of them even growing well under the shade of Conifers, a situation in which but few plants of their character will survive. They are thus capital plants for many purposes. In the rock-garden they can hardly be used amiss. In the border they may be grown to form carpets, whence may rise bulbous or other flowers. In the woodland or wild garden they can be planted with advantage to grow almost unchecked so as to cover a large stretch with their pretty, variously coloured leaves. One of the best for this is A. microphylla, which has hardly a rival among the genus for beauty and usefulness.

The Acænas are far from troublesome as regards the soil they require. They will do well almost anywhere, but I have seen them at their best in a moist, peaty soil, where, if allowed to grow until they form a mass several feet in diameter, they are exceedingly attractive. Here, again, A. microphylla shows its supremacy, especially when in bloom, when its crimson spikelets make a remarkable effect in such masses as these. The finest effect made with this Acæna that I have ever seen was in the delightful garden of the Rev. C. Wolley Dod, at Edge Hall, Malpas, some years ago. No one who saw this mass of Acæna microphylla there could withhold an expression of admiration. It was worthy of that past master of hardy plant-culture. It is not difficult to obtain a mass of this kind if a little time is allowed for the plants to develop. This they do rapidly, by reason of their running or creeping habit at the roots. Propagation by means of division is easily performed, but they may also be increased by means of cuttings or from seeds.

There is a considerable number named in modern books of reference which are not at present in commerce, but a fair number are procurable in good nurseries here or on the continent. I shall thus endeavour to confine my notes to the species which are thus obtainable with more or less difficulty. They are so easily cultivated that they will soon become better known if attention is called to them.

One has already referred to A. microphylla, which, although one of the first to be introduced, is still unapproachable in its value and beauty. It is of evergreen habit, has a neat habit, albeit of a somewhat trailing growth, while its prettily tinted bronzy foliage forms a charming setting for the showy crimson spines which decorate the round heads of greenish flowers. Where space in the rock garden is an object, it may be grown in the rocky paths or stairways among the stones and crevices, where it looks both attractive and ornamental. It only grows an inch or two high. It is a native of New Zealand, and is sometimes known as A. novæ-zealandiæ.

Next to it one should place, for more than one reason, that known as A. pulchella, but also met with in gardens as A. argentea, but which I have also seen labelled A. microphylla var. argentea, the last having much to be said in its favour. It has fine bronzy leaves, and is more vigorous in its growth than the preceding one. On the other hand, it blooms much less freely, so that it is not so handsome when in bloom.

One of my favourites is A. Buchanani, which has not been described in several good works of reference. Its leading feature is its lovely pea-green foliage, while its greenish flowers are quite inconspicuous; it is a New Zealand species. From a continental source I received one named A. Berteroana, which resembles A. Buchanani so closely, that I have some doubt that it is either incorrectly named or not very distinct. Careful observation leads one to think, upon the whole, that its foliage is lighter and more silvery than that of A. Buchanani.

A. glabra is another species not generally known, though I have had it in my garden for some years. It is one of the species of upright habit, though not more than 4 or 6 inches high, and has rather bronzy-green foliage and inconspicuous flowers.

A. ovina is better known to students of books of reference, and it is one which I should class along with the preceding on account of its upright growth. It is a little dwarfer than the foregoing, but is no less attractive on account of its fresh, green, wrinkled, rather elliptic leaflets, which are glabrous on the upper surface in my specimens, but in some are pubescent on both sides. A somewhat similar but more elegant Acæna is A. ovalifolia, a Chilian species, while A. ovina is from Australia. The latter has its flowers in spikes, but they are not ornamental. I find these hardy.

A. millefolia has pretty, finely-cut, light green leaves, and is only desirable for its foliage, as it is rather spoiled by the arrangement of the flowers on its spikes; otherwise it is a desirable Acæna.

A good growing species is A. myriophylla, with pretty, deeply-cut leaves, and growing from 6 to almost 12 inches long; it comes from Chili, and has inconspicuous flowers in close heads.

Among those less frequently grown one may place the Patagonian A. adscendens, with rounded heads of dull purple flowers and obovate leaflets, which are silky beneath but smooth above. This is as yet a rather scarce plant; so is A. sericea, which is synonymous with A. cuneata, and has toothed, oblong leaflets, and rounded heads of small flowers. The leaves are silky underneath.

Two stronger-growing species are A. Sanguisorbæ and A. sarmentosa, which are well adapted for planting on the rockwork, so as to trail over the stones. The first has leaves varying from 2 to 6 inches long, and on the whole a rather coarse habit; it has its flowers in rounded heads, and the leaflets are silky underneath. The second of these two Acænas is of more rampant growth, but is suited for similar positions; it is altogether larger, and grows more loosely, and is thus not so desirable for carpeting as some of the others.

Of the two other species known to me, but which I have not grown myself, the better appears to be A. splendens, a Chilian plant, with leaves of a silky white on both sides. I am doubtful of the hardiness of this species, as from the only plant I have met, it looks as if it would suffer from wet; it has its flowers in long spikes, instead of in round heads. The other, A. pinnatifida, is said on good authority to be only half-hardy, and with so much variety of hardy species, it seems almost unnecessary to cultivate it; it is of erect habit, and grows about 6 inches high. *S. Arnott.*

CULTURAL MEMORANDA.

ECHEVERIA RETUSA.

THIS species is useful for the decoration of rooms, lasting in full flower for several weeks; in a cut state the flowers have a fine effect when associated with Lily of the Valley or Roman Hyacinths. In order to raise winter flowering plants, offsets should be taken early in the spring, and grown on in a warmth of 60° till established in 48's or 32's, and then stored in a shady cold frame, drawing off the lights in fine weather. In October remove the plants to a greenhouse, and bring batches into heat as may be required. As a potting soil, loam three-quarters and leaf-mould one-quarter, with some decayed stable-manure and plenty of sharp sand, is suitable. When the plants begin to show flower-buds, liquid-manure may be freely used. *J. Murray, Sopley Park, Christchurch.*

MOSCHOSMA RIPARIUM.

Any gardener desirous of possessing a good decorative plant at the Christmas season, should grow this greenhouse plant. The plant is easily grown under the same conditions as Salvia splendens; cuttings should be struck in the month of April, and the plants grown in the full sunshine, and be stopped two or three times. The most

Fig. 60.—Group of plants of Primula × kewensis in glasshouse at Feltham. (see p. 146.)

suitable pots are 32's, as the better ripened is the wood, the better the plant flowers. The flowers superficially resemble the well-known Spiræa, but are white with a pale mauve tint; their odour is rather unpleasant to some persons. My plants stood for three weeks in hot rooms without dropping their flowers. The plant is effective when planted in baskets along with Cyperus and small grasses. *J. Dryden, gr., Wyck Hill Gardens, Stow-on-the-Wold.*

Ageratums Swanley Blue and Album.

By sowing seed of the above, or other varieties of Ageratum, in a pan or box, in early spring, a good stock of plants may be raised in time for planting-out by the end of the month of May. Sow thinly in light, finely sifted soil, cover lightly, and then place in heat, covering the pans or boxes with glass or paper. Directly the seeds germinate, remove the covering, prick the little plants out into boxes as soon as large enough to handle, at about 2 inches apart; return to heat, and apply water to settle the soil, and shade from sunshine with paper till the young plants have pushed their roots into the soil. In order to secure sturdily grown plants, it is necessary to afford them a position near the glass, and to ventilate in proportion to the growth being made, and according to weather conditions, increasing the quantity of air given as growth increases and bedding-out time draws nigh. When the plants have attained a little strength, pinch out the points to make them branch. *H. W.*

Salvia patens.

This species of Salvia may be raised from seed sown during February or March in mild heat, and when the plants appear place them near to the light so that growth may be sturdy. When about one inch of growth has been made, dibble them singly into small 60's, filled with leaf-mould and sandy loam, and return them to the shelf. In due time afford them similar positions in a cooler and more airy structure, where they may remain till the end of the month of May, and then be planted out. Salvia patens is well adapted for planting thinly in "mixed" beds, or among variegated-leaved pink-flowered Pelargoniums, as P. Manglesii, or the scarlet-flowered P. Bijou, and the yellow-flowered Cereopsis grandiflora. The latter is a pretty free-flowering hardy perennial, and it looks well in company with the Salvia as a dot plant. Salvia patens is a telling plant grown in a pot for the conservatory. Salvia coccinea, a species with small scarlet flowers, is likewise worthy of cultivation for the same purposes. *H. W. W., Lime House, Rayleigh.*

Thunbergia alata.

The annual species of Thunbergia include several which make pretty basket plants for the greenhouse, and bordering the plant stages. Seed should now be sown in heat, employing pots filled with a light compost. When the seedlings are convenient to be handled, prick them off in pans or cutting-boxes, and replace in heat, shading them for a few days during sunshine. Subsequently the plants may be placed to the number of three in 5-inch pots, and five to nine in baskets. *H. W. W.*

Rudbeckia speciosa (=Newmani).

This is a very useful and effective decorative hardy perennial plant, either for growing among other similar plants in the herbaceous border, or using in a cut state for filling large vases for the embellishment of halls, rooms, &c., for which purpose the long spikes surmounted by large orange-yellow flowers, to which the black centre lends additional beauty in the way of contrast. The plant will succeed in any ordinary soil, and is admirably adapted not only for cutting, but also for planting in isolated positions in garden or shrubbery. Established plants when divided into sundry pieces and transplanted separately soon become good specimens, and yield a mass of flowering spikes from 2 to 2½ or even 3 feet high, according to the depth and fertility of the soil during the summer months. Where the natural soil is unduly heavy, it may be rendered more congenial to the root requirements of the plant by the addition of a little leaf-mould, burnt earth, road sweepings, and such-like corrective ingredients for land of this description. *Essex.*

Ipomœa rubro-cœrulea.

This is a grand plant for producing an effective colour in autumn and early winter. An excellent method of treatment is to sow seed every season in 4-inch pots at about midsummer, and put them in a close frame. When the seedlings are all through, admit air, that they may grow sturdy; and when they have become well rooted, pot them into 8-inch pots, using good "holding" soil. Place them outside in a sunny position until about mid-September, then remove them to a moderately warm house, and afford them manure-water occasionally. They would then produce an abundance of flowers till after Christmas. Associated with Poinsettias, they make a good contrast during the dull days. *Thos. Denny, Down House Gardens, Blandford.*

Shrubby Phloxes.

To cultivate Phloxes of this section successfully, the soil should be well enriched and deep, and water and liquid-manure applied in dry weather. Young plants should be reared to take the place of exhausted stools which fail to produce good blooms. Although the Phloxes are

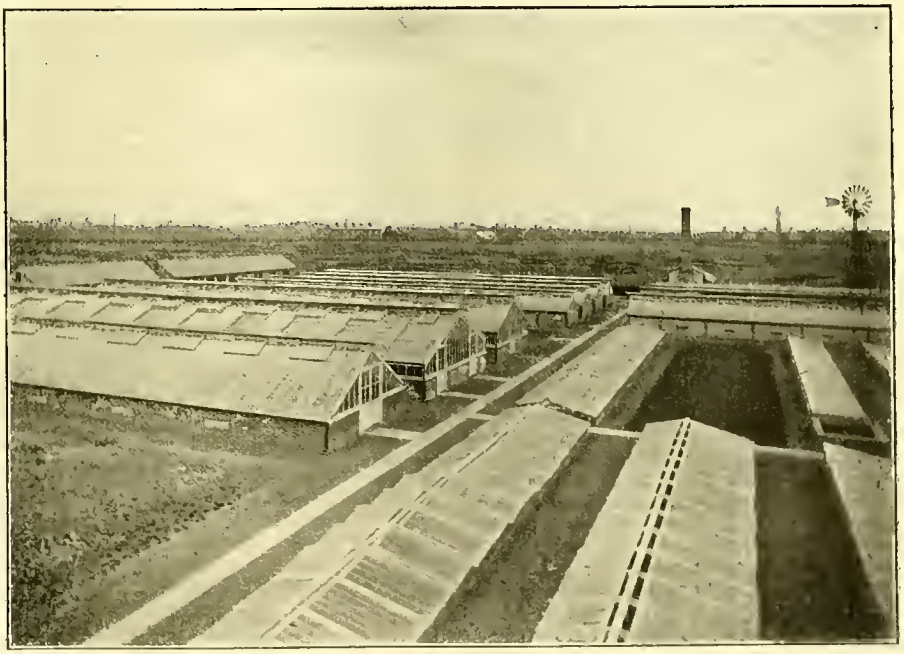

Fig. 61.—View of plant-houses and pits in Messrs. Veitch's nursery at Feltham. (see p. 146.)

readily increased by division, I usually propagate at this season from cuttings when the shoots have grown about 3 inches in length; these being taken off and dibbled either into sandy soil in pots and stood in a little warmth, or put under handlights, and kept close and shaded during sunny weather. Roots are soon formed, and the cuttings can be planted out after due hardening. Seeds of good strains may now be sown, and from these many nice tints and good trusses are obtained, of which the best may be retained and the poorer ones thrown away after trial. *H. M.*

HEUCHERA SANGUINEA.

This is a useful plant, making a pretty display in beds, as edging, and in the herbaceous border. Seed may be sown now in pans, and placed in warmth, and in this way a good stock of plants may be raised. The old plants, when an increase of stock is required, may be taken up, divided, and replanted in nursery beds, where they should remain for a year before planting them permanently; a few may be flowered in pots. *H. Markham, Wrotham Park.*

FLORISTS' FLOWERS.

THE AURICULA IN EARLY SPRING.

THE Auricula, whether cultivated in pots under glass in a cool temperature or in the open border, is on the move. Indeed, it seems to have enjoyed an unusually short season of rest. It experienced a rare growing time through the cool moist summer of last year; it appeared to rollick during the bursts of fine open weather in the autumn. Christmas found the plants well furnished with foliage; the leaves disappeared to a large extent during January until the call of spring came, and the new foliage is being rapidly developed. Despite the vigorous growth of last season, I had but very few trusses of bloom; some of the fine named alpine varieties became flowerless in December, but they kept down and will now, I trust, give me an early bloom, though they occupy, and must do so, a north aspect.

As the plants become active, greater demands are made upon the moisture in the soil, and its application needs careful attention. Not that the plants require a soddened soil; what they want is a comfortable quantity of moisture, enough to keep them moving in a stately manner and without provocation to the rot; clean pots, clean stages; the surface gently stirred at times so that the soil may be kept open, and plenty of fresh air. I take it for granted that the pots were well drained at potting-time, and the compost employed in that process every way suitable under such conditions, then plants ought and will do well.

One of the difficulties attending Auricula culture so near to London as Ealing, is the London fogs. They come westward, swept on in dense clouds before the east winds, and they appear to be loaded with acidulous properties, which fastening upon the points of the outer leaves of the plants, wither them in a short time. My neighbours hard by at Gunnersbury—Messrs. Geo. Reynolds, and James Hudson—have their early blooms of forced Strawberries destroyed in the same way; and the bloom of their forced Peaches and Nectarines affected in the same way. So are those of Carnations, Bouvardias, &c. The sweet Violet appears to shrink from contact with this vile property. I cannot grow it in my Ealing garden. Happily, acid-laden fogs were not so numerous during the autumn and winter as is sometimes the case; at least, symptoms of injury were not so apparent, perhaps something was due to the vigorous growth made in 1902. If any plant may be said to absolutely require a pure untainted atmosphere, it is the Auricula.

The old routine of top dressing the plants in pots, once so religiously performed at this season of the year, is only partially followed now-a-days. I like to see the fibrous roots active near the surface; and to disturb them seems likely to be harmful under such a condition. I prefer to trust to the unexhausted reserve of nutriment in the soil, than to apply anything in the way of a fertiliser. If any do apply stimulants, they are men who know thoroughly what they are doing. I have known amateurs apply sulphate of ammonia with disastrous results. I have occasionally given a little weak soot-water as the plants advance into bloom, but always with great care. I prefer to see smaller pips highly refined, than large ones coarsely proportioned; and I cannot help thinking that at our southern Auricula shows, mere size of truss and pip is a little too much considered by the judges.

There appears to be a bad time in store for the long styled Auriculas; some of our newer alpines show the protruding style among the anthers, and perilously near the top of them. To admit such to competition, and to award prizes to them, is as a kind of challenge thrown down in opposition to the old law in floriculture that the "pin-eye" is a disqualification. To remove the pin is but a form of trickery, as it is intended to mislead the judges. There was, therefore, some necessity for the re-affirmation of the principle that it is a disqualification, and the Midland Auricula-cultivators in meeting at Birmingham last May, made this affirmation with remarkable emphasis. There are now so many new alpines, that defective varieties should find no place on the exhibition table.

The Week's Work.

THE HARDY FRUIT GARDEN.

By CHAS. PAGE, Gardener to J. B. FORTESCUE, Esq., Dropmore, Maidenhead.

Protecting the blossoms.—Peach-trees should now be afforded protection against frost, sleet, hail, and snow; and in gardens having walls furnished with portable glass copings, doubled or trebled fish-netting should be hung from the front edge of the coping, and made fast to stout pegs driven into the ground at 6 feet apart. This kind of protection is, as a rule, ample. When no such safeguards exist, Larch-poles pushed under the usual wall coping, and trebled netting may be employed; and in damp situations thin scrim should be placed over the fish-netting when sharp frosts threaten, removing it in the early morning, but not the netting, which may remain, as it admits as much sunlight and air as the trees need, and it will form a protection to the growth later on. In some gardens no precautions are taken against the inclemency of the weather, and good crops of fruit are obtained in favourable seasons, but our climate is so capricious that the prudent gardener usually takes precautions against the loss of a crop of fruit.

Strawberries.—The ground having been trenched in early winter, and subsequently hoed when in a dry state, it should be in a suitable condition for setting out the plants about the middle of the month. In planting strong-growing varieties, allow 2½ feet between the rows, and 2 feet between the plants in the lines. The varieties Latest-of-All, Elton Pine, and British Queen, which are sparse of growth in some soils, should be planted 6 inches closer each way. Let the planting be carried out firmly, and a mulch of strawy manure applied, not necessarily all over the soil, but on each side of the rows. These plants must not carry fruit this year, but a few early runners may be taken for early forcing purposes or for planting in the month of August. The variety, The Laxton, appears to be a strong grower, and I would advise all who intend to plant it to afford it ample space.

Miscellaneous.—Where Gooseberries have not been pruned, from fear of the birds taking the buds, the operation should receive attention forthwith, as I do not think that anything is gained by leaving them any longer unpruned. Should dry weather prevail in the present month, late-planted wall-trees will be benefited by heavy syringings applied early in the afternoon in mild weather.

FRUITS UNDER GLASS.

By T. H. C.

Cucumbers.—Pinch out the points of the plants when they have grown half way up to the trellis, and stop the side shoots and laterals at a joint beyond the fruit. Avoid over-crowding the foliage, and tie in the shoots with this end in view. Cucumbers succeed in a free, rich compost, with frequent top dressings. A top dressing consisting of rich loam, and spent Mushroom-bed dung, in equal parts, may be afforded as soon as the roots appear at the surface of the soil. Maintain the air at all times in a moist state, and keep a sharp outlook for aphides and red spider. A night temperature of 65° to 70° is necessary, and one by day of 85° with sunheat and ventilation. Do not crop aged plants heavily, or neglect to afford frequent applications of liquid-manure, and light top dressings to the roots. These old plants should be removed as soon as the young ones have come into good bearing. Young Cucumber plants should always be planted out before they become pot-bound. Sow seeds of Improved Telegraph, Cardiff Castle, Every Day, and Perfection for succession.

The Early Vinery.—The bunches on the Vines that were started early in the month of December will be ready for a reduction in their number. Those hanging nearest to the hot-water pipes will be a few days in advance of those in other parts of the vinery. I like to retain a good number of these, as they are usually the earliest and best coloured. If bunches are very numerous, remove all except one to each lateral before flowering begins. Fertilise the flowers daily, and when it is seen which bunches have set the best, reduce these to the requisite number for a crop, which may range from eight to twelve to a rod, more or less, according to the vigour of the Vines. In thinning the berries, commence at the point of the bunch and finish with the shoulders, taking great care not to rub the skin of the berries. The temperature at night should range from 65° to 70°, and by day 10° to 15° higher; ventilation being afforded whenever the weather permits, and closing early, so as to retain some of the solar warmth.

Succession Vineries.—Tie down the main laterals, stopping them at the joint beyond a bunch, and minor ones at the first leaf, avoiding any crowding of the foliage; ventilate freely in mild weather, otherwise the growth will be lacking in strength and become subject to insect and fungoid attacks.

Insect Pests.—Upon the first appearance of red-spider or thrips, let the infested leaves be sponged with tepid water, in which a small quantity of soft-soap is dissolved. Follow up the winter dressing for the eradication of mealy-bug by a weekly inspection of the Vines, preferably in bright weather, when many of the insects recently hatched out will be observed crawling about, or hiding about the spurs. A touch from a brush dipped in methylated spirits will instantly kill them. Likely-looking hiding-places may be cleansed with the same kind of insecticide. Muscat Vines approaching the flowering period may be afforded a night temperature of 70° to 75°, the higher figure in mild weather only. Carefully fertilise the flowers daily, and maintain a dryer atmosphere in the daytime, so as to assist in the distribution of the pollen, ventilating the vinery daily if the weather conditions are in any degree favourable.

Strawberries.—Do not apply manure-water to any plant that is carrying fruit approaching the ripening stage; and towards the finish, the flavour of the fruit will be improved if the soil be kept in a moderately dry condition, but not so dry as to cause shrivelling of the leaves. Thin the fruit on successions, and as the season advances, allow them to carry a slightly heavier crop than the earlier plants. Afford manure at every application of water; syringe the foliage, and maintain a moist state of the air till the fruit begins to colour, when a dry atmospheric *régime* should be maintained.

THE ORCHID HOUSES.

By H. Alexander, Orchid Cultivator to Capt. G. L. Holford, Westonbirt, Tetbury.

The East Indian-house.—The plants of Angræcum sesquipedale, Vanda Bensonæ, V. Sanderiana, the Saccolabiums, and Aërides, should now be examined, and those that stand in need of repotting or fresh surface material should receive attention forthwith, picking out all decaying material from among the roots, without damaging the latter, or disturbing any that are clinging to the pots; this done, make the drainage perfect, filling in amongst the roots with the following compost:—good, rough, partly-decayed Oak-leaves, two-thirds; rough lumps of peat, one-third; a small quantity of chopped sphagnum, and a considerable quantity of silver-sand, clean crocks, and bits of charcoal. Before using these substances, see that they are in a moist state, and warmed. Fill the pots almost to their rim, and afford a surfacing of sphagnum. If a plant has become ungainly through loss of leaves, remove the lower portion of the stem, and place the plant in a much smaller pot, and for some time afterwards afford water with discretion, damping the sides of the pot and overhead being usually sufficient.

Vanda cærulea.—I find that this plant succeeds in the cooler part of the Cattleya-house, with ventilation afforded whenever the weather is favourable. It does well in pots placed on the stage, and in a similar compost to that advised for Angræcums. During the summer months it should be afforded a liberal supply of water at the root, and overhead sprayings on bright days; and in the winter, when the roots are sealed over, scarcely any water is needed. But now the plant is exhibiting signs of growth, the amount of water should be increased by degrees, and repotting and top-dressing attended to.

Oncidium macranthum, O. superbiens, and O. undulatum. — The very large flower-spikes, if allowed to remain on the plant for any great length of time, exhaust the plant; and it is advisable in the case of a plant that has flowered abundantly, or which has carried its flowers for too long a period of time, to remove the flower-spikes as soon as they show the next year. The plant being in active growth at this date, much moisture is needed at the root. Plants destitute of flower-spikes which may require repotting may receive attention, affording ample rooting space, well drained pots, and a compost of leaf-soil two-thirds, peat one-third, with the usual coating of sphagnum. Place in the warmer part of the cool house.

PLANTS UNDER GLASS.

By J. Mayne, Gardener to the Hon. Mark Rolle, Bicton, Budleigh Salterton, Devonshire.

Primulas.—The old double white flowered Primula is regarded as the best for flowering at mid-winter and later in the year. As it is advisable to make an early start in order that sturdy plants may be obtained in November, the plants should now have the bottom leaves removed with a pair of scissors, and a top-dressing of equal parts of sifted loam and leaf-soil, with plenty of silver sand added, applied close round the root-stock of the plants in order that the lateral shoots may take root in it, which they should do in about eight weeks. When roots are observed the shoots may be snipped off. Keep the mother plants near to the glass in a pit having a temperature of 55°, and the compost uniformly moist, with light shading thrown over them on very bright days up to 3 p.m. Some gardeners drop each plant into a pot of larger size before mounding them up, which is an advantage, as it keeps the soil in place, and it does not dry up so quickly. For an early batch, seed may be sown of the single varieties.

Cinerarias.—Plants of C. cruenta or C. stellata for late flowering should be placed in a cool north house or pit, and full ventilation afforded in favourable weather, applying fire-heat only on frosty nights. The sun should not be allowed to shine directly on the plants after this date, as I find the foliage is not so firm as that of the larger-flowered varieties.

Euphorbia Jacquiniæflora.—Remove the flower-heads of this plant, and place the latter in a house having a temperature at night of 60°; keep moderately dry at the root and overhead for the present. Cuttings may be taken in April.

Epacris and Ericas are among the most useful of spring-flowering plants, lasting well whether on the plant or in a cut state, and their delicate colours always attract attention. As the plants pass out of flower, cut the growths hard back, and thin out the spray, and treat similarly to Azaleas, except that they thrive best in peat and silver-sand only. The softer-wooded varieties of Erica, such as Wilmoreana, hyemalis, gracilis, and a few others, may be treated in like manner. Keep the general stock of Ericas as cool as possible, and apply water only when it is really necessary, and make no use of fire-heat unless it be to keep out frost, giving full ventilation on mild days.

Calceolarias.—These plants should be potted before they become pot-bound. Our stock is in 5 and 5½ inch, and these plants will be shifted into 7 and 8 inch ones respectively, in which they will bloom. Use plenty of drainage, and a compost consisting of good turfy loam half, decayed sheep or cow-manure quarter, and leaf-soil, coarse silver or clean river-sand quarter, potting moderately firmly, being careful not to injure the leaves. Having potted the plants, stand them on a shelf near the glass for a few weeks, and fumigate them on the first appearance of aphis. The careful affording of water is necessary at every stage; fire-heat should be but sparingly employed, and plenty of room afforded the plants. After the middle of the month they should be stood on a coal-ash bottom in cold pits, preference being given to those having a northern aspect.

Shadings.—As the month of March comes in, a slight protection from the full power of the sun becomes a necessity with many stove and greenhouse plants, flowering and foliage alike, say, from 10 A.M. to 2.30 P.M., though much depends upon the aspect of the house. Crotons and Dracænas should have the brighter end.

THE KITCHEN GARDEN.

By John Fleming, Gardener to Sir C. Pigott, Bart., Wexham Park, Slough.

Peas.—A sowing may now be made of some of the main crop varieties, remembering that Peas having wrinkled seeds are more influenced by an unfavourable state of the weather and the soil than the round seeded, and should therefore be sown more thickly than the latter. Here, on light land, the seed drills are drawn 6 inches deep, and the seed is covered with about half of the soil which comes out of the drills, the other half being drawn up to the plants when these are 4 inches high. Better crops of main crop Peas are obtained from rows standing at 10 to 15 feet apart, than at 4 to 6 feet apart, the ground between being cropped with early Potatos, Cauliflower, Turnips, or Spinach. It is always wise to roll the seed in red-lead before sowing it. Peas started in pots or boxes should be gradually hardened off, taking care that no check be given them. Do not be in a hurry to plant these out in the open, or they may fail to give satisfaction. When planted, the plants should be moulded up to the leaves, and stakes put to them forthwith, introducing a few evergreen branches among these to afford shelter. Peas sown in the open last month are coming through the ground, and should have nets placed over them. Apply occasional dustings of fresh soot and lime.

Beans.—Make another sowing of Green Windsor. Broad Beans sown under glass need the same kind of treatment as that advised for Peas.

Turnips.—Small and frequent sowings should be made on a south border in drills at 1 foot apart and an inch deep, applying to the land a dressing of soot and wood-ashes when the sowing is finished. Early Milan and Snowball are trustworthy varieties.

Spinach should be sown on a warm border in drills drawn at 15 inches apart. Winter Spinach should have the soil frequently stirred with the Dutch-hoe, applying a slight dusting of soot and wood-ashes in equal proportions about once a fortnight.

Potatos.—Early varieties may be planted in moderate quantity on warm borders, the tubers being planted deeply, and all shoots rubbed off, excepting two or three of the stronger ones. Potatos in pots or in heated pits that were planted in the autumn will soon be fit for the table, and less water should be afforded them, so as to mature the tubers early. Afford abundance of air in fine weather. Successional batches should be examined on warm sunny days, and if the soil be dry, a thorough application of tepid water should be applied. Top dress others with warmed soil as soon as the haulm is well through the soil. Look over the Potato-store, removing all diseased tubers, and rubbing off the sprouts from the remainder. The main crop sets should be spread out thinly on a floor, made secure from frost, and be kept cool.

Celery.—Make a sowing for the main crop in well-drained pans or boxes filled with a light porous compost, pressing the soil firmly, and sowing the seed evenly and thinly, just covering it with fine soil. Place the pans on a mild bottom-heat, covering them with sheets of glass or pieces of brown paper till germination has taken place, after which uncover and keep near the glass in a cooler place.

THE FLOWER GARDEN.

By J. C. Tallack, Gardener to E. Miller Mundy, Esq., Shipley Hall, Derby.

Gladiolus.—Where early flowering is desired, some of the corms should be planted forthwith. The Gladiolus of the Childsii and Lemoinei types being of good constitution, and consisting of beautiful varieties, should be largely planted, choosing solid middle-sized corms, these giving better results than very large ones; and this holds good of other types of Gladiolus. If the ground has not been dug in readiness for planting when the soil is in a friable condition, let it be dressed with farmyard or other rich manure in a decayed state, and dug deep enough to prevent the roots of the corms from coming immediately into contact with it. The Gladiolus suffers by being planted in heavy pasty soils, and where such exist they may be improved and rendered acceptable by the addition of sand, charred garden refuse, road grit, and sandy loam. A handful of sand should be placed under each corm on planting it. Draw drills for planting about 15 inches apart, and 3 to 4 inches deep, and set the bulbs at about 9 inches apart, and after covering them rake the plot over. If not planted in beds, groups of about ten bulbs may be planted among autumn-flowering herbaceous perennial plants, in which position the flower-spikes show to advantage.

Pæonies.—These, as I have pointed out in previous notes, resent disturbance, but they are of such a tufted nature that something must be done to relieve the crowding of the growths, and if half of each big clump be split off, and a big hole dug and partly filled with rich manure and soil, an improvement in growth and in the size of the flowers will take place. The best crowns (outside) of the split-off portions may be replanted in rich soil, and though the result for the first year may not be very good, the plants will grow in strength as time goes on. For naturalising in grass I have found the double forms of P. officinalis among the best for the purpose, and I would advise their abundant planting in the wild garden.

Anemone japonica. — This is another plant which should not be disturbed, and which often may be kept in good condition by splitting the clumps in half, taking away the older or central portion each year, and well manuring that which is left.

Echinopsis ruthenicus.—Dry seasons often affect old clumps of this plant badly, and plants should be raised from root-cuttings put into boxes of soil at this season, planting them out during the summer.

Solomon's Seal.—A position should be found for this plant on the banks of lakes and streams; and replanting should now be carried out. Cover the crowns 3 inches deep so that they have that much of soil to penetrate before reaching the surface.

Sweet Peas. — Though I have recommended sowing the seeds in flower-pots, this is not always feasible, nor is there any fear if sowings be made outside at the present time. An effective mode of growing Sweet Peas is to sow in rings of 4 feet in diameter, one variety in each ring. It is advisable to form a hollow in the centre of each ring in order to facilitate the application of water.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the Publisher.

Letters for Publication, *as well as specimens and plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Illustrations.—*The Editor will thankfully receive and select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.*

Local News.—*Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.*

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY, MAR. 7 { Société Française d'Horticulture de Londres Meeting. Surveyors' Institution (Junior) Meeting.

TUESDAY, MAR. 10 { Royal Horticultural Society's Committees Meeting, lecture on "Natural Selection *v.* Adaptation."

SATURDAY, MAR. 14 { Royal Botanic Society's Meeting.

SALES FOR THE WEEK.

MONDAY and FRIDAY NEXT—
Roses, Fruit Trees, Perennials, Plants, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.

WEDNESDAY, MARCH 11—
Azaleas, Palms, Liliums, Border Plants, Roses, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.—Established Orchids in Flower, specimen and smaller Palms, a fine importation of Japanese Iris, in named varieties, &c., at Stevens' Rooms, at 12.30.

THURSDAY, MARCH 12—
Absolute Clearance Sale of Nursery Stock at the Horsell Birch Nurseries, Horsell, near Woking, by order of Mr. Knowles, by Protheroe & Morris, at 12.

FRIDAY, MARCH 13—
Orchids in great variety, at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.30.

(For further particulars see our Advertisement columns.)

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick—42°.

ACTUAL TEMPERATURES:—
LONDON.—*March* 4 (6 P.M.): Max. 56°; Min. 38° Wind, W.; weather fine; rainfall none *March* 5 (Noon): rainy.
PROVINCES.—*March* 4 (6 P.M.): Max. 52°, Penzance; Min. 4°, Shetland.

Secret Commissions.

THE Bill proposed to be laid before Parliament for the purpose of putting a stop to corrupt practices in business, is calculated to stir up dirty water. Whether it will have other effects remains to be seen. The letter on the subject in the *Times*, which we subjoin, and purporting to come from a nurseryman, will infallibly tend in the same direction, and will lead some to doubt the wisdom of the proceeding. So long as human nature is what it is, say they, so long will these irregular proceedings be indulged in. No doubt that is true, but our inability to attain perfection should not and need not prevent us from making every reasonable attempt to lessen the evil, even if we cannot altogether abolish it. If we do not, the evil is bound to grow worse as competition becomes more severe.

But if we cannot abolish the custom of the trade, or, if from various reasons it is considered desirable not to do so, then let the custom be carried out openly and regularly, according to some recognised scale, and let not one firm endeavour to gain the advantage over another by breaking through the recognised custom.

On this account we welcome the appearance of the letter we have alluded to, and see in it the promise of one means for at least regulating the practice and diminishing its results. The evil being admitted, as we know it is, how is it that the leading firms do not come to some common understanding about it? We are not so Utopian as to suppose that there shall be no more "cakes and ale," even if the mighty ones of the commercial world should make an enactment to that effect. But common interests might, at any rate, lead to an understanding that the amount of the cake and the measure of the liquid should not exceed reasonable limits; and especially that secrecy and underhand proceedings should on no account be tolerated.

Of course, every one recognises the great difficulties there are in the way of improvement. One of the greatest is the impossibility of defining what is or what is not, legitimate on the side of the donor, and honourable on the side of the recipient. No arbitrary division can be laid down, and the matter must be left to the individual conscience and the influence of particular circumstances. To say that in all and every case, without reference to circumstances, it is wrong to offer a gift, and a dereliction from honesty to receive it, is to say what is unreasonable. But the consciences of individuals and their estimates of what is honourable and consistent with reason, may be quickened by association with others with similar interests, and that is why we suggest a meeting of the principal nurserymen and seedsmen to consider the question in all its bearings and to agree on some common action. They could not, of course, enforce their will upon others who chose to remain outside the convention, but these would soon find it to their interests to conform to the practice of the larger houses, as the public would soon find out what firms were likely to treat them most equitably.

Another and a very formidable difficulty is afforded by foreign competition. If "commissions" were to be abolished, or at least regulated here by common consent, what is to prevent our foreign neighbours from availing themselves of the opportunity of wresting the business from our own people by the offer of more liberal commissions? This is no fanciful danger—it is a real one, as we have seen from circulars brought under our notice bearing the names of well-known Dutch houses.

The case of the recipients must also not be left out of consideration. Even in bad cases, their offence against honesty is not so great, and more valid excuses may be made for them than in the case of the tempters.

The wages paid to capable men are in many cases quite inadequate in proportion to the responsibility, ability, and forethought that are required of a gardener. The difference between the payment meted out to the skilled gardener and the position he occupies, and the treatment which other officials on the same estate or household receive, is often apparent enough to anyone except the proprietor. As to the incompetent man, he is, of course, dear at any price, and should select some other avocation.

That the inadequately-paid skilled craftsman should be willing to accept a secret commission, or "agency," is no doubt lamentable, but is comparatively a venial matter, and one which a better education and a higher rate of remuneration would do much to restrain.

The following is the letter in the *Times* to which we have alluded:—

SECRET COMMISSIONS.

TO THE EDITOR OF THE "TIMES."

SIR,—I hope you will consider the enclosed letter of sufficient interest to justify me in asking you to print it. It comes from a leading firm of horticulturists which is in the habit of allowing 5 per cent. discount on all orders to customers, at the same time giving a commission of 5 per cent. to their gardeners. I have lately got a new man who will not accept commissions. I therefore wrote to the firm saying that I proposed in future to deduct 10 per cent. from their account. This, their answer, speaks for itself, and may, I think, revive the interest of the public in the Bill of the late Lord Russell of Killowen concerning secret commissions. Yours,

ERNEST DE LA RUE.

26, Belgrave Square, S.W., Feb. 23.

Feb. 16, 1903.

Sir,—We have your letter, and are very sorry indeed you did not mention the matter to which it refers to our Mr. —— when you were here. He would have been, and now is, quite prepared to speak quite frankly on this deplorable custom, to which we are forced to submit, and on the rights of which we think every right-minded person can have but one opinion.

We must, however, say there are many gardeners to whom we do not give presents, sometimes in obedience to the men themselves, more often in obedience to the wish of the employer.

Prices are fixed by competition and by the quality of the stock supplied, and these "presents" in no way affect such. We have always, and always do, decline orders when we are asked for a "present," which our published and fixed prices do not allow us to pay.

The tone of your letter leads us to think you may not realise how ingrained this custom is, or to what lengths it is notorious some firms go to seduce the loyalty of private servants, and if you would care to talk over the point, our Mr. —— will be only too glad. In the meantime, we beg you will believe we never have paid an improper commission, nor improperly attempted to obtain an order; and that there are gardeners who do not accept any present, and employers who do not permit presents in money to be made—though, on the other hand, there are employers who have no objection.

We cannot allow you more than 5 per cent. for cash payments, and will not send your gardener presents; and beg before you take away your custom, which Mr. —— will be very sorry indeed to lose, you will look at this question in all its bearings.

We are, Sir, your obedient servants,

. . . . . .

ROYAL HORTICULTURAL SOCIETY. — The next meeting of the Floral and Fruit Committees of the Royal Horticultral Society will take place on Tuesday, March 10, in the Drill Hall, Buckingham Gate, S.W., 1 to 4 P.M. A lecture on "Natural Selection *v.* Adaption," will be given by the Rev. Prof. G. HENSLOW, M.A., V.M.H., at 3 o'clock.

—— At a General Meeting of the Society held on Tuesday, February 24, 103 new Fellows were elected, amongst them being Baron Anthony de Worms, Sir John Dickson-Poynder, Bart., M.P., Lady Allen, Lady Cunliffe, Lady Constance Ryder, Lady Edwards, Lady Smyth, the Hon. Mrs. Chas. Trotter, and the Hon. Mrs.

Parry-Evans, making a total of 323 elected since the beginning of the present year.

—— Hyacinth and Tulip Prizes. At the Society's fortnightly exhibition on March 24, Special Prizes will be offered by the Royal Bulb-growing Society of Haarlem, for Hyacinths and Tulips as follows:—

120 Hyacinths in pots (one bulb in each pot), in not less than 40 varieties and not more than 3 pots of any one variety. *Open.* First Prize, £7. Second Prize, £5. Third Prize, £3.

100 pots of Tulips (three bulbs of one variety in each pot), to include 50 varieties at least and not more than 2 pots of any one variety. *Open.* First Prize, £4. Second Prize, £3. Third Prize, £2.

At least six days' notice must be given of intention to compete.

"The Horticultural Directory."—We have received a copy of this useful publication from the office of the *Journal of Horticulture*, 12, Mitre Court Chambers, Fleet Street, London. In addition to tables and notes useful to almost every one, this little publication contains a list of nurserymen and of gardeners in Great Britain, and a number of details of special interest to these classes of the community. A book like this lies on the Editor's table from year's end to year's end, which is the best testimonial that can be given as to its utility.

"One and All Gardening."—A "popular annual" that deserves its name, for the articles are good of their kind, always interesting, never dull, and sometimes surprising; for instance, we did not expect to find a portrait of Mr. Herbert Spencer in a garden annual, but there it is, and there is better reason for its insertion than for the intrusive mention of celebrities who happen to be fond of their gardens, but have otherwise no claim to be immortalised in garden periodicals.

More Open Spaces in London.—Two more lungs have just been added to the long list of those in the enjoyment of London. The first is a large extension of Brockwell Park, which will augment the area of that suburban retreat by one half. It has been acquired at a cost of £64,500, of which the London County Council has contributed £32,250, and adjacent Borough Councils the remainder. The second open space is to be known as Wandsworth Park, just by the Putney Bridge Road, the acquisition of which has cost some £33,000. This has a fine frontage to the road.

National Rose Society. — A meeting of the General Purposes Committee will be held at the Rooms of the Horticultural Club, Hotel Windsor, Victoria Street, Westminster, on Tuesday, the 10th inst., at 11.30 A.M., for the purpose of drawing up the schedule of prizes for the Temple Show. There will be no other meeting of the Committee during the present month. *Edward Mawley, Hon. Sec.*

Medicago arborea.—In the *Journal d'Agriculture Pratique*, M. Ed. Andre calls attention to this shrub, which he calls the Tree-Lucerne. It is a native of southern Italy and the Greek Archipelago, and has become naturalised in some parts of Provence. It is a plant which bears drought and a salt-laden atmosphere; it was therefore thought it would form a valuable forage plant in regions with a similar climate to that of the Mediterranean coast; this assumption is borne out by chemical analysis, which shows a percentage of nitrogenous substances of no less than 13·12. Fearing that possibly there might be some poisonous property in the forage, such as is known to occur in some other Leguminous plants, experiments were made cautiously in feeding animals with it, with the result that, while the forage proved acceptable to the animals, no harm accrued from its use. M. Anré then considers himself justified in recommending the cultivation of the Tree-Lucerne as a forage plant, and gives some details relating to its cultivation and propagation. It should be cut in spring, as soon as the foliage is fully developed, and a second crop may be obtained later on.

A New Rubber-producing Plant.—M. E. de Wildeman describes in the *Comptes Rendus*, 1902, p. 400, a new species of Clitandra (Apocynaceæ), from the Congo. The species is called C. Arnoldiana, and the caoutchouc is obtained by boiling the latex or milky juice with water.

Gardening Studentship.—Mr. John Ettle, F.R.H.S., County Instructor in Gardening, states that the Somerset County Education Committee has founded a gardening studentship of the value of £35, to be tenable for one year at the Bickenhall Experimental Farm, near Taunton. It is open to pupils in the Continuation School gardens, and has been won this year by Mr. Ernest Shearn, who was first-prize winner in 1901-2, at the Paulton centre. There will be, this year, school gardens in sixteen centres, with about 220 pupils.

"Etudes sur la Flore de Katanga."—This is one of the publications published under the auspices of the Government of the Congo. The author is M. Em. de Wildeman, whose name affords a guarantee for accuracy and judgment. Katanga is in the S.E. of the Congo State, and its flora is therefore like that of the country around the great lakes, that of Eastern tropical Africa, and to a less extent that of the south of the basin of the Nile, Mozambique, and Zambesi. It has less relationship to the vegetation of West tropical Africa or of the Central Congo. The collections of M. Verdick contain a large number of novelties, which are described by M. de Wildeman or M. Durand, who have been assisted in the determination of some of the plants by the officials of the Berlin Herbarium. Many of the plants are illustrated by 4to lithographic plates, beautifully executed, and with full details, for which the botanist will be thankful. None of the plants in the present fascicle is of special horticultural interest.

The Surveyors' Institution. — At the ordinary general meeting, held on Monday, February 23, 1903, the President (Mr. Arthur Vernon) in the chair, a paper was read by Mr. Henry Lovegrove (Fellow) entitled "Regulations for Protection from Fire." A discussion followed and was concluded. The next ordinary general meeting will be held in the lecture-hall of the Institution on Monday, March 9, 1903, when a paper will be read by Sir John G. Barton, C.B. (Fellow), Commissioner of Valuation for Ireland, entitled "Valuation for Rating in Ireland."

Passmore Edwards' Settlement, Tavistock Place, W.C.—An address with lantern illustrations will be given at the Settlement by Wilfred Mark Webb, F.L.S., dealing with "Nature-Study, and what the Schools are doing," on Saturday, March 7, 1903, at 8 P.M., admission free. Teachers are specially invited. The following is a synopsis of the Address:—(1) As a part of educational groundwork; (2) As a preparation for a scientific training; (3) As a resource for leisure hours. The origin of modern Nature-study; its advantages — educational and economic—the facts upon which it depends—methods and means of Nature-studies.

The Hammersmith Industrial Exhibition Society.—In connection with the 17th annual Exhibition of Arts, Crafts, and Industries, which will be opened on May 4, 1903, in the Town Hall, by H.R.H. the Duchess of Argyll, a special "Nature-study" section has been organised. This section has been organised by W. Mark Webb, F.L.S. Information in regard to definite exhibits will be afforded by Miss Yeldham, hon. secretary, 12, Luxemburg Gardens, Brook Green.

Charlock.—Mr. Strawson's report for 1902 shows that the Charlock can be destroyed at any period of its growth by copper sulphate, and that whilst the plant is young and soft of fibre, a smaller quantity will effect the purpose than when the plant is older. Fifty gallons of 3 per cent. solution favourably applied to young plants will destroy 95 per cent. of the weed in an average infested crop; in fact, it will destroy all except those few plants that are shaded by other leaves from the spray, and this quantity and strength will affect the corn crops so slightly, that an increased yield of corn more than sufficient to pay all the expenses of spraying may with confidence be looked for. On the other hand, if the weed is sprayed when much older, more copper is required, and this gives a shock to the corn-plant which prevents the likelihood of any material increase in the yield, besides which it must be remembered that the older the weed the more it has robbed the soil, and shaded the corn from the sun. It may be permissible to suggest that those farmers (and there are hundreds of such) that now know from experience the benefit of this work, could do much good to their neighbours by showing them the results on crops that have been sprayed under favourable conditions. In order to exhibit the striking effect of spraying, a breadth of the weed should be left unsprayed in each field, or perhaps better, keep some plots unsprayed by covering them at the time with a sheet or old bags. Neighbouring farmers visiting these fields a week afterwards would then have an opportunity of seeing in well defined contrast the difference between sprayed and unsprayed crops. For successful working the chief points to remember are:—To have everything in readiness well beforehand, and the labourer trained so that it is only necessary to give the order to start when the weather is fine; the material must be pure and correctly measured, and the spray fine so as to cover every plant. Successful spraying should result in average increase in yield of corn from four to six bushels per acre, and the destruction of 95 per cent. of Charlock; but when the weed is in dense mats, one plant overlapping another, a smaller proportion will be killed, but the increased yield of corn will be greater. At the present time I see no reason to alter the main conclusions arrived at in 1901. They have been thoroughly corroborated by extensive experience in 1902, and with slight additions, are as follows:—1, That Charlock can be destroyed in growing corn crops without injury to the latter, by spraying with 50 gallons of 3 per cent. solution of pure sulphate of copper per acre. 2, That generally the corn crops are much improved and give a better yield where Charlock is destroyed, and that young grass-seeds and Clover in the corn remain uninjured. 3, That spraying early when the weed is young and in soft fibre, is most successful. 4, That the larger sprayers with powerful pumps are more successful than the smaller machines. 5, The profit of the operation is diminished in proportion to the delay which occurs after the Charlock is in the most suitable condition for being destroyed. 6, That the increased yield of corn by the destruction of Charlock leaves a profit, after all the expenses of spraying have been defrayed, and that the annual value of all Charlock-infested land will increase until the extermination of the weed is complete.

Flowering of the Victoria Regia.—According to the report of M. Fischer de Waldheim, the Victoria Regia in the Imperial Botanic Garden at St. Petersburg, flowered last year less abundantly than usually. Nevertheless the two specimens produced forty-two flowers; in early June they had put forth three flowers, by

the end of the month nineteen, in July ten, in August eight, and in September two. A considerable amount of seed was collected, so that the Garden was able to distribute some. Many other large gardens had no seed to exchange, owing to the weak growth made by the Victoria last year. Experiments made with regard to the germination of the seed gathered in the Garden proved that a heightened temperature was favourable to it. Thus, of a hundred seed sown on January 20, and cultivated in a temperature of 84° to 92° F., seven germinated in thirty-nine days. Of a hundred sown in a temperature 92° to 99·5° F., twenty-five seeds germinated in the same period of time.

FOOD OF PLANTS.—In the course of an address on "Educational Science," Professor ARMSTRONG, V.P.R.S., spoke of the importance of a sound knowledge of the preparation of food in the household, and made the following interesting reference to the food of plants:—"Could we find tongues in trees we should doubtless find them eloquent on the subject of food supply, and far more delicate in their tastes than any mortals. But how many of us, looking at a green leaf, can in any way call to mind the wonderful mechanism which enables the plant to secure the main bulk of its solid substance from the fleeting stores in the atmosphere; or the manner in which it is dependent on light; or its mineral needs; or its great need of water, and its wonderful transpiratory activity? And yet the chief industry of the world is agriculture—the feeding and tending of plants. At least, those who lead a rural life should have their imagination excited on such subjects at school; it is even possible that much of the asserted dulness of country life might pass away if an interest in plant activity were properly cultivated. And schoolmasters might even find comfort in the reflection that, as Messrs. BROWN and ESCOMBE have recently shown, the translocation of the material first formed in the leaves, metabolism and growth are become so intimately correlated that the perfect working of the entire plant is only possible in an atmosphere containing the normal amount of three parts of carbon dioxide per ten-thousand; they might recognise in the plant an organism after their own heart, with ripened conservative instincts, and unwilling to accept any other than the limited diet long favoured by the craft."

"THE QUEENSLAND FLORA."—The sixth and concluding part of Mr. F. MANSON BAILEY's *Queensland Flora*, extending from the Alismaceæ to the Ferns, with appendix and index, has lately reached us. In plan it follows the other colonial floras, but with such slight modifications as circumstances rendered necessary, and with the addition of eighty-eight lithographed plates, which add considerably to its value. The *Flora* is not only valuable in itself, but also by reason of the proximity to New Guinea. The Flora of Queensland is thus intermediate, as it were, between the Malayan Flora and that of Australia proper. Reference is made in the appendix to Mr. BRITTEN's *Illustrated Botany of Captain Cook's First Voyage*, recently rescued from oblivion. Much pains have been taken also to collect the names of plants as employed by the aborigines, and to give information concerning the uses of plants. A most substantial and valuable addition to systematic and geographical botany has thus been made, for which botanists will feel grateful to Mr. BAILEY, whilst those concerned in the development of the resources of the colony will also have cause to be thankful for the patient labour and judgment of the colonial botanist.

PALMS.—M. BARBOSA RODRIGUES, the Director of the Botanic Garden, Rio de Janeiro, is about to publish a work entitled *Sertum Palmarum Brasiliensium*. This is to consist of descriptions of no fewer than 174 new species of Palms, detected by the author in the course of his journeys in the forests of Brazil, Peru, Bolivia, Paraguay, and the Argentine Republic. The text is to be in Latin and in French, and is to be accompanied by 174 imperial folio coloured plates, from original drawings made by the author, in addition to woodcuts. In addition to the strictly botanical details, information is to be given concerning the utility, geographical distribution, and the native names of all Palms occurring in Brazil, with a bibliographical record and ample synonymy. The book is to be "got up" in the finest style by Belgian printers and lithographers, and is limited to 300 copies A specimen copy before us shows that the work will be one of the most important illustrated works ever issued. It is intended as a continuation of VON MARTIUS' famous *Historia Palmarum*. Intending subscribers should apply to MM. DULAU & Co., publishers, 37, Soho Square. The subscription price for the two volumes is 500 francs (£20).

THE IMPORTATION OF GERMAN SEEDS TO N. ZEALAND.—As marking the growing importance of the trade of Germany in the matter of seeds, we learn from *Thalacker's Allgemeine Samen und Pflanzen Offerte*, that in the year 1900, Germany exported seeds to the value of £1,042 sterling, and in 1901 of £5,302, to New Zealand.

MARKET PRICES IN DURBAN.—It may be interesting to some of our readers to note the latest prices of fruit and vegetables at Durban, which are as follows:—Apricots, 2*s.* 6*d.* per 100; Apples, 2*s.* 6*d.* to 4*s.* 9*d.* per 100; Bananas, 2*s.* per 100; Cabbages and Cauliflowers 3*s.* 6*d.* to 5*s.* 6*d.* doz.; Grapes, 3*d.* to 6*d.* lb.; ground nuts, 5*s.* 6*d.* per sack; Lemons, 5*s.* 6*d.* to 11*s.* 6*d.* per 100; Lettuces, 1*s.*, and Limes 1*s.* 6*d.* to 2*s.* per dozen; Onions, 20*s.* per bag; Oranges, 7*s.* 6*d.* to 10*s.* per 100; Green Peas, 4*s.* 6*d.* per basket; and Pineapples, 1*s.* to 1*s.* 6*d.* per dozen.

THE NURSERY AND SEED TRADE ASSOCIATION, LIMITED.—The annual general meeting of this Association was held at the offices of the Association, 30, Wood Street, Cheapside, London, on the 24th ult., the President, N. N. SHERWOOD, Esq., in the chair. The report of the Association for 1902, which was presented to the meeting, showed that 956 status enquiries had been made for members during the year, and debts amounting to £4,269, which the members had been unable to collect, were collected by the Association on their behalf. Twenty-one members joined the Association during 1902.

PRESENTATION.—Mr. ALFRED CHAS. WOOD, head gardener at East Garth, Westoe, South Shields, completed his twenty-one years' service on February 14 last, and Mrs. ELTRINGHAM and family presented him with a gold hunting watch having a suitable inscription. Mr. A. C. WOOD has also been twenty-one years on the Staging Committee of the South Shields and Northern Counties Chrysanthemum Society. He is well known, highly respected, and comes of an old gardening family, his father having been for many years head gardener to the late Lord RAVENSWORTH at Fulham, S.W.

THE GALE.—We learn from Dublin that the hurricane on Thursday night, February 26, was very disastrous. Gardens, parks, woods, and buildings suffered severely, and many thousands of trees were uprooted. It was the worst storm of the kind in Ireland since that of 1839.

GRAHAME MEMORIAL FUND.—It has been very widely felt amongst rosarians and others that the remarkable services to Rose-culture of the late Mr. C. J. GRAHAME ought to be commemorated by some adequate memorial. Mr. GRAHAME's services to horticulture in general, and to the National Rose Society in particular, were of no ordinary kind. He was an enthusiastic lover and grower of flowers; he was one of the best and most appreciative of judges, especially of Roses; he was always ready to help any flower show with his accustomed liberality; and his gifts include a beautiful Challenge Cup for the smaller growers at the National Rose Society. But his special service was the establishment, after much contest, in which at first he was almost single-handed, of the present system of classes at the National Rose Society's exhibitions, according to the number of varieties grown, which in 1892 for the first time gave the smaller growers an adequate chance in the competition. The great value of this reform is now undoubted, and has been generously acknowledged by those who at first opposed it. If it were for this reason only, there ought to be some memorial of him; but Mr. Grahame's friends were so numerous and so warmly attached to him, that we cannot doubt that an opportunity of the present kind will be very widely welcomed. Subscriptions are earnestly requested as speedily as possible, much time having been already lost. They should be sent to Captain RAMSAY, Yvery House, Fareham, Hants. Cheques should be crossed "Capital and Counties Bank."—JOHN RAMSAY, Yvery House, Fareham, Treasurer; G. E. JEANS, Shorwell Vicarage, I.W., Secretary.

BELVOIR CASTLE:

THE STATUARY GARDEN.

(*Continued from p.* 121.)

[SUPPLEMENTARY ILLUSTRATION].

THE present illustration represents the Statuary Garden, which is situated near the one previously figured, but some 40 feet below it, and a fine view of it is obtained from the top of the bank. The plants shown in the beds here comprise Abutilon Thompsonianum, Ricinus Gibsoni, Veronica Andersoniana variegata, Dactylis glomerata elegantissima, Stipa glauca, Antirrhinum Black Prince, variegated Maize, Tropæolum hederæfolium, Violas, Calceolarias, &c. The group of Palms shown in the centre consists of five large specimens of Trachycarpus excelsa (Chamærops), 9½ feet high, received from Italy in August, 1899, which have survived the last three winters with a little protection from mats during hard weather; and since they were planted they have produced ripe seeds from which plants have been raised. The white mass in the distance is a tree of Acer Negundo foliis variegatum, and behind it are two very fine specimens of Spruce Fir, Picea excelsa, the one on the left is 120 feet high, and 8 feet 7 inches in circumference of stem.* The six statues are of life size, were carved by Caius Gabriel Cibber, in 1680, and the agreement between him and John, 8th Earl of Rutland, is preserved in the Castle. It stipulates that the statues should be set up in the garden for the sum of thirty-five pounds each, the Earl to find the said Cibber and two of his "workemen diett and lodging at Bellvoyer whilest he workes upon the said statues," and to pay for the carriage of the stone, and that they should be of Ketton stone. They are in excellent preservation, and represent Juno, Ceres, Flora, Bacchus, Pomona, and Diana. Another larger one on the top of the bank close by, represents Winter, and belongs to the same set. The flower-beds in this garden were laid out in their present form by Challis, who was head gardener here in 1847.

Below the Castle on the south side, is a series of terraces at varying heights, the soil of which is retained in position by massive stone walls; these are probably the same "hanging gardens" referred to in some verses written in 1679, although nothing remains now to indicate so great an age; the walls are well

* To prevent repetition, all circumferences of stems mentioned are taken three feet from the surface of the ground.

covered with Magnolia grandiflora and M. Soulangeana, Grape-vines, Banksian and other Roses, Chimonanthus præcox, Jasminums in variety, Photinia serrulata, Azara microphylla, Abutilon vitæfolium, Rhus Toxicodendron, Forsythia suspensa, Escallonias, Honeysuckle, Muehlenbeckia complexa, Punica Granatum, Buddleia globosa, &c., many of which are very large specimens.

On a grassy bank below is a fine tree of Cupressus Lawsoniana, planted in 1866 by his Majesty the King when Prince of Wales. It is now 43 feet high and 3 feet 5 inches in circumference of stem. There are also several smaller specimens, planted by other members of the Royal Family. Close by are various plants brought from the south of France by the present Duke. Photinia japonica (Eriobotrya) is now 6 feet high, and it is protected by bracken in severe weather; a plant of Choisya ternata, 5½ feet high and 8 feet across, which flowers freely every year, and receives no protection; some fine plants of Cistus salvifolius, Erica mediterranea, &c. On a lower walk, a plant of Arbutus andrachne deserves to be mentioned; also one of Leptospermum scoparium, which proves hardy here, and flowers freely. A conspicuous object for some distance is a column of Ivy, 59 feet high; this covers the stem of an old Scotch Fir, which lost its top in a gale early in 1894. *W. H. Divers.*

(To be continued.)

HOME CORRESPONDENCE.

ROYAL HORTICULTURAL SOCIETY.—In your report of the Annual General Meeting of this Society, published by you on the 14th inst., the chairman, Sir Trevor Lawrence, is reported to have said: "He had had frequent conferences with members of the Botanic Society, and he found that any amalgamation would be financially impossible. The Botanic was deeply in debt." He then goes on: "He did not wish to say anything against the Botanic Society or any other society, but the Botanic Society had taken to methods of raising money which were different to those followed by the Royal Horticultural Society. They had taken to clubs, bazaars, and dances, and things of that sort—useful and amusing no doubt in their way; but they were not horticulture, and the very worst thing the Royal Horticultural Society could possibly do would be to associate themselves with the Botanic." As regards the "frequent conferences" to which the Chairman refers, the only official communication made to the Horticultural Society by the Botanic Society was in the letter of Lord Lister, dated December 4, 1901. In that letter was enclosed a copy of a resolution passed by the Council, "that a communication be sent to the Royal Horticultural Society inviting that Society to hold some or all of their shows in the gardens or buildings of the Botanic Society, and assuring them that co-operation between the two societies, with a view to advance the interests of horticulture, is greatly desired by the Royal Botanic Society." His Lordship then went on to recount some of the unique advantages possessed by the gardens of the Botanic, but that amalgamation was ever contemplated is absolutely a new idea to the Council. The statement that the Botanic was "deeply in debt" is absolutely incorrect, and is calculated to injure that Society. It is perfectly true that the Society has not freed itself from its debenture debt, and it never intends to do so until they are honourably paid in full, for which purpose it has started a reserve fund. That the new lease secured to the Society upon most favourable terms, together with the increased income of the Society, has placed it in an excellent and improving position. The Chairman expresses a wish not to say anything against the Botanic Society, and immediately proceeds to do so, objecting to the methods of raising money which were different to those followed by the Royal Horticultural Society. Those who remember the circumstances of the old Horticultural Society, will not be sorry that the methods are different, and the objection that we have taken to clubs, bazaars, and dances as not horticulture, causes one to read with interest the announcement on the site of the proposed Hall to be erected by the Horticultural Society in Vincent Square, Westminster, which is as follows:—"The Society proposes to use the new Hall for Public Exhibition, Concerts, Meetings, and Entertainments of the like kind, and will apply to the London County Council for a license for music and dancing." This, of course, is horticulture! As regards the statement that the Horticultural had not succeeded in securing a portion of one of the Royal Parks for the purposes of their Society, if there was ever any fear of such a grave misuse of a public park, the public may be congratulated that that fear is at an end. I can quite understand that the Royal Botanic Society is a serious rival, with its many natural advantages to a Society largely depending upon the promised attraction of its proposed Hall in Westminster, including its Music and Dancing License, but I venture to assert that this does not justify such grave inaccuracies on the part of the Chairman, and I am sure I need only appeal to your sense of fairness to secure like publicity to my communication in reply. *John Hutton, Chairman Finance Committee, Royal Botanic Society, Regent's Park, Feb. 26, 1903.*"

GINSENG.—Will any of your correspondents who may have had some experience in the cultivation of Ginseng, kindly give me some information as to the best methods adopted for the cultivation of this plant? A young farmer friend of mine, just home from an eighteen months' run through parts of Canada and the United States, seeing the rich soil of my place here, said he thought I might be able to grow Ginseng. In New York State the plants have to be shaded from the sun; if once the plants get "sunstroke," he understood the people to say, these plants would do no more good, but as we have much less sunshine here than where he saw it growing in America, in his opinion, it might succeed in this country. When successfully grown, the cultivation of Ginseng is exceedingly profitable. My friend related to me an instance of a family, who, through some misfortune, have about lost their all; but they had on their farm a good breadth of Ginseng, which, when sold, yielded sufficient to tide them over their difficulty. The market for the root is found amongst the Chinese, who eat pieces of the root when they are weary or exhausted through overwork. It acts as a stimulant, and perhaps a far more wholesome one than tea, beer, whiskey, or other drinks we, in this country, fly to. Ginseng was made known to Thornton, who describes its medical virtues in his *Family Herbal*, from which I quote the following:—"Jartoux, speaking of the effect of the plant on him, says, 'I observed the state of my pulse, and then took half a root raw; in an hour I found my pulse much quicker and fuller. I had an appetite, and found myself much more vigorous, and I could bear labour much better and easier than before. But I did not rely on this trial alone, imagining that this alteration might proceed from the rest we had that day; but four days after, finding myself so fatigued and weary that I could scarce sit on horseback, a mandarin who was in company with us perceiving it, gave me one of these roots. I took half of it immediately, and an hour after I was not the least sensible of any weariness. I have often made use of it since, and always with the same success'" (*Phil. Trans.*, vol. xxviii., p. 239). Thornton gives the Latin name of Ginseng, Panax quinquefolium. *W. Miller, Berkswell House.*

A PROLIFIC POTATO.—The firm of Messrs. Sutton & Sons, of Reading, noted for the fine Potatos they have raised, have made a notable discovery among a batch of seedlings raised in 1899 of a variety that seems in productiveness to exceed in cropping capacity any variety hitherto brought out, and not unnaturally they have named the variety "Discovery." In the early spring of 1899, this remarkable Potato was represented by a single tiny set, and in the autumn of that year by a single plant. In the autumn of last year, 1902, just three years from the lifting of that one root, the stock has grown into some 80 bushels—truly an enormous increase, and one that is probably unexampled, and consisting throughout of tubers fit for consumption, and of good size, not of gigantic Bovinias, or huge, ungainly tubers, fit only for cattle food. The tubers of Discovery are partly round, partly pebble-shaped. I have seen the stock, and like its appearance greatly. The variety is even yet regarded by the firm, in spite of its being a couple of tons, as a very "limited" stock. That is quite correct from their point of view, as it will not be until they can hold from 50 to 100 tons that they will think they have an ample stock. Only last autumn they had to send out to South Africa the enormous quantity of 240,000 cases of medium dimensions of Potato tubers, all hand-picked, for planting there; whilst the ordinary South African orders are always heavy ones, and have to be got away in the autumn. It is so interesting to find that the south has been active in Potato production as well as the north. Probably some Northerners will say, "Wait until you see our great new one from Markinch." I am sure we should be delighted to see both at Chiswick this summer. *A. D.*

GRAFTING THE PEAR ON THE QUINCE.—Recently, I put two scions of Pears on Quince stocks by the fishing-rod method, and covered them with the indiarubber tape that electrical engineers use for making joints. I began whip-grafting thirty years ago, but gave it up long ago for slip-and-tongue. This is the third year I have used the method; it is easier than any other, and answers admirably when the stock is not much larger than the scion. If a tie is put round both stock and graft before the graft is pressed down into its place, the tie is tightened by the pressure used in forcing the graft down, so that contact of the bark is perfect at the top and bottom. The indiarubber tape is cut to the length required to exclude the air, warmed in the pocket, stretched a little, and wound round the stock and graft, beginning at the bottom, and one drop of bicycle solution secures it. Matting is tied loosely around the indiarubber. *Henry Rogers, Hartley, Plymouth.*

BANANAS HOME-GROWN.—At this time of the year, when dessert fruit is somewhat scarce, home-grown Bananas make a welcome change. We have a large house devoted to them, and for the past three months, six plants have borne fruits vastly superior to any that are imported. These plants are planted in round tubs 30 inches in diameter, round the top of which, as soon as the bunch is fully developed, a sheet of zinc about 12 inches wide is placed on the inner side so as to allow them to be more liberally treated. When I was at Sandringham, the late Mr. Penny, then head gardener to the Prince of Wales, used to grow Banana plants successfully at the ends of the Pine-stoves in tubs. From the time a sucker is taken from an old plant till fruit is formed, is about eighteen months or a little more; there are advantages and the contrary in this method. At Paddockhurst we cultivate twelve plants on a stage measuring 17 feet in length by 7 feet in width. In tubs the plants are under more complete control as to feeding and soil, &c., than when in beds; the bunches are perhaps not so large, but about one hundred fruits or more grow on a bunch. *A. B. Wadds, gr., Paddockhurst, Sussex.*

BEGONIA GLOIRE DE SCEAUX.—I was very much struck, when going through the gardens at Park Hatch, Godalming, the other day, to see a very fine display of this handsome Begonia. The plants occupied the entire side of a lean-to house, and certainly the large trusses of rosy-pink flowers, set off by the handsome bronzy metallic foliage, presented a remarkable sight. *W. H. Bailey, Oxshott.*

FRUIT-ROOM.—I think if "Subscriber" has any quantity of Apples and Pears to store, he would find it rather expensive to build a room where the fruit could lay singly on stone slabs. Most gardeners agree in excluding light as much as possible, and in preventing much fluctuations of temperature. For this reason, I think there is nothing better than a thatched building, and it is of very simple construction—just the framework of wood, and then a thatch of reeds or straw on the top, and sides a foot or 18 inches thick,

with a thatched framework to fit over the door in hard weather. It can be fitted inside with shelves or trays; but where the quantity of fruit to be stored is very large, I have found that Apples will keep quite as well in half-bushel baskets about three-parts filled, and stood one on top of the other, and in this way I have kept them till the end of April. *H. Du Rose, Stanwell Moor.*

THE SEASON.—The past month has been the mildest for the last twenty-four years. The day (maximum shade) temperature for the month averaged 50°, which is 5° above the London averages, and no less than 15° above the exceptionally cold February of 1895. Five gales blew during the month, but without any bad effects except to newly-planted trees. Apricot blossom is remarkably fine this year, and well distributed over the trees, even on north walls, and on standards in the open. I have never seen finer blossoms or more of them, and this notwithstanding the sunless summer of 1902. The season is about three weeks "forward" compared with recent seasons, most of which have been late. I gathered Tulipa Kaufmanniana fully expanded in the open border on February 25. Japanese and other Oriental Acers are dangerously advanced; and some are already in leaf. *A. Worsley, Isleworth.*

SECTIONAL BOILERS.—Noticing your remarks about sectional boilers for garden purposes, I am surprised that they are not more in use in private gardens. I do not know what kind Mr. Wilson has at Chevet Park, but I have had fixed here two horizontal tubular boilers, working over 8,000 feet of 4-inch piping. These boilers have been substituted for two Trentham boilers of 10 feet and 11 ft. in length, which I believe never gave satisfaction, owing probably to bad setting. These sectional boilers were fixed in position with very little trouble, not much brickwork being required, and no machinery for lowering them into the stoke-hole. Every piece was handed to the fitter by his assistant, and they were fixed for a little more than half what one Trentham would cost, and the saving of fuel is very considerable. They are no trouble to stoke; the fires can be banked up early in the evening, with the certainty of having the proper degree of heat in the houses in the early morning. The pressure here is about 20 feet, and for a boiler to work under that amount of pressure I can recommend this kind of boiler. I should be pleased to show them to anyone, or afford particulars concerning their working. *J. Hill, Ruxley Gardens, Claygate, Surrey.*

CALANTHE VEITCHI.—I did not enter into full cultural details of the above Orchid in my note a fortnight ago, as Mr. Fulford had done so a few weeks previously. I ought perhaps to have been more explicit as regards the kind of structure our plants are grown in. Our Melon and Pine-range is in reality more of a pit than a house. It is span roof, runs east and west, the path up the centre is sunk 6 inches below the ground level; the width of the pits is 15 feet, and the height from the path to the ridge is but 6½ feet. The pots are stood on wooden trellises or pieces of slate placed on top of the bottom heating materials for the Melons, which consists of Oak and Spanish Chestnut-leaves, with the usual hot-water pipes beneath them. This leaves the plants about 2½ feet from the glass roof, and they are placed on either side of the walk, and are moved from one division to another as the Melon-plants become dense in foliage, though at times for want of space they perhaps remain there a bit longer than is good for them; still, many of the flower-spikes, and it is quite safe to say the majority, carry from thirty-five to forty blooms each, and many of the pseudo-bulbs carry two flower-spikes. Our plants are usually potted the second or third week in March, placing one in a 5½-inch pot, or three in a 6½ or 7-inch pot, according to the size of the pseudo-bulbs. *J. Mayne, Bicton.*

PHEASANTS AND CROCUS-CORMS.—I am astonished that none of your correspondents have recommended coating the bulbs of Crocus, Tulips, Narcissi, and other bulbs, with red-lead; doing this will effectively keep pheasants and other depredators from interfering with them. First

F.G. 62. OAKS FROM CHATSWORTH.

spread out the bulbs and corms in shallow boxes or trays, drop a little Olive oil on them, and then gently shake them, in order to coat them with the oil; now shake a little of the red-lead over them, and gently shake them again, so that each bulb becomes coated. I venture to say that neither pheasant, mouse, or bird of any kind will interfere with them. I also adopt this plan with most kinds of seeds. With regard to the Quassia-chip extract, it is excellent. We could not possibly keep a single Crocus in the turf or beds here until I syringed them with the extract. Both pheasants and hares had molested the Crocuses. Of course, heavy rains will wash the bitterness away, and repeated syringings will be necessary in rainy weather. One more remedy I may call

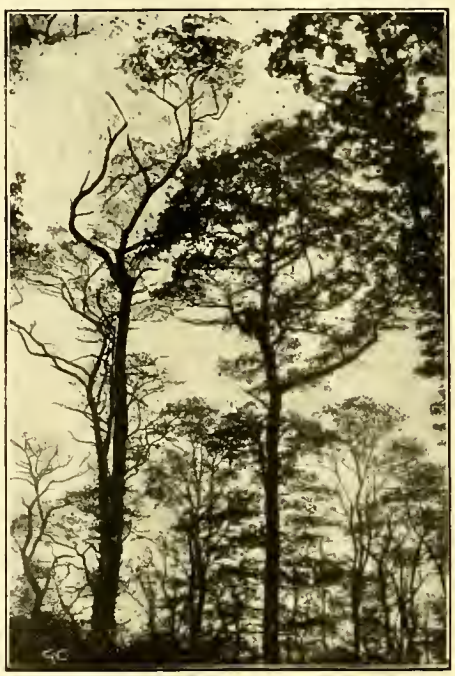

FIG. 63.—OAKS FROM CHATSWORTH

attention to, viz., gas-water. If a few gallons of clear water be placed in a vessel containing a small quantity of gas-tar, and after this has stood on the tar a few days, and then skimmed off carefully, taking care not to disturb the tar, and further diluted with water, so that it is not too strong, and the bulbs or their leaves are syringed with it, no hares or pheasants will go near them, and I know of nothing better for preventing the birds from molesting fruit-buds. I have also mixed the Quassia-mixture with the tar-water. The tar causes the water to adhere to the trees more firmly than it otherwise would, and is not so easily washed away by rain. I hope these few hints may be useful to those troubled with pheasants and other birds, hares, &c. *Thomas Arnold.*

A TWIN-FLOWERED ABUTILON.—I have forwarded you an Abutilon with two flowers on one stalk. I do not know if it often comes like that, as I have never seen one before. I should like to hear through your paper, as I am a *Constant Reader.* [We never saw such a case before in Abutilon. ED.].

PEAS AND NITRATE OF SODA.—Having read Mr. Slade's interesting remarks on Peas in the last issue of the *Gardeners' Chronicle*, may I be allowed to make a few remarks upon the subject. My experience with Gradus has been similar to his. I tried it for several seasons in the hope that it would prove what it was advertised to be, but every year my expectations were disappointed. As a main crop Pea, Yorkshire Hero cannot be excelled if the season be dry. Dr. McLean is also an excellent variety. In regard to the effect of nitrate of soda upon the yield of Peas, I find that this manure does not improve the crop of Peas in the least in a season like that of 1902. I applied nitrate to several rows of Peas last spring, and the only difference noted was that the haulm grew 2 or 3 feet higher than in the case of varieties not afforded nitrate of soda. On the other hand, last season was an ideal one for Peas to which basic slag three-quarters, and kainit one-quarter, were applied the previous winter. *J. Murray, Sopley, Christchurch.*

SESSILE AND PEDUNCULATE OAKS.

ON September 22, 1900, a paper of mine appeared in the *Gardeners' Chronicle* on "Oecological, or adapted, differences between the sessile and pedunculate Oaks," in which I attempted to show the reasons why the former thrives on drier soils than the latter. I explained that in the sessile Oak, the leaves being on long petioles, did not absorb much water from the twigs of the tree, and that owing to their leathery nature, they did not part with their water so readily; while the bark of this tree is harder and thicker than that of the sessile Oak, and especially its bast more abundant, containing more tannin.

As regards the acorns of the two Oaks, that of the sessile Oak is close to the twig, where it obtains water more readily, and is sheltered by the foliage from the heat and excessive transpiration; the acorn of the pedunculate Oak is on a long peduncle, and thus comes beyond the leaves into the sunshine, so that it can mature more readily in the damper air where the pedunculate Oak thrives, the sessile Oak getting more heat on hillsides, and its acorn consequently requiring more shelter from the foliage.

The ramification of the trees is similarly adapted to their requirements, that of the pedunculate Oak being much more open, and admitting sunlight to all parts of the tree and to the ground, which, in its proper habitat, being very moist, is not exposed to desiccation so readily as the drier soil below the sessile Oak. The latter, on the contrary, produces a much denser crown of thick, dark green, coriaceous leaves, the comparative weights of sessile and pedunculate Oak-leaves being as 34 : 40 for leaves of equal surface (Mathieu). I also referred to the Turkey Oak

(Quercus Cerris) as having the same properties as the sessile Oak, but in a more marked degree, hard leaves on petioles, a shady crown, acorns sheltered by bracts on their cups, the latter covering the seed in the first year, for they take two years to mature, and are situated when mature on the thick twigs of two-year-old wood, where their water-supply is assured, in spite of the dry hot climates of Greece and Turkey, where they are indigenous.

Although these facts have long been recognised by European foresters, they do not seem to have met with much favour from your readers, many of whom criticised my paper severely, saying that my plates showed abortive acorns, the fact being that the acorns were young, picked in August from the Chatsworth woods. One critic also stated that no one would think of growing any Oaks on comparatively dry, sandy soil, the fact being that, given sufficient moisture and depth, Oaks will thrive on very sandy soil. I also made an undoubted mistake in stating that the Chatsworth Oaks were growing on mountain limestone, as the rock was millstone grit. That circumstance, however, is in support of my case, as the millstone grit on Derbyshire hills gives a dry, well-drained soil, which is only rendered moderately moist by the heavy rainfall of the Peak district.

As regards the facts on which I based my inferences that all the Chatsworth pedunculate Oaks are stag-headed and dying (fig. 64), while the equal aged sessile Oaks growing with them on hillsides on the millstone grit are flourishing, Mr. J. P. Robertson, the forester of the Chatsworth estate, has confirmed this in the most striking manner. He has sent me three photographs of these Oaks, which I enclose, and in every case the defective Oaks are pedunculate, and the flourishing Oaks sessile; and he has written to me as follows :—

"The sessile Oak (fig. 62) is indicated in the photographs by a white patch near the base of the tree. I am more convinced every day of the advantage of using this variety on light soils. In the wood from which these photos were taken—a very light soil on the millstone grit, altitude 750 to 900 feet, I have carefully compared the sessile with the pedunculate variety, and find the former average nearly one-third more in cubical content. There is a good sprinkling of the sessile, every one being in robust health; while the pedunculate variety is going fast. Indeed, last winter we cut over 600 trees of the latter variety that were back-going, and the fall did not include a single sessile Oak, showing very clearly the advantage of using this variety on light soils. I think it is time that nurserymen should recognise the need of growing each variety separately."

It is a pity that Mr. Robertson did not come to Compiégne this year with the English Arboricultural Society, for there on a hillside, above very sandy soil, we saw what I believe to be the finest sessile Oaks in the world, while the pedunculate Oaks growing near them were extremely poor.

When I wrote the former paper I could have brought forward any number of Continental instances of this failure of the pedunculate Oak on dry soil, but I preferred to have a good example of it from our own country. There are spots, as in Sussex, where both Oaks thrive equally well, as they do in the Ardennes, but the soil is then generally loamy; and Mr. T. Roberts, of Midhurst, has sent me a photograph of both sessile and pedunculate Oaks from the Midhurst woods, both in thriving condition. I am not, however, sure that the tree on the right (fig. 65) is, as Mr. Roberts says, a well-marked sessile Oak, though that on the left is a true pedunculate Oak. In all woods where the Oaks flourish side by side, intermediate varieties appear, and this large Midhurst Oak appears to me, from its foliage, to be an intermediate variety.

Owing to its thicker and harder bark, the sessile Oak does not produce epicormic branches so readily as the pedunculate Oak, and this is another reason for its comparative immunity from stagheadedness on dry soils. It is more liable to frost-crack, and to have its foliage frozen, than the pedunculate Oak, and for this reason also prefers hillsides, where cold air does not stagnate, to low, damp, cold situations. The facts I have stated about the acorns of the two Oaks also correspond with those of the Ilex and Cork Oaks, both of which grow in hot, dry situations, where the acorns require shelter from the sun, and they are consequently sheltered by the foliage of these trees; and those of the latter are almost sessile, while the bracts on the cups are always more developed in these Oaks, as well as in the sessile Oak acorn, than in that of the pedunculate Oak. In the pubescent Oak the foliage is protected against transpiration by a thick reddish-grey tomentum, and this Oak grows on hot limestone hillsides in the south-west of France, and throughout the Mediterranean region, while the pubescence of the leaves and acorn-cups increases as its habitat becomes more southerly.

Fig. 64.—Oaks from Chatsworth.

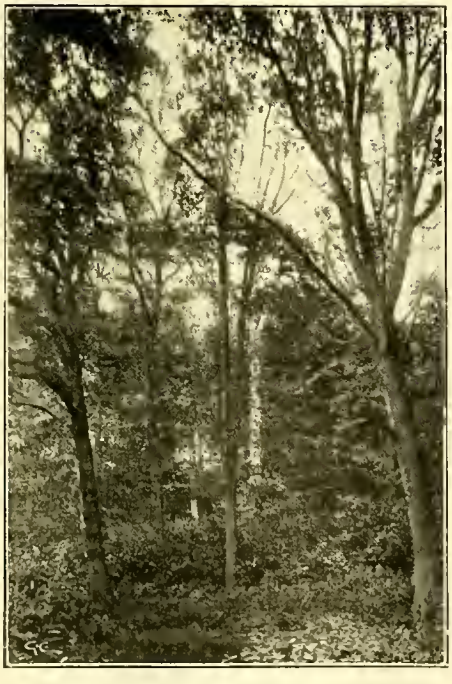

Fig. 65.—Oaks from the Sussex Downs.

In the correspondence in your pages that arose from my former paper, Mr. Clinton Baker gave some figures to show that on sandy loam in Bedfordshire a sessile Oak was growing much faster than a neighbouring pedunculate Oak; while Mr. Divers, of Belvoir Castle gardens, states that pedunculate Oak thrives there on very wet soil, where there is not a single true specimen of the sessile Oak. There is a curious variety of Oak growing on hillsides near Lake Vyrnwy in Wales, the leaves of which are petiolate, while the acorns are clustered together on very short peduncles. It appeared to me to be a kind of sessile Oak, but it is several years since I saw it growing.

Summing up the matter, I believe that Nature has been adapting the varieties of Oaks to their habitats for thousands of years, and that in the process the widely divergent pedunculate and sessile Oaks have been evolved on wetter and drier soils, and now produce acorns from which spring trees like their progenitors. The sessile Oak has abandoned the struggle on wet, low situations, where it fears the frost, and clings to the drier hillsides, leaving river-valleys, and occasionally inundated plains to pedunculate Oak; while on hillsides with sufficient clay in the soil and an abundant rainfall, the two Oaks grow amicably side by side, as we see in the Ardennes, and on the Sussex Downs. *W. R. Fisher.*

LAW NOTES.

A RADISH-SEED CASE.

At the Liverpool assizes, on Wednesday last, before Mr. Justice Grantham and a common jury, the plaintiff sought to recover from defendants damages for breach of warranty as to seed supplied by them. The defence was a denial that any warranty was given.

Plaintiff is a farmer and market gardener carrying on business at Leasowe Road, Wallasey, and the defendants are seed merchants in Manchester. In November, 1901, one of their travellers called upon plaintiff, and asked him for an order for seed, bringing to his notice a certain Radish-seed, which he said he would guarantee to produce 92 per cent. of Radishes. He received an order for two pecks, and afterwards a second one for a larger quantity. The seeds were sown in the usual way, but the Radishes failed to come up as represented, and plaintiff thereupon wrote to the defendants. They replied that the seeds were well tested before being sent out, and that the plaintiff must admit that the weather had been against the germination of seeds. Plaintiff retorted that the weather was not to blame, and took proceedings to recover damages. Counsel stated that plaintiff estimated his loss at £191, after deducting expenses.

His Lordship: A profit of £191 out of an expenditure of £42! I thought market gardening and agriculture were deteriorating in this country.

Mr. Rycroft: That is only a paper profit, my lord.

Plaintiff, in the course of cross-examination, admitted that he had a similar action pending against another firm.

His Lordship: You seem to be making a good thing out of this Radish failure. I see you are making precisely the same claim as in this case.

Plaintiff: Yes.

Mr. Rycroft: Were these Radishes a failure?

Plaintiff: Yes.

Did they not come up?—They came up splendidly.

Well, why do you claim £191 from this other company?—Because there was not a Radish amongst them; they were anything but Radishes.

On the conclusion of the evidence of the plaintiff, his Lordship directed the jury that no warranty was proved, and they must return a verdict for the defendants. Judgment accordingly.

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

FEBRUARY 24.—*Present:* Dr. M. T. Masters, F.R.S. (in the Chair); Messrs. Gordon, Bowles, Shea, Holmes, Michael, Saunders, Massee, Worsdell, Douglas, and Baker; Drs. Cooke and Rendle; Revs. W. Wilks, and G. Henslow, Hon. Sec.

Chrysanthemum Diseased. — With reference to the specimens sent to the last meeting, Mr. MICHAEL reported that there were only one or two aphides, but sections showed abundance of eelworms, which had caused the injury.

Cypripedium Fairrieanum hybrids.—With reference to the fact that hybrids of this plant refuse to cross with each other, Mr. JAS. DOUGLAS sent the following communication:—"Some remarks were made at a recent meeting of the Committee on crossing Cypripediums, and a misunderstanding arose thereupon. It was stated as a fact, and so far as I am aware the statement is correct, that hybrids of C. Fairrieanum will not cross with each other. C. Fairrieanum is so scarce a plant in Britain, that with the exception of a small plant in the collection of the President of the Royal Horticultural Society, I am not aware of any other. Consequently, hybridists are anxious to obtain seedlings with as much of the character of this scarce variety as possible. They have made many attempts by recrossing the C. Fairrieanum hybrids in existence, but have always failed, although other hybrid Cypripediums will cross with C. Fairrieanum. For instance, C œnanthum superbum crossed with C. Fairrieanum produced a very scarce and beautiful variety, "Baron Schröder"; C. vexillarium was obtained by crossing C. barbatum with C. Fairrieanum, and this hybrid on being crossed with C. bellatulum produced C. bellatulo-vexillarium, but C. vexillarium was the pollen parent. The object of bringing this matter before the Scientific Committee would be to ascertain why, if other hybrid Cypripediums will cross with each other, how is it that C. vexillarium will not cross with C. Niobe, or why C. Juno will not cross with C. Arthurianum, or any other of the numerous ways in which the C. Fairrieanum hybrids may be crossed with each other? The pollen is potent enough if used on other species of Cypripediums."

Parasite on Daphne Mezereum.—Dr. COOKE sent the following report:—"The mould on twigs of Daphne Mezereum, submitted by Mr. Holmes, consists of dense tufts of Polyactis, with coloured hyphæ and elliptical spores, probably Polyactis cana. In each instance there appears to have been a wound in the bark, upon which the mould became established, but originally it was saprophytic in its habits. Like others of the genus, it may become parasitic, but in this instance there is no indication of its having injured the plant whilst sound, but to have attached itself to wounds already existent."

Alcohol from Sawdust.—Mr. A. RICKMANN wrote to inquire for information as to the probable cause of the difference in the behaviour of Pine and Oakwood sawdust in Europe and America. The process of the manufacture of alcohol from it being identical, the result was that 40 per cent. less of alcohol was obtained in the United States than at Aix-la-Chapelle. The names of the trees of which the wood was employed were not mentioned, but the Committee agreed with Mr. Rickmann's suggestion, that "the American wood must be in its component parts different from wood grown in Europe, in a similar manner as American Wheat is different from English Wheat." The cause of the difference could only be discovered by separate analysis and experimental tests.

Carnation Cuttings Dying.—Mr. E. H. JENKINS sent some cuttings, the upper part of them dying. The cause was pronounced to be the hard stem (not sufficiently herbaceous), which resulted in insufficient root action. The damp weather had possibly encouraged leafy growth, so that the main shoot was drained of its supply of sap. There was no disease present.

Mendel's Principles applied to Calanthe Hybrids.—Capt. Hurst sent the following communication on this subject:—"With reference to the hybrids C. × Oakwood Ruby and C. × Sibyl, sent to the last meeting by Mr. Chapman, and to his expression of opinion that they 'prove the inapplicability of Mendel's laws to Orchids, I may say that if the pedigree of these two hybrids is correctly recorded in Mr. Chapman's notes, it seems quite clear that we have in them a typical Mendelian case, and that Mr. Chapman's opinion to the contrary must be due to a misunderstanding of the Mendelian principles. According to Mr. Chapman's notes, C. × Oakwood Ruby (with darkly coloured flowers) and C. × Sibyl (with pure white flowers) were raised from the same capsule with the following pedigree, which, for the sake of simplicity, I have reduced to Mendelian terms:—

First generation.

C. rosea × C. vestita = C. × Veitchi vars.
Rose × White = Light rose to deep rose-carmine.
Dominant × Recessive = D.R.

Second generation.—D.R. × R. = 1 D.R. + 1 R.

Third generation to seventh generation.—D.R. × D.R. = 1D + 2 D.R. + 1 R.

In this case, therefore, by continued selection of the darkest D.R.'s in each generation, the seventh generation produces the darkest variety, C. × Oakwood Ruby (D.R.), and also the pure white C. × Sibyl (R.), which is in strict accordance with the Mendelian expectation Further, according to the Mendelian principles, C. × Oakwood Ruby, being an impure Dominant (D.R.), should, when self-fertilised, continue to throw dark forms, rose forms, white forms, and all intermediate colours; while C. × Sibyl, if a pure Recessive when self-fertilised, should throw whites only. Here, then, is a fine opportunity for Mr. Chapman, with his well known cultural skill and his Oakwood advantages, to test Mendel's principles by actual experiment."

Cineraria diseased.—Some plants were received from Mr. C. BUCKLAND, Braintree. Mr. Saunders reports as follows from his examination of them:—"The Cineraria plants were in a very sad condition; the leaves were infested by green-fly, and the roots with one of the Poduridæ, or Springtails, I believe by Lipura ambulans, which were present in large numbers, and by some small worms belonging to the family Enchytræidæ, which are nearly related to the true earthworms. They were very abundant, particularly at the base of the roots. They die almost instantly on being placed in lime-water, so that they would easily be destroyed by soaking the soil in which they were with lime-water; but whether they would be reached by watering when on the roots close up to the stem I cannot say. Both the worms and the Springtails are very injurious to plants; the latter do not appear to be much affected by lime-water. Probably a strong solution of nitrate of soda or common salt would have more effect on them, but I do not know of any experiments that have been made on them."

Azaleas and Fumago.—Mr. MORTIMER sent samples attacked by the common Fumago, due to a too close an atmosphere. A good washing would be desirable in such cases. They had also been attacked by Thrips.

Arctic-garden at Kew.—An extract from the *Times* was sent by the Editor of the *Cold Storage and Ice Trades Review*, in which it was suggested that an "Arctic-house" should be formed at Kew, "wherein Dwarf Willows and other curious vegetation of the Polar regions might be seen associated with some pretty effects of snow and ice, which might be produced in summer." It was observed by the Committee that Arctic plants grow better in temperate climates than in the Arctic regions, as Papaver nudicaule, which is found in Spitzbergen, and that many of them are now growing in Kew Gardens, so that the addition of a "cold house" of this character would be superfluous.

Cyclamen monstrous.—Mr. A. SUTTON sent a plant with one or two of the flowers having a foliaceous bract below it, a not uncommon occurrence, inquiring if it is likely to be perpetuated. Mr. GORDON observed that he found a considerable percentage of seeds raised from flowers thus provided with a leafy bract were reproduced; but if it were cultivated, as Mr. Sutton observes, "one flower stem would give an almost perfect buttonhole of a flower and leaf together."

Stone embedded in a tree.—Rev. A. HARVEY, Shirehampton Vicarage, Bristol, sent a photo of a portion of a root of an Ash-tree. It was cut down in 1870; the root had evidently grown over the stone, a not uncommon occurrence.

Experiments at Chiswick.—Mr. GORDON raised the question whether it would not be possible to utilise a house in the Chiswick Gardens for the express purpose of carrying out experiments, chemical or otherwise, which have various bearings in horticulture. After some discussion, in which the members of the Committee fully agreed, it was proposed to reconsider the matter at the next meeting, with the object of laying some suggestions before the Council of the Royal Horticultural Society.

Conifers.—Dr. MASTERS exhibited a large series of cones of various species from Westonbirt, as well as several of the novelties discovered in Central and South-West China by Mr. Wilson when collecting for Messrs. Jas. Veitch & Sons, explaining their localities and other details. A vote of thanks was given for his interesting communication.

LIVERPOOL HORTICULTURAL ASSOCIATION.

FEBRUARY 11.—The members of the above Society had the pleasure at this meeting of listening to what proved to be one of the most interesting and instructive papers of the session. Mr. PAUL, of Manchester, was the essayist of the evening, having for his subject "Stove and Greenhouse Plants for Exhibition." As is well known, no one is more capable of dealing with such a subject than this gentleman, who in past years had exhibited some of the finest specimens ever seen at the Manchester, Liverpool, and other exhibitions. He attributed the decline in the growth of some of the Australian and Brazilian plants at our shows to the death of those fervent and ardent employers whose desire it was to have the largest and best-grown specimens it was possible to produce; whereas the present system aimed at is to secure two, and possibly three, crops of flowers where one was grown in the '60's. The lecturer described the cultivation necessary for the principal exhibition plants of the day.

Mr. FOSTER, chairman of the meeting, expressed a desire that the meetings of the Association in the future might be better attended by the younger members, for whose benefit they are mainly arranged, which would put more heart into the lecturers who so kindly give their services.

DEVON AND EXETER GARDENERS.

THE paper read at the last meeting was one by Mr. SIDNEY BAKER, gr. to Sir Dudley Duckworth King, Bart., Wear House, the subject being "Forcing Vegetables." In forcing Asparagus, Mr. Baker said, unless allowed to buy forcing roots ready for action, the gardener must begin three or four years before by stimulating the Asparagus plants annually with nitrates, bone-meal, or other artificial manures, to make them ready for the supreme effort when required; the chemical manures should be applied during the spring and summer, when the plants were making growth. Perfect drainage and liberal manuring were necessary to success. For beds to be drawn on for forcing roots, a liberal coating of stable manure in autumn was necessary. Seakale, Rhubarb, Dwarf Beans, Mushrooms, &c., were also dealt with in a practical and exhaustive manner; and the very interesting discussion which followed amongst the members, of which there was an unusually large number present, proved the interest taken in the subject.

BRISTOL & DISTRICT GARDENERS' MUTUAL IMPROVEMENT.

FEBRUARY 26.—This Association met at St. John's Rooms, Redland, on the above date, Mr. E. Poole in the chair, to hear Mr. W. STADDON, of Weston-super-Mare, read a paper on "Annuals, and their Employment in Gardens." His visit was the means of bringing together a good attendance.

THE SYDENHAM AND DISTRICT GARDENERS' GUILD.

FEBRUARY 27.—The opening meeting was held on the above date in the Wells Road Parish Hall; Canon Moberly, President, in the Chair. After a short speech by the President, Mr. BAND gave an interesting exhibition of lantern views from photographs taken by himself. The first part of the exhibition consisted of floral studies of flowers as growing, and as cut for decorative purposes. The next series of pictures shown upon the screen represented plants and features of interest in the Royal Garden, Kew; and the third series showed places and incidents of interest observed by the lecturer on his journey from Victoria to the Paris Exhibition of 1900. The Hon. Secretary of the Society is Mr. W. H. Brown, 2, Prospect Road, Sydenham.

LINNEAN.

February 19.—Professor S. H. Vines, F.R.S., President, in the Chair.

Mr. John Clayton, of Bradford, presented a set of thirty-two photographs to illustrate the celebrated Cowthorpe Oak, near Wetherby, Yorkshire. From the time of John Evelyn, this Oak has been described, measured, and its age guessed at. Mr. Clayton, in a printed summary of 22 pages, gives an account of the various observers who have mentioned the Oak in question, and many of the photographs are designed for comparison with other remarkable trees, amongst them the Crowhurst Yew in Sussex, the great Chestnut at Tortworth, and the Greendale Oak in Welbeck Park. In 1893, careful measurements and photographs were made of the tree, on four different visits in January, April, June, and October. The author's deductions from these data are, that the age of the tree has been greatly over-estimated; his own belief being that 500 years is the extreme limit of its age, from sapling to its present decrepitude and decay.

Dr. George Henderson, F.L.S., offered "Some Remarks on the possible uses of Essential Oils in the Economy of Plant-life." Adverting to the well-known fact that moisture in the air prevents radiation and consequent loss of heat, he suggested that emanations of essential oil from plants might possibly prevent damage by night frost during the period of flowering, basing his suggestion on Prof. Tyndall's researches thirty-two years since, on the presence of infinitesimal quantities of essential oil in the air. Tyndall found such presence increased the absorptive power of the air as regards heat-rays: taking dry air as 1, air-saturated with moisture as 72, then traces of essential oil rank as follows:—Rosemary 74, Cassia 109, Spikenard 355, and Aniseed 372. Dr. Henderson brought these remarks before the meeting as an interesting question for botanic investigation, since essential oils are usually regarded as mere waste products.

The Rev. T. R. R. Stebbing, V.P., having taken the chair, the first paper was summarised by the President for the author, "On the Electric Pulsation accompanying automatic Movements in Desmodium gyrans," by Prof. J. C. Bose, C.I.E., M.A., D.Sc. In communicating this paper, the President pointed out that it had long been known that stimulation of the irritable tissues of animals causes a change in their electrical state. When, for instance, a nerve is stimulated, an electrical current, known as the "current of action," is produced, travelling in the tissue from the relatively more excited to the relatively less excited portion. A good many years ago it was ascertained that a similar electrical disturbance is caused by stimulation of parts of plants known to be irritable, inasmuch as they respond to a stimulus by a movement. This was demonstrated by Sir John Burdon Sanderson in the case of Dionæa, and by Prof. Kunkel in the case of the Sensitive Plant (Mimosa pudica). It might be inferred from this that only those parts of the plant are electrically affected by stimulation which are capable of responding to a stimulus by a movement. As long ago as 1886 the President had pointed out that such an inference was not warranted, a criticism that has been justified by subsequent research. In fact, Prof. Bose demonstrated to the Society, just a year ago, that any living part of a plant, when stimulated mechanically, gives an electric response.

On the present occasion Prof. Bose has broken new ground. In the paper before the Society he gives the results of his investigation of the question as to whether or not spontaneous movements are accompanied by an electric disturbance comparable to that resulting from external stimulation. Spontaneous movements are not uncommon in the higher plants, but for various reasons there are but few instances suitable for an investigation of this kind. The most striking case is that of Desmodium gyrans, the Telegraph-plant. The leaf of this plant is trifoliolate, consisting of two small lateral leaflets, and a larger terminal leaflet. The lateral leaflets move up and down, like the arms of a semaphore—whence the popular name of the plant, the period of a complete up-and-down movement, in the plants observed, being about 3½ minutes. Having placed one electrode on the petiolule of a leaflet, and the other on the petiole of the leaf, both in connection with a galvanometer, Prof. Bose found that the spontaneous movement is associated with an electrical disturbance of a peculiar kind. There is first a large principal wave of disturbance, followed by a smaller subsidiary wave; the period of the former being about 1 minute, that of the latter about 2½ minutes. This disturbance is the expression of a "current of action" travelling in the plant from the excitable petiolule to the resting petiole.

The relation of the double wave of electrical disturbance to the movements of the leaflet was found to be this:—The principal wave attains its height during the downward movement of the leaflet; the leaflet rests for a brief space at its lowest position, during which time electrical recovery takes place. The leaflet now moves upwards, and then the second or subsidiary wave of electrical disturbance is produced. This relation is established by simultaneous records of the movements and of the electrical disturbances, which further show that the greater amplitude of the principal wave of electrical disturbance is the concomitant of the greater velocity of the downward, as compared with the upward, movement of the leaflet.

Some interesting observations are given upon the recurrence of periodic fatigue in the leaflets, followed by a restoration of activity; as also upon interference effects resulting from placing the two electrodes upon the petiolules of the two leaflets in different phases of movement.

The second paper was by Miss A. L. Embleton, B.Sc., communicated by Prof. G. B. Howes, Sec. L.S., and read by Mr. A. D. Michael for the author, on "Cerataphis Lataniæ, a peculiar Aphid." This insect was observed in 1901 on various Orchids in the Cambridge University Botanic Garden. The first description was by Boisduval in 1867, who considered it a Coccus; and the following year Signoret referred it to a new genus near Aleurodes, styling it Beisduvalia Lataniæ. In 1879 J. O. Westwood described a similar insect as Astero-lecanium orchidearum (fig. 66), "a new species of scale-insect," occurring on Cypripedium, and sparingly on Sobralia, Cattleya, and Dendrobium. [See *Gard. Chron.*, Dec. 20, 1879, p. 796.] On comparison, this proved to be identical with the species under review, which in 1882 received the name Cerataphis Lataniæ from Lichtenstein. The author gives the detailed synonymy of the creature, which is well known to cultivators on the Continent, and proceeds to set out its life history; in this country it exists in only one form, reproduced parthenogenetically, corresponding to an aleurodiform stage of a migratory aphis. The author concludes by suggesting that it is one of the migratory aphides, which has been deprived of its usual series of metamorphoses owing to an artificial mode of life.

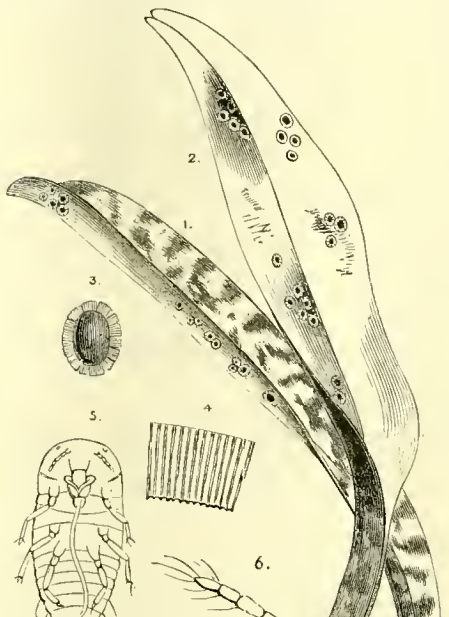

Fig. 66.—Fringed scale insect (Astero-lecanium).

1 and 2, Insects of natural size; 3, Enlarged insect; 4, Small portion of marginal scales; 5, Under-side of a young specimen; 6, Short antennæ, much magnified.

Mr. G. S. Saunders remarked that many years before he had observed the winged female, but, not then being aware of its peculiar position, he had not taken special notes of its life-history.

The last paper was by Mr. E. S. Salmon, F.L.S., "On Specialisation of Parasitism in the Erysiphaceæ." The author began by explaining the term "biologic form," or "species," by instancing two fungi which were not distinguishable morphologically, acting in diverse fashion on the same host-plants. This phenomenon has been known in the Uredineæ for some time, but its discovery in the Erysiphaceæ was more recent. Thirteen species of Bromus proved to be completely immune against the four forms of the fungus used, thus indicating the existence of four, or probably five, biologic forms.

The author also pursued his researches on the forms of Erysiphe graminis on Wheat and on Oats; the result showing that the Wheat-form cannot touch Barley, Rye, or Oats, nor Agropyrum repens, but it infected Triticum Spelta. The Oat-form cannot infect Wheat, Barley, or Rye, but it can attack other species of Avena.

Finally, experiments were made on Erysiphe Polygoni from Trifolium pratense, which proved unable to infect seven other species of Trifolium, but it always succeeded on its own host plant. Species of other Leguminosæ, Lotus corniculatus, Medicago sativa, Melilotus arvensis, Lupinus luteus, and Pinum sativum were also immune.

READING & DISTRICT GARDENERS' MUTUAL IMPROVEMENT.

At a recent meeting of this Association, Mr. W. Townsend, gr., Sandhurst Lodge, gave a paper entitled "A Berkshire Garden in Summer," illustrated with limelight views. Of course, the garden dealt with was that under Mr. Townsend's charge, and which is noted for the beautiful outdoor flowers grown therein.

Mr. J. Gibson, gr., Danesfield, Marlow, made a splendid exhibit of the Sutton Variegated Kale, staging about three dozen heads, each showing two or more distinct colours of every conceivable shade of colour.

LEE, BLACKHEATH, LEWISHAM, & WEST KENT HORTICULTURAL.

February 27.—On the occasion of the meeting of the above, at the Old Institute, Old Road, Mr. Bastin gave an instructive lecture on the cultivation and diseases, &c., of the Caladium. There was also exhibited an excellent display of Apples, showing good keeping qualities, by Mr. Johnson, gr., Kemnel Manor, Chislehurst; a plant of Dendrobium Wardianum, beautifully flowered, shown by Mr. Judge, gr., Beechdale, Eltham Road; and Primula sinensis, by Mr. London, gr., Blackheath Park, showing good blooms. *H. J. H.*

NATIONAL CHRYSANTHEMUM.

March 2.—A meeting of the Executive Committee took place on the above date. A letter was read from the President, Mr. C. E. Shea, thanking the Committee for the honour they had done him in electing him President, and expressing his desire to give a President's Special First Prize at the exhibition to be held in November next. The Secretary reported he has seen Mr. Shea in reference to the matter, and it had been arranged that, if found agreeable to the Committee, the President would give the sum of £5 5s. as the President's Special First Prize in the class for twenty-four Japanese blooms. Mr. Shea's offer was accepted with thanks.

A letter was read from Mr. Stanton, steward, Park Place, Henley-on-Thames, stating that he believed, were Mrs. Noble's permission asked for, she would be willing for the Society to hold its annual outing at Park Place on July 13 next. It was agreed to take launches at Reading and go down the river to Park Place, dine at midday, and have a river trip in the afternoon, the arrangements being left in the hands of the Secretary. It was reported that no agreement with the Crystal Palace Company had yet come to hand and the Secretary was instructed to go down to the Palace, and press for the completion of the agreement, so that the arrangements for the year might be definitely settled. Acting upon a motion passed at the last meeting of the committee, the Secretary brought up an estimate of receipts and expenditure for the present year, so that the committee might be in possession of knowledge of the financial position of the Society before passing the schedules of prizes.

From this estimate it appeared that with the balance in hand at the commencement of the year, and the £200 offered by the Crystal Palace Co., an income of some £800 might be anticipated; and with the sum of £121, offered as prize money at the three shows, the expenditure was estimated at £780. The Secretary pointed out that some expected sources of income were problematical, but he thought it, on the whole, a fair estimate. After some discussion, the statement was accepted.

A report was made as to a somewhat serious decline in membership, and to the fact that several of the affiliated societies were in a state of financial collapse, and urged the importance of efforts being made to secure an accession of membership. A report was then brought up upon the Schedules of Prizes, showing that while the number of classes at each exhibition had been very sparingly produced, there had been a slight reduction of the prizes in most of them; also that the institution of grades of entrance fees had made an entire re-arrangement of the schedules of prizes, which the secretary set forth in detail—these were passed, together with some alterations in the general and special regulations affecting exhibiters.

The following persons were elected as judges for the various exhibitions: October show, Messrs. M. Gleeson, Stanmore, and A. Jeffries, Harlow. November show, Messrs. J. F. McLeod, Rochampton; A. Turner, Slough; C. J. Salter, Reigate; J. Fulford, Maidenhead; G. Inglefield, Tidworth; W. Robinson, Westbury; J. Jennings, Ascot; O. Thomas, Ealing; J. Smith, Mentmore; and W. Allan, Gunton Park Gardens. December show, Messrs. C. Orchard, Bembridge, and W. Ring, Waltham. The votes were taken by ballot.

Obituary.

F. W. BURT.—We are informed of the death recently of Mr. F. W. Burt, head gardener to Francis Reckitt, Esq., at Caen Wood Towers, Highgate, Middlesex.

Answers to Correspondents.

*** EDITOR AND PUBLISHER.—Our correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all communications relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication, or referring to the literary department, and all plants to be named, should be directed to the EDITOR. The two departments, publishing and editorial, are quite distinct, and much unnecessary delay and confusion arise when letters are misdirected.

A PIG-STYE THAT IS A NUISANCE: *G. A.* If the owner of the stye will not remove it to a greater distance from your cottage, on your requesting him to do so, you should invoke the aid of the local authorities, who may have a bye-law that touches such cases.

BEGONIA GLOIRE DE LORRAINE SEEDING: *H. K.* This plant has formed fruits apparently fully developed, but we know of no authenticated case of seedlings having been raised. If you are successful in crossing with Sutton's Fairy Queen, kindly make the fact known.

CARNATION: *G. R., Wilts.* We cannot undertake to name florist's flowers. Send them to a specialist.

CEDAR OF LEBANON: *A. G.* The cones do not come to maturity till the end of the second year. There is no necessity to split them open to obtain the seed, as the scales open of themselves if laid out thinly in the sun and they are protected from rain. The seeds should be stuck into the soil in the seed-pot to half their depth, point downwards, and covered with a layer of moss, or lightly with soil, as described in our reply to a correspondent in last week's issue; and when they are pushed out of the soil by the downward thrust of the root, they may be raised out of the soil very carefully with the blade of a knife, and pricked out in thumb-pots.

CORRECTION: Manchester and North of England Orchid Society. Award of Merit (see *Gardeners' Chronicle* for February 28), Cypripedium Eurydice Robson's var., shown by Mr. J. Robson, should have read Lowe's var.

CUCUMBER PLANT: *Perplexed.* The disease is that caused by the fungus Cercospora melonis, first described in *Gardeners' Chronicle*, Sept. 5, 1896, p. 271; see also *Gardeners' Chronicle*, October 4, 1902, and frequent references in this column.

DAISIES AND DANDELIONS: *W. R.* Let the larger plants be spudded out of the soil, and apply Lawn Sand, which will cause a dense growth of grass, and smother the weeds. The Daisy-rake might be passed over the lawn at short intervals, which will greatly reduce the amount of seeds shed, sweeping up the heads and destroying them.

GARDEN DIRECTORIES: *H. W. D. J.* There are two, both of which are revised and brought up-to-date annually, viz., *The Horticultural Directory and Year Book*, published at the office, 12, Mitre Court Chambers, Fleet Street, E.C.; and the *Garden Annual Almanac and Address Book*, published at the office of *Gardening*, 17, Furnival Street, Holborn, E.C. Price of each, 1s.

LAUREL LEAVES INJURED: *Turnslo.* There is no disease present in the specimen, but the injury is due, we think, to noxious fumes.

LEAVES OF THE PINK DYING OFF: *W. Gasper.* The densely-tufted leaves and other characters strongly suggest eelworms; but this cannot be definitely ascertained unless roots are sent for examination.

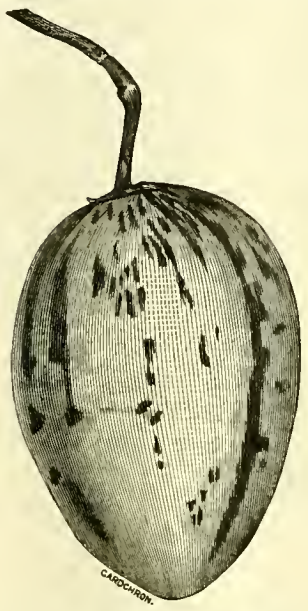

FIG. 67.—FRUIT OF THE MELON-PEAR: SOLANUM (MURICATUM) GUATEMALENSE. *Reduced.*

LIMING APPLE-TREES: *Broadhead.* The caustic soda-wash is effective as against lichens and moss, and brine would have the same effect; but it is now too late to use either. Mix fresh soot with the lime, and thus lessen the conspicuous whiteness.

"MAGGOTS" ON INDOOR PEACH-TREES: *G. A.* Before we can advise you on the mode of destruction, you must send specimens of the creatures, shoots, leaves, and fruit, all carefully packed, to this office.

MELON-PEAR: *C. W. D.* The fruit sent is that of Solanum muricatum (Guatemalense), see fig. 67, and known popularly as the Melon-Pear, because it has nothing whatever to do with either of those fruits. The plant forms an erect sub-shrub, and is a native of tropical America. The fruits are sometimes seen in English markets, are as large as a good-sized hen's-egg, aromatic and juicy.

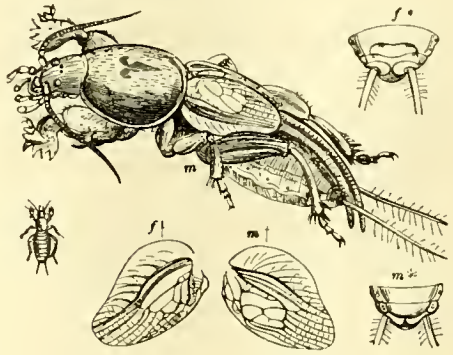

FIG. 68.—THE MOLE CRICKET.

NAMES OF PLANTS: *Correspondents not answered in this issue are requested to be so good as to consult the following number.—W. C., Kylemore.* 1, Pinus, perhaps muricata, but without the cones we cannot tell; 2, Pinus contorta; 6, Cupressus Corneyana.—*M. P. E.* 6, Cupressus, perhaps C. torulosa, but without cones it is difficult to say.—*Mrs. E. N.* No. 4, Davallia ornata. Please, when possible, send fertile and barren fronds of Ferns for naming. The barren frond only, as in this case, is not sufficient.—*Mrs. Janet R.* A Pleurothallis, but which species we cannot say from the specimen sent.—*J. M., Aberdeen.* A very fine variety of Dendrobium nobile.—*J. O., Berks.* Maxillaria picta.—*C. E.* 1, Cypripedium × Harrisianum; 2, C. × Godseffianum; 3, C. × politum.—*No name.* The yellow Dendrobium is D. fimbriatum.—*Zola.* 1, Calanthe nivalis; 2, C. Regnieri; 3, Dendrobium primulinum; 4, D. Jenkinsii.—*A. J. B.* 1, Cypripedium × Barteti; 2, C. × Hera.—*P. Wolter.* Cypripedium × Ashburtoniæ Barteti, as figured in *Iconographique des Orchidées*; Hippeastrum aulicum stenopetalum.—*H. F., Cosham.* Begonia coriacea.—*T. G.* One of the many forms of Cupressus Lawsoniana.—*J. H.* Pinus pinea, the Stone Pine, the seeds of which are eaten.—*A Reader.* A variety of Buxus sempervirens.—*N. W. O.* 1, next week; 2, Anemone Hepatica.

PEACH FOLIAGE DEFORMED: *G. R., Wilts.* The crinkling of the leaves is caused by greenfly, which puncture the skin. Fumigate on one or two quiet nights, then apply clean water with the garden-engine or syringe. Avoid cold draughts in the Peach-house.

POTATO: *R. B. Laird.*—The tuber is attacked with Fusarium Solani, which appears to be a deadly foe to stored Potatos. See *Journ. Roy. Hort. Soc.*, vol. xxvii., part 1, Sept., 1902; *Proceedings*, p. liv.; Scientific Committee, May 20, 1902.

PRIMROSE: *Rosavenu.* A leafy condition of the calyx is by no means uncommon. Illustrations have been frequently given in our columns. The plant is undoubtedly worth preserving, although it is by no means a new departure.

THE GARDENER DURING ILLNESS: *Ess*, and *Enquirer, Kingsheath.* The gardener being in law a domestic servant, cannot be discharged for absence from his employment during illness, unless the illness be much protracted, nor could his wages be legally stopped. The gardener, in default of a written agreement, is bound to give a month's notice, as also the employer. It does make a difference if the gardener reside off the premises, seeing that he cannot claim a sum of money in lieu of house accommodation, coal, and other perquisites.

THE MOLE-CRICKET (see fig. 68): *G. P.* If you have access to our volume for 1849, you will find a very interesting account of this insect, which is very destructive to roots, but is much less common here than on the continent.

THRIPS ON FERNS: *W. G.* As you have given the newer remedies a trial, and have not destroyed the pests, why not go back to earlier remedies, such as mild fumigation with Tobacco on alternate nights for a week; or employ a weak solution of Tobacco-water only—do not use Tobacco-paper or rag! We used to annihilate our insect foes with these simple means years ago.

VICTORIA PLUM SHOOTS DISEASED: *W. H.* Frost has produced the cracks, and then come fungus-spores, which find in them a fitting place to vegetate, feed on the bark, and ultimately destroy the wood.

VIOLET-ROOTS DISEASED: *W. Gasper.* See answer under "Violet-roots Dying Off," in *Gardeners' Chronicle*, February 28, 1903.

YEW: *Ascot.* The Dovaston Yew.

THE NEIGHBOURHOOD OF OPORTO.

THE coast line running both north and south of Oporto (or Porto, as the natives call it) for some distance, consists chiefly of rocky sea-shores and sand dunes, merging gradually into heaths, and these again in turn giving way to Pine forests of somewhat stunted growth. Among the forested country and heaths, there is a good deal of cultivation which is continued up to the serras or rocky hills of the "back" country.

Deciduous trees are comparatively scarce in the close vicinity of the coast, though a little further inland there are many Oaks. Near small rivers there are grassy dells and glades, and often very marshy places bordering the streams. The contour of the land around Porto is undulating, but here and there occur low rocky hills of a more abrupt character, sprinkled with granite boulders, or dotted with a dry heath and bush-like vegetation. There are more or less six floral areas in the Porto district, though many of the plants of course are not confined entirely to their own area, overlap into the others.

1. Sea-coast and sand dunes.
2. The heaths or "Tojoes."
3. Cultivated fields and roadsides.
4. The Pine woods or "Pinhaes."
5. Grassy margins of rivers where there are deciduous trees and brushwood.
6. Exposed rocky hills.

Sea-coast and sand dunes. — The underlying rock near Porto is all granite, and this along the coast is often piled up into jumbled masses of boulders, in the crevices of which Asplenium marinum grows abundantly; while trailing on the sand, in company generally with Silene littorea, is the white downy-foliaged Medicago marina, which is very common. On the sands near Mattosinhos, a suburb of Porto, are groups of Pancratium maritimum. These have often been transplanted into gardens in Porto, but do not seem to do well away from their native haunt of pure sand.

On the sandy wastes, and near the three-cornered Martello forts with their pepper-pot turrets, which line the coast at intervals, quantities of Mesembryanthemum have been naturalised, both the rose coloured and yellow kinds, forming large patches where they occur. Paronychia argentea is frequent on the coast, its prostrate habit and close white membranous flowers being a noticeable feature on the sand. Ophioglossum lusitanicum grows usually in damp spots, just where a rock crops out, and is hardly ever found in any other situation; it can scarcely be said to grow in the sand dune area, perhaps, though very close to it. Other dune plants which are noticeable in April, are the beautiful blue Anagallis linifolia, with its feathery red stamens; Malcolmia littorea, with whitish or glaucous foliage; and the pretty Eudiantha lactea.

The Heaths or "Tojoes." — On sandy soil and always in close proximity to the sea, yet not actually on the dunes, grows Trichonema Clusianum. It grows very thickly in certain spots, covering large areas, very often right in the middle of the narrow foot-paths along the shore line. Gorse is very common. Cistus salviæfolius with white flowers, is the usual Cistus met with. Among other heath plants are Genista anglica, Silene gallica, the brilliant blue Lithospermum prostratum, which is very abundant, with its masses of flowers and compact, almost bushy growth; and Æthiorrhiza bulbosa, with its curious pale yellow tubers like miniature new Potatos.

Cultivated Fields and Roadsides.—There is a great deal of cultivation interspersed among the heaths of the Porto district. The fields are usually fenced in by banks of earth and stones, which are covered and grown over with Gorse, and often form sheets of purple, amethyst, and gold, with Echium plantagineum and Chrysanthemum myconis. Oxalis purpurea, which was introduced from South America, has completely naturalised itself, and is frequent; it is a brilliant rose colour, and very pretty. In damp spots Ranunculus ophioglossifolius, and on the hedge-banks a little white but scentless Mignonette, Astrocarpus Clusii; and Arenaria montana are found. Vicia sativa is abundant, and Cotula coronopifolia on wet ground; Anchusa sempervirens is common.

Pine-forests and Woods.—Among the Pine-woods, which consist principally of Pinus Pinea and P. Pinaster, the rust-coloured, powdery male cones of which form a very striking feature at this time of year, certain open spots are carpeted with the cream-coloured Narcissus triandrus. The greater part of the undergrowth of Gorse and undershrub is usually systematically shaved off by the peasants, so that the woods often present a bare appearance. The fine blue Omphalodes lusitanica is common, also locally, Simethis bicolor. In sheltered, shady places, Aristolochia longa, Asphodelus cerasiferus, Osyris alba, Polygonatum officinale, and Digitalis purpurea; also Aquilegia Dicksoni in more open, grassy situations; and in wet ground Serapias cordigera, an Orchid worth cultivating in a bog-garden.

Margins of Rivers.—Here, abundant though rather local, are found colonies of the rich yellow "Hoop-petticoat" Narcissus (N. bulbocodium), Saxifraga granulata, Ornithogalum umbellatum, Cardamine pratensis, Doronicum plantagineum, I have only seen on the banks of the Douro river on steep, grassy banks, where also, but in more rocky situations, grow Saxifraga umbrosa, Arnica montana; in glens and dells grows Osmunda regalis, which however had scarcely unfolded its fronds at this time of year.

Exposed rocky surfaces and hills.—In these places a good deal of Genista is found; Genista anglica (mentioned above), G. triacantha, G. berberidea, and Cytisus albus, a very graceful bloom. Near Vallona we found a quantity of the handsome dark blue Polygala microphylla, and the curious Drosophyllum lusitanicum, with its long narrow leaves covered with sticky glands. It has a very xerophytic appearance, and is associated with Erica umbellata. These dry, rocky hills are rather barren of species, but what there are, are usually of interest.

There are many lanes in and around the city where certain plants are very common, i.e., Cotyledon umbilicus; and among Ferns, Cystopteris fragilis, and Gymnogramma leptophylla. Also a new Holland Daisy, Vittadenia triloba, a weed which has completely established itself in the city; and another somewhat curious weed, Soliva Barclayana, which appears to have been introduced from South America.

The above mentioned plants are only a few of the more conspicuous species occurring in and around Porto in the month of April in the various floral areas. Earlier in the year, a greater proportion of bulbous things are out; while later in May and the beginning of June, the sand spits which occur here and there on the banks of the river Douro, are carpeted with many orders of polypetalous flowers. *C. Orfeur.*

NEW OR NOTEWORTHY PLANTS.

LYCHNIS YUNNANENSIS, *Baker fil., sp. nov.**

This new species of Lychnis has much the habit of L. sibirica, Linn.; the petals are white, and considerably longer than the calyx, and generally

Lychnis yunnanensis, Baker fil.—Radix perennis, multicaulis; caules erecti vel adscendentes teretes graciles pubescentes, 10–16 cm. longi; folia lanceolata vel lineari-lanceolata, sessilia, opposita, virentia, pubescentia, apice acuta, 2·0–2·8 cm. longa, 2·0–6·0 mm. lata; pedunculi axillares solitarii vel terminales, 2–3 cymosi; florea erecti vel suberecti; calyx 10-nervius, 7–8 mm. longus, tubuloso-campanulatus, ad margines rubro tinctus nervis viridibus dentibus ± 2 mm. longis, ovatis, acutis, tenuiter glandulosis; petala in sicco alba plus minus bifida calycem superantia ± 1·3 cm. longa, unguibus glabris filamentis gracilibus calycem longioribus; styli 5, subanthesi 2 mm. longi, graciles; ovarium oblongum, gynophorum longior subanthesi 2 mm. longum. *E. G. Baker.*

bi-lobed. It was received by Herr Max Leichtlin from Yunnan, who has sent specimens to the National Herbarium at South Kensington.

Root perennial, multicaulescent; stems in specimen examined eleven from one rootstock (varying doubtless in other specimens), erect, terete, pubescent, slender, 10 to 16 cm. long. Leaves lanceolate or linear-lanceolate, sessile, opposite, tapering to an acute apex, glaucous-green, pubescent, 2·0 to 2·8 cm. long, 2·0 mm. to 6·0 mm. broad at the broadest point, which is sometimes near the base, or occasionally nearer the middle of the leaf. Calyx ten-nerved, tubular-campanulate, 7 to 8 mm. long, reddish at the margin, veins green, segments ovate, acute, somewhat glandular. Petals in a dried state, white, generally bi-lobed, lobes rounded, considerably longer than the calyx. Filaments slender, longer than the calyx. Ovary oblong, longer than the gynophore, when the plant is in flower 2 mm. long. Styles five, slender, 2 mm. long.

Dr. F. N. Williams, who kindly undertook to examine the specimens, tells me he considers it a near ally of Lychnis Flos-cuculi, Linn., and he would place it in the genus Coronaria. *E. G. Baker.*

UGANDA.

WE take the following extracts from an official report of Mr. J. Mahon, relating to the plantations made in the Botanic Gardens at Entebbe :—

"While some plants make only moderate progress in this country, which in other parts of the tropics are known to grow very rapidly, still, it may be said that on the whole, the things mentioned in the lists thrive most satisfactorily, and are eminently suited to the climate for either useful or ornamental purposes. .

RUBBER TREES.

It is well known there are large areas in Uganda containing abundance of rubber-vine (Landolphia) yielding excellent rubber, but as it is practically impossible to systematically cultivate this plant, we are introducing all the celebrated rubber-yielding trees with the object of demonstrating that this country offers a field for establishing rubber-plantations on a commercial basis. As I have pointed out before, timely preparations require to be made to furnish supplies for the demands of the future.

The standard by which all rubber is judged is the Pará (Hevea brasiliensis). When I came to Uganda in 1901, the Director of the Royal Botanic Gardens, Kew, forwarded in my charge a consignment of plants, amongst which were several sorts of Pará-rubber seedlings, with stems about as thick as a lead pencil, and 9 to 12 inches high. One of these, in the Botanic Gardens, is now over 7 feet high, and otherwise of proportionate growth. As I reached Entebbe, during one of the worst droughts remembered here, the young plants, after a trying journey of almost two months, had a hard battle to exist, and some of them succumbed, so that the success of the survivals is all the more satisfactory to record. But as this Amazonian plant affects low levels, it remains to be seen whether our climate and elevation will suit it. I am certain the lake will exercise a very favourable influence, and it would, in my opinion, be a mistake to experiment with these and other extra-tropical plants elsewhere in Uganda than on the lake shores.

Castilloa elastica, Central American rubber, was another item in the Kew consignment. This also has done very well, and being more or less of a highland plant in its native country, it is reasonable to assume the conditions here will prove suitable. A considerable quantity of Castilloa plants have been ordered, and an experiment in introducing its seeds here direct from Mexico is being conducted.

Ceara rubber (Manihot Glaziovii) is growing with its accustomed vigour. A seedling of eight months is nearly 4 feet high. It seems quite at home in Central African climates, but it is not a first-class rubber, and instances are on record where it was proved not worth the trouble of planting; still, it might be a most suitable sort here.

A serious loss occurred last June in the burning down of a large nursery-shed through native carelessness, when a fine batch of the celebrated silk rubber of Lagos (Funtumia elastica) was lost, in company with other valuable things. I feel certain Lagos silk rubber will prove a suitable culture here for plantations in the lake region.

We have a large number of Landolphia seedlings, which were obtained from Sesse in 1900. Nothing is more puzzling than the slow rate at which this common native plant grows under cultivation. It is quite clear it requires to be sown where it is intended the plants are to remain. It resents transplanting, and some seedlings we put at the base of trees in a stretch of forest to grow *au naturel* have remained practically as they were put out six months ago.

CACAO.

The two cases of Cacao (Theobroma Cacao) sent out from Kew in August, 1901, have thriven exceptionally well. They arrived during the drought already referred to, and as there could be no thought of planting them out I had them all put in pots, and, to shade them, had recourse to converting my tent into a greenhouse, and it suited the purpose admirably. Whilst there they were attacked by rats, which gnawed the stems of many quite close to the soil. Trapping several frightened the others away eventually. It was not possible to plant out the Cacao till December, 1901. Their progress in nine months permanently planted out has been, and continues to be, most satisfactory. I am not aware of any country where Cacao is grown commercially at 4,000 ft. altitude. If we prove it can be done here, the experiment will be valuable.

COFFEE.

As an excellent Coffee is frequently found in this country in a wild state, it is perhaps only to be expected

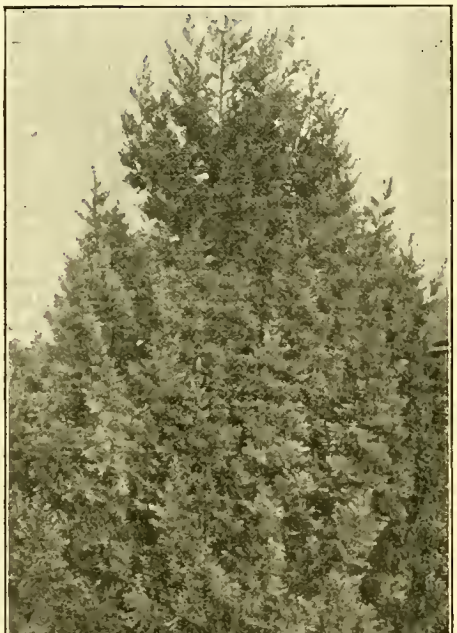

FIG. 69.—WIDDRINGTONIA WHYTEI
About three years old, growing in the Entebbe Botanic Gardens, Uganda.

that introduced sorts should do well. The London Market Report, recently to hand, on a sample of Nyasa plantation Coffee, grown and prepared here, proves that the country can produce Coffee of first-rate quality. Some of the books dealing with this country call the indigenous Coffee a form of Coffea arabica. It is nothing of the kind. It is probably a distinct species, and certainly allied to the well-marked large-leaved West Coast types. It responds most readily to cultivation, and grows rapidly after the seedling stage is passed. A Congo species (Coffea robusta) bears a striking similarity to it. This latter grows splendidly here. Our plants are from seedlings given by Kew. One plant has just flowered. I believe Coffea robusta has a considerable market in parts of Europe.

Maragogipe Coffee, a South American hybrid, and a splendid cropper, is growing freely. I have a number of seedlings of Sierra Leone highland Coffee (Coffea stenophylla), raised from Singapore seed.

TEA

grows with but moderate rapidity just here. Our rainfall is not great enough. When we have a period of rains it flourishes nicely. If its cultivation were carried on here even on a moderate scale to meet some of the local demands, it would be necessary, I feel certain, to call in the aid of irrigation. Mr. Scott Elliot, the naturalist and traveller, seemed satisfied from his explorations in the Ruwenzori country that large areas there offered a fine field for cultivating Tea on a large scale.

Vanilla is growing moderately well. Our forest belt on the lake shore suggests a climate where it ought to thrive apace, but doubtless our elevation accounts to a great extent for its tardiness.

The fruits mentioned in the accompanying lists are practically all well-known tropical sorts. We are pushing on their culture as fast as possible, for fruit is one of our scarcest commodities. Our plants are doing excellently, but the majority are not old enough to have reached the fruiting age yet. A number of Pine apple suckers I brought from Kew are now bearing their first crop of fruits; they are choice dessert sorts grown in British gardens. Already a quantity of shoots from these have been distributed to local residents and to some out-stations. This distribution will continue to be carried out whenever opportunities occur.

TIMBER TREES.

A great deal of attention is given to the introduction of timber trees. The fine Mlanji Cedar of Nyasaland makes most satisfactory progress here. Specimens about three years old are now over 15 feet high. A large quantity of seeds of this tree was recently obtained from the Botanical and Forestry Department, Zomba, and distributed widely in Uganda. There is a considerable number of trees planted in the gardens here and about the station. Establishing the useful and ornamental Eucalypti is practically impossible, owing to the depredations of 'white ants' (termites). One avenue alone has been planted no fewer than four times by myself. Fine young trees from 15 to 20 feet high are ringbarked in a short time just below the surface and quickly die. A wide selection of species have been tried, but all seem equally vulnerable to the attacks of this insidious pest. We have tried all methods of fighting it, but with little or no result. It is rather interesting to know that in one of the worst portions of the gardens for 'white ants' the common Guava thrives and is never attacked by the creatures.

West Indian Mahogany, various Coniferæ, Palms, and several timber trees of the Straits Settlements, &c., are amongst recent introductions. Mahogany will be extensively planted and distributed. A barrel of seeds (through Kew) from the Commissioner of Agriculture, Barbados, is due to arrive presently. Some seedlings of a few months old planted out lately are thriving well.

A large selection of species of Australian Acaciæ, useful and ornamental, in addition to other trees from that country, have recently been sown.

FIBRES.

There is already some local enterprise in the matter of exporting native fibres. Sanseviera (Bowstring Hemp) is abundant and there appear to be three or four species. A favourable report was received from London on specimens we sent, and one was valued at £25 per ton. Raphia fibre from the magnificent Palm so common on the lake-side is, like Sanseviera, extremely abundant. Both of these items could be propagated to any extent by planters here at a trifling cost. We have some common Ramie, or 'China grass,' growing very favourably. I consider that many parts of this country are peculiarly well suited to Ramie-growing. I am not aware if the difficulty of finding a really suitable and practicable machine to prepare this splendid fibre on the field has yet been overcome.

The indigenous cotton is a very fair sample, and imported sorts which we have experimented with on a small scale do very well; the fibre was favourably reported on in Manchester. The only drawback is a tendency on the part of some varieties of known perennial habit to become annual, dying off as soon as the crop is matured."

[The Mlanji Cedar, Widdringtonia Whytei, was first described by Dr. Rendle in the *Transactions of the Linnean Society*. Our illustration (fig. 69), which we owe to the courtesy of the director of the Royal Botanic Gardens, Kew, shows a young plant growing in the gardens at Entebbe. In our number for June 16, 1894, p. 746, we extracted from the *Kew Bulletin* of 1894, some interesting particulars relating to the tree. ED.]

SOWING SEEDS OF GRASSES.

THOSE about to lay down lawns of any kind with seeds, should dig or trench the land; and in the case of simple digging, remove all coarse-growing weeds, root and top, and by scuffling and raking reduce the surface to a fine tilth. If the land be very poor, manure in small quantity may be dug in, or some fine rich soil spread over it, made level, either hanging or dead level, and all inequalities taken out by raking or filling in with soil from the higher parts. Having done this, let it be trampled evenly and regularly all over, rake again, and finally pass a roller over several times. The ground being thus got into a nice condition, sow Ryegrass seed first in the desired quantity, also fine Clover-seed, and hack and rake these into the surface, following with the finer grass-seeds. Choose a windless day and

the surface dry for carrying out the work. It is a good plan to peg out the land to be sown in strips, and sow each separately. Scatter some small quantity of finely-sifted soil free from weed seeds over the surface. In order to finish off the work properly, pass the roller again over the sown land. If cats or seed-eating birds be feared, the land should be netted, or protected by black thread supported on thin sticks thrust into the soil. *W. A. Cook.*

PRUNUS SUBHIRTELLA.

This is one of the latest acquisitions to the flowering Cherries, having been introduced to Kew in 1895 from the Arnold Arboretum. It is a native of the mountains of Japan, and appears to be largely cultivated by the Japanese for its flowers. The native name is "Higansakura." In this country it promises to be a very ornamental tree. The original plant at Kew is now 12 feet to 14 feet high, of pyramidal outline, and has a distinct, well-formed trunk 2 or 3 inches in diameter. It is evidently a small or medium-sized tree when mature; the branches are rather erect-growing, and the leaves are 2 inches to 3 inches long, ovate, pointed, and toothed, each tooth terminated by a gland. The are dark, rather dull green above, paler beneath, and hairy on both surfaces, especially on the veins. The flowers are borne in clusters of

Fig. 70.—PRUNUS SUBHIRTELLA.

from two to five, each flower of about ¾ inch in diameter, of a soft rose tint when first expanded, and becoming paler with age. The illustration (fig. 70) will show how abundantly they are borne. In an average season the flowers are in full beauty about mid-April, but in very mild seasons as early as the end of March. A distinctive character is given to the flower by the petals being slightly lobed or notched at the tips.

The specimen from which the illustration was made was cut from a young tree forced into bloom in February in the greenhouse at Kew. For such a purpose the species is evidently well suited. It not only develops its flowers well, but they last in good condition for some weeks. The flowers, moreover, are not only very pretty, but also very distinct from the other Cherries commonly used for early forcing. In the open-air they are of a much more deeply-tinted rose; they do not, however, always escape the blighting frosts of spring. But seen at its best, Prunus subhirtella is one of the loveliest of April-flowering trees.

Among the other Cherries already established in our gardens, P. pendula—or what is more commonly known as Cerasus rosea pendula—is the nearest ally to P. subhirtella. It differs, of course, in its pendulous habit; also in its leaves being more lustrous and less hairy when mature than those of P. subhirtella. The flowers, however, except in having rather longer stalks, are almost identical—the fruit I have not seen.

The present species can be struck from cuttings put in about mid-June, or whenever the young shoots have become firm and half woody. A stock of young trees has been raised in this manner at Kew, and from their rapid free growth the method is evidently a suitable one. The species can, no doubt, be rapidly increased by budding also; but in the case of flowering Cherries there are objections to that method. *W. J. B.*

THE MARQUIS DE WAVRIN'S CATTLEYAS.

THE Château de Ronsele, the country seat of the Marquis de Wavrin, is situated near Ghent, Belgium; and here the Marquis has collected a choice lot of Orchids, including what is probably the finest selection of Cattleya Trianæ ever made. The famous "Lee" collection, which was sold by auction some years since, was particularly rich in varieties of this splendid winter-blooming Orchid, the stock of the noted variety C. T. Leeana realising 700 guineas. Both the collection and the sale are well within the memory of many orchidists, who will recollect the fine quality of the plants, and the excellence of the varieties. But good as the Lee collection was, it is surpassed by that of the Marquis de Wavrin, which may truly be said to be unique.

At the time of the writer's visit, there were some 200 distinct forms in bloom, and among them at least twenty white varieties, or with white predominating in the flowers, from the pure albino, C. T. alba, to a very lovely form designated Comtesse de Flandre, bearing fourteen large glistening white, blush-tinted blossoms.

My visit was too late by some weeks to witness the finest part of the display, as at the previous meeting of the Ghent Horticultural Society the Marquis staged a group of a startling character, which was unanimously accounted to be the best collection of C. Trianæ ever brought to the Society's exhibitions. It is surprising that such an immense number of distinct and good varieties could be found in any one species of Orchid, or in any one collection; but such is the enthusiasm of the owner, that every source of this species has been exhausted to furnish the Ronsele collection; while the Marquis's *chef de culture*, M. Gerard De Geest, cultivates these plants to perfection. One example may be cited, that of a pseudo-bulb matured this season which measures 6 inches in circumference, with leaves of proportionate size, and of that leather-like consistency so dear to the cultivator. The general condition of the plants is so good, that De Geest was asked what was the kind of compost in which the plants were cultivated; his reply was: "Polypodium fibre and sphagnum, with a surface layer of pure sphagnum." The results are certainly extraordinary, and decidedly the best I have ever observed, though I have studied the cultivation of Cattleya Trianæ from the time of the introduction of the plant into Europe.

I well remember the grand plants of Mr. Marshall, of Enfield, who made a specialty of Cattleya Trianæ from the first, and who gained the Royal Horticultural Society's Gold Medal for a splendid exhibit of varieties in 1865, staged in the Council Room, at South Kensington.

The following were among the best of the varieties of C. Trianæ in flower at the time of my visit to Ronsele. Prince Albert, a grandly shaped form, sepals and petals of a deep rose-red, the front area of the frilled labellum being of a rich crimson, rendered the more conspicuous by the deep golden-yellow shading of the throat. Comtesse de Flandres, already mentioned; Lady Tennant, of the plumose or Backhouseana section, the broad crimson flaked petals being particularly broad and good in shape and colour. The Marquis has at least a dozen forms in this group, all of which are distinct and good. These include a specimen of the original var. Backhouseana Regina, a pleasing form of a shape and colouring closely resembling Mendeli var. Fairy Queen, the sepals and petals being pure white, as is the greater portion of the lip, the exception being the central rose-coloured rayed blotch; the throat is of a soft yellow tint, much lighter than is usual.

"Perfect" is one of the red varieties, and well deserves its varietal designation; the petals measure 3½ inches across, and the flower is of admirable proportions, besides exhibiting a wonderful depth of colour, particularly the front portion of the lip, the velvet-like crimson tint of which is reminiscent of Cattleya Hardyana, though the throat is similar in colour to that of the variety Prince Albert.

Mademoiselle Adrienne de Wavrin ranks high among the white-flowered varieties; sepals and petals milk-white, broad and shapely, and the lip suffused with a tender shade of rose-lilac, with a pure white frilled margin; an effective feature of the flower. The variety "rubens," a gem among the darker varieties, finely formed and conspicuous, owing to the intense crimson-lake colouring of the lip; the sepals and petals are nearly as dark. "Le Czar" is remarkable for its ideal shape, sepals and petals snowy white, of great substance, and contrasting effectively with the broad-frilled magenta-crimson coloured lip. "Angelica," a lovely form, difficult to describe, the labellum exhibiting a most uncommon shade of colour, briefly defined as slaty-blue, but the term does not convey the beauty of the living tint; the sepals and petals are white with a slight rose tint, which adds to the general effect. "Bella" is a very large form, chiefly notable for its large size and perfect shape, the great breadth of the petals, and the rich crimson colour of the lip, which is bordered with French-grey. "Victoria" has light rose-coloured sepals and petals that are unusually broad, appearing lighter in tint than they are in reality, owing to the intense purple-crimson tint of the lip. "Transvaal" has equally large flowers, the sepals and petals of a deep rose-pink tint; the lip is of plum-purple, shaded with crimson, and the throat entirely of a clear orange-yellow colour. "President Oswald de Kerchove," named in compliment to the President of the Ghent Horticultural Society, is a particularly handsome flower—one of the finest in the collection, with sepals and petals of a clear rose-crimson tint, and a very broad lip of the deepest crimson-maroon. "Tessellata" is a finely-shaped form, remarkable in colour, the sepals and petals being dappled with rose and white, rendering still more vivid the bright crimson-lake colouring of the lip. "Illuminata," a very large and finely-shaped flower, having the whole front of the lip of a rich purple-crimson colour, and sepals and petals of a soft rose tint. "Marginata" is not perhaps so aptly distinguished by its name as many of the other forms; it is, however, a grand variety, and of a brilliant colour, with pearly-white sepals and petals, and lip of a rich crimson-red tint, and a frilled margin of white, that passes into orange-yellow in the throat.

"Faseinator," the last of which mention can be made here, but by no means the least attractive, has bright cherry-red sepals and petals; the front lobe of the lip is a deep maroon-crimson, abruptly terminating at the entrance of the throat, where it is met by a deep orange ochre shade of colour.

The foregoing varieties are representative of the many grand forms acquired by the Marquis, and of the general excellence of the collection; but the interest of the Marquis is not confined merely in varieties of Cattleya Trianæ, although they certainly form a grand feature of the Rousele collection. Excepting Odontoglossums and Cypripediums, all the most popular species of Orchids are represented here, especially the albinos of Lælia and Cattleya. In some cases, six or more examples of the same albino find a place in the collection, while a large number of beautiful hybrids have been raised or acquired. *J. G.*

ORCHID NOTES AND GLEANINGS.

DENDROBIUM BOXALLI.

BURMESE Dendrobes of the more showy species are imported largely by Messrs. Hugh Low & Co., Bush Hill Park, where there is now a good show of the finest of those that flower in the spring, amongst others D. Boxalli, which has always been a rather scarce plant. The stout upright pseudo-bulbs are thickly clad with showy white flowers, tipped with rose; the disc of the lip is of a deep yellow tint, and is edged with white, the apex being of a pink colour. In appearance it is intermediate between D. crystallinum and D. crassinode, and it is probably a natural hybrid, for it seems to have never been imported in quantity. It is closely allied to D. gratiosissimum (Bullerianum).

CATTLEYA TRIANÆI LEEANA.

A flower of this fine variety, sent by Mr. T. Stafford, gr. to F. Hardy, Esq., Tyntesfield, Ashton-on-Mersey, proves that its distinctive features of great size, breadth of petal, and finely expanded labellum, so often noted in the *Gardeners' Chronicle*, from the then famous Downside collection, are well sustained. Fashion in Orchids changes, and probably the high-priced favourites of that day would not realise the exceptional prices they then did, although they would always command high figures. In a note in the *Gardeners' Chronicle*, May 7, 1887, of a sale of Orchids at Downside, it is recorded that the 550 lots of the first day's sale brought £3,388, some of the Cattleya Trianæi varieties being among the favourites: "Cattleya Trianæi Leeana, with thirteen bulbs, £199 10s.; C. T. Osmani, £63 and £94 10s.; C. T. eboracensis, £42; C. T. Dayana, £56 14s.; C. T. Dodgsoni, £73 10s.; C. T. Emperor, £46 4s."

"FLORA BRASILIENSIS," FASCICULUS CXXVI., ORCHIDACEÆ VII., EXPOSUIT ALFREDUS COGNIAUX. PP. 381—642, TAB. 82—119.

In our issue of July 13, 1901, p. 26, we favourably commented on the part of vol. iii., in which

M. Alfred Cogniaux had so well continued his enumeration of the Orchidaceæ in this stupendous work on the flora of Brazil. In that fascicle the genus Epidendrum was continued, and Cattleya, Lælia, Leptotes, Brassavola, Schomburgkia, Sophronitis, and other genera elaborately dealt with.

The present fascicle is accompanied by a full index, and takes up the work of completing Govenia, and continues with Cyanæorchis, Mormodes, Catasetum, Cycnoches, Lycaste, Paphinia, Bifrenaria, Peristeria, Sievekingia, Lycomormium, Coryanthes, Paradisanthus, Aganisia, Acacallis, Stanhopea, Houlletia, Kegelia, Gongora, Cirrhæa, Koellensteinia, Colax, Zygopetalum, Menadenium, Eriopsis, and Bulbophyllum.

Of Catasetum, fifty-two Brazilian species are described, ten of them being illustrated; of Bulbophyllum, forty-two species are described, and over twenty of them are illustrated. The descriptions and illustrations of these two genera are specially interesting. The species of Catasetum, although not of much use to growers for florist's purposes, are always interesting, and their peculiar structure, and the production of male and female flowers, some of which are also illustrated, give additional interest to the genus.

The enumeration of so many species of Brazilian Bulbophyllums will surprise even the orchidists who collect botanical Orchids; for although the Indian, African, and Malayan Bulbophyllums frequently get imported, it is singular that the South American kinds rarely appear in gardens. Many of those illustrated, such as Bulbophyllum barbatum, B. laciniatum and its var. Janeirense, B. nemorosum, and B. plumosum, have hairy lipped, insect-like flowers, which would render them of equal interest with the singular African B. barbigerum, which never fails to attract attention when in bloom.

All the genera and species dealt with are most carefully and minutely described, and the same exactness extends to the analytical representation of the species illustrated.

As a purely scientific work devoted to a given area, it is difficult to conceive how the Orchid parts of the *Flora Brasiliensis* could be improved. Of course, M. Cogniaux has his own opinions about the classification of certain sections, but for any departures in that direction he has doubtless satisfied himself that the course pursued is correct. It will be useful to enumerate the illustrations in this part as we did in the preceding:—

Mormodes tigrinum, M. roseum, Lycomormium Serronianum, Catasetum Gnomus, male and female; C. rioularium, C. Hookeri var. lahiatum, C. cernuum var. umbrosum, C. Lemosii, C. ciliatum; C. albovirens, C. micranthum, C. discolor; Cycnoches Haagei, C. pentadactylon; Paphinia grandiflora, Batemania Colleyi, B. Yanaperyensis, Bifrenaria sabulosa, B. aurea, B. calcarata; Coryanthes maculata var. splendens, C. biflora; Paradisanthus paranænsis, P. Mosenii; Stanhopea oculata, Gongora nigrita, Cirrhæa saccata, C. Loddigesii; Koellensteinia tricolor, K. graminea; Zygopetalum Mackayi, Z. maxillare, Z. Sellowii, Z. triste, Z. Mosenianum, Z. microphytum, Z. rostratum (Menadenium labiosum); Bifrenaria vitellina, Eriopsis Sprucei, Bulbophyllum atropurpureum, B. micranthum, B. rupicolum, B. macroceras, B. mentosum, B. insectiferum, B. micropetalum, B. epiphytum, B. glutinosum, B. punctatum, B. barbatum, B. granulosum, B. monosepalum, B. laciniatum and var. Janeirense, B. nemorosum, B. ochraceum, B. quadricolor, B. plumosum, B. bidentatum, B. cantagallense, B. chlorepterum, and Stenia pallida.

Regular Peloria in Cattleya Trianæ.

Mr. Butcher, of the gardens, Heath Lodge, Hampstead, kindly forwards us a regular flower of Cattleya Trianæ in which there are three sepals, three petals all lip-like in colour and form, a straight column, with a terminal anther. The ovary is three-celled, but without ovules. It might be briefly described thus:—$S\frac{1}{2}$, $P\frac{2}{1}$, Col., $O\frac{2}{1}$, where S signifies sepals, P petals, Col. column, and O ovary. When expanded, the whole flower has the appearance of a Japanese Iris.

Lælio-Cattleya Orpetiana and var. Massiliensis.

In the *Gardeners' Chronicle* for April 12, 1902 (p. 238), I described, under the name of Lælio-Cattleya × Gladys, a hybrid from C. Harrisoniana × L. cinnabarina, which was figured in the June issue of the *Dictionnaire Icon. des Orchidées* (Lælio-Cattleya hybr.), t. 20. On September 6 following, five months later, M. E. O. Orpet described, under the same name of L.-C. Gladys (*American Gardening*, p. 574), another hybrid from L. tenebrosa × C. Gaskelliana alba. The name of this latter hybrid had therefore to be changed, and I altered it to L.-C. × Orpetiana.

Some time afterwards I received from M. Cleverly, gr. to M. L. Fournier, of St. Barnabé, near Marseilles, a third hybrid (from C. Gaskelliana × L. tenebrosa), the inverse to the other cross, and this I named L.-C. × Orpetiana var. Massiliensis. The sepals and petals of this are cream-white, and much flushed with bright rose, especially towards the tip; the lip is bright violet-purple, with fine yellow lines on the throat. *A. Cogniaux.*

ODONTOGLOSSUM CRISPUM "GRACE RUBY."

There have been exhibited some striking varieties of this exceedingly popular Orchid during the past few years. The one illustrated in fig. 71 is certainly handsome. The flowers are of large size and excellent form; they have a white ground, which is evenly spotted with purple spots, and the petals and lip are prettily fringed. The First-class Certificate of the Royal Horticultural Society was awarded to the variety when it was shown by Messrs. J. & A. A. McBean, Cooksbridge, at a meeting on February 24.

Fig. 71.—Odontoglossum crispum "Grace Ruby."

THE ROCK GARDEN.

PLANTS IN FLOWER.

Some interesting subjects are now peeping up on the rockery, one of the prettiest being Anemone angulosa, and the old favourite of country gardens, Hepaticas, which, when planted in clumps, is very effective; but I have found by experience that when left alone a number of years the flowers are more numerous. Just now, the pink, white, and blue are quite charming. Narcissus minimus is a very striking flower, and it shows to perfection in warm nooks. Scilla bifolia grows about 4 inches high, and is very pretty, and the sunshine of the past week has caused them to open their flowers, which are blue in colour, somewhat earlier than usual. Iris reticulata, another charming flower at this season, is always well worth a place on the rockery. Saxifraga oppositifolia, of a deep pink tint, is exceedingly pretty, and showing to advantage. Erica carnea makes a pretty display on the top of the rockery, and forms a shelter to small plants.

Great care should be exercised in the rock garden in not allowing any weeds to grow, or they will soon rob the soil and starve the plants. Labels, if old or illegible, should be replaced with new ones, or the interest in the plants will be lost. If additional soil or nutriment be required by any plant, this is the proper season to apply them. If sparrows or other of the feathered tribe are troublesome to the flowers, place a few small sticks in the ground, pass black thread round them, which will have the effect of frightening them away; and if mice are troublesome, place some of the American breakback traps about. *W. A. C.*

Schizocodon soldanelloides.

It is questionable if there are many hardy flowers which have given as much trouble to establish as the charming little Schizocodon soldanelloides, which is yet rarely seen in rock

gardens. It is a very cheap plant at home, and has been imported in great quantities, with a profoundly disappointing result to many. It is thus not surprising that the price asked for it in this country is apparently out of all proportion to that it can be bought for in Japan. The percentage of losses to importers must be very large, and of the plants obtained by private growers only a very few become established. The first really thriving plant of this Schizocodon I saw was in the wonderful garden of the late Mr. G. F. Wilson, of Oakwood, where it was growing well, and beginning to make increase. The plant was in a peaty soil, under the shade and shelter of some shrubs. Although I had previously been baffled in my attempts to grow it, seeing it thus healthy and happy I made another trial. A position was chosen on a ledge of rockwork, facing almost due east, and the pocket in which the plant was to be inserted was filled with a compost of peat and sea-sand—about equal parts. The plant was put in firmly, the soil brought up to its neck, and frequent top-dressings of a similar compost given when necessary. During dry weather in summer, free supplies of water are afforded, not mere surface waterings, but a thorough soaking of the soil. The Schizocodon gets hardly any sun, owing to a higher ledge of the rockery partially shading the position. This plant is now well established, and produces annually several of its delightful little pink, fringed flowers. The blooms are not its sole charms, for the little leaves are exquisitely coloured with chocolate, and various other tints of brown, and occasionally becomes at times almost crimson. The same position might not suit S. soldanelloides in every garden, but similar treatment might be tried with a prospect of success. From various districts I have heard of the plants becoming established, and flowering under something like the same conditions. *S. Arnott, Carsethorn, by Dumfries, N.B.*

The Week's Work.

PLANTS UNDER GLASS.

By J. Mayne, Gardener to the Hon. Mark Rolle, Bicton, Budleigh Salterton, Devonshire.

Grasses.—These are invaluable to the gardener when arranging groups of plants in the dwelling or at horticultural shows. Of these plants the Eulalias and Isolepis gracilis are indispensable, and add finish to floral arrangements. The first named should have been resting for the past three months, but it is a mistake to allow them to get very dry even in the winter. The plants may now be relieved of most of the exhausted soil; and if necessary to increase the stock, the varieties japonica and j. zebrina may be divided, but japonica foliis striata not being such a strong grower resents too much interference at the root in that manner. Do not cut away the old stems until growth is active. Useful sized pots for these grasses are those of 4 or 5 inches in diameter; and as a potting soil, employ about equal parts of loam and leaf-soil, with a sprinkling of peat, and plenty of sand. Place in a temperature of 60°, and afford water carefully till they are re-established, when greenhouse treatment is the best for them. The Isolepis may be divided freely, and put into 3-inch pots. A few of the Carex family are useful as edgings, while Cyperus alternifolius should be raised from seed annually, sowing forthwith in heat, with merely a dusting of sand over the seed.

Forced Hardy Plants.—Deutzia gracilis, Staphylea colchica, Cerasus Watereri, double-flowered Cherry, and Ghent Azaleas should be placed in slight heat, and freely syringed, so as to encourage the growth of shoots, and afterwards afforded a gradual hardening off before placing them outdoors in April. The first-named plant may require to be trimmed into shape, the weaker shoots removed after flowering, and the spent flowers of the Azaleas removed, or growth will be poor. Less heat will be required now to bring into bloom successive batches of these plants, though overhead moisture is beneficial.

Lilies.—Keep a watchful eye on early batches of L. longiflorum Harrisii; fumigate the plants once a week, placing them near to the glass. As the blooms begin to expand, remove to a cooler house, and introduce others for succession. The pots of L. auratum, L. lancifolium, and others, should be plunged in a bed of coal-ashes in cold frames, the lights of which on mild days may be taken off. Top-dress with loam three parts and peat one part, together with crushed mortar-rubble, as soon as roots appear on the surface. I have just potted-up a batch of these, which will flower in the late autumn.

Camellias.— Plants that have passed out of flower should be syringed daily; and if any cutting back is required let it be done before the plants have made much new growth. Plants in pots or tubs do not need much pruning, but others planted in borders, we find, require to be thinned annually. They are growing in a large span-roof structure devoted to their culture, in which sun and air can penetrate among the branches, and thus ripen the new wood. Any repotting is best done immediately after flowering, and the borders may be dressed at the same time, using turfy-loam and peat in equal parts, and enough coarse silver sand to keep it sweet and porous. During the next few weeks a little fire-heat will be beneficial, and the house may be closed at about 3.30 p.m., directly after syringing. Do not let the plants become dry at the roots.

Gardenias.—Take cuttings of these, and insert half-a-dozen around the edges of each 4-inch pot, which should be nearly filled with a sandy soil containing a little fine peat; afford a bottom-heat of 75° or so in a close case. In about four weeks' time they should be fit to pot up singly, using a similar soil, and returning the plants to the case for a few days, until they have taken hold of the new soil; they may then be placed near to the glass, and be syringed once or twice daily. Stop the shoots after they have made two pairs of leaves, and repeat the process when two additional pairs have been made. Repot them again into 5½ or 6½-inch pots when fit, and they should flower well in these next spring. The soil used at the final potting should be more lumpy, and consist of equal parts of loam and peat, with a little charcoal and plenty of sand. These plants grow into good specimens if lightly pruned after flowering, and eventually placed in 8 or 9-inch pots, affording plenty of heat and moisture when growing, and giving but very little shade at any time.

THE KITCHEN GARDEN.

By John Fleming, Gardener to Sir C. Pigott, Bart., Wexham Park, Slough.

Asparagus.—Those beds that were top-dressed with manure in October or November should now have the manure removed, and if the soil be light, a good dressing of salt and a ½-inch layer of rich soil should be spread over the beds. Many gardeners throw the soil from the alleys in sufficient quantity to cover the beds, but on light and well drained ground I prefer to have the beds on the flat, and merely dig the alleys lightly; but in wet land, or that not well drained, or is cold and tenacious, the beds should be raised about 1 foot above the general level of the garden, with sunken alleys between. In gardens in which Asparagus is forced largely, every winter preparation should be made for sowing Asparagus-seed. The land for this vegetable should have been heavily manured, and trenched 2 to 3 spits deep; and if retentive, a heavy dressing of road-grit, wood-ashes, or finely broken mortar-rubble, should be incorporated with it. The beds may measure 4 feet in width, and the alleys 2 feet. Having squared the beds at the sides and ends, and made the surface level with the rake, draw three drills on each bed, one in the middle, and the two side ones 10 inches distant from the outer edges of the bed. In the drills sow clusters of seeds, the clusters at 1 foot apart. As soon as the seedlings are large enough to handle, thin each cluster to the strongest plant. If plants are raised annually from seed, and transplanted the next year, the preparation of the ground and the formation of the beds are the same as that described. Let the rows be thrown out with a spade to the depth of 4 inches and width of 8 inches, and having carefully spread out the roots of the Asparagus plants, cover them without loss of time, as a very slight exposure to dry air is injurious. Early Cauliflowers or Lettuces may be grown in the alleys between the beds during the first two years.

Globe Artichokes.—If offsets were potted in the autumn, and these were wintered in cold pits or frames, they will have been hardened off ere this, and may now be planted. The ground for this crop should be well manured and trenched, and the suckers planted at 3 feet from plant to plant and 4 feet between the rows, setting them rather deeply, and trampling the soil firmly about them. Place a 1 inch layer of sifted wood-ashes around each, and mulch the ground between them with stable-dung. Remove the mulch from established plants, and apply a dressing of rotten manure, forking it into the land. Decayed seaweed may be applied where obtainable in place of manure. Globe Artichokes may be grown from seed, and treated as an annual or biennial; but the method is unsatisfactory, as the varieties cannot be relied on to come true from seed.

Seakale.—The plants reserved for furnishing the latest supplies should be covered forthwith with finely-sifted coal-ashes put over the crowns to a depth of about 15 inches, so as to preserve them from the sunlight. Cuttings that were laid in as advised in an earlier calendar to callus may now be planted in trenched and manured ground in an open position. Let the surface be stirred with a fork, and the plants set out in rows 2 feet apart, and 15 inches between the plants. Plant with a dibber, just covering the crown, and placing finely-sifted coal-ashes over each. In forming permanent beds, to remain to be forced annually, it is very important to allow ample room, that is, 4 feet between the rows, and 3 feet between the plants, planting in clumps of triangular shape.

THE ORCHID HOUSES.

By H. Alexander, Orchid Cultivator to Capt. G. L. Holford, Westonbirt, Tetbury.

Dendrobiums that have passed out of flower, and commenced to grow, should now be repotted or top-dressed, whichever is most necessary. Avoid any disturbance of plants well established in materials in a sweet condition. Pots or pans may be used if of sufficient capacity to last for two or three years, and the potting compost should consist of the best turfy peat one-half, leaf-soil one-quarter, clean chopped sphagnum one-quarter, the whole being mixed together with a sprinkling of finely broken crocks and silver-sand. The pots or pans must be well drained, and over the crocks a layer of sphagnum should be placed, and the plants potted with a moderate degree of firmness. A few heads of living sphagnum may be pricked into the surface for neatness sake. Small plants of Dendrobium should be grown in pans hung from the roof, and the larger ones placed on the stage. When a plant has become exhausted from too much flowering, pull it to pieces, remove the older useless pseudo-bulbs, and make up the plants anew; or better still, let the pieces be potted up singly in small pots, in which they may stand for a season, and the following year be put together again. The affording of water is an important part of the treatment of these plants, especially at the present season, and new growths are frequently lost through excess of water, especially newly-potted ones.

The Propagation of Dendrobiums.—The cultivator should make it his practice to propagate a few of the choicer species and varieties, which in the course of time would take the places of those that have become exhausted. The propagation is effected by cutting off well ripened back-growths, and severing at short intervals, taking the precaution to preserve a sound bud with each, and discarding any that have borne flowers. Place these to the number of four in small well-drained pots filled with chopped sphagnum and silver-sand, and resting the base of the bud upon the surface of the potting material. Place the cuttings in a warm propagating pit, and afford them an occasional syringing, but do not saturate

the compost with water. When the cuttings have made a small amount of growth a few roots will be sent forth, when a small amount of moisture may be applied, and the pot soon afterwards transferred to a light position in the warmest house to complete the season's growth.

Odontoglossum-house.—It is the usual practice to overhaul the inmates of this house generally early in the autumn, repotting those plants standing in need of it; but it sometimes happens that a great many plants at that season have not started into growth, and therefore repotting cannot be performed—however, the present season is suitable also. O. crispum and the hybrids and crosses therefrom are benefited by being placed in a leaf-soil compost, providing proper care in the subsequent treatment is afforded. A suitable compost would consist of Oak-leaves two-thirds, turfy peat one-third, a small quantity of chopped sphagnum, and a good deal of silver-sand. The pots should be large enough to accommodate the plants for a space of two years without root disturbance. The drainage should be good, but not excessive in amount, and a layer of sphagnum should cover it. Pot firmly, and insert the potting material in and amongst the roots, finishing off just below the rims of the pots, and putting some fresh sphagnum over all, clipping it evenly. If the materials used are in a moist state, no water will be required for some little time, but frequent damping between the pots and spraying overhead at suitable times are beneficial. Shade from bright sunshine; afford as much moisture when the compost becomes dry as will moisten the whole of it, but do not afford water in driblets and often.

FRUITS UNDER GLASS.

By T. H. C.

Vines raised from Eyes.—Place these in clean, well-drained 5-inch pots as soon as they are well rooted, and have made 3 to 4 inches in height, employing a compost consisting of good turfy loam two-thirds, and equal parts of leaf-mould and finely sifted horse-manure one-third, to which a small portion of pounded charcoal and mortar-rubble may be added. If the loam is not of the best quality, add a 5-inch potful of Thomson's Vine-manure to every wheelbarrowful of the compost; pot moderately firmly. If convenient, carry out this operation in the house in which the Vines are growing, and see that the soil is of the same temperatnre as that of the house. Place a thin stake to each Vine, to which it should be fastened as it increases in height. Keep the plants near to the roof-glass; maintain a warmth at night of 70°, and one of 80° to 85° by day, with ventilation more or less according to the weather. Lightly syringe the foliage on bright afternoons, and damp the paths and other surfaces.

Planting Vines.—If a vinery has to be planted, do this in June, with Vines raised this year and grown in pots or shallow boxes, carefully planting them by preference as early as possible in June. They usually grow strongly and get thoroughly established by the end of the season. By planting thus, an early crop of something else may be secured from the vinery previous to planting the Vines. At this season young one-year-old canes may be planted, just as they are bursting into growth. For the first year a well made border of 4 feet in width is ample, and if it be considered necessary, make a concrete bottom to the border. Lay up on the concrete a 9 inch layer of stone, chalk, brickbats, &c., and upon that compost to the depth of 2½ feet, consisting of rich turfy fresh loam in a rough condition, to which may be added, more or less according to the quality and texture of the loam, a sprinkling of ½ inch bones, mortar-rubble, and charcoal, or charred garden refuse or soil. Enclose the border with a temporary brick-wall set in cement, which can easily be removed backwards as the border is extended. As soon as the soil has got warmed throughout, proceed with the planting, disentangling the roots, which should have been previously afforded water, spreading them evenly out at different depths in the upper 8 inches of soil. Apply tepid water in some quantity, and a mulch of exhausted mushroom-bed manure. No matter what is the style of training that will be adopted, the Vines should not be less than 3½ to 4 feet apart when taken up the trellis. Shade them from strong sunshine till they are growing strongly, syringe them twice daily, and maintain a warm, moist condition of the air in the vinery.

Orchard-house.—As the various fruit trees come into flower, distribute the pollen daily. Syringe Plums and Cherries and other trees thrice daily as they go out of flower; and if they are infested with green or black fly, apply weak quassia extract. After all the trees have finished flowering, vaporise with XL-All, which is certain death to aphides. Ventilate continually, more or less according to the state of the weather. If the weather is cold and dull, turn on a little heat in the hot-water pipes, but at no other time, except when the weather is severe. Attend carefully to the affording of water to trees growing in pots, and after the fruits have commenced to swell, afford manure in some form. When the trees have set their fruits, syringe the foliage vigorously daily with tepid water. Close the house early in the day so as to retain some of the solar warmth.

THE HARDY FRUIT GARDEN.

By Chas. Page, Gardener to J. B. Fortescue, Esq., Dropmore, Maidenhead.

The Black Currant-bud Mite.—If this pest has obtained a footing in the plantation, the infested buds should be collected and burnt forthwith; a work which, if it receive careful attention for a few weeks, will do much towards saving a crop of fruit, but I fear it is impossible to eradicate this mite entirely from a plantation. In dry weather, let the land between all kinds of small fruit-bushes, &c., be hoed with a Dutch-hoe.

Wall Trees.—The weather in the south during the past week has been very unfavourable for the flowering of the Apricot and Peach, and the use of nets, tiffany, canvas, &c., as protection against frost and sleet, has been imperative. All nailing and tying of fruit-trees should be finished off soon; Cherry-trees should be copiously syringed forthwith with diluted Quassia extract, or Quassia-water, so as to carry the trees safely over the blossoming period.

Miscellaneous Hints.—On wet days prepare grafting-clay by removing stones from it, and adding a fourth of the whole of cow-dung, a sprinkling of chaff, and as much water as will make the material of the consistency of stiff mortar, putting this in an open shed, covering it with a mat. Young standard Apples and Pears, planted and staked early in the autumn, should be examined, refastening the trees, and placing the stakes upright where necessary.

THE FLOWER GARDEN.

By J. C. Tallack, Gardener to E. Miller Mundy, Esq., Shipley Hall, Derby.

Pruning Roses.—During the next week or two dwarfs and standards of the Hybrid Perpetual and Tea Roses should be pruned, commencing with the first-named, these not being so quick to break as the Teas. The unusually mild weather in most parts of the country has excited the buds near the tops of the shoots, and in some cases it will be difficult to discover any dormant buds to which the shoots may be cut back, and there will probably be much bleeding after pruning this year. All weak wood and as much other wood as can be spared from the centres of the plants should be removed, and the remaining growths shortened to a good bud pointing outwards. The method of pruning has a considerable influence on the quality and number of flowers produced; hard pruning, leaving but few buds to break on the plants, tends to high quality and the production of fewer flowers. In Moss and Cabbage Roses, all of the strong, sucker-like growths should be left intact or merely tipped, and room should be made for these by removing some of the older shoots. Pruning finished, a dressing of good manure should be applied, either to be forked into the soil lightly or as a mulch.

Ivies.—No plants are so generally serviceable as Ivies, in some of the many varieties, to clothe a wall or hide unsightly objects. They may be planted at this season, and if established plants in pots can be secured, the growth will be finer than that of plants lifted from the open ground. Though the large-leaved Ivies grow quickly, they are not so satisfactory as the smaller-leaved species for general purposes. One of the best means of keeping Ivy foliage clean and bright during the growing season is to clip it over, cutting away all old leaves.

Hollies.—Many of the finer variegated-leaved varieties exhibit a tendency to revert to the green-leaved type, and such of the shoots as do this overpower the more desirable growths, that it is very necessary to remove them, as gaps so formed in the bushes can readily be closed, provided the green shoots have not been allowed to exist for too long a period of time.

Shrubberies.—A pretty effect is obtained by planting low-growing flowering plants, and especially bulbous ones, at the margins of shrubberies, the shrubs forming the background. Vacant spaces should now be prepared by manuring and digging for plants that will be set out at a later date. When the forcing of plants is over, many of the bulbs ripened off in pots may be planted in such borders, and these will afford a quantity of flowers in the second year afterwards.

THE APIARY.

By Expert.

Seasonable hints.—The enterprising bee-keeper will now be looking forward to having everything in readiness for the bees, section-crates being cleaned, scraped, and numbered to correspond with the hives; old sections looked up and cleansed, and the worst ones destroyed, as it will be found better policy to buy new ones than to use old dirty ones which look so very bad, either exposed for sale or on the table, particularly the latter. The bee-master cannot be too particular in buying good white sections, the cost being very small; and in the matter of comb, it is quite as well to fill the sections half way across, and to take care that the comb does not bulge, or the section is likely to be built much thicker on one side than the other, which is an annoyance when packing sections in cases, especially made to take those of 1 lb. weight. Having examined the sections, ascertain how many more will be required, and order them forthwith, as many firms offer a bonus for goods ordered up to the end of March. There is a great demand for split top sections, and which for many reasons are the best, as they do away with the trouble of fixing in the foundation with glue, &c. Moreover, they are cleaner, cheaper, and certainly much more secure than others. The average number of sections should be based on the principle of sixty to one stock. It is not a good plan to order more than are required, as they get dry and brittle, and the following year a good many will get broken in the handling. In purchasing foundation, too much care cannot be taken in obtaining the best; and new foundation, like old stocked comb, is almost sure to be brittle, although it may be made a little more pliable by exposing it to the sun, or warming it before a fire.

Protecting hives.—Many bee-keepers find a difficulty in taking precautions against high winds, but there are many simple methods of securing them, viz., to drive a stake in each side of the hive, each having a notch sawn out, and secure the hive by tying a stout rope over it. Another plan is to lay a piece of rope over the hive, and attaching a heavy weight at each end, or by fastening it to a stake with a bit of hoop iron. A neat and tidy way is to fence the hives round with sheep hurdles, particularly if they are thatched.

The Great Gale in Ireland.—Further reports which reach us only confirm and extend the record we have already given of the destructive gale of February 26. Thousands of trees, including Elms, Thorns, Cedars, Silver Firs, Beech, Willows, Poplars, and even Yews, were uprooted in the Dublin parks and gardens, and at Glasnevin, Phœnix Park, Carton, Straffan, Powerscourt, and other places. The gale occurred suddenly and unexpectedly, and has occasioned more devastation than any since the "big wind" of 1839.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the Publisher.

Letters for Publication, *as well as specimens and plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Illustrations.—*The Editor will thankfully receive and select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.*

Local News.—*Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.*

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY, MAR. 17—St. Patrick's Day.
THURSDAY, MAR. 19—Linnean Society's Meeting.
SATURDAY, MAR. 21—Spring Quarter begins.

SALES FOR THE WEEK.

MONDAY NEXT—
Roses, Fruit Trees, Liliums, Perennials, &c.. at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.

TUESDAY and THURSDAY, MARCH 17 and 19—
Palms, Bay Trees, Japanese Liliums, at Pollexfen & Co.'s Rooms.

WEDNESDAY, MARCH 18—
Azaleas, Palms and Plants, Roses, Border Plants, Ferns, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.30. — Consignment of Japanese Liliums, &c , at 5 o'clock.—Bulb and Plant Sales at Stevens' Rooms.

THURSDAY NEXT—
Orchids in great variety, at 67 and 68, Cheapside, E C , by Protheroe & Morris, at 12.30.

TENDERS.

Competitive Designs for the Laying-out a Park, &c. Town Clerk, Romford.
Supply and Delivery of Shrubs, &c. Town Clerk, Tottenham.

(For further particulars see our Advertisement columns.)

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick —42·8°.

ACTUAL TEMPERATURES:—
LONDON.—*March* 11 (6 P.M.): Max. 53°; Min. 36° *March* 12 (Noon): 53°; Weather fine and bright.
PROVINCES.—*March* 11 (6 P.M.): Max. 49°, Lands End; Min. 45°, Dorchester.

The future of Chiswick.

THE paper by M. LEMOINE, translated and read by Mr. WILKS at the meeting of the Royal Horticultural Society on Feb. 24, suggests some comments—comments not altogether flattering to our powers of initiation and our enterprise as a nation, furnishing indeed once more a marked instance of our apathy and indifference towards scientific experiments and scientific teaching, even when the results are likely to be of directly practical value. In the present instance, as has been on several similar occasions pointed out in these columns, it is to Denmark, a small but eminently progressive nationality, that we owe the first experiments on the use of ether in forcing plants. It is true, of course, that CHARLES BERNARD, and very many other physiologists, long ago investigated the action of chloroform or ether on plants; but before Professor JOHANNSEN, no one, so far as we know, had attempted to turn the matter to practical account. The Danish Professor's work was speedily taken up on commercial lines by German horticulturists, and full details were given in the gardening papers of Germany and France, and a summary of the results therein given was published in our own columns.

The subject, then, is not entirely a new one; but up to the present time very few, if any, experiments have been made in this country. If we seek a reason for this indifference, we may find it in a measure in the busy life that we lead. It is not everyone who has the capacity, the leisure, or the means to carry on experiments, even of so simple a nature as those required in the etherisation of plants; the man of business, in spite of the fact that it is he who will reap the advantages of the enquiry, is in general far too much occupied with what he calls practical work, meaning merely routine, to be able to attend to anything in the least degree outside mechanical methods.

To whom, then, should we look? One reply to this question is obvious. We should look to the Royal Horticultural Society to make some use of its experimental garden; and if it did so, the Society might fairly look for assistance from those Fellows interested in scientific or in commercial horticulture. We do not think anyone who knows what Chiswick does under existing circumstances, and at what cost, can find much satisfaction in the prospect. There is nothing to be alleged against what is done there, so far as it goes. The staff is so highly capable and so zealous, that it is a pity that the labours of so efficient a body should be lost in the execution of what can be done as well or better elsewhere, and in carrying out work that no one can say is as conducive to the advance of horticulture as it might be. Time after time, as circumstances have seemed to call for it, we have urged that Chiswick should be made an experimental station, where experiments such as the ordinary gardener or man of business is precluded from undertaking, should be carried on. We are not thinking of purely scientific experiments, but of those like the use of ether in forcing, or those connected with hybridisation, which are susceptible of direct and immediate application. Suppose the results are negative; would the time and money expended be therefore thrown away? Decidedly not. An unsuccessful experiment, unsuccessful that is as to its immediate practical results, is not to be set down as a loss, but rather as a gain, for it shows what should be avoided, saves future waste of time, and probably will indicate in what direction future trials should be made. We know that the answer of the Council to any request of this kind is likely to be such as it has been before. They will courteously and benevolently say "Yes, we will grant you every facility," and there the matter will end. Years ago experiments of various kinds, one in particular of a very striking character in reference to the Potato-disease, were carried out at Chiswick under the direction of the members of the Scientific Committee. But the members of that body are most of them busy men, whose avocations are as exacting as those of any other body of men. It is unreasonable then to expect them to give their time without fee or reward. What then should be done? Here again we think the answer is obvious. Let the ordinary work of the garden proceed with as much development as possible, but let some young and competent man of science be installed to act under the advice of the Scientific Committee to devise and carry out such experiments and enquiries as seem likely to contribute towards the progress of practical horticulture. The Superintendent would, we are sure, be quite willing to co-operate with and to assist the scientific assistant, and to put at his disposal such space, labour, and material as might be required. The functions of the two officials would be different; each would be independent in his own department, but each should, and no doubt would, co-operate with his companion.

It may be asked, Where is such a man to be found? The answer to that question a few years ago would have been difficult. There were few workers in that special branch of applied physiology, and fewer openings for them. Now the conditions are so altered that there is no lack of trained students who would be competent to undertake such duties as we are contemplating.

The extra cost would be trifling relative to the advantages which might be anticipated; and the Council and the Fellows would at least feel that they got some better return for their expenditure at Chiswick than they do at present.

Instead of abandoning Chiswick, as seems to be the intention of the Council, it would be far more beneficial to retain it so long as the lease lasts, and not to attempt to make provision for an entirely new garden till the Hall has been built and paid for, and its endowment assured.

We call ourselves a practical people, and we let little Denmark take the lead, not in one, but in many, of the applications of science to practice. It is indeed full time that we heeded the injunctions of the Prince of WALES, and "wake up!"

LINNEAN SOCIETY.—On the occasion of the evening meeting held on Thursday, March 19, 1903, at 8 P.M., the following papers will be read:—1, On "Poa laxa and Poa stricta of our British Floras," by Mr. G. CLARIDGE DRUCE, M.A., F.L.S.; 2, "The Botany of the Ceylon Patanas—Part II., Anatomy of the Leaves," by Messrs. JOHN PARKIN, M.A., F.L.S., and H. H. W. PEARSON, M.A., F.L.S.

XANTHO-CALADIUM.—According to the *Revue Horticole*, M. DYBOWSKI has raised some hybrids between Xanthosoma sagittifolium and Caladium pictum. The foliage resembles that of the former plant, but with the irregular red or white spots of the latter plant. M. DYBOWSKI hopes that the hybrids will prove of value for bedding-out purposes in the summer in shady localities. They would be serviceable in the "sub-tropical garden" if their foliage should assume the rich coloration of Caladium pictum.

ASPARAGUS SPRENGERI VAR. FALCATOIDES.—A form occurring in the neighbourhood of the Orange River of robust habit, but not a trailer; the cladodes are elongated, 5 to 6 cent. long; the flowers white, followed by scarlet berries. A full description is given in the *Bulletin of the Italian Botanical Society*, 1902, p. 55.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.—The Liverpool auxiliary of this charity, whose President is the Right Hon. the Earl of DERBY, K.G., K.C.B., will hold its second annual smoker and festival at the Bear's Paw Restaurant, Lord Street, Liverpool, on Friday, March 20, commencing at 7.30 P.M. prompt. The Right Hon. the Lord Mayor, W. W. RUTHERFORD, M.P., in the Chair. The admission is by programme, costing 1s. The proceeds will be handed over to the Treasurer of the Institution.

THE MISSOURI BOTANICAL GARDEN.—We have often had occasion to mention this establishment at St. Louis, which owes its foundation to the far-sightedness and generosity of Mr. HENRY SHAW, an Englishman who had settled in St. Louis in 1819. Under the fostering care of Dr. TEELEASE, the establishment has assumed great importance, and in the *Popular Science Monthly* he has given a very readable account of the aims and present condition of the garden.

BOTANICAL MAGAZINE.—The plants figured in the number for March, are the following:—

Aloe rubro-violacea, tab. 7882, a noble species described by SCHWEINFURTH, who originally discovered it in southern Arabia. It is cultivated in the garden of Sir THOMAS HANBURY, at La Mortola, under the care of Mr. BERGER. The thick stems bear tufts of fleshy lance olate recurved leaves with spiny margins. The orange-coloured flowers are borne in dense spikes. The occurrence of the species so far from the headquarters of the genus in S. Africa is remarkable. Sir JOSEPH HOOKER suggests that further researches may bring to light other Arabian species.

Sophora vicifolia, Hand. tab. 7883, is a spiny undershrub with delicate pinnate foliage, and racemes of small white papilionaceous flowers, supported by violet calyces. It is a native of China, where it was found in Hupeh and also on the Tibetan frontier, where it forms large "heaths," at an elevation of from 9,000 to 13,000 feet. The plant figured was raised at Kew from seeds collected by Mr. HENRY, and is likely to be a valuable addition to our hardy or half-hardy shrubs.

Hamamelis mollis, Oliver, tab. 7884, is a Chinese species, differing from the N. American and Japanese species in its downy leaves and broader petals. It was originally collected in Hupeh by Mr. HENRY, and was afterwards found in Kiang-su by the late Mr. MARIES, by whom seeds were sent to Messrs. VEITCH. The species of Hamamelis are very interesting in the structure of their flowers, whilst their habit of flowering in the open air during the winter months renders them most desirable inmates of our gardens.

Phalænopsis Kunstleri, Hook. fil., tab. 7885.—A native of the Malay Peninsula, whence it was introduced to Sir TREVOR LAWRENCE's garden by Mr. CURTIS. The flowers are of moderate size, about 2 inches in breadth; flower-segments linear oblong, reddish-brown, with broad golden-yellow tips; lip much smaller than the segments, white, streaked with blood-red.

Chrysanthemum grande, Hook. fil., tab. 7886.—Originally described by LINNÆUS as Cotula grandis, and which has subsequently received various other appellations. It is a tall, hardy, herbaceous perennial, with narrow, hispid leaves, laciniate towards the base. The heads of flowers are about 2½ inches across, flattish, plate-like, with an involucre of numerous narrow bracts; the yellow flowers are all tubular, the ray-florets being completely wanting, as in Tanacetum. The plant was obtained by Kew from Mr. SMITH of Newry, to whom our gardens are indebted for the introduction of so many interesting hardy plants. The plant is a native of Algeria.

SELF-HELP EMIGRATION SOCIETY. — We recommend those who are thinking of emigrating to peruse the report of the Self-help Emigration Society, to be had at 39, Memorial Hall Buildings, Farringdon Street. The Society declines to help those who are not likely to become good colonists, but helps those who are suitable. There is ample room in Canada and other Colonies for those who can and will work, and are prepared to "rough" it for a time.

OXLIPS, COWSLIPS, AND PRIMROSES. — In the shape of an address to the Manchester Field Club, Mr. CHARLES BAILEY has given an interesting account of these three plants, contrasting their differences in conformation, their dimorphic structure, and its purpose, their geographical distribution in Britain and the continent. The true Oxlip, P. elatior of Jacquin, does not descend below the level of 200 feet, occurs on the boulder clay, and in newly-cleared woods. The Oxlip area is everywhere invaded by the Cowslip, but deserted by the Primrose; yet hybrids between the Oxlip and the Cowslip are most rare, whilst they are most numerous with the Primrose. The probability is that all three species had a common ancestor, whose characters were nearer to the Oxlip than to the Cowslip or the Primrose.

STOCK-TAKING: FEBRUARY.—The Trade and Navigation Returns for February constitute a volume—some 236 pages, or three-quarters of a pound of tabular returns, and a quarter of a pound heavier than the volume for January. The increase is due to several causes, fuller records principally so, going by weight alone. The Sugar Tariff was answerable for much of the decrease in importations in our last record; things have not yet shaken themselves down into normality. The value of the imports for the past month is £40,560,585, against £41,680,591 for the same period in 1902—a decrease of £1,120,006. In two sections only of these into which the imports are divided is there an increase, as will be seen on reference to the subjoined table, which speaks for itself:

IMPORTS.	1902.	1903.	Difference.
	£	£	£
Articles of food and drink—duty free	7,490,219	7,922,377	+432,158
Articles of food & drink—dutiable	8,647,539	7,736,243	−911,296

There is an increase to note in the wood and timber imports; the value for the past month £775,525, against £701,422 for the same period in 1902—the increase standing at £65,103. We come now to our usually interesting record of the fruit and vegetable imports, as follows:—

IMPORTS.	1902.	1903.	Difference.
Fruits, raw—	Cwt.	Cwt.	Cwt.
Apples	123,651	258,604	+134,953
Apricots and Peaches .	104	72	−32
Grapes	1,089	1,196	+107
Pears	854	1,920	+1,066
Plums	125	200	+75
Vegetables, raw—			
Onions ... ...bush.	637,317	670,591	+33,274
Potatos ... ... cwt.	93,190	196,483	+103,293
Tomatos... ... „	23,938	41,376	+17,438
Vegetables, raw, unenumerated ...value	£35,435	£37,699	+£2,264

From the above it will be seen that only Apricots and Peaches are on a minus scale—all others being in excess of last year. Readers of colonial intelligence, will observe with pleasure that the cultivation of fruit is ever on the increase. The general imports for the first two months of the year are valued at £86,787,100, against £91,822,939 for the same period in 1902—a decrease of £5,035,839; very possibly a different statement will be shown for March. In conclusion, we have to note a continued rise in the value of—

EXPORTS.

The value for last month is placed at £22,775,436, as against £21,312,276 for February, 1902, thus showing an increase of some £1,463,160. A noteworthy fact is shown in the statement recently published, that Glasgow ironmasters have turned the trade on both German and American makers in the matter of rails, both in quality and price. The legend attached to the armorial shield of the great Clyde city is, "Let Glasgow flourish"—so may it be. The value of the exports for the two months of 1903 is placed at £47,679,072, against £45,581,450—a gain of £2,097,622 over 1902.

CROP REPORTS.—Some surprise will, we suspect, be experienced at the report from the Board of Agriculture on the total produce of the principal crops in each county of Great Britain for 1902. The general results so far as bulk is concerned is highly favourable, the exceptions being Potatos and Hops.

FARM SCHOOL, BASINGSTOKE.—The third annual report has been issued, and is of a very interesting character. It is mainly devoted to agricultural subjects, but gardening is not altogether neglected:—

"In the general work, attention has been devoted rather to the need for demonstrating good methods of cultivation than to experiment. Here, as in other departments, explanations are given of methods while the practical work is in progress. It may now confidently be said that the gardens are in such a state that they can be freely used as an adjunct to the class-room, a position impossible while they were being laid out; and students with a previous knowledge of gardening are in a more satisfactory position with regard to demonstrations.

The fruit-trees are well established, and all stocks purchased during the first year have been grafted, with the help of the students.

Weather observations form a part of the instruction, and the students throughout the year keep records of the barometer, maximum and minimum thermometer, the rain gauge, and hygrometer.

It is satisfactory to have to report that two of the students gave up places as under-gardeners to come to the school, and remained over a longer period than at first intended.

GARDEN POTATO EXPERIMENTS.

The most important experiment was one designed to throw light on the advantages or otherwise of a change of seed. Eleven varieties were selected, an equal weight and number taken from the farm stock, and grown against the same varieties purchased from the grower. These were weighed and counted, and all the varieties were planted on April 28, 1902, in soil well worked and in a good state of fertility. The weight taken of each variety for all the experiments was 5 lbs., consisting of thirty sets; the rows were 40 feet long, 2 feet apart; they were earthed up on June 12, and dug on September 24."

The advantages of a change of seed are most marked.

THE GHENT QUINQUENNIAL.—More than 6,000 mètres superficial will be required for the exhibition of plants under cover.

EULOPHIELLA PEETERSIANA [see *Gard. Chron.*, April 2, 1898, p. 200, and Supplementary Illustration].—This handsome Orchid is now in flower under Mr. MOORE's care at Glasnevin. The leaves, ten in number, are about 4 feet in length; the flower-spike is over 5 feet in length, with twenty-eight flowers.

TRADERS IN POISONOUS COMPOUNDS FOR TRADE PURPOSES PROTECTION SOCIETY.—A deputation from this Society, consisting of Mr. T. G. DOBBS (Secretary), Mr. G. H. RICHARDS, and Mr. PEED, were received by the Council of the Royal Horticultural Society, and Sir TREVOR LAWRENCE, President, at their offices, Victoria Street, Westminster, on Tuesday, the 10th inst. After hearing Mr. DOBBS on the subject of the necessity of amendment of the Pharmacy Act of 1868 in favour of allowing licensed persons to retail poisonous compounds required for horticultural and agricultural purposes, the Council passed a resolution in favour of the recommendations of the Departmental Poisons Committee, appointed by the Privy Council, and requesting the Government to adopt the recommendations; and a petition in favour of licensed persons having the right to sell was signed by the Chairman on behalf of the Council of the Royal Horticultural Society.

MR. T. LUNT'S JUBILEE AS HEAD GARDENER AT ARDGOWAN.—"Twenty-five years is a long time in any man's life," but Mr. THOMAS LUNT, the veteran gardener, has just doubled this period, having on Sunday, March 8, completed

fifty years as head gardener at Ardgowan, Renfrewshire. Half-a-century ago, Mr. Lunt was foreman, under the late Mr. J. Collinson, at Eaton Hall, where he remained for seven years; and shortly after the marriage of the Lady Octavia Grosvenor, sister of the late Duke of Westminster, to Sir M. R. Shaw-Stewart, Bart., of Ardgowan, he followed her ladyship to that place as head gardener. The fine range of glass was rebuilt during Mr. Lunt's time, which has been visited by many eminent horticulturists and others from year to year, and described in your columns in the autumn of 1901. As is well known, two of Mr. Lunt's sons are clever members of the gardening profession. Mr. Thomas Lunt, jun., gardener at Keir, Dunblane, who needs no introduction to readers of these pages, as his name is constantly to the fore as a prize-winner at flower shows all over the country, is one; while the other is Mr. John C. Lunt, gardener to the Duke of Buccleuch at Bowhill, Selkirkshire. In spite of his seventy-four years, Mr. Lunt is almost juvenile in his movements, and carries on the work of the extensive gardens in a manner so methodical and accurate, that it would be a lesson to men in any profession. The writer had the pleasure of visiting Mr. Lunt on Saturday last, and it will please his many friends to know that he is still in the enjoyment of the best of health. It is interesting to note that Sir Michael and Lady Octavia Shaw-Stewart celebrated their golden wedding in December last. *D. G. P.*

Magnolia Campbelli.—In reference to the flowers of this handsome species shown by Mr. Gumbleton at the meeting of the Royal Horticultural Society on Tuesday last, we are informed by Mr. Gumbleton that his tree is bearing 147 blooms, and the present mild weather permits them to open freely. See also pp. 172, 173, 174.

Meteorology in the Orange River Colony.—A Meteorological Institute has been established at Bloemfontein, and sub-stations are being established in various places, whence records from all points will be passed through to the chief station. So far the observations taken promise a very interesting study, and, it is said, show remarkable variations of conditions throughout the Colony, both as regards one part in relation to others, and in the daily changes at some stations. The systematic study of the subject should prove of much value to the Colony.

Shakespeare and Virgil Gardens at Harvard.—In the Harvard Botanical Gardens there are certain beds devoted to the cultivation of plants mentioned by Virgil and by Shakespeare. The idea has been well thought out, and as all the specimens are clearly labelled, visitors have no difficulty in recognising plants hitherto known to them by name only. Shakespeare's flowers are, for the most part, as familiar to Englishmen now as they were to the bard himself; but all Americans have not the same acquaintance with our wood and garden favourites, and so take much interest in these plantations. The plants of Virgil, not so well suited to the North American climate, come fresh to the unbotanical but classical scholars of both nations.

Ginseng.—Repeated attempts to grow this plant (Aralia quinquefolia) at Kew have been uniformly unsuccessful. I should be very much indebted to anyone who would tell me how to succeed under the climatic conditions which obtain in the south of England. The *Kew Bulletin* for 1893, pp. 71—75, contains an account of the plant, and of the method of cultivation adopted in the United States. The only market for the root is in China, where it is highly esteemed as a stomachic. Whether it has really any definite physiological or therapeutical properties has never been ascertained. *W. T. Thiselton-Dyer.*

Horticultural Hall.—Among those who have responded to the appeal is Lord Llangattock, who sends a cheque for £100 with a sympathetic message. We have received a cheque for £2 2s. from the Chester Paxton Society, which we have forwarded to Mr. Ingram.

The Priaulx Patent Trough.—In regard to the trough for the cultivation of Tomatos and other plants, illustrated in our issue for February 7, we understand the Company has applied for patent rights in France, Belgium, Germany, and the United States. The first English cultivator to test the troughs on a large scale is an enterprising grower at Worthing.

Prevention of Corruption Bill.—The Lord Chancellor moved, in the House of Lords on Tuesday last, the second reading of a Bill for the better prevention of corruption. His lordship said that the practice against which the Bill was directed, of giving secret commissions, was, he regretted to believe, very much on the increase. Few people realised the extent with which it had spread, and was spreading; and the report of a committee of Chambers of Commerce from which he quoted showed that it had extended also to the professions, for there was an example cited of a medical man who received commissions from undertakers. His lordship also quoted from the letter which appeared in the *Times* on the 2nd inst. from a member of a leading firm of horticulturists, complaining of the extent to which bribery was carried on among gardeners, and representing themselves as the helpless victims of a practice which they deplored. The latest development was in the motor car industry. Motor cars were very complicated pieces of machinery, and required great care on the part of those who managed them; and the form of secret commission adopted in this case consisted in a payment to the person who was responsible to his employer for the care of the machine on the annual bill for repairs. Under such circumstances nobody would suppose that the motor would be very well cared for. The Bill provided, *inter alia*, that "if any agent corruptly and without the knowledge of his principal accepts or obtains, or agrees to accept or attempts to obtain, from any person, for himself or for any other person, any gift or consideration as an inducement or reward, for doing or forbearing to do any act in relation to his principal's business, or for showing or forbearing to show favour or disfavour to any person in relation to his principal's business; or if any person corruptly gives or offers any gift or consideration to any agent as an inducement or reward . . . . shall be guilty of a misdemeanour, and shall be liable on conviction on indictment to imprisonment." He anticipated that such an enactment would have an indirect as well as a direct effect. No doubt there were many people who submitted to this evil with great reluctance, but who might feel at the same time that in the keen competition of trade they had no alternative. The indirect effect of such an enactment would be even greater that the actual putting of it in force. He hoped their lordships would facilitate the passage of the Bill, in order that this great blot on our mercantile system might be removed. The Lord Chancellor further said that the word "corruptly" governed the whole matter, and he thought that without it there was no chance of passing the Bill into law. No jury would convict, and indeed ought not to convict, unless they came to the conclusion that the money passed corruptly for the purpose of influencing business. Lord Alverstone said the evidence showing the necessity for the Bill was growing day by day. Many people thought that the Bill struck at the payment of commissions in any circumstances. But there were many honourable trades in which the remuneration was solely by commission, and therefore it was absolutely necessary to retain the word "corruptly," so that the Bill might affect only the agent who secretly paid commissions for the purpose of influencing persons to buy his master's goods. There was one point in regard to which he thought the Bill needed amendment. He did not think it sufficiently dealt with commissions paid for past services. It often happened that corrupt commissions were not paid at the time of the business transaction, but after the order was completed some method was found of remunerating the agent. The Bill was read the second time. *Times.*

Use of Leaf-mould in Orchid Culture.—M. Lucien Linden writes to us as follows concerning the use of leaf-mould for Orchids, he says: "I thought it right last year to utter, through the *Gardeners' Chronicle*, a warning against the employment of leaf-mould in the cultivation of Orchids. I have since had still further occasion to notice how prejudicial the material is for these plants, which at first seem improved, but afterwards are killed by it. You would render a service to Orchid-growers by repeating this caution, using my name in connection with it if you wish to do so."

ECHINOCACTUS DELAETI: MELOCACTI AND ECHINOCACTI.

[Supplementary Illustrations.]

The species Echinocactus Delaeti is very rare in its native country, the Argentine Republic, and more so in cultivation. The stem is hemispherical, the crown rounded and somewhat depressed, without woolly tufts, and surmounted by interlacing spines; in the young plant it is dull (that is, not glossy), and light green in colour. The warts are arranged in the eighth and thirteenth rows, and are bluntly four-sided. On the obliquely-set tips are situated the elliptical areoles, which bend forwards, and are about a ¼ inch long. They are at first covered with white felt, but this turns grey and soon falls off. The spines are, as a rule, in sets of seven. They are crowded together, curved, sharply-pointed, and dark in the new shoots; but later they become reddish, and finally, dull grey.

The second pair, counting from above, is the longest, and attains to a length of 1¼ inch. The flowers appear on the front part of the stem in the neighbourhood of the crown. The ovary is slender, cylindrical, olive-green, and covered with a few semi-elliptical scales. They are olive-green in colour, and are bordered with rose colour. The length of the whole flower is about 2 inches; its diameter is inconsiderable, because the flower rarely opens fully. The outermost sepals are trapezoidal, becoming spatulate in form, contracting almost to the shape of a finger-nail at the base, and blunt at the end. The petals are oblong, hollowed, and finely pointed, and of a rosy-red colour. The stigmas reach quite to the edge of the petals; they are placed, as in Echinopsis, in two rows, of which the inner circle rests on the edge of the lower, narrow, outer-most petals, where these widen out cup-like, but the upper row is separated further from it, and is adhering in the upper part. The filaments are white, the anther case greyish-white; the fairly strong white style is marked by twelve yellow scars.

The plant shown in the Supplementary Illustration has seventeen flowers, which form a circle round the plant, and remain open four to six days. The colour of the flowers is pale rose, and the fruits are oval in shape. The plant thrives in a compost of peaty soil and leaf-mould.

It is necessary, in order to avoid all error, to mention here Echinocactus Schickendantzii (Web.), which M. de Laet says that he had just received from the Argentine Republic. This variety, while greatly resembling the Echino-

cactus de Laeti (K. Sch.), appreciably differs, however, in the placing of the tubercles, the form of the spines, and the season of its flowering.

The upper fig. in our illustration shows Echinocacti and Melocacti in the possession of Mr. C. Darrah, Holly Point, Heaton Mersey, Lancashire. These interesting plants are of easy cultivation, needing in most cases the shelter of a greenhouse, and to be potted in turfy loam, to which a very small portion of leaf-mould may be added if the loam be of poor quality, and some finely-broken sandstone or charred loam to let moisture pass readily away. Potted in these materials, the plants require root-disturbance but seldom if worms be kept out of the pots and the drainage is not clogged with soil. For neatness sake, a surfacing of fresh soil should be applied once a year after removing as much of the stale soil as can be done without disturbing many of the roots. The taller plants observed in the view are either Cereus or Euphorbias, which require much the same kind of treatment as Melocactus.

OXALIS CRENATA.

This excellent vegetable is but little known in European gardens, although it has been introduced for many years (fig. 72). This is due to a little technical difficulty in its proper cultivation, which can be easily overcome.

This Oxalis is synonymous with the "Oka" of Peru, and is known in some parts of Bolivia as "Camote," this term being applied indiscriminately in various parts of Bolivia to almost any small, sweet edible tuber. It has never flowered at Isleworth, but is sufficiently hardy to make a luxuriant growth every summer. It is said that the foliage and stems are edible when cooked, but it is the tubers upon which I depend as a vegetable.

The formation of underground tubers is subject to laws at present obscure, not only in this plant, but in many others. In the case of Oxalis crenata, no tubers are formed (in the ordinary course) until the growth of foliage suffers arrest from the declining temperature of autumn; this usually occurs early in October at Isleworth. Now follows the critical period. If October and November are free from frost, a fine crop can be gathered in December.

If, on the other hand, frost follows shortly on the arrest of leaf-growth, it is obvious that no large tubers can be formed, because once the foliage is killed, there is nothing left out of which they can be formed. Therefore, the sole technical difficulty in securing a crop is that of keeping the foliage alive through October and November. This can easily be done in many parts of England. It is rare, even in the London district, for any frost in these months to penetrate the ground, and a few hurdles, bracken, or litter, form a sufficient covering to ward off danger. Generally, the plant is of the same hardiness as our garden Potato, but the Oka has this advantage, that it can grow through severe drought, and is not subject to disease. It will never be a rival to the Potato; the tubers are not large enough, being only 1½ to 2 inches long. Yet it has many advantages in its unique and delicious flavour, in its long-keeping capacity, and in the fact that it requires no preparation whatever before cooking, so that the relatively small size of the tubers is no disadvantage it only there are enough of them.

Again, if a vegetable is wanted in a hurry, these tubers can be prepared for table in about three minutes, and can be put to endless culinary uses. I do not, however, see how it will be possible to raise any improved varieties, unless flowers can be produced under glass.

On one matter I am in doubt, and that is whether two different plants have not been described under the same name in British gardens.

The Oxalis crenata of Sweet's *British Flower Garden* (series ii, 125) is described in Nicholson's *Dictionary of Gardening* as an "annual," with "erect leafy stems." My plants are true perennials, and have prostrate and ultimately ascending stems. The shape of the tubers is also different. Still, descriptions are often imperfect, and the plant shows much variability. *A. Worsley.*

HOME CORRESPONDENCE.

THE ROYAL HORTICULTURAL SOCIETY.—The reading of the remarks by Sir John Hutton on the above Society gave me much amusement. Sir J. Hutton's letter has, I fear, "let the cat out of the bag," which has been kept so closely tied up. We country Fellows had no idea of the proposal to let out the new Hall for exhibitions, concerts, meetings, music, dancing, &c., which is all perhaps innocent enough, so far as we know, or care to know. According to present arrangements, the Hall will only be required for horticultural purposes once a fortnight, and it would be both a pity and a waste that such a grand Hall should remain unused from one fortnightly meeting to another. We do not find fault with this, because it is all in a legitimate way of making money, "though it may not be horticulture." "It is money that makes the mare to go," and this is just what the Royal Horticultural Society is much in need of. After all these years of purely horticultural sailing, the Council have evidently come to the conclusion that they cannot sail their ship successfully without their sails being filled with more propitious breezes; and for this purpose they show their wisdom in copying the methods of the Royal Botanic Society, the Shropshire Horticultural, and many other similar ones, by introducing any kind of a respectable show to draw people to bring them gate-money. 'Tis true, and of which this is another proof, namely, that nothing is more likely to happen than the unexpected. The building of the great Hall long wished for has at last been settled, artificers have been set to work, and money must be found somehow to pay the cost. We hope to see the new Hall opened by a great banquet to nurserymen and gardeners. I remember one of this sort at which many were brought together, and without which they would never have come; but somehow, in coming away the hats got mixed, and everybody went home wearing some other person's hat. Next morning, Mr. Harry J. Veitch, then a beardless boy, on hearing of my loss, sent along to my lodgings a tremendous great hat, which, when put on, completely encased my head and rested upon my shoulders. *W. Miller.*

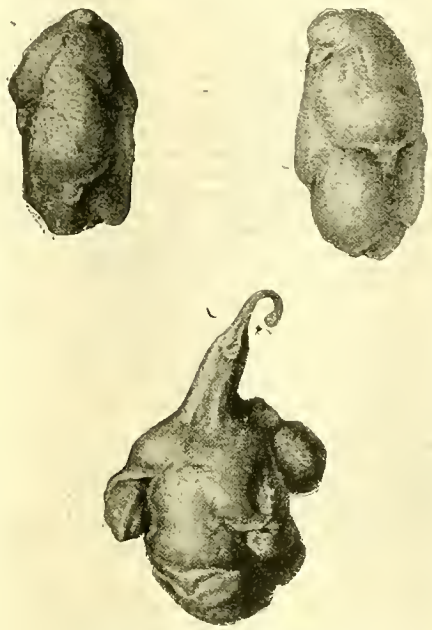

Fig. 72.—Tubers of "Oxalis crenata" sub-scaley (like a lily-bulb), but solid.

Colour carmine-red, on exposure to light; yellow when first lifted; weight ½ ounce.

GINSENG (PANAX QUINQUEFOLIUM). — In Rhind's *Vegetable Kingdom*, I find a very good description of Ginseng; but Rhind is evidently sceptic of its reputed reeuperative value as believed in by the Chinese, and gives it as his opinion that Jartoux allowed himself to be converted to the belief that the eating of the plant, or rather root, in its raw state, had the stimulating effect described by him. Jartoux, however, continued to eat the root, and one would think that such a man would not lend himself to the dissemination of views in which he did not believe. Be that as it may, it must be a long time since either Jartoux or Rhind wrote. It is nevertheless true, that at the present time, no matter who believes in its efficacy or otherwise, there is evidently a large demand for the root, as it appears to be extensively grown in the United States, whether in all of them, I am not aware, as a valuable commercial enterprise. The seed of Ginseng, my friend told me, was very dear in the State of New York, where he made its acquaintance. Obseek, alluding to Rhind, says that he never looked into an apothecary's shop in China but they were always selling Ginseng; that poor people, and those of the highest rank, made use of it; and that they boiled ½ oz. in their tea and in soup every morning, as a remedy for consumption and other diseases. Probably the enquiry in last week's *Gardeners' Chronicle* may elicit some information, and throw some light upon the reason for the cultivation of such a remunerative plant in the United States. In this country the plant, on the contrary, is known only as an occasional herbaceous plant in botanical collections. Whether the Americans owe their success to their more clever adaptation in catering for that for which there is a demand than is the case with ourselves, or have they some advantage in the matter of climate, we do not know; for be it remembered that whilst their climate is sometimes much hotter than ours, it is also at times very much colder. *W. Miller, Berkswell.*

—— In answer to your correspondent, Mr. W. Miller, in a recent issue of the *Gardeners' Chronicle*, p. 155, with respect to the cultivation of Ginseng, the first consideration is that of soil, which should be a light, friable loam, rich in vegetable mould, should possess good drainage. The choice should not fall upon a clay soil, or a heavy clay loam. Ginseng seed will not germinate until it has been kept eighteen months after maturing, and during this interval it must not be allowed to become dry. The soil should be well prepared by digging, and be enriched with farmyard manure. The roots or seed may be planted during the month of October, setting them 8 inches apart each way. In planting the roots, a dibber 10 ins. long is required; and the holes must be made deep enough to admit the longest root without bending. This is an important matter, to insure the development of straight roots for the harvest. The top of the root, or "bud," should be placed 2 inches deep. The seeds may be planted in shallow drills, dropping them 1 inch apart, and covering them with an inch of fine soil, afterwards thinning out to the proper distance. In November the entire bed may be mulched with a good covering of leaves; and this mulch should be removed in the following April. About three times during the growing season the surface soil may be broken up, and the weeds removed. In America artificial shade is always required, a lattice-work structure being erected over the beds. The care of Ginseng after it is planted and shaded is exceedingly light and simple. The roots should be taken up in the following October, care being taken in the digging to avoid breaking them. All roots under ½-inch in diameter should be set apart for future planting. The selected roots for marketing are

dried by spreading them on trays or tables in the sun. This method will require six or eight weeks. A quicker and better method is to use artificial heat, and subject the roots to a temperature of 100° to 120° Fahr. By this method the roots may be dried in nineteen days. Roots in drying lose about two-thirds of their weight. *J. J. Willis, Harpenden*

MAGNOLIA CAMPBELLI AT ABBOTSBURY.—This somewhat rare species of Magnolia is now very nicely in blossom here; its first blossom opened at the end of February, and now four of them are fully expanded. The tree which has been fostered with greatest care for many years was at the instance of the Earl of Ilchester transferred from its former place against a south wall, where it had grown steadily, to a more open position, which it was thought would be required if the species were to assume here anything like the dimensions described by Sir Joseph Hooker in his *Illustrations of Himalayan Plants*. The Abbotsbury specimen mentioned was removed from its snug situation against a wall in the spring of 1896, at which time it measured about 8 ft. by 8 ft., having been trained somewhat in espalier fashion. At this time his lordship considerably enlarged the subtropical grounds, and personally selected a site, which was more open, by the side of a bank which slopes down to a moist dell, of which the soil was alluvial. Here the tree assumed its true character, and it is now a well developed, branched specimen of 25 feet high, representing an annual growth of over 2 feet from the time of its removal. It is quite the earliest of the many species and varieties of deciduous Magnolias to flower here, being two to three weeks in advance of M. conspicua, M. stellata, and others. M. conspicua in the new winter garden is barely open at the time of writing; and the aged specimens of the same about the grounds are only just showing signs of swelling their hairy-like calyces. The flowers of the Abbotsbury tree are a bright flesh colour, much resembling Nymphæa carnea. The essential organs, style and stigmas, are suffused-crimson. In size the flowers are equal to those of M. grandiflora, measuring 8 inches in diameter, but more delicate in substance. Luckily for our specimen, it is flanked on the north-east by a goodly Quercus Ilex. Not far distant, again, is a crescent-shaped group of the same, which being evergreen, form a screen against the colder winds. M. Campbelli is delicately scented, in spite of the recent heavy rains and cloudy skies; and although not so robust, perhaps, as M. grandiflora, it is not quite so sensitive to injury by rough weather. In spite of heavy rains and wind, M. Campbelli has come through the ordeal very well. I have lately sent away two perfect expanded blossoms of M. Campbelli, which have been quite exposed to the recent inclement weather. *Joseph Benbow, gr. to the Earl of Ilchester, Abbotsbury Castle, Dorsetshire.* [A photograph of Magnolia Campbelli, kindly sent by Mr. Benbow, was unsuited to our uses. Ed.]

COMMISSIONS.—The question of commissions to gardeners is a very important one, and much further-reaching than appears on the surface. I think it is the greatest cause of the low wages paid to gardeners, who accept low wages knowing they will receive an addition by commissions, whilst employers in general are quite aware of the practice, and feeling their inability to prevent it, are content to let their gardeners' wages be supplemented in this way by the tradesmen, and this state of things must continue until the practice is absolutely abolished. There would perhaps be little objection to it, if it were merely the question of a gardener receiving a certain amount with the knowledge of his employer, but the mischief of it is that the servant has a strong inducement to increase his requirements of all sorts of sundries, as well as of seeds and plants; and it must be an exceptionally upright man who can resist the temptation held out to him, backed up by the pressure of keen travellers. Besides, he is encouraged by the knowledge that it is the tradesman, and not his master, who would benefit by his refusal to accept the commission. I have it on good authority that every firm in the horticultural trade gives at the least 5 per cent., and that a great many firms exceed this amount considerably. One nurseryman tells me that it is his rule never to make any promise even when asked as an inducement to give orders. This is sheer nonsense, for every gardener knows perfectly well that he can rely upon the usual payment being forthcoming. There is, no doubt, some advantage in ventilating the subject, and it may tend to strengthen the hands of those who are trying to bring about legislation against secret commissions, otherwise I fear it will not have much effect in abating the evil. *Investigator.*

GRADUS PEA.—Having read in a recent issue of the *Gardeners' Chronicle* statements to the effect that Gradus Pea is difficult to grow, I would like to bear testimony to the fact that it has proved the reverse of this at Barton Hall, being there a strong grower, an exceptionally good cropper, and the peas are of excellent flavour. I am growing the variety extensively this year; it has become a general favourite in the eastern counties. *L. E. Walker, gr., Barton Hall, Bury St. Edmunds.*

BUILDING A FRUIT-ROOM.—The information "Subscriber" says he had given him by a gentleman, that Apples and Pears keep best set simply in a dark cellar with little light and ventilation, is good. My experience coincides with this advice, and I would recommend that he should give it a trial, as I am sure he will be pleased with the result. I have always found fruits do not keep so well above-ground, for the injurious sudden changes of temperature cannot then be avoided. Through some building operations I lost my Apple-room, and had to store the fruits in a cellar for a few seasons, and I was surprised at the difference in the length of time that the fruits kept in good condition. On referring to my book, I note that I was supplying dessert and culinary Apples to the family in London as late as June 8, 1900. Unfortunately, I have lost this useful place, but hope to imitate it, or improve upon it, at some future time. The advice given to "Subscriber" by different writers in your paper is good, and need not be very costly. I would not excavate below the level of the ground, as for cellars, if it could be avoided; and banks and mounds of soil are often found in gardens, which might be made use of for this purpose. Let the walls be built upright, the roof arched over with brick, having ventilators at the top and ends, to close at will, the top ventilators being made to open to admit the light. In building the side walls, I would insert inch-thick slates of the width required to form the shelves for the fruit, which would avoid objectionable uprights, that are always in the way. The outside of the brick-work should be cemented to make it water-proof. Drain the building thoroughly, and next to the cement covering put gravel, stones, or broken bricks, and then cover it with soil at least 2 feet deep all over; or make the outside of the covering of soil of any desired depth to suit the purpose. Shrubs might be planted all over it, or it might be turfed. Only the doorway need show, and the other end could be masked with earth, putting in 6-inch socket pipes to admit air to the end ventilators; these pipes should also have a perforated covering. A brick or stone floor would be the best; rough bricks might be used for all parts except the one end that will be seen. Pears will not ripen very quickly in the low temperature of such a store, and would have to be removed to a warmer room as required, thus prolonging their season. The slate shelves should not be much wider, if any, than one can reach over comfortably, and not be set too closely together. *J. Lambert, Powis Castle Gardens, Welshpool.*

A NATIONAL PANSY AND VIOLA SOCIETY.—We have national shows for Carnations, Chrysanthemums, Dahlias, and Roses; why not a National Pansy and Viola Show in England? There can be little doubt, I think, that of late years much progress has been made by professional and amateur growers in the cultivation and improvement of Pansies and Violas, more especially in the latter, which are becoming exceedingly popular, having made rapid strides in their size, form, substance, and other good qualities, that I believe the time is now ripe for an endeavour on the part of growers in England to form a society which shall have the power to re-classify, lay down new properties suitable to the present age, award certificates of merit to varieties submitted for adjudication, and to organise a national show. I shall be glad to receive communications from any gentlemen, professional or amateur, who would kindly co-operate in such a movement by sending me their views on the subject, and the extent of support I might expect from them prior to calling a meeting to go more fully into the matter. *A. S. Treacher, Viola Specialist, Leicester Road, New Barnet.*

ARAUCARIA IMBRICATA.—Being interested by reading the particulars of the Araucaria imbricata, figured in *Gardeners' Chronicle* for February 14, I have measured a tree which grows in these grounds. The dimensions are as follows:—height 46 ft. 8 ins.; spread of branches at 8 ft. from the ground, 33 ft. 6 ins.; and circumference of stem at the same distance from the ground, 6 feet 5 inches. *F. Juniper, The Gardens, Rydinghurst, Cranleigh, Surrey.* [The P.O. for 1s. 6d. has been passed to the Secretary of the Gardeners' Orphan Fund. Ed.]

SOCIETIES.

ROYAL HORTICULTURAL.

March 10.—The ordinary fortnightly meeting of the Committees was held on the above date in the Drill Hall, Buckingham Gate, Westminster. The weather out-of-doors being wet and disagreeable, a most striking contrast was made by the extensive display of flowers exhibited. In the afternoon particularly, the number of visitors was large. The season for Orchids to flower having now well commenced, exhibits of them are becoming numerous at each meeting. On this occasion the Orchid Committee recommended as many as ten Medals, also a Botanical Certificate, a First-class Certificate, an Award of Merit, and two Cultural Commendations. The Floral Committee awarded nine Medals, two First-class Certificates, and three Awards of Merit. The groups of plants before this Committee included Cyclamens, Clivias, Hippeastrums, Hardy Rhododendrons (Azaleas), Ferns, forced shrubs, and hardy plants in flower.

The Narcissus Committee met for the first time this season, and awarded two Medals, but no award to a novelty.

The Fruit and Vegetable Committee sat for a very short time, and had little but the state of the weather to discuss.

In the afternoon seventy-seven new Fellows were elected to the privileges of the Society, making the number elected since December 400. The Rev. George Henslow delivered a lecture upon "Natural Selection *v.* Adaptation," in which he traversed some of the statements of Darwin.

Floral Committee.

Present: W. Marshall, Esq. (in the Chair); and Messrs. J. Hudson, G. Nicholson, R. Dean, Jno. Green, J. Jennings, A. Perry, W. Howe, J. A. Nix, C. R. Fielder, C. Dixon, C. W. Knowles, C. J. Salter, C. Jeffries, H. J. Cutbush, R. W. Wallace, J. W. Barr, R. C. Notcutt, H. J. Jones, C. E. Shea, W. P. Thomson, E. H. Jenkins, C. Blick, G. Paul, and H. B. May.

Messrs. J. Hill & Son, Barrowfield Nursery, Lower Edmonton, had a large and attractive exhibit of Ferns. At the back of the group were plants of some of the larger-growing species, as Asplenium caudatum, Cibotium Schiedii, &c.; and in suspended pots, two excellent plants of Gymnogramma schizophylla gloriosa. Among tinted Ferns, small plants of Lomaria L'Herminieri were prominent, and Doodia aspera multifida, Blechnum brasiliense, B. latifolium, &c. (Silver-gilt Banksian Medal).

Mr. H. B. May, Dyson's Lane Nurseries, Upper Edmonton, London, N., exhibited more plants of Clematis than on the previous occasion, the varieties were much the same, but in addition were Lady Londesborough, pale mauve, medium size, excellent form; and the well-known white one, Mrs. Quilter. The exhibit also included tree Carnation, Prince of Wales, colour, deep crimson; the new Pteris Summersii, and other choice Ferns, Boronia heterophylla, some well-grown plants of Gardenia florida, in flower, &c. (Silver Flora Medal).

A group of Clivias (Imantophyllum), from Lady Bathurst, Cirencester House, Cirencester (gr., Mr. T. Arnold), was remarkable for the quality of the plants, and for their cultivation. There were about twenty

plants in 7-inch and 8-in. pots, and many of them had two good flower-spikes. In one case an Award of Merit was recommended (Bronze Banksian Medal).

Messrs. Jas. Veitch & Sons, Royal Exotic Nurseries, King's Road, Chelsea, exhibited a batch of the new Primula × Kewensis, and a batch of Cinerarias of the type described as Feltham Beauty. This strain is a dwarf, compact growing form of the stellata section, and produces good heads of bloom in a great variety of colours.

A group of Hippeastrums was shown by F. A Bevan, Esq., Trent Park, Barnet (gr., Mr. H. Parr). There were about fifty plants, all of which had strong spikes of flower. The varieties were all more or less red in colour, and the collection might be improved by the addition of some varieties that produce flowers of lighter colour (Bronze Banksian Medal).

Messrs. Hugh Low & Co., Bush Hill Park Nurseries, Enfield, exhibited a number of varieties of Rhododendron (Azalea) indica, nice little plants in 5-inch pots, and full of flower. Very attractive were the varieties John Uytens, light red, with white margins; Niobe, pure white, double; Vervaeneana rosea, rich in colour, and double; Queen of Whites, very fine, single white. Boronia megastigma, Japanese Acers, Acacia Drummondi, A. ovata, and other choice plants, were included in this exhibit.

Another large exhibit of varieties of Rhododendron (Azalea) mollis, and of the "rustica" section, was made by Messrs. R. & G. Cuthbert, Southgate nurseries, Middlesex; the flowers generally were rather richer in colour than when plants were shown on the last occasion. The best of the mollis varieties were Madame C. Legrelle d'Hanis, reddish colour and bronze; Théresa, rich pink colour; Comte de Quincy, yellow; and some very attractive varieties yet unnamed. Of the rustica section, Apelius, a double red variety, is worthy recommendation. Throughout the group were interspersed varieties of Japanese Maples and of Ferns (Silver Banksian Medal).

Mr. Jno. Russell, Richmond Nurseries, Richmond, Surrey, exhibited a prettily arranged group of forced trees and shrubs, amongst which several nice specimens of the variegated variety of Dimorphanthus (Aralia) mandchuricus were noticeable. Of the forced species, Cerasus Watereri, "Ghent Azaleas" or Rhododendrons, Laburnums, Prunus triloba, Cratægus oxyacantha alba plena, &c.; and the group included varieties of Clematis, including C. iodivisa, some large plants of Dracæna Russelliana, and the little Campanula Balchiniana.

Mr. G. Reuthe, The Fox Hill Hardy Plant Nursery, Keston, Kent, exhibited a collection of hardy plants in pots. There were numerous specimens of Shortia galacifolia in flower, also the new and charming Fritillaria askhabadensis, which was figured in these pages last season; Hepaticas, Iris histrioides, and the trumpet Daffodil N. spurius coronarius.

Some excellent flowers, cut with long stems attached, of Camellia reticulata were shown by Ernest Hills, Esq., Redleaf, Penshurst (gr., Mr. Geo. Ringham).

Messrs. W. Cutbush & Son, Highgate, London, again exhibited flowers of their newer Tree Carnations, as Mrs. S. J. Brooks, white; Viscount Kitchener, red and white; Lady de Ramsay, Sir Hector Macdonald, &c. Also several of the best varieties of the Souvenir de la Malmaison type.

A collection of young Cactaceous plants, in 3-inch pots, including a few of the hardy species of Opuntia, was shown by Mr. Richard Anker, 54, George Street, Baker Street, London, W.

A collection of forced Tulips, in pots, from Messrs. B. S. Williams & Son, Victoria and Paradise Nurseries, Upper Holloway, London, N., included all the best varieties for forcing or for massing in the flower garden. The newest is a yellow variety named Prince de Ligny, which is probably better than Canary Bird, or even Chrysolora.

A few pretty blooms of new Roses were shown by Messrs. Frank Cant & Co., Braiswick Nursery, Colchester; the varieties were Lady Battersea, Lady Roberts (already figured in these pages), and Lady Mary Corsy, pale lemon yellow.

Messrs. H. Cannell & Sons, Swanley, Kent, exhibited another display of Cyclamens, which included over seventy plants, abundantly flowered.

A beautiful illustration of the greenhouse shrub Rogeria cordata was contained in a group of plants shown by Messrs. T. Cripps & Son, Tunbridge Wells. Those of Rogeria were well-flowered and delightfully attractive; in addition there were some choice Japanese Maples, and a few Palms.

From Messrs. Geo. Paul & Son, Cheshunt, came several Tree Carnations in pots, including the bright red-coloured variety, America; Governor, deep maroon-crimson, fringed; also a few forced plants of varieties of Lilac.

The best of a very interesting collection of varieties of Lachenalia, from Mr. Moore, of the Glasnevin Botanic Gardens, Dublin, is mentioned under "Awards."

Messrs. Geo. Jackman & Son, Woking, exhibited a very pretty collection of hardy and alpine plants, which were put out in a natural fashion in rockwork. We noticed Gerbera Jamesoni, Ramondia pyrenaica, Gentiana verna, Pulmonaria mollis, Anemone pulsatilla, and the variety alba; Ranunculus amplexicaulis, &c.

Messrs. T. S. Ware, Ltd. (1902), Feltham, exhibited hardy plants in pots, including Shortia galacifolia, Narcissus, Primula frondosa, P. Sieboldi varieties, P. verticillata, Fritillarias, &c.

Messrs. Wallace & Co., Kilnfield Gardens, Colchester, exhibited groups of a few species of hardy plants, as Fritillaria citrina, a greenish-yellow species, growing about 5 inches high; the pretty new F. askhabadensis, Crocus aureus, C. Tommasinianus, Iris reticulata, Galanthus Ikariæ, Hepaticas, Hyacinthus azureus, &c.

Messrs. B. S. Williams & Son, Upper Holloway, London, N., showed a floor group, consisting of Palms and forced flowering shrubs, Cœlogyne cristata var. hololeuca, Azalea mollis in variety, Lilac Charles X., L. virginalis alba, very pretty, densely flowered, but whether this is a peculiarity of the variety, or due to the previous treatment of the plant, we do not know.

Messrs. John Peed & Son, Nurseries, West Norwood, S.E., filled a table at the end of the hall with a mixed collection of plants in season, and others that had been forced, such as Prunus triloba, Azalea mollis, Syringas (Lilac) in variety, Clivia miniata varieties, Orchids, chiefly Odontoglossums and Cypripediums, including C. bellatulum Vannerianum and C. Lathamianum; besides these was a quantity of Dracænas in variety, and other foliage plants.

Mr. Maurice Prichard, nurseryman, Christchurch, exhibited a quantity of alpines grouped together in

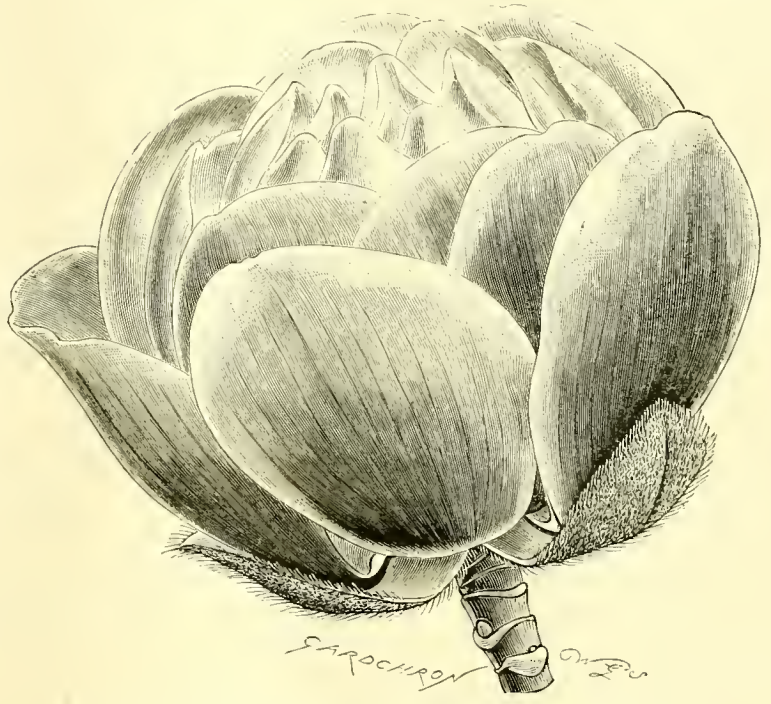

Fig. 73.—Magnolia campbelli.

Awarded the Royal Horticultural Society's First-class Certificate on Tuesday last.

Richardia Childsiana, shown by Messrs. de Graaff Brothers, Leiden, Holland, appeared to resemble very closely the common R. africana, the base of the leaves were broader, but the spathes possessed no apparent difference.

Mr. Robert Sydenham, Tenby Street, Birmingham, again showed plants growing in his preparation of fibre.

Some useful and pretty vases for containing cut flowers were shown by Messrs. Jas. Green & Nephew, 107, Queen Victoria Street, London, E.C. They are known as the "Munstead" flower glasses.

Mr. John May, Gordon Nursery, St. Margarets, Twickenham, showed an excellent lot of Cyclamen grandiflorum of all known shades and colours, having in many instances very large blooms and good dwarf foliage (Silver Flora Medal).

Messr. Barr & Sons, 11, 12, and 13, King Street, Covent Garden, exhibited, embedded in boxes filled with moss, plants in bloom of Scilla bifolia, Chionodoxa gigantea, C. Luciliæ, and C. sardensis, to show effect in the mass, but it was overdone, if meant to show the plants as they bloom. Among the many Narcissus shown in this stand we may specify Constellation, with white perianth and yellow corona, having a margin of an orange tint; Victoria, a trumpet variety, with papery-white perianth and bright yellow trumpet; Frilled Beauty, with perianth and trumpet of almost one tint of yellow; Shurtia galacifolia, unbroken (Darwin) Tulips in some variety, Hellebores (Lenten Lilies), Chionodoxa sardensis, beautiful in the mass as shown, &c.

three show boxes; there were Helleborus in variety, Megasea Strachyi, Wilson's blue-flowered Primula, Anemone blanda, Dentaria digitata, Campanula Balchiniana, a plant having small leaves, margined at the edge with white; Erica vulgaris aurea, with distinct reddish foliage and shoots; Saxifraga appendiculata splendens, Helleborus niger, rosy-purple petals and whitish anthers; Scopoliana Fladnickiana, pale yellow flower (Silver Banksian Medal).

Awards.

Clivia T. E. Arnold.—This variety was shown by Lady Bathurst, and was remarkable for the rich colour of the flowers, and for their bold appearance and large size (Award of Merit).

Jasminum primulinum.—Plants of this new species introduced from China were shown by Messrs. Jas. Veitch & Sons, Royal Exotic Nurseries, Chelsea. For horticultural purposes, it resembles a glorified form of Jasminum nudicaule, but possesses additional qualities of great value, being an evergreen, and flowering twice in the year. The solitary flowers are 1½ in. across, and are produced from the axils of the leaves; colour rich yellow. We hope to describe the plant more fully, and to publish an illustration in a future issue. The species has resisted 16° of frost on a north wall in Messrs. Veitch's nursery. It is said to flower sparsely in the autumn and then again in spring. The

flowers show a tendency to become semi-double. Judging from the plants shown, the plant may be less free flowering than J. nudicaule, but the presence of the leaves make it more decorative (First-class Certificate).

Lachenalia "*Ruth Lane*."—This variety was the best of a number shown by Mr. MOORE, of the Glasnevin Botanic Garden. The flowers are of large size, and are remarkable for the expansion of the corolla tube, the segments reflexing a little at the end, making the flowers more showy (Award of Merit).

Magnolia Campbelli.—Flowers of this handsome species were shown by Mr. W. E. GUMBLETON, Belgrove, Queenstown, co. Cork; and by Messrs. ROBT. VEITCH & SON, Exeter. The flowers are large, and globular in form, measuring nearly 8 inches across. We published an illustration of the species in *Gardeners' Chronicle* for January 5, 1898, prepared from a flower produced in Messrs. R. VEITCH & SON'S nursery. The petals are rich rose-pink colour on the exterior, and creamy-white inside, with marginal colour; the petals are wide and imbricate (see fig. 73). The species was first described in Sir JOSEPH HOOKER'S *Illustrations of Himalayan Plants*, accompanied by a splendid plate. Mr. GAMMIE records the flower as measuring 10 inches in diameter. A coloured figure was also given in the *Botanical Magazine*, January, 1885, tab. 6793, from a flower produced in Mr. CRAWFORD'S garden near Cork. We may add that the species is shy in blooming in most districts, especially near London, but Mr. GUMBLETON'S experience with it is more happy (see p. 170), also note upon plant blooming at Abbotsbury (p. 172).

Orchid Committee.

Present: Harry J. Veitch, Esq., in the Chair; and Messrs. Jas. O'Brien (Hon. Sec.), Norman C. Cookson, J. Gurney Fowler, J. W. Potter, De B. Crawshay, R. Brooman-White, F. Wellesley, F. A. Rebder, W. A. Bilney, H. T. Pitt, A. A. McBeau, J. Charlesworth, E. Hill, M. Gleeson, F. J. Thorne, J. W. Odell, W. Boxall, W. H. Young, H. A. Tracy, F. Sander, H. Ballantine, and W. H. White.

At this meeting, Orchids were again in the majority, a large number of groups being staged.

W. A. BILNEY, Esq., Fir Grange, Weybridge (gr., Mr. Whitlock), was awarded a Silver gilt Flora Medal for a fine group of magnificently-grown Dendrobiums, in which were five large specimens of the richly-coloured D. nobile nobilius, and good representatives of other fine varieties of the species, including the pure white D. n. virginale; also a very large number of fine hybrids of the D. × Ainsworthi splendidissima class, the best being D. A. Gwendoline, a very large white flower, tipped with rose, and with a dark centre, the whole very effectively arranged with Ferns and other foliage plants.

H. T. PITT, Esq., Rosslyn, Stamford Hill (gr., Mr. Thurgood), secured a Silver Flora Medal for a fine group, rich in good species and varieties. The group included good forms of Odontoglossum crispum, O. × Rolfeæ, O. × Hunnewellianum, a very finely flowered selection of Dendrobium, a number of varieties of Cattleya Trianæ, forms of Epidendrum × Endresio-Wallisii, Cymbidium × Lowio-eburneum, fine Miltonia Roezlii, and its variety alba, Cypripediums, &c.

Sir FREDERICK WIGAN, Bart., Clare Lawn, East Sheen (gr., Mr. W. H. Young), was awarded a Silver Flora Medal for a good group, including Odontoglossum × Rolfeæ, O. × Harryano-crispum spectabile, O. Rossi-majus, O. Cervantesii, O. × Wilckeanum, a fine specimen of Cymbidium grandiflorum, with two spikes; C. eburneum, C. × eburneo-Lowianum, Lycaste × Balliæ, with six flowers; Phaius × Cooksoni, a pretty specimen of Dendrobium Kingianum, &c.

JEREMIAH COLMAN, Esq., Gatton Park (gr., Mr. W. P. Bound), staged a good group, the central plant of which was a large specimen of the pretty Dendrobium nobile "Gatton Park variety," with about 250 flowers. With it were Spathoglottis × aurco-Viellardi, Ansellia lutea, Phaius grandifolius, a fine specimen of Lælia Jongheana, and excellent varieties of Cattleya Trianæ (Silver Flora Medal).

Sir TREVOR LAWRENCE, Bart., Burford (gr., Mr. W. H. White), showed a good selection, including a grand mass of Dendrobium × Euterpe, a fine Wardianum, raised at Burford; D. × pallens, D. nobile Berkleyanum, white, tipped with pink, and with claret disc to the lip; Cattleya Trianæ Osmani, one of the oldest, and still one of the finest; and another fine C. Trianæ from the Downside collection, &c. (Silver Banksian Medal).

DE B. CRAWSHAY, Esq., Rosefield (gr., Mr. Stables), showed a small group of good Odontoglossums, which included large O. crispum, with distinct spottiog on the sepals, and a singular result of crossing a good O. crispum with the finely spotted O. c. Crawshayanum, the result being in this instance to prove a poor white crispum. Mr. Crawshay also showed varieties of O. × Adrianæ, O. triumphans rosefieldiense, and O. nevadense Crawshayanum (Silver Banksian Medal).

Messrs. CHARLESWORTH & Co., Heaton, Bradford, secured a Silver Flora Medal for a group of very fine hybrids, of which Cattleya × Enid magnifica secured the only First-class Certificate given; also fine Lælio-Cattleya × luminosa, L.-C. × Gottoiana, L.-C. × Myra "Princess," of a soft yellow colour; L. C. × Digbyano-Mossiæ, Sophro-Lælia × Psyche, dark scarlet; Cypripedium × Mauditæ, the remarkable C. × Colossus, and other good things.

Messrs. JAS. VEITCH & SONS, Chelsea, were awarded a Silver Banksian Medal for a select group, chiefly consisting of hybrid Orchids. Among those noted were pretty varieties of Epidendrum × elegantulum, E. × O'Brienianum, Dendrobium × splendidissimum Leeanum, and other Dendrobes, the most remarkable of which was the new D. × Pirene (Wiganiæ × Ainsworthi intertextum), a very pretty flower; Lælio-Cattleya × Vacuna, Zygopetalum crinitum, Cattleya citrina, &c.

Mr J. CYPHER, Cheltenham, staged a group of Dendrobiums, &c., very finely flowered, for which a Silver Banksian Medal was awarded.

Messrs. HUGH LOW & Co., Bush Hill Park, staged a group of varieties of Cattleya Trianæ, Odontoglossums, Dendrobiums, &c. (Silver Banksian Medal).

NORMAN C. COOKSON, Esq., Oakwood, Wylam (gr., Mr. H. J. Chapman), showed Phaius × Norman pulcherrimus, a distinct yellowish-cream flower, with pale rose front to the lip; Odontoglossum × Rolfeæ, Oakwood variety, a beautifully formed flower, richly coloured; and O. × crispo-Harryanum oakwoodense.

FRANCIS WELLESLEY, Esq., Westfield, Woking (gr., Mr. Gilbert), showed Lælio-Cattleya × Gottoiana, "Westfield variety," a very large and well marked flower; and a cut bloom of his Cypripedium × Ville de Paris, a very large flower, with some appearance of C. insigne "Harefield variety," but with evidence also of C. villosum in its form.

Mrs. HAYWOOD, Woodhatch, Reigate (gr., Mr. C. J. Salter), showed forms of Dendrobium × Cybele nobillus, D. × melanodiscus Salteri, &c.

J. RUTHERFORD, Esq., M.P., Blackburn (gr., Mr. Lupton), again showed the beautiful Odontoglossum × Queen Alexandra (excellens × triumphaos), for which he received an Award of Merit at the last Temple Show.

R. I. MEASURES, Esq., Camberwell (gr., Mr. Smith), sent Cypripedium × villexul (villosum × exul), a pretty flower, well intermediate in character, and with the colouring and glossy surface of C. exul.

J. FOSTER ALCOCK, Esq., Northchurch, showed Cypripedium insigne, "Mrs. Brown."

Messrs. DE GRAAFF BROS., Leiden, sent cut examples of Habenaria Bonatea (Bonatea speciosa).

C. J. LUCAS, Esq., Waruham Court (gr., Mr. Duncan), sent Cypripedium × Chapmani, Arddarrock variety.

M. FLORENT CLAES, Brussels, showed two good forms of Odontoglossum × loochristyense; a very dark coloured O. × Adrianæ, and a light one with pale yellow ground colour.

Mr. JAS. DOUGLAS, Edenside, Great Bookham, showed Dendrobium × Florence (nobile album × Bensonæ), a pretty, white variety with dark purple base to the lip.

Mr. A. J. KEELING, showed Hybrid Cypripediums, &c.

Awards.

FIRST CLASS CERTIFICATE.

Cattleya × *Enid magnifica*, from Messrs. CHARLESWORTH & Co., Heaton, Bradford.—A large, beautiful, and floriferous cross between C. Warscewiczii and C. Mossiæ, and well blending the best features of these two fine species. The flower of C. × Enid is of fine proportions, the sepals and petals of a warm rosy-lilac, the front of the large and exquisitely frilled lip ruby-crimson, with a well-defined lavender coloured margin.

AWARDS OF MERIT.

Dendrobium × *Thwaitesiæ* (splendidissimum grandiflorum × Wiganiæ), from R. G. THWAITES, Esq., Streatham (gr., Mr. J. M. Black).—A very distinct cross, in which the influence of the yellow colour of D. signatum, through D. × Wiganiæ, effectively appears. The flowers are large and well formed, of a yellowish-cream tint with a slight purplish hue; the disc of the lip being claret coloured. It is a free grower, the pseudo-bulbs being over 3 feet long, and the flowering one well furnished with flowers.

Odontoglossum Rossii, Low's variety, from Messrs. HUGH LOW & Co.—A colour-suppression on the sepals leaves the marking on those segments, and also on the bases of the petals, of a pale green tint, instead of the ordinary purplish colour. The lip is pure white, as are also the blades of the petals.

BOTANICAL CERTIFICATE.

Bulbophyllum occultum, from H. T. PITT, Esq. (gr., Mr. Thurgood).—The singular species with purplish flowers with large bracts forming a triangular head; and remarked upon in the *Gardeners' Chronicle*, February 28, p. 130.

CULTURAL COMMENDATION.

To Mr. Thurgood, gr. to H. T. PITT, Esq., for a splendid plant of the fine old Dendrobium aggregatum majus, with about a score of fine spikes of orange-yellow flowers.

To the ROYAL BOTANIC SOCIETY, Regent's Park (gr., Mr. E. F. Hawes), for a very large and well-flowered specimen of Cœlogyne cristata.

Fruit and Vegetable Committee.

Present: Geo. Bunyard, Esq., Chairman; and Messrs. W. Poupart, Jos. Cheal, S. Mortimer, A. Dean, Ed. Beckett, H. J. Wright, Geo. Keif, H. Markham, G. H. Maycock, J. Jaques, Geo. Reynolds, F. Q. Lane, R. Parker, G. Wythes, Jas. H. Veitch, A. H. Pearson, J. Willard, and Owen Thomas.

The exhibits before this Committee consisted only of a sample of Kale from F. A. BEVAN, Esq.; and an unnamed Apple from W. ROBINSON, Esq., Gravetye, Sussex (gr., Mr. H. Kempshall).

Narcissus Committee.

The NARCISSUS COMMITTEE met for the first time this season, but there were not many novelties for consideration.

Messrs. W. CUTBUSH & SONS, Highgate Nurseries, London, N., exhibited a representative collection of forced Narcissus. There were upwards of forty varieties, each represented by five pots of bulbs. The varieties included some of most of the sections, from Telamonius plenus to N. poeticus grandiflorus and King Edward VII. The Leedsii varieties as Amabilis, the Barrii section as Maurice Vilmorin, Nelsoni varieties, &c., being represented, the group possessed very considerable variety (Silver Flora Medal).

DEVON & EXETER GARDENERS'.

MARCH 4.—Mr. Geo. Merritt, gr. to Mr. R. B. Ashby, Matford House, Exeter, gave an excellent lecture upon Orchids at the fortnightly meeting held on the above date. He contended that the Orchid was not necessarily a rich man's plant, but might be successfully cultivated by anyone having a heated glasshouse in which to grow them, and some slight provision, such as a partition to check extremes of temperature, and to retain moisture in the air. Among those recommended were Cœlogyne cristata, Cypripedium insigne, C. barbatum, C. Spicerianum, C. villosum, C. Harrisianum, Lycaste Skinnerl, which lasted a long time; Dendrobium aromatica, D. nobile, cheap to buy, and easy to manage; D. Wardianum, Odontoglossum grande, O. Alexandræ, O. bictonense, O. cirrhosum, Cattleya labiata, Lælia anceps, Brassia verrucosa, Oncidium flexuosum, Epidendrum Veitchianum, Zygopetalum intermedia, and other well-known species. Terrestrial Orchids, such as Calanthes, Lycastes, Phaius, and Cypripediums, require the admixture of peat, a little loam, and leaf-mould; and flower-pots filled to the extent of three-fourths with clean crocks, and over these a layer of fresh moss. In regard to temperature, the lecturer said that more Orchids are lost through excessive heat than from cold. Most of the Orchids named above stand a temperature of 45° without injury.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

MARCH 5.—Lady BRUNNER, Druid's Cross, Wavertree, exhibited a good form of Cattleya Trianæ var. "Lady Brunner" (Award of Merit).

Messrs. HUGH LOW & Co., Enfield, exhibited a good form of Dendrobium nobile var. virginale.

H. PARTINGTON, Esq., Glossop, sent two Odontoglossums, O. × Adrianæ and O. × Andersonianum.

W. DUCKWORTH, Esq., Flexton (gr., Mr. Tindall), exhibited a good group of Dendrobiums, for which a Silver Medal was awarded. There were several good plants in this group, the best being Dendrobium × "D'Alroy Salamon" (prov. named). The parentage of this hybrid is not at present known, it is much in the way of D. × intertextum, but the lip is of great size, and has a very dark centre; a First-class Certificate was

awarded. D. nobile var. Burfordiense and D. × Cybele, Oakwood variety, were given Awards of Merit.

Messrs. James Cypher & Sons, Cheltenham, staged a choice collection of plants, Dendrobium × spendidissimum var. albens and Cattleya Trianæ var. triumphans, were voted Awards of Merit (Silver Medal).

O. O. Wrigley, Esq., Bury (gr., Mr. Rogers), received a Silver Medal for a group which consisted principally of Cypripediums and Dendrobium Wardianum.

S. Gratrix, Esq., Whalley Range (gr., Mr. Cypher), exhibited among other plants, Cypripedium × beechense, C. × Cardosianum, and Odontoglossum × Amelia, received Awards of Merit.

W. Thompson, Esq., Stone, Staffs (gr., Mr. Stevens), staged a very distinct form of Odontoglossum × Harryano-crispum var. albens; this is possibly one of the most distinct forms yet seen, and is remarkable for the general pallor of the flower, the markings being very sparse. A fine pan of Dendrobium Kingianum with about thirty flower-spikes, was given an Award of Merit and a Cultural Certificate; Cypripedium × Miss Fowler, C. insigne var. Chantini × C. Chamberlainianum, received an Award of Merit.

Messrs. Sander & Co., St. Albans, staged several good Cattleyas, Phaius, and Cypripedes, &c, &c. (Bronze Medal).

Mr. A. J. Keeling, Westgate Hill, near Bradford, exhibited a good plant of Cirrhopetalum picturatum (Award of Merit).

Mr. S. Allen, Sale, staged a group of plants containing a number of well flowered Dendrobiums, Cypripediums, Lycastes, &c. (Bronze Medal). *P. W.*

CHESTER PAXTON.

Bottled fruits formed the subject of an interesting and instructive lecture delivered at the Grosvenor Museum, on Saturday, by Mr. John Weaver, of Christleton. In his introductory remarks, Mr. Weaver said this was by no means a new idea, as books tell us that it was largely practised by the ancient Egyptians, and he presumed had been in fairly common use ever since. He, however, contended that much more might be done at the present time in the way of "bottling," or more correctly speaking "sterilizing," fruits of all kinds, as the means of doing so were within the reach of all. If this were more largely adopted, there would be a less likelihood of the summer markets being glutted, and consumers would be ensured of supplies of fresh fruit at all seasons of the year. He proceeded to give detailed particulars of the methods which should be adopted to ensure success; and illustrated his remarks by a collection of carefully sterilized fruits in bottles, which consisted of Plums, Nectarines, Gooseberries, Raspberries, Red and Black Currants, Mulberries, &c., all of which appeared to be in perfect condition, although some were over two years old. For dietetic purposes, he said, there was no comparison between fruits sterilized in this way, and fruits preserved in tins, either with or without sugar.

Mr. H. G. Little, who presided, gave some interesting particulars as to imported fruits.

UNITED HORTICULTURAL PROVIDENT AND BENEFIT.

March 9.—The annual meeting of this Society took place at the Caledonian Hotel, Adelphi, on the above date, Mr. John Green, Norfolk Nursery, Dereham, presiding over a fair attendance. Evidently, the members are perfectly satisfied with the way in which the Society is conducted by the Committee, and show their confidence by their absence on such occasions. The solvency of the Institution is shown by a remark from Mr. W. Gunner, one of the auditors, that were the funds of this Society shared out, the amount which each member would receive would astonish other benefit societies, and be a highly favourable one. The Annual Report shows that ninety-three new members were admitted during the past year, which brought the roll up to 997; from death and other causes there had been a loss of 31 members. Financially the Society is in a very flourishing condition. During the year the sum of £324 6*s*. 8*d* had been paid in respect of withdrawals and monies paid to deceased members. Sick pay amounted to £291 18*s*. only, a less sum than in the previous year, the balance in the hands of the treasurer on the receipts and expenditure for the year being £147 6*s*. 1*d*. The accounts of the Benefit, the Benevolent, the voluntary Convalescent, and the Management Fund, are set forth in detail in the balance-sheet; and one pleasing item in the accounts of the Benevolent Fund is that the subscriptions from honorary members realised £32 19*s*., in addition to donations amounting to £26 15*s*. In further proof of the financial prosperity of the Society, the sum of £1,630 had been invested during the year, bringing the total invested funds of the Society up to £20,600. Eight deaths had occurred during the year, the largest number on record; but as the members who joined in the early days of the Society advance in age, the death-rate is pretty certain to grow.

In moving the adoption of the report and balance-sheet, the Chairman dwelt on their satisfactory character, and expatiated on the growth of the Society since its establishment in 1860, and especially during the past twenty five years. The motto of the Society was "Union is Strength," and they had shown the truth of it by working together harmoniously and successfully for the good of all. One valuable principle of the Society was that the members were able to make some provision for old age. For a gardener, he knew no Society likely to be so beneficial to him as the one in whose interests they were met that night, and he attributed much of the success they had gained to the cordial good feeling existing, and the business capacity shown by the Officers and Committee. They were under a great obligation to the Horticultural Press, for the publicity the various journals were in the habit of giving to their proceedings. Considering the large number of gardeners about the country, the Chairman thought the number they had reached, viz., 997, was very small; they should have a membership of 2,000 at least, and even more. He thought the rules of the Society were pattern ones, for the Society was an investing as well as a benefit one, and if a member ceased to be connected with the Society, he could be paid the money standing against his name, and not lose it as is the case in some other benefit Societies. The Benevolent Fund and the Convalesent Fund, the latter especially, were the most valuable. After further setting forth the advantages accruing to young gardeners from joining this Society, the Chairman concluned by stating that very much of the success of the Society was due to their excellent Treasurer, Mr. J. Hudson, and their painstaking Secretary, Mr. W. Collins, and the Committee.

Mr. A. J. Brown, Chertsey, seconded the motion, and in the course of a forcible address he threw out some excellent suggestions which will be considered in due course. It was resolved that 300 copies of the report and balance-sheet should be printed for circulation; and steps taken as is customary to enlist the co-operation of head gardeners in bringing before the young men under them the advantages held out to them by the Society. Hearty votes of thanks were passed to the Trustees, Messrs. Geo. and J. Wheeler, and Riley Scott; also to the Treasurer, Mr. J. Hudson, who met with a very cordial reception on rising to respond, and stated he had been Treasurer for the space of twenty-one years. Mr. W. Collins was re-elected Secretary, and thanked, this being the completion of sixteen years of service. The outgoing members of the Committee were re elected; and Mr. C. H. Curtis, as Chairman, thanked for his services.

A meeting of the Committee was held on the same date. Thirteen new members were elected. Ten members were reported on the sick fund. A cheque for £30 7*s*. was granted to a lapsed member, being the amount standing to his credit in the ledger, and having attained the age of sixty years, is entitled to the same by rule. The sum of £1 10*s*. was granted to a sick member from the convalescent fund.

THE HORTICULTURAL CLUB.

March 10.—The usual monthly dinner of this Club was held on the above date at the Hotel Windsor. Mr. Harry Veitch presided, and some fifty members and friends attended. Mr. Pickstone, who for a long time has supervised the various fruit plantations established at the Cape by the late Mr. Cecil Rhodes, was the guest of the evening, and gave a most interesting and instructive address. On his arrival in Cape Colony he found that for more than a century fruit-culture had been carried on exclusively by the Dutch, and despite the fact of long-continued occupation by the British, they did absolutely nothing in that direction. Mr. Pickstone, indeed, found himself to be the first and solitary pioneer in the cult on that ground. Mr. Cecil Rhodes, with his usual forethought and consideration for the future of South Africa, devoted his attention to fruit-culture as being the particular branch which was recognised as employing more men, in comparison with area, than any other; and he consequently availed himself of Mr. Pickstone's experience by engaging him to acquire, in the first place, a considerable number of farms; and in the second, the suitable orchard trees. The Dutch industry at that time had greatly deteriorated, and the area under fruit cultivation was very small. The sorts grown were also of the most heterogenous description, so that Mr. Pickstone found it impossible to obtain the necessary stock on the spot, two or three of a sort being alone available. Owing to climatal conditions, he found that deciduous fruit-culture was limited almost entirely to the vicinity of Table Mountain, since it was only in that limited region that there were winter rains. Elsewhere there were only summer rains, and the general temperatures were such that fruit-trees obtained no rest, and were consequently a prey to all kinds of fungoid and insect pests. Irrigation being practically non-existent, formed also a bar to extended fruit culture, but this difficulty Mr. Pickstone surmounted by constant surface tillage, owing to which he found it practicable to establish orchards where the local farmers predicted the impossibility of so doing. Wind storms of intense violence, however, are of not infrequent occurrence, and though these may be guarded against in various ways, the granitic gravelly soil is of such a loose nature, that the blasts lift it and drive it sand-blast fashion with such force, that the trees are eroded to the very pith, and killed outright. To remedy this, the adjacent land was put under Oats, but a storm supervening after reaping, actually blew the retaining stubble out of the ground, and thus destroyed the trees a second time, when the task in that locality was abandoned. Many of the choice English Apples will not thrive in South Africa, but a few of the American ones do well. Many of the choicer kinds of Pears, however, grow to perfection; and some of the Japanese Plums do better than anywhere else, even than in Japan. The lack of flavour in Cape fruits was referred to, and admitted to a large extent by Mr. Pickstone, but he pointed out that the fruit-growing industry there was still young, and stated that he was quite sure that with continued and systematic selection, this fault would be rectified. A possible glutting of the markets by over-production, if the cultivated area under fruit were constantly extended, he also admitted, subject to the reservation that there was always room for the best, so that with high-class fruit and careful packing on systematic lines, fruit-growing may be relied upon to pay. Careful supervision and guidance were, however, essential to avoid the risk indicated.

An animated discussion followed the speech, in which Messrs. Pearson, Engleheart, Bunyard, Browne, Paul, Druery, H. Veitch, and others took part. Space precludes further details of this interesting contribution to our knowledge of Cape conditions, which will however appear *in extenso* in the *Journal of the Royal Horticultural Society*.

METEOROLOGICAL OBSERVATIONS taken in the Royal Horticultural Society's Gardens at Chiswick, London, for the period March 1 to March 7, 1903. Height above sea-level 24 feet.

Remarks.—Wind and rain have been the prevailing features of the past week, with sunshine on one or two days.

THE WEATHER IN WEST HERTS.

The past week was the seventh warm week in succession. During this remarkably mild period there occurred only three unseasonably cold days, and but five unseasonably cold nights. On the warmest day in the week the temperature rose to 53°, and on the coldest night the exposed thermometer registered 9° of frost. At the present time the ground is at about a seasonable temperature, both at 1 and 2 feet deep. More or less rain has fallen on all but two of the last eighteen days, and to the total depth of nearly 2¾ inches. Of that amount, about 8¾ gallons of rain-water have come through the bare and turfed soil percolation gauges, both gauges being a yard square. On two days the sun shone for respectively seven and eight hours, but on an average for only one and a quarter hour a day during the rest of the week. The winds have come exclusively from some southerly or westerly point, and have been as a rule moderately strong. The amount of moisture in the air has varied considerably, but on

the whole the atmosphere has been rather humid. An Early Rivers' Peach growing on a south wall in my garden came first into blossom on the 6th, or eighteen days earlier than its average date in the previous seventeen years, and earlier than in any of those years with the exception of 1894 and 1899. *E. M., Berkhamsted. March* 10, 1903.

MARKETS.

COVENT GARDEN, March 12.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Thursday, by the kindness of several of the principal salesmen, who revise the list, and who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but often several times in one day. ED.]

REMARKS.—At the corresponding time last year Cobnuts were worth 1*s.* per lb., as against 3*d.* this year. Cape fruits, viz., Nectarines fetch 4*s.* to 7*s.*; Peaches, 5*s.* to 10*s.*; Plums, 4*s.* to 7*s.*; Pears, 2*s.* 6*d.* to 6*s.*; Grapes, 10*s.* per case; Chicory fetches 3*d.* to 3½*d.* per lb.

POTATOS.

Various samples, 70*s.* to 90*s.* per ton; Dunbars, red soil, 105*s.* to 110*s.* Seed Potatos in variety, prices on application. *John Bath, 32 & 34, Wellington Street, Covent Garden.*

WILLIAMS' MEMORIAL FUND.—At a meeting of the Williams' Memorial Trustees held recently, Dr. MASTERS in the Chair, it was decided to offer two Medals for competition at the British Fruit and Vegetable Show at Chiswick to be held in September next. It was also resolved to subscribe the sum of £10 to the funds of the new Horticultural Hall.

ANSWERS TO CORRESPONDENTS.

ADDRESS, WM. WHITMAN BAILEY: *M. Buysman.* Professor of Botany in Brown University, 6, Cushing Street, Providence, Rhode Island, U.S.A.

BOOKS: *A. B.* Mr. Upcott Gill, *Bazaar* Office, Drury Lane, W.C., would supply you with a manual on surveying, upon your stating your wants to him; price trifling in amount.

CROCUSES GROWING IN FRAMES: *C. W. D.* The plants are attacked by Botrytis cinerea, and numerous Sclerotia are present in the cornfibres. There is also a quantity of the Eucharismite in the rotten corms. Nothing short of removing every particle of soil from the compartment, and disinfecting, will check the spread of the disease to the remainder of the Crocuses.

DENDROBIUMS WITH SPOTTED LEAVES: *W. P., Northampton.* Such an unhealthy condition in deciduous Dendrobiums is often brought about by their being given too little heat and moisture when growing, and too much when they should be at rest. As it is, the best thing to do would be to cut away all the back pseudobulbs affected and burn them. Remove all bad leaves, and place the plants in a warm, moist house. When the new growths are completed, rest them in a dry, airy greenhouse or fruit-house. Cut the bad pseudo-bulbs off close down to the rhizome; they are of no use on the plants.

GRAPES HANGING TILL THE MONTHS OF NOVEMBER AND DECEMBER: *W. R. B. L.* No harm to either the Grapes or the Vines will result if the border be kept in a fairly moist condition, and a thick coating of hay or clean straw be put over the entire surface.

HYACINTH BULBS: *H.* The bulbs have evidently been imperfectly dried before storing. This has led to their being attacked by Cladosporium and other fungi, which have destroyed most of the roots. *G. M.*

INSECT OR SCALE, &c.: *Young Gardener.* The round bright red objects in the fork of the Apple-twig are the eggs of a species of Bryobia belonging to the Harvest Mites (Trombidiidæ). They are often extremely abundant on various kinds of fruit-trees, and sometimes occur in such numbers as to almost cover the bark of the tree. A dressing of lime and sulphur would destroy them. Gouty twigs of the Gooseberry: this is a physiological malformation.

KALANCHOE FLAMMEA WITH IMPERFECT GROWTH: *W. A. A.* The house in which the plants were kept being too cold and damp, would, as you suggest, cause the imperfect development seen in the specimens sent.

NAMES OF PLANTS: *Correspondents not answered in this issue are requested to be so good as to consult the following number.*—*N. W. O.* Helxine Soleiroli.—*Cannes.* 1, Acacia longifolia; 2, Euryops virgineus.—*Alva.* 1, Codiæum (or Croton) Johannis; 2, C. variegatum; 3, C. angustifolium maculatum; 4, Adiantum hispidulum; 5, Selaginella viticulosa; 6, Cymbidium eburneum.—*C. H.* Sprekelia formosissima, often called Amaryllis.—*Vernon.* 1, Cypripedium villosum; 2, Cypripedium × Harrisianum; 3, Odontoglossum × Coradinei.—*G. R.* 1, Codiæum angustifo'ium; 2, C. volutum; 3, C. chrysophyllum; 4, C. irregulare; 5, C. trilobum; 6, C. Queen Victoria. All these are commonly called Crotons in gardens.—*W. J. G.* Heheclinium ianthinum.—*Haslemere.* 1, Anthericum lineare variegatum; 2, Abutilon Savitzii; 3, not recognisable from the scrap sent; 4, Eulalia japonica zebrina, so far as we can judge; 5, Tradescantia repens; 6, A garden-raised Begonia, impossible to identify without seeing leaves.

NATIONAL AMATEUR GARDENERS' ASSOCIATION. The Secretary of this body of amateur gardeners is Mr. T. Finch, 117, Embleton Road, Lewisham; and not Mr. A. J. Foster, as we inadvertently stated in last week's *Gardeners' Chronicle.*

PAYMENT FOR REMOVAL: *W. J.* The employer is not bound to reimburse the gardener the cost of the removal of his household goods, unless there exists a written agreement to that effect.

RHODODENDRONS: *W. R. B. L.* The plants are weakened by being allowed to carry numerous seed-vessels. Take them as soon as the blooms are over.

THE NARCISSUS.

THE Narcissus is one of the most classical of flowers, its glory having been sung by Homer, Sophocles, Shakespeare, and Wordsworth, in imperishable strains. It seems to have inspired the great poets of all ages with imagery of the most beautiful and memorable kind. The immortal tribute of him who has been called, not without expressiveness, "the High Priest of Nature," to the queen of vernal flowers, is simplicity itself; yet who that has ever read them can forget such exquisite lines as these:

> "They flash upon that inward eye,
> Which is the bliss of Solitude."

Nor is the Narcissus, in any of its manifold forms, an exacting plant in the matter of adequate culture; for the humblest cottar who has the smallest allotment of good garden ground can grow it grandly there. It is a great pity, for the sake at least of such poor yet earnest cultivators, that certain varieties of great beauty, such as the Weardale Perfection, and others of even more recent introduction, whose attributes need not be characterised here, are so prohibitive in their prices; but those who are not affluent, and cannot therefore indulge in such expensive floral luxuries, have the consolation of knowing that other forms, of almost equal impressiveness, and what is of great importance, of easier cultivation, are quite within their reach. Few flowers, for example, are more beautiful than the "Scottish Garland Lily," with its pale primrose perianth, and artistically-serrated golden trumpet, which, naturalised in grass, luxuriates here. It always seems to me to be a greatly-improved version of the English Lent Lily, which blooms contemporaneously. Either of these, though very accommodating when compared with other

FIG. 74.—"SIR WATKIN" DAFFODIL. (SEE P. 178.)

varieties, succeeds much better when planted in fibrous, mossy soil, under trees, than in garden soil.

Of all Narcissi, undoubtedly the supreme favourites are the bicolor Daffodils, which for refinement of aspect and delicate beauty could not easily be surpassed. Conspicuous among these is the magnificent Weardale Perfection, to which allusion has already been incidentally made; the massive and splendidly-formed Empress, which is hardly less commanding, while it is much more accessible; Grandis, a late-flowering bicolor, worthy of the name; Victoria, a grand form (introduced by the Messrs. Barr, of Covent Garden), with creamy-white perianth, which I have seen at their nurseries, exceptionally fine; the uniquely-coloured Apricot, and the venerable Horsfieldi, which still retains much of its primal popularity.

Hardly inferior to these in artistic attractiveness are such pure yellow varieties as the almost incomparable Emperor, which I have always regarded as a very close approximation to floral perfection; Ard Righ, a very early flowering introduction, of Irish origin; Alvarez, which has well been described as a miniature Emperor, with much of the refinement of the latter imperial flower; Glory of Leiden, one of the grandest of this section; Johnstoni Queen of Spain, an extremely interesting and attractive flower, which, however, I have not found very easy of culture, not being able, manifestly, to provide for this beauty a congenial soil; Monarch, Lady Helen Vincent, Maximus, and Golden Spur.

All the various forms of Narcissus incomparabilis, and especially such representatives as C. J. Backhouse (with rich yellow perianth and orange-scarlet cup), Gloria Mundi, Mary Anderson, Queen Sophia, Frank Miles, the great Sir Watkin, and Princess Mary, are highly interesting; so also are Narcissus Barrii and Leedsii, of which beautiful sections the special hybrid variety entitled Barrii conspicuus remains by far the greatest and most abiding acquisition. Very fascinating are also the exquisitely fragrant Narcissus odorus, and Narcissus odorus plenus, "Queen Anne's Double Jonquil."

The classical Narcissus, a sweet native of Greece, which inspired the Homeric and the Sophoclean muse, is N. Tazetta. This is doubtless a species of considerable beauty, with its splendid fragrance (almost too pronounced), and its clustering, miniature flowers; but much superior to this renowned plant is Narcissus poeticus, of which the finest form is Narcissus p. poetarum. No flower could possibly be more perfect than this. *David R. Williamson.*

"SIR WATKIN" DAFFODIL.

THIS truly "incomparable" Daffodil (fig. 74) when first exhibited in 1884 as "James Dickson" caused a deep impression, not only among the small band composing what some one in a happy moment designated "The Narcissus Cult," but also among flower-lovers generally. When highly cultivated it still maintains a position of the first rank, not alone as a garden plant, but also for forcing; and on grass none of its congeners surpass it. It will be remembered that the name was almost immediately altered on the suggestion of the reputed raiser, from James Dickson to Sir Watkin. It is not my purpose to follow the slow but sure process by which, in the course of some ten years, the history of the new Daffodil was elucidated. As a not uncommon variety in Merionethshire, Messrs. Dickson, of Chester, procured from various parts of that county in the space of two years some 23,000 flowering bulbs, for which, it was said, about £1,000 was paid. Thence it was traced to Bideford, where the bulbs that in time stocked the above county were derived, in the beginning of last century, and where as a living plant all trace of it is lost. The engraving at p. 484 of Hill's *Eden* (1757) carried the history of the plant downward a bit further, and with one exception, I believe no one has ever suggested that the Daffodil referred to in that book was other than Sir Watkin of to-day. It was thence an easy leap to Parkinson, the engraving in this case being less true to the character of the flower; but the description, on the other hand, tallies in a remarkable manner, with one or two exceptions only, which will be mentioned presently. Parkinson's figure was traced finally to the *Hortus Floridus* of Crispin de Passe (1614).

One of the exceptions in Parkinson's description is the remark, "The flower hath little or no scent at all," when as a matter of fact it is so sweet-scented, that on that account alone Narcissus biflorus has been suggested as one of its parents. The other exception is that "This doth sometimes bring forth a flower with ten or twelve leaves, and a cup much larger, as it would be two even as the flower seemeth." I have cultivated the plant somewhat extensively, and do not remember ever to have seen a flower of the above type. Parkinson was unaware whence this Daffodil was derived, but its French name, "Nonpareille," under which it was received, suggests a continental origin. The same variety is described in Johnson's edition of Gerarde's *Herbal;* and he gives a figure with the remark, "it is somewhat too little." He might have added the figure had been previously employed by Clusius to illustrate a novelty sent him in 1601, the outer segments of which were pure white. It is also described by Rea, who adds he had cultivated for a long time a double variety, which he had received many years previously from Paris "by the name of the 'donble Nonpareil Daffodil,' as in truth it is." From the description, this seems to have been the well-known "Butter-and-Eggs," and Gilbert, who mentions both, says the latter forms "a large and beautiful flower, it being a pity 'tis so great an increaser!" Daffodils seem to have been too common during the eighteenth century to have called for any but the barest notice. However, in addition to that in Hill's *Eden*, Justice notices it in his *Scots' Gardeners' Director* (1754). Justice is an original writer, and in the chapter on Daffodils he declares he treats of no genus of plants "but of those whose culture I know by my own practise." Those he treats of are only Narcissus nanus, N. (spurius) Trumpet major, N. Telamonius plenus, N. "Butter-and-Eggs," N. Orange Phœnix, N. poeticus flore-pleno, The Nonsuch double; N. biflorus, a yellow with reflexed sepals; and the "greatest Nonpareille Daffodil" of Parkinson. I think I possess the works of all the early writers on gardening in Scotland, and no one but Justice mentions this plant. Gordon, who published in 1784, names indeed the Incomparable among a very good list of kinds. Justice is so altogether reliable, that it is somewhat strange, "Sir Watkin" and Parkinson's "Nonpareille" being identical, no trace of the first-named has been discovered in Scotland. Hill, on the other hand, is the opposite of Justice as regards reliability; but his figure corresponds so exactly with a bloom of Sir Watkin of moderate quality, while part of his description points to its identity with that of Parkinson, that one is almost forced to accept the position as it stands; at the same time admitting that variety as an old denizen of Scottish gardens. Perhaps someone could throw more light on the subject. *B.*

THE ROSARY.

FORTUNE'S DOUBLE YELLOW ROSE, ROSA FORTUNEI.

THIS variety is synonymous with Beauty of Glazenwood, a Noisette or climbling Rose, and has been shown by me on several occasions at the meetings of the Royal Horticultural Society, where it was much admired, and by many persons it was regarded as quite a novelty. No Rose with which I am acquainted flowers more freely; the colour is buff, blotched and striped with crimson, and from the gracefulness of both flowers and foliage, it is one of the most suitable in the cut state for dinner-table and other domestic decorations. Its freedom, too, from mildew and rust is remarkable, and aphides seem to be the only enemy; of which fumigation with XL-All will relieve the plants. It is a very fast and strong grower, and will live for a considerable number of years when established in good soil. There is a plant of this Rose at Lockinge which was planted about 1873, which during the last ten years has greatly increased in vigour. In all, there are six plants growing very well here under glass, in four different houses, some being planted on two sides of a house standing east and west; and in another that runs north and south, and also on the south side of a large span-roofed house running east and west, and in a ridge-and-furrow house standing north and south. The blooms that we cut number many thousands annually, cutting commencing in February, and continuing up to the end of the month of May. A suitable structure in which to cultivate Fortune's Yellow Rose is a lean-to or span-roof with a 10 or 12 feet stretch of rafter, having wires running lengthwise, and fixed at 12 inches distant from the glass, and should be about 8 inches apart. If span-roofed, the border should be on opposite sides, and separated by a path. The borders need not consist of any special compost, ordinary garden soil, with a good proportion of rather coarse sand or gravel, answering the purpose admirably. If the house be span-roofed, from 20 to 30 feet long, let one plant be planted on each side in the centre of each bed, and beneath the lowermost wire, and cut the plant back to that wire, and take two shoots and allow them to run, in the form of a double horizontal trained cordon, the entire length of the house. From these horizontal trained shoots, upright shoots will arise the second year at about 2 inches apart, which should be thinned to about 12 inches apart, and trained to the wires, the greater proportion of which will grow to a length of 8 to 10 feet when the plants are established. These upright growing shoots will produce flowering shoots the following season. When flowering is over, the upright shoots should be cut back to the horizontal, leaving one bud from which will produce other shoots in great number, which will be thinned and regulated as before. Trained in this manner, little difficulty is experienced in growing the other ordinary occupants of the houses, and slight shade afforded by the Rose-shoots are sometimes more an advantage than otherwise. That it can be cultivated with success upon its own roots some cultivators would consider an advantage, and cuttings of matured shoots root freely, with the result that Briar suckers and probable decay at the point of union are thereby avoided.

The large quantity of chalk in the soil at Lockinge may be considered by some as contributing to success in Rose-growing. Yet upon a general look round the gardens in this neighbourhood, one finds the greater portion of the Rose family in anything but a flourishing condition, the plants being devoid of vigour. Hearing, as I often do, of failures in Rose-culture, I am forced to the belief that in the training and pruning must lie the principal cause of failure. *Wm. Fyfe, gr., Lockinge, Wantage.*

FIG. 75.—BOUQUET OF TRANSVAAL ORCHIDS PRESENTED TO MRS. CHAMBERLAIN AT JOHANNESBURG, AND ARRANGED BY MR. FUCHS, RAND NURSERY, JOHANNESBURG.

(SEE P. 180.)

TRANSVAAL ORCHIDS.

OUR knowledge of the Orchids of Cape Colony and of Natal is much more complete than in the case of those of the Transvaal; and accordingly it is with pleasure that we avail ourselves of the opportunity of illustrating a bouquet (see fig. 75), largely composed of those flowers, which was made by Mr. H. Fuchs, Rand Nursery, Johannesburg, for presentation to Mrs. Chamberlain, when the Right Hon. Joseph Chamberlain visited the "Golden City." The letter of Mr. Mainwaring, manager at the Rand Nursery, informs us that the groundwork of the bouquet was of Violets, Smilax, and Fern-fronds, but Transvaal Orchids formed the chief feature. The names of the kinds used are not given, but they are most probably varieties of Eulophia Dregeana, E. ensata, and other of the chain-tubered Eulophias, whose pretty flowers are of various shades of white, pink, and yellow. The larger flowers, described in Mr. Mainwaring's letter as Phaius-like in growth, are doubtless those of Eulophia streptopetala.

The African Eulophias and Lissochili are not well understood in gardens, and, as treated, are apt to prove ungrateful subjects; therefore it will be of service to quote Mr. Mainwaring's remarks on the conditions under which they grow in a wild state. He says: "They seem to thrive best on light, stony soil, and generally on the slope towards the water; so that in the rainy season (their growing season) they are sometimes flooded, and in winter, their season of rest, they are quite dry." With regard to the Phaius-like species with pseudo-bulbs above ground, he says: "They seem to require a moister situation than the others (the chain-tubered), and a richer soil."

Calanthe sylvatica, numbers of pretty Disas, Satyriums, and other terrestrial Orchids, abound in the Transvaal, and there are also some epiphytal Orchids, such as Megaclinium Sandersoni, Angræcums, and Polystachyas. In considering their requirements under cultivation, however, it must be borne in mind that the winter the writer mentions as the Transvaal Orchids' season of rest, is the hot dry season comparable to our winter only by a similarity in the names of the months of the year during which it takes place. Therefore the resting season under cultivation must be cool and dry, for if hot and dry treatment at that season is attempted, the plants will perish.

ORCHID NOTES AND GLEANINGS.

LÆLIO-CATTLEYA × ELEGANS.

RECENT importations of Lælia purpurata, and the rarer natural hybrids of it, Lælio-Cattleya × Schilleriana and L.-C. × elegans, found growing with it, have introduced great variety into the forms of those natural hybrids now found in gardens, each different importation seeming to bring a set of varieties differing in some respects from others. Two fine varieties of L.-C. × elegans from an importation by Mr. E. Kromer are now flowering with Mr. H. A. Tracy, Amyand Park Road, Twickenham. The flowers are larger and broader in all their parts than the old forms represented by L.-C. × elegans Turneri, and of a fine tint of rose-purple colour. The labellums of these varieties are much broader, and more attractive in shape, than in the older forms.

"LINDENIA": ICONOGRAPHIE DES ORCHIDÉES.

THE seventh and eighth numbers of the seventh volume of the second series, and the seventieth volume of the work, are issued together, and the quality of the pictures and value of the letter-press are well sustained by M. Lucien Linden, its versatile founder, director, and publisher. The subjects illustrated and described are:—

CATTLEYA LODDIGESII VAR. HARRISONIÆ, SUB-VAR. JORISIANA.—Flowers as in the normal form, but with the rosy-lilac sepals and petals spotted with dark rose.

CATTLEYA TRIANÆ VAR. TRIUMPHANS.—A very beautiful flower, with light purple-tinted sepals and petals and lip of rich claret-crimson, with yellow disc.

CATTLEYA TRIANÆ VAR. MEMORIA RODIGASII.—The description of this remarkable variety, dedicated to the memory of the late Emile Rodigas, who worked so ardently to advance Belgian horticulture, and a sympathetic obituary notice is also given; but the plate of the variety is to be issued with the next number, as it could not be got ready in time for the present one. The flower is said to be of a clear yellow colour, tinted with rose, and the front of the lip reddish-cerise.

CYPRIPEDIUM LAWRENCEANUM VAR. ARDENS.—A very showy flower, with the labellum, dorsal sepal, and the tips of the petals suffused with amethyst-purple.

CYPRIPEDIUM × LEEANUM VAR. OLIVACEUM.—Flowers yellow, and upper half to the dorsal sepal white, the base of which as well as the petals are marked with olive-brown.

CYPRIPEDIUM × MISS LOUISA FOWLER.—The fine hybrid between C. Chamberlainianum and C. insigne, for which J. Gurney Fowler, Esq., received an Award of Merit at the Royal Horticultural Society, January 31, 1899. The upper sepal in this flower is of an emerald-green tint, which at the base changes to yellow towards the white margin; petals and lip tinged with rose-purple.

ODONTOGLOSSUM CRISPUM VAR. GRISELIDIS.—One of the much-sought-for blotched crispums of a high degree of merit. Flowers white, with one very large red blotch on each segment, and a few small ones round the yellow crest of the lip.

VANDA TRICOLOR TENEBROSA.—A very handsome variety with yellow sepals and petals heavily marked with reddish-brown; base of the lip and column white, front lobe bright rose with purplish lines.

NOTES FROM ISLEWORTH.

(*Concluded from p.* 116.)

HARDY FRUITS, ETC.

DURING the past season Tomatos were a failure. Pears were a good crop, and kept very well; flavour varied a great deal, some of the best

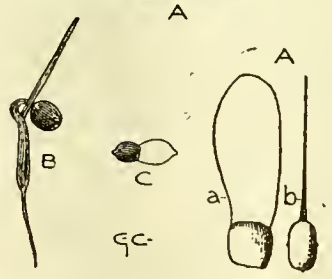

FIG. 76.

A. Acer palmatum.—One seed (*a*) flat, and (*b*) on edge. This tree flowered in May, and matured its fruit in September. Germination not yet tested.

B. Zephyranthes roseo.—Life-size seed of Z. rosea. The original process is terminated in a true root, which will not die for many months. The first true leaf is rising upwards. This is typical of Hippeastrum in all respects.

C. Agapanthus Mooreanus.—Life-size drawing. The true seed shaded; the wing not shaded.

flavoured kinds in good seasons (such as B. Bosc) falling to second-class, whereas other kinds (such as B. Brown) were much better in flavour than usual; in fact, this latter Pear was quite first-class in flavour this year, and as good as Marie Louise—which is high praise.

I had quite a failure among dessert Apples.

Among Strawberries, an interesting break occurred in this garden among a bed of Countess and Latest-of-All; the sport was isolated, and propagated, and this year bore a fine crop of large late fruit. It is the finest Strawberry I have ever tasted for flavour, melting in the mouth like a soufflée; yet it will never be of use commercially, because it is not firm enough to stand travel, and has a dull appearance. It was identified as Helen Gloede by an expert to whom fruits were sent, yet, as I have never had this Strawberry, I cannot help thinking that it must have made a spontaneous appearance in my garden either from seed or reversion.

The Plum-maggot has increased of late years on wall-trees. There is no doubt that the insect finds a lodgment in the crevices of the walls. After pointing the worst places, it is a good plan to paint the whole wall over with a boiling mixture of quicklime, oil, &c. This is cheap, expeditious, and lasts several years, filling up all the small holes and crevices.

Seedling Peaches and Nectarines should be transplanted every year until fruiting age (four years). If this is not done, the trees may be lost when lifted for planting in permanent places.

DISEASES.

"Silver leaf" in Peaches and Nectarines.—This broke out in early spring on one Nectarine under glass (for the first time in this garden). Determined to eradicate the disease, I cut out the entire branch, and sawed it up into short lengths. Here and there appeared dark marks in the sawn ends, which under the microscope appeared to be dead woody tissue. Not satisfied with this, I determined to sacrifice the entire tree, which was also sawn up into short lengths throughout. I found (1) the same dark marks in boughs as yet unaffected with any sign of "silver-leaf;" (2) that such marks extended as far down as the graft. Below this were no certain signs of dead tissue.

From these data I came to the following provisional conclusions:—

(1.) That the portions of dead tissue in the wood were either the cause or the effect of the disease.

(2.) That such disease was antecedent to the appearance of "silver-leaf," which was itself an effect of the disease.

(3.) That the disease had apparently entered or commenced at the graft.

I took the pieces of wood to the Scientific Committee of the Royal Horticultural Society on April 22, and reported my observations. Subsequently I exhibited the trunk of the tree before the Committee, who referred the matter, at my request, to Prof. Percival. His report on the matter, with observations on the organisms he recognised as connected with the manifestations of the disease, are published in the *Journal of the Royal Horticultural Society.*

Disease in Brunsvigias, and some Crinums.—Recently I have noticed that in bulbs "summered" out-of-doors a disease attacks them beneath the tunics. Softness, dampness, and rotting of the tissue occur, and the foul odours of decay are very noticeable. Among the decaying mass, small white maggots are common, and occasionally brownish-red cocoons. I think it probable that these maggots may cause the original lesion in the tissue of the plants, admitting some specific disease; if not, or perhaps in addition to such introduced disease, these organisms probably deposit ptomaines of a nature deadly to the tissue. I have never found them except in association with active disease in these plants.

Mr. E. E. Austen kindly determined these maggots and cocoons to belong to the common British fly, Lonchœa vaginalis. When these flies are seen hovering above the bulbs, and ready to deposit their eggs, I shall try the result of a few fumigations; it is probably this which hinders their operations under glass.

Among seeds raised at Isleworth for scientific purposes, I have found time during the past year to note the following:—

Acer palmatum.—This tree rarely carries seed in this country; in fact, I am not aware of its

ever having been notified. I have noted flowers on a few garden varieties of this species, but have never seen seeds form on any of these varieties. The type, carrying about forty seeds in this case, was quite a small pot-plant in my greenhouse. The fruit consisted [*vide* full-size drawing (see fig. 70, A, p. 180)] of twin seeds adhering to each other, and inclosed in one membrane. Each seed was hard, round, somewhat smaller than the Sweet Pea seed, and remarkably winged.

Agapanthus umbellatus. — I have never succeeded in raising that wide-leaved, large-flowered form (which I take to be the typical "umbellatus") from seed. This is the form so widely spread in English gardens as a greenhouse plant, and which is largely used about London during the summer for the decoration of porches, verandas, &c. The foliage will not stand any frost, nor will the bulbs. I have more than once raised seed, but it has never proved virile. Not improbably it has been propagated so long from offsets as to have partly lost the capacity for producing virile seeds.

Agapanthus Mooreanus.—This is held by many writers to be merely a variety, or geographical form, of the preceding, smaller in the flowers, narrower in the foliage, and hardy in dry soils. At Isleworth this plant is of doubtful hardihood, ranking in this respect, probably, with the garden Kniphofias. However, it carries seed freely, ripening in the open borders, even in such an unfavourable summer as the past (1902).

Both plants have five ovules in each half of the ovary, or thirty ovules to the fruit. In umbellatus I have never found more than three seeds to the fruit (generally only one), and these are dull black. In Mooreanus I have found as many as twenty seeds to the fruit, and they shining black.

In both cases the seeds might be mistaken for those of Hippeastrum, if superficially observed, but present this great difference—that they are winged on one side only. Hence their contour resembles to this extent the seed of Acer palmatum [vide preceding drawing (fig. 76, c)].

Romulea rosea.—Seeds about thirty-nine, brown, shining, flattened at both sides, not at all winged. Fruit dehiscing.

Herbertia pulchella.—Fruit resembling Romulea rosea except as follows. Fruit dehiscing at the top only, the seeds remaining tightly fixed in the tough and almost woody casing of the fruit. Thus, although in Romulea the seeds would quickly fall to the ground after dehiscence, yet in Herbertia this would certainly not occur for a long time, unless by the application of some external force. Rain would soon fill the capsule with water (owing to the dehiscence at the top), cause the seed to swell and germinate, and thus burst the case and allow the seeds to fall to the ground. Frost and other agents might have the same effect. The seeds are smaller than in Romulea, of the same colour, but dull, and number about twenty-four to the fruit. *A. Worsley, Mandeville House, Isleworth.*

FOREIGN CORRESPONDENCE.

CULTIVATION OF GINSENG.

Allow me to say, in reply to the Director of Kew Gardens, Sir W. T. Thiselton-Dyer, that the cultivation of Aralia quinquefolia (the Ginseng) is quite an easy matter here. In summer the plants are cultivated outside, but during the winter in the orangery. The compost we use is good rotten leaf-mould. Cuttings taken in autumn strike very easily, and some nurserymen raise nice young market plants, which sell well. *J. K. Budde, Botanic Garden, Utrecht, March 14, 1903.*

FORCING STRAWBERRIES.

The production of very early Strawberries is not easy, even if the necessary means for their culture are at command, and the plants have been properly prepared for forcing. The real difficulty arises in the necessity there is to afford time for the essential organs to properly develop. This is a slow process, and failure often happens in cases of early forced plants, because too high temperatures are permitted during the early stages of growth, with a view to advance the crop. By early Strawberries are meant fruits that are ripened by the beginning of March, and in order to obtain such fruits, plants of suitable varieties must be started in November, when the plants have had comparatively little rest. The forcing of plants later in the season for affording successional supplies of fruit is a very different thing, for these have their organs further advanced, and therefore having in a measure passed their critical stage will safely withstand a greater degree of warmth.

Although excellent crops are grown in vineries, Peach-houses, and similar structures, it is best to devote structures entirely to Strawberries during their forcing season, if this can be done. The common practice, which we used to adopt, of commencing early forcing by placing plants in cool pits upon beds of tree-leaves is a good one, although we are equally successful with the following method. We have a range of pits upwards of 100 feet in length, and 9 feet in width, divided into four compartments, and having an inside walking way by the back wall, and beds firmly filled with tree-leaves in front. These pits are provided with a flow and a return hot-water pipe, placed by the front wall, with hit-and-miss ventilators in front of them. This range admirably answers the purpose of Strawberry forcing, the plants being arranged near to the glass upon removable stages placed over the leaf-beds and walking way.

When the Strawberry season is over, the stages are replaced by trellises for Cucumbers, Melons, and Tomatos. With a view, however, of securing ripe fruit as early as possible, a batch of plants is drafted as soon as the fruits are set from those that are first started, and placed upon shelves in Pine-houses; while those for affording late supplies of fruit are grown and fruited in a house possessed of an eastern aspect, where they can be subjected to cooler and more suitable treatment than is possible in the pits which have a southern aspect.

The plants are taken from their winter quarters in batches at intervals of ten days or a fortnight, and introduced into the pits, and are not watered until the soil has become sufficiently dry to be top-dressed with fresh compost and an artificial fertiliser, made quite firm in their pots with a rammer. They are arranged upon the stages with a thin turf beneath each pot, from which they are at no time disturbed, even if they are moved into another structure, until their fruit is gathered. This use of turf has been declared out of date, but it is a good one, and was handed down to us from the "old school," who left us other valuable lessons, together with some ludicrous ones.

During the early stages of growth the pipes are merely warmed, and this, together with the humid warmth arising from the fermenting beds of leaves, a slight circulation of air both by night and day, and close attention to other details, exactly meet the early wants of the plants, for under this treatment they are found in the morning with their leaves bedewed with moisture. The progress is slow, but strong flower-spikes and robust foliage result. At this stage the temperature is slightly increased by artificial means and the sun's rays. Increased ventilation prevents condensation of moisture upon the plants, and otherwise promotes suitable atmospheric conditions for the proper fertilisation of the blossoms. This is assisted by artificial means, especially in cases of early forcing, so that pollination may be effected perfectly, and the fruits be consequently perfect in form. The fruit once set and thinned, swells freely in a night temperature of about 65°, with 10° more by day from artificial aid, but reaching 85° to 90° from sunheat. As soon as the fruits commence to colour, a high temperature, even if it be from solar-heat, is prevented by affording more ventilation, which, together with a comparatively dry atmosphere, is necessary to promote good colour and flavour.

The plants are regularly supplied with diluted stable-manure water from the time they commence to push their flower-spikes until the fruit begins to change colour. We are in a limited way testing the new variety, The Laxton, both for forcing purposes, and for outdoor culture. *T. Coomber, The Hendre Gardens, Monmouth.*

FORCING ASPARAGUS IN OPEN BEDS.

Some years ago, the *Gardeners' Chronicle* (vol. xxi., p. 201), published a note of mine treating of the forcing of Asparagus in permanent beds. For many years Asparagus forcing has received especial attention in these gardens; in fact, I believe that I am now forcing two beds planted by my predecessor some twenty-five years ago. Most of the beds have been altered; but two of the original ones remain as they were made, which shows that forcing does not weaken the plants, for I can truthfully assure your readers that these beds are in excellent condition, comparing favourably with those which are ten and fifteen years younger. Of course, much depends upon the kind of forcing employed, and if much heat were employed the plants would be weakened thereby. Another important point is, the sort of materials used for forcing. I have observed Asparagus-beds which were forced with smoke-fines and with hot-water, and the plants were very inferior as compared with those forced with fresh tree-leaves and a small proportion of stable-manure.

Formerly the beds here were forced each alternate year, and the shoots were allowed to grow naturally. A different method is now followed, and each bed is forced in turn, and the results are as good as under the earlier one, the only difference being that the beds force more easily, and a crop can be reckoned on in six weeks from the date of beginning to force.

I have previously described the method pursued here, and need only point out the desirability of growing Asparagus for forcing in permanent beds if much produce is required; and that the crop taken from beds forced slowly by fermenting tree-leaves of Oak and Chestnut is but little inferior to the best produce from beds in the open in the months of May and June; also that the largest heads are edible throughout their length, which is not the case with Continental Asparagus as sold in the market. Home-grown Asparagus is much better than was once the case, our large market-growers sending splendid produce into the market, a large portion of the stalk of which is edible. In order to get these fine heads, the cultivation must be of the highest excellence; much space being afforded the plants. At Sion, I wish more space could be given them. The plant must be afforded manure in some form, and in abundance during growth after cutting has ceased, and copious applications of water in dry weather if the soil is naturally light and porous. Our forced beds from May to the end of August are often flooded in dry weather, and manure applied. *G. Wythes.* [As forcing with tree-leaves in the open is a somewhat slow process, it does not answer for the

earliest crops, and these have still to be obtained from lifted roots forced on hotbeds in pits and frames; but there is great saving in the matter of plants and labour by the permanent bed system, when applied to early spring supplies. Ed.]

PLANT NOTES.

METROSIDEROS FLORIBUNDA.

(Bottle-Brush Tree.)

This peculiar looking shrub is very attractive when in flower, and it lasts a long time in flower, and is therefore useful for decorative purposes when grown in small pots or larger ones, or it may be trained up the roof or sides of a greenhouse. I saw a large plant recently, in a garden in a London suburb flowering profusely. The various species grow well in peat, leaf-mould, a small quantity of loam and sand, made very firm with a rammer. During the late autumn and winter, the plants should be kept moderately dry at the root, but never very dry, these being evergreens. After flowering, repotting may be carried out; indeed, it is advisable to do this yearly, affording fresh drainage as well, and clean pots, and if increase in size of ball be not required, the latter may be reduced in size by shaving off an inch or more all round, and repotting in the same sized or a smaller pot. Young plants may receive another shift early in July, August, and the first half of September. The plants may be plunged in a bed of coal-ashes out-of-doors. M. tomentosa, M. ciliata, and M. floribunda, have crimson coloured flowers; M. florida, has scarlet ones; those of M. scandens (buxifolia), are white. Those mentioned here are native of New Zealand. The sort of cultivation adapted for the Myrtle is suitable for Metrosideros. *W. A. C.*

Veitch's Hybrid Aquilegias from Seed.

These plants make a bold show in beds and borders during May and June; they will also grow and flower freely in partial shade. Their flowers are much esteemed for cutting. The beauty of the flowers lies in their graceful spurs, which are about 2 inches in length, and the delicate tints of the flowers. If the seed be sown in May, or early in June, on a border outside, and the seedlings afforded water in dry weather, good plants for flowering in the following season should be obtained. *J. Kerry, gr., Faulkbourne Hall, Witham.*

Camellias at Clare Lawn.

Camellias have in many places fallen upon evil times, possibly owing to their slow growth and the unsuitability of their flowers for sending long distances. But when the plants are grown well, they produce an extraordinary number of flowers. In Sir F. Wigan's garden, Clare Lawn, East Sheen (gr., Mr. Want), there are some splendidly grown specimens from 10 to 12 feet high, and equally large in diameter. They were one mass of bloom a day or two ago, and the foliage is dark and glossy, showing extra health and vigour. They are planted out in a large house having a northern aspect, and are in a line with the famous fernery, in which Mr. Young grows such marvellous Cymbidiums. There are many plants grown nowadays of less interest and usefulness than the Camellia, and where big houses are available for planting them out, many might do worse than plant a few well chosen varieties. *W. A. C.*

"Our Poultry."—The ninth fortnightly part of this useful publication is now ready, and is quite up to the standard of the former numbers. There are plates of a buff Shanghai cock, a prize Malay cockerel, of a black-breasted modern game-cock, and many smaller illustrations. The present part deals with game fowl.

The Week's Work.

PLANTS UNDER GLASS.

By J. Mayne, Gardener to the Hon. Mark Rolle, Bicton, Budleigh Salterton, Devonshire.

Chrysanthemums.—Cuttings which were put in towards the end of January, and are now well rooted, must be repotted at once, or they will suffer a check. Let the compost be one of loam, leaf-soil, with a dash of sand. The pots should be 3 or 4 inches in diameter. Stand the plants in a cold frame, and keep it closed for a couple of days, shading the plants lightly from very bright sunshine. Afford water sparingly until the roots are again active. Earlier-rooted plants may now be repotted into 5 and 6-inch pots, as they become fit; keep them near to the glass, and protect them with mats at night in case of frost. Plants intended for specimens, or if grown as bush or decorative plants, should have the points removed when about 4 inches high, and this may be repeated when a similar length of growth has again been made. Those intended to produce large blooms should be guarded from a check of any kind until the first "break," provided the glass accommodation will permit of this, otherwise pinch the plant as before mentioned, and subsequently remove all but the three best-placed shoots, which will be sufficient to make a plant.

Gesneras.—By potting up a batch of plants every few weeks during the next three months, a succession of flowers may be kept up for a very long time, using as a compost about equal parts loam, peat, and leaf-soil, with sand to keep it porous. Place three to five bulbs in each 6-inch pot, and cover them an inch deep with soil. Stand them on an ash bottom in a temperature of 60° to 65°, affording little water until they are growing actively; then shade them during the brightest part of the day, but do not use the syringe too freely. A little weak guano-water may be afforded them when the roots have filled the pots. Gesneras and Tydæas may be raised from seed sown now, and treated similarly to Gloxinias.

Achimenes.—Part of the stock may now be started. Shake the tubers out of the old soil, and put them into pans or shallow boxes which have been carefully drained and nearly filled with light sandy soil, covering the tubers half an inch deep. Afford a temperature of 60°, and syringe overhead daily in preference to pouring much water through the soil until growth is proceeding freely. Afterwards transfer the plants to other pans, pots, or baskets, as desired. Achimenes require shading similarly to Gloxinias, and should be syringed frequently. Scarce varieties may be easily increased by cuttings when the growth is 2 inches long, or by leaves.

General Work.—Do not allow Freesias to form seeds. Stand the pots on a shelf in a light position in the greenhouse to finish their growth. Solanums and Libonias that have bloomed and will be retained another year, should be pruned close back and placed near to the glass. When growth has again started, rub some of the old soil away from them, and shift them into pots of similar size.

THE FLOWER GARDEN.

By J. C. Tallack, Gardener to E. Miller Mundy, Esq., Shipley Hall, Derby.

Bedding Plants.—Should the present mild weather continue, remove all forward stock of the more hardy kinds of bedding plants from the houses to cool frames in a sunny and sheltered position. At the time this is done, the soil should be in a rather dry condition, remaining so for a few days, until the plants get acclimatised. This is especially necessary in the case of zonal Pelargoniums. Do not let cold draughts chill the plants. Provide mats to cover the frames at night for the first week or two, even if the nights are not frosty. The gradual hardening of bedding-plants is a matter needing great care.

Abutilons, Fuchsias, and other shrubby plants that are intended for use as "dot" plants in the beds should be potted on as the need arises, preventing them from deterioration through being pot-bound.

Cannas should be shaken out, cut up into pieces with one or more strong crowns to each, and either potted up into some light and rich soil, or put into boxes containing similar material at sufficient distances apart to allow of their remaining in such boxes until planting time comes. They should be started into growth in gentle heat, and induced to grow away very gradually. If too much heat is afforded, the plants make top-growth out of proportion to root-growth. For the first week or two after potting in fairly moist soil, no water should be afforded beyond that supplied by syringing.

Seeds of most kinds of half-hardy annuals that have to be raised under glass should now be sown in pans or boxes, and put in a warm house or frame to germinate. An exception should be made in the case of Zinnias, and a few others which cannot brook anything in the way of a check after being sown; the sowing of these is better postponed to about the second week in April. Among others that need sowing now, special mention may be made of Aster sinensis, Celosia pyramidalis, and Ten-week Stocks. Many who have given up the culture of the ordinary double forms of Aster from any cause, will do well to grow the single one mentioned in one or both its forms, mauve and rose, as both are useful; and the former especially so, either for effect in the borders, or for cutting, and up to the present I have not seen the plants attacked by disease. Celosia pyramidalis, when grown under cool conditions, is excellent for planting out late when in feather, for filling up blanks, or taking the place of plants which are over before summer is ended. Ten-week Stocks are everybody's flowers, but I may draw attention to the new improved perpetual-flowering kinds, of which Princess Alice was the pioneer, and some of which are to be found mentioned in all the leading catalogues; also to the "giant" strain, the spikes and flowers of which are very fine. When the seedlings have grown a few inches, discard all the darkest green plants with fat leaves, and especially those with leaves much rounded at the tips, as these are mostly singles.

FRUITS UNDER GLASS.

By T. H. C.

Peaches and Nectarines.—The earliest fruits are now "stoning," and should not be excited by high temperatures; but afterwards the temperature at night may be increased to 60° or 65° according to the weather, and by day 10° to 15° higher. Let the increased temperatures be accompanied by a moist atmosphere and judicious ventilation. Close the house early in the day, and at the same time syringe the trees and damp the paths and other surfaces, especially those surrounding the hot-water-pipes. The final thinning of the fruit may be done as soon as the "stoning" process is past, leaving, in the case of vigorous trees, one to every 10-inch square of surface, and on old trees one to a square foot. Nothing is gained, but much is lost, by over-cropping. When affording water to the roots, take the opportunity to apply some form of stimulant. Old trees that are carrying full crops of fruits may be benefited by a mulch of farmyard or old Mushroom-bed manure, and if applied now, leave a little ventilation by night and day, that the ammonia, &c., may escape. Tie in the young shoots, cutting out any that have not sufficient space for free development.

Succession-houses.—Where there is a heavy set of fruit, partially thin them out, removing first all from the under sides of the branches. Disbud later trees as soon as the flowers have set, doing the work by degrees, and commencing with the upper portion of the tree. Vaporise with XL-All directly aphides are observed, and syringe the foliage morning and afternoon. Afford trees in flower a night temperature of 50° to 55°, and with ventilation 10° to 15° more during the day. Maintain a fairly dry atmosphere, and pollinate the flowers daily with a camel's-hair or other soft brush.

Melons grown in pots for early supply need to have the female flowers pollinated. After securing a set of three even-sized fruits to a plant, the remainder may be cut away, along with the lateral growths not required. Syringe the plants overhead each morning and afternoon

if the weather is fine. When the fruits are swelling, stimulants may be given at each watering; drainings from the cowsheds if diluted are excellent. A night temperature of 70°, and one of 10° to 15° more by day, will be suitable. Ventilate upon every favourable opportunity, and frequently damp the paths and other surfaces in the house.

Succession-houses. — Plant out into raised mounds of soil, as previously advised, plants for succession crops. If there is plenty of roof-space, the plants may be set out 5 feet to 6 feet apart, and grown on the extension principle, by which several fruits in various stages may be taken from the same plant. If the structures have low roofs plant more thickly, and secure an even set of three to four fruits to a plant, which will ripen about the same time. Sow seeds for plants to produce fruits in July.

Forcing Pines.—Early fruiting Queens that are passing out of flower may be afforded a bottom-heat of 85°, and a night temperature of 65° to 70°, according to weather. Ventilate early on fine mornings, but the temperature may rise to 85° at closing time. Lightly syringe the plants on fine afternoons, and maintain the atmosphere moist. Do not overwater plants potted into their fruiting pots last month. Keep plants in pits well up to the glass, and afford air whenever practicable. The top and bottom-heat may be 5° less than for fruiting plants. Whenever suckers of a suitable size are obtainable, insert them in 5-inch pots, and plunge them close up to the glass in a brisk bottom-heat, keeping the pit close and damp until roots have formed.

THE ORCHID HOUSES.

By H. Alexander, Orchid Cultivator to Capt. G. L. Holford, Westonbirt, Tetbury.

Thunias.—These plants having been dormant through the winter are now starting into growth, and when the young growths are about 2 inches long, the plants will make new roots freely, and need attention at once. They should be repotted annually, shaking all the old soil from the bulbs, and cutting away the roots which, being dead, are of no further use, excepting a short length to help hold the bulbs firm when repotted. The bulbs may be potted singly, or made up into specimens. A very good practice is to place five bulbs in a 24-size pot, which should be made about one-quarter-full with drainage material. The rooting medium may consist of equal parts turfy peat, fibrous loam, and leaf-soil, with plenty of coarse sand and crushed crocks added. Make this moderately firm, securing the plants to neat stakes, and finish off ½ inch below the rim of the pot. Abundance of water is needed when the plants are in full growth; but following the operation of repotting, water must be afforded only after careful examination. The plants may be grown in the Dendrobium-house, or in any plant-stove where they can be exposed to full sunshine, and be syringed frequently.

Damping and Watering.—Damp the surfaces in the houses each morning as soon as the minimum daily temperatures are reached, and again in the afternoon, if the weather be fine. Most species will now need an increased supply of water at the roots, and should therefore be examined more frequently. No plant requires a full supply of water directly new growth commences, but it should be increased gradually from that time. If the plants are growing in leaf-mould it is even more important that they should not be overwatered.

Temperatures. — The temperatures may now rise a little above the figures given in this Calendar in January, but do not employ artificial heat in excess; check the fires in the morning as much as the weather will allow.

Ventilation should be given extra attention during the present month, as the winds are very treacherous, and all the plants will suffer if they are subjected to cold draughts. Admit what air is necessary by bottom ventilation only, except on mild fine days, when those at the top of the house may be used advantageously in the cooler departments.

THE HARDY FRUIT GARDEN.

By Chas. Page, Gardener to J. B. Fortescue, Esq., Dropmore, Maidenhead.

Re-grafting Apple and Pear-trees (figs. 77, 78, 79). —Trees that were headed back in February with a view to grafting them, may now be operated upon. In the case of orchard standards of large size, the method known as "rind" or "crown" grafting is the best to employ. Remove about 6 inches of wood from the stems that have been retained, using a tenon-saw for the work; make the cut smooth with a pruning-chisel. Then with a sharp

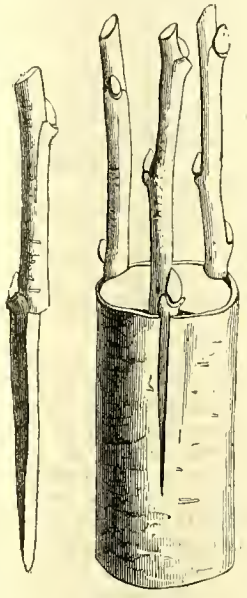

Fig. 77.—"Rind" or "Crown" Grafting.

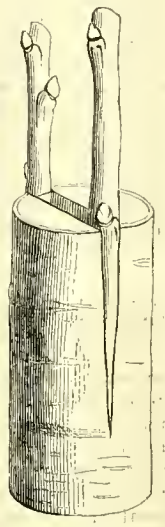

Fig. 78.—"Cleft" Grafting.

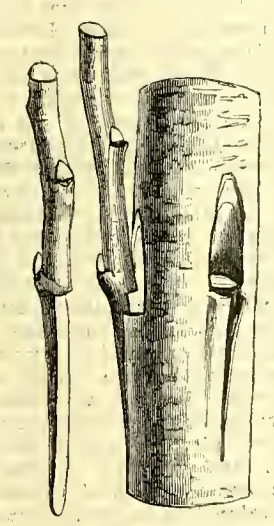

Fig. 79.—"Side"-Grafting.

knife make a downward cut in the bark about 4 inches deep, cutting through to the wood. A piece of hard wood a quarter of an inch in width, and thinned down at the point by a sloping cut resembling the scion to be used, may then be inserted in order to raise the bark. Prepare the scion by removing from the lower part the bark and a small portion of the wood upon one side by a sloping cut of corresponding length to the cut made on the stock. Then push it gently downwards into position, taking care that the bark joins that of the stock on each side. Two scions [or even more] may be put on, one on each side of the branch in the case of large trees. Bind the scions in tightly with matting, and cover the parts with clay prepared as advised in last week's Calendar, leaving the upper part of the scions projecting about 6 inches. Cover the clay afterwards with moss, which will prevent it cracking in dry weather. For small stocks, cleft and side grafting (see figs. 78, 79), are generally the methods used. These have often been explained in the *Gardeners' Chronicle*, and need no further description than that afforded by the figures.

General Work.—Raspberries planted last autumn should be cut back to two or three sound buds at the base. Employ the Dutch-hoe between the lines during dry weather, and cover the ground with a mulch of strawy manure. Employ the Dutch-hoe on fine days between the lines of Gooseberries and Currants, but in heavy soils the prong-hoe is an excellent tool for the purpose.

THE KITCHEN GARDEN.

By John Flemino, Gardener to Sir C. Pigott, Bart., Wexham Park, Slough.

Cabbages that were pricked out in late autumn should be planted out in deeply dug and abundantly manured ground. Set out the smaller-growing sorts at 1 foot apart and 15 inches between the rows; and the larger-growing sorts 18 inches apart and 2 feet between the rows. Stir the surface of the soil between rows of spring Cabbages, and fill any vacancies; also draw up the earth towards the stems of the plants. Prick out seedlings in cold frames as soon as ready, and keep them close to the glass. Sow seeds of early varieties in drills drawn at 1 foot apart on a warm border, and net them securely against birds.

Brussels Sprouts.—Make a sowing of these on a warm border, and as soon as the seedlings are fit, prick them out at distances of 4 inches apart; prick off into frames early sowings made last month under glass.

Cauliflowers.—Make small sowings of early varieties and Autumn Giant, also Self-protecting Broccoli. Prick out early sowings into frames as soon as ready, and afford autumn-sown plants abundance of air, only covering them when frost threatens.

Carrots.—Seeds should be sown occasionally to ensure a continual supply of young roots, which are always preferred. The drills may be drawn 10 inches apart. Sow the seeds thinly, mixing them first with fine soil. Sutton's Champion Scarlet Horn, Scarlet Intermediate, and Veitch's Model, are excellent varieties for early sowing. The main crop and long-rooting sorts are best sown early in April.

Leeks may be sown in the open ground, and then transplanted from the seed-bed at a very early stage for a succession to those raised under glass. Young plants raised in boxes in warmth should be transferred to a cold frame, and gradually hardened off preparatory to planting-out early in April.

Hints on Arrears of Work.—Sowings of Onions, Parsnips, and Celery should be completed. Pull up all winter greens, leaving sufficient only for kitchen use, for if left to flower they will impoverish the soil. Have vacant ground dug or trenched.

Tomatos.—Sow seeds in well-drained pans containing a light sandy soil for plants to be grown in the open air. The varieties Open Air and Outdoor are good ones for the purpose.

Potatos.—The early, second early, and late varieties may be planted in quantity, should the land be sufficiently dry for working. Early short-haulmed sorts may be planted 15 to 18 ins. between the rows, and 9 to 10 inches between the sets. Late varieties require double this space. Drills may be drawn 6 inches deep, or if the soil be light and dry, the sets may be dibbled-in, taking care to make the holes of an even depth. The tubers may also be planted as the ground is dug, and manured, which is a good method on heavy land. Ashleaf, Sharpe's Victor, and Duke of York, are reliable early varieties; Windsor Castle, Snowdrop, and Beauty of Hebron, are good second early sorts; for late varieties rely principally on Magnum Bonum, Triumph, and Up-to-Date.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the Publisher.

Letters for Publication, *as well as specimens and plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Illustrations.—*The Editor will thankfully receive and select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.*

Local News.—*Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return the unused communications or illustrations, unless by special arrangement.*

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY, MAR. 23—Surveyors' Institution Meeting.

TUESDAY, MAR. 24—Royal Horticultural Society's Committees Meeting (Hyacinth and Tulip Show), lecture on "Photomicography."

WEDNESDAY, MAR. 25—Lady Day. Royal Botanic Society's Meeting. Liverpool Horticultural Association, Bulb and Plant Exhibition.

THURSDAY, MAR. 26—Royal Agricultural and Horticultural Society of Jersey, Show of Bulbs. Irish Gardeners' Association Meeting.

SALES FOR THE WEEK.

MONDAY, MARCH 23—
Hardy Border Plants, Roses, Fruit Trees, Perennials, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.—Nursery Stock, Merstham, by Wilson & Cleather, noon.

TUESDAY, MARCH 24—
Orchids, by John Cowan, at Trades Hall, Glassford Street, Glasgow, at 12.30.

WEDNESDAY, MARCH 25—
Roses, Azaleas, Palms, Bay Trees, Cannas, &c., at Stevens' Rooms, at 12.30.—3000 Roses of sorts, Azaleas, Palms and Plants, Perennials, Carnations, &c., at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.

FRIDAY, MARCH 27—
Imported and Established Orchids from various sources, at 67 and 68, Cheapside, E.C., by Protheroe & Morris, at 12.30.—The Leasehold Nursery Property, No. 182, Green Lanes, Finsbury Park, with 2¼ acres of Land, and 21 Glasshouses, at the Mart, Tokenhouse Yard, E.C., by Protheroe & Morris, at 2.

(For further particulars see our Advertisement columns.)

AVERAGE TEMPERATURE for the ensuing week, deduced from observations of Forty-three Years at Chiswick —44·1°.

ACTUAL TEMPERATURES:—
LONDON.—*March* 18 (6 P.M.): Max. 53°; Min. 43°. *March* 19 (Noon): 55°; Showery, windy.
PROVINCES.—*March* 18 (6 P.M.): Max. 50°, Scilly; Min. 41°, Shetland.

Electric Light in Forcing.

EVER since we saw the very marvellous results obtained by the late Sir WILLIAM SIEMENS, we have urged the desirability of making further experiment as to the use of the electric light in forcing plants, and are, in consequence, the more interested in reading in the *Revue Horticole* of the 1st inst. of some results obtained by M. HARANCOURT.

This gardener made use in his forcing-house of an electric lamp of eighteen candle-power, to be used at night during the forcing of White Lilac. By so doing, he obtained flowers for cutting in fifteen instead of in twenty-five days by the ordinary methods. It is of little use advocating new methods to so-called practical men, unless they can be made to see that there is "money in them." We think the bare fact above recorded must show the most unimaginative that their requirements have been met, or are at least in a fair way of becoming so. The Lilacs are dug up in autumn after the fall of the leaf, and planted in a corner of the stove, and a good watering given, which is not repeated. The electric lamp is placed above the plants, at what height is not stated; but other experiments have shown that it is desirable that it should not be too close to the plants. The temperature is kept at fifteen degrees Centigrade for the first day, seventeen degrees the second day, and twenty degrees for the rest of the period. We need not give full details; suffice it to say in general terms, that under a maximum temperature of twenty degrees Centigrade, and of uninterrupted light—the application of the electric light at or a little before sunset—the Lilacs can be forced into bloom in fifteen days. Coleus, Pelargoniums, Ageratums, and other plants have been treated in like manner with excellent results.

This, again, is another of those experiments that might be carried out at Chiswick without special assistance when once started, at trifling cost and trouble, but to the great advantage of the horticultural community.

The Royal Horticultural Society.

WE notice in the letter of our old correspondent, Mr. WILLIAM MILLER, published at p. 171 in our last issue, as well as in the report of the annual meeting of the Royal Botanic Society (see p. 190), a statement which, if not corrected, may prove mischievous. It is perfectly true that there is, or was some days since, an announcement that the Hall to be erected by the Royal Horticultural Society might be let for concerts and other purposes, when not in use for the fortnightly horticultural meetings. This notice furnishes the opportunity for a scoff at the Royal Horticultural Society. We submit, however, that it is one thing to let a Hall occasionally for legitimate purposes, and quite another thing to include in the programme of the Society itself the inane frivolities which characterise a Society established for widely different purposes. The great local show at Shrewsbury, the York gala, and other annual events also, are on an entirely different footing from the proceedings of supposed learned societies; and if they find it requisite to avail themselves of "attractions," other than those which horticulture furnishes, no reproach attaches to them, for they make no pretentions to do otherwise. When we consider the work for the advancement of horticulture that has been done continuously by the Royal Horticultural Society, even during its darkest days, it does seem anomalous that a portion of a public park should be refused to it, though granted to another Society whose claims are so very much less important, and some of whose proceedings have been of a nature that provokes adverse criticism.

The Shrewsbury Show.

THE Schedule of Prizes to be offered by the Shropshire Horticultural Society at the annual show to be held in Shrewsbury on August 19 and 20, has been issued. It provides for classes in every section of horticulture, as comprehensively as usual, the cash prizes offered amounting to £1,100, with a Silver Challenge Vase for Grapes, value fifty guineas, Silver Cups, and Gold and Silver Medals.

The section for plants opens with Classes 1 and 2, previously in one class. The first is for fifteen stove and greenhouse plants in bloom or foliage, not fewer than ten in bloom; and the second class for six stove and greenhouse plants in bloom or foliage, not fewer than four in bloom. The prizes for the first class are £20, £14, and £8; and in the second class £8, £6, and £4.

Class 17 is a new one for a group of tuberous-rooted Begonias in pots arranged for effect, with Ferns or other foliage plants on a table space of 15 feet by 4 feet. This competition will be likely to bring together some excellent displays of one of the most popular of greenhouse flowering plants. The prizes offered are £10, £6, and £4.

In the cut flower section, the classes from 27 to 44, for florists' exhibits, have been rearranged with a view to obtaining exhibits of greater interest and novelty, and the rest of the classes for the displays of cut flowers of every description, that are one of the features of the Shrewsbury Exhibition, remain very much the same.

Turning to the classes for fruit, we find that the class for a dessert-table decorated with plants, cut flowers, and foliage, and furnished with not more than fifteen dishes of fruit, is retained; and the instruction to the judges to regard quality before size in all fruit classes will operate in this one. The prizes will amount to £40.

In the Champion Grape class, the 1st prize will consist of the Champion Fifty-guineas Cup, at present held by the Marquis of HASTINGS' gardener, Mr. SHINGLER, and £20 in cash; whilst £44 will be divided between the rest of the prizes. We are glad to notice that in this class the pointing has been altered a little, in order to give greater value to the admitted superiority of the Muscat-flavoured Grapes over other varieties. Thus, a maximum of eleven points may be given to all Muscat varieties, white or black; ten points to Black Hamburghs, and nine points to all other varieties. Superior cultivation will be the determining factor in this interesting and important competition, and the decorations that lend additional charm to the fruit will very properly be judged quite separately. Other important fruit classes are those for sixteen dishes of fruit in sixteen varieties, twelve dishes of fruit in twelve varieties, and nine dishes of fruit in nine varieties.

There are numerous classes for vegetables, and we seldom see better vegetables than are shown at Shrewsbury; but most of the prizes, other than those for cottagers, are provided by seed firms, and are accompanied by restrictions that should not be permitted at such an exhibition. The Shropshire Society is so strong that we hope it will yet see its way to refuse any money offered for prizes, unless it is done unconditionally. The Society itself offers about £30 in prizes for vegetables in the open classes.

The exhibition will doubtless be as successful as former ones have been, the Shrewsbury event having come to be regarded as an occasion where Northern and Southern gardeners can meet each other at a sort of halfway locality, convenient to both sections. The arrangements for the show, are as usual in the hands of the courteous honorary Secretaries, H. W. ADNITT and W. W. NAUNTON.

Royal Horticultural Society. — The next meeting of the Committees will be held on Tuesday, March 24, in the Drill Hall, Buckingham Gate, Westminster. Special prizes will be offered for Hyacinths and Tulips by the Royal Bulb Growing Society of Haarlem as follows: 120 Hyacinths in pots (one bulb in each pot) in not fewer than forty varieties, and not more than three pots of any one variety. Open. First prize, £7; second prize, £5; third prize, £3. 100 pots of Tulips (three bulbs of one variety in each pot), to include fifty varieties at least, and not more than two pots of any one variety. Open. First prize, £4; second prize, £3; third prize, £2. A lecture on "Photo-micrography as an aid to the Study of Plant-life" (illustrated by lantern-slides), will be given by F. Martin Duncan, Esq., F.R.H.S., at 3 o'clock.

—— At a general meeting of the Royal Horticultural Society held on Tuesday, March 10, eighty-two new Fellows were elected, making a total of 405 elected since the beginning of the present year.

—— Examination in Horticulture.—The Society's annual examination in the principles and practice of horticulture will be held on Wednesday, April 22, 1903. Full particulars may be obtained by sending a stamped and directed envelope to the Society's offices, 117, Victoria Street, London, S.W. Intending candidates are requested to send in their entries by March 31, if possible. The questions set at all the previous examinations are now published, price 1s. complete.

The National Horticultural Hall.—We are glad to record that among other recent contributions, Amy Lady Tate has given £500, and J. Wernher, Esq., £100, towards the building fund of the Royal Horticultural Society's new Hall.

Linnean Society.—The last meeting of the Society was held on Thursday, March 19, 1903, at 8 p.m., when the following papers were read:—Mr. G. Claridge Druce, "On Poa laxa and Poa stricta of our British Floras." Messrs. J. Parkin and H. H. W. Pearson, "The Botany of the Ceylon Patanas. Part II. Anatomical investigations of the Leaves of the Plants occurring in the Patanas." Exhibitions:—By Mr. Clement Reid: (1) Drawings of seeds from British preglacial and interglacial deposits—Thalamifloræ, including a species of Hypecoum; (2) Recent seeds of Hypecoum procumbens, Linn.

The Ghent Quinquennial: Respectful Suggestions to the Authorities.—1. That at the forthcoming exhibition the columns of the Winter Garden be draped with climbers, and that hanging-baskets be suspended here and there from the girders, so as to break the rigidity of the iron structure. 2. That an office be opened in the centre of the town, where jurors and others may get their tickets on arrival, obtain information and guidance, and especially where the addresses of the visitors staying in the city may be obtained. If each juror would write his name and address, much time would be saved in procuring interviews and meetings between friends—interviews now left to chance.

—— The President and Council of the Royal Horticultural Society have requested the following gentlemen to be so kind as to act as representatives of the Society at the forthcoming Ghent Quinquennial Show, viz., the Right Hon. the Lord Redesdale; Frederick G. Lloyd, Esq., High Sheriff of Buckinghamshire; Mr. James Hudson, V.M.H., all members of the Council of the Society. Mr. Chas. E. Pearson is attached to the deputation as their Secretary.

—— We are requested to remind those intending to exhibit at the forthcoming exhibition at Ghent, that it is necessary they should address their demands to M. Fierens, Secretary of the Royal Society of Agriculture and Botany of Ghent, not later than March 22, or it may be found impossible to include their exhibits in the classes.

Royal Caledonian Horticultural Society.—Mr. P. Murray Thomson, S.S.C., Secretary and Treasurer, 5, York Place, Edinburgh, writes as follows:—"I have been for some time reading over the old minutes of this Society, and have been endeavouring to trace some representatives of old exhibitors, and some of the old prizes which exhibitors selected in place of the Society's Medal. I find that such articles as volumes of the *Botanical Magazine*, silver cups, spectacles, watches, spoons, snuff-horns, &c., were taken; but although I have found a number of these, I have not yet traced one of the original medals. Perhaps in the early years of the century our exhibitors preferred more useful articles. I should also like to trace some representative of James Anderson, who was gardener at Stobo Castle, and who died, I understand, about thirty years ago; James McIntosh, who was gardener at Dalkeith; another Mr. McIntosh, who was gardener at Biel, in East Lothian; or of Archibald Reid, gardener at Balcarres. It occurs to me that among your readers there may be some who could give me particulars regarding the old prizes of the Society, or of the representatives of the above, and other exhibitors; and I shall be very glad if anyone able to give me information will communicate with me. I should be pleased also to receive any old prize lists issued by the Society prior to 1850."

Surveyors' Institution.—On the 9th inst., a paper was read by Sir John G. Barton, C.B. (Fellow), Commissioner of Valuation for Ireland, entitled "Valuation for Rating in Ireland."—The next ordinary general meeting will be held in the Lecture Hall of the Institution on Monday, March 23, 1903, when a paper will be read by Mr. J. L. Crouch (Professional Associate), entitled "The Rating of Brickfields."—The second of the two afternoon meetings arranged for the convenience of country members will be held on Monday, April 20, 1903, at 4 p.m.

Double Red Daffodils.—The following letter from Messrs. Barr & Sons, of King Street, Covent Garden, has appeared in the *Times*:—"We must apologize for trespassing on your valuable space, but we think it only right that the public should not be misled when they purchase from West-end flower-shops flowers which are sold to them as 'double red Daffodils,' with the additional information that they are of natural growth. These flowers are nothing more or less than the old double yellow Daffodil called Telamonius plenus, or Van Sion; the plant has been naturalised in this country for centuries. The red colouring in the flower is simply obtained by placing the stems in a coloured dye, which is immediately absorbed, and enters into the tissue of the petals. The flower is sold now under various names, such as 'Enfield Pride,' and 'Farnboro' Beauty.'"

Hamamelis mollis.—We learn that this winter-flowering shrub was originally introduced to the Veitchian nurseries by the late Charles Maries in 1879, whilst it was not till about 1887 that the plant was collected by Dr. Henry. We took our information (given on p. 169) from the *Botanical Magazine*.

The Olive in South Australia.—From a report just published, we learn that the cultivation is much in favour, the climatic conditions, nature of the soil, and the introduction of the best varieties, all tending to the success of a highly remunerative industry—of the production of fruit and oil of the best quality. The number of trees returned for 1902 is 66,852, against 61,740 in the preceding year.

Correspondence of Robert More and Linnæus.—We are informed that a quantity of letters from Robert More, of Linley, Shropshire, to Linnæus, have been discovered in the King's Library at Stockholm. It is possible that these letters may throw some light on the incidents of Linnæus' visit to England. That Dillenius knew Linley well is shown in his work referred to in these columns in our account of Linley, the seat of Jasper More, Esq., M.P., on Dec. 11, 1880, p. 747.

"Alpine Flowers for Gardens."—We are informed that a new edition of this book, long out of print, will shortly be published by Mr. John Murray. It is revised, considerable additions have been made, and many alpine and mountain shrubs added, the author thinking that these give the best and most enduring of rock gardens for many situations.

Disease in Sweet Chestnuts.—In many departments of France, the Chestnuts are attacked by a disease of which the superficial appearance is such that the cultivators have given to the malady the name of Phylloxera. It appears, however, to have nothing to do with that insect. It occurs on old and on young trees alike, on all descriptions of soil and under the most varied circumstances. According to M. Mangin, in the *Comptes Rendus* for February 16, it is due to the presence of a parasitic fungus which he names Mycelophagus castaneæ. It is one of the Oomycetous fungi, and preys not on the Chestnut root, but on the filamentous fungus threads called mycorhizæ, which envelope the roots, not as parasites, but as co-operators. This necessary co-operation is put an end to by the intruder, and the question now is how to dislodge it or to render it harmless? Bisulphide of carbon is mentioned as a possible remedy, but one which is only practicable in certain soils. Further suggestions for restoring the devastated Chestnut plantations are promised in the future.

Pinguicula caudata superba.—This plant was exhibited at the Royal Horticultural Society's meeting on March 10, by J. T. Bennett-Poë, Esq. (gr., Mr. Downs). The flowers are of very rich colour, being reddish-carmine, with white eye, and in size are about 2 in. by 1¾ in. It is a superb variety of this well-known stove-plant, and deserved the Award of Merit accorded it by the Floral Committee.

Garden Pests.—Sir Jas. Rankin has introduced a Bill into the House of Commons to provide for the eradication of disease and of injurious insects amongst fruit trees in nursery gardens. The Bill has been read a first time.

Royal Geographical Society.—The Back grant was bestowed at a recent meeting, on our correspondent, Dr. William G. Smith, of the Yorkshire College, Leeds, for his investigations into the Geographical Distribution of Vegetation in Yorkshire, with maps, &c.

The Gale in Ireland.—In the House of Commons recently, Mr. J. O'Connor asked the Chief Secretary to the Lord Lieutenant of Ireland if he was aware that during the recent storm 1,242 forest trees and 1,706 Thorn trees were blown down in the Phœnix Park, Dublin; whether the Board intended to dispose of this timber by sale, and if so, to what fund would the proceeds be credited; and whether the Board of Works would take steps to replant this area? Mr. Wyndham, in replying, said that irreparable damage had been done to the finest park in the world. The proceeds of the sale of timber had been appropriated in aid of the replanting. The work could not be undertaken before the autumn.

Chrysanthemums.—The next Congress of French "Chrysanthemists" will be held at Lille, from November 6 to 8 inclusive. Visitors and exhibitors, without distinction of nationality are invited. The schedule will be issued later on.

BELVOIR CASTLE.

[Supplementary Illustration].

(*Continued from p. 155.*)

The Duchess' Garden.—The Duchess' Garden occupies a natural dell on the side of a hill, and is about 8 acres in extent; the shape is like a horseshoe, with the opening to the south-east at the bottom. It has a fall of 100 feet from top to bottom, and by large timber trees is well sheltered, and therefore warm.

It takes its name from Elizabeth, Duchess of Rutland, wife of John Henry, the fifth Duke; a stone pillar and vase (near the steps shewn in the picture) is inscribed with a reference to her, and a splendid portrait by Hoppner in the Castle represents the Duchess leaning against this vase. Some of the flower-beds shown have still the form cut by her directions. To this clever and artistic lady most of the extensive works at Belvoir may be attributed, including the designing of the Castle, the commencement of the Duchess' Garden, and the design of the kitchen-garden.

Near to the steps, but not shown in the picture, is a fine specimen of Araucaria imbricata, planted in 1842; it is now 59 feet high, and its stem 6 feet in circumference. In a corresponding position there is a plant of the rare Cunninghamia sinensis, also planted in 1842; this is 33 feet high, and 3 feet in circumference. A large standard tree of the Portugal Laurel near here has a stem 6 feet 6 inches in circumference; the tree of Cupressus Lawsoniana, shown on the right, is 41 feet high. In front of this the pillar covered with Ivy supports a granite tablet, which commemorates two visits of Fanny Kemble, as follows:—

March 26, 1842.

Farewell, fair Castle, on thy lordly hill,
Firm be thy seat, and proud thy station still:
Soft rise the breezes from the vale below!
Bright be the clouds that wander o'er thy brow
O'er the fair lands that form thy broad domain,
Short be the winter, long the summer's reign.
Pilgrim of pleasure to thy stately towers
Fain would I leave among the friendly bowers
Some votive offering—and, ere on my way,
With many a backward glance I turn to stray.
Bid virtue, strength, and honour crown thy walls,
Joy, love, and peace abide within thy halls;
While grateful mirth and noble courtesy,
As now, for ever held their seat in thee;
And still upon thy lordly turrets rest
The grateful blessing of each parting guest.

* * * * * * *

Two things remain unaltered in this place,
Tho' forty years since I came here are told;
The lovely aspect of fair Nature's face,
And the fine spirit of kind courteous grace
Which still presides here, as it did of old.

March 29, 1883. Fanny Kemble.

Beyond the flower-beds near the Birch-tree, the round-headed shrub shown is Daphniphyllum glaucescens; and close by its side is a large plant of Olearia dentata, an interesting shrub when in flower, but somewhat tender. *W. H. D.*

(*To be continued.*)

ARUNDINARIA SIMONI.

Our illustration (fig. 80), showing the flower and fruit of this species, is taken from a sketch obligingly forwarded to us by Mr. F. W. Burbidge, M.A., of the Trinity College Botanic Gardens, Dublin. In the open air it frequently produces fruit, and contrary to the custom of most Bamboos, it does not die down afterwards, but grows again the following year. The sketch was taken from a plant growing in a cool-greenhouse, with its roots restricted. A. Simóni was introduced in 1862, and an interesting account of it is given in *Lord Redesdale's Bamboo Garden*, 1896, p. 59.

Phyllostachys nigro-punctata has produced fruit at Abbotsbury, Dorset, and seedlings have been raised by Mr. Benbow, to which we shall allude on another occasion. The same species has flowered in Ireland: at Dingle, Tralee, co. Kerry, and at Straffan, co. Kildare.

VEGETABLES.

THREE GOOD EARLY PEAS.

To those gardeners who are desirous of hearing of good early varieties of Peas, I commend to their notice Harbinger, Ideal, and Duchess of York. These Peas were on trial at Chiswick in the season of 1901, and each received an Award of Merit when examined by the Fruit and Vegetable Committee. As seen growing at Chiswick they were everything that could be desired in a Pea in habit and cropping, and a subsequent trial of them made last season by myself served to strengthen the favourable opinion I then

Fig. 80.—Flowers and fruits of Arundinaria Simoni.

formed of them. To those unacquainted with these three excellent varieties, Harbinger may be described as being somewhat similar to American Wonder in appearance, but is superior in bearing, in quality, and earliness. The haulm grows 9 inches in height. It is a fine Pea for sowing at the foot of south walls, or on warm, narrow borders for the earliest crop, and as such it will commend itself to those who have but limited space at command. Ideal is a fine-looking Marrowfat, distinct in appearance, the haulm being very vigorous and of a dark green colour. In height it grows to between 2 and 3 feet, and the pods, which are long, broad, and well filled with from nine to eleven peas, are dark green in colour, and the flavour is delicious. Another strong point in its favour is its earliness, as it is ready for gathering several days in advance of William 1st. Duchess of York is a taller grower than the preceding, and has lighter coloured haulm and pods, which are, however, very broad, long, and well filled, and the peas of a fine flavour. It is a very heavy cropper, and ready as soon as Ideal. All three gave such excellent results last season, that I am relying on them almost exclusively as first crop Peas this season. *A. W., Kent.*

Peas.

I am surprised that anyone should find that grand Pea, Gradus, not to succeed with them. It has been most successful with me for four or five years, part of the time in Cumberland and part in Surrey. I usually sow Chelsea Gem for earliest supply, and Gradus to follow for main early crop. I have also sown it to crop with mid-season varieties, but find it most satisfactory when sown in March. Several years ago I made a selection of varieties of Peas, and have kept religiously to the same, as I found them to be most productive and good in flavour. In addition, I give one or two new varieties a trial annually. I sow Chelsea Gem to commence with, followed by Gradus, then a good sowing of Prodigy; and for the main mid-season crop have always used Ne Plus Ultra (a tall grower, perhaps some will object), but not surpassed in cropping qualities or in flavour. For late crops I always sow Autocrat; and any gardener who has to maintain a long succession of supplies, by carefully sowing the above varieties, will not run short of Peas at a time when the house is full of company, as he might do if he cultivate varieties that do not turn in when expected. *A. C. Smith, Woodlands Park Gardens, Leatherhead.*

Cabbages in February.

I cut some well-hearted Cabbages on Feb. 28, and could cut at least thirty more now. The seed was sown on Aug. 1, and the plants were put out in the middle of October. They began to grow straight away, and I feared they would all "bolt," but to my surprise on returning to the garden after a fortnight's absence, I found a large number had already turned in. I have never heard of anyone cutting Cabbage in February, but probably many more were able to do so. In 1901, I sowed Cabbage-seed on July 29, and cut the first heads about the first week in May, but a great number "bolted." I then grew Ellam's Early, Nonpareil, and Enfield Market, but this year I have Earliest-of-All and London Market. There are no signs of "bolting" at present, and some really good hearts are available. There being an abundance of other vegetables this year, Cabbages are not so much wanted, but they are a novelty. *B. E. G. Bowyer, Morton Hall Gardens, Swinderby, Lincoln.*

Broccoli Chelsea Favourite.

This is a very valuable variety for cutting during March and April, according to the date it is sown. The leaves are close-folding, and the growth closely resembles that fine late variety Model, but the heads are larger. I have also had this variety very good in May, but this season it is turning in earlier than usual.

A good type of Broccoli should be of sturdy growth, with the head well protected to withstand the winter, whether the plants be exposed to severe frosts or excessive rain. *T. H. Slade.*

FIR GRANGE, WEYBRIDGE HEATH.

Although previous attempts at gardening had been made on the beautiful Fir-tree-clad property on which Fir Grange is situated, it was not until it came into the possession of its present owner, W. A. Bilney, Esq., that the favourable site was so cleverly developed. Indeed, the garden which Mr. Bilney acquired was more in the way than otherwise when he settled down, with the assistance of his diligent gardener, Mr. Whitlock, and an ample garden staff, to carry out his ideas of gardening. The plan was to disturb the fine Fir-trees, and other natural beauties, as little as possible, and to arrange a series of garden nooks, dells, rockeries, and shrubberies, which have been so naturally arranged as to have the aspect rather of an orderly wild garden, than of one of recent

formation. In some places Rhododendrons are planted as an undergrowth beneath the trees, and on the sides of the informal walks are patches of pretty hardy and alpine flowers. In one nook are various Primulas, Primula obconica having well withstood this mild winter was lately in bloom.

In a moist dell is a hardy fernery, with spring bulbous plants flowering, and Foxgloves and other showy flowering plants that will bloom later. Beyond is a patch of Japanese Maples, with a bush of Hamamelis flowering, and plants of the blue Omphalodes verna, and its white variety; Leucojums, Hellebores, &c., in bloom. Tree-Pæonies in a group are already shewing their buds; and clumps of most of the showy Lilies will soon break through the ground. In one of the glades a large clump of Bamboos is thriving. These seem quite at home, although, as with many other moisture-loving plants, it is found necessary here to afford them water in dry weather, the soil being light and shallow.

This season has been a very favourable one for spring flowers, and thousands of the different varieties of Narcissus, from the small but pretty-flowered N. cyclamineus, to the more ornate garden-raised kinds, are in bloom; large patches of Crocuses planted in the grass are making a fine show; also Chionodoxa, Scilla, Chionoscilla, and other spring bulbs planted in the alpine rockeries and garden nooks.

Other arrangements have quantities of the showy Iris, Phloxes, and other summer flowers. Another good effect is being prepared by utilising the shortened trunks of the Fir-trees which have had to be cut down, or removed, during the formation of the garden for rustic pillars and arches for supporting climbing Roses, Honeysuckles, Clematis, &c.

Near the large dwelling-house are fine trees of Sequoia sempervirens, S. gigantea, Cedrus Deodara, and other Conifers; on one side of the house Choisya ternata is one of the best evergreen wall shrubs, and thickly set with the buds of its orange-blossom-like flowers.

The brightly-furnished conservatory at one side of the house, some plant-houses and pits provided for the general culture of plants, fruits, and vegetables, are all neatly kept; but a long row of modern houses connected with each other on one side of the large kitchen garden is principally devoted to—

Orchids,

which form special subjects of interest to both Mr. Bilney and his gardener. In them the Dendrobiums which made such a fine display at the Drill Hall on March 10 form the chief feature, and one which well proves the correctness of the choice of them, for the house they occupy is literally a mass of flowers. Most of the forms of D. nobile, including good specimens of D. n. album, D. n. Amesiæ, and other rare forms, are present; but in point of beauty and showiness, half a dozen large specimens of the richly-coloured D. n. nobilius more than hold their own. Others were D. × Socius, varieties of D. × Wiganæ, the new D. × Pirene, D. × Juno, D. × Luna, D. × Cassiope, D. × euosmum virginale, and a very fine lot of varieties of D. × Ainsworthi, D. × splendidissimum, &c., two of the best being D. × Ainsworthi, Hazelbourne var., and Mr. Bilney's latest new one, C. × A. Florence, a very large, nearly white flower with claret disc.

With the Dendrobes appear the bright spikes of Lælia cinnabarina, L. harpophylla, and other showy species; and in the other houses, where the Cattleyas especially are in good condition, there are Dendrobium Wardianum, D. crassinode, D. Brymerianum, Cymbidium eburneum, Sophronitis grandiflora, Masdevallias, Cypripediums, &c. In one house is a large specimen of Dendrobium nobile, covered with flowers, which is interesting for two reasons. This plant and a few others being given Mr. Bilney by a friend first caused him to commence the cultivation of Orchids; and the plant is known to have been ever fifty years in cultivation, having been once in the collection of the late Bishop Sumner.

The Odontoglossums are in a thriving condition; O. triumphans, O. Pescatorei, and a few others are in bloom, along with the scarlet Sophronitis. *J. O'B.*

WARTY POTATO DISEASE.

This new disease appears to have been first recognised in specimens from Cheshire in 1900, afterwards to have been sent from North Wales, and more recently from other localities (fig. 81). It attacks the tubers whilst in the ground, causing warty or nodular outgrowths, either partially or wholly investing the young tubers. Just beneath the surface of these pretuberances, the outer layers are filled with nearly globose dark brown sporangia, about 60 to 70 by 50 μ.

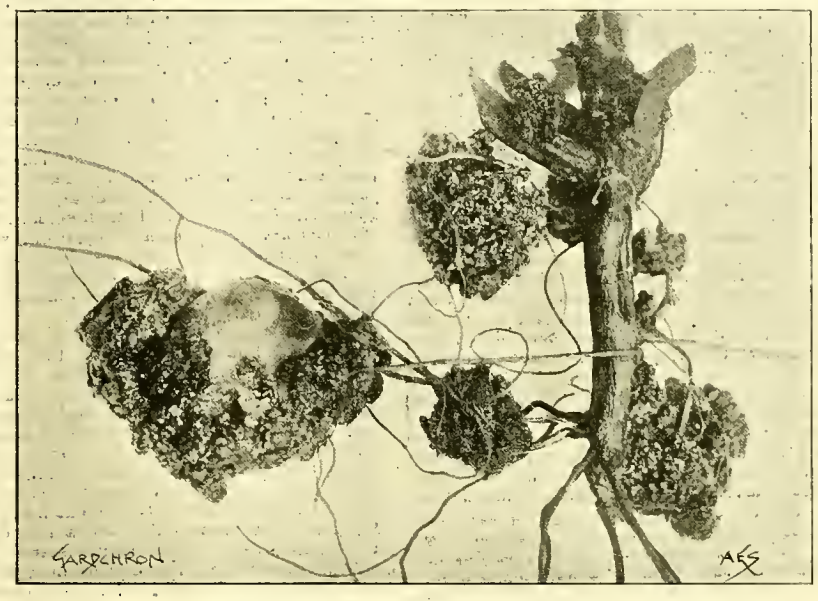

Fig. 81.—Warty disease of potatos.

It has been assumed that this fungus is the same as was described under the name of Chrysophlyctis endobiotica by Schilbersky (*Ber. d. Dent. Bot. Ges.*, xiv., 1896), but no figures or measurements were included in the original description.

A similar disease attacked Beetroot in the grounds of the School of Agriculture at Rouiba (Algiers), and this Trabut examined in 1894, and described under the name of Œdomyces leproides. This was afterwards examined by Dr. Magnus, of Berlin, and he applied to it the name of Urophlyctis leproides. At any rate, it is quite certain that Dr. Magnus was acquainted with the Beetroot tumour, and we are assured that upon his examination of specimens of this warty Potato disease, sent to him from this country, he has pronounced it to be identical with the Beetroot tumour, and therefore should be called Œdomyces leproides. No one could call in question the authority of so old and experienced a mycologist as Dr. Magnus; and when it is taken into account that he has personally been made acquainted with both forms of disease, on Beetroot and on Potato, it is rather presumptuous, without better evidence than a description without figures or measurements, to call in question his decision. At present, therefore, we are content to accept the view adopted by Dr. Magnus, that the Beetroot tumour and the warty Potato disease are produced by the same fungus, for which the accepted designation is Œdomyces leproides.

Of one thing we may be quite certain, that this threatens to become a troublesome disease, unless heroic measures are undertaken to stamp it out, and especially by taking care not to plant Potatos again on ground where warted Potatos have been found, until the soil has been thoroughly disinfected, and then to cultivate some other crop for two or three years. If the Colorado Rhizoctenia finds its way to us across the Atlantic, our Potato crops will be in grave danger from two such powerful enemies. *M. C. Cooke.*

Obituary.

James J. Fromow.—We much regret to have to record the death on the 13th inst. of Mr. Jas. J. Fromow, aged forty-eight, second son of the late Mr. William Fromew, who established the now well-known Sutton Court Nursery a Chiswick more than half a century ago. About the middle of last month deceased injured one of his knees so badly, owing to an unnoticed excavation in the road, that he was obliged to take to his bed. For a time progress seemed to be favourable, but on the 11th inst. blood poisoning set in. The deceased was the senior partner of the firm of Messrs. W. Fromow & Sons, and was of a retiring, kindly nature. He was greatly respected in West London, where he had been identified with religious work almost from childhood. Nearly the whole of his life had been spent in Chiswick, but he took special interest in the expansion of the firm's branch nursery at Bagshot, upwards of 200 acres in extent. It is in a very large measure due to his untiring energy, perseverance, and plodding industry, that the firm of Messrs. W. Fromow & Sons is held in such high esteem among nurserymen and seedsmen. His remains were interred in Ealing Cemetery on Wednesday the 18th inst., in the presence of his two brothers and other members of the family; also the staffs from the Chiswick and Hounslow establishments, many of whom have been in the firm's employ for more than twenty years. Deceased, who married about two years ago, leaves a widow and one child.

HOME CORRESPONDENCE.

WIDDRINGTONIA WHYTEI.—The notice and illustration on p. 162 of this beautiful Conifer makes one wish it were hardy. In 1900 several plants were planted out-of-doors at Pencarrow, and but one is alive; the first winter it suffered severely, but although the growth made last summer scarcely compensates for what it has lost since planting, the plant now looks much healthier, and appears likely to grow stronger this year. I planted a one-year-old plant last May, and although we had as much as 19° Fah. of frost, it has not suffered. These examples are surrounded with wire netting of 1½-inch mesh 3 feet high, as a safeguard against the ubiquitous rabbit. I place about 3 inches of leaves inside this wire cage, with a light covering of bracken to prevent them being blown away. Then I stick into the soil around the plants several good-sized branches of the common Rhododendron ponticum. This is a capital method of protecting tender plants and shrubs, as it permits a fair amount of light and air to reach them. In spite of this partial success, I am not sanguine regarding the future of the Mlanji Cedar as a tree out-of-doors, even in Cornwall. As a wall plant it would no doubt live, and to a certain extent thrive, but one would not care to grow a Conifer in such a position. In the greenhouse young plants are really beautiful, a group of plants 2 or 3 feet high in 5-inch pots is very striking. If cuttings are inserted firmly in sandy soil and placed in a cold pit, they will root readily. *A. C. Bartlett, Pencarrow Gardens, Cornwall.*

COMMISSIONS, SECRET OR CORRUPT.—It is a libel on gardeners to say they "all" ask for commission; it is, as every man with foresight can see, offered to obtain the trade of a particular place. I myself am a head gardener of eight months' standing, and have had offers and inducements, and some very bold ones. Even when my employer bought stuff and paid for it not through myself, the firm concerned sent me 1s. in the pound, which, sooner than cause friction, I handed over to the Gardeners' Orphan Fund, and sent the firm a receipt. Personally, I am out of pocket over this business, but I fail to see how any man with a conscience can accept the money for his own use. I have a letter from one firm who declare I am one of five or six out of 3,000 customers (do not mistake the figures, they are as written to me), and I have kept this letter as of special interest. I saw one "old bird" retire for dishonesty on this very line of business; he used to say, "Make all you can, no one cares for you; then care for yourself." Then to be put off after fifty years of gardening career, and the gardening Press do not know with what "honours" such persons retire. You can publish any part of this letter you may think fit, but you need not append my name, which may remain a *Clean Slate.*

ÆSCULUS INDICA.—The tree of Æsculus indica, referred to by Mr. Bean (see p. 139 in issue for February 28), which was planted at Mildenhall from seed brought from the Himalayas by the late Col. Bunbury, died many years ago. As the same fate has also befallen two more trees planted there since that time, it would seem that the soil—a good light loam on chalk—does not suit this tree. This, rather than the climate of the east of England, was probably the cause of this tree not succeeding there; for at Barton Hall, a distance of 13 miles, some specimens of this species are healthy and flourishing trees. *L. E. Walker, The Gardens, Barton Hall, Bury St. Edmunds.*

PEARS OF RECENT INTRODUCTION.—I agree with all that your correspondent, Mr. Wythes, says, p. 32, about Pears Marguerite Marillat and President Barrabé. They are the finest in their season of those which he mentions. President Barrabé is of very fine quality, and its season, mid-winter or later, according to locality, should commend it to all who are in search of winter ripening varieties. Michaelmas Nelis I have not yet fruited, but I hope to do so this season. *T. H. Slade.*

RICHARDIA.—In the notes about the Royal Horticultural Society's meeting on March 10, you confuse the Richardia æthiopica var. Childsiana with the ordinary Richardia africana. The two varieties are as distinct from one another as the sun and moon. Richardia Childsiana is pure white, while the R. africana has a green base. Richardia Childsiana turns the flower somewhat in the way of an Anthurium. The stamper (spathes?) of the Childsiana is of a soft creamy-white; the habit of the plant is dwarf and compact, while R. africana is very tall, with up-growing leaves; and last, not least, the Childsiana gives five flowers to one compared with R. africana. *De Graaff, Ltd.* [Our remarks were written after inspecting the cut specimens exhibited, and we have still the opinion that the spathes resembled very closely those of the species R. africana, of which Childsiana is only a variety. R. æthiopica is a synonym of R. africana. ED.]

CALANTHE VEITCHI.—That which has appeared recently in these pages will have been puzzling to some of the readers of the *Gardeners' Chronicle*, more especially as to what is the most suitable compost for growing of these plants. The Calanthe requires a high temperature, copious applications of water, and high feeding, whilst making its growth; and an important point is porosity of the soil. Calanthe roots are very sensitive to stagnant moisture, which will often cause the roots to decay in part before growth is finished, and thus spoil the next season's flowering. Turfy loam of middling texture four parts, good turfy peat and dried decayed cow-manure two parts each, with as much coarse sand and finely-broken crocks as will insure the free passage of water, is a good compost. If the loam is light, peat may be omitted, and the loam and cow-manure increased; on the contrary, if the loam is stiff, and contains but little fibre, let loam and peat be employed in equal proportions, with the other additions. The dry cow-dung should be in such a state as will allow of its being passed through a half-inch-meshed sieve. Make use only of 6-inch pots. The next point that is not clear is the sizes of the pseudo-bulbs, Mr. Fulford contending that those of middling size are the best, while Mr. Mayne tells us that you cannot get them too large. If Calanthes are grown in a very high temperature, and receive an excessive amount of nutriment, they will attain to a very large size; but such pseudo-bulbs, as a rule, are not so satisfactory as lesser ones, and the flower-raceme often comes coarse and congested, instead of extending gracefully, and the pseudo-bulbs are apt to decay in the resting season. Mr. Mayne seems to have misunderstood Mr. Fulford about hurrying them into flower, as in support of his contentions he mentions the temperatures in which the pseudo-bulbs are started; whereas I think that what Mr. Fulford meant by "not hurrying the bulbs into flower" was not to subject them to too high a temperature after the growth had become matured, and the foliage showed signs of decay. When this stage arrives, the temperature may be gradually reduced, and water lessened in quantity. Shading should be discontinued as early in the autumn as possible, and as the racemes make their way up, and the flowers commence to expand, the plants should have a free position in a well-lighted house, and a temperature of 60° to 65° at night, or the flowers will be wanting in size, texture, and colour; and when the racemes have little more than half their flowers expanded, no more water should be afforded the root. There is not much to be said in favour of top-dressing with an inch or so of cow-dung when the racemes are coming up, as all benefit could equally well be afforded by diluted manure-water; and where the plants have to be used for house and conservatory decoration, such aids to growth are most objectionable. *W. C. R.*

WEATHER PREDICTION.—Mr. Mawley, in his review of *Natural Law in Terrestrial Phenomena*, seems in his criticism to allow his prejudice to outrun his intelligence. Upon only partial evidence he condemns me. It is stated in the book that only samples of my predictions are given, and upon a sample of my prediction as to the appearances of the sky and atmosphere on pp. 330, 331, he adversely criticises my rainfall predictions, which do not appear in the book, but which were given in a separate column in my *Weather Calendar* for the year 1894, and in the *Clerk of the Weather* for April, 1895. My predictions for one month, February, were compared with the Meteorological Office predictions and with the Greenwich records. There was no room in the book to put in the full comparison, hence the rainfall comparison is omitted. In fact, my predictions during the last twenty years would fill several portly volumes. And surely it was enough to state in the book that only samples were given from my predictions. If critics will ignore this, and themselves make unfounded statements, that is their own, not my fault. My predictions were made the previous year, and it may be seen from my Calendar for 1894, and from the 1895 April number of the *Clerk of the Weather*, on reference to the rainfall column, that I predicted rain on fourteen days, whereas the Meteorological Office predicted rain on twenty-one days, there being fourteen days on which rain fell at Greenwich. Surely this does not confirm Mr. Mawley's statement, that the weather can only be satisfactorily predicted for twenty-four hours in advance. There were during February, 1894, three periods of a different character as to rainfall, namely, a wet period from the 23rd to the 28th, a dry period from the 18th to the 22nd, and an alternately wet and dry period from the 1st to the 17th. As regards the wet period of six days, there was rain on every day except the 26th. I predicted rain on each of the six days, so that I was wrong on one day; but the Meteorological Office predicted rain on the 26th when there was none, and did not predict any on the 25th when it rained. The Meteorological Office was wrong twice against my once. Surely this is not much in favour of twenty-four hours' predictions of the Meteorological Office. Now, take the dry period of five days. There was not any rain recorded at Greenwich, and I did not predict any in my rain column, but as the Meteorological Office predicted rain on the 18th, the Meteorological Office was wrong once. Surely again, there is not much here in favour of twenty-four hours' predictions. Finally, we will take the period from the 1st to the 17th, when rain fell on nine days, and I predicted rain on eight, and the Meteorological Office on fifteen. Surely this ought to convince even the most prejudiced person that the Meteorological Office cannot predict the weather for even twenty-four hours in advance, and as I predicted rain for fourteen days for the whole month and rain only fell on fourteen days, it ought to even convince Mr. Mawley that I can satisfactorily predict the weather a year ahead. Further, the fact that these predictions of mine were based entirely upon the moon's motions, the sun being taken as a constant, shows that a very close approximation in prediction can be made by taking the moon only into account; and that by any method by which the sun is also taken into consideration, the weather can in all cases be accurately predicted, or as near accuracy as may be desirable. *Hugh Clements, Dulwich, S.E.*

ROSA GIGANTEA.—My first bloom opened a few days ago, and was really so lovely that I am sure all lovers of single Roses should try this Rose. I sent it off to Alnwick Castle for Her Grace the Duchess of Northumberland to see. It was just over 5 inches across, of a creamy white, with faint perfume, and well repays my twelve years' wait. *W. C. Leach, Albury Park Gdns., Guildford, Mar. 12.*

ENGLISH CHESTNUTS.—May I be allowed to supplement Sir W. Thiselton-Dyer's note in a recent issue of the *Gardeners' Chronicle*, by saying that there are a great number of Spanish Chestnuts in the park here, which produce some of the finest nuts I have ever remarked in this country. When living in the West Midlands, I had ample opportunities of observing the crop produced by numbers of trees in the park, but the nuts were small compared with those yielded by trees of all ages at this place. Some of these trees are of very fine proportions, and two girth 21 feet 6 inches and 19 feet 4 inches respectively at 6 feet from the ground. Others have stems less in circumference, but they have attained an unusual height for Spanish Chestnuts; two in particular having clean straight stems for about 56 feet and 69 feet before the first branch is reached, and the total height measured with a dendrometer is 103 ft. and

109 feet. The yield last year was poor, but on making enquiries, I find that in nine seasons out of ten these trees bear excellent crops. Last year was an exception, owing to spring frost, and it was a difficult matter to find sufficient under the trees to store for culinary uses during the winter months. *A. W., gr., Godington, Ashford, Kent.*

SHOOTS OF HORSE-CHESTNUT.—Enclosed are some shoots I picked near here from a Horse-Chestnut-tree on March 11, and which measure nearly 6 inches in length, and are as far advanced as the majority of Chestnut-trees should be by May 1 in this district. The tree stands on a bank with a north-east aspect, and appears to be about seventy years of age. From what I can learn from local sources, the tree has come into leaf about the end of February annually for the last forty years, and probably longer. It would be interesting to know if there is another Horse-Chestnut-tree in the country as precocious as this one. If not, I think it may fairly rank with the Cadnam Oak and Glastonbury Thorn as a vegetable phenomenon. *A. C. Forbes, Wilts, March* 11.

THE BRITISH OAK.—The following is from Mr. Fisher's article of March 7, but it is impossible for anyone to subscribe to it who has seen the two Oaks growing under various conditions of soil and climate:—

> "Summing up the matter, I believe that Nature has been adapting the varieties of Oaks to their habitats for thousands of years, and that in the precess the widely divergent pedunculate and sessile Oaks have been evolved on wetter and drier soils, and new produce acorns from which spring trees like their pregenitors."

I would advise Mr. Fisher to visit Windermere and Rydal Water, the wettest district in Britain, the rainfall I believe ranging from 80 to 150 inches. The Oaks there are a feature, they are so fine, old, and sound, and nearly all are of the sessiliflora variety. The owner of Rydal Hall showed me beautiful furniture made from these Oaks by Gillow, of Oxford Street, London, as we happened to talk on the subject. It is a fact, open to the most casual observer, that Quercus sessiliflora and pedunculata are constantly found growing promiscuously together and equally well, and all the varieties between these two. Prof. Fisher persists in writing of the two extreme types only, and ignores the varieties between, and the fact that neither of the types come true from seed. I still assert that the figures in your pages on Sept. 22, 1900, p. 219, of the acorns picked up at Chatsworth showed abortive examples, and I wondered at the time at Mr. Fisher regarding them as anything else. August was too late to find anything but nearly fully swelled acorns or abortions. Mr. Fisher's hypothesis about the shape and position of the leaves and acorns are too far fetched. And now about the paragraph from Mr. Robertson's letter: Mr. Robertson states that last winter he cut down 600 trees of the pedunculata variety, all going back, and the fall did not include a single sessile Oak. Now, I want to know, did Mr. Robertson go over all these Oaks when they were in full acorn, and see that they were Q. pedunculata, and if he did not, at what season did he pick them out? I doubt if either Mr. Robertson or Mr. Fisher could pick either variety out when not in fruit. I think I know the trees at Chatsworth, they are either big or old; and what I should like to know, and I daresay some of your gardening readers would like to know, is, that if these trees are dying now from an unsuitable soil, how they ever grew to be so old and so big as to become stag-headed, and sold for timber at a good price? Moreover, the climate of Chatsworth is the wettest in the Midlands, according to statistica, and the soil is the usual heavy cold soil found on the millstone grit. Yet, according to Mr. Fisher, we have the Oak that should live, dying for want of moisture, and the Oak that should die is flourishing to perfection! *J. Simpson.*

ENQUIRY.

Couch-grass amongst Young Fruit-trees.—"H. S." will be obliged to any reader who has had experience in cleaning ground of Twitch-grass amongst young fruit-trees, if he will describe the best means of getting rid of it. It cannot be forked out, as the trees, unfortunately, are planted in it.

RAILWAY RATES AND THE NATIONAL FRUIT GROWERS' FEDERATION.

The Conference between the delegates from this Federation and the Board of Railway General Managers, which took place on November 4 last, is bearing excellent fruit, already fully justifying the existence of the organisation.

The appointment of the Advisory Committee, with its sub-committee, for dealing with the various Companies, was a happy thought, and the plan is working admirably. These sub-committees have obtained from the Midland the provision of ventilated vans constructed on their own plan, and from the Great Western an improved system of sheeting. Both these Companies have also granted the following substantial concession:—They will now carry consignments of fruit in 5 and 10 cwt. lots by passenger train, at greatly reduced rates, by which means medium-sized towns will be supplied direct from the grower, instead of being compelled to go to large markets. This means a saving in carriage of 7*s.* 6*d.* on 5 cwt. for 100 miles for the grower, and fruit in good, fresh condition, with all the bloom on it, for the provincial dealer. The new and old rates are as follows:—

NEW SCALE.

CONVEYANCE BY PASSENGER TRAIN.

Scale of Rates for Fruit (Not Hothouse),

At Owner's Risk, not including Collection or Delivery.

Miles	Per Cwt.		Miles	Per Cwt.
