INDEX OF CONTENTS.

JANUARY TO JUNE, 1902.

A

ABERDEEN Botanic Garden, 245
Aberdeen University, prizes for botany and zoology, 342
Acanthus arboreus, 221
Achillea rupestris, 430
Adonis davarica, 180
Aesculus and *Pavia*, species of, 187; *A. californica*, fruiting in Bath Botanic Garden, 187
Africa, South, 232
Agave recurvata at Santa Barbara, California, 80
Agricultural statistics for Ireland, 95
Ailanthus, as an annual, 192
Almond, first flower of, 193
Alnwick Castle gardens, 273, 286
Alpines at Edinburgh show, 319
America, fruit culture in, 95; fruit and flower culture in, 229; gardeners in, 20, 48, 90, 132; the plant trade on Memorial Day in, 431
American Apple crop, the short, in 1901, 22
Anæctochili, 106; culture of, 130, 138
Anemone cernua, 233, 256
Angelonia grandiflora alba, 18
Angræcum ichneumonium, 194
Anigosanthus pulcherrimus at Belgrove, 311
Anthuriums, seedling, 395
Apiary, the, 12, 143, 275, 307, 344, 437
Apple, a new, 11; The Houblon, 79
Apple-trees, horizontal cordon, at Sherborne Castle, 387; the American blight on, 47
Apples, Australian, 145, 163, 290; with synonyms, 377
Apricots, 175
Arauja graveolens, fruit of, 139
Arbor Day in Britain, 162
Archontophoenix *Alexandrae*, 19; *A. Cunninghami*, 19
Arctotis breviscapa, 39
Arenaria purpurascens, 430
Aristolochia arborea, 186
Aristolochia, insects in the flowers of, 329
Artocarpus integrifolia, 205
Ash and Larch on the chalk, 311, 328
Ashwick Hall, 255
Asparagus Sprengeri, 165, 233, 263
Aster Tradescanti, 177
Aster-worm, notes on the, 202
Asters, China, diseases of, 293
Aucuba, 241
Auricula Celtic King, 319
Azalea mollis, 170

B

BACHELOR'S Button, what is the, 69
Bachelor's Button = *Gomphrena globosa*, 193
Bacteria in soil, 183
Bacteriosis in Orchids, 12
Baker, Mr. J. G., 192
Bamboos, growth and propagation of, 133; hardy, at Batsford, 278
Bananas at The Oaks, Emsworth, 225

Barbados, an interesting gathering at, 93; volcanic dust in, 435
Barkeria Skinneri, 18
Bath, Royal Victoria Park and Botanical Garden at, 156, 179
Bean and Pea hybrid, alleged, 96
Bean, dwarf, crossed with the Pea, 59
Beans, climbing, French, for forcing, 335, 379
Begonia Buisson Rouge, 204; *B. Gloire de Lorraine*, 75, 164, 202, 204; fungus on, 421; *B. socotrana*, 84
Begonia-mite, the, 376
Begonias, winter-flowering, 204
Benevolent Institution, Gardeners' Royal, 26, 161, 384; (annual dinner), 363
Berberis congestiflora hakeoides, 310
Berlin, note from, 139
Bilberries and the like, 75
Birds, nest-boxes for, 229
Black Currant-mite, the, 105
Bletia Hyacinthina, 430
Blight, American, on Apple-trees, 47
Boerhaavia diffusa, the, catches chickens, 175
Books for young gardeners, 224

SIR HENRY GILBERT.

IN our last issue we briefly announced the death of Sir Joseph Henry Gilbert, the able and devoted coadjutor of the late Sir J. B. Lawes, Bart., the eminent authority on scientific agriculture and chemistry. Sir Henry passed away at his residence at Harpenden, at ten minutes past twelve o'clock on Monday morning, the 23rd inst., in the presence of his family.

Sir Henry, who had long been ailing, was first taken seriously ill in August last at Strathpeffer, Scotland, where he had gone for his summer's holiday, being attacked by acute hæmorrhage, followed by nervous exhaustion and neuralgia of the stomach.

Sir Joseph Henry Gilbert was born at Hull, August 1, 1817, and was therefore in his eighty-fifth year, being three years the junior of Sir John Lawes. His father was the Rev. Joseph Gilbert, the author of several theological works. His mother, Ann Taylor, of Ongar, who survived until 1866, was well known as an authoress of poems, writing

originally with her sister under the names of Ann and Jane Taylor.

After his school education, and the loss of several years by a gun-shot accident, which much impaired his health and deprived him of the sight of one eye, Dr. Gilbert commenced his college courses at the University of Glasgow, where he had as contemporaries Sir Joseph Hooker and Dr. T. Thomson, the Indian botanist. Here, as elsewhere, he paid special attention to chemistry, devoting some time to analytical chemistry in the laboratory of the late Professor T. Thomson. He next studied at University College, London, attending the classes of Professor Graham and others, and working in the laboratory of the late Dr. Anthony Todd Thomson. A short time was afterwards spent in the laboratory of Professor von Liebig at Giessen, where he took the degree of Doctor of Philosophy. Returning to University College, London, Dr. Gilbert was class and laboratory assistant to Professor A. T. Thomson in the winter and summer session of 1840-41, and attended other courses at the College at the same time. On leaving college, he devoted himself for a time to the chemistry of calico-printing, dyeing, &c., in the neighbourhood of Manchester.

In June, 1843, Dr. Gilbert became associated with Mr. (afterwards Sir John) Lawes in the Rothamsted investigations, and from that time until his death has been engaged as director of the Rothamsted field and laboratory experiments, which consisted of a systematic series of researches in agricultural chemistry and physiology of animals and plants. In the early part of his career at Rothamsted he was engaged in the manufacture of calomel in an old barn which served as a laboratory. At that time Mr. Lawes sought his services as chemist in some commercial undertakings, but Dr. Gilbert preferred to remain at Rothamsted, and commenced that brilliant series of researches which conferred so much honour on the two investigators. These researches began as "flower-pot experiments," but were gradually extended till they became field experiments on a scale hitherto unattempted.

The Rothamsted experiments may, indeed, be pronounced unique, and are certainly without parallel, either as to extent, character, or scientific and practical usefulness. It is not asserting too much to say that these researches have done more to advance agricultural and horticultural science, and have been and will be of greater service to agriculture than can ever be fully realised. Other countries can boast of very numerous agricultural stations supported by Government, whilst we have very few; but the Rothamsted experiments carried out by private individuals surpass all that has been done in any other country with or without Government aid.

Sir Henry was elected a member of the Chemical Society in 1841, the year of its formation, and was President of the Society in 1882-83. He was elected a Fellow of the Royal Society in 1860, and in 1867 the Council of the Society awarded to him, in conjunction with Sir John B. Lawes, one of the Royal medals. He received the honorary degree of M.A. at Oxford in 1844, that of LL.D. at Glasgow in 1883, and at Edinburgh in 1890, as also that of Sc.D. at Cam-

bridge in 1894. He was Sibthorpian Professor of Rural Economy in the University of Oxford for six years, from 1884 to 1890.

In May, 1893, the President and Council of the Society of Arts awarded the Albert Gold Medal to Sir John Lawes and to Sir Henry Gilbert for their joint services to scientific agriculture, and notably for the researches which, throughout a period of fifty years had been carried on by them at the experimental farm at Rothamsted; and the medals were presented to them at Marlborough House by H.R.H. the Prince of Wales (now King Edward VII.), President of the Society, in the presence of many members of the Council. Like his collaborator, Sir John Lawes, he was an honorary or corresponding member of numerous home and foreign agricultural and scientific societies. On August 11, 1893, that is, about a fortnight after the jubilee celebration at Rothamsted, Dr. Gilbert received the honour of knighthood.

The jubilee of the Rothamsted Experimental Station in 1893 was made the occasion of a ceremonial which was of an unique and interesting character. At a meeting of the Royal Agricultural Society of England, presided over by H.R.H. the Prince of Wales, it was resolved that, to mark the completion of half a century of continuous research in the Rothamsted station, some public recognition should be made of the invaluable services rendered to agriculture by Sir John Lawes and Dr. Gilbert. It was decided that the testimonial should take the form of (1) a granite memorial with a suitable inscription to be erected in the front of the laboratory at Harpenden; (2) illuminated addresses of congratulation; (3) a portrait of Sir John Lawes painted by Mr. Hubert Herkomer, R.A., and a massive silver salver to Dr. Gilbert, bearing the following inscription: "Presented by the subscribers to the Rothamsted Jubilee Fund to Dr. Joseph Henry Gilbert, F.R.S., in commemoration of the completion of fifty years of unremitting labour in the cause of Agricultural Science, July 29, 1893." The various presentations were made, and the commemorative granite boulder was formally dedicated at a meeting of the subscribers held at Harpenden on Saturday, July 29, 1893. The Right Hon. Herbert Gardner, M.P., President of the Board of Agriculture, presided, and there was a large attendance of leading agriculturists, scientists, and others.

The Lawes Agricultural Trust, established by the munificence of Sir John Lawes, provides that someone shall periodically visit the United States of America and give a series of lectures upon the results of the Rothamsted investigations. At the request of the committee of management, Sir J. Henry Gilbert undertook this duty in 1893, and thus for the third time he visited the world beyond the Atlantic, his former visits having taken place in 1882 and 1884.

The results of the Rothamsted researches are embodied in print in many forms in the records of the Royal Agricultural Society, the British Association, the Chemical Society, the Royal Society, the Horticultural Society, the *Society of Arts Journal*, and the Dublin Royal Society. In articles in technical newspapers, and in numerous reports, pamphlets, and letters to the general press, too long for enumeration here, which, as

regards the agricultural history, progress, and literature of the past sixty years are, we may confidently say, to be reckoned among the most remarkable achievements of the century.

It is satisfactory to know that the researches at Rothamsted will be carried on in the future under the direction of the Lawes Trustees.

The funeral of the late Sir Henry Gilbert

NOVELTIES OF 1901.

DURING the past year, as in the preceding one, the hybridist, or novelty-maker, has had a decided advantage over the importer, whose expensive occupation has in a large degree

FIG. 1.—*HELICHRYSUM GULIELMI* VAR. *MEYERI*. (SEE P. 4.)

He was twice married, first in 1850 to Miss Laurie, daughter of Dr. Laurie, who died in 1853; and afterwards, in 1855, to Miss Smith, the present Lady Gilbert; he leaves no issue.

took place at Harpenden on Friday, Dec. 27, and was attended by the members of the Lawes Agricultural Trust Committee, and representatives of many of the scientific societies of the country.

been made unremunerative so far as the bulk of the importations is concerned, by competition with the home-made novelties. Signs are not, however, wanting that plant-collecting abroad, which we have to thank for the many showy

plants and the host of interesting things dear to the heart of the botanist and true plant-lover, will soon again be on a better footing. In the matter of high prices, and prices which have been maintained, if we turn to the Orchids especially, we find that the standard best forms and the "albinos" have always commanded the market better than even the best hybrids. Take, for example, *Cypripedium callosum* Sanderae, *C. insigne* Sanderae, and *C. Lawrenceanum* Hycanum, we have each by multiplication acquiring perhaps something like £2000—a record which in the face of easy production no single plant of a hybrid can attain.

THE ORCHIDS,

as represented by the importations during the past year, have been mainly Brazilian, and the ever-acceptable Colombian *Odontoglossum crispum* has been imported in great quantities, notwithstanding the disturbed state of the country they come from. The spotted forms of *Odontoglossum crispum* have proved the most beautiful and valuable Orchids of the year, the *O. crispum* Pittianum, for which H. T. Pitt, Esq., was offered 700 guineas, reaching the highest estimate of value, although several others reached three figures. So important has the bold of these beautiful *Odontoglossums* on Orchid growers become, that several collections are now almost entirely devoted to them, while in most collections they form special features.

In the famous collection of Sir Trevor Lawrence, Bart., Burford (gr., Mr. W. H. White), considerable accommodation is given the *Odontoglossums*, and of the collection there it may be said that in point of vigour and excellence of flower, they are equal to any in the country. Many fine spotted forms of *Odontoglossum crispum* have flowered at Burford, but the best are *Odontoglossum crispum* purpurascens, which received a First-class Certificate on March 26, and *O. luteo-purpureum*, "Burford variety." Other fine things, new or re-introduced to Burford, are *Dendrobium rubens* grandiflorum, and other hybrids; the yellow *Sophranitis grandiflora* Rossiteriana, the fine *Sobralia Rackeri*, Schomburgkii, Thomsoniana, *Laelia præstans*-bicolor, and among the rare botanical species the very remarkable emerald-green *Acanthes dentiens*, the singular *Stanhopea connata*, *Liparis tri-callosa*, *Mormodes Oberlanderianum*, and various singular *Cirrhopetalums*, *Bulbophyllums*, &c.

Baron Sir H. Schroder (gr., Mr. H. Ballantine) still maintains his magnificent collection as one of the best ever formed. Into it the best procurable are generally admitted, and new things are constantly flowering there. Now and then the inflorescences of such grand and priceless things as *Odontoglossum Pescatorei* Veitchianum, *O. P. Schroderianum*, and some of the rest of the blotched *O. crispum* and hybrids, are sent up to the Royal Horticultural Society, and which often indicate, especially with the two first-named, that out of the thousands since imported, nothing in the same class or anywhere near it has again appeared.

Sir Frederick Wigan, Bart., Clare Lawn, East Sheen (gr., Mr. W. H. Young), is a steady exhibitor of superb new Orchids. At the last Temple Show, the fine *Laelio-Cattleya* × *Edgar* Wigan, the first of the *L. Digbyana* crosses to show bright colour, attracted much attention; and his *Cattleya Mossiae* dulcis was a remarkable variety. Other novelties have flowered at Clare Lawn during the year, among those exhibited and certificated being *Cattleya quadricolor* variety alba, *Laelio-Cattleya* × *Wilsoniae*, and *Phalenopsis Boxalli*; while

Dendrobium × *Wiganianum*, *Laelio-Cattleya* × *Clytie*, and others, have been recorded.

Norman C. Cookson, Esq., Oakwood, Wylam (gr., Mr. Wm. Murray), who not only grows his fine *Odontoglossums* admirably, but also propagates them with reasonable rapidity, flowered some grand things in the past year, four of the best being *Odontoglossum* × excel-

H. T. Pitt, Esq., Rosslyn, Stamford Hill (gr., Mr. Thurgood), has been great in *Odontoglossums*, his *O. crispum* Pittianum and his *O. Hallii* Edward VII. being the two best shown during the year in their sections. *O. crispum* Annie, certificated at the Temple Show, is also fine; and *O. c. punctatum* Rosslyn variety, *Miltonia vexillaria* Rosslyn variety, *Cattleya Schroderae* Heatonensis, and *Lycaste Balliae* superba, good things of lasting reputation; *Cypripedium* × *Savageanum* Pitt's variety, a singular form with variegated flowers; *C. × Nellie*, and *C. × Ajax*, a novel hybrid of *C. Chamberlainianum*.

De Barri Crawshaw, Esq., Rosefield, Seven-oaks (gr., Mr. Stables), has made *Odontoglossum*-lore and *Odontoglossum*-culture special studies, and he is continually proving that his researches have not been in vain. Among other fine things certificated to him at the Royal Horticultural Society, or recorded, are *Odontoglossum crispum* Raymond Crawshaw, well worthy of the First-class Certificate awarded, its flowers being fine in form, and the glowing orange-tinted brown of its blotching unique; *O. × Crawshayanum* (Hallii × Harryanum) is a very pretty hybrid, in which both parents are recognisable; *O. × Adriane* Crawshayanum, a finely-blotched flower; *O. × loochristyense* "Mrs. de B. Crawshaw," a fine hybrid of *O. triumphans*, with the same rich colouring as that species, a point which other forms lack; *O. Nevadaense* Rosefieldiense and *O. × Denisoniae* nebula, two interesting forms, the latter especially, as it verifies the original figure, which some considered a doubtful representation; and *O. Lindleyanum* aureum, a pleasing addition, as it nearly completes the chain of yellow forms of brown-blotched *Odontoglossums*. The second Rosefield specialty, *Laelia anceps* varieties, have also been augmented by distinct things, and especially by *L. a. Amesiana* Theodora, an advance on the hitherto best of its section *L. a. A. Crawshayana*.

Captain Holford, Westonbirt, Tetbury (gr., Mr. A. Chapman), maintains the reputation of Westonbirt as the leading Orchid establishment in the West of England, which it has sustained for over half a century. A choice collection of botanical and floral interest used to be the aim; now showy things, both species and hybrids, are acquired and cultivated up to their best. The *Odontoglossums* are specially well grown, and some distinct ones have flowered, the best being *O. × Adriane*, "Mrs. Robert Benson." The latest hybrid *Cattleya* at Westonbirt is *C. × mollis*, var. *Lois*.

Robert Tunstall, Esq., Monkholme, near Burley (gr., Mr. Balmforth), has been steadily acquiring good Orchids for some time past. During the year he received Awards at the Royal Horticultural Society for *Lycaste* × *Tunstalli*, a rosy red-and-white natural hybrid of *L. Skinneri*; *Cypripedium* × *Helei* (bellatulum × *insigne* Chantini), a great beauty, named in honour of his wife; *Cattleya* × *Portia* and the showy *Laelio-Cattleya* × *Haroldiana*, and also showed the clear yellow *Odontoglossum grande* citrinum, Monkholme variety, and the finely-formed *Cypripedium insigne*, Sanderae Monkholme variety, probably a true seedling from the original.

The following best selection from the new or specially developed plants of the season credited to our amateurs plainly show the favour given to the genus *Odontoglossum*. W. Thompson, Esq., Walton Grange, Stone (gr., Mr. W. Stevens), an *Odontoglossum* specialist, showed *Odontoglossum crispum* Quocou Empress, *O. × crispum* - Harryanum roseum; the very fine *O. maculatum* Thomp-

FIG. 2.—SEED-VESSELS OF *WISTARIA JAPONICA*.

(See p. 4.)

lens Cooksoni, a large and finely coloured flower; *O. × loochristyense* Cooksoniae, which might be taken for a large, heavily blotched, yellow-tinted *O. crispum*; *O. × Wilekanum* Oakwoodiense, and *O. × W. Sibyl*, both excellent. Of the famed Oakwood hybrids, further extensions of the remarkable blood-red *Calanthe* × *Oakwood* Ruby have flowered, and *Cypripedium* × *Mrs. Rehder*, Oakwood variety, *C. × Lawrebel*, Oakwood variety, and others.

sonianum; the blotched yellow O. × Willeke-anum Golden Queen, and other distinct Odontoglossums.

Elijah Ashworth, Esq., Harefield Hall, Wilmslow (gr., Mr. Holbrook), secured Awards for *Lælia Jongheana* Ashworthiæ, the finest white *L. Jongheana*; *Cattleya* × Miss Harris, var. "E. Ashworth"; and the remarkable white *Dendrobium* Ashworthiæ from New Guinea.

Richard Ashworth, Esq., of Ashlands (gr., Mr. Pidsley), flowered the finely blotched *Odontoglossum crispum* Rossendale, O. c. Margery, O. × *Adrianæ aureum*, and other good varieties.

J. Leemann, Esq., Heaton Mersey (gr., Mr. Edge), in his fine group of *Odontoglossums* at the Temple Show, secured awards for O. crispum Confetti, O. c. Domino, O. c. Countess of Derby, O. c. The Nizam, and also flowered the finely spotted O. × *Adrianæ Lindenæ*, the richly coloured *Lælia* - *Cattleya* × *callistoglossa magnifica*, and the pretty white *Brassocattleya* × *nivalis*.

George Singer, Esq., Coundon Court, Coventry (gr., Mr. Collier), has for his best of the year *Odontoglossum* × *loochristyense* coundonense, O. luteo-purpureum, Coundon Court variety, *Cattleya Trianaei* Godiva, C. Mossiæ Earl Leofric, C. M. coundonensis, and *Cypripedium* × T. W. Bond, Coundon Court variety, all very handsome and distinct.

R. Brooman-White, Esq., flowered *Odontoglossum* × *Ruckerianum*, Mrs. R. Brooman-White, and other fine *Odontoglossums*.

G. W. Law-Schofield, Esq., produced *Odontoglossum crispum* Beauty, a model flower, and *Cypripedium* × *Mandilæ magnificum*; W. P. Burkinshaw, Esq., of Hesse, showed the bright rose-tinted *Lælia* - *Cattleya* × *Digbyano-Mendeli* Hesse variety; Mrs. Briggs-Bury, of Accrington, flowered *Odontoglossum* × *loochristyense* Fairy Queen, O. × I. King of the Belgians, and O. crispum Charlemagne. Fred Hardy, Esq. (gr., Mr. T. Stafford), produced several pretty hybrid *Dendrobiums*, the forms of D. × *Cybele* being especially fine; also D. × *Staffordi*, a pretty cross of D. Bensoniæ; *Sophro-Cattleya* × Geo. Hardy, Tynesfield variety; *Cypripedium* × *Leeano-Chamberlainianum*, and others. R. I. Measures, Esq. (gr., Mr. H. J. Chapman), was fortunate enough to flower the white *Lælia purpurata* Kromeri, *Cypripedium* × *Unxia superbum*, and other hybrids. W. M. Appleton, Esq., Weston-super-Mare, showed the very pretty and distinct *Cypripedium* × *Rolfei* (Rothschildianum × *bellatulum*).

J. Bradshaw, Esq., of Southgate, from his fine collection of remarkable varieties of *Cattleya labiata*, secured awards for C. l. G. G. Whitelegge, a fine white form; and also flowered other good whites, the blue-tinted *C. labiata glauca*, and the pretty *Odontoglossum* × *Adrianæ Bijou*.

Walter Cobb, Esq., flowered *Odontoglossum* × *Adrianæ Cobbianum*, the darkest in colour which has yet appeared; and during the year *Phaius Warpuri*, now known as *P. tuberculatus*, and a few other new plants by the same collector have been added to our gardens, and a very large number of hybrids and varieties have flowered here and there.

Not a single fine new Orchid, either imported or hybrid, has appeared during the year in sufficient quantity to render it available for gardens generally. Among recently exhibited hybrid *Cypripediums*, C. × Mrs. Alfred Fowler and C. × *salus* Mrs. F. Wellesley are among the best.

(To be continued.)

SOME AFRICAN HELICHRYS.

SOME time since (*Gardeners' Chronicle*, November 10, 1900, p. 334, fig. 103), we had the opportunity, owing to the kindness of Mr. W. E. Gumbleton, of figuring a new species of *Helichrysum* which Professor Engler had named *H. Gulielmi*. The species, as cultivated by Mr. Gumbleton, was not only remarkable for its beauty, but for the locality in which it grew, viz., the mountain of Kilima-njaro, in Central Africa. The genus is abundantly represented in South Africa, in tropical Africa, and in Australia.

In the same paper Dr. Engler mentioned, without describing or naming it, another *Helichrysum* as allied to *H. formosum*. This is supposed to be the plant now illustrated (fig. 1, p. 2). Mr. Gumbleton received the seeds of it from M. Max Leichtlin under the appellation "H. affine formosum." In due time it flowered; specimens were sent to Kew for identification, and were considered by the authorities to be a variety or form of *H. Gulielmi*. Mr. Worthington Smith's drawing was also submitted to Professor Engler in Berlin, who requested Dr. Hoffmann to report on it, which he did in the following terms:—"So far as I can judge from the illustration, the plant may well be *H. Gulielmi*, Engler; but in the illustration the inflorescence is looser; the species varies, however, in this respect, and the influence of cultivation has also to be taken into consideration. In the illustration the hairs look as if they could be pulled off singly, while in *H. Gulielmi* the hairs are soft and shaggy. This appearance may arise from a defect in the illustration."

It seems evident that we have here not a new species, but rather a variety of *H. Gulielmi*. Longer cultivation must determine this point, and if it eventually prove sufficiently distinct, it may be called *H. Gulielmi* var. *Meyeri*, in compliment to Dr. Hans Meyer, who discovered it, and sent the seeds to Mr. Max Leichtlin. Mr. Gumbleton is also the possessor of another species from the same mountain, viz., *H. Newi* (Oliver and Hiern), *Flora of Tropical Africa*, ii. (1877), p. 349.

WISTARIA JAPONICA.

I HAVE grown this fine and free-blooming species for many years trained to a wall, and though it has bloomed each year most abundantly, the plant being literally covered with its beautiful pendulous racemes of white and lilac flowers, many of them 2 feet long, I never saw a seed-pod form on it till 1899, when a single one was discovered when the leaves fell. In 1900 three were found, and this year four, one of them much larger than the others, which is the one illustrated (fig. 2), and which I think must be the normal size of the pod when fully developed. Each pod only contains one seed. I have not yet tested the fertility or germinating power of these seeds, but hope to do so next year. I believe this *Wistaria* has also ripened seed at Kew, and at Mr. Walpole's garden at Mount Ussher, co. Wicklow. W. E. Gumbleton, Queenstown, co. Cork.

ORCHID NOTES AND GLEANINGS.

CALANTHE × TRIUMPHANS.

A FINE inflorescence of a very richly-coloured hybrid *Calanthe*, a triumph of patient crossing and selecting, is sent by the raiser, Norman C. Cookson, Esq., Oakwood, Wylam, Northumberland (gr., Mr. Wm. Murray). It is of the same section as the ruby-crimson C. × *Oakwood Ruby*, and the purplish-crimson C. ×

atro-rubens, both raised by Mr. Cookson, who gives the following information about the new variety sent:—

"It is the fifth generation by selection from *Calanthe vestita rubro-oculata* × C. × *Veitchi*. It is in the way of C. × *Alexandri*, but much better, and a much more robust grower."

The many flowered inflorescence has flowers in which the lips have a strong resemblance to those of C. *vestita*. The upper sepal and petals are dark purplish-crimson; the lateral sepals are similar to them in colour, but with more or less white showing on the outer halves; the lip is ruby-red, with a dark claret-purple blotch at the base. It is a very showy addition to a class of winter flowers which Mr. Cookson has done so much to enrich. J. O'B.

SOPHRONITIS GRANDIFLORA COCCINEA.

A very finely-formed and large flower of a rosy-scarlet tint, is sent by C. R. de la Salle, Esq., Enbridge Lodge, Newbury (gr., Mr. G. Ellwood), who remarks on its resemblance to the variety known in gardens as *S. grandiflora rosea*. But that variety appears as an occasional plant out of importations of the scarlet-flowered species, whereas Mr. de la Salle's plant is but a more rose-coloured variety of the section, which has more crimson flowers, and has been named *S. coccinea*, although experience has proved the variability of *S. grandiflora*, and "coccinea" and *militaris* are now placed as varieties of it. *S. grandiflora* is one of the brightest of Orchids of small growth, and when it is hung up in a cool-house they make a fine show when there are not many other brightly-coloured blooms open.

CYPERORCHIS MASTERSII AND VARIETY ALBA.

Flowers of varieties of *Cyperorchis Mastersii* are kindly sent by Mr. J. W. Moore, Cragg Royd Nursery, Rawdon, Leeds, who calls attention to their dissimilarity. This peculiarity was noted in the *Gardeners' Chronicle* by Reichenbach, under the old name *Cymbidium Mastersii*. "There is great pleasure felt in England now about that lovely *Cymbidium Mastersii* with purple, or violet, or mauve spots or blotches on the anterior lacinia of the lip. The most enthusiastic lover of the plant compared it to *Lælia anceps Dawsoniana*. That is a question of taste. I have several correspondents who grumbled (in the bad month of November) that the 'variety' had no especial name."

"I am sorry I cannot follow that order, as, *candide lector*, very many names are proscribed. A glance at the two oldest representations (Lindley, *Bot. Reg.*, 1846, 50, and Lindl., *Paxton's Flower Garden*) afford evidence that those were blotched with purple, or mauve, or violet; hence the second variety, now regarded the 'old one,' because the oldest is forgotten, with white flowers, and only yellow on the middle lacinia of the lip and keels, might be distinguished as *C. Mastersii album*." The fine spotted flower sent by Mr. Moore appears to be the form once described as C. *affine*, and the pure white flower with yellow keels is identical with that for which the name *album* was suggested. The varieties of *Cyperorchis Mastersii*, with their fine arching racemes of fragrant flowers, produced in winter, are very desirable plants for the cool or intermediate-house; and even when not in flower, their elegant evergreen foliage makes them ornamental plants.

CATLEYA × ELVINA (TRIANÆ × SCHILLERIANA).

This hybrid, raised by Messrs. Veitch & Sons, Chelsea, bears much resemblance to C. × Miss Harris, which was raised from C. Mossiæ × C. Schilleriana, and consequently it is an affinity of the fine C. × Miss Harris var. *E. Ashworth*, which appeared as a sup-

plement in the *Gardeners' Chronicle*, May 11, last year, although the flower kindly sent by Messrs. Veitch is not so large as that one, the plant being of smaller size. The sepals and petals are of a delicate lilac-rose, with a thickened silvery band running up the middle of each, and a few purple spots. The lip is of a bright rose-purple with darker purple veining and a white margin to the fringed front-lobe—a pretty flower. In these hybrids of *Cattleya Schilleriana*, that species is distinctly apparent in the form of the lip. In *C. × Elvina* the sepals and petals are those of *C. Trianaei*, but rather narrower, and of more substance, but the lip, though much larger, closely approaches that of a good *C. Schilleriana*.

LÆLIO-CATTLEYA × VESTA (*C. SUPERBA* × *L. VITELLINA*).

Lælia × vitellina, for which Baron Sir H. Schroder, The Dell, Egham (gr., Mr. H. Ballantine), received a First-class Certificate at the Royal Horticultural Society in 1893, and which was illustrated in the *Gardeners' Chronicle*, March 25, 1893, p. 365, is a supposed hybrid between *Lælia harpophylla* and *L. Perrini*, with flowers of an Indian-yellow tint. Messrs. Jas. Veitch & Sons succeeded in crossing it with *Cattleya superba*, and named the progeny *L.-C. × Vesta*. The sepals are lanceolate; the petals narrowly ovate-acuminate, and both of a bright copper-tinted orange colour. In all hybrids of *C. superba* the peculiar form, and rather hard substance, of its labellum are transmitted in a marked degree, the present case being no exception. The base, side lobes, and centre of the lip are of an orange colour, which extends as lines into the rosy-purple front lobe, which has an undulate, whitish margin. The tips of the side lobes of the lip are turned back, and are rose-tinted. It is novel in shape and pleasing in colour. James O'Brien.

A HANDSOME HARTSTONGUE.

WE reproduce a photograph (fig. 3) of a frond of *Scolopendrium* var. *Drummondæ* *superba*, recently exhibited by Mr. Chas. T. Druery, and which obtained an Award of Merit from the Floral Committee of the Royal Horticultural Society. As will be seen, this variety is characterised not merely by the plumose or crispum frilling peculiar to some of the more charming varieties of this species, but is also furnished with a deeply-cut, lacy-looking, curly fringe, adding greatly to its ornate character. It originated as a seedling from *S. v. crispum Drummondæ*, found wild many years ago by Miss Drummond, near Falmouth, and was given with a few others in a very small state to the exhibitor by Mr. T. Bolton, of Warton, near Carnforth. The parent is a unique Fern in several respects, having two forms of frond—smooth-edged ones, long and slender, slightly frilled, and terminating in a spreading ramose tassel; and others of similar shape, but with edges projecting into filaments forming a stiff fringe. These filaments suggested to Mr. Druery a tendency to apical apospory, or the development of prothalli from the tips—an idea which was fully confirmed when portions were placed under close culture. In the improved variety the dimorphic character is eliminated, no smooth-edged fronds appearing, while the fimbriate and plumose character is developed on a far greater scale. To bring out the full features, close culture in a Wardian-case or large bell-glass is essential, since it has been found that the tips are so sensitive to drought that during the hot weather, despite every precaution, they wither and turn brown, even under glass in a fernery; hence, though

strong or robust plants result, the ultimate delicacy of the fringing is lost. This remark applies, of course, to culture near London, but probably in the more humid counties of the west and north-west, the difficulty would disappear. The beauty of the Fern, however, entirely justifies Wardian-case culture, and as a central specimen plant, surrounded by other smaller-growing varieties, such as *Spleenworts*, or dwarf forms of other species, would constitute a group which would well repay the little trouble entailed. A north window, with ample light, but little direct sunshine, could not be occupied to better

FIG. 3.—*SCOLOPENDRIUM* VAR. *DRUMMONDÆ* *SUPERBA*.

advantage. So treated, this Fern, besides developing its curly fringe, develops also prothalli at the tips, enhancing the effect, and rendering it additionally interesting to the botanist as well as the non-scientific amateur.

A MIDLAND GARDEN.

I HAVE read recently a capital article on "The Garden, and its Development," in a book which I fear is not likely to be seen by many English gardeners. It is the *Annual Report of the Smithsonian Institution of Washington, U.S.A.* This important institution is liberally supported by the United States Government, and it issues every year a report of its operations, finances, &c., with an "Appendix" of some 500 pages, containing a

number of articles by first-class authorities on the burning questions of the day in physics, natural history, archæology, astronomy, and other branches of science, illustrated in the most elaborate manner with photographs, woodcuts, diagrams, &c. This volume is presented annually to most of the scientific institutions and free libraries throughout the world, but the great value of it does not seem to be generally known in this country. The United States Government is noted above all others for its liberality in giving away free copies of its most valuable publications wherever they are likely to be useful.

THE WHITE HEATHER.

There is a popular superstition that it is lucky to find a spray of White Heather. Of the three common forms of Heather only two occur in Leicestershire, viz., the Cross-leaved Heath (*Erica tetralix*), and the Ling (*Calluna vulgaris*), and of both of these the white variety is occasionally found. I have always supposed that the plant bearing white flowers was a true variety, and would always bear white flowers. My daughter, who has lately returned from the south of France, has brought me a branch of the purple Heather (*Erica cinerea*), which has on it two spikes of flowers, one entirely white and the other entirely purple. It appears, therefore, that both may grow on the same plant. She tells me that the French people believe that the Heather bears white flowers when it grows old.

THE COLOURS OF FLOWERS.

Has there ever yet been discovered a blue Rose, or a blue Poppy, or a yellow Campanula? It has long been noticed that in the flowers of certain genera there may be all shades of yellow, red, and purple, but no blue; while in others there may be all shades of blue, purple, and crimson, but no yellow. Fifty years ago, when it was supposed that the three primary colours were red, yellow, and blue, it was thought that the two primaries, yellow and blue, represented two extremes, which could either of them blend with the other primary, red, producing various intermediate shades, but that if they blended with each other they could only form a compound-green. Scientific gardeners of those days made out lists of plants which might be grown together because their colours would harmonise on these principles. It is now known, however, that if there are any colours which can be called primary they are dark red, dark green, and dark violet. Yellow is a compound of green and red. Blue is a compound of green and violet. Anyone can prove this by a careful manipulation of two prisms, so as to make the coloured spectra cross each other. It is the blending of green with violet on one side that produces the blue series, and the blending of green with red on the other side that produces the yellow series. It is difficult to make people believe that green and red make yellow, or that yellow and blue do not make green, because they are more accustomed to the blending of paints than of pure-coloured light; and the colours of paints are always impure, but the two prisms show it clearly enough, or two strips of white paper looked at through a single prism will show it equally well.

FAVOURITE FLOWERS.

A favourite flower of mine is the old-fashioned *Fraxinella*, which I rarely see in gardens now. It bears spikes of white or rosy flowers, and when slightly rubbed, gives off a rich, aromatic scent. It always associates itself in my mind with the hot and sunny days of summer, "when all the garden paths are warm and fragrant." A dry, sunny border

suits it best, and in such a situation it modifies the midsummer heat with its Lemon-like aroma. I suppose everybody who cares for his garden has his favourites among the flowers; something in the colour or the form or the expression pleases him, or reminds him of some "golden days," that are gone for ever, or of some long-lost friend for whose sympathy he sighs in vain. I have still a spray of Heliotrope which once in the dim past whispered "I love you," and through all these many, many years I have never met that fragrant flower without a friendly recognition, and a feeling as if it had still some message for me. The pretty purple alpine, *Saxifraga oppositifolia*, carries me always to the summit of Ben Lomond on a cloudless summer evening, with all the mountain-land of Scotland spread around me like an embossed map. The Almond-tree and the White Broom remind me of my father's garden as I remember it nearly seventy years ago. All of us have some such memories, and they are treasures to be thankful for.

A PROLIFIC DAMSON-TREE.

There is one large Damson-tree in this garden, and we find the only practical way of getting the fruit is to shake it down, spreading large cloths underneath to keep it clean. When this was done last year, we collected from this tree just about 100 lb. of fruit, and as five of them weighed 1 oz. on an average, there were 8,000 Damsons on that tree. The retail price of Damsons here is 1d. per lb., or 8s. 4d. for the 100 lb. If the lot were worth 5s. wholesale, and the tree occupied or made useless 10 square yards of ground, it would have produced 6d. per square yard, which is the standard at which allotment gardeners should aim.

THE WORK OF A PLANT.

An astonishing plant is the Giant Sunflower. I had a number of them 8 feet high, with stems an inch thick, and leaves and flowers 12 inches across. What a mass of organised tissue to be produced in six months from one single seed! If the plant went on growing at full speed night and day without intermission, it would be necessary for many cells to be formed in each second of time in order to build up such a fabric. And yet how silently and unobtrusively the work is done! Does the busy protoplasm know what it is doing, or what it has got to do? Does it enjoy its life, and sing at its work? and are there any creatures sensitive enough to hear it? Do not laugh, my practical brother gardener, at such fancies. Let us not forget the poetry of the garden while we dig up the Potatoes.

SPIDERS AND THEIR WEBS.

In the misty mornings of the declining year came the wonderful revelation of the spiders' webs. Spread out in thousands on bush and hedgerow, they are all unseen till the mist hangs liquid diamond-dust on every thread. Then suddenly we realise that we are surrounded by a huge population of spiders. I calculate that there must be 50,000 of these webs in this garden, each inhabited by a pair of spiders. They are chiefly of three genera, viz., *Epeira*, the geometric spiders, who spin the beautiful lace-like webs, and often sit in the centre watching for their prey; *Theridion*, spiders whose web is a mass of interwoven threads; and *Linyphia*, whose webs are like sheets suspended horizontally by the edges. Near to each web, and generally on the under-side of a leaf, may be found the spiders' refuse-heap, consisting of the wings, legs, and fragments of the bodies of the flies which have been captured and sucked dry. If each of the 100,000 spiders destroyed only ten flies in the course of the season, it would mean that without their presence we should have

had a million more of these little buzzing pests. I am disposed to regard spiders as friends of the human race. Flies I abhor. It is said, however, that the female spider is larger than the male, and more ferocious, and that when her partner ceases to please her, she simply eats him and gets another. I am bound to say that I think this a bad example. F. T. Mott, F.R.G.S., Birstal Hill, Leicester.

The Week's Work.

PLANTS UNDER GLASS.

By J. C. TALLACK, Gardener to E. MILLER MUNDY, Esq., Shipley Hall, Derby.

Codiciums (Trottons).—Where tall, single-stemmed plants are needed for grouping with other things during the late summer and autumn months, propagation should at once commence, and the method employed should be that of "ringing" the stems of nice, clean tops of shoots as low down as possible without including any bare stem or defective leaves in the portion left above the ring. Enclose in a fairly large mass of sphagnum or other moss, which should be tied closely into place, and kept damp until sufficient roots have been formed to allow of complete severance preparatory to potting. The value of this method of propagation lies partly in the facility with which big plants can be obtained quickly, and partly in being able to keep them always well up to the light, which is impossible with cuttings taken off in the usual way and put into a propagating-box or handlight.

Ixoras.—These, too, may be propagated now, if cuttings are available, striking them singly in small pots in a bottom-heat of about 80°. Any old plants intended to be brought into flower six months hence should be pruned into shape, cleansed thoroughly, and afforded for a few weeks a somewhat drier atmosphere and less water at the root than they require when in full growth. Too much importance can hardly be laid on keeping the plants free from insect pests, which are the cause of much injury.

Gardenias.—A careful watch should be kept on any plants now showing buds for the shoots which show immediately round each bud, which must be removed, for if this be not done, the flower-buds will probably succumb, and the plants will grow on and form a later and probably less useful set of flower-buds. Plants in bud may be afforded manure-water occasionally, and plenty of sunlight and bottom-heat, the latter being very essential to plants flowering in winter.

Carnations.—The propagation of winter-flowering Carnations must go on as rapidly as suitable shoots are formed, the actual time of propagation not being so essential as the proper sort of cuttings, which should be small side-shoots some 3 inches long. They may be struck singly in small pots, or several placed round the sides of larger ones; shallow boxes, too, may be used for the purpose, if the plants are to be grown in quantity. The main point to observe is that there shall be a good bottom-heat in the bed—80° to 85°—on which the pots and boxes are to be stood or plunged, and a much lower overhead temperature, so that roots may form while the tops are at a standstill. Some gardeners advocate striking the cuttings two months hence in preference to the present time, but my experience is that we cannot get the plants as big as they should be if we propagate late, and this must be left to growers more favourably situated as to climate.

Forcing Plants.—Most of these can now be forced easily, the more difficult part of the season being over. Shrubby plants, such as Azaleas, Deutzias, Staphyleas, Lilacs, Gueldres Roses, &c., should be put in an intermediate temperature at first, and be well and frequently syringed with tepid water. A fermenting bed of leaves will be a great help to them. In forcing future batches of Lily of

the Valley, ordinary crowns should be substituted for the retarded crowns, so useful at an earlier date.

THE HARDY FRUIT GARDEN.

By J. MAYNE, Gardener to the Hon. MARK ROLLE, Bickton, East Budleigh, Devonshire.

Fruit-tree Planting.—Although details for this operation were rightly given in these pages early in November last, circumstances may have prevented the cultivator from carrying them out. Should such be the case, the work may still be performed providing the weather is not wet or frosty, deferring the necessary pruning of such trees for some weeks. Opinions vary as to the usefulness or otherwise of mulching newly-planted fruit-trees, and while favouring this practice, especially in districts where severe frosts are experienced, I think this is often carried to extremes. A mulch of strawy manure, 2 to 3 inches in thickness, placed over the soil as soon as the trees are planted cannot but be of some service where the roots have recently been curtailed, and they are unable in consequence to seize upon the soil before all growth is checked. This mulch should be removed as soon as severe frosts are past for the season, and the soil lightly broken up with the fork to the depth of 3 inches, so that sun and air may act upon it.

Pruning Orchard Trees.—Even now, after much advice given for years by the County Council horticultural experts, pruning is sadly neglected in this county, but surely fruits finer, better quality, and colour, are obtainable when the sun can shine into the crowns. In pruning neglected trees, the crown should be kept fairly open, and branches which cross each other removed entirely, not perhaps all at once, but in the course of two or three years. All dead wood should also be cut out; cuts on living branches, if made with a saw, should have the surface smoothed with a knife or chisel, and if large then painted over with Stockholm tar. Some varieties are prone to push up a quantity of shoots from the centre, which should be shortened to the second or third bud, or entirely removed, otherwise a crowded head will result. Should there be much moss or lichen on the bark, scrape it with a painter's knife, using care in so doing not to injure the bark; then follow this with a bast scrubbing-brush, and lastly, painting the same with a mixture of soot and lime that has been passed through a fine-meshed sieve, and syringe the mixture on to the smaller branches, choosing a fine, calm day for the job. Trees that are to be grafted with other varieties may have their limbs sawn off at points a few inches higher than those at which the grafts will be inserted later on. Be sure that such trees are free from canker, and are vigorous in growth. Shoots for making scions should now be secured, selecting them from healthy young trees, and taking, whenever possible, those of the previous year's growth. Tie these in bundles of about a dozen, fasten a label with the correct name on each, and lay them in 3 inches deep in the soil on the north side of a wall.

THE FLOWER GARDEN.

By R. DAVIDSON, Gardener to EARL CADOGAN, Culford Gardens, Bury St. Edmunds.

Early-flowering Shrubs.—Plants of *Chimonanthus fragrans grandiflora* on walls are now opening their deliciously fragrant flowers, and during severe weather some protection must be afforded, in order to prevent injury to the blooms by frost and cold winds. The same care should be extended to *Jasminum nudiflorum*, for where cut flowers are in much request, the golden masses of bloom of this plant when in good condition are much appreciated. The plants of *Lonicera fragrantissima* growing against a south or other warm wall, are likewise developing their sweet-scented flowers, and the necessary protection of these will, later on, well repay the gardener.

Summer-bedding Plants.—Where varieties of bedding Pelargoniums, Marguerites, Gazanias,

&c., have been wintered in cold frames, let them be forthwith removed to a Peach-house or vinery in which forcing has begun, and where the plants may gradually begin to grow. A careful estimate should be made of the different kinds and varieties of plants employed in bedding, so that a sufficient number of each may be obtained. Lobelias, Alternantheras, and Iresines should have considerable care bestowed on them, and they should not at any time be allowed to get dry or excessively moist at the root, this being very detrimental, Lobelias especially being kept, if anything, rather on the dry side, and in a position near to the glass, in a house having a temperature of 55°. Alternantheras and Iresines are the better for a temperature of 65° to 68°, and in sunny positions quite near to the glass.

Hints on Work in General.—In the pleasure-grounds something may be done at the present time in cutting off and collecting all dead branches that are conspicuously unsightly on Laurels, Hollies, Aucubas, Yews, &c., and if any of the trees are lacking symmetry, this may be remedied by regulating the branches, and fastening them with strong tar-twine or galvanised wire where the necessity exists. Do not, in doing this, bend or strain the branches unduly, or the results may be disastrous. Sweep up tree-leaves that may have got blown on to the paths and the margins of shrubberies and borders. Where alterations are in prospective, such as the extending or widening of the garden paths, materials should be obtained so that the work once begun can be rapidly completed. An ordinary path intended for pedestrians or light wheel traffic, need not be more than 18 inches deep, and in dry soils 9 inches is sufficient. The excavation may be filled with brick-bats, chalk, rough stones, &c., to within 4 inches of the surface, and the remainder completed with suitable gravel as soon as practicable after the return of mild weather. Where existing borders of trees and shrubs are to be made larger, the additional ground should be manured and trenched, and allowed to settle before the trees and shrubs are planted. Recently-planted clumps of herbaceous perennial plants should have sufficient mulching material placed over or round about them as will protect from frost, especially *Eremurus robustus* and *hyalaicus*, *Incarvillea Delavayi*, *Anthericum*, and *Paeonies*.

THE KITCHEN GARDEN.

By T. TURTON, Gr. to J. K. D. WINGFIELD DIGBY, Esq., Sherborne Castle, Dorset.

Ordering Seeds.—What gardener at one time or another has not experienced a drawback by not having received his seeds in time to take advantage of the ground being in the right condition for sowing for early crops? I cannot, therefore, urge too strongly the procrastinating gardener to send his order to the seedsman with as little delay as possible, for although at the date of writing prospects of seed sowing in the open ground cannot be thought about; directly the days begin to lengthen, and if only a short spell of open fine weather prevail, much advantage may be gained by sowing seeds, which I shall mention in future calendars.

Order of Cropping.—If not absolutely necessary to insure success with the various crops, it is at least a great assistance to any gardener with many other matters upon his mind to have a fixed rotation for the several quarters into which the majority of kitchen gardens are divided, but more especially for the principal crops, chief amongst which are Peas. For early Peas, the most suitable place is a south border, and where two such borders in a garden can be set apart, as here, it is my practice to plant in alternate years with early Potatoes. When for early Peas, the border is deeply trenched, placing a good dressing of rotten dung at the bottom of the trenches, and the following season a good dressing of well-rotted dung is simply deeply dug in for the early Potatoes. The main crop of Peas is sown where the Celery has been grown, and exactly over the trenches, without any further

preparation of the land beyond levelling it, marking the Celery trenches previous to so doing. Savoys, winter Turnips, &c., follow the Peas. After the above-named crops are cleared off, part of the quarter is heavily manured and trenched for Onions, the other portion being simply dug over for the various root crops. The earliest-sown Cabbage follows the Onions in the autumn, and when the roots are all cleared off, the remaining portion of the quarter receives a good dressing of well-rotted dung, and is then bastard-trenched, and planted with an early kind of Cabbage, which succeeds the autumn-planted ones, the stumps being always cleared off as the heads are cut, and the whole quarter planted with Brussels Sprouts.

THE ORCHID HOUSES.

By W. P. BOUND, Gardener to J. COLMAN, Esq., Gatton Park, Reigate.

Temperatures in the various houses.—Temperature is a most important factor in the successful cultivation of Orchids, and at no time of the year is a greater amount of discretion needed than the present, in order to keep the plants in a healthy state. The outside thermometer must be carefully watched, as, for example, a temperature, say, in the Cattleya-house one day of 68° or 70° would be quite right, but a similar degree of warmth the next day would be quite wrong. I consider that any hard-and-fast rule by which the temperature of a house should always be of this or that degree at any given time of a day, is unsuited to the requirements of the plants. In order to maintain as near as possible the ideal temperature of an Orchid-house, one must be entirely governed by the outside temperature. On all occasions let some air in by the lower ventilators, and this should never be taken off entirely unless the wind is very cold, or there is severe frost. For the present, the temperatures may run as follows, taking the reading of the outside thermometer at night 40°; in the morning 36°; and at noon 50°:—

| | Night. | Morning. | Noon. |
|----------------------|--------|----------|-------|
| Stove Orchid-house, | 68° | 65° | 72° |
| Cattleya-house, | 63° | 60° | 68° |
| Intermediate-house, | 60° | 57° | 65° |
| Odontoglossum-house, | 52° | 50° | 55° |

During severe frosty weather the temperatures should be reduced about 5° all round, and the plants and houses kept on the dry side. I strongly advise at such times the use of the roof blinds and the covering of the side lights in order to curtail as much as possible the use of fire-heat, and thus do no harm to the plants.

Miltonias.—Most of the autumn-flowering varieties, viz., *M. Clowesii*, *M. candida spectabilis*, *M. Regnelli* and the hybrids of these species, *M. leucoglossa*, *M. Binotii*, *M. Bluntii*, *M. Joiceyana* and others, are now pushing out their new growths and roots; if re-potting or top-dressing be necessary, this is a very suitable season for carrying out such work. Do not pot or disturb them till they are ready, then the young roots will take hold of the new compost before it can become soured. The compost may consist of turfy peat $\frac{2}{3}$ well chopped to pieces, and chopped sphagnum-moss $\frac{1}{3}$; the whole being well mixed together. I prefer to use bracken-roots taken out of the peat as drainage material, chopping them up a little so as to get them down to the bottoms of the pots without having to squeeze them much. The pots should be half filled with bracken-roots, and the potting done rather firmly, keeping the base of the plant a little below the level of the rim of the pot. I do not advise re-potting being carried out unless the plant really needs it; and if the plants were well potted last year, surfacing will be sufficient. I advise surfacing them so that the young roots that are thrown out with the young growth can at once find fresh compost of which to take hold. After potting, afford water very carefully, affording it only when the compost is dry, until the roots have seized upon the new compost and the young growth more advanced; afterwards water may be freely applied. Let the pots be damped at

the sides, this being of great benefit at this season, and as soon as the days get longer and we have more sunshine they are greatly benefited by over-head syringing, and if the house is properly ventilated no one need be afraid of using the syringe freely overhead.

FRUITS UNDER GLASS.

By JAMES WHYTECK, Gardener to the DUKE OF BUCCLEUCH, Dalkeith.

Pot Vines.—Where very early crops of Grapes are desired, forcing Vines in pots is the best and most economical method. Excellent instructions have been given in quite recent numbers of this Journal for the preparation and starting of these Vines, and they are now in active growth. The present season is not favourable for early forcing, as there has been little sun and much fire-heat that has had to be employed. If the Vines are plunged in a bed of warm leaves, it will be very helpful to growth. Avoid very hot pipes on cold nights; a mean temperature of 60° will do for Hamburgs, and even less on a very cold night. As they approach flowering, and weather permits, give a mean temperature of 65°, rising 10° in the daytime, or more with sunshine; and where no provision is made to warm the admitted air in cold weather, the ventilation must be arranged very carefully in the forenoon, conserving sun-heat soon after midday so as to run the warmth up to 80° or higher. Stop syringing when the Vines are in flower, but avoid a dry, arid atmosphere by damping the paths frequently; and if the Vines were top-dressed before starting with vine-manure and fresh soil, give the roots clear warm water as they require it till the fruit is formed and swelling, when weak and frequent warm manure waterings may be given. Early forced planted-out Vines that were forced early in the previous year, and started at the beginning of last month, will now be making growth. If a bed of leaves mixed with a very little stable-dung is put inside the house, and turned over occasionally, it will hasten a natural, healthy growth; and with medium fire-heat, the houses should be kept about 60° at night. It may be 2° or 3° less on very cold nights rather than have excessive fire-heat. When they flower, raise the temperature if possible to 65° at night, and 10° to 15° higher in the day, according to the weather. Try to change the air daily in the forenoon. Do not be in a hurry to disbud and tie down the shoots, but wait to see which shoots promise best for fruit. If any shoots press against the glass, bring them slightly away from it, and day by day gradually bring them down to their proper place. The overcrowding of Vine-roots and laterals is a mistake. The rods may be 4 feet apart; the laterals should extend two or three joints beyond the bunch. Encourage all the growth possible on early forced Vines. Remove surplus bunches, reserving the best, but avoid over-cropping. If the border was top-dressed with vine-manure at starting, warm water afforded when the Grapes are set will be sufficient at the present. The next vinery, to yield Grapes in June, should be started at the beginning of the present month. The house having previously been thoroughly washed down, the Vines should be cleared of loose bark, and washed thoroughly as advised in a former number. If the border is dry, it should be well soaked with warm water. If the Vine-roots in the border are right, they will be a close network on the surface, and only the merest loose surface need be removed, after which apply a good sprinkling of bone-meal, and the same of Thomson's vine-manure; on the top of that put 2 inches of finely-cropped fresh soil, finishing with a dressing of short horse-manure. The outside border is better for being covered with a foot of leaves thatched with straw. The night temperature, according to the weather, may be kept at 50° to 55°. 10° to 15° higher in the day, till the buds begin to break. Syringe daily more or less, according to the weather. Avoid keeping the Vines constantly wet; damp occasionally by day to counteract aridity from fire-heat.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be WRITTEN ON ONE SIDE ONLY OF THE PAPER, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

SALES FOR THE WEEK.

MONDAY, JAN. 6.—Perennials, Bulbs, &c., by Protheroe & Morris, at noon.
TUESDAY, JAN. 7.—Bulbs, &c., by Rendell & Searle, 12.30.—Orchids and Stove Plants, Beechen Cliff Villa, Bath, by Fry & Asprey, and on Jan 8.
WEDNESDAY, JAN. 8.—Lilies, Shrubs, &c., by Protheroe & Morris, at 12.—Bulbs, Palms, Shrubs, &c., at Stevens' Rooms, 12.30, Lilies at 2.30.
THURSDAY, JAN. 9.—Blackberries, Bulbs, &c., by Protheroe & Morris, at noon, Orchids at 12.30.—Bulbs, &c., and on Friday, Rendell & Searle.

TENDERS.

Purchase of Turf, Tooting, London County Council, Spring Gardens, S.W.
(For further particulars see Advertisement columns.)

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three Years at Chiswick—36° 3'.

ACTUAL TEMPERATURES:—

LONDON.—January 1 (6 P.M.): Max. 54°; Min. 48°.
January 2.—Fine; mild; moist.

PROVINCES.—January 1 (6 P.M.): Max. 53°, S.W. Ireland: Min. 35°, Shetlands.

OUR American cousins are now much exercised in their minds as to what flower they shall adopt as a national badge. The discussions have been long and varied. Even now, no conclusion has been definitely arrived at. The same question has turned up here in connection with the Coronation ceremony next June. We should not have thought that there was room for any dispute on the subject. The Rose has been for centuries so entwined with our history that we should have supposed no other flower could have been budded on a British stock. The Rose is said to have been the badge of EDWARD I. in the thirteenth century; in 1397 JOHN OF GAUNT bequeathed to the altar in St. Paul's his coverlet of cloth of gold sprinkled with golden Roses. We had thought it possible that on one or more of the numerous shields on the tombs of the BLACK PRINCE and of HENRY IV. in the Cathedral at Canterbury, a conventional representation of the Rose might have been found. Through the courtesy of the Dean, we are enabled to say that this conjecture is erroneous, and that neither on the tomb of the BLACK PRINCE, nor on his hauberk still preserved in the Cathedral, is there any representation of a Rose. Its connection with the houses of Lancaster and of York is, of course, known to all of us, and was forcibly recalled to mind last summer when a Rose show was held in the historic Temple Gardens. In Tudor times the Rose was constantly used as an architectural adornment, and may still be seen at Westminster, and many a similar fane.

From this point of view it is interesting to quote what EVELYN, writing in 1679, says: "For even the very Damask Rose itself, as my Lord BACON tells us, Cent. 2, Exp. 659, is little more than an hundred years old in

England." Compare this with what is said by PARKINSON, writing, in 1629. PARKINSON mentions thirty sorts in his garden, everyone notably differing from the other.

But when the Rose was adopted as a national emblem, Canada, Australia, Tasmania, and New Zealand had not been discovered; and—except in Canada—there is not a native Rose in either colony; nor is there in any part of South Africa, the West Indies, Mauritius, or Ceylon. Half the British Empire then has no Rose unless by introduction.

When we get a federated Greater Britain, it is clear we shall have some difficulty in fixing upon a flower that is common to all the component elements. This being the case, it will be best to disregard points of geographical distribution as pedantic in the circumstances, and to fall back on the old

The Red Rose on the back is plac'd
Thereon a crown of gold;
The White Rose on the breast is brave
And costly to behold;
Bedeck'd most rich with silver studs
On coat of scarlet red;
A blushing hue, which England's fame
Now many a year hath bred."

The warders of the Tower still wear tunics embroidered in the manner here described.

But in spite of the claims of long descent on the part of the Rose, a claim is set up in some quarters for the Iris, which some say is the Fleur-de-Lys. Unfortunately for this contention, it is not yet settled whether the device is really intended to represent an Iris, a Lily, or a spear-head!

Again, Fleur de Louis is considered to have been the original name, and this has been converted into Fleur de Luce, Fleur de

FIG. 4.—BASAL PORTION OF THE GREAT CEDAR AT ADDINGTON PARK.

(See p. 10, and our Supplementary Illustration. From photographs by J. Gregory.)

heraldic, conventional Rose as the floral badge for the whole empire.

The Hon. Mrs. BOYLE, in her charming *Ros rosarum*—*Dew of the Ever-living Rose*, cites from an old ballad some lines, which are so appropriate to the occasion, that no apology need be offered for quoting them. Alluding to the White Rose of York and the Red Rose of Lancaster, the ballad proceeds:

"These Roses sprang and budded fair,
And carry'd such a grace,
That Kings of England in their arms
Afford them worthy place.
And flourish may these Roses long,
That all the world may tell
How owners of these princely flow'rs
In virtues did excel.

To glorify these Roses more,
King Henry and his Queen
First placed their pictures in wrought gold
Most gorgeous to be seen.
The King's own guard now wear the same
Upon their back and breast,
Where love and loyalty remain,
And evermore shall rest.

Lys, and Fleur de Lis. PRIOR, in his *Popular Names of British Plants*, mentions the legend that a shield charged with these flowers was brought to CLOVIS from heaven while engaged in battle against the Saracens. They were assumed by LOUIS VII. in 1137 as his device, and later on they were bestowed on JOAN OF ARC.

No doubt several of our monarchs did quarter the Fleur-de-Lys on their coats of arms as a testimony of their rights in France, rights now happily long become obsolete, and consequently also the claim to quarter the Fleur-de-Lys.

Another claimant put forward for heraldic recognition is the Lily - of - the - Valley, a native plant of unsurpassed elegance and delicious fragrance, but having no claim whatever to be accepted as a national emblem. Much historical interest attaches to the Rose and to the Fleur-de-Lys, but the Lily-of-the-Valley is totally devoid of any such relation. What the "Lily-of-the-Valleys" of the Canticles may have been we do not know, but we may be pretty sure it

was not what we call the Lily-of-the-Valley, which is not a native of Palestine.

The Christmas Rose puts forth no claim to historical significance, but its lovely flowers, expanding at this season, are so beautiful, that they confer a right to the popular name Rose, although botanically they have nothing to do with the genuine Rose.

Whatever flowers be adopted for merely decorative purposes at the Coronation, we plead that as a matter of ceremonial usage, no other than the Rose of England be adopted.

ROYAL HORTICULTURAL SOCIETY.—The first meeting of the Committees of the Royal Horticultural Society in 1902 will be held as usual in the Drill Hall, Buckingham Gate, Westminster, on Tuesday, January 14. An election of new Fellows will take place at 3 o'clock. To prevent misunderstanding, it may be mentioned that the committees of 1901 do not vacate office until the date of the annual meeting, 1902, and in like manner all Fellows' tickets of 1901 are available until the end of January, 1902.

NEW CHRYSANTHEMUMS.—We have received from Messrs. W. WELLS & Co., Earlswood Nurseries, Redhill, Surrey, a sheet containing illustrations of novelties for next season. Most of them are about 6 inches by 5 inches, and are large enough to afford some idea at least of the general character of each flower. Although the sheet will probably be distributed with a descriptive catalogue, it would have been convenient if the colour, as well as the name, of each variety had been given upon the sheet itself.

M. FERD. MASSANGE DE LOUVREX.—We regret to learn, from the *Revue de l'Horticulture Belge*, of the death of this gentleman, who was a keen horticulturist, and a well known cultivator of Orchids.

LILIES.—Mr. BARR, who is now in South Africa, or was when we last heard of him, has been discoursing on Lilies. To illustrate the reading, a fine group of *Lilium longiflorum* eximium was placed in front of the chairman, to show the one Lily of the world which represents the greatest amount of circulating capital. It is estimated that Bermuda exports from £15,000 to £20,000 worth of bulbs annually of these Lilies to New York and London; Japan exports about the same amount of money, and as these Lilies are thrown away by nurserymen after they have sold the flowers, instead of a decrease in the demand, it has been annually increasing, since its value as a cut flower and for forcing was discovered in 1882. The flats around Cape Town could be profitably used for the production of this Lily, and an industry started which would add a nice little item to the profitable exports of the colony.

M. DÉSIRE BRUNEAU.—The death is announced of this well-known nurseryman, who yearly obtained the highest awards at the Paris exhibitions. M. DE BRUNEAU was seventy-four years of age, and last year retired from business, leaving his large nurseries at Bourglaine-Reine, near Paris, to his son-in-law, M. NOMBLET BRUNEAU.

PRESENTATION AT EXETER.—At the Castle Hotel, Exeter, on Saturday evening, Mr. F. W. MEYER, landscape gardener with the firm of Messrs. ROBERT VEITCH & SON, of the Royal Nurseries, Exeter, entertained his fellow employees to supper to celebrate the completion of twenty-five years' service. His colleagues took the opportunity of presenting

Mr. MEYER with a handsome silver-mounted smoker's cabinet and outfit and an address of congratulation on their behalf, subscribed to by thirty-six members of the staff. Mr. VEITCH sent a handsome silver salver with a cheque and a letter, in which he expressed his appreciation of the services of Mr. MEYER and the efficiency with which he had fulfilled his duties as professional landscape gardener to the firm during these years.

LIST OF SOME PLANTS IN FLOWER IN THE OPEN AT CHRISTMAS, 1901, AT LA MORTOLA.—Sir THOMAS HANBURY, K.C.V.O., sends us the following list of some of the more remarkable plants in flower at La Mortola this Christmas. It appears there has been no frost as yet this winter in that favoured locality; and while in many parts of England distressing droughts have prevailed, the year 1901 there has proved one of the wettest on record, no less than 46·4 inches of rain having fallen, or about double the average—of this, 15 inches fell in the month of October.

| | |
|-----------------------|--------------------------|
| Acacia Farnesiana | Grevillea alpina |
| A. salicina, &c. | G. longifolia |
| Albizzia lophantha | Hakea eucalyptoides |
| Aloe ciliaris | H. pugioniformis |
| A. socotrina | H. suaveolens |
| Amicia zygomeris | Hexacentris coccinea |
| Anagryis fetida | Huernia aspera |
| Anthocereis viscosa | H. Penzigi |
| Banksia marcescens | Linum trigynum |
| B. verticillata | Lotus Jacobæus |
| Brassica rupestris | Melanthus Trimenianus |
| Bryophyllum crenatum | Odontospermum sericeum |
| Buddleia americana | Passiflora racemosa |
| Canarina campanulata | Pilocarpus pinnatifolius |
| Caralluma europæa | Rosa sinica |
| C. maroccana | Royena pubescens |
| Cassia coquimbensis | Senecio angulatus |

| Ephedra altissima | Yucca gloriosa |
| Gerbera Jamesoni | |

MEETING OF THE FRENCH POMOLOGICAL SOCIETY.—The French Pomological Society lately held a meeting for the election of a President to succeed the late M. DE LA BASTIE, and various other new members. M. LUIZET was elected President, M. JACQUIER, fils, and M. TREVE, père, were elected Vice-Presidents. The nomination of a Secretary was postponed until the next meeting, which will be held at Pau; M. J. NICHOLAS discharges the duties in the interim. M. DE VEYSSIERE is made Treasurer. The late President, M. DE LA BASTIE, has bequeathed to the Society all his manuscripts, part of his library, and two thousand francs.

THE BATTLE OF ROSES.—Mr. WM. BAYLOR HARTLAND, of Patrick Street and Ard Cairn, Cork, sends his friends and clients a charming picture of a playful Battle of Roses between two pretty maidens under a sunny sky. The picture, which is nicely coloured, is mounted on rollers all ready to be hung up, and some appropriate verses by Mrs. HEMANS are appended to it as well as the patriotic sentiment that: "This Green Isle of ours will yet win its way and put its goods over the wide world by Industry."

CYPRIPEDIUMS IN SEASON.—A very fine set of *Cypripedium* flowers has been kindly sent for our inspection by O. O. WRIGLEY, Esq., Bridge Hall, Bury (gr., Mr. E. ROGERS), and in which a very high state of cultivation is indicated, for in each case we have never seen the flowers of the varieties represented so fine. *Cypripedium* × *Swinburnei* magnificum is a gigantic, heavily-blotched flower; *C. insigne* macranthum equals the stately *C. i.*

Harcfield Hall variety, and somewhat resembles it; *C. i.* Marion has the blotching in the upper sepal of a light purplish-brown, the spots being merged; *C. i.* Dorothy and *C. i.* Luciani are two fine clear yellow varieties, the latter the brighter and better; *C. × nitens* superbum and *C. × J.* Howes have fine dorsal sepals, with purple spotting on the white upper half; *C. × Calypso*, Oakwood variety, has the upper sepal white, heavily marked with purple; *C. × Lecanum* superbissimum, giganteum, conspicuum, Cypher's variety, and aureum giganteum show a very wide range in this fine hybrid, and afford ample excuse for their distinguishing names. The others are *C. × Manselli* (Chamberlainianum × villosum), a very singular-looking hybrid, with greenish flowers, tinged and striped with purple-brown; and *C. × Fascinator* (Spicerianum magnificum × hirsutissimum), the twisted, purple-tinged, densely-spotted petals of which very closely resemble those of *C. hirsutissimum*; the dorsal sepal, however, more nearly resembles *C. Spicerianum*, being white, with a broad purple-coloured band running up the centre, and a rose-purple tint on each side.

OXTON HALL.—We understand that in consequence of the death of the elder Miss HARRIS, the Oxtan Hall estate, near Tadcaster, has changed hands. Mr. CROFT, the head gardener, has retired on an annuity, after serving the Misses HARRIS and their parents for the long period of forty-five years. He is succeeded by Mr. T. MARSH, who for a good many years has been second gardener at Oxtan. The new owner of Oxtan is Mrs. OLIVER, of Bolton Lodge, near Bolton Percy, Yorks, a lady who takes much interest in horticulture generally.

XANTHORRHEA HASTILIS.—The "spear-headed, grass gum" tree of Australia is throwing up a strong flower-spike in the Trinity College Botanic Garden, Dublin. The same plant flowered before prior to 1879, and the old flower-spike is still kept—dried, of course. These tree sedges are not very common in gardens, both seedlings and old imported plants being difficult to establish.

CHRYSANTHEMUM SALAD.—At the meeting of the French Society of Chrysanthemum growers at Grenoble some large flower-heads of Madame Carnot were prepared as salad. Some approved, some disapproved, others said they were not so very bad. In any case, we gather that the experiment is not likely to be repeated.

HOW M. CALVAT BECAME A CHRYSANTHEMUM GROWER.—There is a tendency towards self-disparagement amongst us Britons. This arises from the progress made in Germany, the United States, and other countries which have distanced us in the applications of science, and in consequence threaten our commercial supremacy. It is pleasant therefore to read in *Le Chrysanthème* that M. CALVAT's success as a Chrysanthemum raiser is directly attributable to the treatise of Mr. E. MOLYNEUX, which he purchased, and of which, being able to read English, he knew how to avail himself. If M. CALVAT had not known English, he would not have read MOLYNEUX. If he had not read MOLYNEUX, he would not have enriched horticulture with so many fine varieties—the moral is obvious.

ROSE MRS. AMES.—As we stated in our last issue, we received from the United States a dozen blooms of this new Rose. They were brought over by Mr. DIMMICK in a case; the stalk of each Rose being inserted in a small pial of water, so packed that the water did not run out, nor the bottle become

broken. They arrived on the 23rd ult. in excellent condition. We noted this the more particularly as some that were sent over on a previous occasion fell to pieces as soon as the case was unpacked. One or two of the outer petals which had been bruised, and were browned, were removed, and the next morning we had on our table a bunch of Roses as fresh as if the month had been July, instead of December. The flowers had slightly expanded and showed to advantage, their central pink petals almost of the colour of those of "Blairii n. 2." Still, we expected the petals to fall; still they remained intact, so much so that some thought the flowers had been gummed, but that was clearly not so. On the 29th ult. they were voted no longer suitable for the drawing-room, though even then they had not cast a petal. The Roses were cut with long stalks, and the foliage was solid and dark rich green, so that the flowers had a supply of nourishment at their disposal, and this may have accounted for their persistence.

PUBLICATIONS RECEIVED.—*Nature Notes*, Dec.—*West Indian Bulletin*, vol. ii., No. 3. Contents: Cacao, Thrips and Fungoid Diseases; Sugar-cane, Disease, Bud-variation, Manuring, Planting, and Crop Seasons; Formation of Sugar; Sour Grass; Insectivorous Birds. —*Principal Government Crop Report, Nova Scotia*, Nov., 1901. "The season was unusually early, and up to the first week in July the weather was favourable for the growth of all kinds of crops, but a drought set in about that time, and retarded the growth of all kinds of crops except hay. The hay crop in Cape Breton fell short, and had the effect of reducing the production in the whole province to an average one. All other field crops are under the average. The fruit crop varied to a considerable extent, but taking it as a whole it has been fairly large, and the quality excellent."—*Journal of the Kew Guild*.—*Profitable Fruit-growing*, by John Wright (Collingridge).—*A Study of San Luis Obispo*.—From the Department of Agriculture and Technical Instruction for Ireland: *Agricultural Statistics, Ireland*, 1901. *Report on Irish Migratory Labourers*; also, *Journal of the Department*, December, 1901. Contents: Early Potato Growing; "Field Experiments," and "Demonstration Plots," Art-craft Classes at the Glasgow School of Art, Use and Purchase of Manures, Canadian Store Cattle, Trade Notes and Memoranda.—Imperial Department of Agriculture for the West Indies: *General Treatment of Insect Pests* (second edition).—Jamaica Board of Agriculture: *A Report on the Cultivation of Pineapples and other Products of Florida*, by Robert Thomson. *Agricultural Bulletin of the Straits and Federated Malay States*, edited by H. N. Ridley. Contents: Timbers of the Malay Peninsula (continued), Treatment of Insect Pests, Elementary Notes on the Propagation of Plants, by C. Curtis, F.L.S.; Vitality of Seeds, Foxy Coffee, Diseased Roots of Para Rubber, &c.—*The Agricultural Gazette of New South Wales*, October. Among the contents are papers on: Millet, Hay, Useful Australian Plants, No. 73; *Deyouxia montana*, J. H. Maiden; Large Roots of Salt-bush, A Fodder Plant for the Arid Interior, Sand-drift at Newcastle, &c.—From the United States Department of Agriculture, Division of Entomology. *The Life-History of Two Species of Plant-Lice Inhabiting both the Witch-Hazel and Birch*, by Theo. Pergande.—Publications of the University of Pennsylvania, New Series, No. 6: *Contributions from the Botanical Laboratory*, vol. ii., No. 2.—*Observations sur les Apocynacées à Latex*, recueillies par M. L. Gentil, dans l'Etat Indépendant du Congo en 1900, par E. De Wildeman.—*Mitteilungen der Deutschen Dendrologischen Gesellschaft*, 1901.

A MAMMOTH CEDAR-TREE.

[SEE SUPPLEMENTARY ILLUSTRATION.]

THE Lebanon Cedar (*Cedrus Libani*) which we illustrate this week (fig. 4), may certainly be described as one of the most remarkable trees in the country, and it would be most interesting if information was forthcoming as to the approximate date when the specimen was planted in the position that has supplied its needs so well. There is, however, nothing but conjecture, and after appealing to many persons connected with Addington Park estate, including the "oldest inhabitant," who is familiar with events which have happened during a period of nearly seventy years, the least indefinite statement is that "the tree has been planted considerably over 100 years."

There being no evidence as to its actual age, we shall content ourselves by affording some

particulars of the present condition and size of the tree, and leave to all who may visit Addington the fascinating task of evolving a theory of their own upon so interesting but dubious a matter.

We visited the little church at Addington, some 600 years old, and from effigies and memorial tablets contained there, it is evident that the Park Estate, previous to it being purchased many years ago by the Ecclesiastical Trustees, belonged to the "Leigh" family, who lived in the parish as early as the middle of the sixteenth century.

The present steward and gardener, Mr. W. Whalley, removed to Addington with Archbishop Tait from Fulham Palace thirty-three years ago. The late Archbishop Benson was the last ecclesiastic who resided here, and about four years ago the estate was sold by the trustees to F. A. English, Esq.

The house is a plain building of grey stone, and the Cedar stands upon the small lawn on the south-east of the building. The best view of the tree is naturally obtained from the south, whence our photograph was taken, growth being rather more vigorous, and the branches better clothed on that side. The spread of the branches from east to west (from right to left of the illustration) is 127 ft., thus affording a covered walk in a direct line of 42 yards. From north to south the spread is rather less, being 104 feet. The view of the area covered by the tree is very impressive, and there is a little more room than is necessary for an average man to walk upright beneath the branches, which are supported by forty-five props, many of them being distinctly shown in the photograph.

The illustration on p. 8 of the base of the tree shows the numerous branches which proceed from near to the ground-level. Two of these come from the ground-level itself, and a third is only 1 foot higher. One of these three divides again almost immediately. We put the tape around the bole immediately above the lower three branches, and it measured 23 feet 4 inches, and the limbs thus shut off measured, in one instance, 7 feet in circumference, and in the case of the forked one, 10 feet 4 inches. The tree has apparently lost one limb from the base on the N.E. side, the scar being covered with lead. Altogether, there are about one dozen main limbs, and four of these are more or less upright. Of the upright ones, three are in good condition, but the fourth has been broken off at some time at about 25 feet. This has been quite overgrown by other branches. The measurements we have given of the spread and girths of the branches were obtained by the tape, but the weather being very wet we could only estimate the height of the tree to be rather more than 50 feet.

No wonder that the Archbishops in their turn were proud to entertain their friends under the branches of this magnificent tree; and not their personal friends alone, but some of the poor from the East of London, who were invited to Addington each year, and were entertained under the same tree, several hundreds being able to sit beneath it at one time. The care of the present owner is to guard this valued link with the past from possible injury, and all upon the estate know their master's instruction that in case of snow falling, the first duty to be discharged is that of attending to the great Cedar, for the loss of a limb would be lamented more than that of a thousand pounds. The tree is in a vigorous condition at the present time, and shows no signs of decrepitude.

There are several other trees of importance at Addington. Two Cedars on the lawn near

to the fountain were planted about 1830. A splendid Tulip-tree (*Liriodendron tulipiferum*) was planted about the same date, and there is an excellent specimen of *Paulownia imperialis*. A very good tree of the Black Walnut (*Juglans nigra*) is said to have been raised from a seed of the great Hickory-tree at Fulham Palace, and is one of the best specimens that exist. There is a Maidenhair-tree (*Ginkgo biloba*) upon the lawn also, and a pinetum in the park. The specimens in the pinetum, however, especially the species of *Abies*, are not flourishing.

The forcing and plant-houses at Addington are very old, and there are two walled-in kitchen-gardens, which together with an orchard, make an area of about 7 acres. The present owner will probably restore the gardens and build new glasshouses when the restoration of the dwelling-house has been completed. For three years past there have been 100 men employed at this task, and the work is not yet finished. We may add for the benefit of arboriculturists who may like to visit Addington, that they should proceed to East Croydon Railway Station, and drive or walk the remaining 4 miles. Our illustrations are from photographs taken by Mr. J. Gregory, Croydon.

KEW NOTES.

THE following plants were in bloom in the greenhouse (No. 4) on the 26th ult., Bank Holiday. *Begonia Gloire de Lorraine* and its varieties, Turnford Hall and Caledonia; *B. semperflorens gigantea rosea*, *B. President Carnot*, *Jasminum nudiflorum*, *Aster rotundifolius* (*Agathæa cœlestis*), *Daphne odora* (indica), *Salvia splendens grandiflora*, *Freesias*, *Peristrophe speciosa*, a bushy little plant with purple flowers; hatches of *Cyclamen* and Chinese *Primulas*, including the stellate form of *Primula sinensis*; *Camellias* upon bushes planted out in the beds; a beautiful display of the attractive and fragrant *Luculia gratissima* upon a plant more than 6 feet high, planted in a bed, and bearing nearly fifty trusses of flowers; *Reinwardtia* (*Linum*) *trigyna*; varieties of *Erica* and *Epacris*; *Calceolaria Burbridgei*, which has flowers during the greater part of the year; *Centropogon Lucyanus* × *Cytisus fragrans*; Roman Hyacinths; *Rhododendron Illuminator*, and *R. Princess Alexandra*; *Tibouchina* (*Lasiandra*) *macrantha* (on roof); *Primula obconica*; the new flowering *Coleus*, *C. thyrsoides*, figured in our columns last year, with cobalt-blue flowers, a plant that should be obtained by all who have not yet this species; *Eupatorium odoratum*; *Eriostemon cuspidatus*; *Moschosma riparium*, a Labiate plant 2 to 3 feet high, bearing white flowers produced from the axils of the leaves; *Richardia* (*Calla*) *africana*; *Cestrum* (*Habrothamnus*) *aurantiacum* and *elegans*; *Acacia fragrans* variety, *A. platyptera*; *Tecoma Smithii*, a hybrid from *T. velutina* ♀ and *T. capensis* ♂, and figured in *Gardeners' Chronicle*, July 21, 1894; a *Bignoniaceae* plant with orange coloured flowers, very free, and lasting a considerable time—a capital greenhouse plant; *Chrysanthemums*; *Prunus japonica*, fl.-pl., a pretty hardy shrub, with long, slender shoots wreathed with small, pure white, double flowers, &c. There were also some well fruited Orange-trees (*Citrus aurantiacum*) in pots, *Solanum integrifolium*, and *Rivina humilis*. In the Cape and Begonia-houses were *Ruellia macrantha*, the beautifully veined *Acanthaceae* flower illustrated in these pages last week; *Jacobinia chrysostephana*, a species with orange-coloured flowers; *Eranthemum albiflorum*, and *E. An-*

dersoni. Eranthemums are very pretty plants for the stove or intermediate-house if flowered in pots of moderate size, and fresh stock be raised each spring from cuttings.

In the Water-Lily (*Victoria Regia*) house, the mammoth species of *Grammatophyllum* (*G. speciosa*) was in flower, but the spikes appear weak and injured. They will probably not grow more than 2½ feet in height, but in *Gardeners' Chronicle*, August 28, 1897, flowers were illustrated from a spike which was 7 feet high, the individual flowers being 5 inches across. The prevailing colour of the flowers is dull yellow, spotted with reddish-purple. An abnormal (male) flower produced at the base of a spike in Sir Trevor Lawrence's garden, and figured in the same issue of the *Gardeners' Chronicle*, was very handsome by reason of its profuse and rich spotting, but it had only four nearly equal segments, and no true lip. On the roof of the same house, a large plant of *Ipomœa Horsfalli* Briggsæ bore scores of bright carmine flowers, and made a

BOOK NOTICE.

THE JOURNAL OF THE ROYAL HORTICULTURAL SOCIETY.

THE December part has lately reached us, and we may say of it that it more than merits the commendations we have expressed on previous numbers. It opens with an account of decorative gardening in the London parks, by Colonel Wheatley. Then follow the abstracts of certain lectures given by Professor Henslow to the Chiswick students, in one of which the Professor attributes, to the recommendation of Prof. Daubeney, the glazing of the houses with green glass. We believe it was the late Robert Hunt who made the suggestion; but in any case, the green glass has been abandoned wherever practicable. Another lecture of great interest is that on the effect of London fog on plants, in which the valuable observations of Prof. F. W. Oliver, published in an exhaustive report in an earlier volume

a direct or even an indirect bearing on horticulture; but that abstracts relating to pure botany be omitted. Discussions on the chromosomes of *Larix leptolepis*, or on the "middle lamella," for instance, seem out of place in a horticultural journal. Again, in the "abstracts" it would be well to cite at first hand, or, at least, to note where necessary, the fact that a particular plant, or whatever it may be, has already been figured and described elsewhere, often more satisfactorily than in the publication to which reference is made.

The "common-place notes" by the secretary and superintendent are excellent. Amongst other things they suggest attempting a cross between *Anemone nemorosa* and *A. coronaria*. This would indeed be an interesting cross; may we be there to see it! Following these chatty and useful notes comes a descriptive record of the Gladioli and other plants grown for trial at Chiswick last summer, and then a very valuable report on Plums, important to all fruit-growers. Lastly come the reports of the various meetings of the several committees.

We should like, as we have said before, to see the irrelevant tail-pieces removed; or if that be considered undesirable, that some descriptive legend be attached to them, and that they be separated from the text by a "rule." The details of the flower-head of Composites on p. 457 have, like the other tail-pieces, nothing to do with the subject in hand, although they are not even separated from it by a "rule." Moreover, the so-called "seeds" are technically something more than seeds.

The other illustrations have, we think, without exception, appeared previously in the horticultural papers. So important a publication as the *Journal* might, now that the finances of the Society are in a flourishing condition, depend more upon its own resources.

But these are points of detail of very minor importance. What is of consequence is the fact that the Fellows of the Society get a high-class journal of excellent quality which, of itself, is of considerably greater monetary value than the average amount of their subscription. The labour of editing amid all the multifarious duties of the Secretary must be very considerable, but the work is thoroughly well done, and whilst it adds greatly to the position of the Society, it confers the highest credit on the Editor.

A NEW APPLE.

MR. C. ROSS, gardener to Captain Carstairs, Welford Park, Newbury, has raised several good Apples from crosses between the varieties Cox's Orange Pippin and Peasgood's Nonsuch, and one of these which was figured in the *Gardeners' Chronicle*, Sept. 30, 1899, p. 259, as Thomas Andrew Knight, but has since been re-named Charles Ross, promises to combine the excellent quality and flavour of the former variety with increased size and attractiveness from the showy but comparatively worthless Apple Peasgood's Nonsuch. The new Apple shown in fig. 5, and named "The Houblon," had the same parentage as Charles Ross. Fruits were shown at a meeting of the Royal Horticultural Society on the 17th ult., when an Award of Merit was recommended the novelty. The fruits were not larger than those of Cox's Orange Pippin, but were very highly coloured, especially on one side, the colour occasionally having the appearance of splashes. The eye is open, and set in a moderate-sized basin; stalk less than half an inch long, proceeding from an even, funnel-shaped cavity. The quality of the flesh is good.

FIG. 5.—APPLE "THE HOUBLON."

rich display of colour. This is an old stove climbing plant well worth recommendation.

In the Orchid-houses the varieties of *Calanthe* were making a good show, the colour of *C. Veitchi* being varied with those of several of the *C. vestita* and other hybrids. In addition were *Oncidium varicosum*, *Laelia anceps* var. *Barkeriana*, *Zygopetalum Mackaii*, *Epidendrum vitellinum*, *Dendrobium endocharis*, species of *Cypripedium*, including *C. Fitchianum*, a pretty and distinct flower, the prevailing colour green, with a little purple on the petals; *Cymbidium giganteum*, *Masdevallias*, *Odontoglossum Andersonianum*, and its variety *Ruckerianum*, *Lycaste Skinneri*, *Habenaria carnea*, *Sophranitis grandiflora*, &c.

From the above list it will be seen that in the greenhouse and the T-range alone there were very many interesting plants for the holiday-makers whose tastes led them to Kew, whilst in all the other houses and museums open to the public, much information could be obtained by those desirous of improving their horticultural knowledge.

PLANT PORTRAITS.

CYSTOPTERIS BULBIFERA.—*Meehans' Monthly*, Dec.
PITCAIRNIA MICHELIANA, Ed. André, sp. nov.—A new Mexican species, with pendent, linear leaves, and erect racemes of crimson flowers.—*Revue Horticole*, Dec. 16.

are summarised. A paper of special interest is that of the Rev. H. Ewbank on the *Oncocyclis* group of Irises, the proofs of which were corrected by the author only a few days before his death. A second paper on the same subject by Mr. John Hogg, of Haarlem, is divorced from the first by the interpolation of a representation of the leaf and flowers of some unnamed *Eucalyptus*.

But the chief value of this part consists in the full report of the Lily Exhibition and Conference at Chiswick last July. We need not do more than allude to this conference, as it was very fully reported in our own columns. But we may repeat that this conference again illustrated the fact that, of all the work done by the Society, none equals in permanent value the records of these conferences. After the Lily Conference comes a long paper on Vine-culture as exemplified at the Paris Exhibition by Sir James Blyth, which is the same paper that was read before the London Chamber of Commerce. Another very important paper is that by Mr. C. G. Wyatt on the origin and development of the Cactus *Dahlia*.

The notes on recent research are most useful, but it may not be irrelevant to suggest that these notes be confined to subjects having

BACTERIOSIS IN ORCHIDS.

On October 5 last, Mr. William Murray, gardener to Norman Cookson, Esq., Oakwood, Wylam, handed me a portion of a diseased plant of *Cattleya Mendeli*. Some of the pseudo-bulbs were black and soft, the youngest on the point of collapse, whilst others were yellowish-brown. The blackness was extending from the infected bulbs into the leaves from the base towards the point. The infected bulbs were full of a dark brown liquid, smelling something like Worcester-sauce. The liquid was in very large quantity, was distinctly alkaline, and was swarming with motile bacteria, amongst which were a few fungus-cells like those figured by Wahrlich in the *Botanische Zeitung*, July 16 and 23, 1886, and called by him *Fusisporium sporen* (?). The liquid also contained isolated empty cells in plenty, and the tissue of the bulb was reduced to epidermis, fibro-vascular bundles, and empty collapsed cells. After a very thorough examination, no wound through which the bulbs might have been infected was to be seen, though doubtless the plant is infected through wounds.

The next day, having no *Cattleyas* available for experiment, a bulb of *Odontoglossum grande* was stabbed by a needle which had been dipped in the brown juice from the infected *Cattleya* bulb; and at the same time drops of the fluid were placed on uninjured bulbs, leaves, and roots of another plant of the same species. The stabbed bulb immediately began rotting, and in a week was rotten throughout, but unchanged in colour; the uninjured portions were unaffected.

The ordinary methods of isolating the bacterium which causes the rot by means of plate cultures was used. Isolated colonies were obtained and transferred to tubes of nutrient gelatine, and after a month's work I was satisfied that I had isolated the bacillus of the rot. It liquefies the gelatine, forming a funnel-shaped growth, with at first a large bubble at the top; the growth, however, is limited to about $\frac{1}{4}$ -inch of the top, and a tube following the line of the stab. The organism grows very well in bouillon with peptone neutral to litmus.

From a pure culture in gelatine I have induced black rot in young *Cattleya* bulbs, and a rot which leaves the bulb unaltered in colour in bulbs of *Odontoglossum grande*, *O. crispum*, and *O. Pescatorei*. Old bulbs of *Cattleya* were not infected, probably because there is an accumulation of organic acids in such bulbs. Turnips, yellow and white; Potatoes, bulbs of *Lilium* (sp.), Hyacinth, Tulip, and *Narcissus* are not affected. Bulbs of *Epipendrum vitellinum* were rotted and blackened, those of *Miltonia spectabilis*, *Celoglyne cristata*, *Sophranitis grandiflora*, and *Oncidium Forbesii* were rotted, but the colour was unchanged. A young *Dendrobium* bulb succumbed to the bacillus, but an old one which was very acid was not affected; *Cypripedium insigne* also was unaffected. Leaves of *Odontoglossum crispum* were unaffected when the epidermis was unbroken, but rapidly succumbed when infected on a scratch. They are not darkened in colour, at least, in the early stage of infection. Always, so far as I have experimented, a strongly acid Orchid tissue is unattacked. The reaction of infected tissue is always alkaline.

I have followed the action microscopically in bulbs of *Odontoglossum*: the middle layer of the cell-walls is first attacked. By this means, the cells are entirely isolated, and one finds in the fluid the large, apparently empty, mucilage cells, the smaller cells loaded

with starch grains, or with a bundle of raphides in them. The protoplasm of the cells is attacked, and slowly disappears. The cell-walls become exceedingly thin, and I think that bacteria enter the cells, but of that I am not at all sure. In parts where the action has not extended strongly, the cell-walls appear swollen, and the splitting along the middle lamellæ is very evident.

The organism is a short motile bacillus whose flagella I have not yet succeeded in staining. I am still engaged in investigating the exact effects of this bacillus on the tissues of Orchids, and the nature of the products of its fermentative action. J. B. Gateshead.

THE APIARY.

BAR FRAMES.

In my last article I left off at the price of sections at 8d. each, and considering that the cost of the bees should only be about 5s. and the crate 3s. 6d., this is a very good return. I now come to the modern system of bee keeping, namely, keeping bees in bar frames, or what is known as the standard hives; by this is meant that all hives are made of one size, so far as depth and width go—it does not much matter what the length is; but a hive holding from 10 to 14 frames is best, as the smaller the hive the greater the heat, and for winter purposes this is proved to be the best. Now, as to the cost: a complete bar frame hive should not cost more than 12s. 6d. to 15s. 6d. complete, as this answers all purposes for honey-raising, and the cost of the bees, 5s., make a total of 17s. 6d., and in a good season three crates of sections, each crate containing twenty-one 1 lb. sections of honey can be raised, and reckoning this at 6d. each section, the bee-keeper more than covers his outlay.

It should always be borne in mind that bees require looking after just at the right time, and when all is going well they should be let alone. I mentioned just now about the hive being of standard size; this is important, as then the frames from one hive will fit another hive, so that you can strengthen your weak stock from a strong one. And another item of importance is, that should you at any time wish to dispose of them, you stand a much better chance of securing a good price than you would if your hives were all of different sizes. All beginners in bee-keeping should try and remember that it is far better to understand how to manage one or two hives properly than to undertake a large number all at once.

The most successful bee-keepers are generally those who study the practical part first. Another particular item, too, in bee-keeping is, that everything should be kept as clean as possible, and this applies most strictly to honey for market, for everything should be clean and up to the sample. It is well known now that no garden is complete without bees, because every gardener will agree that unless there are bees to inoculate the different blossoms, but little fruit would set. In conclusion, I would again recommend every beginner to get someone to give him a lesson, and be as simple as possible in all manipulations, and he will find that as the bees interest him, the better and more expert a bee-keeper he will become. Expert.

HOME CORRESPONDENCE.

RAILWAY SLEEPERS.—In answer to an enquiry, I may say that on the Canadian Pacific from the Atlantic Coast to the base of the Rocky Mountains, the ties are probably made of *Thuja occidentalis*, as in most of the lines

in the Northern United States. In the Rocky Mountain region traversed by the line, *Picea Engelmanni* yields the best timber. Towards the Pacific coast, the Douglas Fir and the Red Wood, *Sequoia sempervirens*, this last being universally used in the Arizona railways. In Oregon and Washington, Red Wood and Douglas Fir are used, and occasionally *Pinus ponderosa*. C. S. S.

VEGETABLES AND FARM PLANTS THRIVING IN SOUTH AFRICA.—In reply to Mr. Jas. Crabbe's enquiry concerning seeds of farm and garden plants in the eastern provinces of Cape Colony, I have much pleasure in giving that gentleman the desired information. Many of the garden vegetables are farmed; I therefore give but one list. I believe Runner Beans are a failure in Cape Colony, as I have never seen them grown or sown:—

| | |
|------------------------|--------------------------|
| Asparagus | Lucerne |
| Beet | Lentils |
| Beans (French) | Melons (sweet and water) |
| " (Broad) | Maize (Mealies) |
| Broccoli | Mangel-wurzel |
| Borecole | Millet (Kaffir Corn) |
| Brussels Sprouts | Onions |
| Barley | Oats |
| Cauliflower | Parsnips |
| Cabbage | Potatoes |
| Carrots | Peas |
| Clover | Parsley |
| Cucumbers | Radish |
| Celery | Rhubarb |
| Capsicums | Savoy |
| Egg-plant (Aubergines) | Seakale |
| Gourds and Vegetable- | Spinach |
| Marrows | Turnips |
| Herbs, all sorts | Tomatoes |
| Kohl Rabi | Wheat. |
| Lettuce | |
| Leeks | |

All the above pay for growing, some of them being very remunerative. W. Miles, late of South Africa.

— In reply to Mr. James Crabbe's enquiry in your last issue, I spent some sixteen months in South Africa with my yeomanry regiment. During that time we traversed parts of Cape Colony, Bechuanaland, Griqualand, Orange River Colony, and Transvaal, where I noticed with infinite pleasure how luxuriant and rapid was the growth of all imported Conifers and deciduous trees. The climate is admirably adapted to almost every form of vegetation, but the curse of the country is its locusts, which at certain seasons sweep over huge areas, leaving not a single green blade in their track. The absence of irrigation is also, of course, against success in some parts, but this can be overcome, as water may be found almost anywhere by boring. All the vegetables Mr. Crabbe enumerates should flourish exceedingly; indeed, I have seen most of them growing. Some common Gourds and Melons are indigenous to the Transvaal, and Maize is the staple crop of South Africa. Already large sums of money have been made by market-growers around Johannesburg, where high prices were given on the Rand for such vegetables as Mr. Crabbe names. I shall be happy to give Mr. Crabbe any further information in my power, if you will put me in communication with him. James Wm. Watt.

CABBAGE CLUBBING.—All experience goes to show that gas-lime, to be a successful destroyer of the club or slime fungus in the soil, or even of the maggot-club, must be spread over the ground early in the winter, left untouched a few weeks to become pulverised, then spread more thinly and dug in. But surely, no one of any experience would plant a successional crop of the Cabbage tribe in ground which had just previously carried a diseased Cabbage crop! But if all the contiguous ground alike is infested with club-fungus or maggot, then is it well to dress every vacant plot in the way advised; and if there be a breadth of young Cabbages close by, dress them with the lime in mid-winter, and after it has been exposed a few weeks, hoe or point it in. It has been said that it is the sulphur in the gas-lime which destroys the fungus. No doubt it does, but rather less as pure sulphur than as sulphuric-acid, hence the need of applying it so carefully. A. D.

CANTALOUPE MELONS.—In reference to your article on p. 465, I may state that I have grown a variety of Cantaloupe for the past three years, and have no difficulty in getting fruits that weigh 12 lb. each, with flavour equal to many of our English varieties. Unfortunately, my present employer objects to Melons of this size, preferring those of 2½ to 3 lb. each, and I have heard of others who make the same objection. Cantaloupe Melons make excellent jam when mixed with equal proportion of Apple, Keswick Codlin preferred. *Hy. Harris, Castle Gardens, Wenvoe, near Cardiff.*

RUST ON CHRYSANTHEMUMS.—A writer on p. 460 suggests that this is caused by artificial manure. The same suggestion was made, I well remember, in respect to the Potato-disease, and the doom of that vegetable was promised. I am of opinion that manure has little or nothing to do with the rust in Chrysanthemums; in fact, I hold a contrary opinion, and that a well-fed, vigorous-growing plant is not so liable to be attacked as is a weakly one. There are two periods in the growth of the plants when the disease generally breaks out. Growers look for its appearance, and generally first find it, on the bottom and almost exhausted leaves of a plant, say during the early part of September, when it (the plant) is finishing its growth. Another period for the appearance of the "rust" is soon after the cuttings are inserted, and before they grow away freely. They may be clean, apparently, when inserted, but shortly afterwards the disease is found in the soft, decaying foliage. Most growers know that if these leaves are removed, and the plant started into growth vigorously, there is little to fear until the end of the summer, as already mentioned. Almost my first experience of this disease was with a bed of early-flowering varieties, which had stood on the same ground two seasons; they were planted in rows, one row of each kind. The plants had no manure or water, and the ground was in poor condition. Early in August, when growth was finishing, a variety well known as "Flora" was so infested that the leaves and flowers, or what would have been flowers, were as brown as snuff. On each side the plants were affected, but had a green appearance. It was sufficient proof for me that manuring or high culture had nothing whatever to do with the disease, and it also proved that some varieties were much more liable to its attacks than others. With the Potatoes, the remedy was found in growing only these varieties which were not liable to disease, and the result is that crops were never heavier or Potatoes more plentiful. The same will occur with Chrysanthemums, only those varieties must be grown which will withstand the ravages of the "rust." Growers should make a note of these, and form their collections accordingly. Some varieties always show it first, and seem to encourage an outbreak; let these be avoided, to commence with. *W. J. Godfrey, Exmouth.*

—Doubtless very many readers of the note on above by A. J. Long, appearing in the *Gardeners' Chronicle*, p. 474, Dec. 28, will, with a sigh, perhaps, wish they could believe the writer to be a true prophet. He says, "but I think the disease is rapidly dying out." This is not my experience of it. That some localities will be subject to its ravages more than others, also that some seasons will favour the disease more than others, I have no doubt whatever; but that it is "dying out" I doubt very much, and gardeners should be lulled into no fools' paradise by any such belief. Anyone who has studied the habits of these micro-fungus pests, and knows the vitality of their resting spores, will not be so sanguine as the writer. I am sure that artificial manures do not cause the rust—I am as sure as A. J. L.; but that plants afforded high living, especially when nitrogenous manure is employed, are more susceptible to the attacks of these minute leaf diseases. Anyone who doubts this fact has only to take note of the ravages of *Phytophthora infestans* in Potatoes grown upon poor land, and in those

where the tops indicate a plethora of high living. Perhaps some other of your correspondents will take up this question for the general good. *W. F. E.*

LATE PEAS.—In reply to Mr. T. Lockie, who asks whether I have grown the two late Peas, *Late Queen* and *Michaelmas* together, I have to say that I have not. I grew them in diverse years, and therefore could not, of course, submit them to that severe test as to identity or otherwise that is found by growing them side by side. I do not recollect either as to how the seeds compare, but both are wrinkled Marrowfats. I found both capital late varieties, and have also seen them in good condition as such in various gardens. But both are too late to suit the purpose for which I grow Peas chiefly. In Mr. Lockie's case, something depends on the source from whence he obtained his stocks. I fear that there is not even now in seedsmen so great an excess of virtue as to prevent in the case of a stock being exhausted the sending of one good variety for another. Still, we see enough of Pea varieties at Chiswick to know that very many differ more in name than in appearance. *A. D.*

CANNA MRS. KATE GRAY.—I know nothing of the parentage of this very large flowering *Canna*. It is extremely handsome, but here by no means of dwarf habit, as stated in a previous issue of the *Gardeners' Chronicle*. Last season I grew several dozen plants, most of which exceeded 5 feet in height. Your correspondent, W. Müller, Naples, is in error when he states that *Italia* cannot be seeded. I obtained three seedlings from this variety the first year it was grown here. Of this fact I am quite certain. *W. J. Godfrey, Exmouth.*

THE IDENTIFICATION OF WOODS.—I should be sorry if your readers should go away with the impression that my paper before the Society of Arts on Dec. 4 was chiefly an attack upon any section of botanists. Anything of the kind was far from my intention, and I should be the last man to overlook the services of the Indian School of Botanists, whose labours have furnished us with a very large share of the knowledge we possess of Economic Botany. The key to my remarks lies in the following sentence, which I used: "Perhaps if the scientific side of our study can be developed sufficiently to attract the attention of botanical explorers, we may achieve our end by their assistance." I think that these words imply that we shall do little without them, and an anxiety to solicit their aid. Apart from all this, the names you cite are chiefly typical economic botanists whose work, compared with that which remains to be done, embraces but a small portion of the earth's surface. Omitting India and those regions under the influence of European civilisation, such as Australia and North America, we find scarcely any information of a reliable character, and I could mention scores of species of timber trees of which the proper names can only be guessed at. No one knows what tree the African Ebony comes from, nor the African Mahogany, of which vast quantities are imported, nor African Oak, to mention one locality only, yet the region has been fairly well explored in the interests of systematic botany. I am well aware that they are reputed to belong to certain species, but it is only when one seriously attempts to trace a wood to its origin that one finds how meagre is the information on record. Horticulturists are far more fortunately situated, because explorers know that efforts made by them to introduce or call attention to new plants will meet with appreciation at home. It is otherwise with timbers, for there are so few who would recognise their work upon them, and they have no encouragement to collect information. I have no doubt that, could they rely upon sympathetic co-operation here, the explorers will respond cheerfully enough, and it is to this end that we are looking forward with much hope. *Herbert Stone, Little Hay House, near Lichfield, December 26, 1901.*

SOCIETIES.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

DECEMBER 12.

LIST OF AWARDS.

FIRST-CLASS CERTIFICATES.

Cypripedium × *Lecanum* var. *Clinkaberryannum*.—A fine distinct form, with an unusual amount of white in the dorsal sepal; this segment also, instead of recurving, bends its sides forward. O. O. WRIGLEY, Esq.; also G. W. LAW SCHOFIELD, Esq.

Laelia autumnalis alba.—A fine variety from J. LEE-MANN, Esq.; also awarded a Cultural Certificate.

AWARDS OF MERIT.

Cypripedium × *Niobe* var. *excelsa*.—A good-sized flower, and well coloured. A. J. KEELING.

Cypripedium insigne var. *macranthum*.—A large, densely-marked var. O. O. WRIGLEY, Esq.

Cypripedium × *aureum* var. *belgica*; *Cypripedium* × *Helen*, C. *bellatulum* × C. *insigne* Chantini. R. TUNSTALL, Esq.

Cypripedium × *nitens* var. *albens*.—A form approaching an albino, very distinct. G. W. LAW SCHOFIELD.

Cypripedium × *Lecanum* var. *Albertianum*. E. ROGERSON, Esq.

Laelia anceps var. *Amesiana*.—A variety with a very brilliant frontal lobe to the labellum. Mr. J. CYPHER.

Vanda coerulea var. *magnifica*.—A finely-shaped and richly-coloured form, bearing about 12 flowers on the spike. STANLEY, ASHTON & CO.

GOLD MEDAL.

For a group of *Cypripediums*. O. O. WRIGLEY, Esq.

SILVER-GILT MEDAL.

For a group of Orchids. Mr. J. CYPHER.

SILVER MEDAL.

For a group of Orchids. STANLEY, ASHTON & CO.

For a group of Orchids. Mr. A. J. KEELING.

For a specimen *Cypripedium insigne* Harefield Hall var. (also Cultural Certificate). W. DUCKWORTH, Esq.

VOTES OF THANKS.

For a group of plants. R. TUNSTALL, Esq., E. ROGERSON, Esq., JOHN COWAN & Co., Messrs. H. LOW & Co. P. W.

WARGRAVE GARDENERS'.

DECEMBER 28.—The last meeting for the year 1901 took place on the above date, when Mr. Crechley, of The Honeys, Twyford, read an interesting paper on "Ferns: their Culture and Classification." He dealt with spore formation and sowing, the treatment of the plantlets, suitable temperatures, moisture, potting, soils, manures, &c. The different varieties were described for stove and greenhouse cultivation. Insect pests were mentioned, and a list of Ferns most suitable for cutting, and nursery work was given, after which a splendid collection of dried fronds, fully named, was passed round for inspection. These proved a capital object-lesson, and greatly enhanced the value of the paper. A discussion ensued, and many doubtful points were cleared up. A vote of thanks was accorded Mr. Crechley for his paper. Seven new members were admitted. *H. Coleby, Hon. Sec.*

PARIS.

THE National Horticultural Society of France paid a well-merited compliment to M. Victor Lemoine, the well-known nurseryman of Nancy, when, at the meeting of December 12, they conferred on him the title of Membre d'Honneur. Elections were held on December 26 to fill up vacancies in the Council. Several lists were submitted, of which that from the Council was accepted, except in one case. M. Albert Truffaut, of Versailles, was re-elected as first vice-president; the two other vice-presidents are M. Opoix, head gardener of the Luxembourg, and M. Maurice de Vilmorin, brother of the late M. Henri L. de Vilmorin, and President of the Comité des Rosicristes. M. Eugène Vallerant, Begonia-grower of Taverny, near Paris, is the new member of the Council elected by his colleagues in opposition to a candidate proposed by the Council. The place of the late M. Ernest Bergman, general secretary, has not yet been filled, the election having been deferred as a mark of respect for the deceased.

The Minister of Public Instruction has nominated M. Costantin as Professeur de Culture at the Natural History Museum, in succession to M. Maxime Cornu. M. Costantin was proposed by the Council of the Professors of the Museum, and by the Académie des Sciences.

M. Schlagdenhauffen, the Honorary Director of the Nancy École de Pharmacie, has lately published, in the *Bulletin of the Nancy Société Centrale d'Horticulture*, an interesting paper on *Coronilla*. Having noticed that seeds of *C. varia*, *C. scorpioides*, &c., which are often mixed with the seeds of cereals communicate a peculiar bitter flavour to bread or to beer, the author investigated the matter, and isolated the active principle, to which he has given the name of Coronilline; stating that this substance is poisonous. The effect of it on the heart is analogous to that produced by digitaline, and in small doses (less than one-fiftieth of a gramme) it is beneficial in some forms of heart disease. *Coronilla emerus* is the only species which, under these experiments, yielded no bitter principle. G. T. Grignani.

ENQUIRIES.

FAILURE OF LILY OF THE VALLEY TO FLOWER WELL.—A correspondent resident in a midland town would be glad to know if any other reader of this journal can advise him in the following circumstance. He says: "I have been growing large quantities of retarded Lily-of-the-Valley, and have been very successful with them, always potting them in Cocoanut-fibre; but having run out of fibre, I put 1500 crowns into peat, the result being that about half of them rotted off, and the other half came deformed. Some would throw up the flower-spike and not the leaf; others the leaf and not the flower-spike. Do you think the peat would have anything to do with it? The crowns looked all right before they were potted, and they were grown by the side of others in Cocoanut-fibre which were doing well."

Obituary.

JAMES FITZGERALD LOMBARD, J.P.—It is with deep regret that we have to chronicle the death of Mr. J. F. Lombard, which took place on December 23 at his residence, South Hill, Upper Rathmines, Dublin. For many years Mr. Lombard has been a well-known and spirited citizen of the Irish metropolis, having taken a deep personal interest in the initiation of many important commercial projects and industry, and he was financially interested in business concerns, and years ago took a deep interest in the development of the Dublin Tramway Company. He was a member of the French Legion of Honour.

To horticulturists he was known on account of his interest in florist's flowers, such as Tulips and Gladioli, while he was also famous for the cultivation of some of the best Apples and Pears in the Dublin district, having secured the premier awards for many years from the Royal Horticultural Society of Ireland.

Always a staunch friend of the poor and afflicted, he did much on their behalf through the boards and committees of the numerous civic and charitable institutions, hospitals, &c., to many of which he belonged. Not only did he give freely of his fruit and flowers to his friends and acquaintances whose gardens (if they possessed any) were less prolific than his own, but he sent large quantities to the Dublin hospitals as well.

His home at South Hill stands on the bank of the Dodder River, above Miltown, and sloped south or south-east, and both position

and soil suited trees, flowers, and fruit remarkably well. Although he kept a practical gardener, the initiative was his own, and he grew everything he undertook to great perfection. He was well known to most of the best fruit and fruit-tree growers in England, as to the florists of thirty or forty years ago; and the late Mr. T. Rivers, Dr. Robert Hogg, and many others, used to visit him and his garden whenever they were in Ireland. Only last autumn Mr. Geo. Bunyard spent an evening with him amongst his pictures, &c., of which he was very proud, and his fruit-trees and greenhouses. He was one of the very few amateurs who kept up a collection of Camellias during recent years. He was in every good sense a hospitable and genial man, and was deeply respected by all who had the privilege of knowing him.

Mr. Lombard was in his eighty-fifth year, and his funeral took place on the 26th ult. He was one of the last of amateur horticulturists that linked the gardening fashions of the first half of the century to the last in Dublin and its vicinity. F. W. B.

COL. SIR HENRY COLLETT.—We have to announce the death, at his residence, 21, Cranley Gardens, last Saturday, of Col. Sir Henry Collett, a distinguished Indian officer, who had seen much active service. Apart from his profession, Sir Henry Collett was a keen student of botany, and at the time of his death he was preparing a handbook of the flora of Simla.

JNO. CROSFIELD, J.P.—Many of the readers of this Journal must recall the glorious displays of Camellias and Chrysanthemums at Walton Lea, Warrington. The large numbers of the working classes who had the privilege of inspecting them will share great sympathy which must now be extended to the bereaved family of the late Mr. Jno. Crosfield, J.P., whose death occurred on Thursday last from an attack of bronchitis. Art and horticulture the late Mr. Crosfield made his own particular hobbies, and many encouraging testimonies can be readily adduced. *Orchid*.

G. ST. P. HARRIS.—The death of Mr. George St. Pierre Harris, of Leads Hill House, Orpington, Kent, on the 26th ult., at the advanced age of 94 years, removes a remarkable man from the list of cultivators of the Dahlia. For a man of his age, he had kept wonderfully well and active, taking a great interest in his garden, and especially in the Dahlia. It is as a raiser of Dahlias that Mr. Harris had been so well known amongst florists, and for years he had cultivated the flower, occasionally exhibiting, but devoting his energies mainly to the production of seedlings, both show and fancy. During the past year he exhibited at the Crystal Palace, at the Royal Aquarium, and also at the meetings of the Royal Horticultural Society, such show varieties as Flower of Kent, Brilliant, Queen of the Primroses, Sunset, and Standard, the last-named a deep chestnut-red self, obtained an Award of Merit from the Royal Horticultural Society. A highly promising fancy, named Mariner, had a First-class Certificate of Merit awarded to it at the Crystal Palace; at the former exhibition it also received the Special Prize offered by Mr. Richard Dean for the best seedling fancy Dahlia of the year. A few show Dahlias of Mr. Harris's raising are found in catalogues. One of the best known is Ruby Gem, ruby-crimson, with slight yellow tip to each petal; and some years ago Mr. George Rawlings named a scarlet-crimson self after Mr. Harris, which is still a popular exhibition variety.

During his lifetime Mr. Harris filled certain public offices in the county of Kent, and when he went into retirement from Chelsfield, he built himself a charming mansion on Leads Hill, Orpington, and laid out a delightful garden; and here he found pleasant occupation, especially in cultivating his named and seedling Dahlias. Mr. Harris passed away peacefully after a short illness, leaving a widow. He had the rare experience of living under the reigns of five English Sovereigns. R. D.

Remarks.—The temperature remains much about the same as last week, with cold winds, slight snow-showers, and rain on five days.

GENERAL OBSERVATIONS.

The following summary record of the weather through out the British Islands, for the weeks ending Dec. 21 and 28, is furnished from the Meteorological Office:—

"The weather during this period was cold and unsettled generally. Snow, sleet, or cold rain were frequently experienced in the more northern and western districts, but in the south and south-east the weather was drier and fairer, and the rainfall slight. Thunder and lightning were experienced at some north-western stations on the 18th or 19th.

"The temperature was below the mean in all parts of the kingdom, the deficit in most districts being as much as 5° or 6°. The highest of the maxima occurred as a rule during the middle of the week, and ranged from 53° in the Channel Islands, and 48° in Ireland, S., to 41° in England, E. and the Midland Counties. The daily maxima at inland stations were frequently only of a few degrees above the freezing point. The lowest of the minima which, with some exceptions, were recorded either on the 20th or 21st, ranged from 12° in the Midland Counties, 19° in England, S.W., and from between 20° and 23° in most other districts, to 31° in the Channel Islands.

"The rainfall was more than the mean in England, N.E., and just equal to it in Scotland, E., England, N.W., and Ireland, N.; in all other districts, however, it was less.

"The bright sunshine exceeded the normal amount in most parts of the kingdom, especially in the south and south-west; but was deficient in Scotland, W. and E., and England, N.E. The percentage of the possible duration ranged from 48 in England, S., 33 in the Channel Islands and England, S.W., to 11 in Scotland, W., 9 in Scotland, E., and 6 in England, N.E.

"The barometer and wind.—The distribution of pressure over our Islands changed frequently during this week. The principal disturbances were: one that moved quickly southwards over the western part of our islands soon after the commencement of the period, and disappeared over Spain, and another system which, after travelling southwards

down the North Sea to our north-east coast, remained stationary, and gradually filled up. As pressure to the westward of these disturbances was comparatively high, the northerly winds on our western coasts were generally strong, and at times attained the force of a gale; but in the east and south the winds were more variable, and lighter in force. At the end of the week the barometer was falling decidedly along our western coasts, and the wind in that region shifted to S. or S.E., and was increasing in force.

"The weather was again in a very unsettled condition. Rain was of almost daily occurrence in the more southern and western districts, and rain, sleet, or snow in the north. The falls were at times large—especially those experienced over England on Saturday.

"The temperature was below the mean in all districts, the deficit ranging from 2° in Scotland, N., and the Channel Islands, to 4° in Scotland, E., and England, N.E. and N.W., and to 5° in the Midland Counties and Scotland, W. The highest of the maxima were recorded on Saturday, when they varied from 52° in the Channel Islands and England, N.W., to 42° in Scotland, E., and England, N.E. The absolute minima, which were registered on irregular dates, were very low in many inland places. At Newton Reigny on Sunday the thermometer fell as low as 4°, and readings of 20° or below occurred sometime during the period in most inland localities. In Ireland, S., and the Channel Islands, however, the thermometer did not fall below 24° and 31° respectively.

"The rainfall was much in excess of the mean over the Kingdom as a whole, but less in Scotland, N. and W. In many districts the fall was twice as much as the normal amount.

"The bright sunshine was deficient generally, but somewhat exceeded the mean value for the time of year in England, N.E., E., and S., and also in Ireland, N. The percentage of the possible duration ranged from 26 in the last-named district, and 21 in England, E., to 13 in England, N.W., and to between 9 and 5 in Scotland."

THE WEATHER IN WEST HERTS.

In the early part of the week the weather remained cold, and on one night the exposed thermometer registered 17° of frost. On the other hand, the last few days have been exceptionally warm, the shade temperature on one of them rising to 56°. This sudden change has caused the ground temperatures to rise rapidly, but as might be expected under such conditions, there is a great contrast between the reading at 1 foot deep and that at 2 feet deep—the latter being at the present time 1° colder, while that at 1 foot deep is 4° warmer than is seasonable. Rain fell on four days, to the total depth of an inch. Owing to the recent heavy rains, the ground has become saturated; in fact, as much as 9 gallons of rain-water came through the percolation gauge covered with grass during the week, and 8 gallons through the bare-soil gauge. The winds have been as a rule rather high, and the atmosphere humid.

DECEMBER.

This was a cold month, but at no time did the thermometer on the lawn show more than 19° of frost, which is by no means an exceptionally low extreme minimum for December. The cold period of the month lasted rather more than a fortnight, when on six nights the exposed thermometer showed from 13° to 19° of frost. The total rainfall amounted to 4½ inches, which is nearly twice the average quantity for the month—making this the wettest December since 1886, or for fifteen years. So saturated did the ground become that very nearly the whole of the heavy rainfall came through the 2½ feet of soil in both the percolation gauges. On two occasions during the month the ground was covered with snow to the depth of 2 inches. Although such a wet month, the record of sunshine was rather in excess of the average. Both the strength of wind, and the amount of moisture in the air, were about seasonable.

THE YEAR.

This was another warm year. January proved warm, while February and March were unusually cold. The next seven months, with the exception of June, which was rather cold, were all more or less warm, July being exceptionally hot. The two closing months of the year were both cold. The rainfall proved very light; indeed, in the last forty-six years there have been only six other years as dry. The deficiency amounted to 5½ inches, which is equivalent to less in water to about twenty-six gallons on each square yard of surface in this district. It was not only a warm and dry, but also a very sunny year—with two exceptions, the sunniest in the last sixteen years.

RAINFALL OF THE LAST THREE MONTHS.

Since the winter half of the drainage year began in October, the total rainfall has come short of the average for those three months by about an inch. *E. M., Berkhamsted, December 31, 1901.*

MARKETS.

COVENT GARDEN, JANUARY 2.

CUT FLOWERS, &c.—AVERAGE WHOLESALE PRICES.

| Garlic, per lb. | 0 | 3— | — bag | 1 | 6-26 |
| Horseradish, foreign, bunch | 1 | 0-16 | Watercress, per doz. bunches | 0 | 6-08 |
| Leeks, 12 bunches | 1 | 6— | | | |
| Lettuces, Cabbage, per dozen | 1 | 6— | | | |

REMARKS.—Cucumbers are easier in price. Custard Apples fetch 4s. to 8s. per dozen. Chow-Chows, 1s. 6d. per dozen. Apples, such as Cox's Orange, Ribston, and King Pippins, are practically over, but some good

Blenheim Orange Pippins are still coming in, as well as Cockle Pippins. Italian Cauliflowers fetch 3s. 6d. to 4s. per basket of 18 heads. The supply of Mistletoe was greatly in excess of the demand, and many cratesful were thrown away.

POTATOS.

Dunbar Main Crop, 90s. to 95s.; Up-to-Date, 85s. to 90s.; Blacklands, 50s. to 55s.; various, 55s. to 80s. *John Bath, 33 & 34, Wellington Street, Covent Garden.*

SEEDS.

LONDON: January 1.—Messrs. John Shaw & Sons, Seed Merchants, of Great Maze Pond, Borough, London, S.E., write that to-day's seed market, as was to be expected, was thinly attended; and with the holiday spirit which prevailed, transactions were naturally few and unimportant. Meantime, both as regards Clover seeds and Rye grasses, a very firm feeling is current, and a healthy, active business in these and other articles is shortly anticipated. The high rates demanded for foreign Spring Tares have been stopping the English buying. There is no alteration this week in either Mustard, Rape, or Linseed; Canary-seed, although inactive for the moment, manifests a strong undertone. The mild weather diminishes the sale of boiling Peas and Haricot Beans. Some choice new Giant Scarlet Runners are now obtainable on very moderate terms.

FRUITS AND VEGETABLES.

GLASGOW, January 1.—The following are the averages of the prices during the latter half of last week:—Apples, Newtown Californian, 9s. 0d. to 11s. per case; Oregon, 12s. to 13s. do.; Nova Scotia Baldwins, 22s. to 26s. per barrel; Maine, 20s. to 24s. do.; Canadian, 22s. to 25s. do.; Grapes, 9d. to 1s. 6d. per lb.; home do., 1s. 2d. to 2s. do.; Oranges, Valencias, ordinary, 420's, 7s. to 8s. per case; do., large 470's, 9s. 6d. to 11s. do.; extra large do., 12s. 6d. to 14s. 6d. do.; large 714's, 9s. 6d. to 12s. 6d. do.; Jaffa, 8s. to 9s. do.; Mushrooms, 1s. 3d. to 1s. 6d. per lb.; Onions, Valencias, 5's, 7s. 6d. to 8s. 6d. per case; globes, 5s. 6d. do.

LIVERPOOL: January 1.—Wholesale Vegetable Market.—Potatoes, per cwt.: Up-to-Date, 2s. 2d. to 2s. 8d.; Main Crop, 2s. 9d. to 4s.; Lynn Grays, 2s. to 2s. 4d.; Bruce, 2s. 2d. to 2s. 8d.; Turnips, 6d. to 10d. per 12 bunches; Swedes, 1s. 4d. to 1s. 6d. per cwt.; Carrots, 3s. to 3s. 6d. per cwt.; Onions, foreign, 5s. 6d. to 6s. 6d. per cwt.; Parsley, 8d. to 1s. per dozen bunches; Cauliflowers, 1s. 6d. to 3s. doz.; Cabbages, 8d. to 1s. 8d. do.; Celery, 8d. to 1s. 6d. do. *St. Johns:* Potatoes, 1s. per peck; Cucumbers, 8d. to 1s. each; Grapes, English, 1s. 6d. to 2s. 6d. per lb.; do., foreign, 6d. to 8d. do.; Pines, foreign, 3s. 6d. to 6s. each; Mushrooms, 1s. per lb.; Filberts, 1s. do.

CORN.

AVERAGE PRICES of British Corn (per imperial qr.), for the week ending December 28, 1901, and for the corresponding period of 1900, together with the difference in the quotations. These figures are based on the Official Weekly Return:—

| Description. | 1900. | | 1901. | | Difference. |
|---------------|-------|-------|-------|-------|-------------|
| | s. d. | s. d. | s. d. | s. d. | |
| Wheat | 26 | 4 | 27 | 7 | + 1 3 |
| Barley | 25 | 10 | 26 | 8 | + 0 10 |
| Oats | 17 | 2 | 19 | 10 | + 2 6 |

CULTURAL MEMORANDUM.

TOMATOS.

It has been my practice for several years to sow seed of the Tomato for an early supply of fruit towards the end of the month of November, and invariably with very good results. When rearing plants at the dead of winter, it is very essential to keep them in a warmhouse or pit, as near to the glass as convenient, so that they may receive all the sunlight possible, otherwise growth will not be sturdy, or substance of leaf and stem firm; such plants should now be making growth slowly in 3-inch pots. At this season, perhaps two of the worst mistakes that can be made is to afford too much pot room and to afford much water, young Tomato plants in winter requiring but little water before the plants get fairly well furnished with roots. Another evil is to crowd the plants closely together, as to do this tends

to spindly growth. If no seed as yet has been sown, I would advise a sowing to be made without delay, sowing thinly and evenly in well-drained pots filled with a compost consisting of leaf-mould, loam, and sand, pressed by hand firmly. The seeds should be scarcely covered with fine soil. Stand the seed-pots in a frame or house having a temperature of 60° to 65°, and should the soil be fairly moist, no water should be afforded for some days, but this will depend in great measure upon the condition maintained in the house or frame, and the position in which the pots are stood or plunged. As soon as the seedlings are large enough to handle transplant them, putting two or three plants of equal size round the sides of 3-inch pots, using soil of moderate warmth. If the seedlings have spindled in the seed-pans, pot them down to the first pair of leaves. At this stage the plants must have no check whatever, and they should be placed in a moderately moist house, having a warmth of 60° to 65°, more or less, according to the state of the weather. When the roots touch the sides of the pots, repot this time singly, and using the same size of pot, or repot without disturbance into others of larger size; repeatedly repot when necessary till the plants come into 10 and 12-inch pots, a pair of plants in each. The best place in which to fruit the plants is a light span-roofed house, the stems being framed near to the glass on wires or rods arranged for the purpose. All lateral shoots must be pinched out, and some of the larger leaves reduced in length. Where growers for market adopt methods differing somewhat from the above, as for example, they drop the seeds in boxes of soil at about an inch apart, lift the seedlings when large enough and transfer them to small pots. Turfy loam that has been in stack for a year, and decayed manure, suit Tomatos when fruiting. H. Markham, Wrotham Park.

BOOKS: *Davenport.* The *Book of the Rose*, by Rev. Foster Melliard, published by Macmillan; small publications of the National Rose Society, as "Report on the Constitution of Rose Soils," "Report of Conferences held by the N.R.S. in 1900," "On Roses for Garden Decoration," "Hints on Planting Roses," "The Hybridisation of Roses," the N.R.S. Prize Essay.—Z. *How to Lay Out a Garden*, by A. Kemp (Bradbury, Agnew & Co., Ltd., 10, Bouverie Street, Fleet Street); *The Art and Craft of Garden-Making*, by T. H. Mawson (London: B. T. Batsford, 94, High Holborn); *Landscape Gardening*, by H. E. Milner (London: Simpkin, Marshall, Hamilton, Kent & Co., Stationers' Hall Court).

DECIDUOUS FLOWERING SHRUBS AND TREES FOR A NORTHERN COUNTY: *Agricola.* Amelanchier botryapium, double and single-flowered Cherries, Tulip-tree, Pyrus Malus (The Crab) in many varieties, Lilacs, Philadelphus coronarius and others, Forsythia viridissima, F. suspensa, Sturtia californica, Staphylea colchica, Sea Buckthorn, Catalpa syriaca, Viburnum Opulus, V. levigata, V. lantana, Kolreuteria paniculata, Almonds, and Prunus in variety.

DESTRUCTION OF PLANTS AND OTHER COARSE WEEDS IN TURF: J. A. L. We do not know the composition of Watson's Lawn Sand, but there are other substances that will make grass grow vigorously, viz., nitrate of soda, blood, and fish manures, applied when growth has begun, and again twice or thrice in the course of the summer. These may be

given together with dressings of loam, finely sifted, and wood-ashes. If the grass is thin, sow the finest lawn grasses and clovers, but these should contain no Rye-grass; cover thinly with loam, and roll or beat with a spade. This treatment must be persevered in for two or three years. Grass seeds may be sown in March and April, and dressings of loam, &c., given at the same time, or earlier. The effect of the extra vigour imparted to the grasses is to smother the weeds out of existence.

GROS COLMAN GRAPES DECAYING: A Subscriber. The inability to use fire-heat during the month of December has undoubtedly induced mouldiness in the bunches, as that spreads very rapidly from berry to berry. The damaged berries should be removed, stalks and all, and burned forthwith. If the flue or hot-water pipes cannot yet be made use of, place vessels containing quicklime in the house, or burn charcoal in braziers or old iron buckets on days when air can be given.

LAWN-SWEEPING MACHINES: W. S. If you will furnish us with your name and address, we shall be enabled to put you into communication with a firm dealing in these machines.

LILIU SPECIOSUM: E. B. The bulbs should be planted in a warm, sheltered situation, the ground, if possible, being shaded by dwarfier plants. The soil should be manured, and well worked and stirred to a depth of 1½ to 2 feet. Make firm and plant the bulbs in late autumn, or immediately they are obtainable at the florist's, putting them at the least 6 inches deep, with sand above and below them. If rats and mice be not feared the bulbs may be left in the ground when the stems die down, otherwise remove them to pots, half filled with loamy soil, and preserve them in a cold pit bedded in fresh leaves, so as to keep the frost from them, but not in such bulk as to impart heat, and cover the pots with slates, &c., so that mice or rats cannot enter. See an article on Lilies, p. 23, in the issue of the *Gardeners' Chronicle* for July 13, 1901.

MESEMBRYANTHEMUMS AND ALTERNANTHERAS: W. M. You cannot raise the variegated forms of either from seed so as to be available for bedding out, but you would do well to purchase stock plants, and raise plants from cuttings. The first should be started in an intermediate temperature, and the second in the stove, say from 60° to 75°. It will be soon enough in February to make a start with the propagation of the plants.

MUSHROOMS: J. Hamlin. Withdraw them from the soil with as little disturbance of the soil as possible. It is not a safe practice to cut off the stem at the ground-level, and leave the root and remains of the stem to decay in the bed.

NAMES OF FRUIT: *Fairlawn.* 1, Beurré d'Arenberg; 2, Notaire Minot; 3, Caroline; 4, unknown; 5, Cockle Pippin; 6, Rymer; 7, Nelson Codlin.—T. H. B. 1, Bergamotte Dussart; 2, Royal Russet; 3, Harvey's Pippin; 4, Hunt's Deux Ans.

NAMES OF PLANTS: F. E. S. & Co. We cannot undertake to name varieties of Chrysanthemum, or other "florists'" flowers.

OLD GARDENING BOOKS: F. W. M. The books named have little horticultural value. Book collectors might value them as curios, and the prices given in your note are the utmost you could obtain for them.

PEARS: R. W. R. The supposed B. Diel was much over-ripe, besides being damaged, so that it, and the long Pear, also over-ripe, could not be identified. The round Pear we will endeavour to name for you in our next issue.

PETROLEUM AND PARAFFIN: A Reader. The first consists of several substances of a bituminous nature found in rocks in many parts of the globe. Liquid petroleum or mineral oil is found in all localities where bitumen or asphalt exists in quantity in

the rocks. It varies in composition and density according to whether it be obtained from shallow or deep wells, the former giving the heaviest and darkest product. Paraffin is mostly obtained by destructive distillation in retorts of shales, cannel-coal, wax, peat, wood, &c.

ZONAL PELARGONIUM: J. Hamlin. As it is during the winter and late autumn that these plants when grown in pots are most valued, the gardener will in a measure be guided by the state of the weather in applying artificial heat. On sunny days, not much heat may be needed, as but little ventilation is given and in bad weather scarcely any, although what is called "a chink of air" should always be afforded when frost is not severe. Generally speaking, the temperature may range by day from 55° to 60° with sunshine, 5° less in cloudy and very cold weather, and by night 45° to 48°.

THE OLDEST HORTICULTURAL NEWSPAPER.

THE

3^D. Gardeners' Chronicle

WEEKLY. Postage 1d.

15^S. YEARLY. Post Free.

(THE "TIMES" OF HORTICULTURE.)

FOR OVER SIXTY YEARS
THE LEADING JOURNAL.

Its contributors comprise the most

Experienced British Gardeners,
and many of the most

Eminent Men of Science

at home and abroad.

IT HAS AN INTERNATIONAL REPUTATION FOR ITS ILLUSTRATIONS OF PLANTS.

Specimen Copy sent free on application to the Publisher,

H. G. COVE, 41, WELLINGTON STREET, STRAND, LONDON.

* * May be ordered of all Booksellers and Newsagents, and at the Railway Bookstalls.

THE

OF

COTTAGERS' CALENDAR GARDEN OPERATIONS.

A new and revised edition of this little book, of which 280,000 have been already issued, is NOW READY. It was originally drawn up by the late SIR JOSEPH PAXTON, and has been repeatedly revised and brought up to date by the staff of the *Gardeners' Chronicle*. It is particularly suited to the needs of cottagers and allotment-holders, and forms an excellent manual for County Council lecturers and their pupils.

Price 3d., Post-free 3½d.;

Twenty-five Copies, 5s.; Fifty, 10s.; and One Hundred, 20s.

Money Orders and Postal Orders should be made payable to H. G. COVE, at the Post Office, Great Queen Street, London, W.C.

Parcels of not less than twenty-five delivered, Carriage Free, in LONDON only.

Not less than one hundred Carriage Paid to any part of Great Britain.

THE GARDENERS' CHRONICLE, LIMITED,
41, WELLINGTON STREET, STRAND, LONDON, W.C.

THE GARDEN AS A HOBBY.

IN an article under the above heading, which appeared on December 14, Dr. Bonavia ridicules the advice given by Mr. F. T. Mott in one of his papers on "A Midland Garden," to the effect that "old men who retire from business and have nothing to do but eat and sleep, and read the papers, die off rapidly. They should take to gardening, and do part of the actual work themselves." According to Dr. Bonavia, it is useless for anyone who has not studied gardening from childhood to attempt the acquirement of even the rudiments of that art in advanced years. The poor retired business man is portrayed as incapable of doing anything in the garden with intelligence, and as being ignorant even of the rational method of plucking a Rose. Such a sweeping assertion is calculated to carry despair to the heart of every inoffensive leisured individual who contemplates solacing his declining years by taking an intelligent interest in his garden, and may well add yet another to that inane crowd of "creatures," who are pictured "waiting for death" in their club armchairs. But let the successful business man, when he seeks his well-earned retirement, and turns his thoughts gardenwards, take heart of grace, for there are many, whose knowledge of garden-lore is by no means limited, who will echo the comforting advice given by Mr. Mott, and assure him that there is no valid reason why

that intelligence which has led him to success in business should utterly desert him as soon as he sets foot in his garden. That a life-long apprenticeship to gardening is of inestimable worth will be admitted by all who are conversant with the subject practically and theoretically; but there is no more reason for a man's refusal to turn his attention to horticulture because he is not qualified to take the place of the late Sir John Lawes or Sir Henry Gilbert than there is for a child's objection to learn the alphabet because it cannot read a book.

There was a time when those eminent men knew nothing about soils; and when the writer of the most learned book could not read. Knowledge comes by slow degrees, and never attains perfection. There is no finality in learning. The more a man knows of any subject, the more conscious he becomes of how much pertaining to it there still remains to be learnt. The wisest among us never cease being learners. If a man were to set himself to the study of a subject from his earliest childhood to his death-bed, he would not learn all that might be known of it. Years, perhaps ages later his knowledge would be amplified in directions he never dreamed of. If, therefore, any have perforce delayed their initiation into the mysteries of Flora's lore until maturer years, let none dissuade them from devoting the remainder of their lives to its study, but rather urge them so to do. They will not in all probability become deeply learned, and they can no more hope to acquire the experience possessed by those who have been studying from their youth upwards, than can the man who takes to golf in middle age expect to rival the supple agility of the player who has wielded a club from a lad, but they will gain useful knowledge even in this incarnation, knowledge acquired amid the delightful surroundings of the fresh air of heaven, and the breath of countless fragrant flowers.

There is much that the veriest tyro in gardening can do without running the risk of committing any fatal blunder. Staking and tying plants requires an artistic eye, rather than horticultural knowledge. Picking off dead flowers and seed-pods, training climbers, syringing aphid-infected foliage with insecticide, occasional use of a light lawn-mower, and numerous little odd jobs, that, although they are done in the garden can scarcely be termed gardening, will suffice to employ the beginner's time. Bulb-planting and seed-sowing are not difficult operations, and advice on these and kindred subjects is given in detail in gardening books, ranging in price from a shilling to a sovereign or more, advice that is far more readily assimilated by the trained brain of the business man than by the undeveloped mind of youth.

Most of us can number among our friends and acquaintances amateurs who are devotedly attached to their gardens, and possessed of a fund of valuable horticultural knowledge, but who did not commence to make gardening their study until middle life or later; nevertheless much good work has been done and is being done by such as these in widening the appreciation of gardens, independently of the enjoyment they themselves experience in performing their labour of love.

Hybridising offers a wide and interesting

field of work to those who take up gardening in their later years. It is no difficultly-acquired art, but its possibilities are infinite. Thousands of seedlings may doubtless show no improvement on their parents, but there is always a chance of a break in a new direction.

Humility is, perhaps, a somewhat rare virtue, yet it is one that should be cultivated by every aspirant to knowledge in gardening matters, for the first advances are only to be made by the help of the oral or printed advice of others. It is very true, as stated by Mr. Mott, that "gardening is an art full of complex details, and cannot be taught by books alone. Experience and practice are necessary to every gardener." Personal experience is certainly the best teacher, but at the first there is none to guide, and until its lessons are slowly and reverently garnered, each day adding something to the priceless store, the teachings of those qualified to instruct are the only stand-by.

The beginner generally credits the acknowledged experts of the art with an omniscience that is almost supernatural. Later on he finds to his comfort that no human mind is capable of acquiring and retaining an exact knowledge of the countless genera of trees and plants in the world in all their endless varieties.

Many years ago, when I first began to interest myself in horticulture, I was, although fortunate in having known the care of a flower-loving mother such as Dr. Bonavia appreciatively describes, painfully conscious of my ignorance. As time passed on, I found that even the greatest gardeners did not know everything. The best dictionary of gardening gave a white-flowered plant as bearing purple blooms; another dictionary classed a certain deciduous shrub as evergreen; one of the most widely-known men in the gardening world hesitated to name a variety of German Iris; another had no knowledge of a particular florists' Tulip, and so on. These instances, which at the time proved somewhat disquieting, led to the consideration that the sum of gardening knowledge now at our disposal was accumulated, not by each master mind learning afresh everything that had been learnt before, but by working independently in different directions and adding the wisdom thus gained to the general store. The specialist in Irises has not necessarily an intimate acquaintance with all the Composites of the American continent, nor does it follow that because a man possesses a unique knowledge of Orchids that he is competent to pass an exhaustive examination on the Coniferae.

Dr. Bonavia's story of the old gentleman who enquired if there was any connection between a Datura and a Date-tree, points to the folly of jumping at conclusions in subjects with which one is totally unacquainted, and emphasises the fact that in such cases silence is especially golden. Like ignorance would be displayed by all sorts and conditions of men who ventured to talk on unfamiliar subjects, and the opinions of a gardener on the crojaek-yard of a clipper would doubtless appear as ludicrous to a sailor as did the old gentleman's well-intentioned but unfortunate attempt to interest himself in horticulture to your correspondent. Most probably the gentleman in

question was not among those under consideration, who are anxious to acquire a certain insight into the pleasures of gardening—pleasures that are unfortunately not unalloyed with possibly salutary disappointments. If, however, he belongs to that much-to-be-applauded body, and applies himself to his new hobby with an earnest desire to gather what knowledge he can concerning it, there is no question but that his efforts will eventually be crowned with a qualified measure of success. He may but master the alphabet of gardening, but even that is something gained, for it may be laid down as an axiom that the more in number are those that embark in that entrancing pursuit, the more will the health and happiness of the world be augmented. *S. W. Fitzherbert.*

NEW OR NOTEWORTHY PLANTS.

CATTLEYA × ROTHWELLÆ.

A NEW hybrid, between *C. Eldorado* and *C. Bowringiana*, raised in the collection of Mr. J. E. Rothwell, Brookline, Massachusetts. It is described by Mr. Oakes Ames in *American Gardening*, 1901, vol. xxii, p. 845, fig. 174, under the name of *C. × Portia* var. *Rothwelliæ*, as follows:—

"Plant intermediate . . . sepals oblong; petals broadly ovate; lip with contracted, apical lobe; sepals, petals, and lip pale purple-red, the apical lobe of the latter and the margins of the side lobes deep rich purple-red; throat rich yellow; flowers about 4½ inches across."

An excellent photograph is given showing the whole plant bearing four flowers.

The publication of this hybrid, under the name of *C. × Portia*, raises a rather interesting question. Mr. Oakes Ames, apparently following Veitch's Manual, makes *C. Eldorado* a variety of *C. labiata*, and as the hybrid between *C. Bowringiana* and the latter is known as *C. × Portia*, he therefore applies that name in this case.

But this rather complicates matters, because according to the same system, *C. Warscewiczii* would also be considered a variety of *C. labiata*, and a hybrid between *C. Bowringiana* and *C. Warscewiczii*, named *C. × Wendlandiana* was described in 1894 (*Orch. Rev.*, 1894, p. 144), while *C. × Portia* was first published in 1897 (*Orch. Rev.*, 1897, p. 375).

Mr. R. A. Rolfe in his revision of the genus *Cattleya* (*Orch. Rev.*, 1895, p. 269), makes both *C. Eldorado* and *C. Warscewiczii* distinct species, each having its own set of varieties, and on the whole, this seems to be the most convenient arrangement.

In accordance with this, therefore, I venture to amend the name of this hybrid, as above. *C. C. Hurst, F.L.S.*

VITIS (?) VOINIERIANA.

Under this name M. Charles Baltet describes in the current number of the *Revue de l'Horticulture Belge*, a Vine introduced from Tonkin and dedicated to M. Voinier.

As the flowers have not been examined, the position of the plant is uncertain, but the leaves are palmatisect, each of the five segments being stalked, about 20 cent. long, rounded at the base, oblong-acute, coarsely toothed. M. Baltet says it will be a delight to plant-lovers, for it will make a splendid adornment of our winter gardens. Its characteristics consist in its vigorous habit, and superb evergreen foliage.

ORCHID NOTES AND GLEANINGS.

CATTLEYA × CYBELE (GASKELLIANA × LUDEMANNIANA).

THE union of two rather widely separated forms of *Cattleya labiata* has, in this showy hybrid, brought about pleasing results, even although the new arrival still remains a form of *Cattleya labiata*. Its chief features are such as might be expected, and the notable departure is in the almost abnormal breadth of the petals, which in a great degree resemble those of *C. quadricolor* (*chiocensis*). The general appearance of the flower is of a very fine form of *C. Trianei*, with the labellum displaying the trumpet-shaped expansion of the front and side lobes of the lip, inherited from *C. Ludemanniana*. The flower, which is 6 inches across, has petals over 2½ inches wide, both sepals and petals being white, delicately tinged with rose. The base of the lip is pale rose, with purple lines running up the middle, and extending into two yellow patches in the middle area displayed as in *C. Warscewiczii*. Front of the crimped labellum bright reddish-purple. It is one of the novelties which the raisers, Messrs. Jas. Veitch & Sons, of Chelsea, were prevented by the frost from showing at the December display of the Royal Horticultural Society.

BARKERIA SKINNERI.

A splendid inflorescence of twenty-five bright magenta-purple flowers, with orange-coloured erect to the lip, is sent by Joseph Broome, Esq., Sunny Hill, Llandudno (gr., Mr. A. C. Axtell), where it has been in flower for some time. It is one of our brightest-coloured and most elegant winter-flowering Orchids, but it does not thrive so well in towns as do some other species of Orchids. In the bright sunlight and pure air of Llandudno the colours of the flowers are very bright. It is botanically an *Epidendrum*, and was first discovered by Mr. G. Ure Skinner, growing on trees in the mountains of Guatemala, in 1835, a region which possesses an uniformly cool climate. In our glasshouses it grows best on a raft, or in shallow baskets suspended in an airy intermediate-house, when making its growth; but when at rest, the plant should be kept dry in a coolinery or greenhouse, in the full sunshine. A sojourn in the open air, suspended from the branch of a tree in the hot weather, has been found to benefit it.

LYCASTE SKINNERI.

Some magnificent flowers of this species are kindly sent by J. Broome, Esq., Sunny Hill, Llandudno, who calls attention to their gigantic size. The largest has a flower-stem about 14 inches in length. The sepals and petals are tinted with rose, and the front lobe of the lip is of a purplish-rose colour. The flower is of fine form, the sepals each 3½ inches long and 2½ inches broad. In another of the flowers the segments are tinged with purple on the inner halves, and the rose-purple lip is bordered with white. A fine flower of the singular *Lycaste gigantea*, and some good flowers of *Cypripedium × Lecanum* are also sent, which in all cases show remarkable development and bright colours. *Jas. O'Brien.*

PLANT NOTES.

ANGELONIA GRANDIFLORA ALBA.

No one requiring a graceful and free-flowering plant for autumn and winter decoration should fail to procure a packet of seed of this plant, sent out last year, I believe, by Messrs. James Veitch & Sons. It is a

perennial, but for practical purposes may be treated as an annual. It grows to a height of from 18 inches to 2 feet. Seed may be sown in the spring, and the plants grown in an intermediate-house, and flowered in 5 or 6-inch pots. If the points of the shoots are pricked out once or twice during growth, extra bushiness will result. The extremely numerous flowers are a creamy-white, and slightly aromatic. It reproduces itself true from seed, with occasionally a break in colour, which might afford scope to the ingenuity of the hybridiser. *James Baxter.*

THE ROSARY.

ROSE GENERAL SHABLIKINE.

A SEASON or two back this Rose was brought into some prominence in the horticultural papers, but since I have seen little notice of it. A dozen plants obtained last planting-time from a continental source have given great pleasure. Though the plants were small when received, they flowered fairly well during the past season, and gave us a number of their delicately-tinted flowers. It appears too small for exhibition, but for those who love Roses apart from that consideration, I would advise the purchase of a plant or two. The colour of the blooms is somewhat like that of *Madame Lambard* but deeper, yet clearer and brighter; in the bud and half-opened stages a really charming flower. *J. W.*

THREE PALMS OFTEN WRONGLY NAMED.

ROBERT BROWN, in his *Prodromus Floræ Novæ Hollandiæ*, gives the character of a new genus of Palms, which, in honour of Francis Lord Seaforth, he named *Seaforthia*. The species which he created was called by him *S. elegans*, R.Br. Amongst the characteristics, R. Brown mentions the fronds with pinnules erose at the apex. He says that this genus is nearly allied to *Caryota*. The characteristic apex of the pinnules much attracted him. This plant was afterwards united with *Ptychosperma* of Labillardière, and named *Ptychosperma elegans*, Blume.

Afterwards Sir W. Hooker gave in the *Bot. Mag.* a description and figure of a Palm under the name of *Ptychosperma elegans*, which differs from *P. elegans*, Bl., in its pinnules, which are not erose but acuminate at the apex. I have long wondered how it could be possible to confuse two such distinct plants, and I think that the mistake arose from the geographical distribution of the two plants. Robert Brown's plant is a native of Queensland, where it grows near Endeavour River, Cape York, Sunday Island, Cumberland Islands, and Rockhampton. The Hookerian plant is also a native of Queensland, growing at Sunday Island, the east coast of Cape York, and Rockhampton. I suppose that seeds arrived at Kew from one of these places, that it was known from Brown's paper that the Palm called by him *Seaforthia elegans* grew there, and that the seedlings were therefore named *Seaforthia elegans*. Those who know how sometimes names are affixed in botanical gardens by the under-gardeners will not be astonished at this.

The Hookerian Palm belongs to another genus, named at a different time. Wendland, who distinguished the genus at once, called it *Archontophoenix Cunninghamii*. Another species of this genus is *A. Alexandræ*, Wendl., very similar in habit to *A. Cunninghamii*, but differing by its segments, which are only green

above, whilst underneath they are ashy glaucous or white. The plant is also a native of Queensland, where it grows at Rockingham Bay. As the general habit is very similar

true *Ptychosperma elegans* (fig. 7), Blume, viz., the *Seaforthia elegans* of R. Brown, is met with but rarely in European gardens. What is cultivated under this name in most cases

youth they form bifid leaves, the blade almost horizontal. After having made some four to six such leaves, each larger than the foregoing, there appears a fully pinnate leaf, much

FIG. 6.—ARCHONTOPHOENIX ALEXANDRÆ. (SEE P. 18.)

to *A. Cunninghami*, it is often met with under the name of *Seaforthia elegans*. Our illustrations show the totally different habits of *Ptychosperma* and *Archontophoenix*. The

is either *Archontophoenix Cunninghami*, or *Archontophoenix Alexandræ* (fig. 6). The latter are decorative hardy Palms, forming on the Riviera very fine high-stemmed specimens. In

differing in mode of growth from *Phoenix* and other pinnatisect-leaved Palms. On the Riviera the plants were exposed to 6½° R. without any harm. For rooms these two species are very

good plants, growing rapidly. The two photographs (figs. 6, 7) showing plants in the Botanic Garden at Buitenzorg, were kindly sent me by Prof. Treub. Dr. Udo Dammer, Gross Lichterfelde, Berlin.

UNITED STATES OF AMERICA.

GARDENERS IN THE UNITED STATES.

It is of America as a field for emigration that I should like chiefly to speak. The great number of good men advertising for positions, and the low rate of wages paid to those engaged, shows, I think, that some outlet is necessary in order that the overflow of talent existing in England in the horticultural line shall not flood the market to a more disastrous extent than it does at present. To my mind, the United States provide that outlet. My time here has been short, but it does not require a long time for one to see that here good gardeners are as scarce as they are abundant in England; and my eight months' experience of this State has proved to my satisfaction that there is room here for many of those who feel the ill-effects of the keen competition at home. That I, in applying for the post I now hold (being less than three months here, and almost entirely ignorant of the methods in vogue), should have received the preference over a dozen established and capable applicants, and the fact that all the important positions around here are held by men who received their training in one or other of the British Isles, proves that gardeners from them are looked upon very favourably by Americans generally.

A man who does not mind work, and is not over-particular what he does whilst waiting his opportunity, need not be out of work a week, and can earn good wages whilst looking for better. A head man receives from 50 to 70 dollars per month, with house, vegetables, milk, and often coals, and sometimes as much as 80 dollars; and positions are not so scarce or hard to obtain as in England.

But it is the young man who stands the best chance—one who can manage a greenhouse or two, and who is willing to lend a hand outside when required. There is a dearth of such men. I know gardeners who have been trying for weeks for such places without success. My best man receives 25 dollars per month, with board and lodging. The board is superior to that which a young gardener is usually able to provide for himself at home, and I have to use him fairly "square" to retain him, as he could get another post as good to-morrow if he wished.

For the labourer in nurseries who knows his work there are as good prospects. A friend of mine, a nurseryman and landscape contractor, who has more work than he can manage, is handicapped by a staff consisting chiefly of Poles, many of whom cannot speak a word of English, and coloured men, none of them having even an elementary knowledge of nursery work. These men receive 5s. and 6s. per day, and there are not enough of them.

When these figures are compared with the wages at home, America shows, I think, to advantage. A man with a family would find house-rent and provisions a little more expensive than in England, but not in proportion to the increase in his income. The climate is healthy and enjoyable, and the country beautiful. The servility too often expected at home is unknown here, and life all round is more free and pleasant. Any able-bodied man who can control his taste for drink, and who gives the whiskey a wide berth, can, if he

wishes, either make a home here in comfort, or return home in a few years, the better in wisdom and pocket by the change. To any such, desiring to try their luck, I shall be pleased to give any details or assistance in my power. A. Harding, Villa Nova, Pennsylvania, U.S.A.

FRUIT-DRYING.

MR. UDALÉ has, as our readers know, been conducting experiments on the evaporation of fruits, &c., for the Worcestershire County Council. He has made these experiments the subject of a detailed report, which we commend to the notice of our readers. In the meantime we may quote the summary given by Mr. Udalé:—

1. Ripe fruit dries more quickly than unripe fruit, the latter being several hours longer in the process, and therefore more costly to produce.

2. Unripe fruit loses a larger percentage in weight during the drying process, and is not a good colour for its kind or variety when dried.

3. Large fruit of the respective kind or variety produces the finest dried article of the same variety or kind.

4. Small specimens of the same variety of fruit or vegetables dry more quickly than larger specimens.

5. Stone fruit, such as Plums, Cherries, &c., should be exposed to a low temperature at first for several hours, and have the temperature gradually increased as evaporation proceeds.

6. Apples and vegetables may be exposed at once to a moderately high temperature, and finished in a lower temperature.

7. Stone fruit should be placed on the trays with the stalk ends uppermost.

8. Fruit of equal size should be placed upon the same tray, and not small mixed with large fruit.

9. Apples and Pears should be immersed in a weak solution of salt and water immediately after peeling, 1 ounce of salt to 3 quarts of water; if left exposed to the air after being peeled, they quickly go discoloured.

GENERAL REMARKS.

I think there is a prospect of Plum-drying becoming an industry in this country; and that in years of great abundance of fruit and of very low, or no prices, the fruit may be dried and sold wholesale at remunerative prices. Clearly we have varieties which are at once prolific and suitable for drying; notably Monarch, Czar, Prince Englebert, White Perdrigon and Victoria.

I think it is tolerably safe to say that each of the varieties mentioned is worth, for drying purposes, from 3s. per bushel upwards.

The operation of preparing and drying fruit and vegetables is soon learnt by any intelligent man or woman; and I think it is labour well adapted for women.

If 5s. and upwards can be obtained per cwt. for good Apples, I think it will be best to sell them in the undried state. Perhaps small Apples will pay for drying; and they might also be remunerative for making into jelly.

Although we have made jelly from the peelings and corings of Apples and Pears—that "nothing be wasted"—I fear that the balance would be on the wrong side the ledger if a strict debtor and creditor account had been kept.

We have demonstrated that all kinds of vegetables may be dried successfully—from pot herbs to Cauliflowers, but we have not tested them sufficiently extensively to be able to say if or how far they could be dried with commercial success.

I have tested the eating qualities of the second grade Victoria Plums (I thought if the second grade were good, the first grade would be better) after gentle stewing for thirty minutes, with the addition of a little lump sugar, and I was more than satisfied with their quality. They were clean and delicious, and superior to any French Plums I have bought at any time at 6d. per lb. retail. I selected the Victoria for the test because it has been condemned as unsuitable for drying by a certain writer in the horticultural Press, and because I know the better varieties can take care of themselves.

Although it may be admitted that—so far as our experiments have gone—the best varieties for drying at home are Monarch, Prince Englebert, and Czar, and that they now realise remunerative prices when sold undried, we cannot be certain that they will be so remunerative five years hence, or even three years hence.

Monarch and Czar are being extensively planted, and we may have such abundant supplies of these—and of others as good—in the near future, that the prices realised for them may fall to a comparatively unremunerative amount in the fresh state; then the grower may dry them, and profit thereby.

Samples of French and Californian dried Plums have been bought at 10d. and 6d. per lb. respectively, for comparison with the home-grown and home-dried Plums, and the following are the results:—

Competent judges are agreed that in appearance—

| | |
|----------------------------------|-----------------------|
| The Monarch surpasses the French | at 10d. per lb. |
| Prince Englebert | " " " " 6d. " |
| Victoria | " " " " " " |
| White Perdrigon | " Californian " 6d. " |
| Czar | " " " " " " |

and that their quality in order of merit when stewed gently for thirty minutes is as follows:—

(1) White Perdrigon; (2) Victoria; (3) French, at 10d. per lb.; (4) Californian, at 6d. per lb.; (5) French, at 6d. per lb.; (6) Pershore.

The tenderness of the skins before stewing varied in the following order:—(1) French at 10d.; (2) Victoria; (3) Pershore; (4) White Perdrigon; (5) Californian and French at 6d.

Two Silver Medals and a Bronze Medal have been awarded to the samples of dried fruit and vegetables by the Royal Horticultural Society, Birmingham and Midland Counties' Chrysanthemum, Fruit, and Floral Society, and the Tamworth Chrysanthemum and Fruit Society. James Udalé."

ON PRUNING.

SOME time ago considerable discussion was evoked on the question whether, after a certain stage, it was productive of any practical or fruitful results to prune fruit trees. If I recollect aright, I believe it was mutually understood that at the start the trees were all prepared for the purposes they were intended for, either as standards, bushes, espaliers, or pyramids, and as discussion was confined principally to the staple fruits for the million, viz., Apples, Pears, and Plums, these three I shall only now deal with. I do not propose here to go into the culture, management, and training of each form of tree, but rather to speak on the principles of pruning generally in relation to all forms, with its ultimate results on the tree, whether for the production of fruit or otherwise.

Working from the above data, it is a well-known fact that earlier crops will be obtained from unpruned trees after a certain stage of their growth, but it may be at the sacrifice of a well-balanced crown, through the neglect of pruning. As the matter stands, it will be the

FIG. 7.—*PTYCHOSPERMA ELEGANS* (SEAFORTHIA). (SEE P. 18.)

aim of the gardener to pursue a middle course, i.e., not to prune unduly hard in the attempt to check exuberance of growth while the roots are neglected, as this will only intensify the evil and arrest the fruit bearing capacity of

the tree, and cause numerous shoots to be formed. Many writers on pruning overlook this fact. The two operations of root-pruning, or lifting and branch-pruning, should not be carried out the same season, as this would

tend to lower the vigour of the tree and its growth, which is as much to be deprecated as a too great exuberance, but the growth of each should be reciprocal. Another point I should like to refer to is, that when the old

soil is taken out in order to sever the roots all round the ball of the tree, new soil should take its place; and there is nothing better than good turfy loam, which should be well worked in among, and made firm amongst the roots.

The head of the tree will require scarcely any attention for some time, except to remove spindly growths and crossing branches, shortening very long branches to a reasonable length, and keeping the head of the tree open, so that sunlight can enter. The above remarks apply especially to standards. Espalier and pyramid Apples and Pears, through being mostly grafted or budded on the Paradise and Quince stocks, have a tendency to remain dwarf, and fruit earlier than the former without much pruning. The occasional lifting the trees, and summer-pinchings, comprise most of the pruning required, and these processes will, with good manurial surface-dressings in the spring and autumn over the roots, keep the trees in a high state of fertility for a number of years. Trees of this kind are very suitable for planting in gardens. After a time, long fruit spurs will require removal, and the shoots in the middle of the head should be thinned out, the best and safest time to prune being either after the fall of the leaf or just before the sap rises.

Some years ago when I visited Byrkley Lodge Gardens, near Burton-on-Trent, there was a useful object lesson there in two rows of splendid pyramid Apples on the Crab-stock, which carried enormous crops of fruit. Mr. Hamilton, the head gardener, assured me that these trees had never been touched with a knife since he planted them, except that they were systematically root-pruned when this was required. I cannot say much for the shapeliness of the trees at the time of my visit, which careful pruning at an early date would have secured; but they were certainly marvels of fertility, and this, it seems to me, to be more the object striven for than anything else. J. D. G.

NOVELTIES OF 1901.

(Continued from p. 4.)

NURSERYMEN.—Messrs. James Veitch & Sons have been constant exhibitors at the Royal Horticultural Society, and during the past year have secured a large share of the awards. Four of their best new Orchids are *Laelio-Cattleya* × *Digbyano-Mendeli*, Veitch's var., of an uniform bright rose-pink tint, and with a wonderfully-fringed lip; *L.-C.* × *Semiramis superba*, the largest and best of the winter-flowering *L. Perrini* crosses; *Cattleya* × *Browniæ* Veitch's variety, a very remarkable and beautiful hybrid; and *Laelio-Cattleya* × *Ilione*, the largest, best, and brightest in colour of the hybrids, bearing a general resemblance to *Cattleya* × *Mantini*. Other fine things of Messrs. James Veitch & Sons' of the year were *Phaio-Calanthe* × *Schroderiana*, *Laelio-Cattleya* × *Yacuna*, *L.-C.* × *Robin Measures* var. *Ena*, *L.-C.* × *Cybele*, *L.-C.* × *Ophir*, *Cattleya* × *Bactia*, *Epidendrum* × *Clarissa superbum*, and *Masdevallia* × *Alceste*.

Messrs. F. Sander & Co., of St. Albans and Bruges, have evolved many fine novelties during the year, the greater part of which have passed out of their hands before they could be recorded to their credit. *Odontoglossums*, always a great specialty of theirs, have in their hands produced some fine forms during the year, among which are two clear yellow *Odontoglossum crispum*—*O. c. citrinum* and *O. c. Sunshine*; and *O. c. King Edward VII.*, *O. c. King-Emperor*, *O. c. album*,

and *O. c. majesticum* have bloomed with them. Also *O. Pescatorei* Emperor and *O. P. Empress*; and among the hybrids *O. × Adriane nobiliss*, *O. × A. memoria Victoria Regina*, *O. × A. Canary Bird*, *O. Rolfæ pulcherrimum*, *O. × R. Mrs. R. H. Measures*, *O. Harryano-crispum* "Duchess of York," *Miltonia* × *Bleuana* "Queen Margherita," *Cattleya Reineckiana*, *C. Mendeli Queen Alexandra*, *C. Kitty Lloyd* (velutina × *Rex*), and a large number of hybrid *Cypripediums*, in many of which the effect of secondary crossing is seen.

Messrs. Charlesworth & Co., of Heaton Bradford, have reaped the reward of skill and diligence in the number of new and fine hybrids they have flowered during the year. One of their most satisfactory crosses was *Cypripedium* × *Maudie* and its varieties, resulting from crossing *C. Lawrenceanum* *Hye-anum* and *C. callosum* *Sanderæ*. *Sophræ-Laelia*

Gratrixiæ and *Sophræ-Cattleya* × *Nydia* are finely coloured flowers; *Cattleya* × *germania*, *C. × Iris* and its variety *aureo-marginata*, *C. × fulvescens*, *C. × Lottie*, *Laelio-Cattleya luminosa*, *L.-C. × Ivernia*, and *L.-C. × Haroldiana* Charlesworthi are all very fine things of which the raiser may well be proud. Also at Messrs. Charlesworth's many pretty hybrids of more moderate pretensions, but interesting withal, have flowered for the first time during the year.

Messrs. T. Rochford & Sons' best were the white *Cattleya* *Hardyana*, Rochford's variety; the large and handsome *Odontoglossum* × *loochristyense* Rochfordianum, *O. crispum* *Edward VII.*, and *O. × Wilekeanum*, Turnford Hall variety.

Messrs. Stanley, Ashton & Co., Southgate, flowered two specially fine albinos—*Cattleya Luddemanniana* Stanleyi and *C. Mossiæ* "Mrs. F. W. Ashton"; and their large importations of *Odontoglossum crispum* have produced promising spotted forms, of which the best shown was *O. c.* "Abner Hassel."

Messrs. Hugh Low & Co. flowered *Cypripedium* × *Kimballianum*, "Low's variety"; *C. Mendeli* Mrs. R. Tunstill, *C. M. His Majesty*; *C. Mossiæ* Sir Alfred Milner, and some good *Odontoglossums*.

Mr. Ed. Kromer had the largest and finest coloured *Laelia Jongheana* in his var. *Kromeri*. And all the other growers have in some degree produced desirable novelties.

CONTINENTAL NOVELTIES.

M. Linden, in his famous collection of *Odontoglossums* at Moortbeek, has bloomed during the year a great number of fine things, some of which have been figured in *Lindenia*, and duly noted in the *Gardeners' Chronicle*. Their *Odontoglossum crispum* "Quo Vadis," figured March, 1901, is a gorgeously-coloured form, a thing of beauty to dream about; *O. c. auriferum*, a yellow-blotched form of the *O. c. xanthotes* class; and some of the varieties of *O. × Adriane*, very large and showily blotched. Among the *Cypripediums*, *C. × Glonerianum*, *C. × Bruxellense*, *C. exul aurantiacum*, *C. insigne* *Chantini* *Lindenii*, and *C. × Lansbergiæ*, are all showy novelties. Several very handsome new hybrid *Cattleyas* and *Lælias* have also been flowered by Messrs. Linden, and their Bornean type of *Phalenopsis* named *Rimestadiana* has proved good, many of the flowers being distinctly tinted with purple. Out of other importations the fine *Oncidium varicosum* *Lindei* and *O. v. Moortbeekense*, both bearing rich chestnut red marks on their large golden-yellow labellums, have flowered.

M. Florent Claes at the last Temple Show exhibited several fine *Odontoglossums*; and Mr. A. A. Peeters, of Brussels, some interesting hybrids, &c.

The following Orchids among others have been illustrated in the *Gardeners' Chronicle* in 1901:—

- Arachnanthe Cathcarti*, March 9, p. 159.
- Cattleya* Miss Harris var. *E. Ashworth*, supplement, May 11.
- Coryanthes Mastersiana*, Jan. 12, p. 19.
- Cymbidium Lowie-eburneum*, July 13, p. 25.
- Cynorchis purpurascens*, Feb. 9, p. 87.
- Cypripedium Maudie magnificum*, Aug. 17, p. 129.
- Cypripedium* T. W. Bond, Coundon Court var., Feb. 23, p. 127.
- Dendrobium Ashworthiæ*, Feb. 9, p. 86.
- Epidendrum Claesianum*, Feb. 2, p. 70.
- Laelia* Mrs. Gratrix var., supplement, Jan. 5.
- Laelio Cattleya Digbyano-Mendeli*, Veitch's var., Sept. 14, p. 207.
- Liparis tricallosa*, April 6, p. 223.
- Moorea irrorata*, April 20, p. 248.
- Phaius Warpuri* (tuberculosus), February 2, p. 77.
- Odontoglossum crispum* Annie, January 8, p. 365.
- Odontoglossum crispum purpurascens*, Apr. 13, p. 233.
- Odontoglossum crispum* Rossendale, Apr. 20, p. 249.
- Odontoglossum* Crawshayanum, July 27, p. 77.
- Odontoglossum* × *Ruckerianum* Mrs. R. B. White, May 4, p. 279.
- Odontoglossum maculatum* Thompsonianum, July 27, p. 77.
- Odontoglossum crispum* Pittianum, Aug. 24, p. 149.
- Sobralia Ruckeri*, July 27, p. 67.

(To be continued.)

THE SHORT APPLE-CROP OF 1901.

A RECENT issue of the *American Agriculturist* states that their earlier reports pointing to the shortest Apple-crop for years have been fully confirmed. October sunshine did something to develop the fruit where there was any chance for it, but in the main the crop was a disappointing one. The only exception is found in the important Apple sections of the south-west, including Missouri, Kansas and Arkansas, where the yield is proving very much better than at one time seemed possible, and buyers from all parts of the country are clamouring for sound fruit; and exceptionally high prices rule. In what has long been considered the commercial Apple belt, phenomenally light yields were the rule.

The surprising thing, as noted, is the development of the Apple crop in the south-west, many counties reporting the largest yield for years past, and of fine quality. As a result, eastern buyers are making heavy drafts upon south-western Apple orchards, paying farmers big prices. As is often the case in seasons of practical Apple failure, the quality of the fruit in the older, middle, and eastern States, is on the average poor. There are some exceptions, but, as a rule, much of the fruit is wormy, coarse, or lacking in flavour.

In practically every instance where there is any fruit available for the markets, growers are getting the highest prices they have done for years. This will in a degree offset the shortened rate of yield, except in sections where the crop is a practical failure. High prices at the same time induce growers and dealers to utilise every barrel possible, and this means the foisting upon the market of much inferior fruit, resulting in a wide range of prices.

The commercial Apple crop of the United States approximates 23,000,000 barrels, against

more than double that amount last year, being, in fact, the smallest output for many years past.

In the Canadian provinces the Apple-crop is extremely uneven. In the Apple section of Ontario the crop is probably the worst failure ever known. At the same time the quality of Ontario Apples is said to be good, but not brilliant, the leading varieties being Spy, Baldwin, and Russet. In Quebec a moderate yield has been secured, while Nova Scotia has a good, but not a full crop. Reports from the Annapolis Valley state the average yield of Apples to be 70 per cent. of a full crop. The quality is among the best for years past, far ahead of 1901, and growers are receiving splendid prices, ranging from 10s. 6d. to 12s. 6d. per barrel.

London dealers say the crop of winter varieties of Apples, both in England and on the continent, is better than was at one time anticipated, but that there will be a demand at good prices for Canadian and American fruit, provided quality and packing are right. It is also stated that markets are favouring highly-coloured Apples. *J. J. W.*

THE HUMUS OF SOILS.

A GARDEN soil must contain in addition to the necessary mineral constituents of plants, a suitable supply of available nitrogen, or the plants cannot make the necessary growth requisite for full development of flowers and fruit. It has been found by analysis that one part of nitrogen in a soil will correspond to about 10 or 12 parts of humus. Any increase or decrease of the nitrogen in soils is followed by a corresponding increase or decrease of humus. The loss of humus and organic matter from a soil not only reduces the stock of nitrogen, but also reduces the amount of available mineral-food as well. The decaying animal and vegetable matters present in all good soils produce acids which act upon the inert and inactive plant-food elements and render them available. The humates or organic products which are formed by the union of the organic acid products derived from the decay of the humus, combined with the mineral matter of a soil, form valuable plant food.

Experiments have shown that humate of lime is capable of being assimilated and utilised by plants. Potash, phosphoric acid, and all of the mineral elements of plant-food when combined with humus and nitrogen, constitute valuable forms of food for all kinds of garden crops.

The high fertility of old kitchen garden soils is due to the large store of humus. The loss of humus changes the physical properties of a soil, both as to colour, weight per cubic foot, and retention of soil-water. A loss of humus and vegetable-matter causes a lightness in soil-colour, an increase in density and compactness, with a less capability to retain moisture. A dark-coloured soil becomes hotter in the sun's rays than a light coloured one; but at night all soils will cool to the same point.

Humus conserves the moisture of a soil, while a rotation of crops, the use of stable-manure, and the digging-in of vegetable refuse conserves the humus. If the soil contains too much humus the vegetative system of plants becomes overfed by an excessive quantity of nitrogen, luxuriance of foliage and stem-growth is encouraged, while flowers and fruit development are retarded. In general it may be said, that an abundant supply of potash and phosphoric acid, especially the latter, tends to increase fruitfulness, hardiness, and firmness of leaves and stems; while an abundance of

nitrogen and humus has a tendency to produce just the reverse conditions. While the plant cannot be at its best without a suitable supply of nitrogen and humus, plants which are grown chiefly for their fruits may easily be injured by an amount only slightly exceeding a sufficiency.

It has been found that the store of plant-food in a soil is of little value unless the physical conditions and the available moisture which it contains are also considered. This brings into prominence the question of proper tillage. No matter how fully the soil may be supplied with plant-food, if it does not furnish a comfortable home for the plant, or if for considerable periods there is not enough moisture present to convey the plant-food to the roots, little benefit may be expected from the real or potential nourishment existing in the ground. Plants growing in a garden suffer oftener from a lack of moisture than they do from lack of soluble food. *J. J. Willis, Harpenden.*

A HALL FOR THE ROYAL HORTICULTURAL SOCIETY.

THE present time may not be that quite the most appropriate for the favourable consideration of a "Hall for Horticulture" in London, but we must be careful not to allow the project to slip out of our memory altogether. Judging as a mere outside Fellow of the Society, however, I should say that despite many and varied disadvantages, the Royal Horticultural Society itself was in times past rarely, if ever, in a better position financially than it is to-day. When we hear of depression in some other crafts and callings, it is very refreshing to read of nearly 900 new Fellows of the Society having been elected within the past twelve months. As a matter of fact, none of us, however old and experienced in matters horticultural, can remember a time of greater popularity and enthusiasm for gardens and gardening, and for gardening literature than that which exists in our own time. Palmy days the Royal Horticultural Society has seen, the hey-day of Chiswick and its exhibitions, its breakfasts, and *fêtes* of various kinds, but those sunny days were the result of aristocratic ascendancy and patronage, the days when Dr. John Lindley, autocrat that he was, used to drag on the gardeners, and tell them to go and get shaved, or to have their boots cleaned ere they allowed the wind to blow between themselves and the nobility! Now-a-days all this is altered, and whilst there is all due respect paid to the comparatively few nobly-born patrons of horticulture, the same is also true of the democracy of gardens and gardening, the working gardeners, and of those who deal in plants and seeds, or in gardening materials.

The Royal Horticultural Society to-day has H.M. the King as its patron, and consists of "all sorts and conditions of men."

We are at the beginning of a year fraught with many auguries for the general good and welfare of England, the year of their Gracious Majesties' Coronation, a year when memorials and all sorts of monuments will be erected in commemoration of a most remarkable epoch in our national history, progress, and welfare. Now comes the question: What will horticulturists do to mark for ever the crowning of England's King and Queen? One of the long-felt, and of late, one of the most keenly felt wants of the many horticultural supporters of the Royal Horticultural Society has been that for a meeting-place and hall of horticulture in London, in place of the conveniently

situated, but small and often overcrowded Drill Hall now rented at Westminster. The money to buy, to select the site, and to build the hall in a convenient place or position, will take time to collect, select, and carry through, of course, and in these matters "hasten slowly" is a good motto; but cannot we take advantage of a great national pageant and of patriotic rejoicing, and at least start a fund for a Royal Hall of Horticulture in 1902, the year of the Royal Coronation?

It is, in one way perhaps, unfortunate that horticulture so far has not found its Carnegies, its Lord Iveaghs, or its Yates Thompsons in London; but if it is denied the advantages of wealthy patrons who are generous also, it at least has an enormous following of amateur and professional gardeners who are willing, and many of them only waiting for an opportunity to aid and assist the Royal Horticultural Society in this question of a hall and meeting-place of its own.

The Society is unendowed, even a Government grant has so far been denied; but now that alterations are in the air, it might be well to approach the proper authorities and obtain from them, if possible, a suitable and central site for the long proposed hall. Surely a good position might be spared for such a building, either in St. James' or in the Green Park alongside Piccadilly. If the project of demolishing some of the houses in Spring Gardens be carried out, so as to open up a broad avenue from Trafalgar Square to Buckingham Palace, might not a Royal Hall of Horticulture find a fitting place thereon? Seeing that the so-called Royal Botanic Society has long enjoyed the grant of a site in Regent's Park, how comes it to pass that our Royal Society of Horticulture is left unprovided for in a similar way? Between the work and usefulness of these two societies, from a national point of view, there is no comparison whatever, and why the least important and less useful of the two is favoured, to the exclusion of the other, seems past all reasonable understanding. Some equitable amalgamation of the Royal Horticultural Society with the Royal Botanical Society has often been suggested, but there are financial and other reasons likely to prevent such a union.

Lord Rosebery suggested in a speech the other day that business men were much to be desired in Parliament nowadays, and if we gardeners could get a few good men of business to take up this important question of a Royal Hall for Horticulture, I believe their efforts could be brought to be successful, and I feel sure that gardeners everywhere throughout the country would influence their employers, as well as otherwise do the best they could, for this project themselves. We shall be told, no doubt, that there is "a lion in the way," but how often do we find, in reality, that it is not the lion that is in the way, but a mere fear of failure, that prevents united action and consequent success. *F. W. Burbidge.*

METROPOLITAN PUBLIC GARDENS' ASSOCIATION.—At the last monthly meeting of this body, it was stated that the receipts during 1901 amounted to about £3,300, showing a decrease of about £1,200 as compared with the preceding year, which was stated to be greatly attributable to the adverse effects of the war and its allied causes in having deprived the Association of certain especially generous supporters, and in having diverted or lessened the flow of general contributions. The work done by the Association is surely sufficient advertisement of its value.

The Week's Work.

THE ORCHID HOUSES.

By W. H. BOUND, Gardener to J. COLMAN, Esq., Gatton Park, Reigate.

The Cattleya-house.—Our plants of *Cattleya labiata autumnalis* have now passed out of flower, and will be afforded just sufficient water to keep the pseudo-bulbs in a plump condition. *Laelia pumila* and its varieties may be similarly treated for the time being. Plants bought in of recent importations of this species should be potted in a compost consisting of peat two-thirds, and sphagnum-moss one-third, the latter being chopped up finely, and the whole being well mixed together before use. Imported plants with all their leaves retained on them should be hung up in a cool house, so as to induce a start in growth, afterwards shifting them to the intermediate-house. During the time they are in the *Odontoglossum-house* they will require little or no water, an occasional syringing on bright days being all that they require.

Cleansing the Plants.—This kind of work should be completed before the end of the month, and doing this affords the opportunity to cleanse the roof, glass-ends, partitions, and front lights of the various houses, also the stages—very necessary operations in districts within a few miles of big towns. It is a most important matter during the winter to afford the plants the utmost amount of light, and only perfect cleanliness will secure this. The leaves of every plant should be sponged at the least once a month, whether there are insects upon them or not, this being a matter of great importance to the well being of Orchids, or of other plants.

Insects.—At one time thrips were the worst of pests in Orchid-houses, but thanks to Richards' XL-All vapour used once a fortnight, and not of great strength except in very bad cases, the plants can be kept quite free of these insects. This substance should be employed, whether thrips are noticed or not. Scale insects, especially the small white one that frequently infests *Laelias* and *Cattleyas*, are still a great plague to cultivators, and difficult to eradicate; and we more often than not spread scale insects about among the plants by removing them with a small stick or dry hard brush. At a certain stage of development, they conceal myriads of eggs and young under their minute shelly covering, which when disturbed alight on plants all over a house; so that it often occurs that after the cleansing of the plants is finished, as we fondly suppose, we have but spread about the insects that were infesting one plant over a dozen. My practice is to touch the scale insects with methylated spirits, and then rub them off with a brush dipped in the spirit, and even then the workman should take the infested plant into a shed whilst cleansing it. Red-spider sometimes gives trouble in the winter season, especially infesting *Cymbidiums*. As a means of ridding a plant of this acarus, I sponge the plants with a preparation of petroleum, soft-soap, and flowers-of-sulphur, which is a very effectual one. Mealy-bug, although one of the worst of pests, can be easily eradicated if carefully watched, and when found touching them with methylated spirits. It is when allowed to breed and harbour on plants unchecked that it is so difficult to destroy. The only advisable method is then to examine the plants at weekly intervals, employing the remedy above given.

PLANTS UNDER GLASS.

By J. C. TAILLACK, Gardener to E. MILLER MUNDY, Esq., Shipley Hall, Derby.

Anthuriums.—Species of the *Scherzerianum* type are now beginning to grow and throw up their earliest spathes, and this is the most suitable season for repotting or dividing any of the plants, as the plants are not then subjected to any great fluctuations of temperature from sun-heat, of which they are very impatient at all times, but never so much so as

they are just after being potted. Sourness of the soil renders the plants inactive, and to obviate this, all, or nearly all, the old soil should be carefully removed, even to the extent of baring the portions of the stem or root-stalk which have been buried. The new soil should be lumpy, and freed from some of its finer particles, but not to the extent of leaving nothing but fibre. A suitable compost consists of good loam, peat, charcoal, and silver-sand; and I would insist on the use of a rather large proportion of loam. Peat is usually looked on as the staple soil, and in it the roots run freely, but the roots made in peat are of quite a different nature to those made in good loam, and not nearly so effective in the production of spathes and leaves. Ample drainage should be provided, and the crowns elevated well above the rims of pots or pans. Strict attention to this, and to afford water on the surface, will certainly help to keep the soil sweet for a long period of time. Plants which stand in no need of repotting may be afforded weak liquid-manure once or twice a week to the surface of the soil. A fair amount of humidity in the air of the house, and a temperature of 58° Fahr. at night, with a rise of 10° by day, should be afforded. These figures are lower than those generally advised, but have been proved as much more suitable than higher ones.

Climbers.—Many climbers both in stoves and greenhouses may be pruned at about this date. In the case of *Allamandas* and *Clerodendrons*, only those intended for flowering early should be dealt with; and the same may be said of *Bougainvilleas* in the intermediate-house. But in the greenhouse, *Plumbagos*, *Heliotropes*, *Tecomas*, *Swainsonias*, *Jasminums*, and various *Clematis* may be pruned forthwith, as they will not start too soon in the temperature maintained in the cool greenhouse. For the present, all the plants mentioned should be kept rather dry at the roots, as they will have sufficient stored sap to cause the buds to start, and much water applied to the soil might do harm to the roots.

Chrysanthemums.—The cuttings should be frequently inspected, and any that appear to be rooted should be removed to a pit, &c., where air may be afforded; this being necessary from the fact that some varieties take a longer time in forming roots than do others, and to treat all alike is a mistake. Again, cuttings are not available or suitable for propagation all at one time, and the removal of some shoots makes room for others. Of late years, the propagation in the spring of many varieties suitable for producing one large flower on a plant has been found advisable. The old plants intended for producing suitable shoots should have extra attention, so that the shoots may be sturdy and strong when wanted.

Conservatory.—In this building there will be a dearth of tall flowering plants at the present time, and the display of flowers will be mostly furnished by the various bulbs which have been forced. These should be frequently changed, and the house kept thoroughly clean, so that there may be always a general appearance of freshness and tidiness to make up for lack of variety.

Tuberose.—A batch of African Tuberose for early flowering should now be started, plunging the pots in a bottom-heat of 70° to 75°. No water should be applied until growth starts, as the plunging material will provide sufficient moisture for the unrooted bulbs. Each bulb should be covered with an inverted pot.

FRUITS UNDER GLASS.

By JAMES WHYTECK, Gardener to the DUKE OF BUCKLEUCH, Dalkeith.

Peaches and Nectarines that have been forced early for several years, and were started this season in November, will now be in full flower. At this stage a constant circulation of air is needed, and sufficient heat in the pipes to maintain a night temperature of 50° when the

weather is very cold, and 55° when milder; during the day the temperature may be 10° higher. As the pollen ripens, shake the trellis each day, and if upon any variety the pollen is scarce, convey some from others with a camel's-hair brush. When fruit is set, do not admit air constantly, but increase the night temperature to 60°. Do not syringe the trees until the fruits are the size of large Peas, but damp the house frequently according to the weather outside. Secure a change of air in the house daily. Disbudding of the trees must be attended to as soon as the fruit is set, removing at first those on the front side of the shoot and those on the opposite or back side of the shoot, leaving those right and left and the leading bud; any buds that show a tendency to grow stronger than the others should be removed. A little later the disbudding may be continued until no more shoots are left than will be necessary for furnishing the trees with fruiting-wood for next year, namely, one at the base of each growth, one half way upon upside of branch, and the leading growth; any buds with fruit at the base, and otherwise would be removed, should only be pinched, leaving three leaves. Guard against having young growths at the extremities of the trees, and little or none in the centres. When the fruit is set, afford the inside border a watering with warm water, and before doing this sprinkle some of Thomson's Vine-manure, or other artificial manure, over it.

A Succession-house to the earliest Peach-house should have been closed at the beginning of this month. It should contain such varieties as *Peaches*, *Amsden June*, *Hale's Early*, *Stirling Castle*, and *Violette Hâtive*; *Nectarines*, *Cardinal*, *Précoce de Crooneels*, *Early Rivers*, and *Lord Napier*. A temperature of 45° to 50° at night will be sufficient until the flower-buds open, then 50° to 55°, with constant air, as advised for earliest house. Daily syringing and damping must be done, but avoid keeping the trees constantly wet in dull weather. In localities where the soil is heavy and suited for Peach-trees, the border need only be examined to give water enough at starting, but in cases of light soil the surface of the border should be removed down to the roots, and a good dressing of artificial manure afforded; also a top dressing of 2 inches of fresh soil, and a coating of farm-manure over all. All trees in other succession and late Peach-houses may now be pruned, and both trees and houses thoroughly washed with soap and warm water. Fir-tree oil is one of the best and safest remedies against scale. If the back wall of the house be smooth enough, oil-paint it, otherwise lime-wash it, but if this work be put off much later the buds will be too forward, and suffer injury. It is necessary, more often than is practised, to lift Peach-trees to check strong growth, and now and again a tree has to be brought in from outside. The autumn is the best season to do all such work, but it is not yet too late. Plant on the surface of border; the roots will get down soon enough. It is not too late to renew or improve late Peach-borders.

Early Muscat Vinery.—It is of little use to start Muscats before the beginning of the year, because the higher temperature required for setting them needs the co-operation of the lengthening day and sunshine. Muscat of Alexandria when in flower require to set them properly a night temperature of 73° to 75°, and in the day as near to 90° as possible, with abundant moisture. For early Muscat we grow here *Sprothoro Muscat*; it suits early forcing because it sets freely should the night temperature go down to 65°. The bunch is broad and dumpy, berries large, and of good Muscat flavour. It requires the same length of time to ripen as other Muscats. Started thus early, Muscats are better for having the roots chiefly inside; the same preparations being made with house and border as those previously advised. The night temperature at starting for Muscats is 55° to 60°, 10° to 15° higher in day. Syringe and damp down according to the weather. Vineries from which the fruit is cut should be pruned to two buds. Vines

with long spurs should have fresh rods brought away from the base of the old rods, as finer fruit is produced on these young rods. Cleanse the house and Vines, prepare the border, and make all ready for starting. Vineries with late Grapes hanging in them should be kept cool and dry, and falling foliage removed every morning.

THE KITCHEN GARDEN.

By T. TURTON, Gr. to J. K. D. WINGFIELD DIGNY, Esq., Sherborne Castle, Dorset.

Hot-beds.—With lengthening days and more sun-heat, a milder heat in the various hot-beds of which use is made will be of advantage in the forcing of all kinds of early crops, including salading. Where tree-leaves are plentiful, a bed should be made sufficiently wide to take two or more rows of frames, according to the demand, for such vegetables as Asparagus, Carrots, Turnips, Radishes, Lettuces, and Potatoes. Such a bed has already been made in these gardens. Apart from being an ideal system for obtaining the above forced vegetables, &c., it is a great saving of labour, compared with the practice of mixing tree-leaves and dung together, which is necessary for the earlier forcing of Asparagus, &c. The outside of the bed is formed with the longest straw from the stables, the short going to the heap for potting, and is from 2 feet to 3 feet thick. All the best of the tree-leaves as they are cleared up in the pleasure-grounds are simply deposited there, and kept well and evenly trodden; one end of the bed is kept open for the carts until it is nearly completed. Such a bed lasts two years, being suitable for frame Cucumbers during the summer, and Lettuces, Endive, &c., in the autumn and winter, followed by Vegetable-Marrows the following season. It is therefore necessary to divide the ground set apart for such hot-beds into two parts, making up one-half of it fresh every year. The leaves from the two-year-old bed make excellent leaf-mould, useful in the kitchen garden where the soil is stiff and retentive, and always acceptable in other parts of a garden.

French or Kidney Beans.—Make further sowings of these as required for succession, using 7-inch pots, which will be large enough for the present. Let the pots be filled to about half their depth with turfy loam three parts, and one part spent Mushroom-bed dung, with a good proportion of charred garden-refuse for ensuring porosity. Three or four large crocks, covered with the rough portion of the old Mushroom-bed dung, will afford ample drainage for each pot. Sow eight or nine Beans in a pot, and thin to five or six in a pot, when it can be seen which are the best plants. The soil should be sufficiently moist as not to require water until the seeds have germinated, and the leaves got free of the soil. Do not cover the seeds more than $1\frac{1}{2}$ to 2 inches, and leave space for a top-dressing, which should be applied when the plants are thinned and supported. Place the pots quite near to the glass in a sunny part of a forcing-house having a temperature ranging from 60° to 70°. French Beans should never be put into vineries, it being an impossibility to keep them free from red-spider. Plants with pods set should be afforded gentle syringings on fine days, in order to keep this pest in check. The plants would also be much benefited at this stage by having clear liquid-manure applied twice a week; that from fowls'-dung, which is easily made by putting about 1 bushel of the dung into a coarse canvas bag, and suspending this in a butt of water, renewing the dung as it gets exhausted of nutriment, and filling up the water-butt. Failing this, a good sprinkling of Clay's, or any of the many artificial manures, which are quick in action, will act as a timely fillip.

Early Peas.—If the border for these is not already prepared as advised above, let no time be lost before preparing it, as after the middle of the present month (January) no opportunity should be missed for sowing the seed if the ground is dryish and friable. Shallow drills

should be taken out with a spade, and if the soil will admit of being trodden, the drills should be lightly and evenly trodden to the proper depth; but if at all wet, then a board about 7 inches wide should be used to press the soil, which prevents the Peas sinking deeply as the ground settles. Of late years the more enterprising seedsmen have so improved upon our early kinds of Peas, that in the private garden at least it is no longer necessary to sow the round, white-seeded, flavourless varieties for early use. William the First is quite as hardy as any of the early round white-seeded Peas, and from long experience with it I have found it to be equally early, and being a green Marrowfat Pea, it is much superior in flavour, and may be depended upon (provided a true stock of it is obtained) for the supply until Exonian and the newer varieties of early Marrowfat Peas sown two or three weeks later come into use.

General Work.—Inspect the plantations of midwinter Broccolis, and directly the heads have reached a serviceable size lift the plants, and lay them where protection from frost can be given. Take up a sufficient quantity of Jerusalem Artichokes, Parsnips, Salsify, and Carrots, to serve the needs of the establishment for a week or longer. Carrots wintered in the ground should be covered with long litter or other light material, so that the roots may be easily dug up in hard weather. Of Seakale take up a sufficient number of crowns to ensure a continuous supply of heads in the event of hard frost setting in; they may be potted or boxed with leaf-mould among the roots, placed in some frost-free spot, and taken into the Mushroom-house or other dark warm place in batches.

THE FLOWER GARDEN.

By R. DAVIDSON, Gardener to EARL CADOGAN, Culford Hall, Bury St. Edmunds.

Violas.—Plants that were struck from cuttings in the early part of the autumn of last year will have made numerous fibrous roots in the light, sandy compost in which they are planted, and an occasional application of soot-water and weak liquid-manure will be very beneficial. This should by preference be made early in the forenoon of bright days, so that the foliage may get dry before the evening.

Calceolarias and Centaureas.—Cuttings which were inserted in cold frames in the autumn will have wintered favourably this year; and in order to obtain a sturdiness of growth, the frame lights should be removed for several hours in the daytime—and should the weather be very mild, the lights may be tilted about 4 inches at the back throughout the night. Let all decayed leaves be frequently removed, and the surface of the soil stirred. Let the side shoots of Centaurea candidissima be similarly treated. Assuming that the cuttings were inserted in the autumn in 60-pots filled with sandy soil, they will have become established in the cold frames, and may have thorough exposure throughout; of course, excluding frost by means of linings of litter, &c., and coverings on the glass at night.

Pergolas.—Where these structures exist, and the framework consists of wood, the pillars and arch-bars should be well examined at this season, and any part that is too fragile to endure for another year should be replaced by sound materials. The plants covering the pergola, such as Vitis Coignetiae, Wistarias, Cydonias, Viburnums, Roses, summer-flowering Jasmines, should be cleared of dead shoots and spurs, refastening the shoots and branches to the framework, and in so doing affording strong-growing and large-leaved species ample space for the development of the foliage. Forsythias, if these are employed, where they have not already been attended to, will require the same kind of treatment, and the removal of the dead shoots. If insects or their larvae be present upon the plants, prepare a mixture of petroleum

$1\frac{1}{2}$ wine-glassful, black soap 3 oz., rain-water 1 gallon, stirring the ingredients together, and applying it to the infested plants with the garden-engine.

Clematis.—Species and varieties of these that are protected from frost should have the protective material removed in mild weather in order that the leaf-buds may not develop prematurely. It should also be removed from varieties of T. and H. T. Roses, whether of bracken or litter, or the bark may decay. Clumps of herbaceous perennial plants should have the same kind of attention. The ordering of flower seeds from the seedsmen should have immediate attention, having proper regard to locality and climate, and the season at which the chief display is desired, or the uses to which the plants will be put.

THE HARDY FRUIT GARDEN.

By J. MAYNE, Gardener to the Hon. MARK ROLLE, Bickton, East Budleigh, Devonshire.

The Peach Wall.—Assuming that the trees have been taken from the wall, pruned, and washed with an insecticide, it will be necessary to lime-wash the wall before fastening back the trees; and if nails are used for the purpose, it is best to go over the wall, stopping all holes with cement, before the lime-wash is put on, for it is here a great many injurious insects hide. The wash may be toned down to slate-colour by adding a little lamp-black. The branches should be tied in small bundles so that the brush may be worked more conveniently. It is the practice in some gardens to keep the trees from the wall until the buds are well advanced, but although it may retard the blossoming period a week or ten days, I do not think the method a good one, as there is the greater evil of knocking off many flower-buds when training, no matter whether tied or nailed, and the work can be much more expeditiously carried out while the trees are comparatively dormant.

Training.—A practised eye is required for this work. The fan-shape is the best style of training for the Peach and for all stone fruits, whose branches are liable to die away. The gaps can be thus more easily filled up than by any other mode of training. The main branches should first be fastened in position and evenly distributed on either side from the centre of the tree, the lateral branches running in the same direction, allowing a space of 3 to 4 inches between the shoots, tying or nailing these at their full length, but not too tightly, shortening to the second bud all surplus shoots or any inclined to grow outward to form spurs. In training these two or three years from the graft, the centre should be kept well open and the shoots almost horizontal, or else most of the sap will rush to the upright shoots rather than to those on either side lower down, and an ill-balanced tree will result. If the nail and shred are used in training, it should be placed above and below the shoot alternately, this keeping the branch in position better than if nailed only on one side. All shreds to be used a second time should be boiled, in case any insects or eggs are contained in them. Nails are the better if made red-hot and before quite cold placed in a bag and hustled too and fro to rid them of rust. Newly-planted trees should neither be pruned or trained for the present. It will be more comfortable for the workman, and better for the border, if boards are laid down for standing upon while the work of pruning and washing is carried out.

Gooseberries and Currants.—Cuttings may be made of strong, straight shoots, 12 to 15 inches in length, with all but the four buds at the top removed, and topped about 2 inches. Black Currants should retain the whole of their buds, so that some shoots may arise from the root-stock annually. These cuttings are the better if struck in a somewhat shady position in trenches 4 to 6 inches deep, and having an upright face. Make the soil firm about them. A good distance for cuttings is 8 inches by 1 foot.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the **PUBLISHER** Letters for Publication, as well as specimens and plants for naming, should be addressed to the **EDITOR**, 41, Wellington Street, Covent Garden, London. Communications should be **WRITTEN ON ONE SIDE ONLY OF THE PAPER**, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY, JAN. 14.—Royal Hort. Soc.'s Committees.
—Scottish Hort. Assoc. (Ann. Gen. Meeting).
WEDNESDAY, JAN. 15.—Royal Botanic Society meet.
THURSDAY, JAN. 16.—Linnean Society meet.

SALES FOR THE WEEK.

MONDAY, JAN. 13.—Perennials, Border Plants, Roses, &c., by Protheroe & Morris, at 12.—Roses, Bulbs, &c., Johnson, Dy-mond & Son, at noon, Japan Lilies at 1.30.
WEDNESDAY, JAN. 15.—Azaleas, Palms, and Bulbs, by Protheroe & Morris, at 12.15.—Lilies, Plants, &c., at Stevens' Rooms, at 12.30.
FRIDAY, JAN. 17.—Border Plants, &c., Protheroe & Morris, at 12: Orchids, at 12.30.—Collection of Orchids, by Mr. Cowan, Coal Exchange, Manchester, at 12.30.
SATURDAY, JAN. 18.—Palms and Decorative Plants, at Stevens' Rooms.

TENDERS.

Construction of Recreation Grounds, St. John's Wood, &c., Borough of Marylebone.

(For further particulars see Advertisement columns.)

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three Years at Chiswick —36° 7'.

ACTUAL TEMPERATURES:—

LONDON.—January 8 (6 P.M.): Max. 47°; Min. 43°. January 9.—Dull; mild.

PROVINCES.—January 8 (6 P.M.): Max. 48°, W. Ireland; Min. 43°, N.E. Scotland.

Culture of Orchids in Leaf-mould. THE subject of the culture of Orchids in leaf-mould is one of such interest to Orchid-growers that the following communication which we have received from M. DE LANGHE-VERVAENE will, we are sure, be read by them with interest:—

"It should first be stated that this new method of culture, introduced by us twelve years ago, at first met with but scanty sympathy from horticulturists, and it was only after some time, when we had given decided proofs of the value of our theory, that here and there some grower of Orchids, after visiting our houses followed our example. So simple a plan of cultivating these plants did not seem feasible. Instead of weighing so important a question, it was negatived *a priori* pending fresh developments. Fresh proofs were soon forthcoming, and year after year the results were more convincing; oddly enough, those whose business it was to instruct Orchid-growers still found our method undesirable, and disparaged it with the object of decrying the use of leaf-mould, which was supposed to do every possible harm to Orchids planted in it.

We did not cease to contend that our system of feeding was more natural, and therefore more acceptable than those formerly pursued, but our explanations of the value of the leaves, and the abundance of nutritive properties that they contained, were unheeded.

In 1890 a congress was held in Paris with the object of determining the cause of the degeneration of Orchids grown under glass, and it was clearly demonstrated that diminution of the pseudo-bulbs was attributable to insufficient nourishment. To escape these

consequences, the use of artificial manures was recommended. Soon after this M. L. CHAURÉ, editor of the *Paris Moniteur d'Horticulture*, having heard of our new method of cultivation, visited us at Brussels with the idea of noting the results obtained by us. Furnished with such information as we could give, he recognised the importance of the matter to French Orchid-growers.

It was after this that leaf-mould was made the object of many experiments which, if not satisfactory to everyone, at least converted many who had previously been much averse to its use; and it may be said that it is now largely used in France. It is likely also to be adopted in England. Misconceptions have arisen from the notion that the compost retains too much moisture, or that watering can never or only very rarely be effected. These are obvious misconceptions, but which must be removed if it is to be proved that cultivation in leaf-mould is preferable to growing in fibre or other soils, and if its use is really practicable.

First of all the cultivation of Orchids as epiphytes under a glass roof should be condemned. None can dispute this.

Plants have constant need of nourishment during the period of growth; in theory, remembering their grasping habit, which enables them to hold on firmly, the possibility of cultivating them as epiphytes seems feasible, but in practice it is not so. In fact, it is a question of supplying the plants with what is essential to them by the intervention of the air, considered as a medium; this is not practicable, so they must be supplied by frequent waterings enriched with liquid-manure, which is hardly easier to accomplish. Then we must use a compost, and decide of what it shall consist. Fibres seem at first sight most suitable for their lightness and permeableness to air, but experience shows that they form too compact a mass, cutting off the necessary air from the roots. Then the most decomposed parts were removed, thus making a lighter compost, but one liable to dry too rapidly. To avoid this drawback, a certain quantity of sphagnum was added, to retain moisture given by watering without intercepting the passage of air. Such was the compost used, except for certain genera; for instance, *Vanda*, *Phalænopsis*, and others whose roots were more impatient of restraint, and which were grown in sphagnum only.

There was little or no nourishment in a mixture of fibre and sphagnum chopped together so as to render it sufficiently permeable; the only parts that the plants could directly assimilate were taken away. Sphagnum itself contains no nutritive matter, and the plants having no means of drawing nourishment from it, are obliged to draw upon the reserve store contained in the pseudo-bulbs; hence their dwindling as demonstrated at the Congress before mentioned. There is justification for the cultivation in sphagnum only of species such as *Vanda*, as these plants are provided with an extraordinary root system. Their roots have strong powers of absorption, and if carefully treated during the period of growth, the necessary matters can be supplied by watering, though there is always some difficulty in this way of growing them.

Now to consider compost made of decayed leaves or leaf-mould: of what should it be composed, and what trees or shrubs should provide the leaves?

Various analyses should be made to determine the relative values of leaves, and to find which is most suitable for each genus or variety of Orchid. Much remains to be done in this respect. We have tried to solve the

question by following natural indications. Leaves from the trees of woods and forests of our countries, after their fall and decomposition, serve perfectly to nourish exotic plants from any locality. A compost formed of these leaves, when used, as is the case with Orchids, for plants of small size, replaces and even improves upon the soil necessary for their establishment; on this theory is based my plan of cultivating Orchids. We will not enlarge on the nutritive properties of leaves after their fall; suffice it that their value is considerable, while such a mixture can be formed as no other manure can equal, especially for application in cases where the plants grow from seed, and are varied in character.

The basis of a compost such as this should always be the leaves of Oak and Beech, which are sufficiently durable, and with which any other leaves can be mixed, forming what we usually call leaf-mould. If our theory is tenable, as results induce us to believe, the culture of Orchids in leaf-mould may become general, provided that the necessary material is obtainable in all countries without fear of its becoming exhausted.

It remains now to describe its uses. Before using the compost, all leaves that are not sufficiently decayed should be sifted out, and if it still seems too compact a little rough sand should be added to ensure the passage of water. We use pots of the usual form, of which the depth is nearly equal to the width near the top; put one crock over the bottom to allow the superfluous water to run away, and so arrange the plants that the bottom of the pseudo-bulbs is on a level with the upper edge of the pot, making the soil firm but not hard, and covering with a light layer of sphagnum chopped into inch lengths. This addition is not essential, but is for appearance sake, and also because if the soil is exposed it becomes covered with minute growths that prevent the air from penetrating. We use fairly large pans when we have vigorous plants likely to remain in them for two or three years—but it is foolish to generalise, as experience only can teach details.

One question that seems to disturb those new to this method of culture is how to give water. We cannot enlighten those unfamiliar with this method without entering into long details; suffice it to say that the amount of water is regulated according to the genus of Orchid, its seasons of vegetation and growth, as well as the condition of each plant. The subject is an important one, and an inexperienced hand may do much mischief. If watering is judiciously managed, the leaf-mould is naturally more apt to dry too quickly, than to retain the moisture long enough to do harm. L. P. De Langhe-Vervaeke, St. Gilles, Brussels.

LINNEAN SOCIETY.—On the occasion of the evening meeting to be held on Thursday, January 16, 1902, at 8 P.M., the following papers will be read:—1. "On the Use of Linnean Specific Names," by Mr. H. J. GROVES. Exhibitions:—1. Branches of Cherry affected by the Gnomonia disease, with remarks on its effects and climatic causes; by Mr. A. O. WALKER, F.L.S. 2. Photographs and specimens of heads of wild sheep, to illustrate a recent suggestion as to the use of large horns in feral species; by Mr. J. E. HARTING, F.L.S.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—A general meeting of the Gardeners' Royal Benevolent Institution will be held at "Simpson's," 101, Strand, W.C., on Thursday, January 23, 1902, at 1 P.M., for the purpose of making certain alterations in the

existing rules, as recommended by the Committee of Management; and the sixty-third annual general meeting of the members of this Institution will be held at the same place, and on the same date at 3 P.M., to receive the report of the Committee, and the accounts of the Institution (as audited) for the year 1901; to elect officers for the year 1902, and other affairs; and also for the purpose of placing twenty pensioners on the funds. The Chair will be taken by HARRY J. VEITCH, Esq., Treasurer and Chairman of Committee, at 3 o'clock, and the poll will open at 3.15 P.M., and close at 4.30 precisely, after which hour no voting papers can be received. All the voting papers have been issued. If any subscriber has not received a copy, it is particularly requested that intimation be sent at once to the Secretary, G. J. INGRAM, at the Offices, 175, Victoria Street, Westminster, S.W. The annual friendly supper will take place on the same date, also at "Simpson's," after the annual general meeting, at 6 P.M., when Alderman ROBERT PIPER (of Worthing) will preside. Friends desiring to be present are asked to kindly notify the Secretary, at 175, Victoria Street, S.W.

"BOTANICAL MAGAZINE."—The January number opens with a fine illustration of *Crinum Johnstoni*, t. 7812, a native of British Central Africa, from which country some forty other species are now known. The present plant is intermediate between *C. latifolium*, which it resembles in the flowers, and the Cape *C. longifolium*, which it resembles in its long, narrow leaves, tapering very gradually to a point, but which are bright green, not glaucous, as in *longifolium*. The flower has a very long, cylindrical tube, expanding into a funnel-shaped limb, with white segments faintly striped with rose in the centre.

Angrecum Eichlerianum, Kränzlin, t. 7813.—A climbing species, with oblong leaves, notched at the apex. Peduncles opposite, the leaves long, slender, 2 or 3 flowered. Flower $2\frac{1}{2}$ ins. in the longest diameter, segments oblong, lanceolate, green; lip broad, spoon-shaped, acute, white. Native of Calabar.

Bauhinia gunnanensis, Franchet, t. 7814.—A graceful greenhouse climber, with tendrils and two-lobed leaves, the lobes short and blunt. The flowers are rosy-lilac, in loose terminal panicles. It is a native of Western China, and is cultivated in our botanic gardens.

Schomburgkia Thomsoniana var. *minor*, t. 7815.—A native of the Cayman Islands, to the N.W. of Jamaica. The pseudo-bulbs are ridged; the leaves broadly oblong-ovate, the numerous flowers in terminal racemes. Each flower is rather over 2 ins. in its longest diameter, the segments spreading, oblong-acute, yellow; the lip projects, its two side lobes wrap over the column, the anterior lobe divides into two oblong, obtuse lobules, rosy-violet in colour, and undulate at the margin. The species was originally described by REICHENBACH in our columns, 1887, vol. ii., p. 38.

Hibiscus Scottii, Balfour fil., t. 7816.—A hispid shrub, with ovate leaves, sometimes slightly lobed. The involucre consists of 10 to 12 linear bracts, and the corolla is $\frac{3}{4}$ inches across, yellow, with a central crimson spot. It is a native of Socotra. Flowered in the Edinburgh Botanic Garden.

TEA-SUPPLY OF GREAT BRITAIN.—According to a recent number of the *Journal d'Agriculture Tropicale*, the importation of Tea into England into 1885 was 182,433,215 lb., of which 63,794,025 lb. was from India, and

4,242,244 lb. from Ceylon; the remainder coming almost wholly from China. And as regards the 303,867,149 lb. of tea imported in 1900, 156,968,149 lb. was from India, 115,322,673 lb. from Ceylon, and only 21,852,642 lb. from China.

PLANTS IN FLOWER ON THE RIVIERA.—Mr. PROSCHOWSKY writes from Nice:—"May I add the names of a few plants in flower in my garden at Nice at Christmas to those named by Sir T. HANBURY as being in flower at La Mortola, a place undoubtedly less cold in ordinary winters than Nice. Here, in parts of my garden where the temperature is noted, no frost has taken place as yet, the lowest temperature recorded being 1.5° Centigr. on December 16, but some days of continual mistral, with the temperature rising in the day to 16° Centigr., caused the usual damage to many plants, in shrivelling up the leaves, flowers, and tender shoots. Several plants having lost the points of their branches through last winter's severe frost abnormalities occur in the season of flowering, which has for all tender plants been considerably retarded, even where no parts of the plants were actually killed, because the growth of all such plants commenced very late in the season. I can name, as an example, the different *Wigandias*, which generally flower here in midsummer, but last year did not flower at all, and only now commence to show the flower-buds. A few plants, among others, in flower here at Christmas, and now in the first days of January, not named in Sir T. HANBURY's list, are:—

| | |
|--|--|
| <i>Ageratum mexicanum</i> | <i>Iberis sempervirens</i> |
| <i>Abutilon</i> var. | <i>Lopezia miniata</i> |
| <i>Begonia</i> Rex and others | <i>Lantana camara</i> and others |
| <i>Berberis nepalensis</i> and others | <i>Maurandia scandens</i> , Barclayana and others |
| <i>Bougainvillea glabra</i> v. <i>Sanderiana</i> | <i>Musa Ensete</i> |
| <i>Ceanothus divaricatus</i> | <i>Nicotiana glauca</i> |
| <i>Chamedorea</i> var. | <i>Pelargonium</i> hybrids |
| <i>Cestrum</i> (<i>Habrothamnus</i>) var. | <i>Passiflora Raddiana</i> |
| <i>Daphne indica</i> | <i>Plumbago capensis</i> |
| <i>Epipremnum mirabile</i> | <i>Polygalas</i> var. |
| <i>Eupatorium Morrisii</i> | <i>Salvias ianthina</i> involucreta v. <i>Bethelli</i> , <i>lantanifolia</i> , <i>eriocalyx</i> , and others |
| <i>Euphorbia</i> (<i>Poinsettia</i>) <i>pulcherrima</i> | <i>Saxifraga crassifolia</i> |
| <i>Eriocephalus sericeus</i> | <i>Senecio</i> <i>Gliesbrechti</i> , longifolius, and others |
| <i>Fatsia papyrifera</i> | <i>Sphaeralcea umbellata</i> |
| <i>Freylinia cestroides</i> | <i>Solanum jasminoides</i> |
| <i>Grevillea Thelemanniana</i> , the most floriferous plant I know, actually in flower every day in the year | <i>Sparmannia africana</i> |
| <i>Genista monosperma</i> | <i>Tacsonia mollissima</i> |
| <i>Heliotropium peruvianum</i> | <i>Tecoma capensis</i> |
| <i>Ischomorus</i> in var. | <i>Thomasia solanacea</i> |
| | <i>Veronica speciosa</i> and varieties |

FLOWERS IN SEASON.—We have received from Mr. A. HATTON, the gardener at The Quarry, Sevenoaks, Kent, a box of very fine flowers of *Helleborus niger* (Christmas Rose), apparently the produce of plants protected by glass during the flowering period. They average $2\frac{1}{2}$ inches in diameter, and are of the purest white, and at a slight distance scarcely distinguishable from those of the Dog Rose. The sender tells us that he had on January 6 cut forty dozen of the blossoms.

THE ULSTER HORTICULTURAL SOCIETY.—Just too late for inclusion in our Almanac, we have received intimation from the Ulster Society that their next Chrysanthemum exhibition will be held at Belfast on November 11 and 12, 1902.

SELECT VARIETIES OF SWEET PEAS.—Shortly after the exhibition of the National Sweet Pea Society in July last, we called upon Mr. W. SIMPSON, at the Grange Gardens, Sutton, who won the first prize in the principal class at that exhibition. We found that the exhibition flowers had been obtained from

a collection embracing as many as seventy varieties, but Mr. SIMPSON considered many of these were so nearly alike, or were inferior to others, that he had come to the conclusion that for garden purposes twenty would be sufficient to represent all the desirable colours and forms. In response to a request that Mr. SIMPSON would give us his opinion as to the best collection of twenty-four varieties, we were favoured by the following list, which may be useful to our readers when ordering seeds for the coming season. The varieties are Salopian, The Hon. F. Bouverie, Duke of Westminster, Othello, Mrs. Dugdale, Venus, Captain of the Blues, Lovely, Lady Grisel Hamilton,* Gorgeous, Emily Henderson, Miss Willmott,* Chancellor, Blanche Burpee, Lady Mary Currie, Prince of Wales, Triumph, Duchess of Westminster,* Prince Edward of York, Colonist, Royal Rose, The Hon. Mrs. E. Kenyon,* Lady M. Ormsby Gore, and Emily Eckford. The four varieties marked by * were figured in these pages August 3, 1901, p. 87. Mr. W. SIMPSON is gardener to R. C. FOSTER, Esq., and it is wonderful that from so small a garden he should have been able to take such a position at an exhibition. He had also some remarkable plants of *Euphorbia* (*Poinsettia*) *pulcherrima*, 7 feet high, with excellent foliage, and the appearance of other plants showed that, given greater facilities, Mr. SIMPSON would show himself a first-rate cultivator.

OTTO OF ROSE.—Speaking at the Pharmaceutical Society on the production of this valuable substance in Bulgaria, Mr. HOLMES continued:—

"I wish to direct the attention of distillers of essential oils in this country and our colonies to the fact that there are in this country localities, as in Devon, South Wales, and Ireland, as well as in our colonial possessions, where the requisite warmth, moist atmosphere and soil to grow Roses to perfection, exist, and that there are Roses more easily grown in this country than the Bulgarian variety, which in sweetness are not excelled by those of any European country. Among these may be mentioned the 'Unique,' a very floriferous, white-flowered form of *Rosa centifolia*; the ordinary *Rosa damascena*, or damask Rose of our gardens, the General Jacqueminot, a hybrid perpetual, and Madame Isaac Pereire, said to be the sweetest Rose grown. The old-fashioned Maiden's Blush has also a very sweet perfume, but, like the ordinary damask Rose, and the *Rosa centifolia*, its period of flowering lasts only during June. The perfume of Tea Roses is remarkably powerful in the yellow Rose *Maréchal Niel*, which has never, so far as I am aware, been utilised in perfumery, although the oil of *Henna* flowers is very similar to it in character, as is also that of *Bulnesia Sarmienti*. There is no reason, considering the advantages of horticultural knowledge and chemical skill and commercial enterprise possessed by this country, why an English otto of Roses should not in the future earn the same reputation that English oil of Lavender and Peppermint already possess. The only difficulty is that of the price of labour, but in this industry, as in that of fruit-picking, children can be employed without interference with their scholastic duties, and there are probably in Ireland many districts where suitable land could be obtained cheaply, and where the moist climate is eminently adapted for Rose cultivation. If a mechanical means of separating the petals from the calyx could be devised, the odour would undoubtedly be far superior to that of ordinary otto of Roses."

BOOKS.—At Messrs. SOTHERY's last book sale of the season at their rooms in Wellington Street, Strand, on December 17 to 19, "English Botany: or, Coloured Figures of British Plants," by J. SOWERBY, 36 vols., 1790 to 1814, realised £14 10s.; "Alpine Plants," by D. WOOSTER, 1874, £1 4s.; "Sylvia Britannica: or, Portraits of Forest Trees," by J. G. STRUTT, 1826, 18s.; "Description of the Genus Pinus, with Directions relative to the Cultivation, &c.," by A. B. LAMBERT, 1832, 14s.; "Illustrations of the Natural Order of Plants," by E. TWING, 1868, 14s.; "The Botanic Garden," by B. MAUND, edited by J. O. NIVEN, 6 vols., coloured plates, 1878, £2 6s.; "Ferns,

British and Exotic," by E. J. LOWE, coloured plates, 8 vols., 1872, £2 14s.; and "Nature-printed Seaweeds," by W. G. JOHNSTONE and A. CROALL, 1850, £1 4s.

A NEW-SHAPED EPERGNE.—Mr. J. WILLIAMS, of Oxford Road, Ealing, is sending out an epergne constructed so as somewhat to resemble a tree with outspread roots and drooping branches, the centre stem being left free of decoration so as not to obstruct the view across the table. Round the base and at the summit are tube-shaped flower-holders set at intervals, and so that, when the epergne is dressed, it has a very light look. The ornament is obtainable in silver-plated and in bronze colour, and measures about 2 feet in height.

FLOWER SHOW AT THE CAPE.—Cape papers record the occurrence of a horticultural exhibition, at which Sweet Peas and Roses formed prominent features. Considering that no country in the world is richer in beautiful and interesting flowers than the Cape peninsula, it seems a great pity that the horticulturists of the Colony do not avail themselves of the riches at their doors, and not copy the European procedures. Sweet Peas and Roses are, of course, both beautiful and attractive, but they should not be allowed to banish the specially beautiful native flora. This would furnish not only beauty, but variety and interest even exceeding that pertaining to Sweet Peas and Roses. There is room for both, and neither need be excluded.

RIVER-SIDE OPEN SPACE.—We are informed that a private Bill will be presented to Parliament next session at the instance of the Earl of DYSART, the object of which is to provide a river-side park extending from Richmond to near Kingston-on-Thames, for a distance of 3 miles along the Surrey shore of the Thames. It is proposed to vest this land in a public body, and preserve it in perpetuity as an open space. Lord DYSART, by way of a return, seeks permission, as Lord of the Manor, to enclose a considerable acreage of Lammas-land to the south of Ham village.

"THE GARDEN ANNUAL," prepared under the direction of W. ROBINSON (37, Southampton Street).—A very useful little book, but which was apparently sent to press before certain changes were made—thus, Mr. BURKILL is no longer at Kew, nor is Mr. JACKSON, nor Mr. NICHOLSON. Professor MACOWAN is not Director of the Botanic Gardens, Cape Town. Mr. THOMAS is not at Frogmore, and the changes at Sandringham have not been noted. Various changes have also taken place in certain private gardens which are not inserted.

"FARM AND HOME YEAR-BOOK" (W. ROBINSON, 37, Southampton Street), is addressed to stock-breeders, graziers, market-gardeners, and agriculturists generally. The information is so varied and good, as to render the publication one of the best of its class.

"THE LIVE STOCK JOURNAL ALMANACK, 1902" (VINTON & Co.), is replete with information suitable for horse-breeders, cattle-raisers, poultry keepers. It is interesting to see that whilst the average height of a race horse in 1700 was 14 hands, now it is 15 hands $2\frac{1}{2}$ inches. The illustrations of various pedigree animals in the advertisements are very interesting to the naturalist as well as to the farmer.

"BIBBY'S QUARTERLY."—*Bibby's Quarterly* (edited by JOSEPH BIBBY; publishers, J. BIBBY & SONS, Exchange Chambers, Liverpool), is very attractive and seasonable. There are

some capital coloured pictures, and the photographs of country life and of cattle are pretty as well as interesting to those learned in stock. The practical articles, such as that on "Uncle Sam in the rôle of Teacher," deserve attention, the following rules laid down for John Bull, junr., embodying some very necessary hints:—1. Be less self-complacent and more receptive of new ideas. 2. Put a little more thought and energy into your work, whatever it may be. 3. Travel around a little and study other methods. 4. Help to reduce the drink bill, alike as an end in itself, and as a means to accomplish the other ends.

FRUIT CULTURE IN THE UNITED STATES: RHODE ISLAND.—On this subject the census returns give us the following figures:—For the State of Rhode Island:—

ORCHARD TREES AND FRUITS.

| Fruit. | Number of Trees. | | Bushels of Fruit. | |
|----------------------|------------------|---------|-------------------|---------|
| | 1900 | 1890 | 1899 | 1889 |
| Apples | 213,598 | 207,230 | 339,445 | 239,367 |
| Apricots | 67 | 28 | 12 | 5 |
| Cherries | 2,193 | 3,014 | 1,329 | 689 |
| Peaches | 48,063 | 11,816 | 6,140 | 1,149 |
| Pears | 23,311 | 20,794 | 12,452 | 10,037 |
| Plums and Prunes ... | 4,327 | 1,183 | 571 | 138 |

The increase during the last decade is especially marked in Peach-trees, having increased 336,217, or 306.8 per cent.; the quantity of fruit produced increased by 434.4 per cent. Apple-trees went up by 3.1 per cent. Pear-trees increased by 12.3 per cent. The Cherry crop was increased by 92.9 per cent., but the number of trees decreased by 27.2 per cent. Plums and Prune-trees went up 265.8 per cent. The total value of all orchard products in 1899 was 155,571 dols. Some 779 farmers cultivate small fruits, the value of the produce being 57,292 dols. The fruits were Cranberries, Strawberries, Raspberries, Loganberries, Currants, Blackberries, Dewberries, Gooseberries, and others.

NEWLANDS, HARROW - ON - THE HILL.

IN all ages gardening has been the chief pastime of the scholar, and the masters of Harrow Schools of the present day pursue the peaceful and interesting occupation with as much zest as any of their predecessors. Some of the schoolhouses have very extensive and interesting gardens, and of them "The Grove" on the Church Hill, until lately held by Edward Ernest Bowen, M.A., whose death occurred recently whilst on a holiday tour, is one of the oldest, and in which the grounds are to a great extent left in their natural state. At a little distance on the hillside the gardens of R. Bosworth Smith, M.A., are rich in hardy flowers and shrubs; and on the slope nearer the town the head-master's garden is pleasantly situated.

Newlands, situated on the eastern slope of the hill which is known as Harrow Park, is one of the finest houses, and its master, Frank E. Marshall, Esq., M.A., who has occupied it since its completion thirteen years ago, has, in the formation of its garden, so liberally and effectively carried out his own ideas, that it is one of the most beautiful in the district. The house, situated on the high ground, is partly clad with *Wistaria sinensis* and *Ampelopsis Veitchii*, and has on the garden side a terrace furnished with flower-beds (see Supplement). On the slope below stand a noble Walnut-tree of considerable age, a fine Spanish Chestnut,

and other large trees. Beyond them are beds of great size and irregular borders, planted with flowering shrubs and herbaceous perennials, two classes of plants which are specially favoured by Mr. and Mrs. Marshall. The large bed nearest to the house is planted with hybrid *Rhododendrons*, among which clumps of *Lilium auratum* find a place, which made a striking display last summer. The next bed is principally of Roses, which were also very floriferous last year; and others are principally of *Azalea mollis* and *A. pontica*, which, after furnishing a brilliant display of flowers, brighten the scene with the bright scarlet, red, and yellow of the autumn tint of their leaves. The long bed at the side of the view is planted with flowering shrubs and hardy herbaceous perennials, among which in summer annuals are planted to fill in spare spaces. In this clump some bushy trees of the Sea-Buckthorn give a novel feature with their branches of greyish-green leaves, and orange-scarlet fruits. Two bushes of the male kind are planted with them, and hence the effective show of berries. Effectively arranged are the different varieties of double-flowered scarlet Thorns, and representatives of most of the finest flowering trees and shrubs, and very fine selections of *Pæonies*, *Irises*, *Delphiniums*, and others of the stronger growing showy perennials; and nearer the margins of the beds, the rarer and smaller growing alpine, and other perennials.

The farthest bed in the home garden, within which the turf is well kept, is a massive one of the best named varieties of *Rhododendrons*, all of which are now large specimens, and well furnished with flower-buds.

Beyond, and stretching away to the kitchen garden, the grass is allowed to grow, a part of the grounds is studded with an occasional flowering and fruit-tree that is very charming, especially in the summer time. The kitchen-garden at the point farthest from the dwelling-house has been well arranged. Mr. Marshall is fortunate in having as head gardener ever since he has been at Newlands, Mr. David Page, a diligent man of very high attainments in his profession, and with over forty years experience in gardening in Harrow, an experience which has taught him much about the peculiarities of a clay subsoil, and other matters which render the district a hard one to garden in to anyone not used to it.

Mr. Page's plan has been never to plant anything without providing for it a good depth of loam or other soil known to be suited to it, hence the fine condition of the *Rhododendrons* and other things in the garden. For plants of large growth the natural soil of the district is excellent after they have attained a good size, but in the earlier stages use of a lighter soil is advisable. On this plan the kitchen-garden was laid out, with a good depth of loam on the surface, and it grows some of the best vegetables to be found in the county. In this part of the garden Mr. Page years ago, having an accumulation of rotten grass which had been deposited in a heap when the lawn was mown, tested its value as a manure, and he found it to be a very strong and efficient fertiliser. Since that he has always had set aside the mown grass as manure, instead of taking it to the rubbish-heap, as is the custom with many. The surrounding country and a lake in the lower ground are of much beauty, although the district in other directions is getting covered with houses.

At one side of the house is the old fruit garden, once part of the old manor-house adjoining. The fruit-trees here are very aged, as are even the fruit-bushes. But age does

not interfere with their bearing, for last season the Red Currant-bushes bore an enormous crop. In the garden is a plantation of a very fine variety of red-fruited Raspberry which originated on the place; and the old fruit-trees on the walls still bear well in some years.

A walk having Roses on arches spanning it runs across the garden, borders of herbaceous perennials being planted on each side—a beautiful arrangement that is being adopted in many gardens (fig. 8). At the end may be seen a singular-looking old brick wall, the purpose of which is not known.

The glasshouses and pits provide for the propagation and cultivation of flowering plants; and in one of the houses there are a few Orchids which thrive and flower well,

times would be better pulled up, and their places filled with fresh plants. By these remarks it will be seen that even for one house of moderate length, say 100 feet long, a selection of 100 plants is not too many, and that it would be wise to have another 100 plants ready in a week or ten days after the house is planted out. I always follow this practice here, planting as we do a great number of houses, and to sow 400 Cucumber-seeds at one sowing is my general rule.

I remember the first year I was here bad luck seemed to follow me; the houses were strange to me then, and I was more or less working as a blind man, and several houses had to be replanted a short time after the start. It was then that I found that it is as necessary to have a good supply of plants as it

trary to most growers, I never use crocks, but moss instead, which we get from the woods close at hand. This is much better than crocks, which take up much space in the pots, and destroy or injure the roots when the plants are repotted or planted.

We take much pains with our Cucumbers. The sowing cannot be done too carefully, for it pays over and over again. All the materials used in the sowing are sterilised, of which there are many methods. A quick process is to heat them, thus preventing all possibility of nematodes, or eel-worms, remaining alive. We are more than troubled with these pests; they have entered the ground in the houses to a great depth, and we cannot get rid of them, which is a very serious matter, although we take greater precautions every year, and find benefit therefrom. I also sterilise the seeds; this I do the night previous to sowing. The plants thus raised have proved to be far superior to others not so treated. The seeds are saved from plants grown entirely in sterilised mould, and only pure water is used. I can fully recommend this practice to all growers of Cucumbers.

To go back now to the propagating-house. The pots, moss, and the mould are put upon clean benches, which have been brought in a few days beforehand, the pots being new or clean ones, it being a dangerous thing to use dirty pots. Half of all the failures in Cucumber-growing are brought about by carelessness, and nothing else. In new places, Cucumbers generally do well, and pay well. No other plant that I know of has so many enemies and is subject to so many diseases, brought about by intense culture. Year after year, the same crop in the same houses, without any change. Only by taking every precaution can failures be prevented. Another plague is rats, and no matter what I do, they will find their way into the houses, and even pull up the young plants after the seed itself has disappeared and changed into plant-food; therefore I always cover the pots at night with sheets of glass or empty boxes, which answer well enough till the plants become too large to be thus covered. It is as well to use the same mould for the young plants as will be used in the beds, never sifting it, but breaking it up by hand when too large, which can be done when using it. When the mixture is too fine, the water does not run away freely, and there is less room for air. A little mould only is required at the time of sowing. A small portion of moss at the bottom, a handful of mould at the top, in which the seed is placed with the finger and thumb, point downwards, and plenty of space is left for a top-dressing afterwards, which for that matter might reach above the rim of the pot.

When long stable-litter is used on the staging in which to plunge the pots, not much water is required, even when there is a good bottom-heat; and this itself is a great saving of labour, and favours the health of the plant. The manure will also surround the plants with moisture containing ammonia, which for Cucumbers is of much benefit. I always make it a practice to re-arrange the plants frequently, afford moisture to the bed—never, in fact, letting it get dry long, or there would be no evaporation. It is a good rule to examine the plants frequently for insect pests. The plants will soon show if the bottom-heat is too high by the weakly growth that they make. The glass should be kept quite clean inside and out, for sunshine is of the greatest help in making strong plants; the staging should therefore be as high as it is possible to make it.

Where young Cucumbers are growing, the gardener will find something to do every day;

FIG. 8.—THE OLD MANOR-HOUSE FRUIT-GARDEN AT NEWLANDS, HARROW-ON-THE-HILL.
(SEE P. 28.)

although they have to a certain extent to take their chance along with the other plants. Both Mr. Marshall and his gardener do all they can to further the interests of gardening in the district, and especially among the cottagers and allotment-holders, who, mainly owing to their exertions, now take a great interest in gardening, and hold a cottagers' show in which the produce is of very fine quality.

MARKET GARDENING.

THE RAISING OF CUCUMBERS.

It is always a wise plan to make sure of a large number of Cucumber-plants, as mishaps will generally occur, and this is but too true where the growing of Cucumbers on a large scale is concerned. The best of us have failures, and many houses have to be planted for the second time, not counting the few plants which might here and there remain at a standstill, and which at all

is of fuel. It is wise, however, not to keep such plants too long in reserve, unless one has the opportunity of repotting them and looking after their wants, or insect pests will very quickly attack them, and are but too soon all over the place.

When it is possible to make a hotbed in one of the houses, no better thing could be made; but it requires more time, and my practice is to clear part of the propagating-house, which is always kept quite free of insect pests by burning flowers-of-sulphur when it is empty. The staging is covered with fresh stable-manure—the longest of it, and in this I partly plunge the pots. Where room is no object, 48's, or even 32's pots are the best sizes to be used. Another plan is to use smaller ones, and repot. Many growers sow the seeds in boxes, and pot off the plants in small pots in a few days. This last practice has much to recommend it, where heavy crops are required in only part of the season, and such plants I have found are more like those raised from cuttings in coming into bearing in a shorter space of time. Con-

in fact, it is on such careful treatment that good results depend. This work, as it is done mostly in the early part of the year, under all possible disadvantages, requires all the attention it is possible to afford on the part of the cultivator. The seeds will germinate freely in a bottom-heat of about 85°, with a lower top-heat, say of 70° to 75°. Air should be admitted to the house whenever the day is sunny and not very cold. A. A. Fabius, Redlands Nursery, Emsworth.

EARLY MELONS AND POT CULTURE.

AN early lot of Melons will be valuable in many gardens where fruit is required in quantity in April or May. I am aware that April is full early, but in the most favoured parts of the kingdom with a good command of bottom-heat, and by growing those kinds that mature quickly—that is, a small or medium-sized fruit—Melons of good flavour may be had at the time named. Pot culture is not generally practised, but much may be said in its favour, as the plants when grown in pots are more readily managed; the roots being curbed, more food may be given when the fruits are swelling. I think Melons are more appreciated early in the season than later, and though there are difficulties to contend with so early in the season, yet they are not so great by this mode of culture. The plants set more freely, and when set will take a liberal supply of food, this causing rapid growth—which is not always the case with plants given more root-space. There are diverse ways even with pot culture. I have seen the Melon fruited in very small pots and do well, but when grown thus the pots were plunged in some rich rooting-material and the plants were grown as cordons, only one fruit being taken from a plant, and of course the plants were much closer together than when larger pots are used, say 12-inches or larger.

There is a gain in running the growths up quickly and securing the first fruit that sets, and plants grown thus in a shallow bed get more bottom-heat and can be fed liberally. I note this mode of culture to show that a hard-and-fast line even with Melon culture is not necessary. Many growers even now have not Melon-pits or houses, and are obliged to grow one crop in frames, and of course at this early period of the year it would not be advisable to sow for frame culture unless there was ample top-warmth from hotwater-pipes. On the other hand, with a good top-heat and only manure to furnish bottom-heat, by using large pots sunk in the manure up to the rims, I have cut Melons in the early part of May. Grown in pots there is a great saving of time, as it is an easy matter to add new heating materials, but the pots should be on a firm base to prevent any sinking, and so arranged that the plants are not more than 12 to 18 inches from the glass. The latter should be covered at night in order to maintain an even temperature and save hard firing.

Of course, with a Melon-house or pit with a path in it the cultivator's task is easier, as the plants can be attended to in any weather; in frames this cannot be done. Even with these difficulties, Melons may be grown with a little extra attention.

My note more concerns house culture, and often shelf-space in houses may be given to pot-Melons when a whole house could not be afforded.

For many years I grew our earliest lot of Melons in 12-inch pots—some in 10, even—in Pine-pits at the back of the pits, and very

well they did, but, of course, heavy crops were not attempted; two fruits to a plant, or three at the most, were obtained, but in the position named the plants could not get bottom-heat. There was, however, a genial warmth from the hotwater-pipes, and the temperature would never fall below 65°. The first fruits that showed were secured, and if only two took the lead we let well alone and did not trouble about others that followed. With pot culture, close stopping is needed, but, on the other hand, the plants make a short-jointed growth and show their flowers sooner than when given more root-space.

When a whole house or pit can be spared for the plants, so much the better, as here much the same kind of treatment can be given, but larger pots can be used and more fruits allowed to each plant, as more trellis space can be afforded. It may be asked, when large pots are used and three or four fruits to a plant secured, what is the gain, as the same results can be obtained by planting out? There is a great saving of time with pot culture; there is less risk of the plants running too much to leaf and failing to set, and some of the strong growers are at times subject to this if the roots get into a body of manure. Another important point not to be overlooked is, that the fruits can be finished better when the grower has good command of the roots. I mean, the supply of moisture can be checked at the right moment.

I need not dwell upon simple details, such as raising the plants; this is well known, but I would add it is best to secure a strong plant at the start, and this at the present time of year is easier said than done. At the same time I think well of the old method of raising the seeds in small pots, sowing two or three seeds in a pot, and when the plants are well above the soil, thinning to the strongest. Many raise the earliest plants by placing fibre in the evaporating pans and plunging the pots. It is a good plan, but the seedlings should never be far from the glass.

I am not an advocate for growing the Melon in poor soil; far better curb the roots and feed freely, thus securing an early set and earlier fruit, and with pot culture these latter points can be attended to—even for a late autumn supply pot culture is valuable. I have also noticed that plants given pot culture rarely go wrong at the base, and this with early plants is a great gain. G. Wythes.

MELIOSMA MYRIANTHA.*

THOSE who look at the multitude of small flowers that bedeck the branching panicle of this shrub, will recognise the appropriateness of the name (fig. 9, p. 31). The flowers are greenish-yellow, and give the plant the appearance of a *Spiræa*. Nevertheless the order to which it belongs, *Sabiaceæ*, is remote from *Spiræa*, and is of interest to the botanist from the position of the stamens opposite the petals. As an ornamental plant it may take a prominent place in the greenhouse, and it might even prove hardy in sheltered situations in the south and south-west. Perhaps also it might prove suitable for forcing purposes. Our illustration was taken by Mr. W. G. Smith from a plant obligingly submitted for our inspection in July last by Messrs. James Veitch & Sons. The plant is a native of Japan, the Corean Archipelago, and probably of some parts of China.

* *Meliosma myriantha*, Siebold and Zuccarini in *Abhandl. Acad. Münch.*, iv., ii. (1843); Hemsley, *Journ. Linn. Soc. Botany*, vol. xxiii., p. 145; Franchet and Savatier, *Enum. Plant. Japon.*, vol. i. (1875), p. 91.

LILIES.

IN some ancient pictures of the Virgin Mary, the artist shows her holding in her right hand a spike of *Lilium candidum*, emblematical of purity; and no better Lily in the whole family could have been chosen. It is as remarkable for its rich agreeable fragrance as it is for its refined form and pure white flowers. Nearly all Lilies are conspicuous for striking colours, and characteristic for perfume. *L. candidum*, *L. longiflorum*, and *L. auratum* on a quiet evening fill the atmosphere with a delicious odour. In such as *L. testaceum* the fragrance is fainter, still very sweet. Some again of the European Lilies are not altogether agreeable. There are, however, some 170 species from the four quarters of the globe to choose from, this being somewhere about the number of species of Lilies at present known, and a few hybrids. Japan gives us somewhere about fifty-six varieties of Lilies, China about twenty-five, and now that the country is being opened up, we have every reason to expect from the recent finds that important species in considerable numbers will be added, and what is of still more importance, species combining great beauty with accommodating habits, and of easy culture. India, including Burmah and Nepal, contributes about seventeen species, all of great beauty, but not all of easy culture in Europe. America contributes about thirty species, amongst which are plants of noble aspect. Europe, including the Caucasus and Siberia, contributes upwards of forty species, representing many of great beauty and value for effect in groups in mixed flower-borders.

Few of the hybrid Lilies appear to be of any great merit, except *L. testaceum*, syn. *excelsum*, and *Isabellinum*. "The Wizard of Santa Rosa," as Mr. Burbank is called by the people of the United States, has been hybridising the Lily family for some years, and I notice one has got into cultivation under his name. Whether he will be more successful than those who have been hybridising to get new Lilies for the last hundred years, we shall see in time. When I saw him in his home at Santa Rosa, he was very sanguine, and had then sent out his first batch of chickens to see what the world thought of his handiwork.

The Lily seems to resist the efforts of man to breed mules, and if one is to judge from the hybrid *L. Parkmanni*, which, in my opinion, to be made a really distinct plant, it wants another cross. It is a seedling from *L. speciosum* and *L. auratum*, but is much too close to *L. auratum*; a further cross with *L. speciosum* might make it a really good mule.

It is some seventy years since the well-known nurseryman, Mr. Groom, of Clapham, near London, had a fine collection of Lilies, and as a boy I remember his price for *L. speciosum* was 5s. to 105s. per bulb; he was what in those days was considered a great importer of Lilies, and from a descriptive list of his, which came into my possession some 25 years ago, containing names and descriptions of some Lilies he had raised, I managed to collect most of them from various sources and under various names, but not Groom's names. By a careful examination of the flowers I arrived at the conclusion he used as parents *Davuricum* var. *spectabile*, from Siberia, with *L. bulbiferum* from the Austrian Alps.

I see some recent writers think that the varieties commonly known in gardens under the name *L. umbellatum*, were raised from the Japanese vars. of *elegans* (*Thunbergianum*), but so strongly was I impressed in studying the parents, *L. bulbiferum* and *L. davuricum*, and taking all the points of the children into con-

FIG. 9.—*MELIOSMA MYRIANTHA*. (SEE P. 30.)

sideration, I see no reason now to change my opinion.

The points which determined my judgment on the parents was the fact that when the flowers of these lilies, which got destroyed

by a spring frost, and the plants not being able to produce seed, they usually produced on the top of the plant bulblets, which, when planted, grew into bulbs. I will not dispute, but some of the stronger vars. of *elegans*

might have been used also, but after all *elegans* is only a geographical form of *L. bulbiferum* and *davuricum*, so I consider my arrangement of all the children remains good under the specific name *L. davuricum* as a pre-

ferable name to *elegans*, and thus it is under the name *L. davuricum* I will describe those I recommend for South Africa. Some will ask, "What is in a name?" I say there is a great deal; it is in plants as important as in children—a mode of distinguishing one thing from another—and in the case of plants it is a great advantage when we can range our garden names under a species; it prevents a great deal of confusion in being able to show the relationship.

Of recent years a new system of naming hybrid plants raised in gardens was introduced by Sir Michael Foster; it has much to commend it. The first syllable of each of the parent's name is taken, and supposing I have rightly determined the parentage, and the mother had been *L. bulbiferum*, the name would read bulb-day, the motive being to know from whence the plant had been derived; but I must say such compound names sound strangely to one's ears. In the very early days, most Japanese Lilies came to Europe through the Dutch, who, I think, were the only Europeans allowed to trade with that country, and I think they were only permitted one vessel a year. At that time Dr. Siebold was settled in Kobe, and, being a plant lover, sent many Lilies and other Japanese plants to Leyden, in Holland, and from thence they were distributed.

The Lily, like the Daffodil, has had its periods of falling out of public favour, so that from Groom's time till some thirty years ago the only Lilies seen about were in old gardens, and those of the commonest kinds, which required no special attention. Now, like the Daffodil, I think it has come to stay, as each year adds some new species requiring less attention and better adapted to the great varieties of soil and conditions in the numberless gardens, small and large, to be found wherever the English language is spoken. The fact that *Lilium longiflorum* eximium succeeds so perfectly in South Africa augurs well for the successful culture of many, if not all, Lilies in this favoured climate.

Lilies are propagated by scales, and this can be done so rapidly that it will be only a few years from the introduction of a new Lily till it is on the market at quite a moderate price. Unlike Daffodils, when a new variety is raised the increase is slow, and it is a long time before a new Daffodil can be bought for a few pence. Happily for us, it is not necessary to wait in either case for moderately-priced bulbs, as there are plenty of both Lilies and Daffodils of the highest order of beauty, which can now be obtained for a few pence per bulb.

It was in 1875 when the first two bulbs of what is now known as *Lilium Harrisii* syn. Easter Lily and Bermuda Lily (*Lilium longiflorum* eximium) were taken to Philadelphia from Bermuda. In three years the two bulbs represented 100, and as the source was known, and the value of the Lily for Easter-flowering appreciated, a supply of bulbs was got from the gardens of Bermuda, and in 1882, under the name of *L. Harrisii*, it was put on the market. The inhabitants of Bermuda, finding they had something of value, collected these Lilies from the different private gardens, and went in for extensive culture. It is recorded that somewhere in the nineties the export of these Lilies from Bermuda amounted to two million bulbs, their estimated value being £15,000. About this time cupidity and ignorance led to sad disaster. Anxious to increase the output, manuring was resorted to, and a correspondent informed me of one farmer who planted two acres, and manured them with all the refuse he could find, including rotten Potatoes: the result being the Lilies were

killed, or so badly diseased that the crop was lost. Of so much value was this export to Bermuda, that the Imperial Government sent out a man almost specially to see what could be done in getting rid of the disease. I chanced to meet this man in New York on his way to Bermuda, and hearing what his main object was, gave him the key to the situation, and asked him to let me know what he found; and when he did so, he stated that manure had been at the bottom of the trouble. In these days it is difficult to turn back the clock of progress, and as Bermuda failed to meet the growing demand for this Lily, it was somewhere about the middle of the nineties a call was made upon the Japs for *Lilium longiflorum*, who lost no time in sending collectors to the islands of the Japanese and Chinese seas, who collected every bulb of this species they could find. The outcome of this indiscriminate collecting was some eight varieties, some tall, some short, some with small flowers, some with large flowers, some with split flowers, some with few flowers, and some with many flowers on a stem. It so happened that a large importer, knowing that I was going to Japan, asked me to look into the matter and report. I did so, and after inspecting some fields of this Lily, I drew the attention of the traders to the most desirable types to cultivate, and advised such should be increased separately, and as the supply of the higher types met the growing demand, to throw away the inferior kinds. I had the pleasure of seeing that, before I left Japan, my advice had been acted upon; and from a photograph of a field of *Lilium longiflorum* eximium now before me, all apparently true, showed me and surprised me that in so short a time this wonderful people, in their desire for trade, should have cleaned their stocks so quickly. I also see from a report that the export of *L. longiflorum* from Japan to New York and London in 1899 amounted to about £15,000, the entire export of Lilies from Japan that year amounting to £25,000. I think Bermuda has not gone back on its £15,000, possibly now £20,000, and Japan equally advanced. You can therefore imagine the extent of the supply and demand, and that mainly to grow under glass for the cut bloom, and then throw it away. The Bermuda Lilies reach the market first, and the grower gets the flowers ready for the Christmas demand. Those from Japan, coming later, meet the Easter demand, and supply flowers during the London season. During five to six months this Lily is to be had in London and all over the British Isles, as also all over the American Continent.

Should anyone desire to start a new industry in the Cape Peninsula, this can be done with *Lilium longiflorum* eximium, and thus share in a profitable enterprise. No need to go abroad for the material; it is at hand, and soon millions of bulbs could be shipped to London. You cannot improve upon the species growing in your gardens. I was curious to know the origin of the stock in the Municipal Gardens; I asked Mr. Chalwin, the Curator, what he knew about the plants, and his reply was: "I have been Curator over twenty years, and they were in the Gardens when I first took up my duties." These Lilies must have been brought here about the same time they were taken to Bermuda, either directly or indirectly from Japan. Prior to our getting *Lilium longiflorum* from Japan, the stock of *L. longiflorum* in Europe was a short-flowered, dwarf variety, possibly worn out from long cultivation in an ungenial climate. It is now some thirty years since we commenced to have consignments of Lilies from Japan, and no doubt some of these

early lots of *Lilium longiflorum* eximium had found their way to the Cape and Bermuda about the same time. It will please you when I say that fifteen flowers on a plant of *L. longiflorum* eximium was the greatest number known in Japan. On this fine form of *L. longiflorum*, Mr. Chalwin informs me that twenty flowers on a stem is no unusual thing. Therefore, according to the size of the bulb you put in the ground will be the height of the stem and the number of the flowers. To prove this, I got Mr. Chalwin to lift a strong plant between 4 and 5 feet high, and measured its bulb, which was 13 inches in circumference, and from base of bulb to surface of the soil 8 inches. I would recommend that you plant 10 inches deep, measuring from the base of the bulb, and my reason for this recommendation is that this plant is supported mainly from the stalk-roots; some Lilies have only roots at the base of the bulb, others have base-roots and stalk-roots. The stalk-roots are the main support of the plant, so that every encouragement has to be given to these; while the roots from the base are working in the interest of the bulb, the stalk-roots are working in the interest of the flowers. One bulb lifted had one flower; this bulb measured 6 inches in circumference, and 28 inches high.

Those species of Lilies which have no stalk-roots, have to do double duty in supporting a flower and remaking a bulb, consequently the increase is less rapid. I ought here to mention the longest flowers I could find in the Municipal Gardens measured 8 inches in length, and from tip to tip of the open flower 6 inches. I question if Japan or the finest culture in Europe ever reached this size, and with twenty flowers on a stem, be it remembered, shows another argument in favour of your charming climate. Some may ask what was the shortest flower I found in the gardens. I think I must say 8 inches long, my eye not being able to detect much difference in the thousands I looked over. P. Barr, in "Cape Times."

(To be continued.)

POPULAR AND STERLING VARIETIES OF PEAS.

DURING the twenty-five years I presided over Longford Castle Gardens, I grew most, if not all, the leading varieties of the culinary Peas, and had opportunities of testing many of the novelties before they were put into commerce. The ground in which I grew the Peas each year was trenched between 2 and 3 ft. deep, and three layers, 6 inches thick each, of well-decayed horse-dung were incorporated with the soil in the process of trenching. In this specially prepared land I sowed my second-early, mid-season, and late Peas in early January, February, and March, and afterwards, at intervals of a fortnight or three weeks up to the end of the third week in May, making a large sowing for late crop the end of the first week in June, as three months later the pods will take a longer time than previous crops did to fill. As soon as the Peas appeared through the ground, a little soil was drawn up to the plants on either side of the rows. They were then supported by spray or spreading sticks stuck firmly into the ground on either side of, and close up to, the haulms, following this with a layer of half-rotten manure to the thickness and width of 6 or 9 inches as a mulch, the Peas being sown thinly rather than otherwise in every case.

I may say that the Peas for yielding gatherings of green Peas towards the end of May were transferred from 3-inch pots to a border at the foot of a wall having a south-west

HOME CORRESPONDENCE.

THE RAINFALL AT RUGBY.—I am sending you the tables of the rainfall, carefully kept here for the past two years. I thought it would interest some readers of the *Gardeners' Chronicle* to compare the rainfall for the two years:—

| 1900. | Inches. | 1901. | Inches. |
|---------------|---------|---------------|---------|
| January ... | 3.84 | January ... | 0.63 |
| February ... | 3.50 | February ... | 0.70 |
| March ... | 0.53 | March ... | 1.31 |
| April ... | 0.58 | April ... | 2.82 |
| May ... | 1.24 | May ... | 1.30 |
| June ... | 3.00 | June ... | 3.15 |
| July ... | 0.83 | July ... | 4.79 |
| August ... | 3.62 | August ... | 2.40 |
| September ... | 0.61 | September ... | 1.85 |
| October ... | 2.42 | October ... | 1.45 |
| November ... | 2.27 | November ... | 0.82 |
| December ... | 4.13 | December ... | 4.39 |
| Total ... | 26.57 | Total ... | 25.61 |

Both years, 1900 and 1901, are below average here, but it will be noticed that December in each year has been far above the average, the average fall for that month being 2½ inches. *H. Berry.*

RAINFALL AT TEMPLE HOUSE, BERKSHIRE.

—The appended table gives the quantity in metric inches of the moisture measured in a rain-gauge having a funnel with the diameter of 5 inches, and placed at 1 foot above the level of the ground, at an elevation of 105 feet 9 inches above sea-level:—

| Month. | Total Depth. | Greatest fall in 24 hours. | Number of Days on which 0.1 or more fell. |
|---------------|--------------|----------------------------|---|
| | Inches. | Depth. | Date. |
| January ... | 1.07 | .16 | 27 |
| February ... | 1.65 | .99 | 4 |
| March ... | 1.47 | .45 | 2 |
| April ... | 2.57 | .73 | 3 |
| May ... | 0.60 | .18 | 30 |
| June ... | 1.33 | .62 | 30 |
| July ... | 2.33 | .78 | 12 |
| August ... | 2.35 | .50 | 25 |
| September ... | 1.18 | .65 | 16 |
| October ... | 2.19 | .98 | 16 |
| November ... | 0.43 | .19 | 13 |
| December ... | 3.60 | .81 | 24 |
| Total ... | 20.85 | .99 | Feb. 4 |

The average rainfall for the year is 27.50 inches, and that for 1900 was 26.35 inches. *George Groves.*

LATE PEAS.—I have read with interest the several articles in this journal concerning late Peas, and I for one should like to see a list published of some ten or twelve good varieties for succession, with dates of sowing the same, if some gardener of wide experience would oblige, as I feel sure there are many young gardeners greatly embarrassed as to which varieties to grow after removing from one county to another. *C. B., Cambs.*

JAPANESE LARCH.—I read with keen interest the remarks of "W. H. Massie" in this interesting Larch, in your issue of 21st ult., and so far as habit of growth and disease is concerned, I endorse all your correspondent says. None of us yet know the timber-value of *Larix leptolepis*, as grown in this country, I admit; but watching its behaviour as I have done for a considerable period, and comparing its hardihood growing alongside of the Tyrolean and so-called native Larches, from one-year seedlings up to several feet in height, I am convinced that this interesting species has a future for general estate purposes. *John Arthur, Carlisle.*

CORDON PLUM-TREES.—Doubtless as Mr. G. Wythes says, p. 473, December 28, Plums, when the soil is suitable, can be successfully grown as cordons; or to be more correct, perhaps, this I think is the inference to be drawn from his remarks. On soils containing chalk where wood growth is not gross, cordon Plums will do very well; but it is a system which should never be attempted upon strong, moist soils, in which the Plum makes a gross

growth. When I took charge of the gardens which I now manage, there were, and are now, upon a west wall, the following Plums, *Heal's Hybrid*, *Gisborne*, *Jefferson*, *Victoria*, *Transparent Gage*, and *Green Gage*, as well as cordon Pears and trained Cherries. The Plums were the usual fan-trained, and were fruitless. The wall was only about 5 feet high. The trees had made a very strong growth, which had as regularly been cut back to the top of wall. I advised the raising of the wall, but this was not allowed. Not to be beaten, I suggested bolting iron standards to the wall, and wiring 4 feet 6 inches above top of wall; this I was successful in getting done. The next season the trees made their usual rampant growth, 3 to 4 feet long in some cases. These long top shoots I carefully tied back to the wire, cutting back only such as were not wanted. To fill the wires at a reasonable distance apart, these top growths were not shortened in the least, the result is that each season since, the trees have borne good crops of splendid fruit. A short time ago I was at the house of a friend, looking at a Gage which he had taken much care of; he was lamenting its unfruitfulness. I observed the gross shoots at top of tree, and I asked what would be done with them. "Oh," said my friend, "the gardener will prune them all off." "Now," I said, "you nail them up to the wall of the house, all their lengths, and you will get plenty of fruit." I may say that the Cherries are coming into fruit by being allowed to extend their growth. The indiscriminate use of the knife has much to do with the unfruitfulness of much wall fruit, especially upon strong soils. *W. F. E.*

THE RUST OF CHRYSANTHEMUMS.—I was amused to read the singular remarks of "W. F. E." on p. 13 with reference to the *Chrysanthemum-rust*, I am thinking he has this fungus-pest rather strongly. However, I beg to assure him that I have no desire to lull him or anyone into what he is pleased to term "fools' paradise." I am thankful to say that our plants are free from the disease, and as there have been scarcely any remarks in the gardening press of late, I concluded the pest to be dying out. If gardeners growing these plants would kindly give their experience of this matter in these pages, we should learn how far I am right. *A. J. L.*

—I have read in your paper with much interest the opinions of your various correspondents on this subject. As A. J. Long and W. J. Godfrey hold contrary opinions as to the trial which I reported as regards the effects of manure, will they kindly explain how it was that the unmanured plants escaped without a trace of the rust? No particular varieties were experimented upon, but cuttings were all taken from the same stock. Several gardeners who saw the plants could not account for it. When the article of "W. S." appeared in the *Gardeners' Chronicle*, p. 420, I thought it would be of interest to give a report of this trial. *McCutloch, gr., Denton, Grantham.*

THE CARNATION OR JULY-FLOWER.—Much has been written of late as to the term "Carnation," whether it designates merely a colour of the flower or plant; perhaps the following from *Flora seu De Florum Cultura*, by John Rea, gent., 1676, may prove both instructive and interesting. He says, p. 156, "July-flowers (as they are properly called from the month in which they bring forth their beautiful flowers) are indeed the pride of summer, as Tulips are the glories of the spring. Heretofore we had of them many good varieties that were not seedlings, as the old Carnation." Here he evidently refers to it as a particular flower of a certain colour. Yet further he says, "The gray Hulo, the blue Hulo, the white Carnation," here it is the plant, not the colour, "and others." He continues, "but now not any of them are to be found in any of our gardens, yet we are plentifully supplied with many fine varieties of July-flowers, such as are yearly imported from Flanders and other parts of the Netherlands; raised from seeds, these

aspect early in February, staked, and protected for a time with Spruce-boughs from the effects of cutting winds and frosts, the rows being planted obliquely in order to ensure the haulms having the full benefit of the morning, mid-day, and afternoon sun.

For yielding early gathering of Peas I relied upon sowings of *Lightning*, *Ringleader*, *William the First*, and *Exonian*, made in pots the end of December, and out-of-doors early in January, at the same time that sowings of *Carter's Stratagem*, *Pride of the Market*, *Telegraph*, and *Telephone*, were made for succession. These four varieties, for vigour, productiveness, size, and handsome appearance of their pods, and the fine quality of the Peas with which they are well filled, have not yet been excelled. *Wordsley Wonder*, containing from nine to twelve large Peas in each slightly-curved pod; and *Royal Jubilee*, a grand, good all-round Pea, the handsome sword-shaped pods each containing from nine to thirteen large and deliciously-flavoured Peas; and *Elephant*, were reliable main-crop varieties. *Carter's Michaelmas*, *Late Queen*, *Veitch's Sturdy* (the result of a cross between *Veitch's Perfection* and *No Plus Ultra*), *Prodigy*, *Autocrat*, and *No Plus Ultra*, still hold the field against all new comers as being the most reliable varieties in every way for yielding supplies of Peas of first-rate quality throughout the autumn months, until cut down by frost; being of vigorous constitution and prodigious croppers, producing, mostly in pairs, large, handsome, well-filled pods, containing from nine to eleven large, high quality Peas each.

Sixteen years ago last September, in looking through *Tynninghame Gardens*, *Prestonkirk*, in company with Mr. *Brotherston*, then as now the head gardener at this picturesque situated residence, I saw the Chelsea "triplet" Peas, i.e., *Sturdy*, *Prodigy*, and *Autocrat*, in fine condition, and heavily laden with large, well-filled pods; the crops being in every respect as good as those at the time growing in *Longford Castle Gardens*, nearly 500 miles farther south.

As the result of the cultural treatment described above, I may say without, I hope, being considered egotistical, that with samples of the produce taken from most of the varieties of Peas indicated above, I have invariably succeeded in taking high honours at London and leading provincial shows, at which "special" and other prizes, as well as medals, were offered collections of single dishes of Peas. In fact, I have never failed to secure extra good crops of any one particular variety of the numerous varieties which I tried and subjected to the cultural treatment described above—varieties not mentioned in this list, in which are only enumerated about one-and-a-half dozen of the very best varieties of the Pea in cultivation. I may add that in time of drought the several ranks of Peas were kept amply supplied with water at the roots; but owing to the fact of good surface-dressings of manure having been laid on the ground immediately over the roots on either side the plants, it was not necessary to incur much labour in this direction. The reading of the interesting and useful notes contributed to the *Gardeners' Chronicle* on this subject by Mr. *Wythes* (p. 388), and other correspondents (p. 440), stirred up a favourite topic in my mind, and to such an extent that I concluded that there was still room for a further note on this important subject that some readers might peruse with advantage now that the seed-ordering time is close at hand. *H. W. Ward, December 14.* [We have always understood that nitrogenous manure is not of any special value to Peas, if it be not actually injurious. *Ed.*]

we call Dutch flowers, of which we have some very good sorts." From this it appears that the Carnation and its variants was distinct from these latter. He then gives a list of 360 named and distinct sorts, so that at this early period it seems to have been the practice of naming any new or good variety after gods, goddesses, men, women, and events. For my own part I had deemed this a modern invention to please, and for mercantile purposes. But of Mr. Rea further, "A multitude of these are often brought over to London, and then sold at mean rates to gardeners, who sell them again to others who delight in flowers, commonly for twelve pence a layer" (this rather exceeds the present usual price); he adds, "but the truth is, most of these mercenary fellows about London are very deceitful, and who ever trusts them is sure to be deceived, as I myself have often been, even by such of them as I had by many benefits obliged." Truly times have much improved since 1676. He presently describes the "Dutch July-flowers" as commonly large, thick, and double; the more ordinary sorts are all of one entire colour [selfs], as red, purple, scarlet, or white, some deeper coloured, others paler; these single colours are little esteemed, but those flowers chiefly valued which are well striped, flaked, or powdered upon white, or bluish with darker or lighter red, crimson, or Carnation, sadder or brighter purple, deeper or paler scarlet; so all the Dutch flowers may be comprehended under these three sorts, that is red and white, purple and white, and scarlet and white; in all which there are fine varieties." Here he appends the florists' names of over 100 of these flakes, so that at this period the Carnation must have been held in high repute, indeed, so much so, that Mr. John Rea there delivers his predilection in verse:—

"For various colours Tulips most excel,
And some Anemones do please as well,
Ranunculus in richest scarlet shine,
And Bear-ears may well these in beauty join,
But yet, if ask and have, were in my power,
Next to the Rose give me the July-flower."

Cultural directions are also freely given, all of which are almost identical with the present methods of the "July-flower" fanciers. With "the Clove" he is not much impressed, for he says, "As for Clove, July-flowers, and others of a more ordinary kind, such may be set on banks or beds, and increased as the former," &c. *Harrison Weir, Poplar Hall, Appledore, Kent.*

FAILURE OF LILY OF THE VALLEY TO FLOWER SATISFACTORILY.—Your correspondent's description of his failure points to too much heat having been employed, but as he had others in Cocoanut-fibre refuse which did well, the cause of the trouble may be in the peat, which may not be porous enough. A good substitute for Cocoanut-fibre refuse, which we always use with success, is a mixture of sifted coal-ashes 4 parts, and loam 2 parts, which, with a steady temperature of 75°, gives no trouble. *E. N., Chatham.*

POTATOS.—In your issue for February 23, 1901, I observed, under the heading of "A New Way of Growing Potatos," some remarks respecting the communication made by M. Noel Bernard to the Académie des Sciences respecting the action of *fusarium solani* in the formation of Potato tubers. Have any of your readers made any experiments this season with a view of ascertaining how far the results obtained by M. Bernard are duplicated in England? If so, a report on their work would be extremely useful and interesting. *S. B. Dicks.* [This is a matter which might well form the subject of experiment at Chiswick. Ed.]

PALMS.—Will you kindly allow me space for a few comments upon the interesting articles on garden Palms by Dr. Udo Dammer, a gentleman with whom I have had some interesting correspondence, and to whom I owe some valuable information about Palms likely to grow here, but which have not yet been

tried. Through a mistake in the delivery of a letter, Dr. Dammer was prevented during his recent short stay on the Riviera from visiting my garden, modest enough as yet in appearance, but containing many different species of plants in a young state, notably Palms, which I have tried for some years to collect, in so far as they can be cultivated in the open. When Dr. Dammer states that some Palms *a priori* to be considered delicate, have resisted 6.5° R. without any protection, may I be allowed to doubt, until precisely informed otherwise, if the temperature was taken just on the spot where the said Palms were growing; and whether these Palms were absolutely without any protection? One must have lived here for years, and tried to make delicate plants live, to understand of what enormous importance shelter is in this climate, especially when it is a question of avoiding cold by shelter from above. I could name any number of species which I have lost in exactly similar conditions of soil and exposure but without any shelter, while plants of the same species and same strength did not even suffer when growing underneath some tree, or protected by a little roof of thin cloth, but open on all sides. The cause is, of course, that the radiation of heat from the ground is lessened in this way, and the layer of cold air sinking down during the night is intercepted. I think that Dr. Dammer's informant, though in all good faith, may have been misled by the temperature taken at some distance from where the said Palms were growing, perhaps even at another level. I have in the *Gardeners' Chronicle*, March 23 and 30, 1901, under the title, "Frosts on the Riviera," published a few notes as to the effect of the frost here; also in the number for May 19, 1900, on the effect of the frost of the foregoing winter (in this last-named article a printer's error has put +2 centigr., instead of -2 centigr.). Now my two thermometers, placed at about 100 and 90 metres altitude, give as the very lowest temperature during last winter -3° and -3.5° centigr., but for weeks without interruption the temperature touched zero, and often descended to -2°; and herein, in the long-continued cold spell of weather, often accompanied by the always pernicious dry mistral-wind, lay the cause of the often (as I found later in the year) fatal result to delicate plants. I know well that the temperature sank as low as -6.5° centigr. in certain places, as for instance in a horticultural establishment situated not far from my grounds, but at about 8 to 10 metres altitude. For all I know, the temperature may even in the lowest parts of my own grounds have sunk as low, but I have no thermometer in those parts. Still I measured on February 16, on a little reservoir, ice 4 centimetres in thickness; ice which had not melted for weeks, but kept on getting thicker by each night's frost. But here I will note a very characteristic thing, namely, that on another reservoir situated still lower, but sheltered above by the dense crowns of evergreen Oaks, no ice whatever was found on the same day. The lowest temperature which I have recorded in my ground, several years ago, namely -4.5°, was followed by numerous losses of plants, even of such species as I do not find delicate in ordinary winters; which here, at Nice, means winters with occasional drops of the temperature to -1° or -2° centigr., so that I should not, until given absolute proof to the contrary, believe that some of the most tender plants have really borne unhurt a temperature of -6.5° R. Places only a few metres distant from each other may, according to exposure and shelter from certain winds, present extraordinary differences in temperature; and there is nothing impossible in the supposition that a thermometer may register -6.5° R., and another 10 or 20 metres away only -3.5°. Lastly, may I add a few other remarks to Dr. Dammer's interesting articles. *Chamaerops Birroo*, which I find indicated in Count Kerchove de Denterghem's list of Palms as synonymous with *Livistona rotundifolia*, Mart., but in C. Solomon's book, *Die Palmen*, as a distinct species of Siebold and Martius is, to judge from the many specimens I have of it here,

as Dr. Dammer thinks, only a variety of *Chamaerops humilis*, a very polymorphous species. In the same book I find *Chamaerops cochinchinensis*, Lour., indicated as a synonym of *Rhapis c.*, Mart.; and in Kerchove's list as a synonym of *Rhapis c.*, Blume. Now I have many Palms under the name of *Chamaerops cochinchinensis*, but none could doubt but that they are real *Chamaerops*, but most of them I have raised myself from seeds presenting apparently no difference from the seeds of *Chamaerops humilis*, L., and which were certainly not seeds of a *Trachycarpus*, while the seeds of *Rhapis* are unknown to me. Now Dr. Dammer has recognised a *Trachycarpus* in a Palm labelled, somewhere on the Riviera, as *Rhapis cochinchinensis*; and there also appears to be found a *Chamaerops cochinchinensis* in the horticultural trade, which really is a *Chamaerops*, only not from Cochinchina, but simply a variety of *Chamaerops humilis*, L. I have bought both plants and seeds from the same firm, but do not know from whence they were originally derived. Will persons living in countries where Palms grow wild, kindly communicate with me with the object of my obtaining fresh seeds of new Palms to try here, either by purchase, or in exchange for other seeds. *A. Robertson-Proschowsky, Parc "Les Tropiques," Chemin des Grottes St. Hélène, Nice, Alpes Maritimes, France.*

NOTICES OF BOOKS.

THE WOODLANDS' ORCHIDS.*

UNDER the above title that pleasant writer, Mr. Frederiek Boyle, has written a book in which he sets forth interesting particulars of how Mr. R. H. Measures came to commence forming his now fine collection of Orchids, and the progress made during the time it was being brought to its present state of excellence, together with an enumeration of some of its specialties, a few of which are represented by excellent coloured plates.

The author does not pretend to give exhaustive particulars of the items of the Woodlands' collection, neither does he pose as giving cultural instructions on any point, but in the matter dealt with much useful information will be found to which even the Orchid expert will not take exception; while, taking the book as a whole, it is lifted out of the specialists' class, and rendered acceptable to the general run of readers of books for amusement by the many pleasant stories told of the adventures of collectors of some of the Orchids enumerated, their wanderings, perils, and dangers before ultimate success was achieved—the stories being in most cases as near facts as it is possible to get under the circumstances.

The work with index extends over 274 pages, and is illustrated by sixteen excellent coloured plates, and a portrait of Mr. J. Coles, the clever gardener at The Woodlands. In the first chapter is told how that Mr. Measures commenced his collection as a healthy relaxation during an exceptionally busy commercial life. The inevitable followed; that which was begun without much thought or faith in it as a welcome change from business cares became of absorbing interest, and brought a great deal of pleasure, thus accomplishing the desired end.

The work goes on to give descriptions of the principal Orchid-houses and their occupants, together with pleasant information relating to some of them. Between the chapters of descriptive matter are stories of sensational incidents in Orchid collecting.

* *The Woodlands' Orchids*, by Frederiek Boyle, 1901. (London: Macmillan & Co., Limited. New York: The Macmillan Company.)

They are founded on fact, being derived from friends of the late Mr. Roehl and others, and contained in letters from the travellers concerned; but in the telling Mr. Boyle has to draw on his fertile brain, and for that reason the stories lose nothing in the telling. Let not the reader think that any of the stories are overdrawn, for the ordinary life of the plant collector on active service is full of such incidents, to which he becomes so inured as to consider them quite in the ordinary course of events; and often, after great perils are passed, he thinks no more about them, and for that reason, together with the fact that some of them never return to tell the tales, thousands of thrilling incidents which the writer of fiction would not dream of are never related. Collectors' stories are told of *Cattleya Bowringiana*, *C. Mossiae*, *C. Skinneri alba*, *Vanda Sanderiana*, *Phalaenopsis Sanderiana*, *Dendrobium Phalaenopsis Schrederianum*, *D. Lowii*, *Cœlogyne speciosa*, *Brassavola Digbyana*, *Sobralia Kienastiana*, *Cypripedium Curtisii*, *C. Stonei platytenium*, *C. Spicerianum*, *Odontoglossum Harryanum*, *Oncidium splendens*, and *Bulbophyllum barbigerrum*; and in them and the rest of the work, Mr. Boyle, being himself a cultivator of Orchids, is enabled to avoid inaccuracies, into which inexperienced writers are likely to fall, although little errors by slip of the pen have crept in. For example, in mentioning *Bulbophyllum Beccarii* as the giant of the genus at p. 253, the author says its "stem is 6 inches in diameter." The rhizome, which is the part of the plant alluded to, may be 1 inch in diameter, and 6 inches between the comparatively small pseudo-bulbs bearing its gigantic leaves.

The work is one which will be read with pleasure both by the Orchid specialist and by the far larger number of readers who know little about Orchids; and it is just one of those books which pleasantly carries the interests of a "hobby" into the far country beyond its present domain, and in all probability it will do good by getting converts to the Orchid cult.

THE SEED CROPS OF 1901.

IN sending you my views upon the seed crops of 1901, I regret I cannot give you a very satisfactory report, as the anticipations of the early part of the year have fallen very short of fulfilment. Perhaps the most disappointing crop has been that of Early Peas, both round and wrinkled. Although at one time they promised well, they only yielded less than half a crop, the consequence is that such varieties as Earliest-of-All, Eclipse, and Gradus are of a higher price than has been known for many years; in fact, the stocks are at the present moment practically exhausted. Telegraph, Telephone, and other market varieties have an upward tendency.

The Radish is another crop which is unusually short. The acreage planted for seed was an average one, but the dry weather and black-fly played such havoc with it that in some districts the crops were practically decimated; and the French crops proving much less than anticipated have made Radish seeds not only very scarce, but unusually dear.

The Brassica tribe: as a whole the crops of these have been fairly good, and have been harvested in very fine condition. I estimate that the supply will be fully equal to the demand. Another disappointing crop has been that of Carrots, of which an average average was put out for seed, but the dry weather so

injured the growing crops that in some districts the yield was less than half of what was anticipated, such leading varieties as Altringham and Intermediate are very high in price, and with a short crop in France, they will further increase in value. The Mangel crop has been a good one, and prices rule very moderate. The acreage of Swede planted out was scarcely up to the average, and the yield varied very much. I doubt if many crops in Essex and Kent yielded more than sixteen bushels per acre, while other districts produced fully forty bushels per acre. The seed was harvested in splendid condition.

Yellow Turnips also yielded well, and prices for these are lower than usual. White Turnips, on the other hand, are short, and for such choice varieties as Grey Stone and Purple-top Mammoth, prices are advancing.

POTATOS.

These have yielded well, with the exception of early varieties, which are advancing in price, while others are comparatively cheap. There has been a brisk enquiry for seed Potatoes for the Cape, the varieties principally in demand being Early Rose, Pink Beauty of Hebron, Windsor Castle, Supreme, and Up-to-Date. I observe that complaints have been made that the Government has placed orders for seed Potatoes with German houses. If this were the case the English growers would have just reason to complain, for as we in England have to pay the War Bill it is only right that the orders should be placed in this country. But as a matter of fact, the Government have not so far as I know of ordered any seed Potatoes. Orders have come from Cape houses for large quantities of seed Potatoes, but the difficulty has been in getting them shipped. One line of steamers possesses practically the monopoly of the quick carrying of goods to the Cape, but the demands of the Government for space on these boats have been so great that English merchandise has been shut out frequently at the last moment. The consequence has been that Cape houses requiring the Potatoes immediately, and finding that they could not rely on the shipments arriving in time for planting, cancelled their orders with English houses and placed them with German and French houses, who were able to ship them promptly. I have had orders for considerably over 1,000 cases of seed Potatoes cancelled by one firm; on the other hand a German house informs me that they despatched between 4,000 and 5,000 cases to South Africa. As we pay very heavily for an efficient Navy, I should have thought that the Government could have employed fast cruisers to take stores and war material to the Cape without shutting out shipments from English merchants, and thus driving trade away from the country. *John K. King, the King's Seedsmen, Coggeshall and Reading.*

Obituary.

CHARLES ROLLISSON, a well-known Yorkshire gardener passed away on December 26, in his eighty-fourth year. In his early days he worked in the gardens at Temple Newsam, and thence he went to Middleton Hall, near Leeds, and subsequently to The Ridge, Pannal, where he served under three masters, during the long period of forty-five years, the present one being W. B. Bateman, Esq. He was a relative of the late Messrs. Rollicsons, of Tooting, a very successful grower of Orchids, and a good plantsman—in fact, he was an all-round gardener. His loss is sincerely mourned by a large circle of friends.

SOCIETIES.

BECKENHAM HORTICULTURAL.

JANUARY 3.—Mr. H. Cannell, Swanley, gave his experience of Canna cultivation during the past fourteen years. Thinking there was something in them as flowering plants he took them up, although he was told he would never do much with them; nevertheless, nothing daunted, he persevered, until now, when staged at exhibitions, as no other firm has ever staged them, they are jokingly called Cannell's Flamers. He told his audience that in raising new varieties, colour, size of petal, and persistence, were very necessary features, and he gave some hints on removing plants in flower to long distances, and the salient points in raising plants by seeds and division of the roots, and in general cultivation. *M. W.*

KENT COUNTY CHRYSANTHEMUM AND HORTICULTURAL.

JANUARY 3.—The fourteenth annual meeting of the above was held on this date at Mr. Lewis's Restaurant, Blackheath, Mr. H. J. Jones, of the Ryecroft Nursery, Lewisham, presiding. There was a good attendance of members, and the report and balance-sheet was read, showing a sum of upwards of £10 in favour of the society on the year's working. Mr. H. F. Tears was re-elected President, and Mr. F. Fox the Hon. Secretary.

CHESTER PAXTON.

THE opening lecture for the present year was delivered by Mr. R. NEWSTEAD, at the Grosvenor Museum, on Saturday, the chair being occupied by the President, Mr. John Weaver, who briefly introduced Mr. Newstead. The subject was entitled "The Mammals of the British Isles (Past and Present)."

The lecturer dealt chiefly with the mammals inhabiting the British Isles within the historic period, which he said amounted to forty-seven terrestrial species, of which the wolf, beaver, brown bear, and wild boar are now extinct, and the two kinds of rats (*Mus rattus* and *M. decumanus*), the rabbit and the fallow deer had been introduced. Excluding the squirrel, which is said to have been introduced, Ireland had only nineteen species of mammalia.

The bats were dealt with at some length, and the food of these somewhat uncanny but highly beneficial animals was described, chiefly from an examination of their rejectamenta, which had been found to contain a large percentage of moth remains. In dealing with the members of the remaining families, nearly all the species were passed in review, most attention being given to those animals which more or less affect the crops and stores of the horticulturist and agriculturist. The fossil animals were only briefly referred to, but illustrations of the remains, together with restorations, were thrown upon the screen, representing the Mammoth, Woolly-rhinoceros, Cave-bear, &c., as found in the cave deposits of North Wales.

The lecture was illustrated by sixty lantern slides, those illustrating the bats being of great interest, as having been taken from life by Mr. Newstead.

In the discussion which followed, questions were asked in reference to the destructive habits of the short-tailed field vole (*Arvicola agrestis*), the common mole, the brown rat, and the long-tailed field mouse.

On the proposition of the Chairman, seconded by Mr. N. F. Barnes, a very hearty vote of thanks was accorded to Mr. Newstead.

AMERICAN BLIGHT ON APPLE-TREES: B. K. There are several remedies, but that recommended by M. C. Joly, a Vice-President of the Central Horticultural Society of France, gives good results. To 7 lb. of soft-soap add 1 lb. of train-oil, two or three handfuls of soot and flowers-of-sulphur, mixing these in a pailful of lime-water. When incorporated, throw in as much powdered clay as to make the mixture of the consistency of butter. Spread a cloth beneath the tree, and scrape off all the moss and rough bark, taking great care in clearing out the crevices and angles about the fruit-spurs, &c. Remove the cloth, and burn everything that has fallen upon it; then paint the whole of the trunk and main branches, giving an extra coat to cracks and crevices. This

should now be done without delay, and the rain will wash the soap mixture down to the roots, killing such aphides as may be lurking round the collar of the root. It is a good plan to lay bare the roots, and dress them and the soil with freshly slaked lime, or drench the soil with soapuds.

ANNUALS FOR CUT BLOOMS: *Bristol.* Hardy species: *Godetia* Lady Albemarle and others, *Linum grandiflorum*, *Centaurea Cyanus* minor, Sweet Sultan, mixed; dwarf Hyacinth, flowered Larkspur; Sweet Peas, in great variety; Wallflowers may be got to flower the first year by sowing early under glass, and transplanting; *Dianthus Hedewegi*, &c. Tender species: such types of *Asters* as Jewel, Cocardean, Victoria, Ostrich Feather, pyramidal, quilled, and many others; *Gloxinias*, *Verbenas*, *Lotus Jacobaeus*, *Zinnias*, *Martynia fragrans*, *Petunias* (also perennial), *Primula sinensis* in great variety, *Salpiglossis variabilis*, East Lothian Stocks, *Tropaeolum Lobbianum*, &c. The tender species flower early if sown in warmth in March, and grown under glass till planted out in May, or grown in the greenhouse all the season, *Gloxinias* excepted, which want intermediate-house treatment.

ANTHRACITE COAL AND A TUBULAR BOILER: *G. S.* As a fuel none is better, it being slow of combustion, and giving off great heat; but it will not burn well unless there is a rather tall chimney, so as to create a strong draught. As the cost of the freight in your town in Gloucestershire would be low, you would doubtless find it as economical as coke.

APPLES ROTTING ON THE TREES: *B. K.* This is doubtless caused by some fungus, as *Monilia* or *Fusicladium*, which gains access to the fruit through the eye, or by wounds and abrasions of the skin. Some varieties of Apples have thin skins, which may be penetrable by the spores of fungi. The trees liable to these attacks should be dressed twice in the growing season with the Bordeaux Mixture.

BEGONIAS, &c.: *Bristol.* It will be about ready for starting the tubers or raising Begonias from seed, at the beginning of February. If you can mix a large proportion of tree-leaves—say, Oak, Beech, or Chestnut, with the stable-litter, and throw the materials into a heap for a week or ten days, turning them twice in that length of time, the bed will not heat irregularly, or get dry in parts. Make it 15 inches wider and longer all round than the frame you intend to put upon it, and thus allow space to put a lining of hot manure round the sides. Do not put any tubers, seeds, or plants into it till the steam thrown off has got sweet; always afford air, if only a quarter of an inch, at night, and cover warmly at night. Top-heat need not exceed 70° by night, or 80° by day: bottom-heat 85°. A bed of finely-sifted coal ashes, half-decayed leaves, fresh tanner's bark, or cocoa-nut fibre refuse, 6 inches thick, should be placed on the bed after the frame is in position—this for plunging pots and pans in.

BOOKS: *Crispium.* The book you describe is the first edition of Miller's famous Dictionary. Except as a curiosity, it is of no value.

GLASSHOUSES: *F. B.* In the absence of an agreement, the "fixtures," if used for purposes of trade, are removable; but there are removable and irremovable fixtures. To the former belong the wooden frames and glass of a glasshouse, with sills simply bedded in mortar on brick foundations set in the soil; and pits, and the hot-water pipes that heat these structures. To the latter belong the boilers set in the earth or below the floors of glasshouses. The law or custom in regard to those fixtures is getting greatly modified from what it used to be. You can use any kind of material for the sides and ends of the houses instead of brickwork; but if the glasshouse has adjoining buildings in the tenancy of other persons, you must be guided by the borough rules,

which differ in various places. In regard to this matter, you will be wise to consult the surveyor of the borough. You may apply for a new lease just previously to the expiry of the old one.

NAMES OF FRUITS: *T. R.* The Apples sent are certainly not Blenheim Orange. There must have been a mistake on the part of the person from whom you had the tree. The variety you have very closely resembles Duke of Devonshire.—*Witley.* 1, Downton Pippin; 2, Scarlet Nonpareil.—*R. W. R.* Ne Plus Meuris.

NAMES OF PLANTS: *Eden.* The specific names of some of the plants sent cannot be given without seeing flowers. 1, *Cotyledon* sp.; 2, 3, and 6, species of *Cereus*; 4, *Rochlea falcata*; 5, *Stapelia* sp.; 7, *Maranta Makoyana*.—*E. W.* *Dendrobium aureum*, often called *D. heterocarpum*.—*R. B., Shrewsbury.* A very good form of *Cymbidium Tracyanum*.—*W. D.* 1, *Eupatorium Weinmannianum*; 2, *Begonia subpeltata nigro-rubra*; 3, *Acalypha marginata*; 4, *Lastrea aristata*; 5, *Cyrtomium caryotideum*.—*W. H.* *Euphorbia (Poinsettia) pulcherrima*, a very old garden plant cultivated in warm-houses, for the highly-coloured bracts which accompany the flowers. Hints upon the cultivation of the plants are given occasionally in our weekly article "Plants under Glass."

NEW ADIANTUMS: *P., Naples.* The small-fronded variety is entirely new to us, but the larger one, is, we believe, *A. Hodgkinsoni*, one of the very numerous forms, or home-raised hybrids from *A. fragrantissimum*, which itself is of garden origin, and probably a natural hybrid between *A. cuneatum* and *A. Moorei* (amabile of commerce), raised at the Pine-Apple Nurseries some twenty years ago. *G. S.*

OUR SUPPLEMENTS: *G. W.* If you have seen photographic representations (sixty in number) of our Supplements, you may be sure this has been done without our sanction. The contents of the *Gardeners' Chronicle* are copyright, and piratical reproductions may entail serious consequences.

PHALLENOPSIS LEAVES: *F. Harrison.* The leaves show well defined examples of what is commonly called Orchid-spot or disease, the cause of which is not yet defined. The cause has been assigned to an unsuitable house, or to one where there is a direct current of heat from the pipes, or to one subjected to sudden falls in the temperature, or anything else likely to cause failure of the tissue in places. Try a change of house, if possible. Place on a shelf, or suspend near the glass.

PLANTING WALL ROSES: *An Amateur.* Plant in February, and cut in moderately severely a month after planting. Select half-a-dozen of the finest resulting shoots, and let the others grow on as they may. Spread out these finer shoots radially, loosely slinging them up with bast, so that they have some movement, and wait with patience. By always laying-in young shoots at the base of the plants, and checking strong growth in the upper shoots by fixing them rigidly to the wall, and giving them tips a downward direction, the upper parts cannot grow to the detriment of the lower. Very strong run-away shoots in the upper parts may be stopped—that is, cut back partially, or be entirely removed. Whenever it is seen that certain shoots are getting a predominance, do not hesitate a day in putting matters right. A floriferous bronzy-orange, deliciously perfumed Rose, not often seen now-a-days, and very good for a warm wall, is *Jaune Desprez*, and one you might include in your list.

PRICE OF ORCHIDS: *A. Gutsell.* Every plant that you have named could be purchased of ordinary trade size for 7s. 6d. to 10s.; a few probably for 5s., from the nurserymen.

RAISING BRIAR STOCKS: *E. O.* These can be raised by sowing the seeds of the common

Dog Rose in the spring in beds in the open ground. The haws must be laid in a heap to rot, and then the seeds must be rubbed out in water and dried. It will then be necessary to separate them by rubbing between the palms of the hands in dry sand. If stratified in fine earth or coarse pit-sand in a cold frame, they will start to grow sooner when sown in the spring. The seedlings appear mostly the first year, but some seed is sure to remain without germination till the next year. The shoots of the Dog Rose taken off with a heel of older wood may be struck in the open ground like other Roses. They should be inserted in late September or in October, without waiting for the leaves to fall. A Rose stock is fit to be worked when of the thickness of a quill-pen, at the least for a bush plant.

SKELETONISING LEAVES: *Skeleton.* There is no better way than to lay them to rot in soft water till the membranous parts can be brushed away with a soft brush. This process does not take "a few years," but may be completed in a few months.

TALL SCRAGGY GLOIRE DE DIJON ROSE ON A WALL: *An Amateur.* Cutting it down to within 3 feet of the soil is one method of getting the wall covered with shoots, but in the case of very old plants, one year's flowers are usually sacrificed, as the plants break slowly and late if they break at all. Another and safer one is to unmail the stem and branches, and retrain them serpentine fashion, so as to bring the uppermost branches to within 6 feet of the soil. By so doing, shoots will arise at each bend almost as surely as if the branches were cut back at these points; and these young shoots should be encouraged, and they will in time cover all bare spaces, and take the place of worn-out branches. Do not curtail their liberty over-soon or over-much, as the greater freedom the better and stronger the growth, and the greater the display of flowers. Of course, the plant must be pruned in the usual manner, laying-in as much of the best of last year's shoots as space can be found for.

THE DECAY OF GRAPES: *A Subscriber.* The loss of fruit was, as we indicated in the last issue, due to damp air.

TULIPS WITHOUT ROOTS: *W. B.* We could detect the rudiments of roots, and suppose that given more time these would become numerous, and the flowers be produced in due course under cool treatment. Each bulb contains a perfect flower. We are unable to tell you why the roots are produced so abnormally late.

THE RATIONALE OF EVERGREENS.

WE do not appreciate our blessings till they are withdrawn. In like manner we fail to realise how much our evergreens contribute to the beauty of garden and shrubbery, park and landscape, till some gale of unwonted force, or some frost of unusual severity, carries them off. It may be we become conscious of something wanting as we leave our own well-stocked grounds and pay a visit to a friend who has not made evergreens a study, and then the thought dawns upon us that the sombre foliage of the evergreen is that which has given colour and life to the surroundings we have left behind us.

But how many have given a thought to the meaning of evergreens? Who of us, in spite of our admiration for them, can tell why some trees and shrubs have deciduous leaves, while others retain their verdure all the year? Has climate, age, situation, soil, individuality, fertilisation, fruit, foliage, mode of growth, anything to do with the problem? Shall we, in these dull days, when the garden is bare, and little can be done out-of-doors, wander round the estate and examine the trees, whether indigenous or exotic, and try to learn something about this important subject?

Close by is a copse, and while the others beat and shoot, we will observe and think. The first thing that strikes us is, that most of the trees are bare. With the peculiarity relating to Beech and Oak pollards, which retain their dead leaves, we must try to deal

another time. As we look around, however, we see a striking contrast. The Elm is bare, but the Holly is as green as at mid-summer, the Hazel is leafless, but the Fir and Yew are verdant. We thus quickly separate all the trees into two groups, and call the one deciduous, because the leaves all fall in the autumn; the other, evergreen, because they have foliage the whole year through. In the first group we have such trees and shrubs as Oak, Elm, Hazel, Poplar, Hornbeam, Birch, Beech, Willow, and even the Larch tree, though it is a Fir. The evergreens contain the Holly, Yew, Ivy, Fir, Laurel, Daphne, Laurustine, Arbor-vitæ, Bay, Aucuba, and many others.

We soon become aware, however, that the number of native trees with deciduous leaves greatly exceeds that of the evergreens. We have to cut down our list by eliminating all the Firs except, perhaps, the Scotch Pine-tree, all the Thujas, Aucubas, Laurels, and other broad-leaved species, till we have only such as the Holly, Yew, Ivy, Juniper, Privet, Gorse and Broom, Butcher's Broom, and a few others left. Put all these together, and see how poor a show they make. Here is a fact which at once sets us thinking. Why are the bulk of our evergreens importations? Why have we hardly a single native species with broad, flat leaves? Why are our indigenous evergreens nearly always provided with needle-shaped leaves, as the aborted Gorse, the Juniper, the Yew, and the Pine; or provided with spines, like the Butcher's Broom and the Holly?

Note, again, that none of our genuine English evergreens are provided with brilliant or conspicuous blossoms. Why is that? Place the Holly and Yew beside the Crab and Wild Rose, put the Juniper, Fir, or Ivy by the side of the Guelder Rose, the Bird Cherry, or the Hawthorn, and observe how noteworthy is the contrast. I grant that the Gorse makes a brave show even in mid-winter, and is capable of making a famous field of cloth of gold in the summer, where it is kept browsed by rabbits and sheep; but the Broom and Gorse are not genuine evergreens. The Privet, perhaps, makes the best display, and the evergreen Daphne (D. Laureola), with its yellowish-green blooms, gives out an equally rich perfume; but after all, what a poor show they make.

We observe, again, that the foliage of evergreens is almost always extremely sombre, and that with the rarest exceptions they supply us with no rich hues, even in decay. There are no autumn tints to evergreens, and seldom are there any soft hues in spring.

Once more I may call attention to the fruit which adorns many evergreens, both native and foreign. The scarlet berry is the favourite form assumed. We have it in the Aucuba and Laurel, the Euonymus—several foreign species of which are evergreen, and thrive well in our shrubberies—the Butcher's Broom, the Yew, and others. In the Ivy, Juniper, and a few other evergreens, the fruit is purple or blackish. Here, then, are a few of the most noteworthy facts. They show us that evergreens are roughly marked off from deciduous trees by the persistent foliage, the sombre hue of the leaves, the general predominance of needle-like foliage in the native species, and the presence of red and dark-coloured fruits, chiefly inedible.

We have now to ask, To what do these curious facts point? How are they to be accounted for? They are too striking not to arrest attention and demand an explanation. We look, therefore, in the first place, to the question of age. What is the testimony of the rocks? What do we learn from a study of the climatic changes which the earth has undergone? I think it is quite certain that the earliest plants were evergreen. The oldest trees of any note, those at least which predominate in the Carboniferous Era, resemble our Pines and Fir-trees. The climate of England has greatly changed since then, and the vegetation has changed with it. If, however, we examine those lands which still possess a very warm and equable climate, and are not subject to periods of intense cold, we find that they have a much larger percentage of evergreens than our flora can produce.

We see, further, that the evergreens abroad are possessed of leaves as large as those which our most robust deciduous trees produce. Now, everyone knows the risks which foreign evergreens run in our climate, by reason of their heavy foliage. Given a fall of snow of some hours' duration, and the trees which have leaves are weighted down and ruined, while those whose branches are bare continue unharmed. We therefore see how wonderfully Nature adapts her offspring to the vicissitudes of life. In England, where snow falls frequently and remains long, the few evergreens we have possess pointed leaves, which pierce the snow-flakes, and offer little surface for their lodgment. Am I told that the Ivy has broad leaves? I reply it is true, but the Ivy in nature climbs around the trunk of a stalwart Ash or Oak, and rarely exposes a flat surface to the snow. Where it does, as when it grows on a wall, or rambles over a building, it seems to rejoice in the consciousness that the everlasting arms are underneath, and no evil can ensue.

These facts throw a new light on the Holly-tree. We have heard much about the prickles and the donkey. There may be truth in the theory; but I think no one can examine our native Ulex in the light of the facts I have been adducing, without feeling that the sharp-pointed and carefully-channelled leaves are a splendid provision against the snow and ice-cold rain of winter. How would it fare at this untimely season of the year if it had the leaves of the Sycamore, Lime, Chestnut, or Laurel?

Thus we learn that evergreens are more frequent in equable climates, and when they persist in these colder zones, they have to be specially equipped to withstand the cold and snow. This they do in various ways. First we have the sharp needles of the Fir, Juniper, Yew, and the pointed leaves of Holly. Next we find that the leaves are very thick and fleshy, in this respect differing widely from nearly all the deciduous trees. The leathery foliage of Laurel, Aucuba, Holly, and other evergreens, is undoubtedly intended to aid the functions of life during the winter season. Further, many of the trees and shrubs are provided with the power to yield a special gum, resin, juice, or other product, which is not found in deciduous trees, unless they are of related orders. The study of exceptions, such as the Larch, is of peculiar interest in such a connection as this.

There remains another fact of great significance. Many ladies and gardeners, whose duty it is to dress the tables with cut flowers, have observed that if evergreens are blended with blossoms, the latter soon droop and fail. Let us put some Daffodils, for example, in a vase, and treat them carefully, and they will last for days. But put a similar bunch of blossoms into another vase with Ivy, Laurel, or other evergreens, and they are very quickly over. Now why is this? The answer is that, almost without exception, evergreens are poisonous. It may seem strange at first sight that there should be any marked difference in this respect between plants whose leaves fall in autumn, and those which retain their foliage all the winter. But a little thought will show us the need for some such protection if the evergreens are not to be swiftly exterminated. Cattle browse in a field where for the present they can get an honest living. Presently snow begins to fall. Everything is covered; and the only green thing anywhere to be seen is the Juniper, Yew or Holly. At once the cattle rush for these; but they soon learn that it is at the peril of their lives they browse on the fleshy leaves. It is hard on the cattle doubtless, but the trees have to live as well as they. I venture to think that the dark green foliage, almost amounting in the winter-time to an appearance of blackness by contrast with the snow, is a colour signal to warn the cattle against the danger of feeding on evergreens. The Holly and Privet, the Juniper and Yew, seem to say, "Beware how you approach us too closely, for there is death in the pot." Rarely, unless pressed beyond measure, will cattle touch the foliage which thus lifts its warning voice, and so tree and cattle alike escape destruction.

In this brief study I have left many important points unnoticed. It was my wish to attract attention to an interesting and fruitful subject of research, rather than attempt an exhaustive exposition. I have probably adduced sufficient facts to suggest along what line we must travel if we are to obtain a reliable clue to the rationale of the evergreen. *A Sussex Naturalist.*

ORCHID NOTES AND GLEANINGS.

STANHOPEA LANGLASSEANA.

FROM a letter of M. Ed. André, who knows the country well, and after a careful perusal of Langlasse's letters, I find there was a slight error in the place I mentioned to Professor Cogniaux as the habitat of *Stanhopea Langlasseana*, described in your issue of Dec. 14. This plant was not gathered near Altaquezo in the valley of Rio Mira, but near Altaquer, on a small river called first Rio Cuaiquez and lower down Rio Cuiza, an affluent of the Rio Mira (altitude 1,700 m.). It is, however, not far from the other locality, and quite in the same region; near also Armada, where M. André discovered *Anthurium Andreanum*. M. Micheli, Geneva.

ODONTOGLOSSUM CIRROSUM KLABOCHORUM.

It is easy to recall the interest which was taken in *Odontoglossum cirrosum* when that fine species from the Andes of Ecuador was successfully forwarded to England by the brothers Klaboch in 1875; and on its flowering in the following year the illustration in the *Gardeners' Chronicle* conveyed an idea of the

flowers to those who were desirous of learning its appearance. Its elegant sprays of white flowers spotted with red-brown caused it to become a general favourite, and for some years it was frequently seen in quantity; of late years, however, it seems to have become less plentiful.

O. cirrosum has its peculiarities, which render it more satisfactory in some years than others, or in some gardens than in others. Frequently the plants send up flower-spikes at the end of the summer and which slowly elongate, but do not produce flowers for several months, and then perhaps only sparsely. At other times their flower-spikes branch and bear flowers quickly, and especially in the late spring months. The finest type of the species was distinguished as *O. cirrosum Klabochorum*, and an inflorescence has been sent by M. Frantz de Laet, of Contich, Belgium, who calls attention to the foliaceous bracts at the bases of some of the flowers. This character is not uncommon in the species, especially when the flowers have been delayed as before mentioned. The long segments of the flowers with their graceful, elongated tips extend four inches and a half from tip to tip. The sepals and petals are white, handsomely blotched with dark purplish-red. The lip is white, with red lines on the side lobes, and some red spots on the narrow front lobe.

PHALÆNOPSIS IN LONDON.

While many of the most experienced cultivators of Orchids in highly favoured parts of the country never succeed in thoroughly mastering *Phalænopsis* culture sufficient to obtain satisfactory results, small lots of them are to be found even in towns in the most vigorous health. In the gardens of W. Shuter, Esq., Belsize Grove, London (gr., Mr. Armstrong), we recently saw a number of plants of *Phalænopsis* in fine health, and which had been growing there for many years in an ordinary plant-house having an intermediate temperature. Some of them were in flower, although the London fogs work the greatest mischief by destroying such of the advanced buds or open flowers which may be on them at the time. The plants, however, do not seem to be damaged at all by the fogs. The species represented were *P. Schilleriana*, *P. Aphrodite* or *amabilis*, *P. amabilis*, known in gardens as *P. grandiflora*, and *P. Cornu-cervi*. With regard to these *Phalænopsis*, Mr. Armstrong says that when he first came to the gardens a good many years ago, the *Phalænopsis* were badly affected by "spot," or disease, and that they have gradually been grown out of it, so that for several years past no trace of "spot" has appeared. This is in opposition to the opinion of many experts that once "spot" takes an Orchid it is not to be eradicated. They do not become large specimens, but always keep healthy and flower well. Mr. Armstrong modestly attributes the good condition of the plants to his having been fortunate in finding a position that suited them; moreover, the temperature is very evenly maintained at all times. Several *Saccolabium giganteum* and other of the distichous-leaved Indian Orchids were flowering and in fine health.

PLANT PORTRAITS.

A GARDEN AT NAPLES.

I THINK that of all Europeans, Neapolitans are the most privileged, as far as gardening is concerned. Mild winters, no extreme heat in summer, and a moderate number of rainy days during the year, allow a large number of Palms and Ferns to be cultivated in the open, while a good many northern plants are also easily grown.

My garden, situated in the centre of the city, contains some remarkable specimens, the description of which may be of some interest to lovers of gardening. Amongst the Palms there are two *Washingtonia robusta*, 50 feet high, and about thirty years old; *Washingtonia filifera* (see fig. 10) is represented by a specimen about 32 feet high. A *Phoenix leonensis*, about twenty years old, has a diameter of 30 ft.

A remarkable Fern is *Balanium antarecticum*, also grown all the year round in the open, like the above-mentioned Palms. Its stem is about 14 feet high, and the leaves form a splendid crown about 10 feet in diameter. Another much-admired Fern is *Cibotium spectabile*, a fine specimen, some leaves of which are 12 feet long. This Fern, however, has to be kept in the greenhouse during the winter.

Among the trees growing in my garden I must mention a *Magnolia grandiflora* 65 feet high, which when flowering is all covered with splendid white blooms, the fragrance of which is so strong that I have to keep the windows closed on the front of my house before which the *Magnolia* stands. This tree, as well as *Arancaria Bidwilli* and *ex-celsa* and *Camphora officinalis* give a fine effect in the garden, but are frequent in Neapolitan gardens. A large summer-house of mine is wholly covered with one single plant of *Wistaria chinensis*, which is about 480 ft. in span. When blooming it is a splendid sight, and is the admiration of all who see it. More than a hundred thousand mauve racemes cover the summer-house, and the fragrance is delicious.

As regards flowers, there is scarcely a day without blooms opening throughout the year. Now Roses, Camellias, and a few Violets are flowering in the open, as well as Carnations and Daffodils. Geo. A. Pfister, Naples.

NOTES FROM ISLEWORTH, 1901.

NEW PLANTS, or those which have come under my observation for the first time during the past year are:—

Hippeastrum Kromeri, Worsley.—This is a new species fully described in another issue. It carries two flowers, individually resembling *H. Johnsoni*, and has remarkably fulvous foliage.

Hippeastrum psittarinum var.—I recently received a very fine form of this old species, which has also remarkably fulvous foliage. These two individuals, indeed, are the most remarkable in this respect of any members of the genus I have seen. This fulvous appearance, however, is dependent in some measure on the way the plants are cultivated.

Hippeastrum correiense var.—Between the true epiphytal *H. correiense* and the terrestrial *H. stylosum* there exists a number of intermediate forms, presenting difficulties in nomenclature. The same old difficulty which reappears whenever an attempt is made to reduce a mass of individuals into ranks, orders, and degrees.

During the past year I have flowered several hundred bulbs of *H. stylosum*, and noted the numerous slight gradations towards the type of *H. correiense*. Also several Organ Mountain forms near *correiense*, but grading off

towards stylosium. One of these in particular was nearly intermediate between the two. It had a pair of compact flowers, and glaucous, blunt foliage.

Hemantus species from the Congo.—One of the events of the year was the exhibition before the Royal Horticultural Society by Messrs. Linden of several splendid forms of *Hemantus* (see Supplement, August 10, 1901). Not having thus far had any opportunity of critically examining these plants or their fruit, I can only say of them that, as garden plants, they mark an advance upon anything in this genus I

H. J. Elwes I had the pleasure of seeing a splendid collection of these plants, and especially admired those named "Miss Willmott," "Lady Dorrington," "Ellioti" vars., some dwarf *N. sarniensis*, and a very beautiful unnamed silvery-pink form, with very wide segments.

NEW PLANTS RAISED AT ISLEWORTH, FLOWERING FOR THE FIRST TIME IN 1901:—

Hippeastrum, Hort., "Rurik," dark red.

Canna, Hort., "G. B. Mallett," a new break in this section, the majority of the flowers being pollipetalous and unisexual.

THE FOLLOWING PLANTS HAVE NOT FLOWERED IN MY GARDEN THIS YEAR:—

Stricklandia euerosioides (figured in the *Gardeners' Chronicle*, October 5, 1901, p. 263).

Cyrtanthus angustifolius.—A very old plant, although but rarely seen of recent years; it is worthy of a place in every garden.

Crinum Van Tubergen (Lynch).—This shows an alliance with *C. scabrum*, and it seems probable that it is of garden origin, possibly dating back to Herbert's time.

Marica, species Petropolis.—This is a very charming plant, raised from seed, I gathered near Petropolis. It is in alliance with *M. cœrulea* (Saubert), and has a remarkably deflexed scape.

Cereus MacDonaldis pallidus.—A very large, scentless, night-flowering plant of great beauty, without the dark outer segments of the type.

Eremurus Elwesianus.—New to my garden, and a great acquisition; it shows off very well against a background of Bamboo. In the evening only is it fragrant.

Pelargonium "Californic".—This is a dwarf double orange, much resembling Raspail, except in its dwarf habit and dazzling colour.

Pelargonium "Rapkin's Glory".—This is an improvement of Chas. Turner, lighter in colour, but finer in every other respect.

Aretotis breviseapa.—I was very pleased with this annual, and consider it a grand bedding-plant for July and August. Its dazzling orange-and-black flowers open very early and close about 3 P.M.

Hippeastrum stylosum var. nudum.—Among several hundred flowers of the species, some fifteen showed a variety which I thought worthy of record. The filaments were remarkably exerted, far beyond what is usual, even in this species, and the stamens spread out as in *H. ealyptatum*.

Hemantus sanguineus (Jacquin).—This can hardly be called a new plant, yet it has been so completely lost sight of that I think it must be new to this generation of gardeners. It flowered with me early this autumn in the open at the base of a heated wall. It possesses more historical than horticultural interest, from which point of view it is in no way superior to the common *H. tigrinus*.

Hidalgoa Werklit.—This charming climber has obtained a reputation for being a shy bloomer. With me it has belied this, having grown to a large size and flowered in one year from a very minute cutting. It grows quickest and best on a wall outside, with full sun exposure, but is cut down by a sharp frost. The flowers are fine for cutting. It is eminently suited for the pillars and walls of a Succulent-house, and is a very clean plant.

Crinum yuccaeoides (Herbert).—A small-growing species of some beauty. Not much removed from *C. Sanderianum*.

Cactus Hort., "Isabelle Watson."—In this brilliant flower the intense red of the outer segments is heightened by a dazzling blue colour suffusing the inner segments.

HARDINESS OF SOME EXOTICS.

Brodieas (Tritecias) from Uruguay.—*B. aurea* has proved hardy for some few years, and has ripened seeds in the open. It still makes a great effort to flower early in January, but last spring it flowered again in season with *B. uniflora*, and will probably in a few years accommodate itself to our seasons. A flower which opened on January 2 was covered with snow, exposed to 15° of air frost, and yet re-opened practically uninjured a few days

FIG. 10.—A NEAPOLITAN GARDEN, WITH WASHINGTONIA FILIFERA THIRTY-TWO FEET HIGH, THE TWO BEING CALLED "THE TWINS," IN THE BACKGROUND A LARGE MAGNOLIA TREE. (SEE P. 38.)

have previously seen. The habit is that of *H. Lindenii*; the size of the flowers and the various shades of red mark an improvement on that species such as many garden plants show when compared with the original importations.

Some of these were named "Fascinator," "mirabilis," "Diadema" (deep red), and "Queen Alexandra" (pink).

Such mixed nomenclature is open to objection. The first three names would suggest three distinct species, and the last name a garden hybrid.

Nerines, garden forms.—In the garden of Mr.

Tomato, Hort., a cross between "Wonder of Italy" (a many-fruited form raised by Sñ. Herb. of Naples) and one of my own garden forms. In this cross the character of each parent is equipoised. Some bunches of ripe fruit were shown before the Royal Horticultural Society's Scientific Committee.

Tropæolum Lobbi, hybrid.—This hybrid was raised fortuitously between *Lobbi* and garden bedding forms. As they only came into flower in the middle of September, their true merit cannot be ascertained till next summer, but they promise to be useful garden plants.

afterwards. I think this must stamp the species as being hardy in suitable soils.

B. Sellowiana, which may prove to be a valuable garden plant, follows the same seasons as *B. aurea*; but I am not so convinced of its hardiness, although it has lived through one winter outside.

Spathacea bicolor.—This has proved hardy for the last two or three winters, and flowered in the open May 8. The flower-scape pushes up for 18 inches inside the old sheathing leaf, and is thus protected from frost until the very day the flowers expand. The bulbs are very proliferous, and like a dry sunny place. The flowers are sweetly scented for some hours after expansion. It ripened seed in the open.

THE FOLLOWING PLANTS HAVE PROVED HARDY AT ISLEWORTH AS TESTED:—

| | |
|---|----------|
| Watsonias, three species flowering end July ... | 4 years. |
| Cypella platensis, flowering freely ... | 1 year. |
| Chlidanthus Ehrenbergi ... | 1 year. |
| Zephyranthes gracilifolia (early October) ... | 3 years. |
| Gymnatrix latifolia ... | 3 years. |

SEEDS.

As the descriptions of the fruit and seeds of so many exotics have been copied by one writer from another, and errors have thus been perpetuated which original investigation would have corrected, I have allowed certain plants to seed simply to make comparison with the descriptions in books of reference. While thus noting some discrepancies, other interesting observations have been made.

Hymenocallis tubiflora.—During recent years this species has been imported on many occasions, and it seems now to be well distributed in our stoves. It always carries a number of ovules in each ovary. One specimen recently bore (in one umbel) 105 ovules in five ovaries. These were not selected ovaries chosen because of their proliferousness, but were the five fruits carried on the one umbel, and may therefore be taken as representing an average for the individual parent. This shows an average of twenty-one ovules, and one ovary carried as many as twenty-five.

Thinking this worthy of record, I sent the specimen to Kew, and was told that such proliferousness was by no means unusual in this species.

Surely, under these circumstances, it is time the generic description of *Hymenocallis* should be corrected. For it is no longer possible to attribute to this genus the maximum number of "a pair" of ovules in each cell, in view of the facts above stated.

Hymenocallis Moritziana.—I think this is a good species. I have flowered it from seed in 3½ years, and it came quite true to type. This species is always described as indigenous to the neighbourhood of Caracas; but this is an error. In the *Notes on the Distribution of the Amaryllidaceæ* (Wesley, 94), I pointed out the locality of this plant, but I did not then state that the late Dr. Ernst, Professor of Natural History at the University of Caracas, who had personally explored the neighbourhood over and over again, assured me that this species could not be found within some days' journey of the capital, and that he could find no record of its ever having been gathered there. My own visit to Caracas was limited to one month, during which I searched the same district daily, with the result of confirming his statement.

Acotyledonous Germination in Crinums.—As I am preparing a paper on this head, I will merely state here that the radical process issuing from the seed of (at least) some *Crinums*, cannot, in my opinion, be classed as a cotyledon. It is a process terminated by a

bulb or bud, and to include such under the term cotyledon would be to expand, out of all recognition, the definition of this term. I do not say how far this theory of acotyledonous germination in the Amaryllidaceæ may be pushed, that is a matter for prolonged investigation; the object of this note is merely to record that in my view the species *C. Moorei*, *C. giganteum*, *C. Yemense*, and *C. Yuccacoides* come under this head.

Tomato Seedling, Variegation in.—Not infrequently in a batch of seedlings several will show variegation. This spring one seed-pod gave quite 80 per cent. of strongly variegated seedlings. When these young plants had four to six leaves each, they bid fair to grow into decorative plants, but from this point the variegation died out absolutely. Some persons account for this by asserting that such seedlings were weak and lacked colouring-matter, were in fact anæmic, and that sunny weather would cure them. My own observations show that the variegation appears in the strongest seedlings equally with the weaker ones, and I think it is more probable that one of the progenitors of our garden Tomato had, either in itself or collaterally, variegated foliage. Can any of your readers well versed in the Solanaceæ throw any light upon this?

Spathacea bicolor.—The seeds are flat, winged, and yellowish in colour; about sixty in a fruit.

Hemantthus carneus.—The fruit is a transparent, oval, green berry, inclosing the darker-looking embryo, the coloration and transparency being that of an unripe Muscat Grape. (Note. Germination of seed not tested.)

VARIOUS PLANT NOTES.

Romuleas.—It appears that some confusion exists in this genus. The Cape species seem very refractory under cultivation in pots, and are not hardy in the London districts. The species of the Mediterranean are of course much hardier, although not nearly so beautiful.

R. Bulbocodium (var. *bicolor*?).—This form has a yellow base, and is taken in Mr. Nicholson's *Dictionary of Gardening* as the type. However, all the coloured figures I have seen of the type show a white base and longer segments.

R. Linnaesii seems to be another variety of this species. It has a rather larger, nearly self-blue flower.

R. purpurascens is a better plant than any *Bulbocodium* form. It has self-coloured flowers of a brilliant purple. The style is very short, and the stigma remains hidden among the anthers.

Hippeastrum Hybrids.—I thought that those shown by Capt. Holford at the R.H.S. marked an advance, both in colours and in robustness on any previous exhibit I have seen. All that remains to be done in this section is to reintroduce more variety in habit.

Cactus "Urania".—I think that it is quite inadmissible to found genera on leaves only, as has recently been attempted in this order, and that the old name, "*Cactus*," should be reinstated; and the recent divisions into *Cereus*, *Phyllocactus*, &c., reduced to sub-genera. The form "*Urania*" has been in my collection for some years, and is almost certainly of garden origin. Hence it probably exists elsewhere under another name. However, as I think it is the most beautiful form I have ever seen, it was impossible to leave it without a name for an indefinite number of years. This is a day-flowering white *Cactus*, floriferous, and possessing an almost intoxicating fragrance.

Narcissus biflorus.—This species does not flower freely in all soils, and has been superseded in many gardens by more showy forms. In sweetness it surpasses all others. If well done, it will often produce three flowers to the scape. I gathered one specimen last spring with four flowers.

Cinerarias Bedded-out.—One feature of the year in my garden was a bed of these plants. Seed should be sown early in January, pricked out into boxes, and planted out about the first week in May. It is absolutely essential to select a damp and shady position. Early in September the plants will come into bloom, and last until cut down by frost. The later ones may safely be lifted towards the end of October, and potted-up for inside work. For this purpose choose those which have not yet expanded their blooms, and lift them on a damp or foggy day. Of course, such plants can never rival those grown on in pots from the start, yet very fair plants may be grown in this way at about one quarter the expense of the recognised method, in labour, fumigation, &c.

Gastronema sanguineum.—This plant has been a worry to many gardeners. It should never be grown in a pot, but either planted out, or in wide pans 4 inches deep. It does not appear to flower well outside, but the bulbs grow very fast in full sun during the summer, and should be lifted towards the end of September. In winter a night temperature of 45° is sufficient if kept dry.

Summer-flowering Cape and Japanese Amaryllids.—The past summer has not proved favourable for these plants in the open. My *Lycoris* only produced just short of 100 flower-scapes, in place of nearly double that number. *Amaryllis* flowered sparingly, and the *Brunsvigias* and *Cape Crinums* were a complete failure. A. Worsley, Isleworth.

A REVIEW OF THE SEED SEASON.

EARLY Peas, being scarce, are phenomenally high in price this season, the supply, being unequal to the demand, necessitating the probable curtailment of orders. The serious shortage in the harvest is owing to the persistent drought experienced in the seed growing districts during May, June, and July, and to the heat and dryness of the atmosphere when the blossoms were setting their pods, so that the flowers dried up before they could reach the stage of pod forming. It can be readily understood that the yield of seed fell greatly below the average; 2 and 3 acres of a particular sort yielding not more than would a half acre under ordinary favourable conditions.

Early Peas for seed are always grown on light land to preserve their precocity, and it was the light lands which suffered so severely from the drought. To sow early Peas on heavy land is to throw the stock back in point of earliness, and also to increase the height of the growth. Early Peas rapidly deteriorate in regard to these particulars when grown on retarding land. Many late wrinkled Peas are also scarce, and high in price. Three quarters (24 bushels) per acre is regarded as a good average yield of seed, but probably in no single case has the average been reached this season.

Some new Peas show a tendency to improve under cultivation, and perhaps more particularly some of the varieties bearing the name of Laxton. *Gradus* is a case in point, and it is found to be showing improvement as a cropping Pea—as a seed-merchant said the other day, "*Gradus* is working up a constitution of its own." This might be said of all the

crosses made by Laxton; the main aim has been to produce dark green pods. Whether rightly or wrongly, superior flavour is associated in the minds of many with a deep green pod; and in order to produce the desired colour, probably some amount of breeding in-and-in has had to be resorted to, to secure this end, hence some constitutional debility. Green-podded Peas no doubt have the preference in the estimation of the market dealer. Other Peas than Gradus are doubtless going through the same course of improvement

the spring, which did their share of damage, and they were followed by a visitation of insect pests. The year 1901 was a record year for noxious insects of every kind. They seem to have been carried south and west by the cold north-easterly winds, which prevailed so long during the spring; the Brassica tribe in particular suffered from their attacks. So severely felt were the ravages of vermin in the seed-growing districts of western France, that the caterpillar literally cleared fields of large French Cabbages standing for seed; and it is

and Italy, are record ones, both in regard to quantity and quality.

The supply of Italian Onions, represented by the Tripoli section, though not so abundant, is enough to meet an average demand. The large mild-flavoured Onions, introduced by Deverill and others, seem to be taking the place of the Tripolis to some extent in regard to the particular purposes to which they are put. One of the features regarding the development of the Onion in recent years is the increasing popularity of the Queen type, which may be denominated a glorified Silver Skin. It is now largely grown for pickling purposes, thus superseding the red pickling type. When first the latter was pickled, it was found that one effect of the brine was to impart to the clear silver skin a dull brown appearance, but the brine is now so prepared that the silvery appearance of the skin is retained without disfigurement; the appearance of the Queen is therefore more taking than that of the old pickler, while the quality is also better every way. *Pisum*.

NEW FERNS OF 1901.

BRITISH FERNS.—Despite the great number of distinct types of variations in British Fern species, the year has seen the introduction of some decided novelties and improvements of type, viz., a quite new form of *Osmunda regalis* (Royal Fern). Royal Horticultural Society Awards of Merit were given to two forms of *Scelopendrium vulgare*, viz., *S. v. crispum cristatum fimbriatum* Stansfield, prettily fringed, as well as frilled and tasselled; and *S. v. crispum Drummondiae superba*, described and figured in *Gardeners' Chronicle*, January 4, 1902, p. 5, which indicates a still greater advance in the decorative direction in this species. A very remarkable viviparous form of this species was also exhibited by Mr. Druery at the Scientific Committee, the fronds literally crowded with young plants arising from surface bulbils, the original wild find, *S. v. cristatum viviparum* O'Kelly, bearing them but sparsely.

Finally, mention should not be omitted of *Athyrium f.-f. cristatum fimbriatum*, raised by Mr. Garnett, Bowness, a remarkably slender, finely tasselled form, somewhat on the lines of *A. f.-f. clarissima*, and like that Fern characterised by soral apospory, but on a more marked scale; and further differentiated by the apical form of the same phenomenon, plus the tassels, and all the terminals. The parentage is unfortunately unknown, but as it seems certain that it has not arisen from either of the aposporous *Athyria* in cultivation, it being a chance sporeling, it ranks as the first case of combined soral and apical apospory which has originated under culture. C. T. D.

FIG. 11.—LEAVES OF A JAPANESE MAPLE, *ACER POLYMORPHUM* VAR. *DISSECTUM*. (SEE P. 46.)

by cultivation, while some rapidly fall away and are soon lost.

The prices of seeds of Carrots, Beets, and Cabbages, are exceedingly high this season, as they too are very scarce. Parsnip and Parsley were also scarce crops. Some suffered by reason of the dry character of the late summer and autumn of 1900, when owing to the drought many seed plants could not be put out, but had to remain in the seed-beds until quite late in the year. During that time they deteriorated rather than advanced; and then owing to late planting they suffered somewhat from the rigours of the winter, and numbers were destroyed. Then followed late frosts in

recorded that they at one point crossed the Paris and Orleans railway in such numbers, that they actually for a time stopped the progress of one of the trains.

There is therefore a great scarcity of seeds of many of the most useful kinds of culinary vegetables; and the same is true of some of the seed-growing districts of Northern Europe. Onions and Leeks form exceptions to the general scarcity. The Onion glories in hot, dry weather. There is no doubt a reserve of sustaining force in its firm fleshy bulbs, and it sends its roots down deeply into the soil. The crops of Onion-seeds saved in the north of Europe, and particularly in western France

The Week's Work.

THE HARDY FRUIT GARDEN.

By J. MAYNE, Gardener to the Hon. MARK ROLLE, Bicton, East Budleigh, Devonshire.

Wall Fruit-trees.—As soon as the pruning and training of stone fruits have been completed, the borders, which should be from 3 to 5 feet in width, measured from the base of the wall, should be cleared of all prunings and rubbish, and receive a top-dressing one inch thick of lime rubble or mortar refuse, and be lightly dug over, removing at the same time all suckers by cutting them off close to the root. Early last spring I gave to all the wall-fruit borders a top-dressing of this thickness of old "cob" broken up very finely, which was procured from the cob walls of cottages pulled down at Bicton. Some of the older

garden men implied that it would "burn" the roots, but the healthy foliage and abundant crops of fruit the trees carried last summer, told quite a different tale. This kind of top-dressing is not required yearly, and I should be dubious about advocating its use on very retentive soils, but with a light, sandy soil resting on the old red sand-stone, it is an excellent fertiliser. It must be used with care, and then no ill effects will occur. I plant a single row of Violets at the foot of all the fruit walls, excepting those where Peaches and Apricots are planted, keeping the plant 18 inches distant from the stems of the tree.

The Grape-vine.—Established plants growing on walls may be pruned and put in order. If grown on the spur system the laterals should be cut back to the second or third bud from the base, but if on the extension plan, the growths that have been laid in during summer to take the place of those that bore fruit the past season, should be shortened back to a plump bud, leaving about 4 feet of shoots. If red spider infest the Vines, let the wood be dressed with a mixture of water, soft soap and flowers-of-sulphur. The Vine roots are the better for a yearly top-dressing, removing a layer of soil 3 inches deep, and replacing it with maiden loam and bone-meal—one peck of the latter to 4 bushels of loam. The planting of Vines should be done about the middle of March.

Strawberries.—Where these were not mulched in late autumn, the ground between the plants should be cleared of weeds and dressed with short manure 2 or 3 inches thick, pointing this in with a fork, in March. Some gardeners object to using a fork between the plants, but I consider the plants are benefited, the rain penetrating the soil more readily; and if a mulch of clean Oat-straw be applied when the flower trusses begin to push up, the ground will usually be kept fairly moist until the crop of fruit has been cleared. Plantations made in August last will not need any manure this year.

THE ORCHID HOUSES.

By W. H. BOUND, Gardener to J. COLMAN, Esq., Gattin Park, Reigate.

Odontoglossum-house.—Numerous flower-spikes will now be showing on the plants, and constant observation will be necessary to guard against slugs, which otherwise would soon destroy the labours of a season. The leaves of the Lettuce, or Orange-peel laid between the pots form, I think, the best baits for them; but do not trust to a trap, especially if any good variety is showing bloom, but place the plant on a piece of perforated zinc, and keep the leaves clear of other plants—the spike will then be safe. The flower-spikes that have been out during the recent spell of cold weather should not be allowed to remain on the plant very long, or the plant will suffer in vigour. It is better not to allow a plant to flower if it show any falling off from the preceding year in length of leaf or size of pseudo-bulb, which often occur when the plant has been allowed to carry a strong spike the previous year, which remained on the plant for a long period.

Laelia anceps, and the many fine varieties, such as *L. a. Bull's alba*, *L. a. Hillii*, *L. a. Holidayana*, *L. a. Amesiana*, *L. a. Dawsoni*, *L. a. Williamsii*, *L. a. Schroderiana*, *L. a. Ballantianiana*, *L. a. oculata*, *L. a. Sanderiana*, *L. a. Stella*, *L. a. Chamberlainiana*, are the most conspicuous Orchids in flower during the early months of the new year, and they are worthy of a place in every collection. The temperature of the house during the time they are in flower should not be allowed to descend below 55° at night, nor rise above 63° by day, and some air by the bottom ventilators should be afforded when possible by night and day, in volume according to the state of the outside temperature. Water should be afforded with care at this season, when some of the plants are rapidly making new roots, whilst others are still dormant. Plants that are making

roots require more water than others, but even these should only be afforded water when dry, so that the moisture will dry up quickly; for it is when the materials remain in a wet state for several days after water has been applied, that the newly-made roots suffer so much. Any *Laelia* which requires potting this season should receive attention as soon as signs of root-action are noticed. The compost should consist of very good turfy peat, with most of the fine particles of soil shaken out, and as a surfacing only sphagnum-moss should be used, which is readily removed when sour or worn out. In repotting, I advise the use of pans in preference to baskets, these being neater, and the plants are more easily potted on occasion. The pans should be well drained with clean crocks; dead roots should be removed, as also some of the back pseudo-bulbs, not leaving more than three of them behind the leading one; then, if there are several leads to a plant, they can be put together with the leads facing towards the rim of the pan. Let the peat be inserted firmly among the roots till the pan is filled, keeping the base of the plant on a level with the rim of the pan, and finishing off with several clumps of good heads of sphagnum-moss. Plants which have been potted will require very little water at the roots for some time afterwards, beyond an occasional syringing overhead on bright days.

The Back Pseudo-bulbs of Laelia.—Those which are removed when repotting should be suitably labelled, and hung up in a somewhat dry, light position, potting them when they show signs of growth. A good method of increasing *L. anceps* is to remove any lead and two or three of the pseudo-bulbs which may be growing over the edges of the pan or basket, leaving the back pseudo-bulbs to make new leads, which, if in good health, does not take a long time to accomplish. I have seen a strong lead made the first season, and produce flowers. *Laelia anceps* does not like its roots to be interfered with, so I would not advise repotting being carried out unless the peat is quite worn out. Essential points in the cultivation of *L. anceps* are plenty of strong light and ventilation. The plants should, if possible, be placed in an intermediate-house, and where the blinds can be worked to suit them.

[Mr. Bound desires us to say that it was really once a year, and not once a month, that plants should have their leaves cleansed, as was stated in the Orchid Calendar for last week. We erred, it appears, on the side of cleanliness. Ed.]

PLANTS UNDER GLASS.

By J. C. TALLACK, Gardener to E. MILLER MUNDT, Esq., Shipley Hall, Derby.

Regal and Show Pelargoniums.—These should be potted forthwith if not already done, so that the roots may have ample time to grasp the new soil before the trusses develop. Good turfy loam with a little decayed horse-manure, a sprinkling of bone-meal, and plenty of sand or road-grit suits them well; leaf-mould as an ingredient I do not advise, for it has been held, rightly I think, that this is a main factor in the development of leaf-spot, and since discontinuing its use I have had no further trouble with spot. Pot firmly, and do not afford too much room in the pots for new soil. Return the plants for the present to a light shelf or position near the glass in a house where only sufficient fire-heat is used to keep out frost, and the air is buoyant.

Cannas.—Where early flowers are needed, a batch of Cannas should be potted up, first dividing them into single crowns, unless bulky specimens are desired. Cannas do best in a rich soil, into which a considerable quantity of decayed cow-manure enters, and sand in plenty. Good drainage must be afforded, as they take water abundantly when growing. I prefer to pot at this season into the flowering pots direct, placing them in gentle warmth, and applying no more water than they get from the syringe for the first few weeks.

Asparagus Sprengeri.—As a basket plant, the growth of which will cover with graceful

verdure quite a large space, nothing can equal this plant, which grows faster than any of its class, and the sprays are exceedingly durable. Seedlings raised from last year's crop of seed sown as soon as ripe will now be fit for putting into baskets, and will by next autumn make large plants. Employ a good holding turfy loam and sand in plenty round the roots; lighter soil will do, but it gets exhausted much sooner.

Heaths and Hardwooded Plants.—This is probably the worst part of the year for these plants. The ventilation should be as ample as possible, without permitting sharp draught; and in frosty weather no more fire-heat should be applied than will serve to keep out frost. The sulphur-duster should be at hand for use in case of any mildew appearing among the Heaths. Early flowered plants of *E. hyemalis* should be cut back and placed in a slightly warmer house to break.

General Work.—Camellias in flower and bud should be freely fed with clear liquid-manure; healthy plants revel in this treatment to an extent not so well understood as it should be. Richardias which are producing spathes may also be heavily fed, and receive also ample supplies of water. *Euphorbia (Poinsettia) pulcherrima* will require no more water for the present, as the roots have no work to do, and the stems need ripening. *E. jacquineziflora* may also be allowed less water at the root, but not dried off to anything like the same extent, and it should be kept in the stove. Dutch Hyacinths for flowering just before those planted out should be brought into a cool-house and kept near the glass.

THE KITCHEN GARDEN.

By T. TURTON, Gr. to J. K. D. WINGFIELD DIGBY, Esq., Sherborne Castle, Dorset.

Early Potatos.—In gardens where hot-water pits can be set apart for this crop, forthwith fill them with fresh leaves of Oak, Beech, or Sweet Chestnut, making the bed as firm as possible by tramping it. This date will not be too early if new Potatos are required about Easter. The loamy soil in which Melon plants were grown last year forms an ideal one for Potato culture, and should always be reserved for this purpose. The surface of the leaf-bed should come to within 18 inches of the lights, and on the bed should be placed a layer 6 inches thick of soil. Assuming that the Potato sets have already been started, and are growing in a pit having a temperature of 50°, they will have made strong shoots. Do not intercrop with Radishes, &c., as the Potatos will soon require all the space, and require moulding-up, that is, before the Radishes are fit for consumption. Ashleaf varieties of Potatos had a long reign in gardens. They are, however, now generally superseded by Ringleader and other new early varieties. The sets should be planted from 12 inches to 15 inches from row to row, and 9 inches in the row.

Tomatos.—Plants raised from sowings made in October, which have been standing in large 60-sized pots, should, if they are intended for fruiting in pots, be shifted into 6-inch pots, potting them moderately firmly in a compost consisting of good turfy loam three parts and spent Mushroom-bed dung one part, with charred garden refuse in quantity according to the nature of the loam. Place the plants very close to the glass, in a house having a warmth ranging from 60° to 65°, and 5° to 10° higher than that in which they were grown hitherto. Make a sowing of seed forthwith for raising plants for planting-out in pits at the beginning of March. The back walls of vineries newly planted also offer a suitable place for growing an early crop of Tomatos. A selection of Early Ruby still holds its own here as a variety for an early crop, and Sutton's A1 to succeed it. The seed should be sown in 6-inch pots, in a mixture of loam three parts, leaf-mould one part, and enough silver-sand as will ensure porosity. Place the pots in a temperature of 65° to 75°, and as soon as the

seeds have germinated, remove the seed-pots to a shelf near the glass, so as to keep the seedlings sturdy. When the plants are a few inches high, pot them singly into small 60's, and keep them on a shelf in a forcing-house until they are large enough to be hardened off previously to planting them where they are to be grown.

Cauliflowers.—Plants in frames and hand-lights should be fully exposed in mild weather, and be afforded air, excepting during sharp frosts. This is a sure precaution against "buttoning," and prepares them for planting on warm borders in March. Many gardeners have relinquished autumn-sowing, owing to the uncertainty attached to wintering them under protection, and the possibility of obtaining equally serviceable heads of the variety Early Forcing sown at the present date. Let a sowing be also made of The Pearl, which forms a good succession to the first-named. Sow in boxes, and place in a temperature of 50° to 55°, and at all stages keep the plants near to the glass; when they are 3 inches high, a good batch should be potted singly into 3½-inch pots, heaping up the pots with compost, as recommended for Tomatos, using some of the rougher portions of spent Mushroom-dung for drainage. Plant with a blunt dibber, or what is more expeditious, with the index finger, and make the soil firm in the usual manner; return the plants to a growing temperature until they are established and growing freely, then remove them to a cold pit until the weather is mild enough to risk planting them in the open.

THE FLOWER GARDEN.

By R. DAVIDSON, Gardener to EARL CADOGAN, Culford Hall, Bury St. Edmunds.

Spring flowering bulbs.—In many places border varieties of Narcissus are now shooting through the soil, and when plantations have stood for two or three years, a top-dressing of wood-ashes and sifted loam equal parts, adding to every barrowful of the former 1 peck soot and 3 lb. of artificial plant manure, spreading the whole evenly to the depth of about ½ inch or a little less, will do much to invigorate the bulbs. Plantations made last autumn will not need such treatment, though a sprinkling of fresh soot placed around the clumps or lines will be of some benefit, and also prevent the ravages of slugs. Some of the best varieties are Glory of Leyden, Madame de Graaf, bicolor Madame Plomp, Fred. Moore, bicolor Weardale Perfection, and Apricot, very fine.

Border Carnations, Picotees and Pinks.—Assuming that plantations of the different varieties for cutting purposes were made last September in prepared beds, the plants, with few exceptions, will have begun to grow, rendering it necessary to stir the soil slightly with a hand-fork, taking care not to disturb the roots thereby, maintaining a close watch for wire-worm and the grubs of the cockchafer-moth. Carnations of proved excellence are Goldylocks, Mephisto, Mrs. A. J. Palmer, Mrs. McRae, Much the Miller, The Hunter, Verona, Wild Swan, and Germania, a variety which when well grown, is a beautiful flower. Amongst Pinks, very useful are Albino, Ernest Ladhams, and Lady Falmouth.

Ranunculus.—In warm localities the tubers of Ranunculus may now be planted in deeply-dug, prepared beds, well-manured with leaf-soil or other mild manure. Having dug the beds and made the soil firm, the latter should be shovelled out 4 inches deep and thrown into the alleys, the bottom of the excavated part made level, and the tubers, which resemble birds' claws, should be set claws downwards about 4 inches apart, and be pressed firmly into the soil, scattering some sand over the crowns and covering with fine soil and that which was thrown out. The beds should be covered with fir-boughs or other light material, as a protection against frost, which should not be removed till the end of March.

Biennials.—An inspection made at this date of the beds of the various plants employed in

spring bedding is sure to show some losses, and the present mild weather may induce many to forthwith fill the gaps from the reserve garden, but it would be better to defer doing this till about the middle of next month, when growth usually begins in such plants as Erysimum, Mysis, Silene, Limnanthes, &c. Wherever practicable during intervals of fine weather keep the Dutch-hoe at work amongst all such subjects in the flower garden. The vacant ground at the front of shrubberies which it is intended to plant with sub-tropicals, may be heavily manured and deeply dug; also the unoccupied spaces in the borders of mixed herbaceous wherein Dahlias, Salvias and Marguerites will be planted. In the vicinity of the mansion where neatness is required the paths and terraces should be swept, rolling the paths with a heavy roller and the turf with a lighter one. A sufficient quantity of composts should be stored in the potting-shed for future use, which is better than leaving them out-of-doors till wanted. In bad weather let all necessary repairs of cutting and plant-boxes be made, cleanse seed-pans and pots, and get labels of a variety of sizes made, sorted, and put into bundles in readiness for use.

FRUITS UNDER GLASS.

By JAMES WHYTOCK, Gardener to the DUKE OF BUCKLEUCH, Dalkeith.

Early-forced Fig-trees in Pots.—Following the very excellent instructions already given for the starting of these, it will be necessary to maintain a gentle bottom-heat of 75° to help the proper swelling of the fruit, and a mean atmospheric heat of 60°, 10° to 15° more throughout the day, closing early with sun-heat. When the fruit gets to a certain stage, increase in size is arrested till the setting process is over; and care must now be taken in dull weather not to afford much water at the root, nor keep the foliage constantly wet by syringing it, or the fruit will turn of a yellow tint; and on the other hand, the foliage of the Fig is so liable to become infested by red-spider, that syringing must be performed on every bright day. Afford the soil sufficient water, and let the paths and houses be damped frequently, always using warm water.

Cucumbers.—In order to maintain a supply in mid-winter, the plants must be cropped lightly, and the roots kept at the surface by affording small top-dressings of rich turfy loam, artificial manure, and on the top of all some fresh horse-droppings. The syringing of the plants at this season may only be carried out early in the afternoons of bright days, and when the weather is not very cold. The temperature of the house at night should be 65°, and rather than maintain this with excessive fire-heat, cover the roof with Frigi Domo, or let it drop 5°. The bottom-heat should not exceed 80°; make the most of sun-heat, let the temperature run up between 80° and 90°, and only admit air in small quantity in the forenoon when the day is fine.

Pine-apples.—The division which contained smooth Cayennes, which have been affording ripe fruit for the past two months, being now cleared of fruits, should be filled forthwith with the same variety of fruiting size from the succession pit. The bed having a heated chamber underneath, and tanner's bark as plunging material, some fresh bark should be added to the old and mixed with it, and the pots plunged 2 ft. from centre to centre, and as fruit is not wanted before next November and December, the atmospheric and bottom-heat, and the quantity of water afforded the plants, should for some time to come be such as will conduce to rest. The main lot of smooth Cayennes for the supply of fruit from the present time till June, will require as near as possible 65° at night, 10° or 15° more in the daytime with sun-heat, and a bottom-heat of 90°. The plants should be examined regularly twice a week, and water afforded to those that need it, and to plants with swelling fruit frequent applications of weak manure-water. The paths and wall surfaces should be moistened

several times a day, but not the plants. The division of Queen Pines for affording fruit from next June till the autumn, which since last September have been kept cool, both at top and bottom, and rather dry, should this month get a thorough application of water. The night temperature should range from 60° to 65°, 10° more by day, and a bottom-heat of 90°. After water has once been applied, water may be needed twice a week; a moist atmosphere should be maintained by damping down two or three times a day, but the plants should not be syringed.

Strawberries.—For affording the earliest fruit, plants growing in 5 or 6-inch pots should have been plunged in mild bottom-heat about the beginning of December, in a brick pit sufficiently deep to hold a bed of tree-leaves 2½ in. thick, provided with a flow and return 4-in. pipe for top-heat. This bed will afford a bottom-heat of 70°, and a top-heat of 50° to 55° should be maintained, according to the weather. Those plants which were started at the beginning of December are now beginning to show the flower-trusses, and may be removed to shelves in the Strawberry-house if one exists; if not, then to a shelf near the glass in a pinery, a vinery, or Peach-house, that has been started. Whilst in flower, and until the fruit has set, employ a night temperature of 55° to 60°, with a constant circulation of air; 10° to 15° higher by day with sun. When the fruit is set, remove the smaller fruits, reserving only a few of the best, and place the plants in a mean temperature of 70°. If pot Strawberries are properly treated and fed from the first, there is little trouble with red-spider or mildew. Before starting them lightly stir the surface of the soil, and apply a light dressing—¼ oz. of "veltha," mixed in as much sand on the surface as a prevention of mildew; then, when the fruit is set, apply a sprinkling of Thomson's, or other good plant-food. See that the plants do not suffer lack of water, and frequently apply soot-water. In bright weather syringe the plants twice daily, and keep a moist growing atmosphere. The two best varieties for the earliest crop are Stevens' Wonder and John Ruskin.

PUBLICATIONS RECEIVED.—*The Gentlewoman*, acceptable in every household.—*Nature Notes*, January. —*Annual Report for 1900 from the Botanic Station, Grenada*, by W. E. Broadway, Curator. "An interesting feature in connection with the work of the Botanic Station during 1900 was the establishment of seven experimental Cacao plots in various parts of the Island, under the control of the Curator and other officers of the Imperial Department of Agriculture. The Report is, on the whole, of a favourable character." An interesting note is that the non-climbing variety of Black Pepper bore a crop of fruit again. The plant is more productive in Grenada than are those which climb trees.—From the Imperial Department of Agriculture for the West Indies, we have received the following numbers of the Pamphlet Series: No. 11.—*Journal of the Department of Agriculture of Western Australia*, November, 1901. Includes many notes and papers on: The Insectivorous Birds of Western Australia, by Robert Hall; Woodiness of the Passiflora Fruit, by A. Despeissis; Noxious Weed (*Hemeria collina*), &c.—*Annales Agronomiques*, December 25.—*Boletín del Instituto Físico-Geográfico de Costa Rica*, Nos. 10 and 11.—*Syllabus of the Dundee Horticultural Association for the session 1902*, and *Annual Report*.—*Annual Report on the Gardens of his Highness Maharaja Fateh Singhji Bahadur, G.C.S.I. of Udaipur, Mewar*. From the year 1898-99 to 1900-01. The former year was fairly good for the agricultural and horticultural works, although the rains were much below the average. The year 1899-1900 was the worst ever seen in Mewar. The famine of 1888 was nothing in comparison to the present one; the gardens suffered in many places, thousands of plants died, but Mango-trees stood the drought well.—From the Imperial Department of Agriculture for the West Indies:—Pamphlet Series No. 11.—*Bulletin of the Botanical Department, Jamaica*. Edited by William Fawcett. November and December, 1901. Contents: Historical Notes, by the Editor and W. Harris, F.L.S. IV. 'The Mango. Nathaniel Wilson, by F. Wilson, &c.—*Sunset: A Magazine of the Border*. December, 1901. Contents: Garden of the Willow-pattern Plate, by Irene Connell; Carnations by the Sea, by Ednah Robinson, &c. This magazine is published monthly by the Passenger Department of the Southern Pacific Company, 4, Montgomery Street, San Francisco, California.—*Detectus Seminum et Fructum*. Hortus Botanicus Bonariensis, collectorem et pro mutua permutanda offeruntur (List of Fruit and Seeds for exchange from the Botanic Garden, Buenos Ayres. Director, Señor Thays).

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

APPOINTMENTS FOR THE ENSUING WEEK.

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three Years at Chiswick —37°.

ACTUAL TEMPERATURES:—

LONDON.—January 15 (6 P.M.): Max. 40°; Min. 29°.

January 16.—W. wind; dull; milder.

PROVINCES.—January 15 (6 P.M.): Max. 48°, N.E. Scotland; Min. 36°, E. England.

A Home for the R.H.S. THE approaching annual meeting of the Royal Horticultural Society will no doubt induce many of the Fellows to enquire what, if any, steps have been taken to secure adequate accommodation for the Society in London. Mr. BURBIDGE's letter in our last issue we are sure gives utterance to what many beside himself are feeling. At the meeting called to consider the matter in April last, the proposal to purchase a large area of land at some distance from London for the purpose of forming a garden was negated by a very large and very emphatic majority. Although the proposal to secure a hall was not formally before that meeting, yet there could be no sort of doubt what the wishes and aspirations of the Fellows present were, and substantial offers of assistance were then and there made. The Fellows have therefore a right, at the forthcoming meeting, to know what has been done to give effect to their wishes, and, though we are not authorised to make any such declaration, we hope that they will not be altogether disappointed. Several sites have, we know, been visited by a committee elected by the Royal Horticultural Society, and presided over by Baron SCHRODER, and their capabilities discussed. All were very costly, some so much so as to be prohibitive. In one case, however, the conditions, if not fully satisfactory, are more favourable, so that we shall probably hear more about it at the ensuing meeting.

The Society is in a remarkably prosperous condition, and under the judicious management of the Council, and its indefatigable Secretary, a considerable reserve fund has been accumulated. To those of us who remember keenly, the period of financial disaster, the present state of affairs is nothing short of wonderful. The present time is therefore as propitious as any time

is likely to be, and every effort should be made to avail ourselves of it by the erection of suitable premises, which, if costly, will be all the more valuable as an asset, and will obviate the necessity of hiring the Drill Hall and the offices of the Society. Large financial help from outside must be forthcoming, but considering that the Society now numbers some 6,000 Fellows, mostly recruited from the well-to-do classes, we cannot doubt that if a full and straightforward statement of the case were submitted to the Fellows, and an appeal made for help, that the response would be favourable.

In the meantime a courteous communication has been received from the Royal Botanic, inviting the Royal Horticultural Society to hold some or all their shows in the Regent's Park Gardens, and offering every facility for the purpose. There is no doubt the conservatories and exhibition grounds are very suitable for the purpose, but they are out of the way, and the policy followed of late years by the Botanic is not such as commends itself either to botanists or horticulturists.

In reply, the Council of the Royal Horticultural Society have, we believe, stated that they are unable at present to accept the offer of the sister Society, and that until the arrangements for celebrating the Centenary are decided upon, the Royal Horticultural Society is unable to entertain the idea of a change. Moreover, in view of the great advantages which have accrued from moving to Westminster, the Council would have to be very decidedly convinced that such a removal of site as now proposed would not endanger the recently revived prosperity of the Royal Horticultural Society. No doubt the idea of a complete amalgamation between the two Societies would not, under existing circumstances, be acceptable, nor would the Fellows care at their own expense to save the Royal Botanic Society from the cost and trouble of maintaining its own shows.

Another point has been raised by the recent action of certain members of the Fruit Committee, in urging the Society to obtain by hire or purchase a small area of three or four acres just outside London, where trials can be conducted more satisfactorily than they can be at Chiswick. This is a very different matter from the grandiose garden-schemes which have been already negated, and it is one which may be very fairly considered by the Council. The lease of Chiswick has still nearly twenty years to run, but the unfavourable conditions by which it is beset increase in intensity each month. On the other hand, we must remember what fine examples of cultural skill have been exhibited during the last year from Regent's Park, Holland House, Gunnersbury, Camberwell, and other suburban districts, no better off climatically than Chiswick.

Even on Tuesday last several fine bunches of Alicante Grape were shown from a garden some three miles only from Charing Cross. The bunches were not large, but they were well finished and covered with bloom.

So, in spite of climatic difficulties, it is still possible to grow creditable fruit and flowers within a shorter distance from the centre of London than is Chiswick. Nevertheless, sooner or later, Chiswick is doomed; the question is—shall it be sooner or later?

THE NATIONAL ROSE SOCIETY'S EXHIBITION.—The date of the National Rose Society's Rose Show in the Temple Gardens has been definitely fixed by the Committee for Wednesday, July 2 next.

THE BEAUTIES OF CALIFORNIA.—A pamphlet by Mr. C. H. SHINN, entitled *A Study of San Luis Obispo County, California*, describes the beauties and attractions of the "great domain of California, which includes 158,000 square miles of territory, close-packed with possibilities that no man as yet fully comprehends." The many pictures of the district of San Luis Obispo certainly show a lovely neighbourhood, extensive, fertile, and inviting. The mere idea of such abundant space, air, water, and luxuriance of vegetation, is delightful to town dwellers, and we advise those seeking a change of scene to remember the advantages of California.

"FLORE . . . DE LA FRANCE."—The last issued part of this useful publication includes the Rosaceae, and some other orders. The plants are concisely, and, so far as we have seen, correctly described, the descriptions being so arranged as to be readily comparable and easily found. The little sketches, like those of the illustrated edition of Bentham's *British Flora*, are very serviceable. It would have been better if naturalised plants like *Claytonia perfoliata*, for instance, had been printed in a separate type from the true natives, and not numbered in continuous sequence with the aboriginal inhabitants. The author of this serviceable book is the Abbé COSTE. It is published by KLINCKSIECK, Rue Corneille, Paris, and may be had from WILLIAMS & NORGATE, Henrietta Street, Covent Garden, London.

"FLORILEGIUM HAARLEMENSE."—Two parts of this illustrated periodical have reached us from the publisher, DE ERVEN LOOSJES, Haarlem. It consists of coloured representations of the best and most characteristic bulbous plants selected by the General Bulb Society of Haarlem. The descriptions are given in four languages, Dutch, German, French, and English. The plates appeal to plant-lovers of whatever nationality.

Obelisk, t. 46, is a single-flowered Hyacinth, with a compact, cylindrical spike of small yellow flowers. Its origin is not known.

Double Tulips, t. 47, is devoted to the illustration of Lord Beaconsfield, with brilliant crimson flowers, and Parmesiano white, flushed with rose.

Lilium speciosum album occupies t. 48.

Hyacinth Roi des Belges, t. 49, is a crimson-flowered variety, with a very dense, obtuse spike. It was raised from seed by Messrs. E. KRUYFF, of Sassenheim.

Single Early Tulips, t. 50, Gele Prins, has variegated foliage and yellow flowers; Prins van Oosterik is much sought after for its single crimson flowers; Gouden Bruid van Haarlem (Golden Bride of Haarlem) has yellow flowers, mottled with scarlet, and is a sport from Bruid van Haarlem.

Tab. 51 is devoted to the illustration of various forms of English Iris.

PRESENTATION.—The removal of Mr. A. C. FORBES, head forester on the Bowood Estate, to a more important position at Longleat, was made the occasion of a presentation of a handsome onyx clock, and a gold bangle to Mrs. FORBES. The presentation was made at the Institute, Derry Hill, by Mr. H. HERBERT SMITH, agent to the Marquis of Lansdowne, on Friday, January 10. Mr. FORBES, who has

been for ten years head forester at Bowood, has carried out his work with credit to himself, and advantage to the Bowood Estate. During the greater part of this period he has been a contributor of articles on forestry subjects to the pages of this journal.

ROYAL SEEDSMEN.—Messrs. KENT & BRYDON, seed merchants and nurserymen, of Darlington, have been appointed seed merchants by Royal Warrant to His Majesty the KING.

"CASSELL'S DICTIONARY OF GARDENING."—The eighth part of this serviceable publication has been issued. It is well suited for amateurs, and for those who do not require exhaustive information. Within its limitations it is well done, and well illustrated.

"CRAMPTON'S MAGAZINE."—The January number is full of good tales and other domestic matter, and we commend it to all householders who do not already know of it. The editor is Mr. HAROLD TREMAYNE; publishers are ANTHONY TREHERNE & Co., 3, Agar St., W.C.

"HORTICULTURAL DIRECTORY."—This serviceable publication is issued from the office of the *Journal of Horticulture*, Mitre Court Chambers, Fleet Street. It has evidently been revised, as many of the recent changes are inserted, but it is impossible to secure absolute correctness in such a work, particularly as the individuals most concerned so often render no assistance. "Sir JOHN LUBBOCK" no longer exists under that name, which has been superseded by the designation Lord AVEBURY. Mr. G. B. MALLETT is no longer at Mandeville House, Isleworth. Dibden House, Ealing, is untenanted.

FRUIT FROM THE CAPE.—The first ship of the Union Castle fleet of steamers bringing fruit from the Cape is due to arrive here in a few days. The *Carisbrook Castle* left Cape Town on New Year's Day with 358 packages, being the first consignment; the *Kinfauns Castle* left Cape Town on the 8th inst. with 601 packages. The description of the fruit has not been given by cable. The other ships to bring fruit are the *Kildonan Castle*, *Saxon*, *Norman*, *Dunvegan Castle*, *Scot*, *Briton*, and *Dunottar Castle*. The dates of arrival home are January 17, 24, and 31; February 7, 14, 21, and 28; March 7, 14, 21, and 28; April 4 and 11.

ROYAL PURVEYORS.—Messrs. RANSOMES, SIMS & JEFFERIES, Ltd., Orwell Works, Ipswich, have been appointed by Royal Warrant manufacturers of Agricultural and Horticultural machinery to His Majesty King EDWARD VII.

HARDY SHRUBS IN DUBLIN.—Just at present *Jasminum nudiflorum* is gay with its yellow stars and buds. The *Wych-Hazel* of Japan (*Hamamelis arborea*) is also very pretty, its branches thickset with brown buds and fully open flowers, the petals of which look like bits of crumpled gold wire. The *Tassel-Bush*, *Garrya elliptica*, is clothed at the tip of each shoot with bunches of soft grey catkins, and there are odd flowers and buds gleaming on the *Cydonia* (*Pyrus*) *japonica*, and here and there on the walls the golden-leaved forms of *Ivy* gleam brightly in the sun. On the borders are Christmas and Lenten Rose *Hellebores*, *Iris stylosa*, and the striped buff buds of *Crocus Imperati*, are opening on warm, still days.

STOCK-TAKING: 1901.—Before giving the results for the past year, it will be necessary to briefly summarise the figures relating to the trade of December, as stated in the Board of Trade Returns. Briefly, then, the value

of the imports for the past month was £46,770,097, as compared with £46,446,662—or an increase of £323,435. Now, as to exports, the output for December is given as £24,313,777, against £23,611,972 for December, 1900—or a gain of £701,805. This doubly-pleasant record for the closing month of "the year that's awa'" will be hailed with satisfaction by all interested in commerce. We come now to the year's record. The total value of the imports is £522,238,986, against £523,075,163—or a decrease of £836,177. So "things are not so bad after all." The following excerpt from the summary table are worth recording here:—

| IMPORTS. | 1900. | 1901. | Difference. |
|--|-------------|-------------|-------------|
| | £ | £ | £ |
| Total value ... | 523,075,163 | 522,238,986 | —836,177 |
| (A.) Articles of food and drink—duty free ... | 156,090,088 | 162,949,066 | +6,858,978 |
| (B.) Articles of food & drink—dutiable | 49,230,529 | 47,505,501 | —1,725,028 |
| Raw materials for textile manufactures ... | 77,347,363 | 79,401,772 | +2,054,409 |
| Raw materials for sundry industries and manufactures | 65,079,691 | 57,954,510 | —7,125,181 |
| (A.) Miscellaneous articles ... | 16,771,621 | 17,298,198 | +526,577 |
| (B.) Parcel Post ... | 1,119,626 | 1,262,462 | +142,836 |

The figures relating to the trade in fruits, roots, and vegetables, are of perhaps more interest than usual, owing to the opening up of trade. The figures are as follows:—

| IMPORTS. | 1900. | 1901. | Difference. |
|--|-----------|-----------|-------------|
| | Cwt. | Cwt. | Cwt. |
| Fruits, raw:— | | | |
| Apples ... | 2,128,541 | 1,830,208 | —298,333 |
| Apricots and Peaches | 13,689 | 13,463 | —226 |
| Bananas... bunches | 1,287,442 | 2,228,672 | +941,230 |
| Cherries... .. | 212,525 | 212,683 | —158 |
| Currants ... | 64,462 | 70,402 | +5,940 |
| Gooseberries ... | 26,045 | 21,735 | —4,310 |
| Grapes ... | 582,857 | 679,878 | +97,021 |
| Lemons... .. | 947,891 | 1,070,354 | +122,463 |
| Nuts—Almonds ... | 140,359 | 111,312 | —29,047 |
| Others, used as food | 763,295 | 904,154 | +140,859 |
| Oranges... .. | 5,090,896 | 5,281,657 | +190,761 |
| Pears ... | 476,901 | 348,866 | —128,035 |
| Strawberries ... | 423,019 | 263,700 | —159,319 |
| Unenumerated, raw... | 494,722 | 535,246 | +40,524 |
| Fruits, dried— | | | |
| Currants, for home consumption ... | 798,647 | 963,633 | +164,986 |
| Raisins ... | 564,303 | 554,408 | —9,895 |
| Vegetables, raw:— | | | |
| Onions ... bush. | 7,087,105 | 7,295,418 | +208,313 |
| Potatoes ... cwt. | 8,910,962 | 7,076,882 | —1,834,080 |
| Tomatoes... .. | 833,030 | 793,991 | —39,039 |
| Vegetables, raw, unenumerated ...value | £766,394 | £389,828 | —£376,566 |

It may be noted that one of the "unenumerated" in evidence at Christmas time was the Custard-Apple, many splendid samples of which graced the dessert on that day. Come we now to our—

EXPORTS.

Concerning which a few figures are exhibited. The twelvemonth's total is £280,498,889, against £291,191,996—showing a decrease of £10,693,107. This is a serious falling off, but then it might have been worse, and considering the enormous competition to which we are subjected by "all the nations of the earth and America," as a provincial friend put it to us, we have come out perhaps as well as could be expected. Of course, war's deadly blast has shrivelled up many a promising scheme, and the settlement of tariff charges act as deter-

rents to trade; but a nation whose foreign trade amounts to £802,737,875 must certainly be possessed with pluck and energy sufficient to carry it over all difficulties. Let us hope that the final record of 1901—a double increase—may prove a good augury.

POISONOUS EFFECTS OF MISLETO ON THE PEAR.—In the *Comptes Rendus de l'Académie des Sciences*, M. EMILE LAURENT remarks upon the existence of a principle injurious to the Pear in the berries, seeds and young plants of Mistleto. "If this parasite germinates on the branches of some varieties of the Pear (Williams, Joséphine de Malines) it causes death by midsummer. Such is the case, also, according to JEAN CHALON, with *Spartium junceum* and *Ficus elastica*. In the case of the Pear, the cortical tissue is destroyed and contracts, often several centimètres away from the point of inoculation. Inside the vessels gummy lumps are formed which impede the circulation of the sap, thus explaining the quick drying up of the young branches during the hottest days of summer. Following this necrosis of the bark, the young plant which caused it dries and dies without even penetrating the bark. The Pear is thus saved from the further injurious effect of the Mistleto. Varieties which exhibit this peculiarity are immune, while others are predisposed to attacks of this particular parasite."

A "SIGHT FOR SAIR E'EN" has been provided for passers-by in the dreary month of January by the wall of a house close to the gates of Gunnersbury Park. This is entirely covered with *Crataegus pyracantha*, upon which is still left an ample crop of scarlet berries. Among the comparatively compact branches of this creeper *Jasminum nudiflorum* is running rampant, and the clear yellow of its fully-expanded flowers forms a charming contrast to the bright berries and green leaves of the *Crataegus*. It was not our fortune to see this beautiful sight on a fine day, but when the sun is shining the effect must be truly gorgeous.

THE R. DEAN TESTIMONIAL.—A meeting of the subscribers to the above was held at the Royal Aquarium on Tuesday last, Mr. W. MARSHALL presiding in the absence of N. N. SHERWOOD, Esq., who was unwell. It was unanimously agreed that the testimonial take the form of a cheque, together with a handsomely framed address on vellum, the latter to be at a cost not exceeding £5. It was also resolved that the date of the presentation be Tuesday, February 4, being the earliest convenient day to Mr. DEAN's seventy-second birthday, February 1, and that a public dinner be arranged at which the presentation shall be made, at such place as the executive may determine. Also that the presentation be made by Mr. SHERWOOD. Mr. J. H. JONES, Secretary, reported the receipt up to date of £290 1s. 6d., and expressed a hope that it would yet reach a larger sum.

TRADE NOTICE.

Mr. C. F. LANGDON, for the last seventeen years head gardener at Newton St. Loe, has recently resigned that position for the purpose of joining as partner Mr. J. B. Blackmore, Begonia grower of Twerton-on-Avon, Bath, who has just started a nursery in which the principal feature will be tuberous-rooted Begonias. The firm will also cultivate one of the finest collections of Carnations and yellow-ground Picotees, having purchased the entire collection raised by Mr. C. Wall of South Down.

JAPANESE MAPLES AT CASTLEWELLAN, CO. DOWN.

[SUPPLEMENTARY ILLUSTRATION.]

FOR the photograph from which our illustration was taken we are indebted to the courtesy of the Earl of Annesley. The following note has been contributed by his gardener, Mr. Ryan:—

"Of the numerous plant-treasures which have been derived from Japan, this *Acer* (*A. japonicum atro-purpureum*), to my mind, bears the palm. Whether we admire its graceful foliage, its vigorous habit, or its lovely colouring, it is *facile princeps* among ornamental trees. At Castlewellan about eighteen hundred different varieties of hardy shrubs are cultivated, and we think that this plant is the choicest. The specimen shown in the illustration is 8 feet high and nearly 50 feet in circumference, and yet it is not the largest specimen here, but in shape it is very nearly as perfect as a garden shrub. The young foliage, as it comes out in the spring, is of a bright blood-red colour, turning in the middle of summer to a greenish-purple. It makes a second growth towards the autumn, when the contrast between the two colours, the bright red of the young leaves and the dark purple of the general mass of foliage, is very effective. But it is just as it is about to drop its leaves in late autumn that the colour is most remarkable, and at that time for about a fortnight it is no exaggeration to say that it is brighter and more brilliant in colour than a soldier's red coat. No one, who has not seen the forests of Canada in the autumn, can have any idea of its splendour.

Good loam, with a fair proportion of manure from an old Mushroom-bed, makes a suitable soil for Maples. It is a matter for wonder that a plant whose foliage is so magnificent in its tints, and withal so hardy—for it never suffers in the hardest frost—is not extensively planted in gardens and pleasure-grounds. Perhaps the reason may be that it takes some time to raise a stock of the plant. As to its monetary value, I remember at the Temple Show of the Royal Horticultural Society a few years ago a Duke giving £20 for a plant not to be compared with the one in the photograph; and when the traveller of one of the largest English nurseries was making his annual visit, I showed him one of our finest plants, which was then in full leaf—the sun was shining brightly through the young blood-red foliage at the time, making a lovely mass of colour, and asked him, as a matter of curiosity, what he would value it at? He replied, 'Well, if we had a customer for such a plant, and it could be moved safely, we should not think of asking less than 70 guineas for it.' As we have some hundreds of them, I thought to myself it would be a very profitable crop to grow at that price. Last spring a terrible occurrence took place, from a gardener's point of view. Eight of the Japanese deer escaped from the deer park into the spring garden, and made straight for the red Maples, and in one night ate up fifteen of them as far as they could reach, most of them being larger than the plant illustrated."

Apropos of Maples, Messrs. L. Bochmer & Co., Yokohama, send us the following note:—

"In particular, I should like to mention the lovely spring Maples, which are just now so beautiful, and especially the variety *Acer polymorphum atropurpureum dissectum*, of which I send a photograph (fig. 11, p. 41) and also a few pressed leaves, which show the beauty of this variety better than any word description I could give. This tree is one of the most beautiful ornaments in our gardens, not only

on account of its fine-cut leaf (resembling more that of a Fern than a Maple), but also because, unlike the forest Maples, which obtain their wonderful colouring in the autumn (the colouring of Japanese Maples is particularly beautiful), these leaves are at first beautifully tinted, changing later on to green. Besides the variety *atropurpureum*, we have the plain green *dissectum*, also very lovely, and both of the same drooping habit. The only way to propagate these trees here in Japan is by grafting, but as one of the trees in my garden has produced seed so beautifully, I am very anxious to experiment, and to see what the result will be. At last, I wish to say that with us these trees are perfectly hardy, and as far as I have seen in the papers, they are also hardy in England and America."

NOTICES OF BOOKS.

PROFITABLE FRUIT-GROWING.

THE sixth edition of Mr. John Wright's prize essay on this subject has been published by Messrs. Collingridge, 148, Aldersgate Street. We are told on an inset that a copy has been sent to, and accepted by the King; so that the essay, which was premiated by the Worshipful Company of Fruiterers, has now received the recognition of Royalty. It is not necessary to say anything in commendation of a book in its sixth edition. It may suffice to say that the selection of fruits has been revised. "The secret of success," says the author, in conclusion, "rests in exact knowledge, and its application in the form of diligent, well-timed, and well-judged work." Quite so; but land laws, railway rates, commission salesmen interfere with the application of sound principles. Against and for all that, the teaching of Mr. Wright's book affords the best protection.

THE ROSARIAN'S YEAR-BOOK.

THIS opens with a portrait of Mr. Orpen, and a sympathetic account of his work among the Roses, especially the Teas. Miss Jekyll has a word to say on garden Roses, the Editor reviews the events of the Rose-year, and Mr. Pemberton deals with the new Roses of the year, among which Bessie Brown takes the lead; whilst we have it on Mr. Pemberton's authority that "Tennyson, as a maiden, is useful." Mr. B. E. Cant's paper on stocks and their influence, is very interesting. Preference is given to the Briar cutting. Mr. George Paul reviews the development of new types of Roses, and the great extension of Hybrid Teas. Mr. Mawley's meteorological notes are, as usual, full of interest; his statistical data, and the deductions from them as to the chances and amount of rainfall in June and July, when Rose shows most abound, are novel and important.

THE BOOK OF BULBS. By S. Arnott (John Lane: The Bodley Head, Vigo Street).

THIS is another of the series of Handbooks of Practical Gardening, edited by Harry Roberts. Its title is very expressive of its contents. It is wonderful how much the author has been enabled to cram into little more than a hundred pages. We are not sure whether he would not have done better to have confined his remarks to a selection of bulbous plants, rather than to have enumerated so many. None better than the author could make the selection, and none better than he could lay down the general principles of their cultivation. At any rate, those who

want information about bulbous plants (using the term bulbous in a broad sense) will find in this little volume a compact encyclopædia of trustworthy information.

A GOURD PERGOLA.

MR. IRWIN LYNCH, in his interesting paper on Gourds, p. 457, suggests that "These Gourds might be grown very effectively if planted in holes so arranged as to form a pergola." This idea was carried out during the past season in Mrs. Brightwen's gardens, The Grove, Stanmore. A kitchen-garden path, some 180 feet long, was arched over with wooden poles, leaving a clear space overhead of 7 feet. The Gourds were planted out the first week in June, having been previously hardened off in cold frames. By the middle of July the pergola was formed, and large quantities of Gourds set (see fig. 12). The sorts used were those which belong to *Cucurbita Pepo*, such as the Orange, Turk's Cap, Golden Pear, warted and bi-color Gourds. A few Squash Gourds were used, but these have to be kept low down on the pergola, as their great weight twists and breaks the bines. Amongst the species used, *C. ficifolia* and *C. grossularioides* were most effective, the former being the most robust and rapid grower of all the Gourds.

One of the most striking features of the pergola was the fruits of the Long-bottle Gourd (*Lagenaria*); these came to perfection quite as well in the open as when grown in the stove. One of the longest measured 5 feet 3 inches. Plenty of water with occasional weak liquid-manure, and careful tying and thinning the shoots, are essentials to success in forming a Gourd pergola. J. W. Odell.

HOME CORRESPONDENCE.

THE RUST OF CHRYSANTHEMUMS. — Mr. McCulloch asks whether I can explain how it was that certain plants which had had no manure escaped the ravages of this disease? Of course, I cannot do this. If it was produced by the manure used, it was a manure of a very peculiar and unsuitable kind. I am well aware that some poison their plants with manures, and others almost destroy them with pure water. This does not prove that manures and water must be withheld. Manure properly applied to a healthy plant should and will not produce rust or any other disease. Manure should mean nourishment. I am of opinion that too much is made of feeding Chrysanthemums. Beginners seem to think that the best flowers are produced by applying enormous quantities of manures, whereas these are really produced by healthy, properly nourished plants. W. J. Godfrey, Exmouth.

— Not having experimented in the way your correspondent "McCulloch" has done, as given ante, p. 33, by using artificial manures on some and not on others, it is not an easy matter to give an opinion; those who try the experiments should be the best judges of the why and wherefore of the case. There are many questions one might be inclined to ask on the kind of cultivation pursued, and the sort of manure of which use is made. I have quite as puzzling a problem to solve in my case, as stated on p. 474: I may ask why has the rust left us, when artificial manures were used, and the treatment in general was the same as in other years? and again I have had plants in the open ground in the kitchen garden which I lifted in the autumn, using no manure in the potting soil, and yet some of them got the rust, and others did not. I do not think it a desirable practice to use more than one artificial manure during the season; mixing up different makers' manures cannot be right. The whole matter is puzzling, and wants further investigation. A. J. L.

A HALL FOR THE ROYAL HORTICULTURAL SOCIETY.—I am extremely glad to note that Mr. Burbidge has re-opened this subject in your columns, and fully agree with him that this present year of the Coronation of His Majesty the King, who is the patron of the Society, presents a most fitting opportunity for such agitation and ventilation of the question of what so many consider to be a vital need, as will lead to a definite plan, and what is more, to the fulfilment of same on proper lines. In my former communication in this connection, I pointed out the enormous difference existing between the status of the Society at the time of the first attempt to found a hall, and that which it enjoyed at the

entirely from the slough of despond in which it had nearly been smothered; and its executive had yet to gain the confidence to which subsequent success and rapid progress have entitled it. We know, however, that the Council is actively engaged at present in licking a practicable project into shape; and it is to be hoped that on the next general meeting of the Fellows, such a one may be ripe for discussion and adoption. Remembering, however, previous meetings, I would certainly suggest that ample notice may be given not merely of the date, but also as far as possible of the plans and prospects and general data which the Council propose to bring forward for consideration; and also it

should be obtained? This, I think, should certainly be made clear to all, for nothing handicaps schemes of this class more than uncertainty. The support given to the so-called Royal Botanical Society is also, I am glad to see, referred to by Mr. Burbidge. In view of the infinitely greater importance of the Royal Horticultural Society, and the undoubted national benefit it involves, it is an absolute anachronism that the latter is left out in the cold while an invaluable privilege is continued to another body, which is practically little more than a name and a centre for social amusement. I cannot help thinking that once a definite scheme were formulated, involving a Government concession, and supported financially on an adequate scale by the Fellows, representation in the right quarter could be made sufficiently influential to remedy this anomaly, and secure the Society at once its moral rights, its halt, and, as a consequence, an even more brilliant future than its present rapid progress argues. *Chas. T. Druery, F.L.S., V.M.H.*

AMERICAN BLIGHT ON APPLE-TREES.—The remedy given in your issue of January 11, see p. 35, is, I have no doubt, an excellent one, although difficult of application to large trees. I have found paraffin a sure remedy for the destruction of this injurious pest. On taking charge of these gardens some ten years ago, I found the whole of the bush Apple-trees very badly infested with American blight, indeed they were the worst affected trees I had ever seen; many of the branches were wreathed with insects. Knowing what an excellent insecticide paraffin is, I decided to try its effect on American blight. I put at the rate of $\frac{1}{2}$ pint of paraffin to 3 gallons of water, which was mixed by thoroughly agitating it with a syringe for a few minutes previous to applying it, which one man continued to do, while another man syringed the trees with the mixture. The experiment was a complete success, as not a living insect could be found next day. A few appeared the following summer, which were destroyed by another application of the mixture, which was put on as soon as the leaves had fallen. The trees are now quite free from the pest, but as a preventative I have the trees syringed every autumn with a similar mixture. To those whose Apple-trees are infested with this very injurious pest, I would say syringe them at once with a similar mixture to the above, which I have not the least doubt will prove as effectual in their case as it did in mine. *J. H. W.*

EARLY SINGING OF THE THRUSH.—I first noticed that a thrush in my nursery on January 4 of this year had begun piping out an odd note or two of song, and to my astonishment to-day (Jan. 7) just before the sun was setting, it broke out into almost full song and sang for nearly half-an-hour. I should think this is almost the earliest date at which the thrush has been heard in this country. *J. D. Aldridge, Eastgate Nursery, Peterborough.*

CARTER'S MICHAELMAS PEA.—As there have been several paragraphs regarding this fine late Pea in your columns, it may be interesting to send you its complete history. Michaelmas Pea was selected at our seed farms, St. Osyth, from a very tall late Pea that we introduced under the name of "Interest," but which by reason of its height did not become popular. We enclose some seeds of both Late Queen and Michaelmas so that you may see they differ materially; besides this, anyone who is a judge can readily detect a distinction in the pods during growth—the latter resembling *Ne Plus Ultra* type, the other *Autocrat* type. Our Michaelmas Pea went through the critical trials of the Royal Horticultural Society, and was the only late Pea awarded honours in 1896, the Committee regarding it as a late variety of much promise; and it was pronounced by competent judges on the spot to be distinct from all others. *James Carter & Co., Seedsmen to His Majesty the King.* [There is a conspicuous difference in the size of the

FIG. 12.—A GOURD PERGOLA. (SEE P. 46.)

time of writing; since then, nearly 1,000 new Fellows have been elected within the compass of a year, and its onward and upward progress is by leaps and bounds in lieu of an almost despairing struggle for bare existence. The spirit of the Fellows was admirably evinced at the last general meeting, when three of the advocates of the hall promised £1000 each, since, I believe, supplemented by a munificent offer by Baron Schroder of £5,000 more for the same purpose. With a Fellowship of some 6,000 or more, many of which are undoubtedly able and willing to support the scheme if once it were clearly formulated, there should be little difficulty in finding the needful sum, and certainly far less now that there must have been experienced on the last occasion, when nearly £30,000 were practically secured, though the Society had by no means emerged

is to my mind, more important that a meeting held to consider so vital a matter should not be wedged in between other Committees, so that a quite inadequate time is allowed for full discussion. The Fellows should have a previous opportunity of fully studying the pros and cons, which it is impossible to do properly when they are first made known at the meeting itself. One point was put forward and never cleared up on the last meeting, and that was the effect of the Society's charter as regards a hall of the kind desired; and subsequently the point was raised by the writer, how was it that the charter was not an obstacle at the time of the first attempt? And if it was not, while the new charter is, how was it that such an obstacle was introduced in view of the known desire of many Fellows that such a hall

Peas in the two samples, Late Queen averaging 11 to 12 millimetres, whilst Michaelmas does not exceed 10. Ed.]

LATE-FLOWERING DECORATIVE CHRYSANTHEMUMS.—I enclose two varieties of Chrysanthemums that are exceedingly useful for Christmas and New Year's decoration, Mutual Friend, which is white, and Duchess of York, yellow. The size and form of the blooms, which are produced on long, stiff stalks, make them valuable. The specimens were grown in 8-inch pots, and the plants bore six to eight blooms each. *Geo. Nottage, Mill House, Bourne End, January 7.* [The blooms are uncommonly well grown. Duchess of York is of soft yellow colour, and the blooms are of excellent size. Ed.]

NITROGENOUS MANURES FOR PEAS.—The note appended to the article on Peas in your issue of January 11 is of some importance just now, when early Peas are being sown. Many cannot understand why it is that those who supply their early crops, in gardens or in field culture, with an abundance of nitrogenous food, always secure better returns than those who rely upon their plants being able to secure sufficient nitrogen for themselves either directly from the soil, or indirectly through the action of the micro-organisms in the nodules on their roots. It is quite true that Leguminosae have this power, but only under certain conditions, one of which is warmth, and a most important condition it is, because the organisms do not increase to any beneficial extent with a low temperature of soil. Some thirty years ago, when a youngster, I was much impressed with the enormous number of nodules on the roots of a grand lot of late mid-season Peas I was pulling up after the crop was finished, and as I had manured them exclusively with phosphatic and potassic manures, I was fairly puzzled about the matter. Since then scientific research has explained the phenomenon. By careful observation during several seasons your readers will find, as many of us have already found, that for Peas required to be picked green before the end of June it will pay well to supply nitrogenous manure. A crop in June requires energetic growth in April and May, long before the soil is warm enough to enable the micro-organisms to help the plants and their gardener to a satisfactory extent. A large grower for market often assured me he found it profitable to apply nitrogenous manures to Broad Beans required for early picking. As a result of practical experience, we find the early crops have to complete their work before the nodules have begun to do their part. *Practice with Science.*

GARDENERS IN AMERICA.—Having spent a month last autumn visiting the nurseries and private gardens in and about New York, I can verify all Mr. Harding has said on this matter. I found a good man can more than double his home rate of wage. I am not referring to head gardeners who hold high positions, but to young men who have learned their business in a good garden or nursery. They can always get wages that will enable them to save more than they would earn at home. Young gardeners and nursery men from England also appreciate being welcomed in classes of society that they could not join at home. *W. Troy, Cronborough, Sussex.*

LAW NOTES.

BUYING A CHEAP LOT OF SHRUBS.

IN the City of London Court, on Friday, before Judge Lumley Smith, K.C., an action of some interest to gardeners was brought by Lionel E. Townroe, solicitor, 11, Queen Victoria Street, against a firm of auctioneers, to recover the sum of £5 for specific performance of a contract for the sale and delivery of shrubs, and in the alternative as damages for breach of contract.

The plaintiff said that on October 25 last he went to the City Auction-rooms, which the

defendants carried on, and bought an assortment of shrubs and plants. It was a clearance sale which the defendants were holding at the time, and one of the lots, which he purchased for 1s. 6d., consisted of a bundle of Azaleas and Roses, &c. After he had purchased the lot he left defendants' premises, having checked the goods. He then paid for all his purchases, and he asked the defendants' representative about delivering the things. The man assured him that they always undertook the responsibility of packing and the delivery of the goods to the carmen themselves, and he demanded one shilling for doing that. The next day the parcel was delivered to him by Messrs. Piekford & Co., when he found the lot in question missing. It consisted of twenty-two shrubs in all. It was an extraordinarily cheap lot at 1s. 6d., but they were worth £1, and therefore he now asked the defendants to be held responsible for that sum. On a previous occasion when he purchased shrubs at defendants' auction-rooms there was also short delivery.

A gardener named Harrington, whom the plaintiff employed one day a week to attend to his garden, said the parcel consisted of twelve Azaleas, eight Gueldres Roses, and some Lilacs. The twelve Azaleas alone were worth £1, and sometimes they would fetch 3s. 6d. each. It was not a fact that Azaleas could be bought at 4d. each at any time.

The defendants' case was that the whole of the goods that the plaintiff had bought were sent to him.

The auctioneer who sold the goods said that before the sale commenced he explained to the public present that the sale was being held to clear out the rubbish in the rooms. They had held a good many sales, and of course all sorts of plants, dead and alive, were left at the end. There was no catalogue on the day of the clearance sale, and he explained to the people that they must make their purchases on their own responsibility, as he had nothing to do with the goods after the sale. The majority of the buyers paid cash for their goods, and took them away there and then. There were plenty of buyers present, and he well remembered the eighteenpenny lot being knocked down to the plaintiff. They were half dead, having been in their rooms for a considerable period. He could not say whether there were twenty-four or twelve shrubs in the lot. Everything that the plaintiff had bought was put on one side, and the plaintiff asked his porter to pack them together, and this was done. The packing was done under the plaintiff's personal direction, but the next day he came with a complaint. It was ridiculous to suggest that the plants were worth more than 1s. 6d., the amount they fetched, and further, they strongly objected to pay the plaintiff £1. He would be pleased to supply the plaintiff with a dozen of the best Azaleas for 4s. There were quite forty people present on the day of the sale, so it was not likely shrubs worth £1 would be allowed to go for 1s. 6d.

The plaintiff assured the Court that the plants were in a perfect condition, and not as stated by the last witness. He admitted that he had obtained a great bargain.

Lincoln, the defendants' packer, spoke to having put the plants together at plaintiff's request. Everything that he bought was put into the basket. It was not true that on the next day when the plaintiff complained he (witness) said he was not certain whether he included all the things or not in the parcel.

The plaintiff said he paid 12s. for all the plants he bought on that particular day.

Judge Lumley Smith: And you want £1 for not having delivery of an eighteenpenny lot?

The plaintiff: They assured me that they undertook the responsibility of packing, and they demanded 1s., for which they gave me a receipt. When the basket came it did not look as if the shrubs had been stolen in transit. There were eighty different plants, which were packed separately inside the basket.

Judge Lumley Smith said he could not understand why the trade should let the plaintiff get for 1s. 6d. what was worth £1.

The plaintiff said he would have to pay £1 if he wanted to get similar shrubs at a local nursery.

Judge Lumley Smith said he was a little surprised at the plaintiff making a claim for the specific performance of a contract to deliver the shrubs. The plaintiff could not possibly have delivered to him shrubs which had been lost.

The defendants' solicitor urged that under the conditions of sale the defendants were not responsible for anything.

Judge Lumley Smith said they did not apply unless they were agreed to by the purchaser as well as the seller, and they were not. The defendants had been paid 1s. for the packing of the goods, and he was quite satisfied that the defendants' man had left out the shrubs in question. There would be judgment for the plaintiff for 10s. and costs.

A SINGULAR POINT.

A remarkably interesting case occupied the attention of His Honour Judge Coventry, sitting at Preston County Court, the plaintiff being Robert Jones, a property owner, living at Ashton-on-Ribble, near Preston, and the defendant John Taylor, who has been one of his tenants.

From the evidence, it appeared that for a score of years defendant was a tenant of the plaintiff, but received notice to quit, which notice expired on November 30 last. In front of the house was a small garden, planted by defendant, as was admitted, with Laburnum-trees, Auriculas, Pyrethrums, Roses, Raspberry-canes, Lilies, Sage plants, Phloxes, Violas, Campanulas, Crocuses, and plants of various descriptions.

On November 29 Mr. Jones saw Mr. Taylor digging up the Laburnum-trees and removing the flowers. He remonstrated with him, but without effect, defendant contending that as a market-gardener he had a perfect right to take the plants away. Plaintiff, however, instituted an action for the value of the plants, and now claimed £1 5s. 6d.

Mr. Smith, on behalf of the plaintiff, cited the Market Gardeners' Compensation Act, 1895, which defines a market-garden as "a holding or that part of a holding which is cultivated wholly or mainly for the purposes of trade or business of a market-gardener," urging that the small plot of land in question was simply used for ornamentation purposes, and could not be regarded in the light of a market-garden.

His Honour: It does not matter how small the plot of land is, but rather how the occupier uses it?

Mr. Smith: A nurseryman at the end of his term of tenancy may remove trees planted for the purpose of his trade, but a private person may not even remove a flower.

In giving his decision, the learned Judge said the whole question was whether the plants and flowers enumerated would apply wholly or only in part to a man carrying on the business of a nursery-gardener. He should quite think defendant, as he had said, did plant these things, and occasionally sold some, but at the same time others would not possibly come within the scope in question, and there would be a verdict for plaintiff for 10s.

Obituary.

EDWARD JOHN BEALE.—It is with deep regret we record the death of this gentleman, which took place very suddenly on Wednesday, January 8, from heart disease, in his sixty-sixth year. Mr. Beale was the senior partner in the seed firm of James Carter & Co., of High Holborn, London. He entered the employment of the founder of the firm more than half a century ago, and it was largely due to his business capacity and abilities that the firm has reached its present dimensions. He had for many years held a leading position in the seed trade, and the Editor of this Journal remembers

State for India for the promptitude and foresight shown in connection therewith. The full value of this transaction amounted to £16,000.

His efforts some years ago to prove the feasibility of growing Tobacco in this country, and the practical experiments he carried out under the auspices of the Government, will be recollected by many. The results were embodied in a paper read by Mr. Beale before the Society of Arts, and a book was published under the title of *English Tobacco Growing*, which was dedicated by command of her late Majesty Queen Victoria.

THE LATE EDWARD JOHN BEALE.

becoming intimately associated with him during the investigations which led to the passing of the Seed Adulteration Act, in connection with which his experience was found of great value.

Some very large transactions passed through his hands during recent years, a few of which, in view of their importance, it is worth while recording. The request for 1000 tons of seed Potatoes for the Irish famine; an order for 10,000 bushels of English seed Barley by the Canadian Government, for replenishing the stocks of that country. His firm was also entrusted by the Government of India to furnish 200 tons of Carrot seeds, for use in alleviating the famine, and received the thanks of her late Majesty's Secretary of

He was a Justice of the Peace for Middlesex, a Fellow of the Linnean Society, and one of the sixty recipients of the Victoria Medal of Honour for eminence in horticulture. His firm have been annual subscribers to the Gardeners' Benevolent Institution since its formation in 1837. He was also the first annual subscriber to the Royal Gardeners' Orphan Fund, and for many years served on the committees of the Royal Horticultural Society. He was a candidate for Parliamentary honours on two occasions, but beyond lessening a large majority, was unsuccessful.

Mr. Beale had been ailing in health for some few years, during which time he has been much assisted by his sons, and the business will be conducted by them as usual.

SOCIETIES.

ROYAL HORTICULTURAL.

JANUARY 11.—The first meeting of the Committees of this Society since the turn of the year, and following an interval of four weeks, was held on Tuesday last, in the Drill Hall, Buckingham Gate, Westminster. There was a good attendance of members upon each Committee, and a satisfactory display of exhibits, especially bearing in mind the fact that the weather had turned very cold, and in some gardens as many as 12° of frost was registered on Tuesday morning.

Among the Orchids were many interesting plants and valuable novelties, and the ORCHID COMMITTEE recommended as many as twelve awards, including two Botanical Certificates, six First-class Certificates, and two Awards of Merit.

The FLORAL COMMITTEE recommended four Awards of Merit in respect to *Exacum Forbesii*, *Asparagus japonicus* (?), *Amaryllis Impératrice de Brésil*, and *Iris Tauri*. One of the most remarkable exhibits before this Committee was a group of *Begonia socotrana* from Mr. LEOPOLD DE ROTHSCHILD'S garden.

The FRUIT AND VEGETABLE COMMITTEE recommended a First-class Certificate to that excellent Pear Winter Nelis, but no award to a novelty. A collection of late Pears from Messrs. JAS. VEITCH & SONS, Ltd., was interesting.

In the afternoon seventy-one new Fellows were elected to the privileges of the Society.

Floral Committee.

Present: W. Marshall, Esq. (Chairman); and Messrs. Chas. T. Drury, H. B. May, James Walker, R. Dean, G. Reuthe, John Jennings, C. E. Pearson, Jas. Hudson, R. C. Notcutt, W. Howe, W. Bain, Chas. Dixon, H. J. Cutbush, Chas. Jeffries, C. J. Salter, Chas. E. Shea, H. J. Jones, W. P. Thomson, E. H. Jenkins, C. Blick, Geo. Paul, Ed. Mawley, F. Page Roberts, and H. Turner.

Cyclamens were in grand condition from Messrs. H. Low & Co., Bush Hill Park Nurseries, Enfield. There were variations of colour from pure white to deepest purplish-crimson. The plants were well flowered, and the blooms of large size and good form; one variety with salmony carmine flowers was very distinct. The "papillon" section was well represented by numerous varieties (Silver Banksian Medal).

A magnificent group of plants of *Begonia socotrana* from LEOPOLD DE ROTHSCHILD, Esq., Ascott, Leighton Buzzard (gr., Mr. J. Jennings), served to illustrate what a grand plant this is when it is afforded the best cultivation. There were 140 plants in 5-inch and 6-inch pots; the foliage was good, and the richly-pink flowers excellent. The blooms were about a foot or more high, and the stems being stiff, they are exceedingly useful for cutting purposes; whilst the plants themselves are handsome specimens for putting into vases. Mr. Jennings divides the plants in May and cultivates them in a warm greenhouse kept at 55° or 60°. They commence to bloom early in December, and continue until February. They gradually die down after that time, and during March and April are resting (Silver-gilt Flora Medal).

Messrs. JAS. VEITCH & SONS, Royal Exotic Nurseries, King's Road, Chelsea, exhibited small groups of several very interesting plants. In the first place there was *Coleus thyrsoides*, a blue flowering species, which has been figured in these pages and commented upon on many occasions, but which is not yet cultivated in very many private gardens. Messrs. VEITCH, who obtained the plant through the Royal Gardens, Kew, exhibited it in very good condition on Tuesday. The specimens were in 5-inch pots, were about 2½ feet high, and most of them bore four inflorescences, each 5 to 7 inches long. The blue colour of the blossoms was very well developed, and the foliage was good, but it soon showed slight flagging in the cold atmosphere. As much depends upon the time when cuttings of the plants are taken, it may be of service to add that in this case the cuttings were inserted on July 16 last. The species requires the temperature of a warm greenhouse. Also *Moschosma riparium*, from British Central Africa, a plant referred to on p. 10, as flowering at the present time in the greenhouse, Royal Gardens, Kew. The leaves are soft, hirsute on both surfaces, with margins notched regularly; the flowers are very small, produced upon axillary racemes, and are faintly tinted with purple colour. Messrs. VEITCH & SONS had also a nice plant of *Hamamelis arborea*, and branches of *H. japonica* *Zuccariniana*, and *Cotoneaster pumila* (Silver Flora Medal).

Messrs. H. CANNELL & SONS, Swanley, Kent, also showed a group of plants of *Coleus thyrsoideus*, already mentioned; and in this case, too, the plants were well grown and freely flowered. In addition to the *Coleus*, there were plants of *Euphorbia* (*Poinsettia*) *pulcherrima*, and some *Richardia africana* (Silver Flora Medal).

Messrs. H. CANNELL & SONS had also six very remarkable specimens of *Begonia Gloire de Lorraine*, in 8-inch pots, the plants being quite smothered with richly coloured flowers.

The sport from *Begonia Gloire de Lorraine*, known as Turnford Hall, was again shown grandly by the Exors. of the late T. Rochford, Turnford Hall, Broomhouse. The group was of considerable extent, and the individual specimens quite of the type seen on former occasions (Silver Flora Medal).

Mr. K. DROST, Kew Road Nurseries, Richmond, exhibited a great bouquet of forced Lilac, the stems of which were cut 3 ft. or more in length, and inserted closely together in an ornamental vase. The forced plants were English-grown (Silver Banksian Medal).

Messrs. W. CUTBUSH & SON, Ilighgate Nurseries, London, and Barnet, Herts, exhibited a group of plants containing varieties of *Erica*, such as *E. hyemalis*, *E. h. alba*, *E. melanthera*, *E. gracilis vernalis*, and *E. ovata*, with short, pinkish flowers. The *Otaheite Orange*, *Daphne indica*, were also shown.

Messrs. R. WALLACE & CO., Kilnfield Nurseries, Colchester, exhibited several early-flowering Irises in pots, including *I. histrio*, *I. alata*, *I. Bakeriana*, *I. Heldreichii*, and *I. Tauri*.

Zonal *Pelargonium* "Beauty," described as a "perpetual-flowering Geranium," was shown by Mr. GEO. H. TOWNSEND, nurseryman, Malvern Link. Quite a large group of plants was shown, and the flowers which were single, and of bright scarlet colour, would make the variety a very effective one for bedding.

Mr. THOS. S. WAKE, Hale Farm Nurseries, Feltham, had a few hardy plants in pots, including several hardy Cacti, as *Echinocactus Simproni*, *Opuntia robusta*, *O. polyacantha*, &c. *Gentiana acaulis*, *Primula Forbesii*, and other plants in flower.

Mr. W. J. GODFREY, Exmouth Nurseries, Devon, showed nearly 200 flowers of a white Japanese or decorative *Chrysanthemum*, named Winter Queen. The flowers are pure white, of large size, and the variety should become one of the best of its section.

Mr. J. W. SPRINGETT, Holly Nursery, Hammond Street, Cheshunt, Herts, exhibited blooms of a *Chrysanthemum* named Buff Queen.

A new sort of bellows, for applying sulphur and other fungicides and insecticides to plants, was shown by MM. DE LUZY FRÈRES, 41A, Harold Street, Camberwell, London, S.E. It is called the G.C.V.P. Bellows, and we believe that it was considered by most members of the Committee to be a most convenient appliance for the purpose.

Awards of Merit.

Amaryllis Imperatrice de Brésil.—The plant shown under this name by Sir TREVOR LAWRENCE, Bart., Burford, Dorset (gr., Mr. W. Bain), had a thick, bulbous stem, nearly 18 inches long, also long, pendent leaves. The inflorescence bore four flowers, each of them quite 5 inches in length, and pale lilac in colour, becoming nearly white towards the base of the interior, which is much spotted with minute, deep lilac-coloured spots. The flowers were large, and exceedingly handsome in form and colour. The plant is probably a variety of *Hippeastrum procurrens*, and a better one than we have previously seen.

Exacum Forbestii.—This is a new Socotra species, of bushy habit, a foot or less in height as shown, growing in 6-inch and 7-inch pots. Leaves triangular, 1½ inch across at the base; flowers about ½ inch across, in terminal racemes, purple in colour, with prominent yellow anthers. The plants were grown in a house having an intermediate temperature. From Messrs. JAS. VEITCH & SONS.

Iris Tauri.—An early-flowering species, illustrated and described in the *Gardeners' Chronicle*, March 23, 1901, p. 191. The flowers are about 3 in. high, of purplish-blue colour, except the lip, which is very prettily marked with white, and has an orange-yellow-coloured line along the centre. From Messrs. R. WALLACE & CO.

Asparagus japonicus (?).—This plant was shown by Messrs. H. & J. ELLIOTT, Courtbushes Nurseries, Hurstpierpoint, Sussex, and has densely green foliage, with flat, curved phyllocladum ½ in. long.

Orchid Committee.

Present: Henry Little, Esq. (in the Chair); and Messrs. Jas. O'Brien (Hon. Sec.), H. Ballantine, De B.

Crawshaw, E. Hill, F. A. Rehder, W. A. Bilney, H. T. Pitt, H. A. Tracy, G. F. Moore, T. W. Bond, J. W. Odell, W. H. Young, W. H. White, W. Boxall, J. W. Potter, F. Sander, and H. J. Chapman.

There was a very interesting display of Orchids, in which fine *Cypripediums*, *Odontoglossums*, and *Laelia anceps* predominated.

Baron Sir H. SCHRODER, The Dell, Egham (gr., Mr. H. Ballantine), contributed a group of cut spikes of remarkable varieties, some of them unique, and including the beautiful *Odontoglossum* × *Wilkeanum* *Princess Christian*, a pure white purple spotted form, more generally called *O. crispum* *Princess Christian*; *O. Wilkeanum* *Godefroyanum*, *O. crispum* *nobilis*, a very showily blotched variety; two very fine *O. × crispum* *Harryanum*, *O. prionopetalum*, *O. × excellens* *luteolum*, a wholly clear yellow form; *Cypripedium insigne* *Sanderi* and *Sanderianum*, and some good hybrids of them; *C. × Leeanum* *giganteum*, *princeps*, and others; *C. × Acteus* *Langleyense*, *C. × Deedmanianum*, *C. × Morganianum*, and other *Cypripediums*; and a good set of varieties of *Laelia anceps* (Silver Flora Medal).

R. I. MEASURES, Esq., Cambridge Lodge, Camberwell (gr., Mr. H. A. J. Chapman), showed a selection of grand hybrid *Cypripediums*, in which the noble *C. × Leander* "Cambridge Lodge variety" was the gem (see Awards). With it were *C. × Milo* *superbum* (*insigne* *Chantini* × *enanthum* *superbum*), a perfect flower very richly coloured; *C. × Hera* *punctatissimum*, richly spotted both on the petals and dorsal sepal; *C. × Charles* *Richman* *superbum*, of a uniform bright rose, with darker markings; and *C. × Wodea* (*superbiens* × *Leeanum*), a fine flower, of pale tints, and quite a novelty.

Messrs. JAS. VEITCH & SONS, Chelsea, staged a group in which were several varieties of the yellow *Laelia* × *Mrs. Gratrix*, all differing in tint; *L. × Icarus* (*cinnabarina* × *flava*), with yellow flowers having a purple front to the lip; *L. × Clio* (*cinnabarina* × *glaucia*), a small reddish-yellow flower, with purple lines on the side lobes of the lip; *Laelio-Cattleya* × *Orpheus*, a charming white hybrid of *L. glauca* × *L. C. × Remula* (*L. tenebrosa* × *C. Acklandiae*; *L. C. × Epicasta*; and the showy *Cypripedium* × *Leander* var. *rubrum*, with a very handsome purple and rose-tinted dorsal sepal.

DE B. CRAWSHAW, Esq., Rosefield, Sevenoaks (gr., Mr. Stables), showed cut examples of fine forms of *Laelia anceps*, of which *L. a. Chamberlainiana* and *L. a. Hilliana* *Rosefieldensis* secured awards; also *Odontoglossum* *Leeanum* *Crawshawianum*, more densely spotted than the type.

W. SHUTER, Esq., 22, Belsize Grove, Hampstead (gr., Mr. Armstrong), showed a group of well-flowered *Cypripedium* *insigne*, with which were several healthy plants of *Saccobolium giganteum* with two spikes each, and *Angreum eburneum* *virens* with two spikes; all in excellent condition, although grown within three miles of Charing Cross. A Silver Banksian Medal was awarded.

Messrs. B. S. WILLIAMS & SON, Holloway, secured a Silver Flora Medal for a good group in which the forms of *Lycaste Skinneri* were specially good. With them were several *Calanthe* × *Bella*, and *C. × Veitchii* *alba*; *Cypripedium* × *rubrum*, *C. × Harrisianum*, *Williams' variety*, *C. × Williamsii*, *C. × Dauthieri* *marmoratum* and *striatum*, with curiously striped flowers; *C. × Sallieri* *aureum*, *C. × nitens* *superbum*, in several good specimens; *C. insigne* *punctatum* *violaceum*, *C. × Leeanum* *superbum*, and *Laelia anceps* *Hilliana*.

F. W. WELLESLEY, Esq., Westfield, near Woking (gr., Mr. J. Gilbert), sent *Cypripedium* *insigne* *Westfieldense* and *C. i. Gilberti*, both with good distinctly blotched dorsal sepals.

M. FLORENT CLAES, 63, Rue des Champs, Brussels, showed *Odontoglossum* × *loochristense*, the finely blotched *O. × Adriane* *Romulus*, and flowers of *Odontoglossum crispum*; also *Oncidium cucullatum* *Claes' variety*, with nearly white, rose-spotted labellum.

H. F. SIMONDS, Esq., Beckenham (gr., Mr. G. E. Day), showed *Cypripedium* *insigne* "H. F. Simonds," in which the brown colouring in the upper sepal is continuous and not blotched.

Mr. ARTHUR SUTTON (gr., Mr. Alex. Wright), Bucklebury, Woolhampton, showed *Cypripedium* × *Mrs. A. W. Sutton* (*Chamberlainianum* × *niveum*), and *C. × Jessie* *Wright* (*Lathamianum* × *Chamberlainianum*).

Awards.

FIRST-CLASS CERTIFICATES.

Laelia anceps *Chamberlainiana*, from DE B. CRAWSHAW, Esq., Rosefield, Sevenoaks (gr., Mr. Stables).—This

grand variety of *Laelia anceps* originated in the gardens of the Right Hon. Joseph Chamberlain, Highbury, Birmingham, from whence it has on several occasions been noted in the *Gardeners' Chronicle*. It may be regarded as the highest form of the "grandiflora" class, the flower being the largest, best in shape, and with a very remarkable openly-displayed labellum. The sepals and petals are broad, soft rosy-lilac, the lip having purple lines at the base; the fronts of the side lobes and the very broad front-lobe being of a rich crimson purple.

Cypripedium × *Leander* "Cambridge Lodge variety" (*Leeanum* var. × *villosum*), from R. I. MEASURES, Esq., Cambridge Lodge, Flodden Road, Camberwell. A stately variety, of a very fine and variable set of hybrids, of which this is the best of the lighter forms in every respect. The flowers, which are very large, are of very fine substance. The dorsal sepal is white, with a small green base, the central area having some dark purple spotted lines. The petals and lip are massive, yellow, with a glossy red-brown tinge over the surface.

Cypripedium × *Miss Fanny Wilson* (*Sanderianum* × *Argus*), from DREWETT O. DREWETT, Esq., Riding-Mill-on-Tyne.—This elegant hybrid has all the weird beauty of *C. Sanderianum*, with much of the rich colouring of *C. Argus*. The upper sepal is pale green, changing upwards to white, and bearing a dozen or so of purple lines blotched in the lower part, and continuous in the upper. The petals are over 6 inches long, with arched shoulder-like upper part simulating *C. Sanderianum*, which it also continues in the hairy warts at the edge. The petals are drooping, greenish-white, spotted with purple, and tinged with rose at the extremities, which are singularly curved; lip reddish-rose; staminode large, reddish-yellow.

Cypripedium × *Mrs. W. Mostyn* (? *Calypso* × *Leeanum* var.), from F. W. WELLESLEY, Esq., Westfield, near Woking (gr., Mr. J. Gilbert). One of the finest hybrids which has appeared of late, large in size, fine in form, and grand in colour. The upper sepal is green at the base, and white beyond the basal part, bearing some large blackish-purple blotches, from which spreads upwards a rich purplish-rose tint extending to the white margin; the broad petals and lip are light yellow, the petals spotted and slightly veined with purple, and the lip faced with the same tint. The whole surface of the flower is glossy.

Odontoglossum *Wattianum* *Hardy's variety*, from Baron Sir H. SCHRODER, The Dell, Egham (gr., Mr. H. Ballantine).—This fine variety received an Award of Merit May 25, 1893. It is very different from the original form. Its features are those of *O. Harryanum* distinct traces of which appear in the slightly concave base of the lip. The plant bore a very fine inflorescence of pale yellow flowers, heavily marked with purplish chocolate. Lip white, with purple markings at the base.

Cattleya Trianae *alba* "Mrs. Edward Sondheim," from Messrs. HUGH LOW & CO., Bush Hill Park.—A very large, pure white flower, with very broad petals, and a more ample labellum than is usually seen in *C. T. alba*.

AWARDS OF MERIT.

Odontoglossum × *Davivierianum* *Burfordense*, from Sir TREVOR LAWRENCE, Bart. (gr., Mr. W. H. White).—A pretty natural hybrid of *O. nebulosum* and *O. maculatum*. Sepals greenish-white, spotted with chestnut-brown; petals white, with red-brown spots on the inner halves; lip white with brown spots.

Laelia anceps *Hilliana* *Rosefieldensis*, from DE B. CRAWSHAW, Esq., Sevenoaks.—A fine white flower with slight blush tint and a clear pink colour on the side lobes and front of the lip.

Laelio-Cattleya × *Orpheus* (*L. glauca* × *C. Trianae* *alba*) from Messrs. JAS. VEITCH & SONS.—A very satisfactory hybrid having the fine substance and fragrance of *Laelia glauca*, but in size and appearance of labellum more nearly approaching *C. T. alba*. Sepals white, slightly tinged pink; petals and lip white, the latter having a sulphur-yellow disc.

Cypripedium × *Stevensii* (*Calypso* *Oakwood* variety × *Alberti* *Hye*).—From W. THOMPSON, Esq., Walton Grange, Stone (gr., Mr. W. Stevens). A large flower, with distinct traces of the fine *C. Calypso* *Oakwood* variety. Upper sepal white, marked with purple on the lower part; petals and lip greenish-yellow, with a tinge of purple.

BOTANICAL CERTIFICATE.

Gomesa (*Rodriguezia*) *planifolia*.—From Sir TREVOR LAWRENCE, Bart. (gr., Mr. W. H. White). A good speci-

men of this pretty Orchid, also known as *Rodriguezia planifolia*, with a number of racemes of greenish-yellow, fragrant flowers, was sent.

Ornithidium Sophronitis.—From R. I. MEASURES, Esq. (gr., Mr. H. J. Chapman). A fine dwarf tuft of this pretty species, bearing scarlet flowers, was shown.

Fruit and Vegetable Committee.

Present: George Bunyard, Esq. (Chairman), and Messrs. H. Balderson, James H. Veitch, W. Bates, S. Mortimer, Alex. Dean, Geo. Kelf, W. Pope, W. Fyfe, H. Markham, M. Gleeson, Jos. Cheal, H. Somers Rivers, Jno. Basham, F. Q. Lane, J. Willard, Geo. Wythes, W. Poupart, C. Herrin, A. H. Pearson, E. Shaw Blaker, and W. Wilks (Rev.).

A Seedling Pear "Anchor" was shown by Captain CARSTAIRS' gardener, Mr. C. Ross. The fruits were small in size, and of soft texture.

The "Sutton" Rhubarb was shown from the Earl of ANCASTER's garden, Normanton Park, Stamford (gr., Mr. Butler). The stems were 2 feet or more long, of bright red colour.

There was again an object-lesson in the cultivation of the Vine in the neighbourhood of London. W. SHUTER, Esq., 22, Belsize Grove, S. Hampstead (gr., Mr. F. Armstrong), exhibited eighteen bunches of Black Alicante Grapes of very commendable quality and "finish." They were grown within three miles of Charing Cross, and the Vine from which they were cut was said to have been planted in 1876, and this season has ripened forty-five bunches of fruit. A cluster of Oranges came from the same garden (Silver Banksian Medal).

Messrs. JOHN LAING & SONS, Forest Hill Nurseries, London, S.E., exhibited a collection of about sixty varieties of Apples and a few Pears, including many of the best varieties now in season (Silver Knightian Medal).

Apple St. Basil was shown by Mr. JOHN BASHAM, Fairbank Nurseries, Bassaleg. The fruits were of moderate size, and richly coloured.

A collection of seven varieties of Pears from FRANK BIBBY, Esq., Hardwicke Grange Gardens, Shrewsbury, included Glout Moreau, Bergamotte Esperen, Beurré de Rance, Olivier de Serres, Easter Beurré, Passe Colmar, Née Plus Meuris (described as being eatable in that locality this year for the first time in twenty-eight years); Glout Moreau from open standards was described as never having been eatable in the locality previously (Silver Banksian Medal).

Messrs. JAS. VEITCH & SONS, Chelsea, showed dishes of twenty-two varieties of late dessert Pears. Amongst these were beautiful samples of Olivier des Serres, President Barabé, Beurré Dubuisson, Josephine de Malines, Chaumontel, Passe Crassane, Nouvelle Fulvie, Née Plus Meuris, Marie Benoist, Comte de Flandre, Le Lectier, Zoë, &c. (Silver Knightian Medal).

Awards.

Pear Winter Nellis.—This excellent late-ripening Pear, which, according to Hogg, was introduced to this country in 1818 by the Horticultural Society of London, and which was illustrated in the *Gardeners' Chronicle*, in 1845, was recommended a First-class Certificate on Tuesday last. It is so well known for its rich and pleasant flavour, there is no need to describe the fruit here. The variety is recognised as one of the best winter Pears, if not the very best, notwithstanding that, like many other good Pears, it is subjected to faint praise in the *Fruit Manual*, where too much importance is given to experience gained in one district only—Teddington: "As grown at Teddington, it is a good Pear, but of rather flat flavour. Not to be compared with Josephine de Malines." From Messrs. JAS. VEITCH & SONS.

EALING GARDENERS'.

JANUARY 6.—The lecture session of this Society was opened on the date named by an address from Mr. RICHARD DEAN, V.M.H., on "Floriculture and Florists during the past fifty years." In his opening remarks the lecturer dealt with florists and plant cultivators who in the fifties were local residents, such as Dr. Sankey, Mountjoy & Son, Robert Ronalds, Isaac Wilkinson; while the mention of Mrs. LAWRENCE, with some account of the fine specimens at that time grown at Ealing Park, proved very interesting.

The florists of the two past generations were also dealt with, many interesting reminiscences being detailed. The gradual improvements in some of the leading florists' flowers were traced, and due honours paid to those who were prominent raisers and cultivators. The lecturer named as epoch-making flowers, the Fancy Pansy, the Japanese Chrysanthemum, Clematis Jackmanni, Begonia boliviensis and its allies,

with the first new variety, B. Sedeni, Hippeastrums, and Dahlia Juarezii. The improvements made with the Gladiolus, Streptocarpus, and Sweet Pea were also mentioned, and reference made to those mainly instrumental in carrying on the work. Some leading exhibitors, with whom the lecturer had been associated, were passed in review, the interest of the audience being well sustained to the end. A cordial vote of thanks was passed to Mr. DEAN, and the same compliment was paid to Mr. J. HARRIS, the President of the Society, who occupied the Chair.

WARGRAVE GARDENERS'

JANUARY 8.—On Wednesday evening about sixty members and friends of the Wargrave and District Gardeners' Mutual Improvement Society sat down to a dinner at the "George and Dragon" Hotel, Wargrave. The Vicar of Wargrave, a vice-president of the Society, presided. Besides the usual loyal toasts, he proposed that of "The Association" in a very humorous speech. His hits at the gardeners called forth frequent applause. Mr. H. Coleby, F.R.H.S., Hon. Sec., responded, and gave a short account of the Society since its formation four years ago. Opportunity was taken during the proceedings to present a beautiful silver ewer and fruit stand, loaded with choice fruits and flowers, to Mr. Coleby, as a mark of the members' appreciation of the services he had rendered the Association. Mr. Coleby heartily thanked the members for their kind gift. H. Coleby, Hon. Sec.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

ELEVEN new members were elected on Monday evening last, and one other nominated. The committee were compelled by rule to reject two candidates, they being just over forty-five years of age. Two new honorary members were elected. An old member that has been on the sick-fund for eleven months, and being still ill and in distress, was granted £2 from the benevolent fund. Two members were deputed to attend the meetings on January 14 and 15 respecting the Old Age Pension scheme. Three members were transferred from the lower to the higher scale of payments. Messrs. W. Gunner and T. H. Puzey were re-elected to audit the accounts of the past year. The treasurer has a balance in hand of £182 14s. 2d.

NATIONAL CHRYSANTHEMUM.

THE usual meeting of the executive committee took place at Carr's Restaurant, 265, Strand, on the 13th inst., Mr. Thos. Bevan in the Chair. A mass of correspondence was read, including offers of valuable special prizes from Messrs. E. Webb & Sons, Wordsley; Mr. G. H. Richards, Borough High Street, S.E.; and Mr. W. J. Godfrey, Exmouth, which were accepted.

The annual general meeting was announced for Monday, February 3, at Carr's, and it was resolved that in the event of the President, Sir A. Rolit, M.P., being unable to preside, that Mr. C. E. Shea, a Vice-President, be requested to do so. A decidedly satisfactory financial statement was read, showing an income of over £1,000, with a good balance over expenditure; the reserve fund showed a balance of £110, while there was a considerable balance of assets over liabilities. The accounts were passed for audit subsequent to presentation to the annual general meeting. A draft report was also read and passed, and ordered to be printed and circulated among the members in the usual way. Mr. Geo. J. Ingram was nominated for the office of auditor in the place of Mr. W. Seward, who retires by rotation. The secretary brought up the revised schedules of prizes as passed by the revision sub-committee, which were approved; and judges for the various exhibitions in the present year were appointed. A place for the future meetings of the Society was also considered, the present meeting-place having to be rebuilt. Offers of accommodation have been received from the Holborn Restaurant, Anderton's Hotel, and Messrs. Bertram & Co. The matter was left in the hands of the Secretary to see Mr. Bertram, with a view to a meeting-place being appointed at the Royal Aquarium. Some new members were elected, and the Corbridge and District Chrysanthemum Society admitted to affiliation.

CROYDON AND DISTRICT HORTICULTURAL MUTUAL IMPROVEMENT.

THE annual meeting of this Society was held at the Sunflower, George Street, Croydon, on Tuesday night, Mr. W. J. Simpson (The Gardens, Falkland Park) in the chair.

The second annual report, which was adopted on the proposition of Mr. C. A. Blogg, seconded by Mr. W. Turney, stated that the membership at present on the

books was 120, being an increase on the previous year, which showed that the Society was gradually extending its influence. The funds of the Society were in a sound condition. There had been twenty-one meetings held during the year, at which lectures and papers had been given on various topics relating to horticulture, the whole of which had been of a high standard of excellence, and the discussions which followed were most interesting, instructive, and carried on in a most harmonious spirit. The average attendance at the meetings had been fifty. The report also expressed cordial thanks to lecturers and readers of papers and others who had given assistance to the Society. It also expressed regret at the death of Mr. G. Tyler, one of the members of the Society, and tendered their condolence to his relatives and friends. The accounts, which accompanied the report, showed a favourable balance of £3 6s. 9d.

The Chairman having read letters of apology for absence from the President (Mr. Frank Lloyd), who promised, however, to take the chair at the annual dinner on January 22, and others, the election of officers was proceeded with.

A discussion followed on some proposed alterations in the rules, and ultimately, on the proposition of Mr. W. Turney, it was agreed to appoint a committee to revise the rules of the Society and make suggestions to be considered at a special general meeting to be called for the purpose. Messrs. Blogg, Harris, Turney, Laing, and Woodgate were elected to act as the committee.

The valuable services of Mr. J. Gregory as secretary were cordially recognised, and votes of thanks were also accorded to the Chairman, the committee, and other officers of the Society.

FLORISTS' FLOWERS.

NEW VARIETIES OF CHRYSANTHEMUMS.

THE following additions to the list of novelties given in an issue of the *Gardeners' Chronicle* towards the end of 1901, may be of interest to growers and purchasers of young plants in the present year. The Princess was raised in Australia, and is a flower of full size, the florets moderate in width, drooping, and imparting much grace to the flower, which is of creamy-white colour, flushed with lilac. W. R. Church was sent out last season as a new Australian variety, which has come up to the high expectations of the florist, as being an improvement upon many existing varieties; it is an incurved Japanese, with stout florets in the style of Henry Weeks. A well-developed flower will measure 8 inches in diameter, and have a proportionate depth. In colour, the inside or surface of the floret is a ruby-red, and the reverse chestnut, the bloom tipped with silver when unfolding. It will be regarded as being one of the best of the novelties. The plant grows vigorously, and is of dwarf habit.

Madame Herreweghe is said to be a sport from Australia, but it is quite distinct from it in form of flower. It possesses drooping florets, even when expanding, which with age twist at the point; it is an acquisition, and it is white, flushed with rich cream or pale primrose in the centre. Donald McLeod has broad, drooping florets, which curl slightly at the tip, forming a flower about 8 inches in diameter, and fully 5 inches deep, of a yellow colour, lined and speckled with purplish-crimson—one of the best new varieties of this type.

Miss E. Foulton belongs to the incurved form of Japanese, and is a full size flower measuring $7\frac{1}{2}$ inches in diameter, and as much as $6\frac{1}{2}$ inches deep; with broad florets incurving, with a slight twist at the tip. The colour is pure white; and no matter how choice and limited the collection, this variety should be added to it, for I know of no better Japanese incurved variety. Mrs. T. W. Pickett is an Australian seedling, and an exact counterpart of Nellie Pickett in all except colour, which is pure yellow; this will become a great favourite. Henry Baines

bears a resemblance to Edwin Molyneux in form and in petal, excepting that the new-comer has slightly broader petals; it is a variety that is sure to find favour with exhibitors.

Henry Stowe is seen sometimes as a perfect incurving flower, and sometimes it is a semi-reflexed one. When freely grown it is a pretty flower, the colour white, edged and flushed with light purple; and a finely-developed flower will measure 8 inches by 6 inches. Ethel Fitzroy has slightly drooping florets which incurve at the tip. It is a flower of full size, and of a rich yellow-amber tint; a variety which will not fail to become popular. Mrs. J. Cleve has a free and fully reflexed floret, making flower of good depth; rose coloured surface, with a yellow reverse to the florets. Mrs. Frank G. Smith is a flower of deep orange, flushed with bronze, and a promising variety. Master C. Seymour belongs to the incurved Japanese section, reminding one most of Mrs. C. Wheeler; in colour it is deep red inside, with a chestnut-bronze reverse. Nellie Perkins would be best described as a glorified International. Snow-drift is a loosely incurving Japanese of a beautiful tint. Ella Hexheimer is a loosely incurving Japanese, with the lower half a rosy striped purple; the centre of the flower is a rich yellow, and the florets are hirsute at the tips. Major Plumbe is a true incurved Japanese of a rich orange-yellow tint. Mrs. R. Darby has long semi-drooping florets, and is a flower of much depth, of an amaranth tint.

Godfrey's Pride is one of a good type of incurved Japanese, broad, with the reverse of the florets yellow, shaded with chestnut, and the inside of a light crimson tint. Mrs. J. T. Thornycroft has narrow reflexing florets, which form a deep and compact bloom; in colour apricot-yellow, or red and yellow. Madame Paolo Radacelli is an incurved Japanese, with florets of middling size, and of a rosy-pink tint. Marquis V. Venosta: the florets are bifurcated at the tip; in colour it is rose, shaded with silvery-white.

Queen Alexandra is of the Lady Ridgeway section, and when that variety is fully expanded, the florets are broad, reflexed, and possess a charming colour, viz., golden-amber, suffused with terracotta. Godfrey's King is a true Japanese, with middle-sized, semi-drooping florets of a rich terracotta-red, flushed with amber. Kimberley in some instances is a true incurved Japanese, while in others it is quite reflexed, owing presumably to age; the florets are of middle size, and of a deep yellow colour. May Perkins is a rich yellow coloured incurved Japanese. Mrs. J. E. Collins is also a large incurving Japanese, silvery-peach colour. *E. Molyneux*.

(To be continued.)

BEGONIA GLOIRE DE LORRAINE: *Berks.* Allow the plants to flower themselves out, when young shoots will form naturally without cutting back, which may be used for cuttings if an increase be desired. From this period onwards the plants should be slightly rested in a warm greenhouse or pit (45° to 50°) for a period of two or three months, the stems being somewhat cut back, and at the end of the rest period partially shake out and repot.

BOOKS: *Auricula*, Rudolf Beer. One is, we believe, published at the Bazaar Office, 170, Strand, London, W.C.

CANKER IN MARECHAL NIEL ROSE: *S. S. J.* Appearances such as your specimens present have been attributed to injury from frost.

COLLECTION OF SIX KINDS OF VEGETABLES WITH WHICH TO COMPETE AT AN EXHIBITION HELD IN THE FIRST HALF OF JULY: *Exhibitor.* Marrowfat Peas; Potatos, Kidney or Round; Cauliflowers; French Beans; Cabbage, or Globe Artichokes; Carrots or Turnips.

DAFFODIL BULBS NOT FLOWERING: *Hook.* The flowers are not formed in the bulbs, so that you will not get bloom this season. Next year they may produce flowers in the ordinary way. It is not uncommon for bulbs to wait a year or two before they form flower.

DONATION: *A. E.* Has been paid to the treasurer of the Royal Gardeners' Orphan Fund.

EMPTY GREENHOUSES: *Bloemfontein.* Out of nothing, nothing is to be obtained. You must spend money in seeds, plants, or roots. Radishes are not worth the trouble; the market grower will undersell you with their produce from beds in the open. You had better make up sloping beds of soil, and grow Mustard and Cress. Many successional crops can be obtained before the heat in the houses becomes too great to grow these seedlings to a profit. Fill a house or two with Rhubarb-roots, disposing them close together on the floor, and packing light soil among them, covering the whole with litter to draw up the stalks to a considerable length and give a delicate colour. Raise Tomato-plants in sufficient numbers to fill two or all the houses. Not much will be gained by digging up the clay bottom; better put more soil into the house, or better still, grow the Tomato-plants in rough boxes, 1½ ft. wide and 1 ft. deep, filling these with loamy soil, and afford manure-water and manurial top-dressings when you have got a good set of fruit. No fumigation or vaporisation is good for unrooted cuttings. Make preparations for using the houses for forcing Roses, Dutch bulbs, Azaleas, Lilac, &c., another year.

FOUL CALUMNIES: *S. G. L.* We share your abhorrence of the foul and filthy imputations indulged in by some of our continental neighbours, but we do not think your proposal to boycott German seedsmen is practicable. In the first place, they are not personally responsible for the malicious inventions of some of their countrymen; their interests, indeed, lie in the maintenance of good relations; and next, you could not prevent our wholesale dealers from receiving, as they do now, a large proportion of their stock from the Continent.

GARDENERS IN THE UNITED STATES OF AMERICA: *A. E. W.* We would invite you to consider the matter in the light of the statements contained in a letter in our present issue. We should imagine that the chances of success as a gardener are as good in Canada as in the U.S.A., with the advantages of your continuing a British subject.

LICHEN ON LAWN: *H. V.* We should think the lawn requires draining. Next spring apply a dressing of nitrate of soda or other fertiliser to encourage the grass. Spud out the patches, and replace with fresh turf.

MAZE: *R. D.* *Thuja occidentalis*, the common Yew, and Whitethorn, form excellent hedges, The evergreens being the more suitable.

MYRSIPHYLLUM (MEDEOLA) ASPARAGOIDES: *T. S.* We were not previously aware that this plant was hardy so far north as Aberdeenshire. If such is actually the case, we have another handsome climber for warm outside walls. Usually gardeners afford the plant greenhouse treatment.

NAMES OF PLANTS: *Vanda*. *Oncidium Cebolleti*, often called *O. juncifolium*.—*J. W. E.* 1, *Epiphyllum Russellianum*; 2, *Begonia sub-peltata nigro-rubra*.—*A. F.*, *Tottenham*. The hybrid you send a flower of has been named *Cypripedium Kauffmannianum*.—*G. S.* 1, *Kalmia latifolia*; 2, *Andromeda japonica*;

3, *Andromeda floribunda*. The Violets are excellent.—*G. P.* *Eria vittata*.

PEARS DECAYING: *J. T.* The cracking was caused by a fungus, *Fusicladium dendriticum*, and decay followed. The decayed fruit was then attacked by a mould, *Monilia fructigena*.

POTATO DISEASED: *T. R.* The tubers are almost destroyed by *Peronospora infestans*—Potato-rot; and the "grubs" are those of *Julus*, or centipedes, creatures that feed on decaying vegetable matter. Turn out the clamp, remove all diseased tubers and burn them, making a clamp in a fresh place.

SCALE ON PALM: *C. B.* Evidently a scale insect, about which we will tell you more next week. Soft-soap and tobacco would form a good application.

SEAKALE: *J. K.* The roots are attacked by slime fungus, such as causes club in Cabbages. Destroy the plants by fire, and place new plants in fresh soil.

THE GAS TAR MIXTURE FOR KILLING MEALY-BUG ON VINES: *T. H.* It should be applied in a warm state with a stiff brush, after having thoroughly brushed the rougher parts of the stems, or rubbed off the outermost coat of rough bark. No metal instrument should be employed in doing this. There is no need to coat the buds with the mixture, as it is not about them that mealy-bug is found, but in the crevices and angles. To make as good a job of it as possible, the soil should be skimmed off with a spade to a depth of 2 inches, taken out of theinery, and buried in any open trenches on land in the course of being trenched. Then the walls should be scrubbed and washed, all nail-holes and open courses between the bricks filled in with mortar, the whole being washed with hot lime-wash, in which 2 lb. of flowers-of-sulphur per paifal have been mixed. The hot-water pipes should then come in for a thorough cleansing. This course of treatment must be continued for a year or two, and every bug seen touched with methylated spirits.

TREE PROTECTIVE COMPOSITION: *H. H.* A trustworthy one is Ahlbottn's, sold in 56 lb. casks by the maker, 21, St. Andrew Square, Edinburgh.

VITIS VOINIERIANA. Mr. Watson points out that this plant was mentioned in the *Gardeners' Chronicle*, August, 1897, p. 147, and in the Appendix II. of the *Kew Bulletin*, 1898. Large plants of it exist at Kew.

COMMUNICATIONS RECEIVED.—*N. E. Br.*—General C. B. L. S., next week if possible—*H. Weir*—*F. W. B.*—*M. C. C.*—*W. G. G.*—*D. R. GARDENING APPOINTMENTS.

MR. GEO. SMITH, until recently Gardener at Wroxton Abbey, Baubury, as Head Gardener to His Grace the Duke of WELLINGTON, Ewhurst Park, Basingstoke, Hampshire.

MR. E. SNEEGROVE, Gardener to General Lord A. G. RUSSELL, until recently at Ewhurst Park, has gone as Gardener to his Lordship, Uckfield House, Uckfield, Sussex.

MR. A. EDWARDS, for two years Gardener at Woodfield Gardens, Streatham, as Head Gardener to H. STEEL, Esq., Tipton Court, Sheffield.

MR. W. STEPHENS, late of Chorley Wood House Gardens, has been appointed Gardener to Lord CHESHAM, Latimers, Bucks, succeeding G. NEVILLE, deceased.

MR. WILLIAM DYER, as Head Gardener to H. LIVESEY, Esq., Trulls Hatch, Rotherfield, Sussex.

MR. F. W. RICH, for the last three years Gardener at Darwin Bank, Torquay, and previously at Welfield, Bulth Wells, Breconshire, as Head Gardener to Mrs. BAINBRIDGE, Eldfordleigh, Plympton, Devonshire.

MR. ALEXANDER DRYDEN, until lately Gardener at West Green Manor, Hants, as Gardener to Major AVERSTON, Evercrech House, Evercrech, Somersetshire.

MR. JOSEPH TAYLOR, for the last ten years Foreman in the gardens at Claverton Manor, Bath, as Head Gardener to E. H. SKRINE, Esq., Inwoods, Monkton Farleigh, Bradford-on-Avon.

MR. ALEXANDER MCLEAN, late of Dunleckney Manor, Bagenalstown, co. Carlow, as Gardener to M. H. FRANKS, Esq., Garretstown, Ballinspittle, co. Cork.

LOOKING BACKWARD.

I HAVE recently had occasion to turn up the pages of the *Transactions of the National Floricultural Society*, the forerunner of the Floral Committee of the Royal Horticultural Society. The formation of this Society grew out of the necessity for establishing an authoritative tribunal to deal with novelties in florist's flowers, which were at that time becoming very popular, and being rapidly increased. It was a time of considerable friction in floricultural circles. George Glenny, who began to write about florist's flowers in 1832, was a strong force in matters floricultural, but there was a considerable revolt on the part of florists against his leadership, and it was to give substance and organisation to this revolt that the formation of the National Floricultural Society was brought about. In the *Horticultural Journal*, published during the thirties, Glenny inserted violent articles against Joseph Paxton, and Thomas Hogg of Paddington, in particular; he was always in the thick of controversy, and when the National Floricultural Society was established, he attacked its leaders with great violence. The founders of the N. F. S. held that it was urgently necessary that new florists' flowers should be submitted to the opinion of competent judges; varieties had been sent out as first-class properties which when grown proved to be inferior, and this was generally owing to certificates being granted

by censors having but a limited knowledge of the varieties already in cultivation. In consequence, the National Floricultural Society was founded and supported by an influential combination of traders and amateurs, who wished to see a general Society formed, which, by the exercise of strictness and impartiality, should be a recognised authority enjoying public confidence, and competent to take cognisance of any novelties which might be submitted to it.

The Society was formed in March, 1851. Its President was Mr. Edmund Foster, of Clewer Manor, an influential country gentleman of means, who was also then engaged in the improvement of the show *Pelargonium*. There were six Vice-Presidents, viz., Dr. Lindley, the Rev. Chas. Fellowes, and Messrs. J. H. Brown, R. Marnock, C. B. Warner, and J. Wilmore, a prominent cultivator of Tulips at Old Ford, when it was a site of pleasant gardens. A committee of thirty-nine persons was instituted, and it included such names as E. Beck, E. S. Dodwell, J. Gaines, R. Glendinning, R. Headly, Andrew Henderson, J. Keynes, J. E. Lane, C. Lee, Dr. Maclean, W. Paul, T. Rivers, J. Salter, C. Turner, and J. Veitch. Mr. Arthur Henderson, of the Pineapple Place Nursery, was the Treasurer; and Mr. John Edwards, the Secretary. The latter occupied somewhat a unique position among London florists: he was in business in Clerkenwell as a catgut manufacturer, and resided at Wall Cottage, Holloway, where he grew Tulips, Auriculas, &c.

The whole force of Glenny's wrath was poured on the head of John Edwards. Edwards contributed papers to the *Gardeners' Chronicle* on "Florists' Flowers," and was a leading writer on the staff of *The Florist*, which Mr. C. Turner at that time had just commenced to edit. He was also the founder of the *National Garden Almanack*, the first edition of which appeared in 1853. Of all the leading florists who formed the first committee only the veteran William Paul survives. He was also one of the first thirty censors appointed to make awards to novelties, and of these he is the sole survivor. It may be stated that at the end of 1857 Mr. Edwards retired from the secretaryship, and the writer was appointed to that office, and held it until the end of 1859.

For the best part of its existence the meetings of the N.F.S. were held in the rooms of the Royal Horticultural Society, at 21, Regent Street; then they were moved for a time to St. Martin's Hall, Long Acre; but finally were again held at 21, Regent Street, until the period of dissolution of the Society at the end of 1859.

The operations of the Society were carried on in a methodical and complete manner; subjects submitted for Awards were staged by noon, and then from six to twelve specially-summoned censors set about examining the subjects and making the awards. The latter were three in number, viz., a First-class Certificate of Merit, awarded only to productions of a very superior character; a Certificate of Merit to all subjects possessing sufficient excellence; and a Label of Commendation which was affixed to all subjects of a promising character, but not deemed worthy of the higher Awards. In every case where an Award was made a schedule of properties was filled up. Here are the particulars of a very popular show *Pelargonium* named Magnet, raised and exhibited by Mr. G. W. Hoyle, of Reading: colour high scarlet-crimson, violet centre, large black blotch raying towards the margin on a scarlet-

crimson ground, but lighter on the edges, profuse, striking, and constant; it received a First-class Certificate. In the case of a *Cinoraria*, more particulars were adduced; in the case of one named Orpheus, the description runs: "form and truss, good; colour, dull lilac-purple; disc, light; habit, dwarf and compact; size, average." This was shown by Mr. W. P. Ayres, then a nurseryman at Blackheath. These schedules were retained by the Secretary for publication in the *Transactions of the Society*. It would be well if some such schedule could be filled in of the properties of all subjects receiving awards at the meetings of the Royal Horticultural Society. It might prove a desirable improvement upon the somewhat haphazard method now in operation at the Drill Hall.

In consequence of an announcement made by the Council of the Royal Botanic Society that it was their intention to form a body specially to deal with new florists' flowers, and also an announcement by the Council of the Royal Horticultural that it was their intention to form a Floral Committee on the same lines as their Fruit Committee, it was deemed inexpedient to continue the National Floricultural Society; consequently its dissolution was resolved upon, and took place on the occasion of the eighth annual meeting on March 3, 1859. Mr. Richard Stains, Harewood Square, was the treasurer of the Society at the time, and all the books and papers were committed to his care. Mr. Stains died many years ago, and probably the books, &c., have all been destroyed. Mr. Stains, who was the proprietor of the Yorkshire Stingo Brewery in the Marylebone Road, was a keen florist, and invariably acted as one of the censors of new florists' flowers at the exhibitions of the Royal Botanic Society with Mr. Thomas Moore, Mr. Anthony Parsons, and Mr. F. R. Kinghorn.

I have the whole of the *Transactions of the National Floricultural Society* bound up in two volumes, and they are very interesting reading, especially to anyone who has contemporary knowledge of the operations of the Society. It is well at the beginning of a new century to recall some of the horticultural doings of the past half of that which has just closed. They have an interest reaching beyond the past and present generations. The methods of our forefathers are always interesting to examine, and much may be learned from them by those who do not regard such doings in the past as altogether devoid of advantage and instruction. R. Dean.

[It may be worth recalling that the violent vituperations indulged in by Glenny were largely instrumental in causing the foundation of the *Gardeners' Chronicle*. Ed.]

CULTURAL MEMORANDUM.

EARLY PEAS, &c.

As the subject of Peas is now engaging attention, I should like to give my method of securing them; it entails but little more trouble to those who are in the habit of sowing dwarf varieties under a wall, and who have the command of glass. Let the seed be sown as usual, a few inches distant from the foot of a south wall, and cover the seed with leaf-mould, and lay sheets of glass slantingwise against the wall, pressing the lower edges slightly into the soil. A cord drawn tense along the front of the glass, and fixed to a nail at either end, will keep the whole secure against wind. Even earlier pickings may be had by sowing thinly, and afterwards fixing the haulm to the wall or to stakes. In

severe weather it is an easy matter to give protection, but so long as the plants are free of the glass they will stand 10° of frost after a bright day without injury. It will be necessary to remove the glass at intervals during bright weather in order to apply water, and to damp the plants overhead, in order to keep them free of insects; care should be taken to do this early enough in the day to allow of the foliage getting dry before night-fall. Peas grown under these conditions are dwarf and sturdy, and do not suffer any sort of check; this is one advantage gained over those reared indoors, and transplanted to the open air.

Many other plants, besides the early Peas, can be forwarded in this manner. Last year, we tried it on a row of Strawberries, growing along a south border. Boards, standing on edge, and lightly nailed to short posts, took the place of a wall; a narrow strip of wood was tacked on to the boards on the inside, near the top, to carry the glass. If a front board is used, it should be narrow enough to allow the sun to reach the plants. A sheet of glass can be drawn back here and there when necessary, in order to admit the air. As time goes on, the posts can be drawn slightly out of ground to give more air and head-room, and the front board replaced by inverted flower-pots to carry the glass. In this way we were able to pick ripe fruit at least fourteen days in advance of the row immediately in front, which doubtless also received some benefit from the shelter; the variety was Royal Sovereign, but I am not sure but what a less strong growing variety would have been earlier. In the later stages time was lost, owing to the foliage shading the flowers and fruit. *James Baxter, South Hants.*

STRAWBERRY FORCING.

For the earliest supply some gardeners introduce the first batch of plants into heat in the first week of November, and although some of the plants may fruit fairly well, there are, as a rule, a great number which fail to throw up the spikes satisfactorily, and some not at all. From the last week of December and onwards, batches of plants may be brought under glass at intervals according to requirements and accommodation with better results; and it may be taken as a fixed rule that 100 plants put into the forcing-house before the new year will not carry so much fruit as fifty plants after that date. For the first crop I still adhere to Vicomtesse Héricart du Thury, which, all points considered, appears to be the best early variety; and it is not liable to be attacked by mildew and red-spider, whilst it fruits abundantly, and the fruit is of good colour and passable for flavour.

To follow this are Royal Sovereign and Sir Joseph Paxton, President, and Sir Charles Napier. No Strawberry should be put into heat till the pots have been cleansed, and the soil stirred up and top-dressed with moderately dry loam. *H. Markham.*

A VISIT TO THE NORTH.—X.

(Continued from vol. xxx., p. 433.)

EDINBURGH BOTANIC GARDEN.

THE history of botanic gardens in Edinburgh commences in the year 1670, when "a portion of the Royal Garden around Holyrood House was occupied by two eminent Edinburgh physicians, Andrew Balfour and Robert Sibbald, for the making of a physic garden, and James Sutherland was appointed to the 'care of the garden.'"

Accepting this as the foundation of the Royal Botanic Garden of Edinburgh, it is the

oldest but one in the United Kingdom, the exception being that at Oxford, founded in 1632. The same physicians acquired in 1676 from the Town Council a lease of the garden of Trinity Hospital and adjacent ground for the purpose of a physic garden, and they appointed the same James Sutherland to be "intendant" of this garden. About 1702, says an official publication, another botanic garden for the College was established. Thus in the early years of the eighteenth century, there were in Edinburgh no fewer than three distinct botanic or physic gardens.

James Sutherland gave instruction in botany in the Royal Gardens from the very first, and being appointed Botanist to the King in Scotland, established "a profession of botany" there. Later he was appointed by the Town Council Professor in the town's college, now the University of Edinburgh. In 1706, Sutherland resigned his care of the Town's and College Gardens, and his Professorship in the University, but remaining King's Botanist, retained the care of the Royal Garden. When Charles Preston was appointed his successor by the Town Council, there were thus established rival gardens and rival Professors of Botany. Sutherland died in 1712, and was succeeded in the offices of King's Botanist, Keeper of the Royal Garden, and Regius Professor of Botany by William Arthur, Charles Alston succeeding to the same offices in 1716.

In 1724 the College Garden was turned to other uses, and five years later Charles Alston was appointed to the charge of the Town's Garden, and as Professor of Botany in the University. Through Alston, therefore, the Royal Garden and the Town's Garden were again under one keeper, who combined the Professorships of Botany also. They have happily continued so ever since.

In 1763 John Hope, who had succeeded Alston in 1761, proposed to combine the two gardens by transferring both to a site, 5 acres in extent, on the north side of Leith Walk, below that now occupied by Haddington Place.

In 1820, when Robert Graham was Regius Keeper, steps were taken to again remove the garden to the Inverleith property it now occupies, and 14 acres of the field or park of Inverleith were purchased by the Exchequer, the lease of the Leith Walk ground being sold. All the plants had been transferred to the new garden by 1823. In 1858, when John Hutton Balfour was Regius Keeper, a further addition was made by purchase from the proprietor of Inverleith of a narrow belt of two-and-a-half acres on the west side; and in 1865 the Caledonian Horticultural Society having resigned to the Crown its lease of the ten acres of the adjoining ground, which it had occupied since 1824 as an experimental garden, this ground was made part of the Botanic Garden. In 1876 the Town Council purchased from the Fettes Trustees twenty-seven and three-quarter acres of the Inverleith property on the west side of the garden, and transferred it to the Crown for the purpose of making an arboretum in connection with the garden, the Crown at the same time purchasing Inverleith House and two-and-a-half acres of additional ground. The present area—some fifty-seven acres—was thus completed, and as the garden is now surrounded by public roads, no further extension on the site is possible.

John Hugh Balfour died in 1879, and was succeeded by Alexander Dickson, who died in 1887. The present Regius Keeper is Professor Isaac Bayley Balfour, M.D., M.A., F.R.S., who has increased the reputation of the garden as a teaching establishment, and at the same

time has maintained it in such a manner that the people of Edinburgh find there many of the features of a pleasure garden. So far, indeed, as the visitor may see, the management of the Edinburgh Botanic Garden is similar to that practised at the larger and more important one at Kew, where the difficult task of making a garden, which exists primarily for scientific purposes, an enjoyable *rendezvous* for the multitude is carried out with gratifying success.

I approached the garden in Edinburgh from the entrance in Inverleith Row, very near to which are several interesting trees with labels attached, describing by whom and when they were planted. *Sequoia gigantea* was planted by Professor Christison in 1861, and a Cedar near to the Students' Garden is a memorial of the King's visit to the Gardens when Prince of Wales. A label upon *Quercus conferta* describes its planter as having been Dr. Maxwell T. Masters, F.R.S., and the date of the ceremony July 13, 1875. The tree is now about 35 ft. high, and probably 25 ft. through the branches. It is a prettier, better-shaped specimen than another of the same species planted half-a-dozen years later by the late Duke of Edinburgh. Dr. Masters contributed a paper on the botanical history of this tree to the *Transactions of the Botanical Society of Edinburgh*, on January 13, 1876. A tree of *Quercus palustris*, with fine plants of *Mistletoe* growing upon it, is worthy of remark, as the species is not often seen to be a host to this pretty parasite.

The herbaceous or students' garden in which the plants are grouped together in their natural orders, as at Kew, is just under the terrace on which the newer range of glass-houses stands. At the time of my visit, the beds were scrupulously neat, and being cut out of a closely mown, rich and verdant lawn, they appeared much smarter than this part of a botanic garden is usually maintained. On the terrace already mentioned the groups of heather were in bloom, and made a better show than we can get in the south from similar plants. Conspicuous amongst these were the following, *E. cinerea* var. *atro-purpurea*, *E. Tetralix*, the cross-leaved Heath in a variety named *Lawsoniana*; *E. ciliaris*, a showy species with the flowers produced at the end of the shoots; and *Daboecia polifolia* var. *bicolor*, some of the flowers of which were purple, and others white. The numerous varieties of the common Ling (*Calluna vulgaris*) included *Alporti*, very free, about 2 feet high; *argentea*, *alba*, *tomentosa alba*, 2½ feet high; *Drummondii*, &c. A bed filled with *Pieris japonica* variegata among those containing Heaths had a pleasing effect. The collection of *Rhododendrons* is appropriately near to the plants already mentioned.

The rock-garden was formed, I believe, by the late Jas. McNab, and is upon the highest portion of the grounds. At the same time the plants are sheltered, for most of the ground falls to the north, and upon this side there are protective trees. This garden is one of the most interesting features, and affords greater variety of aspect and conditions for the numerous species of plants than do most rockeries. I took notes of a number of interesting plants it contained, but it will suffice to mention a very few of the most prominent. *Rose Wichuriana* covered a bank densely, and was very fine; *R. alpina* var. *pyrenaica* was extremely pretty, because of the numerous elongated fruits it bore; the shrubby *Veronicas* succeed very well, and I was rather surprised to notice *Choisya ternata* growing finely in an exposed position so far north. The species of *Ericaceae* generally succeed in the neighbourhood of Edinburgh,

and the Order is richly represented in the rockery. I noticed *Celmisia spectabilis*, *Lithospermum prostratum* in considerable quantity and excellent condition; *Rhododendron ferrugineum*, *R. latifolia*, *R. amoena*, a fine collection of *Saxifragaceae*, great masses of *Alyssum*, and the interesting *Acaena microphylla* (*Rosaceae*), remarkable for its small, green flowers, inconspicuous in themselves, but furnished with long, showy crimson spines. It is a very dwarf (1 to 2 inches high) New Zealand evergreen of cushion-like growth, and peculiarly suitable for the rockery. There is a water garden, and large arboretum; but there was insufficient time to make so close an inspection of the latter as I could have wished.

THE GLASSHOUSES.

A very convenient and admirable range of houses was built a few years ago, and in these there is a large and useful collection of plants. The *Nepenthes*-house was particularly attractive. It is a span-roofed structure, and Mr. R. L. Harrow, who has charge of the indoor department, has planted-out some of the species. These have made very strong growths, which are tied near to the rafters, and bore numerous "pitchers." The house was very well filled with plants in baskets also, including hybrids such as *N. Chelsoni*, *Mastersoniana*, *Balfourii*, *Dicksoniana*, *N. × mixta*, &c. *N. Burkei* excellens and *N. cylindrica* had succeeded splendidly when planted out, but the work had been done only a year or so, and it will be interesting to hear if they continue to succeed. A plant of the handsome *Anthurium Veitchii* was remarkable, and a climbing plant, *Pergularia odoratissima*, with strongly-perfumed, greenish-yellow flowers.

A new *Hibiscus* (*H. Scottii*, figured in the January number of the *Botanical Magazine*, t. 7816) was in bloom in a house containing *Rhododendrons*, &c. It is a *Socotran* plant, with rich yellow flowers, bearing dark-coloured markings at the base; but the flowers were almost closed at the time—the plant was 8 feet high. In the propagating-house the rare *Adiantum Balfourii* was shown to me; it is a pinnate fern, the fronds 9 inches long, and the pinnae broad, with fringed margins—a very pretty plant. In the porch, *Solanum Rantonnetii* was growing very freely; *Passiflora edulis* was well fruited; *Solanum Wendlandi*, that grand species, bore excellent trusses of flowers; *Tecoma Smithii*, was in flower and fruit; *Mackaya Bella* in flower, &c.

In the Orchid-houses I saw some very fine plants of *Cattleya citrina*, and the pseudobulbs become larger each year, an experience not common with this plant. There is a large greenhouse, and in this I saw a specimen of *Restio subverticillatus*, which I should judge to be the largest in the country, being about 12 feet through.

The Palm-house contained some fine specimens *Macrozamia* planted out, *Dioon spinulosum*, *Euccephalartos horridus*, the rare *E. Ghellinckii*, and others; *Sabal umbraculifera*, an old plant, brought from the Botanic Garden at Leith Walk, &c. The old Palm-house, now used as a "temperate" house, is about 70 feet high. A plant of *Scaevola elegans* reaches within 20 feet of the top. There are capital plants of *Livistona chinensis*, *L. australis*, Tree Ferns, tender *Conifers*, *Cocos flexuosa* 30 feet high, and *Bacularia (Areca) monostachya*, 10 feet high. *Fagus betuloides*, with its tiny leaves, is an interesting evergreen species of the Beech.

The course of lectures delivered at the garden is spread over three years, and the members of the staff have a reading-room and

library provided for them. Occasionally there are lectures by Prof. Balfour that are open to the public, any of whom, if engaged in the study of botany, may obtain the use of the laboratories. The students at the University receive their instruction in botany at the Botanic Garden, which is open to the public as early as 8 o'clock each morning except Sunday, and then at 11 A.M.

There are but three Botanic Gardens in the Kingdom maintained by the State. Edinburgh is one of them, and the others are those at Kew and Glasnevin (Ireland). They are all perfectly worthy of this maintenance, for each is a centre of botanical and horticultural teaching and activity. P.

(To be concluded.)

NOVELTIES OF 1901.

(Concluded from p. 22.)

REFERENCE to the appended list of new or rare plants illustrated in the *Gardeners' Chronicle* during the past year, will show that an unusual number of interesting plants have been produced or specially called attention to during the past year. Reference to notes of the Royal Horticultural Society's shows proves that the eminent firms of Messrs. Sutton & Son, Veitch, Cannell, Webb, Carter, &c., have been successful in improving numerous florists' flowers, in shape and beauty of the flowers, as in *Gloxinias*, *Begonias*, *Chrysanthemums*, *Pelargoniums*, *Cyclamens*, *Primulas*, and others.

Messrs. Jas. Veitch & Sons, Chelsea, have for many years past turned their attention to the introduction of hardy trees and shrubs, have had further successes in that direction, and the assurance of many more in the near future. Their fine strain of greenhouse *Rhododendrons* have been added to the winter-flowering *Begonias*; *B. Ideala* and *B. Agatha* have been certificated. The *Nepenthes*, for which the firm is famed, still improve; and the extraordinary *N. ventricosa* was certificated. Among flowering shrubs, *Berberis congestiflora hakeoides* and *Cyrtilla racemiflora* have both been illustrated in our pages; the Veitch strain of *Streptocarpus* has increased in the size of the flowers, and some new colours have been obtained; the *Cacti*, a fine collection of which was staged at the Temple Show, produced a new set; and the great Veitchian specialty, the *Hippeastrums*, have been as successful as ever in the past year, three of the best certificated being *Averuncius*, *Marathon*, and *Rialto*.

Captain Holford, Westonbirt, whose gardener is Mr. A. Chapman, holds the amateurs' record for fine *Hippeastrums*, or *Amaryllis* as they are more commonly called. The Westonbirt collection of *Amaryllis* is the oldest in the country. Hard on fifty years ago, the late Robert Stayner Holford got together a fine collection of them, and the raising of new varieties was carefully pursued. *A. Aekermani pulcherrima*, that fine dark blood-red old species, now probably extinct, was much used as a breeder, and from that day to this the Westonbirt collection has been well first for dark red and crimson self flowers. Those who saw the fine group for which Captain Holford was awarded a Silver-gilt Flora Medal by the Royal Horticultural Society, on March 26 last year, will readily recall their excellence. The best of his certificated varieties were *Lois*, *Lord Borington*, and *Clovelly*, all grand flowers.

Leopold de Rothschild, Esq. (gr., Mr. Hudson), who has been so successful with *Nymphaeas*, has continued the culture of water

plants by growing equally well a fine lot of *Nelumbiums*, of which the double white *N. album plenum*; the double rose *N. roseum plenum*; and the new Japanese, *N. Kinshirin*, were certificated. The typical *N. speciosum* and its varieties, and the yellow *N. luteum*, also flowered at Gunnersbury—the latter making quite a feature in the new Japanese garden.

Messrs. F. Sander & Co., of St. Albans and Bruges, seem to cultivate decorative plants more extensively each year. Palms form a very large feature, and of the favourite *Kentias* at the Bruges exhibition they showed forty-seven distinct species and varieties, the varieties of course predominating, and including golden-leaved, variegated, and dwarf forms. The trouble is, that each of these distinct forms cannot be increased by propagation in a reasonable time.

Camellias and *Azaleas* at the Bruges establishment have produced some fine new forms, and their culture by a firm conversant with the requirements of British gardens has caused the *Camellias* in bud especially, it is said, to again find favour in this country. The new section of decorative *Caladiums* between *C. albanense*, *C. venosum*, and the best of the garden forms, resulted in a new set: *C. W. Lauche*; *C. l'ami Schwartz*; *C. Countess of Warwick*; *C. Mrs. Oliver Ames*; *C. Lord Annesley*; *C. Mrs. Miller Mundy*; *C. Mrs. H. L. Bischoffshcim*; and *C. A. Siebert*.

Among new Palms distinct in appearance though not easy to determine botanically, Messrs. Sander have *Livistona Woodfordi*, *Arenga Engleri*, and *Linospadix Leopoldi*; and of other plants *Euccephalartos Barteri*, *Carludovica Leopoldi*, *Ficus pandurata*, and *Nepenthes mixta*, Sander's variety.

Lilies were brought prominently into notice during 1901 by the Conference at Chiswick, at which Messrs. Wallace & Co., of Colechester, were the principal exhibitors, some of the best being illustrated in the *Gardeners' Chronicle*. Sweet Peas were equally happily exploited.

Chrysanthemums, *Roses*, *Carnations*, *Dahlias*, and the other large classes of florists' flowers have each been worthily replenished by the many diligent workers among them; and hardy flowers by the endeavours of Messrs. Kelway of Langport, Mr. Ware, Mr. Perry, Messrs. Barr & Son, and others have been recruited by novelties, and their varieties, new and old, have made perhaps more continuous displays at the Royal Horticultural Society's shows than any other class of plants.

Two charming sections have been brought out prominently during the past year, viz., *Irises*, and the charming new hybrid *Narcissus*, enumerated under the popular name *Daffodils*, raised by the Rev. G. H. Engleheart. Miss Willmott, of Warley Place, Essex, a sincere lover of plants of all kinds, secured awards in both classes, among them being *Daffodil Allen's Beauty*, *D. Robert Berkeley*, *D. Earl Gray*, *D. Elaine*, *D. Dorothy Wemyss*, *Iris Willmottiana*, and others, which will be found in the appended list of plants illustrated.

The certificated varieties are mostly of the Rev. G. H. Engleheart's raising, and among those for which he received awards were *Daffodil St. Cecilia* and *D. Florence*, two fine things of the *Ajax* group; *D. Herrick*, of the poetical class; and *D. Master-at-Arms*, a bicolor; *D. Aftermath*, *D. Spenser*, *D. Day Star*, *D. Sea Bird*, *D. Rear Guard*, and *D. Amber*, all valuable additions to this really beautiful and useful class of flowers for which the Rev. Mr. Engleheart has done so much to develop.

Other good certificated *Daffodils* were *D. General Roberts*, shown by Messrs. Barr &

Son in their group on April 23, which secured a Silver-gilt Flora Medal, and in which the fine Daffodil *Lucifer* was so well represented; *D. Stella superba*, of Mr. Walter Ware; and *D. Moonbeam*, of Mr. R. Backhouse.

The following novelties and rare plants have been illustrated in the *Gardeners' Chronicle* in 1901:—

- Adonis amurensis*, March 16, p. 175.
Agapetes macrantha, January 19, p. 47.
Allium Erdelii, May 4, p. 287.
Aloe Lynchi, March 30, p. 199.
Anthurium Bakeri, January 5, p. 2.
Aretotis Gumbletoni, September 7, p. 179.
Aretotis decurrens, April 6, p. 214.
Aretotis stœchadifolia, August 10, p. 109.
Berberis congestiflora var. *hakcoides*, May 11, p. 295.
Brodiaea crocea, August 17, p. 127.
Canna Kate Gray, Supplement, Sept. 21.
Cereus Wittii, January 19, p. 38.
Ceropegia debilis, April 13, p. 238.
Chamærops humilis "Birroo," Nov. 23, p. 371.
Chrysanthemum Queen Alexandra, Nov. 16, p. 357.
Clematis brachiata, November 23, p. 367.
Cocos Yatay, November 23, p. 370.
Colchicum hydrophyllum, February 16, p. 102.
Coleus thyrsoides, January 19, p. 46.
Cyrrilla racemiflora, September 14, p. 199.
Delphinium Dorothy Daniel, Aug. 17, p. 139.
Delphinium William Kelway, Aug. 17, p. 139.
Dianthus ×, May 18, p. 311.
Dianthus pelviformis, August 3, p. 97.
Diascia Barbere, October 12, p. 278.
Dracontium gigas, February 23, p. 126.
Erigeron Coulteri, August 3, p. 99.
Eupatorium petiolare, June 15, p. 379.
Hæmanthus mirabilis, Supplement, May 25.
Hæmanthus Linden's New, Supplement, August 10.
Hoheria populnea, Supplement, Nov. 23.
Hyacinthus lineatus, February 16, p. 103.
Impatiens grandiflora, February 16, p. 111.
Iris paradoxa var. *Choschab*, February 16, p. 104.
Iris Sindpers, February 16, p. 105.
Iris, new hybrid, Supplement, November 30.
Iris Paraver, June 22, p. 298.
Iris Alkmene, June 22, p. 299.
Iris Ewbankiana, June 22, p. 407.
Iris Tanri, March 23, p. 191.
Iris Willmottiana, April 27, p. 271.
Iris flavissima, May 25, p. 337.
Juglans cordiformis, Supplement, Oct. 19.
Juglans mandshurica, October 26, p. 302.
Koehia scoparia, November 16, p. 359.
Leuchtenbergia princeps, March 9, p. 152.
Lilium Bakerianum, July 20, p. 45.
Lilium Parkmanni, July 20, p. 52.
Lilium japonicum Colchesterense, Supplement, July 20.
Lilium japonicum Alexandræ, July 20, p. 54.
Lilium Washingtonianum purpureum, July 20, p. 59.
Lilium Grayi, July 27, p. 69.
Lilium Kewense, Supplement, February 16.
Lobelia tenuior, January 19, p. 46.
Meconopsis heterophylla, June 22, p. 413.
Mimulus Burnettii, August 10, p. 107.
Musa rubra, May 25, p. 335.
Narcissus Robert Berkeley, May 4, p. 278.
Narcissus Chas. Wolley-Dod, May 4, p. 278.
Narcissus King Alfred, Supplement, July 27.
Nepenthes ventricosa, October 26, p. 313.
Nymphaea Diana, March 2, p. 141.
Olearia stellulata, Supplement, October 5.
Opuntia papyracea, March 19, p. 153.
Pear Michaelmas Nells, October 12, p. 273.
Pelargonium Endlicherianum, Aug. 24, p. 149.
Primula sinensis King Edward, Mar. 2, 1901.
Primula sinensis Queen Alexandra, Mar. 2, 1901.

Primula megaseeifolia, April 6, p. 223.

Rose Conrad Ferdinand Meyer, July 6, p. 3.

Rose Soleil d'Or, July 6, p. 7.

Rose The Lion, July 6, p. 11.

THE CULTIVATION OF EPACRIS.

Of all hard-wooded winter-flowering plants, there are possibly none so useful or graceful as the New Holland shrubs called *Epacris*. Failure in the culture of these plants I attribute to three causes, viz., 1, lack of air; 2, loose potting; and 3, the too hard cutting-back of plants after flowering. Of the three, the last-named is the commonest error. I know but too well that many very successful growers cut their plants hard back after flowering, and they succeed well after this treatment; but I have found them succeed best without this barbarous method.

Epacris are usually propagated by cuttings of the tops of the shoots, about an inch long; these should be inserted in pots of silver-sand, and put in a forcing-house under a bell glass, or in a hotbed, air being gradually given as soon as the cuttings have rooted. I have, however, found layering to be the best method of multiplication, and whatever others have to say to the contrary, I always manage to root them by this method, whereas scores upon scores of cuttings have failed by damping.

Fill thumb-pots with a compost of peat and sand, care being taken to have a preponderance of sand on the surface for the layers to root into. Place the plant to be propagated on a hard surface in the greenhouse or elsewhere, bend down the lower shoots, cut a notch in them similar to that made in Carnation-layering, and peg them down in the pots with a piece of wire or wooden layering-pin, and draw the sand round the layer, giving the plants a gentle watering with a fine rose. Place the plants where they may remain undisturbed until they are rooted, which will probably be in six or seven weeks.

When well rooted, cut the connection between the old plant carefully, and remove the young one on to a shelf near the glass; afford water carefully, and see to its various requirements daily. In about a month after this, shift the plant into a $3\frac{1}{2}$ -inch pot, using peat and sand in equal proportions. Crock the pot carefully and well, place some rough peat over the drainage to prevent the finer particles of soil being washed through; be careful and pot firmly, loose potting is a prelude to failure. Press the compost all round the ball of the plant so as to make it quite firm and close. Afterwards remove the plant on to a stage in a cool house, still keeping it near the glass. Apply water carefully, but not fire-heat unless the weather is extremely cold. The following spring, if the plant has rooted well, pinch out the top in order to cause side shoots to form; and in about six weeks after this, when the plant has started to grow once more, shake it out of its pot, and shift into a 5-inch one, employing the same soil as before. In summer, remove the plants to a cold frame, and let them remain there until the end of September, when they should be placed in the cool green-

house; if they have rooted well, a weak application of liquid-manure may be afforded occasionally until they commence to flower.

Treatment of Old Plants.—Never shift the plants into larger pots until they are well rooted; when the plants get large, they will continue in good health for three or four years without shifting, and yet flower well, provided they are occasionally fed with weak liquid-manure. Frequent shifting is not requisite, unless young plants are required as specimens. The proper season for a general shifting is any time from March to August, although upon extraordinary occasions, as the breaking of a pot for instance, they may be shifted with safety at any other time. When potting, provide ample drainage, and press or ram the soil firmly. Some growers raise the centre of the ball 3 or 4 inches above the sides of the pot, their intention being to prevent the roots from being injured by an excess of water, for if by chance the plant does get an over-supply, it can only be round the outside of the pot and at the extremity of the roots; the upper part of the old ball of earth and the stem being so much higher, that the water runs down to the edge of the pot, and the quantity of drainage-material below always keeps the plant from suffering from an over-abundance of water. For my own part, I consider this precaution unnecessary, for provided the plants are healthy, and the application of water is in careful hands, no mischief will accrue from the ordinary potting. After potting, remove the plants to the greenhouse for a time, afterwards place them in a cold frame for the summer; syringe them occasionally, which will serve to keep down thrips.

As soon as the plants have finished flowering, cut back the stronger growths, but leave the weaker shoots at full length. Some cultivators cut all the growths back, but I must confess that, after a trial of the two methods, I find the former practice yields the better result. I do not want to criticise other grower's methods, nor, on the other hand, do I want anyone whose plants do well to follow my rules; but for those who fail to get a maximum quantity of flower, my method of procedure will be found beneficial. Let the plants be syringed daily until the new growths break, afterwards let the treatment be that previously advised.

To recapitulate, the following rules should be carefully followed:—

1. In propagating, employ layering instead of propagation by means of cuttings.
2. Do not shift into larger pots until the plants are pot-bound.
3. Afford an abundance of air, but fire-heat only when the weather is extremely cold.
4. Water with great care.
5. Cut back only the stronger shoots after flowering, but leave the others at full length.

The following is a good selection of varieties:—*autumnalis*, red and white; *Devoniana*, scarlet; *Eclipse*, crimson and white; *Mont Blanc*, white-lemon; *The Bride*, white; *Sunset*, pink; *Vesuvius*, crimson and scarlet; *alba odorata*, white, fragrant; *pulehella major*, white. *John Denman*, *Brynbella*, *Tremurchion*, *St. Asaph*.

VEGETABLES.

HAMPEL'S IMPROVED YELLOW FRAME-FORCING LETTUCE.

THIS excellent variety of Cabbage-Lettuce is highly spoken of by German gardeners as being one of the earliest Lettuces for hot-bed culture, and one of the best autumn varieties in disused hot-beds under frames late in the

year. Growth is extraordinarily rapid, and the handsome, firm heads remain good for a great length of time. For winter use, seed should be sown from August 14 to 30, and the plants form firm heads of about equal size till the beginning of winter, which, on plants in frames which are kept cool and dry, remain in capital condition for more than two months. *Deutsche Gärtner Zeitung*, January 18, 1902.

TRADE NOTICE.

Mr. A. APPLEBY, who has been in the employment of Messrs. Hogg & Robertson for the past twenty-two years, has been engaged by the Irish Agricultural Wholesale Society, Ltd., 151, Thomas Street, Dublin, as principal assistant under Mr. A. O. Watkins, for the new retail department which the Society have found necessary to establish in connection with their largely increasing business. Mr. Appleby, who is well and favourably known throughout Ireland, carries with him to his new sphere of duties the good wishes of a large circle of the gardeners and agriculturists of Ireland.

The Week's Work.

THE ORCHID HOUSES.

By W. P. BOUND, Gardener to J. COLMAN, Esq., Gatton Park, Reigate.

The Cattleya-house.—Afford *Cattleya Trianaei* and *C. Percivaliana*, now developing their flower-spikes, rather more water. Place the plants in a light position, and keep the atmosphere of the house buoyant. *Cattleya Mendeli* and *C. Mossiae* may still remain inactive, but do not keep them so dry as to make the pseudo-bulbs shrivel. Maintain a night temperature of 50° to 55°, rising in the day to about 60°; they will then need less water than if the temperatures were higher. If there should be any plants of *C. Mossiae*, *C. Mendeli*, or *Laelia purpurata* that have not yet finished making their growths, remove them to a warmer house, and place them close to the roof-glass. Admit bottom air freely whenever practicable.

Laelia Jongheana will now need a fair amount of water, and the full advantage of any sunshine there may be. We find that this lovely species grows much better suspended than it does on the stages. The intermediate-house or the cooler end of the *Cattleya-house* is the best position for them.

Dendrobiums.—Most of the deciduous and semi-deciduous varieties will be pushing out their flower-buds, and if not already removed from their resting quarters, this should be done at once. If the plants are left too long in the cool-house after the buds have begun to burst their sheath, they never attain their proper size and colour. The following species are now developing their flowers with us:—*D. Wardianum*, *D. crassinode*, *D. Findlayianum*, *D. aureum*, *D. nobile* and its many varieties, and *D. Linawianum*; and of hybrids *D. × Ainsworthii* and its many varieties, *D. × Cheltenhamense*, *D. × Clio*, *D. × Cybele*, *D. × Sybil*, *D. × melanodiscus*, *D. × chrysodiscus*, *D. × Silvia*, *D. × Wiganiae*, *D. × Curtisii*, and *D. × Owenianum*. Although the plants are throwing up their young growths, water must be afforded with great care, especially if the temperature of the house ever falls below 65°, or their roots will decay. It is better to afford water only when the plants are well dry, until the days are longer and there is more sunshine. "Back" pseudo-bulbs should be taken away, leaving not more than three behind the lead. The present time is a good one to cut off pseudo-bulbs of varieties it is wished to increase. When cut off, carefully label, and lay them on a dry stage till the end of February.

Miltonia vexillarium.—Plants that were potted back in small pots in the July potting, and have made vigorous growth and have well filled the pots with roots, may now be removed to larger pots, taking the greatest care the roots do not get injured in the operation. A suitable compost for them consists of two-fifths chopped fibrous peat, two-fifths clean chopped sphagnum-moss, and one-fifth half decomposed leaves (Oak, if possible). Mix these ingredients thoroughly together. Fill the pots about one-third full with the rhizomes from the peat, for we find this variety succeeds uncommonly well in this form of drainage. Do not disturb the balls of the plant, but simply liberate a few of the outside roots. If the compost is in a moist state, the plants potted will require very little water for a week or two; damp well between them, and syringe lightly overhead on bright days. As soon as the roots get hold of the new compost, they will need water freely until the flowering season is past. The spot so frequently found in this variety arises more from insufficient ventilation and injudicious watering during the short days than from the overhead syringings, which do no harm if the sanitary condition of the house is good and judgment is used. Our plants are in the *Cattleya-house* throughout the year.

FRUITS UNDER GLASS.

By JAMES WHYTECK, Gardener to the DUKE OF BUCCLEUCH, Dalkeith.

The Early Vinery.—Hamburgh Vines in flower should be afforded a temperature of about 65° at night, unless the outside air be very cold, when a few degrees less warmth will be better than employing excessive fire-heat. Start the fires as early in the morning as possible, but do not make a great fire if there are indications of sunshine. Zealously guard against having strong fire-heat when there is sunshine in the early hours of the day; the resulting heat would be most injurious, and the early opening of ventilators at this season is attended with the worst results. If the temperature does rise 15° above the mean, keep the air of the house saturated with moisture, but admit very little cold air. Thin the berries freely when well set. Sprinkle some Vine-manure over the border, water it in with chilled water, or very weak tepid manure-water from the cow-shed. If the Vines are in pots, they may be cropped heavily, being good only for one year; but permanent plants should be relieved of unnecessary bunches as soon as the fruits are set, taking care not to crop these heavily. Tie down the shoots, and leave all the growth beyond the bunch space will allow. The more leaf development there is, the more roots and vigour the Vines will acquire.

The Muscat-house.—Vines started in early January, and afforded a night temperature of 55°, may now be given 60°, and when the buds have burst, 65° to 70°, according to the weather. At all times try to get 10° to 15° more heat in the daytime. When they approach the flowering stage, a mean of 73° is required to induce them to set well; 90° in the daytime, with plenty of moisture, and a little circulation of fresh air evenly over the house.

Mid-season Grapes.—Complete the cleansing of wood-work in succession-houses with soap-and-water; paint or whitewash the walls, and remove the loose bark from the Vine-rods, which may be scrubbed with soap-and-water. A good remedy against bug is syringings with hot-water mixed with paraffin, or mix gas-tar and clay together, and paint the rods with it. Pure paraffin applied to dormant Vines will kill them; but it may be painted on bare rods when in active growth. Afford a good watering to the inside border, then remove the surface to the roots; then afford a good sprinkling of bone-meal, and Thomson's Vine Manure, covering this with 2 inches of finely-chopped turfy-loam, and finishing with a thin mulching of fresh horse-droppings. Before starting the Vines at the beginning of February, apply warm water to the border again, lightly, and through a rose-can.

Tomatos.—Plants raised last July, and grown in 10-inch pots in a Cucumber or similar house during winter months will continue to afford supplies for some time longer. Apply weak doses of "Veltha" or "Veltha emulsion," which will keep the foliage healthy, and the plants vigorous in the close air; high temperature otherwise is prejudicial to the plants. Sow a little seed this month.

Cucumbers.—Sow seeds in a small pot plunged in moist bottom-heat. When they have germinated, place them near to the glass in a temperature of 65° to 70°. Continue to crop old plants very lightly; fumigate the house, and afford moderate dressings of artificial manure to the border. Damp the paths to counteract the effects of much fire-heat. The temperature may rise with sunlight to 90°.

Peaches and Nectarines.—Upon the earliest trees the flowers will either be set, or the pollen of the blossoms will be ripe. Touch them very lightly with a camel's-hair brush or rabbit-foot on end of stick. When all are well set, afford the trees a good syringing with chilled water; and raise the night temperature to 60°. Upon very cold nights, rather than fire hard, let the heat go down to 55°. On bright days the trees may be syringed morning and afternoon; on dull days in the morning only at present. Damp the surfaces of the house frequently, but avoid a stuffy atmosphere. Afford the inside border a watering with warm water as soon as the fruit is set.

THE KITCHEN GARDEN.

By T. TURTON, Gr. to J. K. D. WINGFIELD DIGBY, Esq., Sherborne Castle, Dorset.

The Planting of Horse-radish.—Excellent roots may be obtained from land deeply trenched in the ordinary manner; but better ones are grown in beds in open situations raised somewhat above the surrounding level. Let a bed 6 feet wide be marked out, and the soil within the boundary be thrown out to the depth of 2 feet, then place some fairly well decayed manure to the depth of 1 foot over the bottom, returning the excavated soil. The bed will then stand considerably above the surrounding level. Such a plot will hold four rows of sets at 18 inches apart, the sets being planted at 1 foot apart in the rows. The best kind of Horse-radish sets are straight pieces of the roots about 1 foot in length, with the rootlets rubbed off down to the bottom. When planted, the top of a set should be about 1 inch below the surface of the soil. Sets of a length of 3 or 4 inches may also be planted at the same depth as the longer sets, also crowns, that is bits of root 1 or 2 inches in length furnished with a bud of leaves, but neither makes such serviceable roots the first season as does the longer set. Let the holes made with the dibber in planting be closed with coarse road-grit or charred garden refuse. A much larger quantity of fine roots when cultivated in this manner can be obtained from a small piece of land, than is possible under the more common practice followed in gardens of planting Horse-radish in an out-of-the-way piece of ground, and leaving it to itself.

Spearmint, Tarragon, and Chervil.—In most establishments, a plentiful and constant supply of these herbs has to be furnished by the gardener. The roots of Spear-mint should be dug up and placed in boxes with fine soil sprinkled over them; and the Tarragon in flower-pots, and forced into growth in an early Peach-house or vinery. Should the supply of Chervil from plants growing in boxes be running short, and plants exist in the open ground, hand-lights should be placed over the latter as a protection against frost that may now occur; otherwise let a sowing be made forthwith in shallow boxes.

Mustard and Cress.—Make sowings every three or four days, or according to the demand; boxes measuring 18 inches in length, 12 inches in width, and 3 inches in depth, are convenient for handling when filled with soil. An almost pure vegetable soil is most suitable, favouring

quick growth, and leaving no grittiness on the produce. Apply water to the soil with a fine rose-can. Sow moderately thick, press level with a bit of board, do not cover with soil, and cover with slates laid on the sides of the boxes till germination has taken place.

Seed Potatoes.—All seed Potatoes should by this date be put in order for sprouting, but especially so for early planting, where such has not been carried out. Ascertain the number of sets that will be required for planting in hot-bed frames, lay single layers of these in shallow boxes on sifted leaf-mould, and place in a succession Peach-house or warm greenhouse to sprout. Fill also a few boxes with the tubers set up on end for planting sheltered borders, or at the foot of south walls. Rub off all shoots of those not required for early planting, and, where there is convenience for doing so, lay them in single layers on shelves, or on the floors of any out-house where they can be kept cool, yet safe from frost.

Broad Beans.—A sowing of the Early Longpod Bean should be made forthwith on sheltered borders, and by preference on retentive soil which has been newly trenched or deeply dug. Sow the seed in double lines drawn at 4 feet apart, the seed being dropped at 1 foot apart. This is best done by throwing out shallow trenches with a spade, and dibbling in the seed with a blunt-ended tool about 1 inch deep. As the plants push up through the soil, gradually fill the trench with the earth thrown out, which will serve to protect the plants against frost; and even should the tops get cut by frost, strong shoots will be thrown up from the base. Sow also Longpod Beans at 3 inches apart in boxes filled with soil, and place in a temperature of about 50°, and as soon as the plants are well above the soil, remove the boxes to a cold pit, and plant in trenches when the weather permits in early March.

THE HARDY FRUIT GARDEN.

By J. MAYNE, Gardener to the Hon. MARK ROLLE, Bilton, East Budleigh, Devonshire.

Filbert Trees are improved by annually thinning the branches where they are placed too thickly, keeping the centre of the bushes fairly open. Care must be taken that enough wood carrying male catkins be left for the fertilisation of the female blossoms when in flower. Should the former be scarce, some branches of the common hedge Nut with catkins upon them should be tied on the bushes as soon as the little red point can be seen on the female flowers. Shorten the strong growths made last season 12 or 15 inches, cutting to an eye facing outwards. Afford old bushes a dressing of short manure, forking this lightly in. Planting may still be done, though it ought to have been carried out before the shortest day. It is well to grow Filberts on single stems, as is done with Gooseberries and Red Currants, or the old stools throw up such a quantity of suckers each year, which if left become a mass of unfruitful wood. The Cosford variety should be planted with other sorts, as I find it always has plenty of catkins.

Raspberries.—Any replanting should be carried out forthwith. In cases of new stations the ground should be deeply dug, and plenty of decayed farmyard manure worked in if the soil be light, while that of a heavy nature may be afforded soot and wood-ashes only. The canes are trained in many ways, but I prefer to plant them in rows 6 feet apart and tie the canes to wires tightly secured to posts 5 feet in height, three tiers of wire running the entire length of the row, placed 18 inches apart from the top downwards. The canes must be at least 4 inches apart from each other when tied to the wires. Mulch the ground with straw litter.

Miscellaneous.—The pruning of all fruit-trees, except those newly planted, should be pushed forward as rapidly as possible. I find the birds are again knocking out the buds of Gooseberries, in spite of heavy syringings

with a mixture of soot, lime, and quassia extract. We are now going over the young growths again, painting them with a like mixture, but thicker in substance. The covering of bush fruits with galvanised wire netting is the only sure remedy against these winged depredators. Plum trees, especially the old Greengage, are often attacked by tom-tits. The trees should be treated the same as Gooseberries, or have $\frac{3}{4}$ -inch square-meshed netting placed over the trees. Examine each week all fruits in store, and remove those that are in the least decayed for immediate use. Bergamotte d'Esperen Pear is now in use with us, and though the fruits are rather small, and inclined to be dry, are nevertheless useful. All fruit keeps better in a darkened room, and with but little ventilation at any time.

PLANTS UNDER GLASS.

By J. C. TALLACK, Gardener to E. MILLER MUNDY, Esq., Shipley Hall, Derby.

Seed-sowing.—January is full early for sowing seeds of many species of plants that are grown under glass, excepting some which take rather a long time to develop. Most of those require a well-heated pit or house in which to raise them successfully, otherwise sowing should be deferred till a later date.

Clerodendron fallax.—It is often advised that this plant be raised from cuttings. My experience is that seedlings are better, being kinder in growth, and productive of larger flower-heads. The plant is magnificent through October, November, and even a little later when well grown; its chief fault is that a fully grown plant demands a considerable amount of space. Seeds saved from last year's plants should now be sown, several together, in a 6-inch flower-pot in very sandy soil, and the seed-pot plunged in bottom heat of 75°. The seedlings germinate more freely in pots of this size, and the difficulties of establishing them later singly in small pots are very few, provided that they are so transferred while still in the seed-leaf stage.

Tuberous Begonias, Gloxinias, and Streptocarpus have very small seeds, which should be sown on the sanded surface of well-filled and previously well-watered pans or pots of soil. For the present, the treatment will be identical, but it may be advisable to point out that the sun should never be allowed to shine directly on to the Streptocarpus seed-pan, for this would be fatal while germination is taking place and while the plants are very small. With the foregoing should be associated that pretty little plant Saintpaulia ionantha. All these may be raised in heat, the seed-pots being covered with glass, which should be frequently turned over to disperse the moisture condensed on the lower side.

Caladiums.—These should be shaken out, the tubers divided, where increase is desired and they admit of it, and started for the present in pots of sand, in which they may remain until the growth begins to grow prominently. *C. argyrites* may be divided more freely than the others, and is a most useful little plant.

Acalypha hispida.—Growing tops of this plant strike freely in a few days. The tops should be strong ones from main stems. In connection with this plant I may say, that I have found the tassels finer and better in every way when the plants have been grown in heavy loam, and rammed hard. In the ordinary mixture made up for stove plants the tassels often lengthen out into mere apologies for what they might be.

Dracaenas.—Old plants may be cut up into good tops also, and the "toes" obtained from the thickened root-stems, or suckers in embryo, all provide material from which young plants may be raised. The tops probably are the worst to manage, but should not be thrown away if well coloured.

Pandanus Veitchii.—Suckers should be stripped from the older plants whenever good coloured pieces are available. They will root readily in Cocoa-fibre or in soil if not afforded

much water; and young stock is always useful in decorative work.

Abutilons may now be struck from growing tops; they strike more readily now than later; and in any case advantage should be taken of striking young stock or anything that can be struck, so that they may be got out of the way in time to make room for general plant propagation during the next three months.

THE FLOWER GARDEN.

By R. DAVIDSON, Gardener to EARL CADOGAN, Culford Hall, Bury St. Edmunds.

Seeds.—Of the different species of sub-tropical plants, sow at this date *Melanthus major*, *Wigandias*, *Daturas*, *Eucalyptus*, *Acacia Lophantha*. The seeds should be sown in shallow pans filled with a light kind of soil, and the seedlings grown in warmth till the middle of the month of May, when having attained a good size, they may be gradually hardened off in readiness for putting into their summer quarters. Seeds of *Erythrina cristagalli* and *Francoa ramosa* may also be sown for flowering in the summer of 1903. Groups or beds of these two species in juxtaposition are very attractive. *Ricinus*, *Solanum*, *Ferdinandia* and *Nicotiana* being of freer growth than the foregoing, may be sown the second week in February, and the seedlings will make strong specimens for planting out-of-doors in the month of June. A sowing of *Celosia aurea* and *coccinea* may be made now for planting-out in the beds about the end of that month. They will flower profusely all through the summer and autumn, and are a great acquisition. It is important that all the plants named above should be pricked off into pots and pans, and when sufficiently large potted in clean pots of suitable size according to their requirements. Many a gardener will have experienced a difficulty in obtaining the required number of *Calceolaria* cuttings last autumn, many of the plants having dried off early in the season for want of sufficient moisture. This can be got over by a sowing made now of *Calceolaria* Yellow Bedder in shallow pans or boxes in an intermediate temperature, and as soon as growth commences after being pricked off 3 inches apart in boxes, remove and grow in a cool structure, where they will make satisfactory progress, and be of a useful size by the middle of May. This plant is one of the most indispensable of yellow-flowering subjects. A sowing may also be made, if stock be short, of *Centaurea candidissima*, and if the seedlings be grown in a warm-house, they will become useful by mid-June.

The Rock-garden.—In the wild rock-garden, the various patches and colonies of herbaceous perennials, Ferns, &c., may be afforded a top-dressing of fresh soil, having previously removed decayed flower-stalks, leaves, and weeds, and small shrubs that may be planted on the rockery, with a mulching of well-decayed manure where this is practicable. Remove tree-leaves, especially where there are patches of Primroses, Violets, Anemones, Crocus, and hardy dwarf bulbs. Wooden rustic-work, such as steps, bridges, seats and arbours, should be repaired. The ornamental rockery will need frequent weeding, as many of the rarest alpine do not succeed if weeds of perennial duration abound. Alterations may be carried out now, and the plants placed in position without loss of time, always making a suitable selection of soil when replanting.

DWARF BEAN CROSSED WITH THE PEA.

We learn from our old correspondent, Mr. SMYTHE, late of Basing Park Gardens, that Mr. A. GILLET, of the gardens, Sandling Park, Hythe, has raised a cross between a dwarf Bean and a Pea, the latter being the pollen parent. The seeds are said to be almost exactly like those of the Pea. We have not seen the alleged hybrid, nor are we rash enough to assert that such a cross is not possible. We await further evidence.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be WRITTEN ON ONE SIDE ONLY OF THE PAPER, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editor does not undertake to pay for any contributions, or to return the unused communications or illustrations, unless by special arrangement.

Illustrations.—The Editor will thankfully receive and select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY, JAN. 28. — { Royal Horticultural Society
Committees Meeting,
Annual Meeting of National
Sweet Pea Society, at Hotel
Windsor, at 3 P.M.

SALES FOR THE WEEK.

MONDAY, JAN. 27.—Plants, &c., by Protheroe & Morris, at 12.—Japanese Lily Bulbs, by Johnson, Dymond & Son, at 4.30, and Roses, &c., at 12.

TUESDAY, JAN. 28.—Botanical and General Library, at Stevens' Rooms, at 12.

WEDNESDAY, JAN. 29.—Liliums, Plants, &c., by Protheroe & Morris, at 12 and 5; at The Nurseries, Woodford, Nursery Stock, by Protheroe & Morris, at 11.—Plants, &c., at Stevens' Rooms.

FRIDAY, JAN. 31.—Perennials, &c., by Protheroe & Morris, at 12; Orchids, at 12.30.—Orchids, by Mr. John Cowan, at Liverpool, at 12.

(For further particulars see Advertisement columns.)

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three Years at Chiswick —38° 8'.

ACTUAL TEMPERATURES:—

LONDON.—January 22 (6 P.M.): Max. 53°; Min. 49°.
January 23.—Dull; mild.

PROVINCES.—January 22 (6 P.M.): Max. 51°, W. Ireland; Min. 43°, N.W. Scotland.

To do justice to this volume, whose title is given in the footnote, the reviewer should be a specialist in the same department. But Mr. NEWSTEAD is the acknowledged leader in this branch of entomology, and the would-be reviewer can only bow the head in homage. There have not been many entomologists in this country who have concerned themselves with this group. It may therefore be a source of pride to gardeners that one of their fraternity should, by his own exertions, have raised himself to the foremost place in his department. Gardeners know too much about the ill-doings of mealy bug, American blight, scale, and such like creatures, some of which we figure in the present issue, but they have hitherto concerned themselves with effects, without troubling themselves to understand the causes. And yet till the cause is known, and the manners and customs—the life history—of the creatures understood, the application of remedies must be empirical.

"As a practical gardener," writes Mr. NEWSTEAD, "I had for many years been fully acquainted with the destructive habits of the mealy bugs and scale insects of our fruits and flowers, but it was not till the year 1889 that I began in earnest the study of the group on more scientific lines, when, acting under the advice of my late employer

and friend, Mr. ALFRED OSTEN WALKER, F.L.S., I began a systematic study of the group."

About ninety species and varieties are known in Britain, the majority of which occur in plants cultivated under glass, and are therefore probably of exotic origin. It has been thought advisable to make this monograph representative of all species found living in this country, so that the work may appeal not only to the naturalist, but to all those who are interested in horticultural pursuits. With this object in view, instructions are given on the methods of prevention and remedies, to which have been added from foreign sources the most approved modern systems of combating these insects on a larger scale than is usually employed in this country. Besides this, the horticulturist will also find valuable data on the natural enemies of the Coccidæ, and the extent to which certain birds feed upon the insects in question.

The opening chapters are devoted to the life-history and habitats of the insects, points which are unfamiliar to most people, but nevertheless, of great interest, and in some cases of great importance, as in the case of the introduction of destructive pests to our orchards, of which Mr. NEWSTEAD gives some illustration.

The San José scale, Mr. NEWSTEAD thinks, has never yet been met with in this country, and is not likely to establish itself on fruit-trees in the open-air. The danger to English horticulturists lies, for the most part, in the introduction of destructive coccids into our glass-houses, where, in the absence of their natural enemies, they thrive and multiply, causing us annoyance, disappointment, and loss. The mention of enemies recalls the fact that small beetles allied to our ladybird have been found in other countries very serviceable in keeping the Coccidæ in check. In the United States beetles of this kind (*Vedalia cardinalis*) have been imported from Australia to destroy the fluted scale (*Icerya purchasii*), and with excellent results. The example has been followed with equal success in Egypt and in South Africa. In this country these beetles and the ladybirds are not known to prey on the Coccidæ. Among birds, the titmouse (*Parus coerulesus*), however, renders good service, on which account, in spite of the injury he inflicts on buds, his presence may be tolerated; and the same may, in a minor degree, be said of the jackdaw and of certain other birds. "Their usefulness," says the author, "in checking such destructive species of Coccidæ as the mussel-scale (*Mytilaspis pomorum*), the Willow and the Ash-scale (*C. salicis*), which latter sometimes renders the osiers too brittle for weaving purposes, is not to be overstated. Proof such as has been given is indisputable, and I am convinced that quite 50 per cent. of these insects are devoured by the birds whose names have been appended.

In the chapter on methods of prevention and remedies, Mr. Newstead gives details of the process of fumigation with hydrocyanic acid gas—a process extensively used in the U.S.A., and which has also been tried at Wye College. It is so dangerous that it should never be entrusted to careless or unintelligent operators, but with due precautions it is no doubt likely to be a most valuable method. Less dangerous, though not entirely free from risk, in careless

hands, is the use of XL, from the employment of which for mealy bug we have secured excellent results.

Petroleum emulsion is also recommended by Mr. Newstead, and here again we can testify to the excellent results of its application in the case of mealy bug and scale. Gishurst compound is also well spoken of, but is too costly for use on a large scale. Other remedies are mentioned which are well worth the consideration of the gardener.

The chapters on classification and the full details of structure will appeal to experts, and necessitate minute microscopical comparative examination, for which few have the requisite capacity or time. All that we can say is, that Mr. Newstead's method of treating his subject is unexceptionable, and inspires the fullest confidence. The illustrations are really elucidatory, the coloured plates instructive; the index just what is required. What more remains to say but to congratulate Mr. Newstead on his unequivocal success, and to express our acknowledgements to the Ray Society, without whose aid this most valuable treatise would not have seen the light.

In order to illustrate the subject of scale insects injurious to garden-plants, we reproduce (on p. 57) numerous figures contributed to our columns by CURTIS, WESTWOOD, and other famous entomologists; and may also refer to a paper of Mr. T. D. A. COCKRELL, Curator of the Museum, Jamaica, on May 6, 1893, p. 518, wherein eighteen species of scale insect injurious to Orchids are described.

THE CONSERVATORY AT THE DELL, KING'S NORTON (*Supplementary Illustration*).—We are enabled to afford our readers a view in the conservatory belonging to G. E. BELLIS, Esq., at The Dell, King's Norton, near Birmingham, an example of a thoroughly modern method of arranging the plants. Some of the plants are permanent in the sense of being planted in the borders which flank the sides of the building, and others are portable and stand for the most part on the ground. This is a plan greatly to be preferred to that of arranging the smaller plants on stages and benches, although in the case of plants having small, particularly fragrant, or very interesting flowers, there is often an advantage in bringing them nearer to the eye of the observer. This is, however, better done by arranging such plants on small rustic stands or tables. Where the light is good, plants do not suffer when placed on the floor. The proportion of foliage to flowering plants in Mr. BELLIS' conservatory is a very fair one, and well furnishes the necessary foils to colour; and altogether the arrangements are such as may safely be followed at any season. The gardener at The Dell is Mr. G. BURROWS, to whom our thanks are due for the opportunity to insert the illustration.

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the Committees will be held on Tuesday, January 28, in the Drill Hall, Buckingham Gate, Westminster. A lecture on "The Renovation of Old Fruit Trees" will be given by Mr. GEORGE BUNYARD, V.M.H., at 3 o'clock.

CHISWICK.—Unfortunately, comparatively few of the Fellows of the Royal Horticultural Society exercise their right of visiting Chiswick, especially at this season of the year. It is a pity, for they would learn something, and they would by their pre-

* *Monograph of the Coccidæ of the British Isles*, by ROBERT NEWSTEAD, vol. i. Printed for the Ray Society.

sence encourage the officials to turn to even better account than they do the resources of the establishment. Just now the preparations are being made for the coming spring. The Vines are being pruned, the Figs have been attended to, the beds and borders have been dressed, the rockery has been overhauled, and generally neatness, cleanliness, and order prevail.

PLANTS IN FLOWER, ROYAL BOTANIC GARDENS, KEW, JANUARY 18, 1902:—

Shrubby.

"THE JOURNAL OF THE KEW GUILD."—Of the numerous periodicals which find their way to the Editor's table, there are few to rival in interest this record of the sayings and doings of old Kewites. Kew itself, it is needless to say, is of unsurpassable interest to horticulturists and botanists, and those who labour in it are necessarily more or less intimately known to those concerned in horticultural affairs. But those who labour in it come and go. It is the object of the Kew Guild to secure that those who come shall be linked with those who go, and that those who go shall be in touch with their successors. The extracts from the letters of old Kewites in all parts of the world, not excluding the fighting ones in S. Africa, show how strong is the feeling for the establishment.

RHEA FIBRE.—Mr. JEFFRIES, of the Nurseries, Oxford, sends us illustrations of the growing plant and of the fibre it produces. The value of the fibre of the *Boehmeria nivea* has long been appreciated, but some difficulties still exist in the cleaning the fibre and divesting it of resin.

CYPRIPEDIUM INSIGNE.—Mr. HAWKES, of the Gardens, Osterley Park, Isleworth, obligingly sends us an inflorescence of this species with two flowers, the upper one being the older. The bract from whose axil the flower proceeds is developed in the form of a perfect leaf. Such occurrences are not very uncommon, but are always interesting.

MONUMENT TO BARON SIR F. VON MUELLER.—We learn from *Nature* that the monument erected in the St. Kilda cemetery, Melbourne, to the memory of Baron Sir F. VON MUELLER, was unveiled on November 26 by the Governor-General, Lord HOPETOUN, in the presence of a large assemblage of personal friends and men of science.

"DAS PFLANZEN REICH."—This is a new publication directed by Prof. ENGLER, and devoted to the description and arrangement not merely of the genera, but also of the species of plants. The scope is thus enormous, and the time that must elapse before its completion cannot easily be estimated. What we have to note specially with reference to the number before us is the fact that the present "heft" is the work of our countryman, Dr. RENDLE. It was thought at first that German botanists alone would participate in this gigantic undertaking, but this appears not to be the case. Dr. RENDLE deals with the Naiadaceæ, a small but interesting group. The characters are given in Latin, the comments in English, and in some cases in German.

EARLY THRUSH.—A correspondent writes that on the Thames the thrush always sings on mild days of November in the middle of the day; and that he has heard sixteen thrushes or so on the same day in about 8 miles of distance in January.

THE SURVEYORS' INSTITUTION.—The next ordinary general meeting will be held in the Lecture Hall of the Institution on Monday, January 27, 1902, when a discussion will take place on the paper read by Mr. A. DUDLEY CLARKE (Fellow), at the meeting of Monday, November 25, 1901, and on a paper to be read by Mr. G. S. MATHEWS (Fellow), both entitled, "The Final Report of the Local Taxation Commission."

THE SHOW-HOUSE AT KEW.—Gardeners on the look-out for decorative material for the conservatories under their charge should make frequent visits at all seasons to No. 4 house at Kew. Just now the most attractive things are hanging baskets of Lorraine Begonias, full of bloom, and of a bright rosy-pink. *Primula oboconica* makes a fine show, and the Chinese forms with the "stellata" variety are very attractive. *Moschosma*, which we noted at the Drill Hall last week, is in full bloom. *Tecoma Smithii* × we noticed before, but it is still flowering, as also is *T. capensis*. That such strikingly decorative plants should flower in small pots is a circumstance that should commend them to the notice of gardeners. *Centropogon Lucyanus* × is an old friend whom we should gladly see more of. *Peristrophe speciosa* is one of the winter-flowering Acanthads which are very welcome at this season, though it does not rival the beautiful *Ruellia macrantha* lately figured. *Epæris* makes a bright display, and an effective group is made by combining Roman Hyacinths and red-berried Solanums—but this is what we might expect to find in any conservatory. At Kew we look for novelties and decorative plants not generally met with. Be this as it may, No. 4 is always attractive, and the grouping satisfactory.

GLASGOW BOTANIC GARDENS.—At a meeting of the Glasgow Corporation, on the 16th inst., it was reported that Mr. JAS. WHITTON, Superintendent of the City Parks, had been appointed Curator of the Botanic Gardens, in the room of Mr. DANIEL DEWAR, resigned. An announcement was also made to the effect that a herbarium had been presented to the People's Palace.

THE HERBARIUM AT KEW.—Preparations are now being made for the addition of a new wing to the Herbarium at Kew. The new building will be on the western side of the present edifice, and will nearly double the available space. The additions to the herbarium are so numerous and so incessant that this extra space will be none too great, and

should the proposal to remove the herbaria from the Natural History Museum to Kew ever be carried out, a large extension of the present buildings must be again made. The new wing at Kew is to be built so as to minimise the risk of fire, and when it is completed, various alterations will be made to the present building in order to render it also, as far as possible, fire-proof.

CRINUM NATANS.—In the Victoria-house at Kew this curious species is now in flower. The flowers, for a *Crinum*, are not remarkable. The floating leaves are, however, very striking; they are about 3 feet long, linear; undulate at the margins. It is a native of Western Tropical Africa.

GRAMMATOPHYLLUM SPECIOSUM.—We have already chronicled the flowering of this plant at Kew, and advert to it now to call attention to the imperfect flowers at the base of the spike. In these the perianth is four-merous, with a straight column and no lip. This reduction to whorls of two, together with a straight column, is one of the commonest malformations of Orchids, and is not devoid of significance.

BROWNEA CRAWFURDI ×.—High up amid the rich vegetation of the Palm-house at Kew, the eye is attracted by huge balls of glowing red, the more effective from the setting of the rich green foliage of the Palms. These Leguminous trees are very splendid, but they are not for those who do not possess big houses.

STANGERIA SCHIZODON is sending up its Cycad-looking spikes in the Victoria-house at Kew. This plant is not only very interesting to the botanist, but it is a handsome plant for the stove-house.

MISLETO.—In the Cape House at Kew may be seen some small plants of Olive in a 32-pot (or thereabouts), bearing a species of Mistleto, like our own, but with red berries (*Viscum cruciatum*). The same species may be seen on *Pyrus terminalis* in the Temperate-house.

THE TEMPERATE-HOUSE AT KEW.—*Rhododendron præcox* makes a great show in this house, and so do several of Messrs. VEITCH'S hybrids, some of which may be had in bloom all the year round. The Acacias are coming; *Camellia Sasanqua* has come, but the most noteworthy plant at present in this house is an unnamed species of *Agave* in full flower. It is a noble plant, with the leaves in dense tufts, each leaf very thick, lanceolate from a broad base, recurved, spineless at the margins. From the centre of the tuft uprises a shaft, perhaps 8 or 9 feet high, the upper portion densely covered with greenish-white flowers.

GRAFTING EXPERIMENTS.—According to a recent number of *Le Jardin*, M. LINDEMUTH lately showed before the Prussian Horticultural Society some interesting specimens of grafting, in which the graft had exercised a more or less marked influence on the stock. The plants were:—1st, Yellow Wallflower on Red Cabbage, in which the plant had developed below lateral branches of Wallflower, with a shoot of Cabbage and a head of Red Cabbage. 2ndly, Brussels Sprout on Yellow Wallflower. 3rd, *Abutilon Thompsoni* on *Althæa narbonensis*. The former is a shrub, the second is a herbaceous plant. Owing to the influence of the *Abutilon* the branches of the *Althæa* became persistent, and indeed, are two years old. 4th, *Solanum erythrocarpum* on Tomato (*S. lycopersicum*). The Tomato being the more rapid grower, communicated this property to *S. erythrocarpum*. 5th, *Malvastrum capense* became variegated by grafting

with *Abutilon Thompsoni*. 6th, Hybrid *Petunia* on *Nicotiana glauca*. If *Petunias* are grafted on the stems of *Nicotiana* of rapid growth, fine shoots of *Petunias* on the stems can certainly be obtained. Mr. WINTER, of Bordighera, has already made this experiment, and has grafted *Petunias* on many branches of *Nicotiana glauca*, which in that district grows as a shrub. The effect should have been very fine, but a storm bruised the heavy branches of the *Petunias*. 7th, A new plant, with variegated foliage, *Sida Napæa*, obtained by grafting with *Abutilon Thompsoni*, was a success in one instance, while another specimen remained green. 8th, *Althæa rosea* (Hollyhock) became variegated by the influence of the graft of *Abutilon Thompsoni*. Young seedlings of *Althæa rosea*, of *Malvastrum capense*, and variegated *Anoda hastifolia* have, so far, remained green.

FRUIT FROM THE CAPE.—Doubtless our readers will be pleased to have the figures relating to the imports of fruit from the Cape into this country during 1901, per the Union Castle Company's ships. They are as follows: Grapes, 6,130 packages; Plums, 2,379; Apricots, 434; Peaches, 5,703; Nectarines, 296; Pears, 1,126; Apples, 113; Pines, 37; Quinces, 8; and Tomatos, 2. The first consignment for the present year has arrived, we believe in advance of the listed time, though a week later than the first in 1901, and was made up of 234 packages of Plums; Apricots, 48; Peaches, 75 packages.

IMPROVEMENTS IN HARDY PLANTS.

The following important paper was read at a meeting of the Horticultural Club on Tuesday last by Mr. Amos Perry:—

It is now nearly forty years since I first interested myself in hardy plants. It was at the period of the "flare-up style of gardening," masses of brilliant colour for about three months, and the remaining nine almost bare. Many collections in nurseries were destroyed, and I have had to run through these doomed plants, buy up what I wanted at a nominal price, and to see these same collections reinstated within ten years from the time they were destroyed.

The only collections of repute in those days were those of Rollison of Tooting, the St. John's Wood Nursery, Youell of Yarmouth, and May of Bedale. These collections were limited in extent, but unlimited in price. *Digitalis purpurea* was priced at a shilling a plant; *Gentiana affinis* at the same figure. One had taken five minutes and the other five years to make. These were the sort of inducements offered to the public for buying hardy plants. They were practically ignored by everyone, and the trade always looked upon them as a great nuisance, costing far more than they were worth. To show how much they were appreciated, I will just give you my first experience at the old horticultural gardens at South Kensington. It was suggested that a group of some of the wonderful plants that were being collected together at Tottenham should be exhibited at one of the big summer shows. I believe this was the first time that anything like a representative collection of hardy stuff had been shown. A lot of preparation had been made, space had been written for, and on the appointed day a van with plenty of assistance appeared at the great horticultural exhibition. I saw the superintendent, Mr. Eyles, shortly after my arrival, and asked him for a space. He told me I should have to wait, and see if any were left.

I did not like my reception a bit. After waiting and worrying till about eight or nine o'clock, he told me he would come and see what I had got. "Go and wait in the yard till I come," and I was foolish enough to go. After again waiting some considerable time I went and found him, and got him to go and have a look at the class of plants I proposed to exhibit. He looked at them in the van, laughed, and said, "I cannot have such rubbish here." However, after waiting another hour or so, a man was sent to me stating they had got a place for me in the western arcade among the exhibits of wire-stands, pottery, and other accessories to the garden. I was given two large wire-stands to set up pots, pans, and boxes, and did the best under the circumstances. Now, every show in the country largely depends upon hardy plants to fill the tents.

It is impossible in a short time to go fully into such an important subject as the improvement of hardy plants, the capabilities of which are immense, but it is of vital importance that this matter should be taken up to assist in maintaining an interest in hardy plants. It is becoming more difficult every year to find novelties, and it is new or rare plants that the public want. It is surprising how little has been done in this direction. Some families, it is true, have been thoroughly dealt with, and these now form some of the chief attractions to the gardens of the present day, but how few have received the attention they deserve!

It is unfortunate that nurserymen as a rule have so little time to devote to this important matter. The older they get the more they have to do, and before they have accomplished one tithe the part of their early intentions they find their energies directed to other phases of horticulture. What a vast field there is still for enterprising men to take up hardy plants and improve them by hybridising and selection! What an opportunity many of our gardeners have for this kind of interesting work! They have the materials and opportunities, and in hundreds of cases nothing would please their employers more than to know their gardens were the birthplace of numbers of plants which sooner or later would find their way into every garden in the land.

There is also a vast field open for men fond of mountaineering, but this class of enthusiast is difficult to find, because a young man has not the knowledge to detect a new plant the moment he sees it, while the middle-aged man having the knowledge has not always the energy necessary to take a trip of two or three days' duration in the mountains, carrying all the paraphernalia required for climbing, and knowing there is no luxurious hotel in which he can recuperate for the return journey.

In one of my trips to the Pyrenees, in 1870, I was successful in finding many interesting plants, some of which are now common, while others have, unfortunately, been lost—*Ramondia pyrenaica alba*, *Primula integrifolia alba*, *Gentiana verna alba*, and a solitary double-flowering variety, which never survived the journey, *Anthericum Liliastrium major*—not the major now offered, but one growing 3½ feet, with very large flowers—and many others.

I am afraid we must fall back upon the amateur for the raising of seedlings, selection, hybridising, &c., and if we can only induce more enterprising amateurs to take up this matter no one knows what may be accomplished. Secretaries might greatly assist in the work by offering prizes for any improved variety of hardy perennials, and honouring them according to their merits.

We want more gentlemen like the late Mr. Nelson, Mr. Ewbank, and Mr. Harpur-Crewe, who did valuable work in their time; the Rev. Wolley Dod, Sir Michael Foster, who has done so much for the Iris; Mr. James Salter, the father of the *Pyrethrum*, and many others. Some genera have received a fair share of attention, and to the French florists we are principally indebted for the great improvement in the *Phlox*, which is still capable of further additions. Many of them are too tall, and the Americans have just started a new race only growing 1 foot in height, which for many purposes will be invaluable. The alpine *Phloxes* were taken in hand by the Rev. John Nelson, and to him we are indebted for one or two of the best at present in cultivation.

The Hollyhock is essentially an English flower, and Mr. Chater's name will always be associated with it, but I do not think there is much room for further improvement in that direction. We want a change, and I think the material is at hand in *Althæa ficifolia* for producing an entirely new race of Hollyhocks, dwarfier in growth, of pretty branching habit, and of far more value for many purposes than the present group.

Carnations and Pinks now occupy a prominent place in our gardens, but what a change from the old school of florists, of which the late Mr. Turner was chief! A Carnation with a fringed edge, in those days, was considered a monstrosity, no matter how free blooming or beautiful in colour, and now we hear of fringed Carnations realising thousands of dollars.

In connection with the Carnation we must not forget Mr. Martin Smith, who has done more for this flower than any man living. Long may he continue his work with this species, and set an example to others to try and do likewise with some other race.

Delphiniums have received a fair share of attention, both by English and French raisers, and many splendid varieties have been the result. A remarkable break has been obtained by Messrs. Kelway, but although the results cannot be considered great, yet it is possible that from these may be obtained other varieties of greater merit.

The idea seems to prevail that a Delphinium should be blue, and if you admit a white or a yellow into your collection it must be a good one. It is, however, a great achievement to get a break of this description, and now we have white I see no reason why yellows, scarlets, and every other intermediate shade cannot be produced.

The Oriental Poppies deserve mention as being one of the few recent families that has received special

attention, and among them are many of great merit, and still capable of great improvement. I see no reason why we cannot obtain as much variety, colour, and form, as in the annual varieties. In *Fringed Beauty* we have the first break in form. The flower has a deep fringed edge to the petals, while in Mrs. Marsh we have the first two-coloured varieties, and with this material to work from no one can form any conception of what may be obtained.

The *Tritoma* has received a good deal of attention, but the work is only half done. T. MacOwani should be taken seriously in hand, to endeavour to form a new race of dwarf varieties for summer flowering, and adapted for massing as well as for pots.

Lobelias, Penstemons, Dahlias, Chrysanthemums, and others, we know all about, but they hardly belong to the class of plant under consideration this evening.

(To be continued.)

BOOK NOTICE.

THE GARDEN OF A COMMUTER'S WIFE.

Recorded by the Gardener. With eight illustrations in photogravure (New York: The Macmillan Company. London: Macmillan & Co., Ltd.).

HERE is yet another book about a garden, or at least a book wherein the garden serves as a background, the most prominent features being: the author's domestic, and what should have been her private affairs. The Commuter's wife gives herself an excellent character as an affectionate daughter and wife, and is remarkably well satisfied with herself. As to the garden, that is a "bit of garden-ground framed in the hillside woods, of which it had originally been a part; it was to be itself, and not distorted into a feeble imitation of the classic gardens of other days and times. . . . I desire the most flowers at the least cost, as befits the frugal wife of a Commuter. Flowers for village brides, for the children, and for church festivals, and flowers to make the silent journeys from the hospital that some must take less dreary for those who follow them." This Garden of Dreams the gardener sets herself to manage without professional assistance, and in the scattered reports upon it we gather that, though absolute perfection was, as ever, unattainable, health and amusement and self-satisfaction rewarded her efforts. We on this side of the Atlantic would have been pleased to hear a little more of the hillside garden, and less of matters which (in spite of hinted depreciation of the book) inevitably suggest Elizabeth and her many admirers and followers.

Here is a little descriptive piece of which we could wish there were more:—"The borders, about 6 feet in width, were a hopeless jungle of hardy plants, interspersed at intervals with shrubs and tall bushes of the older Roses, such as *Magna Charta* and *Jacqueminot*. Some of these met over the path and partly barred the way. . . . There was a broad band of Hollyhocks, too well placed against the Honeysuckle bank to be disturbed; straggling helter-skelter were Foxgloves, Canterbury Bells, Larkspurs, Phloxes, Sweet William, Columbines, white *Anemone japonica*, still in bloom, in company with Monkshood, hardy *Coreopsis*, Evening Primroses, Honesty, and Sunflowers; while the autumnal growth of white, yellow, and red Day and Tiger Lilies, and scarlet Oriental Poppies was distinguishable."

Here, again, is a pretty picture of winter:—"The evergreens, so old that they had lost all Christmas-tree stiffness and taken easy attitudes, had been so planted that, as the Elms and Maples lost their leaves, they seemed to disappear into the draperies of these sturdy trees, and be replaced by them; so that on hill, grass slope, or flanking the walk, the furry green of White Pines or the fretwork of Spruce

and Hemlock barred out winter desolation, while the living green in the younger bird-sown seedlings of the old trees crosses the woody pasture until it blends with the sombre tone of the native Red Cedars that gather round the bars.

"Woman, you who have bought the bit of ground with trees on the cross-road, that your children may be born to country life, plant evergreens in the north for a windbreak, and on the south for a pleasure to the eye—not the new-fangled Blue Spruces, Golden Hemlocks, fit only to be confined to the lawn as breeze-excluding ornaments, or the stunted Firs of florists' catalogues, but the sturdy old forest trees that rear their heads laughing in the gale and grow mightily; White Pines and the Scotch Fir of ruddy bark, White and Black Spruce of long or clustering cones, graceful Hemlock Spruce, and the dwarfed Balsam Fir of fragrant breath."

those grown inland; but invariably there is another quality about them, viz., large size, which more distinctly points to the skill of his gardener, Mr. A. C. Axtell.

In the Sunny Hill gardens, the keen winds which at times sweep across the face of the slope on which they are situated had to be guarded against, and Mr. Broome, drawing on the experience gained during the many years he was the leading gardening amateur in the Manchester district, and played a most important part in the affairs of the Manchester Botanical Society, met the difficulty by laying out a number of little gardens, each screened by planting shrubs of different kinds, growing tall enough to protect the flowers in each of the garden nooks.

Our illustration (fig. 26), from a photograph taken in the month of July, represents the central part of one of these nooks, the screen at the back being of dwarf Pines, which are

of Phloxes, Spanish Irises, Roses, &c., which were flowering in great profusion; and some of the gardens were edged with Phlox subulata, Lychnis viscaria splendens fl.-pl., and Pink Mrs. Sinkins. Some good plants specially satisfactory at Sunny Hill are Iris Susiana, I. Gatesii, Cheiranthus Marshalli, Cypripedium spectabile, C. parvidorum, Gentiana verna, G. septemfida cordifolia, Dianthus alpinus, Morisia hypogaea, Lychnis Lagasce, Sedum Ewersii, Chionodoxa sardensis, C. Lucillie, and C. Alleni. Violets also thrive in this garden, and Princess of Wales, Admiral Avellan, and Marie Louise are the favourite varieties.

Among "tender" plants which are grown outside as hardy plants are Francoa appendiculata, Agathæa cœlestis, Lilium Henryi, L. nepalense, Veronica Chathamica, Mesembryanthemum formosum, Gazania splendens, Lobelia cardinalis, Chrysanthemum frutescens, and a number of other subjects.

Mr. and Mrs. Broome take great interest in everything grown in their garden, noting the differences in the times of flowering of various plants in different years. Mr. Broome writes under date January 18:—"We are much later this year. Last year at this time Snowdrops were over with us; this season they are only just showing for bloom. At Christmas we had in bloom in the open garden several varieties of Chrysanthemums, Marie Louise Violets, and the Roses Distinction, Marie Van Houtte, Bouquet d'Or, Gloire de Dijon, and a few others; Cyclamen hederæfolium, Cytisus fragrans, Carnation Germania, Mignonette, and other things. At the present time in flower we have Iris stylosa, I. s. alba, I. s. speciosa, I. reticulata, I. r. Krelagei, I. Bakeriana, and I. histrioides, some of them just commencing; Eranthis hyemalis, Helleborus niger, H. n. major and varieties, Erica carnea, Garrya elliptica, Viburnum Tinus, Veronica linifolia, V. elliptica, Galanthus robustus, Jasminum nudiflorum, J. n. aureum, East Lothian Stocks, Petasites fragrans, Primula vulgaris cœrulea, Narcissus Bouquet; and coming into flower, Saxifraga Burseriana, S. oppositifolia major, alba, and varieties; Saxifraga sardica, Spiræa Thunbergi, Primula denticulata, and a number of other things."

FIG. 26.—A NOOK IN THE GARDENS, SUNNY HILL, LLANDUDNO.

All this, though not very original, or by any means a reliable recommendation for all to follow, is at any rate an expression of individual opinion, and more appropriate in a Garden Boke (as we are supposed to call this) than accounts of how "my lady sat and sipped—she has recently lost a molar, and so used her lips like a beak." Passages like these jar sadly. The character of Martha Corkle, strange name for a still stranger portrait of an English servant, must be purely fictional, the dialect of the woman being that of no known British county. If such a being appeared in England at all, she would be instantly known as an American. However, the Gardener's Boke will no doubt find admirers among her compatriots, and the pictures at any rate are faithful representations of beautiful scenes.

SUNNY HILL, LLANDUDNO.

We have on several occasions noted the excellence of the flowers grown in the gardens of Joseph Broome, Esq., both in the open and in the plant-houses, which, as is not uncommon in plants grown at the seaside, seem to be darker in tint and brighter in colour than

excellent as a protection against the wind, and also afford useful shade in summer. At the end of the walk is a fine bush of Crimson Rambler Rose; behind it Galega officinalis alba; to the left of the Crimson Rambler, and on the left and right of the picture, are large clumps of Erigeron speciosus superbus, a plant which is very showy, and lasts a considerable time in perfection. The other prominent plants in the picture are Montbretias, Dianthus multiflorus Napoleon III., and other mule Pinks; Spiræa filipendula flore-pleno, Campanula glomerata, C. rapunculoides, Anemone japonica alba, Alstromeria aurea, Geranium pratense flore-pleno, G. Armenum and other Geraniums, &c., the whole forming a dense mass of flower arranged by the hand of Nature, for each plant has been growing where it flowered.

A number of such pretty gardens as this go to make up the Sunny Hill garden. Each is different to the other in the nature and arrangement of its plants. At the season when the photograph was taken there were in other parts of the gardens plants of Chrysanthemum frutescens, which grows into great plants, and affords masses of white flowers, Campanula persicifolia alba, some of the newer varieties

LAW NOTES.

DELAY IN SUPPLYING A HEATING APPARATUS.

MESSRS. WM. COOPER, Limited, horticultural providers, Old Kent Road, S.E., were sued at Lambeth County Court, on Thursday, by Frederick Chas. Savage, of Queen's Row, Camberwell Gate, to recover £6 10s., money paid for a heating apparatus. Damages laid at £22 10s. were also claimed in respect to plants killed by frost in consequence of the apparatus not being supplied by the date agreed upon.

Plaintiff's case was that early in October he ordered a heating apparatus for his conservatory, and defendants specifically agreed to supply same within one week. On October 16 an order form was sent him which he filled up and returned with his cheque for £6 10s. The apparatus not coming to hand, he wrote on the 28th of the same month a letter of remonstrance but received no reply. On Nov. 15 he again wrote, stating that unless what he had ordered arrived within 4 days, he would have to get the apparatus elsewhere. On Nov. 25 he received a communication from defendants stating that the apparatus had at length come to hand. They regretted the delay, which they ascribed to the foundry

having been inundated with orders, and asked plaintiff to withdraw his cancellation.

Defendants relied upon the written order which specified no time within which the contract was to be executed, and denied that there had been any verbal agreement.

In the result, upon Judge Emden's suggestion, the case was settled by plaintiff agreeing to take £7 10s., which had been paid into court by defendants.

HOME CORRESPONDENCE.

SQUIRRELS.—On the Wednesday preceding Christmas, Mr. Tom Speedy, a well-known Scots naturalist, lectured on "The Squirrel" to an appreciative audience in Edinburgh. For the pretty little creature he had nothing good to say. It is stupid, and when it buries nuts does not always remember the locality of its hoard. It is dirty in person, and provides food, with a warm lodging, for a vast parasitic population. But these are merely personal characteristics, of interest to itself alone. When it caters for its own food, the outlook includes other interests of great importance. Its food consists usually of fruit, nuts, acorns, haws, fungi, the cones of Pine, the young shoots and bark of Conifers and other trees, toadstools, and birds' eggs. The damage effected by the squirrel on Pine woods in the north of Scotland is so great that on some estates, in order to get rid of the "plague," as much as one shilling is paid for every squirrel's tail. As many as 1,000 to 1,200 are killed annually on a single estate, yet their numbers are never lessened, and damage to the plantation is unabated. Exactly the same state of matters exists on south country estates, but the woods being of less extent less trouble is required to destroy them. The writer is aware of many young plantations, not only Larch, but pure Scots Fir, which have been completely ruined by visitations which lasted only a few days. Squirrels are extremely fond of Sycamores and true Planes, and peel great strips of bark off young trees up to 20 feet in height, while the young buds in early spring provide a favourite dish. During the past year, especially in summer and autumn, squirrels have been the cause of great loss in gardens. One gardener assured me they carried off a fine crop of Apricots in the course of a few days, almost before they were noticed. These trees are protected in spring with glass copings and movable blinds, and it may be said that every effort is made to secure good crops to be eaten by—squirrels! I have heard of several instances, too, where Pears, quite hard and only half-grown, had been carried off; of Peaches on walls denuded of the fruit before it was stoned, and many other instances of crops utterly ruined. It becomes a much more serious affair when it happens that squirrels are preserved, and the gardener is advised not to interfere with them. I have heard of a canny Scot who, placed under these very aggravating conditions, possessed himself of a birch-broom, with a handle longer than usual, and with that instrument "swept" his trees at the moment one of his foes happened to be intent on getting supplies! Squirrels are easily caught by means of ordinary rat-traps, placed on the top of walls, along which they may travel to reach the tree they visit. It is seldom indeed that a squirrel fails to go straight into a trap, and if it does swerve aside, the removal of the trap to another part of the wall is sufficient to cause it to forget its caution. I have known wire-netting, fixed at an angle of 45° on the top of a wall, and stretching over the fruit-tree, to prove an effective barrier, but in a big stretch of wall it becomes rather expensive. B.

CHESTNUTS AT WALWORTH CASTLE.—Referring to a letter I wrote you some time ago respecting the two Chestnut-trees at Walworth Castle, I can now send you the exact dimensions:—Distance between the trees, 15 yards;

the longest branch 100 feet from bole to point; total spread of branches for both trees, 2,480 square yards; height of trees, 85 feet and 90 feet; the girth of one tree at 3 feet from ground, 16 feet; of the other, 17 feet 6 inches. The girth at the place where the first branches break away is about double these figures. W. R. Innes Hopkins, per J. R. I. H.

LORD DYSART'S PROPOSED "PARK."—It is rather a bold description to refer to what Lord Dysart proposes to offer as a public place beside the River Thames at Ham, Surrey, as a park. His proposal, so far as the chief extent of the riverside frontage extending from Ham House to nearly the Kingston Borough boundary, is to set apart a frontage of 150 feet in depth which may be planted with low trees, and be maintained as a promenade. This would be about two miles in length. Beyond Ham House towards Richmond there is an area known as Petersham Meadows, over which the public have at present certain rights of way, and these meadows it is proposed to hand over to the Borough of Richmond as public land for all time. That the view from Richmond Hill, of which these meadows are in the foreground, be not marred, it is not intended to materially change their present pastoral aspect. In Kingston the Bill proposes to grant the borough a new recreation ground, a few acres in extent, on the Dysart estate, and on the northern boundary of the town. This land is almost close to Mr. J. Walker's market garden. The Bill proposes to hand over all manorial rights Lord Dysart may possess over that splendid open space Ham Common, to the Ham Parish Council absolutely. There lies between the common and Ham village, and the River Thames, a very extensive area of open or unfenced land called Lammas-land, over which certain inhabitants of Ham have during the winter what are called Lammas rights. The whole of the land is cultivated as market farms by various tenants in the summer, and as there is no pasture, the Lammas rights of the parishioners are worthless. These rights it is proposed for a sum of money to be paid to the Parish Council to cancel, and thus place this extensive area of land at Lord Dysart's disposal. At present this splendid riverside area often resembles a wilderness more than an open space. One or two indifferent paths traverse it, running to Teddington Lock, but as an open space this land is at present quite worthless. Were this Bill to pass, and the promenade of 150 feet wide made as is proposed literally from Kingston to Richmond, exclusive of the existing tow-path, it would form the finest riverside promenade on the Thames, and the gain to local as well as to town people would be immense. It is unfortunate for Ham, a small parish wedged in between Kingston and Richmond boroughs, that it is not a part of either of these towns, as at present the Bill proposes to place the maintenance of the proposed promenade on to the shoulders of that small parish. Were Ham a part of Kingston, as it should be, then the two boroughs named could come to an amicable arrangement to maintain the promenade, and enable the now worthless Lammas-land to become one of the finest of suburban building sites. A. D.

POPULAR AND STERLING VARIETIES OF PEAS.—In the editorial footnote appended to my note under the above heading, p. 32, it is stated: "We have always understood that nitrogenous manure is not of any special value to Peas, if it be not actually injurious." It would be interesting to know upon what grounds this understanding has been arrived at. The idea is not only new to me, but it is also absolutely contrary to all practical experience in the cultivation of the Pea in the manner indicated in my note. I should like to know what there is in nitrogenous manure, such as I referred to in my article, i.e., well decomposed stable-manure, when well incorporated with the soil in the process of trenching or digging to prevent Peas flourishing in ground thus prepared? The actual facts are

these: The roots of the plants push down into each succeeding layer of manure and soil after food and moisture. To be correct, the roots are allured downwards by nitrogenous influence to partake of the feast of congenial and sustaining (gaseous) food and moisture provided therein for their special benefit, and the ultimate reward of the cultivator in the way of securing prodigious crops of Peas of the best possible quality in every way—results which undoubtedly and most conclusively will go to show that nitrogenous manure applied to the ground in the way described at p. 32, is of "special value" to Peas, and that it most certainly is not "actually injurious" to them. As the editorial footnote might lead readers of the *Gardeners' Chronicle* inexperienced in the cultivation of the Pea to form a wrong opinion on the value of nitrogenous manure, this note is written with a view to prevent any wrong impressions being made in this direction. H. W. Ward.

ABNORMAL ORANGES.—Oranges from Aleira, a town in the south of Spain, are abundant in the market at present, and about 10 per cent. of the fruit have a second Orange inside the skin of the usual one. This malformation is of great interest, as illustrating the origin of the fruit from a branch bearing a whorl of leaves; the axis in this instance has not been content to bear one whorl, and has attempted to continue the process—but the arrestment of the axial growth has caused the larger fruit to enclose the smaller, very much as a fungus surrounds other objects by the rapidity of its cellular growth. The trade-mark of the brand of Orange in which this has been observed is a scythe, but the box contains a mixture of varieties; about 30 per cent. are seedless. The habit of producing a small Orange inside the larger one is also characteristic of the Ladoo Orange of the Deccan. Should the matter be of sufficient interest, I will be glad to send specimens of the fruit. G. M. W.

NITROGENOUS MANURES FOR PEAS.—The Editor's footnote to Mr. Ward's article on Pea-culture, p. 33, January 11, may probably open an interesting discussion on this question. I have tried nitrates on Peas, with kainit and phosphates, but the results were not satisfactory; possibly, the nitrates may not have been applied at the proper time. For some years past I have always, excepting the latest-sown Peas, used Thompson's Le Fruiter and Willis' manure; also on two or three occasions Fertilitas and Vine-border Compound, scattered along the drills when sowing the Peas, the results being heavy crops up to the end of June; after that date, the effect of these manures has not been so noticeable. This I have attributed to lack of moisture, though the mid-season and late Peas have been mulched with ordinary stable-manure. I also applied some of these manures to dwarf Beans last season, with satisfactory results. During a very interesting lecture given by Mr. Shrivell before the members of the Devon and Exeter Gardeners' Association, on Jan. 15, the lecturer stated that in conjunction with Dr. Bernard Dyer he had carried out some interesting experiments at Golden Green with fruit and vegetables; and for Broad and dwarf Beans he recommended 2 parts nitrates, 4 phosphates, and 1 of potash. The results obtained by the use of this mixture at Golden Green showed great increase in the various crops. I hope to use these manures during the coming season on both Peas and Beans, and will give you the results later if you care to have them. T. H. Slade. [Do, please. ED.]

CLEANING THE LEAVES OF ORCHIDS.—I was astonished to read the correction appended to Mr. Bound's Orchid Calendar of last week. My experience has been that amongst Orchids, as well as other plants, a cleaning of the leaves is necessary much more often than once a year. Even if the plants are not infested with scale or other insects, dust will accumulate on the foliage, which, if left untouched for a year, would be black with dirt, and

would be injurious to any kind of plant. I am unable to conceive any gardener letting an ordinary foliage plant alone for so long a period, to say nothing about Orchids, especially Cattleyas and Cypripediums, or anything grown in a house where much moisture is required, and where the foliage cannot be regularly syringed. No doubt many gardeners will comment upon the advice given, as such, if acted upon, would be in many cases disastrous. *B. Bowyer.*

ODONTOGLOSSUM WATTIANUM HARDYANUM.

—This plant has at last bloomed in Baron Schröder's collection, not having shown a spike since it was purchased by him at the "Owen" sale in April, 1895. The grand spike of 26 blooms, having 2 branches carrying 6 and 4, was exhibited at the Royal Horticultural Society on the 14th inst. I can now advert to the article in your issue of Oct. 20, 1900, p. 286, where you figure *Od. W. Crawshayanum*, and I gave its history as relevant to this particular variety. My deduction, that this var. is the product of *Lindleyanum* and *Harryanum*, as proved by my own plant raised at Rosefield, has now been questioned by two eminent Orchidists. To these and to all interested I will now give my reply in detail. I have paintings, lithograph, and dried blooms of *Wattianum*, *W. Crawshayanum*, and live bloom of *W. Hardyman* before me, hence the material is ample whereupon to come to a definite comparison. One objection raised was that the square lip of this var. could not be produced by *Lindleyanum*, but must come from *sceptum*. I contend that this is due to *Harryanum*, as proved by my variety having it, even with *Lindleyanum* as the female parent. *Lindleyanum* was also said not to grow with *Harryanum*. Mr. Claes stated last week to me that it does, for he has seen and collected them in company. Another suggestion was that *Od. nevadense* might be a parent of the form pictured in *Garden*, May 3, 1890, and *Reichenbachia*, II., i., pl. 9. This can be negatived by the fact that it grows far away to the north-east, and there is not a trace of any sort left of the extraordinary processes on the shoulders of its lip. One further objection was, that the immense branching spike and heavy, round form, coupled with such deep colouring, could hardly be produced with *Lindleyanum*. I reply to this that *Harryanum* was the female parent. With this condition the plant can easily be seen to be the result of *Harryanum* × *Lindleyanum*. My plant will prove this, for if it is so characteristic of *Harryanum* with it as the male parent, then necessarily *Od. W. Hardyman* must be much more so with it as the female parent, for *Lindleyanum* could hardly be expected to bequeath as much as half its appearance in a hybrid when crossed upon so much stronger species as is *Harryanum*; though constitutionally in cultivation, many people do not find it so robust as *Lindleyanum*. I think I have now most conclusively proved this disputed matter, and if anyone interested cares to see the material whereon I have my deductions and actual proof, I shall be pleased to show it them if they will take the trouble to come and see it. I may add that my plant promises a larger bulb than ever, and I have no doubt will in time show a branching spike as *Od. Harryanum* often does when strong. *De B. Crawshay.*

THE WET EGG.—An egg when it is laid is a wet egg (the shell is wet), and the longer you can keep an egg wet the fresher it will remain. This is a truth, expounded, I believe, for the first time, and has never before appeared in print. Why do we hear so much, especially through the winter months, about bad and stale eggs? We know that hens, with all their faults, never lay stale eggs; we also know, to our cost, that but few hens during the winter lay any eggs at all, good or bad! Then, where do we get our stale British eggs from? We stupidly make them stale by dry storing. If all British eggs were wet-stored the day they were laid, such a thing as a bad or even an indifferent egg would become a novelty, a

curiosity, instead of being an everyday article of commerce. We all know that an egg becomes stale by keeping; but, let me add, by improper keeping. If an egg is kept a week it is far from fresh, if kept a month it becomes very stale, even objectionable; if kept three or four months it becomes what is termed "the egg," "shop egg," "the foreigner," "not warranted," or, to be more precise, the bad or rotten egg! We all know what dry storing is, when we look at a lot of eggs in a shop window, or upon a shelf in the farmer's larder. Wet storing is the placing of eggs the day they are laid in water-glass, and leaving them there until they are sold or required for immediate use. It matters not whether they have been wet stored a week, a month, or even five or six months, they continue equally fresh, and always good alike. Surely this is a matter of some importance to the British farmer, the shopkeeper, and to every housekeeper. There is one way, and only one way, of forcing our farmers and shopkeepers to practice a little care and attention on the freshness of the eggs they supply. Let all housekeepers refuse to purchase British eggs from any shop unless they see them taken wet out of the preserving-pan, and let all shopkeepers refuse to take in farmers' eggs except with a guarantee that they have all been wet-stored the day they were collected from the nests. There is no more trouble to wet store than to dry store, the only difference being, placing the eggs in a dry box or basket in the one case, and into a bucket one-third filled with water-glass in the other instance. Where, then, is the extra labour? Lime-water has, for a century or more, been used in many private families as a preservative, but water-glass is far better. The American and our own agricultural experimental farms and colleges have conclusively proved that glass-preserved eggs, even after six months' storing, were as nearly equal to a "new laid" as a preserved egg can possibly be. Eggs kept in lime-water, after several months' immersion, are apt to partake of a limey flavour, and are only useful for kitchen purposes, but not for the egg-cup. I can speak personally as to the efficacy of water-glass, for I have just finished two nine-gallon barrels of eggs, which I so preserved last spring and summer. These eggs proved as sound and good as when I stored them nearly six months back; and, indeed, many of them when the top was removed, retained within that "milky" matter so characteristic of an egg taken straight from the nest. All foreign and imported eggs are of necessity more or less stale and of uncertain age, having been laid weeks and sometimes months before they reach our markets. But the foreigner is more alive to his own interests than we are, and already they are beginning to practice the wet storing in water-glass, and unless we mend our ways, the day is not far distant when the stale dry-stored egg will become the specialty of the British farmer and shopkeeper. It took twenty years before our farmers could be induced to adopt, even here and there, the Dutch factory system to secure a good butter of uniform quality; how many years will it take us before we shall trouble ourselves to preserve the freshness of our eggs? As water-glass is now an article of commerce, and quite cheap, let us hope that a jar of it may soon become a fixture in the larder or store-room of all householders in town and country who can appreciate a fresh egg in preference to a more or less stale or bad one. *K. B. Baghot-de-la-Bere, Burbage Hall, Leicestershire.*

THE SPREAD OF THE CODLIN-MOTH IN ENGLISH ORCHARDS.

—The very strong representations made to us by customers and others as to the enormous and annually increasing damage wrought by this insect to Apples in Britain has led us to investigate this subject, with the view of ascertaining either the cause of their rapid increase in numbers, means of stamping out the evil, or holding it in check. The life-history of the moth is now generally known, but we might repeat that, according to Miss Ormerod, it lays an egg in each fruit,

from this the caterpillar or maggot hatches, feeding on the fruit until October or November, when it emerges, and if in the orchard crawls up a tree, finds a crevice where it lodges, covers itself with a web, and in a few weeks passes into the chrysalis state, from which the moth comes in the following June. Now, as we have no method of successfully killing them while in the winged state, it follows that we must attack them while in the caterpillar or chrysalis stage. Our investigations show that while much still remains to be done by our nurserymen, gardeners, and growers, in the efficient winter washing of their fruit-trees, the tying of tarred bands round trunks, &c., the real reason of the rapid increase of this pest (which threatens the very existence of commercially successful Apple-growing in this country) is, we think, due to the wholesale importation of grub-infested Apples from the United States and Canada. Visits to our Manchester Smithfield Market during the past three months revealed a shocking state of affairs, and we are assured the same applies to all markets throughout this country, every barrel of American and Canadian Apples received during October and November swarmed with the Codlin maggot; on the casks being opened, the under side of the lid and topmost Apples were found to be covered with them. Of course, the market salesman promptly sweeps them anywhere out of his customers' sight, and they are then free to crawl into empty produce baskets, straw litter, &c., the result is that the caterpillars are thoroughly distributed all over the country through the medium of these empty baskets and market manure; but in addition, we believe that large numbers are also distributed with the Apples to the public during October and November, to ultimately find their way into every ashpit and manure-heap, where in its weakest stage it finds winter quarters, quite secure from grower's tarred bands, caustic washes, &c. We trust your readers will take up and thresh this matter out, so that this annual importation of a most injurious pest may be stopped before it is too late. We might add, that Tasmanian Apples are quite clear of the pest, and the Nova Scotian nearly so. *Exors., Robert Campbell, John D. Campbell, Manchester, January 11, 1902.*

HARDY CRINUMS.—During the past few months three articles upon Crinums have appeared in the *Gardeners' Chronicle*, the writers of which agree in considering *C. Moorei* and *C. Powellii* as the most ornamental species. *C. yemense*, appreciatively alluded to by Mr. G. B. Mallett, is however well worthy of being grown, and their varieties; since their many-flowered umbels have a very decorative effect, and they appear perfectly hardy, at the least, in the south-west. *C. Moorei*, according to Mr. Mallett, is more tender than *C. Powellii*, and "only thrives under the shelter of a heated wall." This is apparently not the opinion of Mr. J. O'Brien, as he speaks of *C. Moorei* as being "as hardy for the open garden as most of the other bulbs regarded as permanent garden-plants." Certainly in southern Devonshire a heated wall is unnecessary for its well-being, though I must say that I have never come across the 6 feet high flower-scapes spoken of by Mr. Mallett. One of the prettiest floral pictures of the late summer was provided by a large plantation of *C. Moorei* album, which is, I believe, synonymous with *C. Schmidtii* of the Continent, growing in a long bed at the foot of a lofty perpendicular cliff in the public gardens at Torquay. The site is absolutely sheltered from the north and east by the rock wall and is open to the south and west, and is thus particularly favoured climatically, a fact which is emphasised by *Plumbago capensis* passing through the winters unprotected and flowering annually, *Physianthus albens* and *Stauntonia latifolia* fruiting abundantly, and *Habrothamnus* often blooming as late as November. In this spot the great white flower-scapes showed their beauty, not by twos and threes, but by dozens, their pure colouring

being set off in the early autumn by the soft blue of a background of Plumbago. In other gardens this *Crinum* grows in the open border, and is never injured by frost. S. W. F.

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

JANUARY 14.—*Present*: Dr. M. C. Cooke in the chair; Rev. W. Wilks, Messrs. Geo. Gordon, J. W. Odell, C. S. Saunders, E. M. Holmes, G. S. Boulger, C. Bowles, Rev. Canon Ellacombe, Dr. Rendle, and Dr. Masters.

Cyclamens Discased.—Mr. A. J. REID sent corms, the roots of which were clubbed, as happens in Cabbages. On examination the appearances were seen to be due to the presence of Nematode-worms (Eel-worms).

Pelargonium Leaves.—From Mr. G. W. MURTRIE came leaves of *Pelargonium* in various stages of decay. Dr. Cooke, who has since carefully examined the leaves, reports as follows:—

"The leaves of *Pelargonium* were disfigured by large brown indeterminate blotches of dead tissue, which did not reveal any fungus mycelium when submitted to the microscope, and there was nothing local to account for the spotting. The whole appearance suggested at once to members of the Committee practically acquainted with *Pelargonium*-culture that the appearances were of the same character as are known to be caused by sour soil, and that the only remedy was to transplant into fresh soil at once. After twenty-four hours, the dead parts produced a plentiful crop of the common blue mould (*Penicillium glaucum*), which is a 'saprophyte,' and only occurs on dead matter as a consequence of decay, but is never productive of disease. M. C. C."

Arum corms.—Some corms of *Richardia africana* were shown, with here and there a patch of decayed tissue like a bruise. Dr. COOKE, who has examined the specimens since the meeting, reports as follows:—

"Both corms, otherwise of a healthy appearance, exhibited on one side an orbicular, brown diseased spot, about a quarter of an inch in diameter, entering the corm to nearly the same depth, surrounded by a paler ring exhibiting the spreading of the spot. The decayed matter from the spot showed no trace of mycelium, but was almost entirely composed of elliptical colonies of nearly globose hyaline bodies, about 3 to 4 micromillimetres in diameter, reminding one of the colonies found in *Lamprocytis*. I am therefore inclined to the belief that the disease is some obscure form of bacteriosis, hitherto undescribed."

Iris unguicularis.—Mr. BOWLES showed a ripe capsule of this species, which only occasionally ripens its seed-vessels.

BRISTOL & DISTRICT GARDENERS MUTUAL IMPROVEMENT.

UNDER the auspices of this Society an instructive lecture was given in St. John's Rooms, on Thursday evening last, by Mr. F. W. E. SHRIVELL, F.L.S., F.R.H.S., of Golden Green, Tonbridge, his subject being "Chemical Manure in the Kitchen and Fruit Garden," which was based upon the results of seven years' experimental work carried out in conjunction with Dr. Bernard Dyer, E.L.C., F.L.S., F.C.S. H. Cary Batten, Esq., J.P., President of the Association, presided over a good attendance, and was accompanied by Mrs. H. Cary Batten, who also takes a deep interest in the work of the Society.

The President, in introducing the lecturer, alluded to the great importance of the subject to the district where so much attention was devoted to agriculture and horticulture.

Mr. Shrivell, who illustrated his remarks by a series of diagrams, explained that for many years dung was the chief manure both for the farm and garden, but they were now trying by means of a series of experiments at Tonbridge, to discover whether it was better to use large quantities of dung, or to use a smaller quantity with chemical manure, or to use chemicals entirely. With regard to the system upon which their experiments were conducted, the land on which each vegetable or fruit was grown was divided into sections, each being in area a fiftieth of an acre. One section was manured with heavy dressing of dung; a second with light dressings of dung; a third with chemicals only; and the other three with a light dressing of dung, an ordinary dressing of phosphatic manure (either basic slag or superphosphate of lime) and varying quantities of nitrate of soda. Diagrams were shown, proving that after seven years' experiments, the best result was obtained by employing a

small quantity of dung with the use of chemical manures, this being specially noticeable in the case of Broccoli, Potatoes, &c. Nitrogen, phosphates and potash were the elements of farmyard-manure. The value of dung was that it was such a marvellous mechanical agent. On light, sandy soil, for instance, in dry weather it tended to keep moisture in the ground, and prevented evaporation. In the clay soils, it tended to lighten it and aërate it to a very considerable extent. That was the great advantage of farmyard manure, or what was ordinarily called dung; but it had a great disadvantage, and that was its cost.

Speaking with regard to fruit, the lecturer said experiments had been made by treating its culture in the same way as the vegetables were treated—heavy dressings of dung, light dressings of dung, plus chemicals, and chemicals alone. He had experimented on Gooseberries, Black Currants, Red Currants, Raspberries, and Plums with light dressings of dung, plus chemicals, and with chemicals alone, and adduced some interesting information upon the effects on the different fruits. For the purposes of bush fruits—Currants, Raspberries, Gooseberries, &c.—the quantities for 100 square yards (broadcast) should be 10 lb. superphosphate, 10 lb. kainit, to be applied during autumn or winter, and in early spring 7 lb. to 10 lb. of nitrate of soda. With regard to Strawberries, experiments showed that they could not grow Strawberries entirely by the aid of chemicals, but that with a light dressing of dung added to chemicals, they would be much more satisfactory to the grower. Chemical manures were also useful for the purposes of growing Onions, Beet, and Celery. With regard to the latter, he knew that most gardeners were much in favour of sewage, when they could obtain it; but he strongly advised them never to use sewage, for there was a great objection to its use in growing any vegetable that was eaten raw. Sewage should never be used for anything that was not cooked. By its use in this respect, they were apt to spread such diseases as typhoid and diphtheria. In the use of chemical manure for Celery, they would have to use discretion, but they would find that a small quantity judiciously used would ensure a splendid crop. Then again, they could make a good liquid-manure for Cucumbers and Melons. One ounce of nitrate of soda in a gallon of water used once or twice a week would considerably assist them in growing these. Chrysanthemums again were the most difficult plants to deal with; a light liquid-manure of half-ounce of nitrate to one gallon of water, might be used when the buds begin to form, but they should stop to use it when the buds began to break. In the kitchen garden, chemicals for 100 square yards, with half-a-load of farmyard manure, should be used thus: superphosphate 14 lb., kainit 10 lb. This should be dug in with the manure in autumn or early spring; and later on they should sow on the surface 10 lb. of nitrate of soda in two or more dressings. After referring to the dressings for herbaceous borders (basic slag 14 lb., kainit 8 lb., pricked in during autumn, and nitrate of soda 8 lb. in March and April to the 100 square yards), Mr. Shrivell spoke on another subject which he said was important, and especially to the professional gardeners. This was the subject of lawns. He knew that many gardeners were troubled with Daisies, and different weeds on lawns. He thought that wherever they had got a ground with a tremendous quantity of weed on it, that told the tale that the ground was really very poor. If he gave them something to make their lawns grow, they should not grumble at him if they had to cut the grass more often. There was a suggested dressing for a lawn of 100 square yards—14 lb. of basic slag with 9 lb. of kainit, and a later dressing of 5 lb. nitrate of soda. This combination was a plant food to produce the finer grasses and Clover, while it would do away with the Daisies and commoner weeds in a lawn. It did not follow if they put this on one year that they need put it on the next. The basic slag and kainit had a tendency to stimulate the growth of Clovers; and if they did not want Clovers, they must keep these two away; but if they wanted a little Clover or Trefoil, put it on. That would do away with the Daisies. Whenever they saw a meadow full of Daisies and Buttercups, they knew perfectly well that, as a rule, it was a poor meadow. They must use nitrate alone if they did not wish to grow Clover. His own feeling went to the balanced manure. It was very rarely that lawns had a dressing; the only thing they ever got was a little lawn manure, which was simply sand plus nitrogenous manure. The lecturer gave many other instances of the value of chemicals, and concluded his address amid applause.

FRENCH HORTICULTURAL OF LONDON.

JANUARY 18.—The thirteenth annual dinner of the above Society, which was held at the Imperial Restaurant, Strand, was one of the brightest and most successful of the series. Mr. Arnold Moss occupied the Chair, and was supported by a numerous company of members and friends.

The Chairman was in a peculiarly humorous vein throughout the whole proceedings. In his opening

remarks, he dwelt on the usefulness of the Society, and the great necessity of the two great nations being brought closely together in friendly intercourse, and felt sure that when many of the young friends then present returned to their homes in France, they would be able to assure their fellow countrymen that we in England only desired to live in peace and harmony with France. The health of the King, the Queen, and all the Royal Family, and that of the President of the French Republic, were then toasted with enthusiasm.

Mr. Geo. Schneider, in proposing the health of the Chairman, gave some interesting statistics of the Society, and reminded the company of the support the Society had received from English nurserymen and friends in this country, one of the earliest of whom was their present Chairman.

Mr. Moss replied, and said that the French Horticultural Society of London now consisted of 600 subscribers, and the income was rapidly increasing. He congratulated them on having a balance in hand of £140. He had much pleasure in asking them to drink to the continued prosperity of the Society, which helped many of them to feel at home although away from their native land. What we wanted was that they should enjoy themselves whilst here, work hard and take back happy recollections of their stay, and make their friends understand that we English are not exactly the savages some people represent us to be. The Chairman then paid a high tribute to Mr. Schneider for having brought the Society to its present high standing.

After Mr. Schneider's reply, Mr. Navel arose, in the name of the "membres titulaires," and presented him with a gold fountain pen in a case, as a mark of their esteem and affectionate regard for "Papa Schneider's" interest in his young compatriots.

CARDIFF AND COUNTY HORTICULTURAL.

JANUARY 17.—The annual general meeting of the society was held on the above date, when between forty and fifty members were present; Mr. JOHN GRIMES in the Chair.

The balance-sheet and statement of accounts for the past year were produced, and the report showed that the society was in a favourable position. The Mayor of Cardiff was elected President, Mr. A. M. Bailey, Chairman of Committee; and Dr. De Vere Hunt as Vice-Chairman. Mr. H. Gillett was re-elected Secretary, and Messrs. Boisford and Rees Jones were appointed to vacancies on the Executive Committee. The date of the annual show was fixed for July 23 and 24.

It was decided to affiliate the small societies in the Cardiff district. A trophy having a value of 15 guineas has been kindly given by the proprietors of the *Daily News* of Cardiff. The scheme of affiliation has been well received by the whole of the societies interested, and a very interesting competition is looked for. Last year the Committee inaugurated an art section (paintings and photography), embracing horticultural subjects, and the success attending their efforts were considered so good that it will be repeated this year.

Votes of thanks to the late President, the Marquis of Bute, closed the meeting.

BECKENHAM HORTICULTURAL.

JANUARY 17.—Mr. H. O. ETHERINGTON delivered a lecture on "Some Physiological Considerations of Plant Life," Mr. John R. Box in the chair. The lecturer explained the accepted fundamental principles of plant life, beginning with the single cell, with its power of division and adaptation to environment, its gradual development into the complex structure of plants, capable of assimilating carbon dioxide from the atmosphere, and with the aid of chlorophyll elaborating starch. The construction of cells, transpiration, with the cause and effect of the circulation of the sap, was illustrated by living specimens and diagrams on the black-board in such an interesting and simple way that the youngest could follow every stage of the marvellous developments of plant life.

At the close of the lecture questions were asked on "The cause of Vines bleeding throughout a cross-sectional cut," "Variation of cellular tissue in the structure of annual rings in forest trees," "The cause why Beans and Fops twine in opposite directions," "On some illusions of spectral analysis," "The cause of fairy rings in grass," "The construction and use of pith in trees," and "What is protoplasm?" The questions were promptly answered, but the last one defied all human effort to fathom, as a single cell of protoplasm was the beginning of life.

CHESTER PAXTON.

JANUARY 18.—At a meeting of this Society, held in the Grosvenor Museum on Saturday, January 18, under the presidency of Mr. N. F. Barnes, Eaton, Mr. E. STUBBS, Gardener, Bache Hall, read an interesting paper, entitled "The Culture of Chrysanthemums for Exhibition Purposes."

An interesting discussion followed, in which the Chairman, Mr. Lament, Mr. Wakefield, Mr. Ryder, Mr. Newstead, and others took part; and Mr. Stubbs answered several questions that were put to him.

A gratifying announcement was made by Captain MacGillcuddy, who was present, and who very kindly offered to present to the Society a challenge cup and money prizes for the best collection of plants of single-flowered varieties at the next exhibition. The Captain also said he felt sure the Society could organise a successful exhibition of spring flowers; and if this were undertaken, he would be pleased to lend it his support. Needless to say, these announcements were received with hearty applause; and in thanking Captain MacGillcuddy for his handsome offers, Mr. G. P. Miln said he felt sure the Society would in due time take full advantage of both.

LIVERPOOL HORTICULTURAL.

The fifteenth annual dinner and social evening was held at the "Bear's Paw" Restaurant on Saturday evening last. Mr. HENRY MIDDLEHURST presided over an attendance of about 150 members and friends, and was supported by Mr. A. W. Ker, Mr. T. Foster, Chairman of the Association, and Mr. Harold Sadler, Secretary. Amongst others noticed were Messrs. Webster (T. Davies & Co., Wavertree), Rowland Bros., West Derby; Charles A. Young, West Derby; B. W. Ker, F. Ker, H. Ranger, King, &c. (R. P. Ker & Sons, Aigburth); J. Finnigan (H. Middlehurst's), Mr. Guttridge (Wavertree Botanical Gardens), and a large number of the trade.

The dinner was admirably served, the usual loyal toasts following. The Chairman in proposing the toast of "Horticulture," dwelt on its progress, and especially on the capital work being promoted in the Liverpool district by the Parks and Gardens Committee, and by the Liverpool Horticultural Association. In responding for the latter Society, Mr. Foster spoke in the most hopeful terms, stating that things financial were in a much better condition—a remark that met with great applause from those present, and rightly so, for the work that has been done by the Association has, and does still appeal to gardeners throughout the kingdom.

Messrs. Ker & Sons decorated the room most lavishly, and to them and to Mr. Middlehurst the thanks of all present was due for other necessities which go to make up an evening's enjoyment. *Orchid.*

DEVON AND EXETER GARDENERS'.

The subject under treatment at the opening meeting of the session was "Chemical Manures, and their action on Bush and other Fruits, including Tomatoes, Grapes, &c."

The lecturer for the evening was Mr. F. W. E. SHRIVELL, of Tenbridge. He contended that in gardens there was generally too much stable-dung used, and too little, if any chemical manures; and that very much better results were attained by using a smaller quantity of dung, and adding chemical manures at the right time. For Currants, Raspberries, Gooseberries, &c., the quantities recommended per 100 square yards, sown broadcast, were 10 lb. superphosphate of lime and 10 lb. of kainit, applied separately during the late autumn or winter, and, early in spring 7 to 10 lb. nitrate of soda. To this might be added 25 loads of dung per acre, and this would form a liberal manuring for any ordinary garden soil. He qualified this advice as regards Strawberries, for experience had taught him that they did not like potash (kainit). For Cucumbers, he recommended applying once or twice a week a solution of 1 ounce of nitrate of soda to a gallon of water. For Chrysanthemums, half an ounce of nitrate of soda to a gallon of water was strong enough.

He gave a prescription for Vines which had proved to be a good one. It was: to each Vine, $\frac{1}{2}$ oz. of sulphate of potash, 2 oz. superphosphate of lime, and $\frac{3}{4}$ oz. nitrate of soda, to be applied at intervals, and in the order given.

An interesting conversation followed on the results attained by some of the members, who had been treating crops in the way recommended by Mr. Shrivell in former lectures to this Society, showing that the advice then given, and since acted on, had yielded the most favourable results.

The prize for the best three Onions shown at the meeting was awarded to Mr. W. R. Baker, gr. to Lady Duckworth, Knightleys, the specimens staged being Cranston's Excelsior, the three bulbs weighing $5\frac{1}{2}$ lbs. A. H.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

JANUARY 9.—There was a capital display of plants at the meeting held on this date. R. ASHWORTH, Esq., Newchurch, exhibited a large number of Odontoglossums, some choice varieties of *O. crispum* and natural hybrids being noticeable. *O. crispum* var. *Petersii* is a charming flower, but as shown it lacked size, and the Committee requested that the plant be shown again. *O. x "Lady Primrose"* is what some folk would

call *O. sulphureum*, a very nice lemon-yellow coloured flower, which received an Award of Merit. A form of *O. Wilkeanum* received a similar Award, as did also *O. crispum* var. *Francisii*. *O. crispum* magnificum received a First-class Certificate. Silver Medal for group.

R. TUNSTALL, Esq., Burnley, received an Award of Merit for *Odontoglossum crispum* var. *Reedleyense*, a fine spotted variety.

Mrs. GRATRIX exhibited a natural hybrid *Cypripedium* between *C. insigne* x *C. villosum*.

S. GRATRIX, Esq., Whalley Lodge, staged a large number of choice plants, of which the following were noticed by the Committee. *Cypripedium* x *Eurades* "West Point var.," First-class Certificate; *C. x Mons. de Carte*, First-class Certificate; *C. x Lathamianum giganteum* (a very noble variety), Award of Merit; *C. x nitens superbum* Gratrix's var., Award of Merit; *Cattleya Percivaliana* West Point var., Award of Merit.

A. WARBURTON, Esq., Haslingden, exhibited a well flowered plant of *Odontoglossum elegans* "Todd's var."

O. O. WRIGLEY, Esq., Bury, as usual staged a fine lot of *Cypripedes*, a First-class Certificate going to *C. x Mons. de Carte*; while Awards of Merit were voted to *C. x Lathamianum* Bridge Hall var., *C. x aureum* var. *Rogersii*, and *Cattleya Trianae* var. "Smiling Morn," a fine bold flower. Silver Medal for group.

Mr. R. JOHNSON exhibited *Cypripedium* x *giganteum* a well-named hybrid between *C. Lawrenceanum* x *C. Sallieri* var. *Hyeanum* (Award of Merit).

W. THOMPSON, Esq., Stone, had a few good plants, a First-class Certificate going to *Cypripedium* x *Stevensii*, a lovely hybrid between *C. Calypso* x *C. x Albert Hye*; it partakes freely of the former parent, and is a well-balanced flower, of rather large size. The same exhibitor received Awards of Merit for *Odontoglossum crispum* var. *giganteum*, *Laelio-Cattleya* x *Charlesworthii* (*L. cinnabarina* x *C. aurea*), one of the best and brightest of this section yet seen in Manchester; and *Cypripedium* x "Christopher" (*C. Lecanum giganteum* x *C. x Actæus*).

W. BOLTON, Esq., Warrington, exhibited a peculiar form of *Cypripedium* x *Ceres*.

E. ROGERSON, Esq., Didsbury, received an Award of Merit for *Cypripedium* x "Rivieri."

Messrs. F. SANDER & Co. staged a number of good hybrid *Cypripedes*, none of which however came under the Committee's notice.

JOHN COWAN & Co., Gateacre, staged a few good *Odontoglossums*, and received an Award of Merit for *O. Wilkeanum* var. *albens*.

Messrs. HUGH LOW & Co., Enfield, received Awards of Merit for *Cypripedium* x *Euryades* "Gow's var.," and for a hybrid between *C. callesum* x *C. Charlesworthii*, very rich in colour (Bronze Medal for group). P. W.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.

ANNUAL MEETING AND ELECTION OF PENSIONERS.

JANUARY 23.—While these pages are passing through the press, the supporters of this excellent Institution are assembled for the purpose of holding a special general meeting, followed by the sixty-third annual general meeting. The meetings took place at "Simpson's," Strand, and were well attended. Mr. Harry J. Veitch presided.

ALTERATIONS OF RULES.

At the special general meeting the chief business was the consideration of the Committee's proposals in respect to alterations and additions to the rules of the Institution. These were as follows:—

That from and after the registration of the amendments of the 5th and 10th Sub-sections of Rule III., the sub-sections as they now stand be hereby repealed, and the following rule substituted:

"All candidates eligible under Rule III., Sub-section 2, who have been annual subscribers, or the widows of such, shall be entitled to receive a certain number of votes in proportion to the number of years they have subscribed, that is to say:

"For each guinea subscribed for each year 100 votes, and in like manner the votes to be increased for each additional guinea per year subscribed.

All candidates who are or may become Life Members on payment of 10 Guineas, and who are eligible under the same Rule and Sub-section, or the widows of such, shall be entitled to receive 100 votes for each year of Life Membership, but such 100 votes per year shall not continue to be given for more than 10 years, being 1,000 votes for the 10 Guineas, and by payment of 20 Guineas be entitled to 200 votes per year not exceeding 10 years, being 2,000 votes for the 20 Guineas, and so on in proportion, but subject nevertheless to such other rules as apply to the election of pensioners.

Rule III., Sub-section 3.—After "total incapacity" in second line, insert the words "through accident or incurable disease." After "incapacity"

in fifth line, insert the words "from work at any age." After the word "certificate" in sixth line, insert the words "such certificate to be given when required by the Committee of the Institution by a Medical Officer to be appointed by them."

Rule III., Sub-section 11.—Substitute the words "List of Candidates" for "Pension List" in the sixth line.

Rule IV., Sub-section 2.—Strike out the words "one vote for each vacancy" in third, fourth, and seventh lines, and insert the words "five votes."

Rule IV., Sub-section 3.—Strike out the words "one vote for each Pensioner to be elected" in fourth and fifth lines, and insert the words "five votes at all elections of Pensioners."

Rule XIII., Sub-section 1.—Strike out the words "All Life Subscriptions received from those Members who may become eligible as Pensioners under Rule III., Sub-section 2 and."

ADD THE FOLLOWING NEW RULE:—

Rule III., Sub-section 10.—"After each election the Committee may if they think fit award Pensions to not more than two of the remaining unsuccessful candidates."

The Chairman and honorary Solicitor explained the reasons that led the Committee to recommend the alterations, which were supported by Messrs. Arthur Sutton, Geo. Monro, Owen Thomas, George Wythes, Peter Veitch, &c. The first amendment to Rule III. caused a little discussion, but was ultimately carried with but two dissentients. The other amendments were adopted unanimously.

THE ANNUAL REPORT, &c.

Mr. Harry J. Veitch opened the proceedings of the annual general meeting at 3 P.M. The report and balance-sheet of the Institution (as audited) for the year 1901, were adopted with general satisfaction. Officers were elected for the forthcoming year, and other routine business was done.

The Committee recommended that there be twenty new pensioners added to the fund, but in consequence of—

Barnard, John, Cheltenham, aged 64, life member for twenty-five years; Briggs, Alfred G., Reigate, aged 68, annual subscriber for fifteen years; Collins, John, Bristol, aged 59, annual subscriber for eighteen years, totally incapacitated through incurable disease; Dean, Emily E., Oxted, aged 61, widow, late husband annual subscriber and life member for twenty years; Derri-eutt, John, Penrith, aged 66, annual subscriber and life member for seventeen years; Gray, Mary A., Dorking, aged 65, widow, late husband life member for seventeen years; Harris, William, Bromley, aged 79, annual subscriber and life member for twenty-nine years; Long, William, Bristol, aged 67, annual subscriber for twenty years; Morris, Samuel, Burley, aged 67, annual subscriber for fourteen years and life member for twenty years; Mundell, John C., Ryde, aged 67, annual subscriber for twenty-one years; Sandford, Charles, Luton, aged 70, annual subscriber for twenty-four years; Taylor, Matilda, Worcester, aged 70, widow, late husband annual subscriber for twenty-five years; being in distressed circumstances, and having in every way complied with the regulations, the Committee, after investigation and careful consideration in each case, recommended that these twelve applicants be placed on the funds without election, in accordance with the present rules, and the recommendation was adopted.

The Committee also reported that during the year 1901, the following widows of pensioners have been placed on the funds without election, in accordance with Rule III. 13. Foulkes, Eliza, aged 27, Newcastle, Staff.; Parsons, Eliza, aged 79, Lewisham; Perkins, Mary, aged 81, Exeter.

ELECTED CANDIDATES.

An election for the remaining eight vacancies was then proceeded with, and the result is as follows:—

| | | | | |
|--------------------|-----|-----|------|--------|
| EDWIN ATKINS | ... | ... | 4735 | Votes. |
| JOHN WILDER | ... | ... | 4186 | " |
| RICHARD HUNT | ... | ... | 3917 | " |
| SAMUEL HICKS | ... | ... | 3677 | " |
| WILLIAM HERRINGTON | ... | ... | 3202 | " |
| GEORGE MARLOW | ... | ... | 2922 | " |
| ELIZA WIGHTON | ... | ... | 2872 | " |
| ELIZABETH BAXTER | ... | ... | 2711 | " |

There were twenty-five unsuccessful candidates.

In the evening the Annual Friendly Supper took place also at "Simpsons."

ANTS IN HOT-HOUSES: G. E. S. These pests of the gardener can be annihilated by using the Ballikrain Ant Destroyer, sold by Alexander Cross & Sons, Ltd., 19, Hope Street, Glasgow, who can, owing to the operation of the Pharmacy Act, only sell in bulk, which may mean in the case of this article in quantities of 1 gallon.

APPLE SHOOTS: W. T. Affected by *Nectria ditissima*; cut out affected branches and burn them. Spray the young shoots with Bordeaux Mixture.

BOOKS: H. P. and W. H. *Peach Culture*. Mr. Upcott Gill, Bazaar Office, 170, Strand, W.C., published a useful little manual on this subject, from the pen of the late D. T. Fish, which may still be procurable, though it is twenty years since it saw the light.—H. C. Mr. J. Douglas, Edenside, Great Bookham, Surrey, publishes a manual on the Carnation; and another on the Chrysanthemum may be obtained from Mr. E. Molyneux, Swanmore Park, Bishops Waltham.—*Gardening in the Tropics*: R. B. A useful book for a resident in New Guinea is *Tropical Gardening in British Guiana*, by John F. Waby, published by J. Thomson, Argosy Press, Demerara. The author, a gardener, was for many years a resident in Trinidad and Guiana.

CAUSTIC SODA-WASH AND PLUM-TREES: T. S. If employed at the strength given, and in the manner advised, it is harmless to the buds so long as these are closed, but it should not be applied after there are signs of a renewal of growth. The safest period yet remaining would not extend beyond February 14 in parts of the country south of the Humber.

CORRECTION: In Mr. Worsley's article, for fulvous read pulvovous; used as a synonym for pulverulent=dusty.

DENDROBIUMS AND ODONTOGLOSSUMS DENUDED OF THEIR FLOWERS: S. W. To remove the whole of the flowers before or as soon as they open would have the effect of imparting vigour to the plants, other things being equal; and if the plants are not flourishing, the effects are sure to lead to finer flowering and stronger growth the year afterwards.

EARTHWORMS AND SUBSOILS: *Weekly Reader*. Earthworms are not found in pure sand, swampy, or bog-earth, and not in any great number in hard, dry peat, resting on sterile gravel and sand; but in almost all other kinds of soils they exist in enormous numbers.

FUSICLADIUM: H. A. Rott. We cannot tell you which particular *Fusicladium* is meant by your Australian correspondent; probably it is *F. dendriticum*, which causes black patches of rust on the leaves and fruits of the Apple, killing the rind of the latter, causing it to crack. It is very common in this country.

GARDENERS ADVERTISING IN CANADIAN AND U.S.A. GARDENING JOURNALS: C. F. You might advertise in the *Canadian Horticulturist*, published at Grimsby, Ontario; the *American Florist*, 324, Dearborn Street, Chicago; *American Gardening*, 136, Liberty Street, New York; and *Florists' Review*, 520 to 535, Caxton Buildings, Chicago.

HOW TO MIX TAR AND CLAY FOR DRESSING VINES: J. B. The clay, which should be free from stones, should be dried, and then pulverised, added as powder to the tar, and well mixed together, water being afterwards added to bring it to the desired consistency.

MEDIUM FOR ADVERTISEMENTS: B. Wulf. *Cape of Good Hope Agricultural Journal* (official), and *Cape Times*.

MELONS IN A PEACH-HOUSE: H. P. The temperatures suitable for Peach-forcing are too low, generally by 10°, for successful Melon-growing; besides, the means of affording bottom-heat are lacking, and that is the chief point.

MUSHROOMS FAILING TO GROW SATISFACTORILY: G. P. S. The cellar seems a suitable place, but we incline to the belief that the temperature is kept too high; 58° to 60° is sufficiently warm at any season. The soil with which the bed is covered is not one calculated to produce good, fleshy, solid Mushrooms, and you should substitute a heavier one, or mix strong loam with that you are accustomed to employ. The beds must be made up of sufficient thickness—say, 2 feet—so as to be capable of retaining the inner warmth for two months, hence the stable-manure must be heated in a heap, which should be opened and turned and mixed together twice before it is made up into a bed. The bed must be put together piece-meal fashion and made firm as it rises. Spawn at 98°, and soil down soon afterwards. When the heat shows no signs of rising higher, cover the bed with mats and litter to conserve its warmth. Buy *Mushrooms for the Million*, by Mr. J. Wright, at the office of the *Journal of Horticulture*, Wine Office Chambers, Mitre Court, Fleet Street.

NAMES OF FRUITS: C. H. F. Your package, apparently posted on the 15th inst., only reached us on the 22nd inst., and without the label. The fruits are over-ripe, but No. 1 is clearly Glout Moreaux, and No. 4 probably a small fruit of *Ne Plus Meuris*.

NAMES OF PLANTS: Mrs. Ross. *Cypripedium* × *Measuresianum* (venustum × villosum).—A. E. W. 1, *Adiantum capillus-veneris* *Mariesii*; 2, *Adiantum Paotii*; 3, *Adiantum cuneatum* dissectum; 4, *Adiantum excisum*; 5, *Onychium japonicum*; 6, *Adiantum concinnum* latum, or a garden form of it.—J. R. A variety of Linden's *Hemantus mirabilis*.—Gen. L. Smith. The Cowslip Creeper of India is *Pergularia odoratissima*.

ORCHID INSECTS: W. H. D. The grub in the young shoot of *Cattleya* is that of a species of beetle not much unlike the grub of the *Dendrobium-beetle* (*Xyleborus perforatus*), but it is not apparently of this species. The spider got smashed in transit, and cannot be determined; it is quite harmless, however, and has nothing whatever to do with the presence of grubs in the Orchids. Your only remedy is to remove the grubs with the diseased shoots and destroy them. If you could send us one perfect beetle, we might be able to identify it for you.

REMOVAL OF VINE BARK: A. H. So long as only the rough outside loose bark is removed no harm is done, but the living bark below must not be disturbed.

SCALE ON PALM-LEAVES: C. B. *Ischnaspis filiformis*, the "blackthread scale" of Mr. Douglas (see Mr. Newstead's volume on Coccidae, mentioned in our present issue, Pl. xxvii., figs. 1 to 9, p. 210).

SPRINGY TURF AND LEAF-MOULD: *Weekly Reader*. Leaf-mould alone, or even when present in considerable proportion in the staple, does not tend to the making of a good lawn. The "good, sound, springy turf," concerning which you ask our advice, is due, when it is not caused by the growth of much moss among the grasses, to a very long-continued course of careful cultivation; to frequent top-dressings of manure, of soil, wood-ashes, &c., which by slow degrees raise the original level of the lawn, and bring about a vertical thickening of the mass of roots of the grasses and other herbage. Doubtless, much of the grass in old parks and gardens (the individual plants) is far older than the ancient Oaks and Chestnuts standing around. The mowing-machine, by its weight, is ruining the springy turf of our old gardens, and in other ways spoiling them. The most pleasant lawns upon which to walk are not those that are much rolled or machine-cut, or on which crowds of persons assemble, though this last, being at intervals only is not so detrimental; but those which contain quantities of the finest grasses, a large proportion of *Trifolium repens* and *T. minus*, and no coarse-growing species of

grasses, Plantains, Sow Thistles, Yarrow, Daisies, &c. We would not advise the use of a layer of coal-ashes under the turf, excepting for a lawn-tennis court, where a rapidly-drying surface may be a desirable object, as the ashes would have the effect of neutralising the action of the worms in bringing the subsoil to the surface in the form of excreta, but only for a time, for they would certainly burrow through it. If the land is wet, let it be well drained with tile and rubble drains combined, always the best kind of drain where trees exist, putting them in at 3 to 4 feet deep and 25 feet asunder, following the line of the slope if there be any. If there is an average thickness of soil of an ordinary kind, say, of light or heavy loam, or of marl or chalky clay or loam, let this be trenched or deeply dug; and if poor, manured with stable or farmyard dung. The staple, if it can be retained, is to be preferred to any artificial mixture. As regards your inquiry as to the use of lime or ferruginous sand as top-dressings, the former would benefit the grasses if the land is lacking in lime. It should be slaked before using, and preferably mixed with clean loam, and not with road-scrappings and ditch cleansings, although these may do as dressings for arable land, but they contain too many undesirable weed-seeds to fit them as dressings for a lawn. The sand would do no good. Unless an excessive quantity of manure is dug in before a lawn is made, it will not cause unsteadiness. It is not a good practice to lay a race-course up for hay. Sheep penning with roots and cake afforded in the early part of the season, and simple sheep grazing at other seasons are to be preferred.

SLEEPERS OF WEST AUSTRALIAN RAILWAYS: C. These are constructed of "Karri" and of "Jarrah." Karri is yielded by *Eucalyptus diversicolor*, Jarrah by *E. marginata*. See Von Mueller's *Eucalyptographia*, M.

THE USE OF CLAY VINE DRESSINGS: A. H. It has two valuable uses: it gives an adhering and smothering character to the dressing of which it forms part, killing insects by preventing respiration; and it is a vehicle for the retention of pungent odours, as when it is used in conjunction with gas-tar. When used along with sulphur, lime, and soft-soap, as a dressing on Peach-trees infested with scale-insects, its value lies chiefly in its adhesive smothering nature; and when it at length falls off or is removed by the syringe, the scale being dead comes away with it, and the bark is left clean and bright.

XL-ALL LIQUID AS A VINE DRESSING: A. H. We have no experience of the liquid, and should be glad to have that of any gardeners who have used it against mealy-bug, scale, &c., on the Grape-vine. There is no infallible antidote for insect pests, but the gardener must be ever up and doing.

Continued Increase in the Circulation of the "GARDENERS' CHRONICLE."

IMPORTANT TO ADVERTISERS.—The Publisher has the satisfaction of announcing that the circulation of the "Gardeners' Chronicle" has, since the reduction in the price of the paper, more than

TREBLED.

Advertisers are reminded that the "Chronicle" circulates among COUNTRY GENTLEMEN, and ALL CLASSES OF GARDENERS and GARDEN-LOVERS at home, that it has a specially large FOREIGN and COLONIAL CIRCULATION, and that it is preserved for reference in all the principal Libraries.

(For Markets and Weather, see p. x.)

WHAT IS THE BACHELOR'S BUTTON?

MOST people would say, and without hesitation, the double-flowering *Ranunculus acris*, and it might be a surprise to them to be assured that this plant is only one of the many that at some time or other has had that quaint designation bestowed upon it. [See Britten and Holland, *Dictionary of Plant Names*, 1886]. Still greater would be their surprise if it could be shown that this double Buttercup possesses a very slight claim to the name, a claim depending almost entirely on its being so designated by the compiler of *The New Herbal* in 1578, and after a lengthened abeyance, in having its claims revived in these latter days. The name with its meaning has become somewhat involved, so, in order to add to the lucidity of what follows, it will be necessary to pursue it down the centuries, but in the pursuit I shall endeavour to be as rapid as possible, and therefore brief; first explaining, however, that "Bachelor's Buttons" very frequently occur in Garden Literature, and most often as a name complete in itself.

Exactly twenty-one years after the date above-mentioned, Gerarde in *The Herbal*, that chattiest of books, tells us that the double form of *Ranunculus bulbosus* "is called generally about London Batchelours Buttons." This plant has become very scarce, but the single form is not uncommon as a weed. The root, from its shape, has been called St. Anthony's Turnip, and possesses a sap so acrid, that for centuries it has been chosen by able-bodied beggars as the best medium to apply to leg or arm to produce those horrible blisters that appeal so strongly to the simple-minded. Gerarde also adds *R. aconitifolius* fl.-pl., grown in gardens commonly as "Fair Maid of France," though erroneously, the single-flowered form being the "Fair Maid." It is

she who figures with "Cockle-shells and Silver Bells" in *Mistress Mary's Garden*. Johnson, in the 1633 edition of *Gerarde*, introduces the double red and the double white Campion, as well as a sort with greenish flowers, as Bachelor's Buttons, and says, no doubt in all sincerity—"The similitude that these floures have to the jagged cloath-buttons anciently worne in this kingdome gave occasion to our gentlewomen and other lovers of floures in these times to call them Batcheloure Buttons." Johnson's reason has, consciously or unconsciously, appealed to most people since as one worthy of all acceptance.

Four years previously, John Parkinson, that ever delightful writer on flowers, admits into his *Garden of Pleasant Flowers* two plants which he calls Bachelor's Buttons, the one *Ranunculus bulbosus*, and the other the double Mock Marigold; while in his *Theatrum Botanicum*, the double white Campion receives that designation. Then there elapsed the wide space of a hundred years, when *Centaurea montana* was added to the number; and during the succeeding hundred years several more plants acquired the name, e.g., the common red and white Campion, so pretty and sweet during summer in open woods; the double Ragged Robin, double Sneezewort (*Achillea ptarmica* fl.-pl.), while *Ranunculus acris* reappears after its long eclipse.

During last century nothing novel concerning the plant appeared in gardening books, but the unremitting attention bestowed on folk-lore in all its branches has brought to light several plants not hitherto known to have been called Bachelor's Buttons. Thus in Devonshire and in South-west Scotland there is the Burdock; in Wilts and Somerset, *Scabiosa succisa*; in various districts in the South-west of England, Feverfew; the leaves of Navelwort; Herb Robert, which is called "little Bachelor's Buttons"; and Knapweed, or *Centaurea Jacea*. Daisies and Pompon Chrysanthemums have also been thus named, so that no fewer than twenty plants aspire to a designation at first sight so meaningless. I have already quoted a reason for the name, and it is only fair to say there are other Buttons with distinctive appellations, instances of which are Barbary Buttons, Cockle Buttons, and Soldiers' Buttons. It is therefore no ways singular that there should be a Bachelor's Button, though strange that so many plants should bear the name. Johnson has supplied a reason, but an incomplete one. Numerous instances occur of writers of the Shakesperian era using the word, with which it may be assumed Johnson was acquainted. A few are as follows: "I'll weare my bachelor's buttons still," says one. "He weares bachelor's buttons does he not?" queries another. "I am a bachelor," asserts one swain, "I pray you let me be one of your buttons still then;" and, "Here's my husband and no bachelor's buttons are at his doublet," exclaims a wife. Unfortunately in most cases the Bachelor's Buttons are mentioned along with that redundancy of indelicate allusion which is so marked a feature of the period. Shakespeare himself alludes to the same custom in *Merry Wives*, where Mine Host of The Garter declares his belief in the ultimate success of Fenton in his pursuit of Anne Page, because, with other pregnant signs, "'tis in his buttons." It is clear

that, whatever the flower, it must have been carried openly, because in one instance they are mentioned as having been carried in the doublet. Girls also are said to have carried them under their aprons. One of the numerous commentators of Shakespeare in the eighteenth century, when his every word was analysed and criticised, put the question in a new light. Alluding to the remark, "'tis in his buttons," he observes, "It was an old custom among the country fellows of trying whether they should succeed with their mistresses, by carrying the Bachelor's Buttons (a plant of the *Lychnis* kind, whose flower resembles a coat-button) in their pockets, and they judged of their good or bad success by their growing or their not growing there." From what we know of the flowers of any *Lychnis*, we should expect nothing but "bad success" to follow a trial of this kind. But the quotation is interesting as showing that bachelor's desirous of assuming the role of Benedict, the married man, did resort to a mild sort of necromancy, in which the Bachelor's Button played an important part. The custom hinted at above existed till quite a late period in some parts of the West of England, and earlier it would almost certainly extend to many parts of Great Britain. Flowers were without a doubt cut off the living plant, and placed in the pocket with an expectation that growth would follow; but it requires but a slight knowledge of our native flora to be aware that only plants like the Burdock and Knapweed are capable of producing florets after the flowers have been decapitated. The method used in the South-west of England consisted in selecting three forward buds of Knapweed, out of which the florets were extracted. The empty "buttons" were then placed in the pocket of the person interested, and removed at a set time, the growth of florets meanwhile indicating a result favourable to his desires, non-growth the opposite.

It is an interesting fact that a somewhat similar custom existed in Scotland, but the plant in this case was called a carl-doddie, the florets being stripped off, and as girls only used this charm, they named each of the three flower-heads after one of their male friends. Placing the carl-doddies together in her left shoe, the experimenter then placed the latter under her pillow and slept on it for a night: the flower-head that made growth showing the man who should marry her. The word, it may be briefly explained, is "carl," a man, and "doddie," any living thing with a smooth head—as, for instance, a cow without horns is a "doddie." Perhaps a "cropt man" may be a good English equivalent. By all good writers who know Scots' "*Plantago lanceolata*" it is thought to be the "carl-doddie," but *Lilium pomponium*, curled Kale, White and Red Clover, and by Scott in *Border Minstrelsy* a "marsh" plant, have been named. The word is a very old one. I have seen it in a manuscript note of a contemporary date in Lyte's *Herbal*, where *Scabiosa*, in which *Centaurea Jacea* is included, are indicated as carl-doddies. It is not without interest that the same plant used by a male to afford him knowledge in his wooing, and called Bachelor's Buttons, should also be called carl-doddie, a plant which was used for exactly the same purpose, and in nearly the same manner, by the opposite sex. B.

ORCHID NOTES AND GLEANINGS.

LÆLIO-CATTLEYA × BOWRIALBIDA.

The issue of *American Gardening*, January 4, 1902, records the production of this interesting hybrid between *Cattleya Bowringiana* and *Lælia albida*, raised and flowered by Mr. E. O. Orpet, of South Lancaster, Mass. The plant, which is stated to be intermediate in character between the parents, has pseudo-bulbs resembling those of *L. albida*, but much more elongated. The flowers are larger than those of *L. albida*, and of a delicate lilac-red colour; the lip bordered with a deeper shade of the same colour. Its flowers are at present sparsely produced on peduncles 9 inches in length, but when the plant has gained strength the size and number of its flowers will doubtless improve.

ZYGOPETALUM MURRAYANUM.

This rare Brazilian species has recently flowered in the Orchid-houses of J. Wilson Potter, Esq., Elmwood, Park Hill Road, Croydon. The habit of the plant is similar to that of *Zygopetalum crinitum*, and the inflorescence is erect as in that species. The flowers, which measure $1\frac{1}{2}$ inch across, commence within 2 inches or so of the base of the spike. The sepals and petals are of a pea-green tinge; the lip is white, and furnished with a few purple lines at the base. The plant thrives in the *Cattleya*-house, and appears to be very free-growing, and an easy one to flower. It was figured in the *Bot. Mag.*, t. 3674. It flowered also in the Royal Botanic Gardens, Glasnevin, in January, 1900.

LÆLIO-CATTLEYA × LUCY INGRAM.

This beautiful winter-flowering hybrid between *L. purpurata* and *L. Perrini*, raised by Mr. T. W. Bond, gr. to C. L. N. Ingram, Esq., Elstead House, Godalming, is again in flower there. Its flowers are like those of a good *Lælia purpurata*, but with a labellum of the beautiful colour and form of that of *L. Perrini*, though much larger. The flower expands to a width of 7 inches; the sepals and petals are white, the former tinged and the latter veined with rose. The lip in the tube is white, and the fronts of the side lobe and the middle lobe of a rich claret-purple. It is interesting to note the alteration in the time of flowering made by hybridising. In the case of the *Lælia Perrini* varieties (not hybrids), the certificated plants have been shown from the first week in October to the first week in November; the numerous varieties of *Lælia purpurata* in May and June, with the single exception of *L. p. Mrs. R. I. Measures*, which was shown in October. The hybrid between the two, *L. × Lucy Ingram*, received an Award of Merit on January 12, 1897, and it has since regularly flowered in the month of January. The many beautiful hybrid *Lælio-Cattleyas* raised by Messrs. J. Veitch & Sons also follow the same rule, i.e., by crossing *Lælia Perrini* with earlier flowering species, the time of flowering of the progeny comes later, that is more in the depth of winter than that of *L. Perrini*, although the time of flowering of that species forms the basis. The result is much the same in the crosses obtained from the late flowering *Cattleya labiata*, the hybrids flowering in the middle of November. *Lælia × Pileheriana* (erispa × *Perrini*), however, is spring-flowering, probably because the seed-bearer was the summer-flowering *L. erispa*.

CATTLEYA × VICEROY (LABIATA × BRYMERIANA).

This somewhat showy hybrid, raised by Messrs. F. Sander & Co., has flowered simultaneously with Sir James Miller, Bart. (gr., Mr. J. Hamilton), and Sir Frederick Wigan,

Bart. The flower, which is nearly equal in size to an ordinary *Cattleya labiata*, but with a much firmer substance, gives stronger indications of that species than of *C. × Brymeriana*. But examination of the lip with the side lobes turned back clearly discloses traces of both *C. superba* and *C. Eldorado*, the parents of *C. × Brymeriana*, in the orange coloured base with a band of dark reddish-purple extending up the middle, and merging into the bright crimson-purple front lobe. The sepals are creamy-white, tinged with rosy-lilac; the petals rosy-lilac, with a more purple shade on the veining. The lip, which calls to mind that of *Cattleya Percivaliana*, is yellow at the base, with a red-purple band up the middle. The front of the lip is bright crimson-purple, with a narrow rose margin.

MILTONIA ROEZLII VARIETIES.

This fine species, which many fail to grow successfully, thrives admirably in the collection of Sir Frederick Wigan, Bart., Clare Lawn, East Sheen (gr., Mr. W. H. Young), in a house kept at an even degree of warmth. That these varieties do thrive is indicated by the fact of the flowers having improved each year. At the present time some individuals of an importation received in 1896 are in flower, some of which are of extraordinary size and colour; while all of them are larger than the average. The best form of *M. Roezlii alba* has flowers over 4 inches each way, thus forming an almost perfect circle. The petals are $1\frac{1}{4}$ inch wide, and the lip $2\frac{1}{2}$ inches; the whole flower pure white, with a yellow disc with orange lines at the base of the lip. The coloured variety is nearly as large, the colour being the same tint, with a large claret-purple blotch at the base of each petal. Both are very fragrant. J. O'B.

FLORISTS' FLOWERS.

WINTER-FLOWERING CARNATIONS.

THOSE plants which flowered in autumn and mid-winter are now producing numerous side-shoots suitable for the making of cuttings, and the propagation of plants to flower next autumn should not be delayed. The shoots should measure 4 inches in length, and should not be very soft. Place the cuttings in small pots or shallow pans filled with a light, sandy soil, and sink in the plunging-bed of a dung-heated frame, and keep close and fairly moist, admitting air daily in small quantities for half-an-hour.

When the cuttings begin to grow, roots will have already formed, and the cuttings may soon afterwards be placed on a shelf near the glass in an intermediate-house, and gradually inured to the air and light. In a month, pot them off singly in 60's, using a fairly light soil, and replace the plants on the shelf and freely ventilate the house on favourable occasions. When the roots touch the sides of the pots, shift them into $4\frac{1}{2}$ -inch pots, and keep them in a house having a temperature of 55° to 60°, affording abundance of air as the season advances. They may be grown in a lower temperature, but growth will be slower, and to flower the plants early in the autumn they must be kept freely growing. A suitable compost for them after the first potting consists of good turfy loam three-quarters, leaf-mould one-quarter, together with a good addition of silver-sand or mortar-rubble, and a small quantity of soot. Ordinary manure should not be used, but a suitable artificial fertiliser should be mixed with the soil. After making a trial of several manures, I find Willis's "Carnation Manure" gives the best results when used at the rate

of $\frac{1}{2}$ lb. to 1 bush, of the potting soil. When the flower-buds begin to show, apply it in water at the rate of 1 oz. to 1 gall. of water, stirring it well before using. An application of this manure should be followed by one of clear water, when the plants require water. This manure promotes a firm, sturdy growth, and the grass assumes that glaucous hue characteristic of robust health. During the summer, stand the plants in an open position on a bed of coal-ashes; lightly dew the foliage after a hot day, but make provision for shielding them from heavy rains in the autumn. To flower them during the winter the plants should be placed in a light, airy house near the glass, and afforded a temperature of 55° to 60°, with abundance of air at all times. Of the so-called winter-flowering varieties there are many, but kinds that may be relied upon to flower well in mid-winter, may almost be counted on the fingers of one hand. I have found none to equal a variety named C. A. Dana, in colour rose-pink, calyx perfect, with long stalks from which blooms may always be gathered, while the habit is all that can be desired; it is an effective colour under artificial light. Mrs. Leopold Rothschild is a well-known capital variety, but would be still more valued if it was a better bloomer in the winter. Pride of the Market is said to be the best pink-coloured Carnation for winter flowering, and it is certainly a very promising variety; in colour a soft clear pink, calyx good, but subject to rust. Pride of Exmouth is of a salmon-pink tint, with a calyx which does not split, and it possesses stiff stems. Queen of Pinks is of the same tint as Dana, but the flower has rounder petals, which have a little more substance; a sturdy grower, and calyx that does not burst.

Of yellow-ground Carnations generally there are but few that are suitable for winter work, and the best two that of which I know anything are Jessie Godfrey, an improvement on Lady Doreen Long. Lady Poltimore is another variety that is of compact growth, has a good calyx, and the blooms open well in the winter. Of scarlets, Vicar of Exmouth is good; Winter Cheer is still hard to beat. W. Robinson is good at times; while Sir Redvers Buller, sent out as the best scarlet for winter flowering, has unfortunately not proved its worth with me. Novel in colour is Lady Audrey Buller, a satiny mauve, shaded with plum colour, and a rather tall grower. A fine crimson is King Edward VII., a good grower, nicely shaped bloom, clove scented, and good calyx; this should prove a good addition to this class of whites. Flora Hill is free, and usually affords some good flowers which are fragrant, but the petals are flimsy, while it is too tall a grower. Deutsche Brant is a very sweet-scented flower, but it bursts badly, and is an indifferent grower. A very promising white is Mrs. S. J. Brookes, the blooms having smooth, stout petals, a good calyx, while the habit is as good as can be. Then there are America, a very promising variety; also Mrs. T. W. Lawson, of sturdy habit, the blooms opening well in the winter; the stems are long and strong, and the blooms of good size; the colour is very bright, particularly under artificial light—it lacks refinement, but is nevertheless an acquisition. There is yet room for a good winter-flowering yellow Carnation. Primrose Day nor yet Duchess Consuelo can be said to be good for the purpose, though they will at intervals furnish a few nice flowers.

For giving support to the plants and flower-stems there is nothing better than the coil stakes, which are neat in appearance, of a pleasant green hue, and very durable; and as the shoots can be placed in the coils without any tying, there is a considerable saving in labour. T. H. Slade.

LÆLIA ANCEPS CHAMBERLAINIANA.

OUR illustration (fig. 27), which our artist has verified by measurement of the flower, represents the finest form of what is known in gardens as the "grandiflora" section of *Lælia anceps*, which originated some years ago in the gardens of the Right Honourable Joseph Chamberlain, Highbury, Moor Green, Birmingham, from whose collection we have remarked

De B. Crawshay, Esq., Rosefield, Sevenoaks (gr., Mr. Stables), at the Royal Horticultural Society's meeting on January 14, when it was awarded a First-class Certificate, and afforded us the opportunity to obtain an illustration.

BUENOS AYRES.

THOUGH I was unable to land at Rio Janeiro on my way to Chile, and so lost my chance of visiting the celebrated Botanic Gardens there,

cities of Europe in the cleanliness of its streets, the number and beauty of its public squares, gardens, and boulevards, most of which have, I believe, been planted by Mr. Thays.

I was surprised to find that though several species of Palm grow well in this climate, the Oriental Plane is the best shade tree in the town, whilst outside it Australian trees, such as *Eucalypti* and *Casuarinas*, grow so fast that there are already many of 10 to 12 feet in circumference, and they are rapidly altering the

FIG. 27.—LÆLIA ANCEPS CHAMBERLAINIANA.

on it on several occasions. It gives a striking proof that extraordinary qualities of size and colour are maintained, for it has varied but slightly in either since its first appearance. The sepals and petals are of a soft rosy-lilac colour. The base and side lobes of the lip are marked with purple lines, the middle lines being continued by the orange-coloured callus. The front lobe of the lip is of a glowing crimson-purple, and the whole flower of very fine form and substance. It was shown by

I was much pleased to find at Buenos Ayres a garden which, though only formed about six years, has already a most interesting collection of plants, and, under the very able management of Mr. Charles Thays, the director, is likely to become one of the first in South America. This gentleman appears to combine scientific knowledge with good taste and judgment, and has been well supported by the municipality of Buenos Ayres, a town which is already far superior to many of the capital

features of the country round Buenos Ayres, which has very few indigenous trees.

The Botanic Garden, though not large, is nicely laid out, and the soil, naturally sandy, has been improved by the addition of much vegetable mould. Its principal feature is the way in which the indigenous trees and shrubs of the various provinces of Argentina, from the subtropical regions of Tucuman, Catamarca, and Misiones, in the north, to the arid wastes of Patagonia in the south, have been grouped

in separate divisions. Besides this national collection, there is a good selection of the trees and shrubs of North America, Europe, and Asia, arranged geographically, and a considerable collection of plants and shrubs arranged in their natural orders for the use of botanical students. Among the trees which struck me most by their beauty was *Tipuana speciosa*, Benth., a very handsome flowering tree from the north of Argentina, which attains large dimensions. It has been the subject of a special article by Mr. Thays in the *Revue Horticole* (1892, p. 462), and the seeds have been freely distributed by him in Algeria and the South of Europe, where it is hardy. *Juglans australis* is a fine native Walnut, which I had not previously seen, and which would also be probably hardy in South Europe. Another striking small tree or shrub is *Boeonia frutescens*, which has very handsome pinnate leaves, so unlike those of *Boeonia cordata* that I could hardly believe it to be congeneric.

Poinciana Gilliesii is one of the characteristic shrubs of the country, and seems to grow over a large area, as I saw it in the pampas near San Luis. *Habenaria montevidensis* is one of the few terrestrial Orchids of the country, and seems a very robust and free-growing plant. *Bromelia sceptrum* is a striking plant, which might be tried out-of-doors in the South of England; as well as *Dyckia aurantiaca*, which was new to me. *Parkinsonia aculeata* is a very pretty Argentine shrub that I do not remember to have seen in Europe; and *Bauhinia candicans*, *Daubentonia Tripetii* (Sesbania), and (I will not be sure of this name, or of the next) *Pithecoctenium convolutum* [?] are all deserving of cultivation in any situation not liable to more than 6° to 8° of frost.

I saw among the Iridaceous plants two which were new to me, and both were worth growing—*Cypella Herberti*, a bulb which I also found wild near the town; and *Sisyrhynchium convolutum*, a robust, tufted herbaceous plant, with good-sized yellow flowers, said to come from Patagonia, and probably hardy in England.

Mr. Thays published a long list of seeds which have been grown in his garden, and which is well worth consulting by those who are interested in the native plants; and I wish him every success in his labours, which must greatly benefit his adopted country. *H. J. Elwes.*

CINERARIAS IN THE OPEN BORDER.

It is not often one can see between 300 and 400 *Cinerarias* planted for flowering in the open border, but having planted that number last May, and enjoying the effect it has since produced, it is quite evident to me that many of our north wall borders can be made to produce an effect seldom seen, and quite different from the usual style of border flower gardening. The somewhat heavy appearance of the *Cinerarias* was relieved by introducing *Humea elegans* and *Grevillea robusta* in an irregular manner about the border, these two contrasting well with the foliage and habit of the *Cinerarias*. The forms used were of the florist's type, *C. stellata* and *C. cruenta*, and by mixing them the flatness of the whole was broken up; *C. cruenta* being the tallest, *C. stellata* of medium height, and the florist's type the dwarfest. No special treatment of the soil is called for beyond digging and manuring. The seeds should be sown in pans in January, and when the first rough leaf has expanded they should be transferred singly into small 60-sized pots, and placed on a shelf in the greenhouse, or in a frame where they

get plenty of light and a fair amount of air. The seedlings soon make sturdy little plants, and in a few weeks are ready to be potted into 48-size pots, from whence they are to be planted out in the border. During the months of March, April, and the beginning of May, no place suits *Cinerarias* better than cold frames or pits, where the minimum temperature is not less than 40°, and the maximum 50°. Should the highest allowable temperature be approached, the lights must be pulled off the frames. Warm rains do the plants much good, and assist in keeping them free from aphids.

No fear need be entertained about the plants getting too much moisture at the root, a sturdily grown *Cineraria* having its foliage so arranged as to throw off much of the rain falling upon it. Some of the plants thus treated (of the *cruenta* and *stellata* type) will make panicles of flowers nearly a yard through, and the hybrid or florist's section the same size in proportion. The frost of October 26 and 27 last apparently did not hurt our plants, owing to the protection afforded by overhanging trees, so that on November 1 they were affording a wealth of colour in spite of heavy rain and dense fogs.

A few of the plants that were for some unexplainable reason very late, were carefully transferred to pots, kept close, and quite cool. These gave a good display in the conservatory far into the winter. These plants have practically given no trouble, beyond the potting-up, and an occasional application of water during the summer—a contrast to the tedious everyday attendance needed by *Cinerarias* when grown in pots. *J. W. Miles, Isleworth.*

BOOK NOTICE.

MONOGRAPHIE DER GATTUNG SORBUS. Von T. Hedlund (Stockholm, 1901).

IN this work of 145 quarto pages the author has given a careful classification of the genus *Sorbus*, under which he includes as sections, *Cornus*, *Aucuparia*, *Aria*, *Torminaria*, *Chamaemespilus* and *Aronia*. He enumerates 55 species, and many forms and hybrids. All the species mentioned by him are included by many authorities under the genus *Pyrus*, but *P. alnifolia*—a Japanese species recently introduced to British gardens—is regarded as belonging to a genus apart, viz., *Micromeles*. Altogether 155 species, forms, and hybrids are carefully described, and 34 figures of leaf outlines and character of pollen help to elucidate the text.

The German, in which the monograph is written, is sometimes unnecessarily involved, and is consequently at times difficult to understand. The following sentence may be taken as an example in proof: "Die zusammenfassung derjenigen in der Natur entstandenen Pflanzen, welche—von den Anomalien abgesehen—dieselben konstant erblichen Abänderungen anweisen können, stellen die niedersten Einheiten des systems, d.h. die Sippen im Sinne Wettstein's dar." This phrase appears to mean that to treat collectively plants, growing under natural conditions, which—apart from anomalies—are subject to the same inherited variations, represent the lowest units of the system, i.e., the "Sippen" as understood by Wettstein. *Sippe* means a clan, and in botanical parlance there seems to be no exact English equivalent. During the printing of the work, however, the author found a word which he preferred, and he suggests in a footnote that *Elementar Art* (primary species) should be substituted for *Sippe* wherever it occurs in his pages.

A good deal of importance is attached to the character of the pollen—if it is irregular in shape and colour, it is assumed that the plant which furnished it is a hybrid. Some undoubted hybrids, however, have fairly regular pollen, and bear fertile fruits—for instance, the Scarlet Chestnut of gardens, which is a cross between the Horse-Chestnut of Europe, and the Scarlet Buck-eye (*Aesculus Pavia*) of the United States.

Our author recommends the raising of large numbers of seedlings of all the different forms, species, &c., of *Sorbus*, and the careful study and comparison of these, in order to arrive at just conclusions. In studying a group, he says one must begin from below and work upwards. In an angiospermous group it is of first importance to ascertain clearly, to what extent in each instance, different conditions have influenced the plant in size, habit, &c., in its development from seed. How important this method is, he proves by stating the fact that in some of the lower *Algae*, the different modifications of one and the same species have been generally treated as distinct genera, and even placed in different families. Unfortunately with trees much space would be required, and a long series of observations extending over many years would be necessary.

Lack of space prevents our giving Hedlund's key to the genus—it extends to nearly a score pages. Many new names occur, amongst which we mention the following:—

| | |
|--|--|
| <i>Sorbus commixta</i> , Hedlund | = <i>S. Aucuparia</i> var. <i>japonica</i> , Maximowicz. |
| <i>S. parviflora</i> , " | = <i>Pyrus micrantha</i> , Franchet & Savatier. |
| <i>S. splendida</i> , " | = <i>S. sambucifolia</i> , Koehne. |
| (This is probably a hybrid between <i>S. microcarpa</i> and <i>S. Aucuparia</i> .) | |
| <i>Sorbus sibirica</i> , Hedlund | = <i>S. Aucuparia</i> var. <i>glabra</i> , Trautvetter. |
| <i>S. decurrens</i> , " | = <i>S. lanuginosa</i> , Kitaibel. |
| <i>S. Meinichii</i> , " | = <i>S. Aucuparia</i> × <i>fennica</i> . |
| <i>S. quercifolia</i> , " | = (?) <i>S. longifolia</i> × <i>Aucuparia</i> . |
| <i>S. persica</i> , " | = <i>Pyrus flabellifolia</i> , Decaisne. |
| <i>S. salicifolia</i> , " | = <i>P. rupicola</i> , Syme. |
| <i>S. incisa</i> , " | = <i>P. scandica</i> , Babington. |

P. pollveria, L., or as it is now called in *Kew Hand-list* of the Arboretum, *P. auricularis*, Knoop, does not fulfil Hedlund's idea of the generic characteristics of *Sorbus*, and so is only incidentally mentioned on p. 84. It is a hybrid between a member of the *Aria* group and a cultivated Pear.

P. malifolia, Spach, another hybrid of similar origin, the author of the monograph thinks has disappeared from cultivation. We have, however seen it both in the Paris Botanic Garden and at Kew. *Geo. Nicholson.*

IMPROVEMENTS IN HARDY PLANTS.

THE following important paper was read at a meeting of the Horticultural Club on Tuesday, Jan. 21, by Mr. Amos Perry.

(Continued from p. 62.)

Now I will hastily run through some of the most important genera that I think should be dealt with, and the first on the list will be the—

Asters, the capabilities of which are endless, and I believe before many years they will become one of our most popular families and be grown by millions, both in pots and in the open. In a very short time we shall have as many pinks and reds as we have blues and whites, and Perry's Pink, one of the *lævis* section, is a fine one to work from, the colour being a good, bright pink and the first of this section of a good colour. It is a seedling raised from Miss Stafford, a Winchmore Hill variety. Great care must be exercised in raising Asters to keep to the stick-at-home varieties. Do not touch those that run all over the border. A favourite group of mine is the *cordifolius* section, forming sheaves of the most graceful flowers, and favourites with everyone for cutting. I find this group is far better grown in partial shade.

The *Amellus* group will take a first place for pots, their natural habit lending themselves to this mode of

treatment. The flowers are large and of every shade, from the richest violet imaginable to very pale blues. The white we have is of no use horticulturally, but what the progeny will be I do not know. In Perry's Favourite we have the first good pink in the *Amellus* section, and one that must become popular. There is no question that from this may be obtained varieties brighter in colour and invaluable in every way.

A good type of *Aster* to work from is *Esme*, a seedling of the Rev. Wolley Dod, 3 feet high, with a large spreading head, pure white, and remarkable for lasting a very long time in bloom. One can imagine what a double-white of this description would be worth, and it is coming. We have already semi-doubles, and one fully two-thirds double, and I am looking forward to the coming season for many others of this character. A race of good double *Asters* will be a grand addition to our list of decorative plants, and also for pots, and it is only a question of time to obtain them.

Anemone japonica is in very successful hands, and great improvements have taken place, and many more to follow. Queen Charlotte, Mont Rose, and *Rosea superba* are grand. I should like to see the Parsley-leaved variety taken in hand. The foliage is wonderfully effective, but the flowers very poor.

Agrostemma flos-jovis is capable of great improvement. It is a good all-round plant for cutting or decoration, and there is no reason why we should not get a double. There used to be a large double variety of *A. coronaria* thirty years ago, which I believe is now lost.

The common white *Arabis* has made a great bid for popularity. The double form is splendid for cutting, lasting well into summer. We have several species with rose and pink flowers. Why cannot we get this colour into the double one?

Asphodels form a very characteristic group, and I think the Asiatic and European species might be brought together with very good results.

Aconitums offer many opportunities for improvement. A good yellow *A. japonicum*, or even a yellow *A. Napellus* would be a great acquisition. Do you think it possible to obtain them? I say, yes.

The capabilities of the *Aubrietia* have been fairly tested, and we have now a good range of colour, but there is no reason why they cannot be still improved both in size and colour.

The *Calystegia*, I believe, is capable of a great transformation, and I see no reason why flowers of immense size and of almost every shade of colour cannot be obtained in the perennial varieties. If the annual varieties would not produce these results, we might seek the assistance of its American ally, the *Ipomoea*.

Campanulas.—We all know their capabilities, and there is not a single species in the whole race that cannot be improved. As a rule, the great bulk are raised from seed, no attempt being made either to discard the bad forms or to retain the good ones, and many are becoming so poor as to be not worth growing.

A few good hybrids we have, Van Houtte, G. F. Wilson, and Henderson being still among the best. I should like to see this group taken up by two or three enthusiasts, as they are so easily done, requiring little attention, and the results quickly seen.

Cheiranthus alpinus, the alpine Wallflower, would well repay a little attention. Crimson, red and yellow varieties, would be very effective, and I think can be obtained.

Chrysanthemum maximum has shown a remarkable development, and some of the flowers are really superb. For decoration or for cutting they are matchless, and still I believe can be much improved. Some of the more recent seedlings have shown distinct signs of doubling, and I shall not be surprised any day to hear of one being raised. I have just read that American seedlings are showing signs of colouring, but I am doubtful about it.

The Shasta Daisy, which has been hurled at us from the other side of the Atlantic, is described as being a marvellous production, but whether the plates are overdrawn or not, I cannot see that it will bear any comparison with what we have already got. I like the name Shasta Daisy, and shall certainly use it.

Coreopsis lanceolata I think would pay well for a little attention, seeing we have some perennial species with rose-coloured flowers, which we could fall back upon, providing the annual ones could not be induced to assist us in obtaining different shades from those already in cultivation. A red or rose-coloured variety of *Coreopsis lanceolata* would find many admirers; a great deal might be done in selection, as I do not consider the present one anything like so good as the one I knew twenty years ago.

Echinacea purpurea has degenerated considerably during the last twenty years, and many of the strains now offered are not worth growing, whilst the good ones are among the best of our autumn perennials. The colour is being improved upon each year, and reds and purples will soon take the place of the poor varieties so often seen.

The *Erigeron* contains some good material for further developments, and in *E. speciosus* we have a very useful plant for all purposes and a great favourite, as it lasts so long in bloom. Among the perennial species we have white, orange, and flesh, and among

the annual varieties yellows. Transfer either of these shades to the speciosus, and the result would be very pleasing. I find the "Composite," as a rule, especially after the first break, very easy to cross.

Eremurus, white, lemon, and apricot varieties of robustus are in existence, and many other shades of colour will, no doubt, follow, but a man wants to start very young if he wishes to see the result of his labour in hybridising this genus.

The species of *Geranium* are, as a rule, somewhat weedy, but there are some among them remarkably showy, and could very easily be improved upon. The white variety of *G. sanguineum* is one of the very few varieties we have in this family.

The *Geums* are somewhat important, as they last a long time in bloom, are easily grown, and very variable. There are now several good varieties of *Heldreichii*, *montanum*, and *coccineum plenum*, but these can be improved upon very considerably.

Gypsophila paniculata.—The double variety, which was shown before the Royal Horticultural Society during the past season, I think will become a very good plant, providing it can be propagated, but I have never been very successful in propagating this by cuttings, and I am somewhat afraid of the double.

In the *Heleniums* we have two or three good varieties, the best of all without a question is *H. pumilum magnificum*, and this, I consider, is one of the best twelve hardy perennials in cultivation; it is in flower well for at least four months, and during the drought of the past season was a mass of flower. *H. striatum* is a plant that will well repay a little attention, and I can see no reason why a crimson could not be obtained with care by selection. I have raised many, all striped more or less, but no self-coloured flowers.

Helianthus has been worked upon for some years past, and the new *Helianthus tomentosus* (certificated under the name of *mollis*) is excellent for crossing purposes. It is certainly the most characteristic in the family, distinct in foliage and formation from any of the others, and one that does not run about.

Heliopsis levis is still capable of further improvement. The colour is unique at that season of the year, and for cutting it is invaluable, but it is not a good habit. A variety 2 feet or 3 feet high, covered with rich orange flowers, would find many admirers.

The Oriental Christmas Roses are very useful, but I do not think can be much improved upon; they are no good for cutting, and never will be, but in a shrubby border they are very useful.

It is possible to get some fine varieties of *Hemerocallis*, but they will have to be remarkably distinct to find favour with the public. Commercially there is not much value in them, I suppose from the fact that they cannot be killed!

Among the *Heucheras* there is a possibility of very great improvement. A crimson *H. erubescens* would make a charming plant, and as these are easily crossed, and the results quickly seen, would be a nice group for some impatient enthusiast to take up. *H. zabethana*, a Continental introduction, is one of the first hybrids we have, and a very good plant it is. *H. sanguinea* appears to be degenerating. Even the variety *splendens* does not come up to the standard of what I grew in my private garden at Tottenham. Originally there were six plants—one died on the road—brought by the late Andrew Murray from Lower Mexico, which he gave to me. The description he gave of this species growing wild was of a plant 3 feet or 4 feet high, with flowers more than double the size, and scores of branching spikes emanating from quite small clumps; and when he saw them at Tottenham for the first time he was more than disappointed, and did not consider the plant worth the trouble he had bestowed upon it. The spikes he saw at Tottenham were far more beautiful than those usually seen in English gardens.

The *Irises* present a fine field for the hybridiser, although they are not so easily managed as one might suppose. They have always been popular. We have had a few new varieties of *germanica*, a good many new varieties of the *olbiensis*, and a few hybrids of *Max Leichtlin* and Sir Michael Foster, and a few others are the net proceeds of the last twenty years. There has never been much done in the way of hybridising, *Max Leichtlin* being one of the first. One of the best of his was *Warei*, a cross between *I. Susiana* and one of the *germanica* sections; but he does not appear to have been very successful with them. Sir Michael Foster has many hybrids, some most charming, and he appears to be crossing everything. His "monspur" sections are good, the result of crossing *Monnierii* and *spuria*. "Parsam," a cross between *paradoxa* and *sambucina*, is very pretty, and there are many others that we know little about. I had almost forgotten the *Iris Kiemperli*. A marvellous change has taken place in these since the late Baron von Siebold introduced his first set from Japan. These had quite small flowers, and were not worth growing by the side of those now in cultivation. I believe the first information we had of these large ones was at Tokenhouse Yard, when Messrs. Protheroe & Morris offered some thirty or forty clumps, one or two plants of each variety, accompanied with the usual Japanese drawings. These caused quite a sensation, and realised several pounds a clump. The Japanese were not slow

in sending over many more, and for the last twenty years a regular trade has been done in them; but I do not think we have any more varieties now than then—*Iberis*, *Inulas*, *Lathyrus*, *Liliums*, and *Liriaris*, we must pass. All are good popular genera, from which improved varieties could be obtained.

The *Megasea* has received a fair share of attention. Mr. Smith, of Newry, having raised a great number of seedlings, some very interesting, but there are not enough whites and light shades of colour. Unfortunately, this group has never been very popular with the public.

The Evening Primroses (*E. Enothera*) present many opportunities for hybridising and selection. Sooner or later we shall have some one finding a white microcarpa or fruticosa, both of which would be eagerly sought after, and if whites, why not roses and reds? Has anyone seriously attempted to cross these species? I have never heard of one, and I feel sure they would pay well for a little attention.

I must not pass the *Pentstemons* without mentioning *P. heterophylla*, a lovely Californian species of a beautiful blue colour. I see no reason why we could not get blue ones among the hybrids, seeing both are very similar in growth.

Potentillas.—What a wealth of colour we have in the hybrid *Potentillas*! The combinations are marvellous, but all spoil by the habit of the plant. Could we not obtain a new set, less rampant in growth, and erect? If we could, it would be a great boon, for we have no other genus possessing so much brilliancy of colour as these.

Scabiosa caucasica is now producing a nice range of colour, and as the plants can be propagated by division, will become very useful. Unfortunately, they are slow in increasing, and it will be some years before we see much of them. Some of the new shades are delightful.

The *Spiraeas* are an important genus, and there is no question that many improvements can be made in them, especially in point of colour. A coloured variety of *S. japonica* or *S. Aruncus* would cause quite a sensation. I would not say they can be obtained, but I know they are well worth trying for.

We have a good pink variety of *Spiraea gigantea*, and I remember having offered to me a bright pink variety of *S. filipendula*, but such a fabulous price was asked that it was impossible to secure it. Twenty-five years ago this class of plant was at a very low ebb. What became of it I never knew, but I can see it in my mind's eye now, and should like an opportunity of obtaining it.

Sedum spectabile contains many points of great merit, and if we could get a batch of seedlings, improvement only in colour would be a great commercial success.

The *Statice* are becoming more popular now attention has been given to selection, &c. In *S. limonium* we have a very variable species, varying from the purest white to all shades of blue and pink, with dense heads of flower 2 feet across. The individual flowers are smaller than those of *S. latifolia*, but far more graceful for cutting. These are much sought after for this purpose.

There are hundreds of other genera that could be mentioned, all of more or less interest, and from past experience with other groups I feel sure similar results could be obtained. It will be useless for anyone to take up this matter unless it is done systematically, keeping to the object in view.

There must be nothing left to chance, as the cost of planting out, say, 1,000 *Aster* chance seedlings is great, especially if you get no results; whereas twenty carefully selected might produce one or two worth keeping, if only for further trial. One is not likely to get desirable novelties the first time of asking. It is a question of close watching and perseverance, and if only one or two are taken up by anyone here to-night with an idea of improvement, my work this evening will not have been thrown away.

CALIFORNIA.

PINUS INSIGNIS.—Mr. R. W. ADLAM, in the *Gardeners' Chronicle* of December 31, writing from Johannesburg, asks whether the timber of *Pinus insignis* has any commercial value. Thousands of acres around Monterey are covered with this Pine. I have never heard of it being used for any other purpose than that of fuel. Owing to its quick growth, its timber is not durable enough for building purposes; it decays quite rapidly after being cut.

During the past two or three years the *Pinus insignis* has been attacked, especially in private grounds, by a beetle, which I believe flies from one tree to another. I have found the remains of wings where they enter the tree. This beetle bores into the tree close to the

ground in a downward direction; it no doubt breeds, afterwards the young burrowing between the bark and wood, until after a year, or sometimes a little longer, the tree succumbs. I have noticed that trees from fifteen to twenty-five years of age are more susceptible to attack from this beetle than at any other age. *Thos. Lee, Supt. of Hotel Del Monte Grounds, California.*

IPOMCEA AUREA.

This was described by Kellogg in the *Proceedings of the California Academy of Sciences*. It is indeed a noble plant, but a shy bloomer I am afraid, unless it can get very intense heat in summer. It bloomed with me two years ago, five years from seed, and never again, probably because I was obliged to transplant it, and for a year it hardly gave sign of life.

IPOMCEA CHRYSANTHA,

said to come from Fernando Po, grows exceedingly rank here, but not one flower has ever appeared.

DOUBLE-FLOWERING PEACHES.

Not only is it a common occurrence for these to bear fruit, and the seeds to germinate freely, but it is worth remarking that seedlings will bear flowers of shades different from the parent plant, in many cases pure white, variously striped, and more or less intense crimson flowers, appearing on the same seedling.

CANNA MRS. KATE GRAY.

There is no mistake in my correspondence published at p. 366 of the last volume of the *Gardeners' Chronicle*. The facts pertaining to the origin of this variety are exactly as stated in my correspondence, namely, it was a plant of Italia which was fertilised with the pollen of Madame Crozy, and not *vice versa*, as asserted by Mr. W. Muller. Furthermore, it may interest your readers to know that it was through extraordinary perseverance that the result was obtained. The employer of Mr. Morse did not like his time to be taken up by such breeding work, and exacted that strict account should be kept of the time employed. Well, it took 900 hours of patient work to obtain that lone seed, from which Mrs. Kate Gray was born. *Dr. F. Franceschi, Santa Barbara, Cal.*

ALPINE GARDEN.

PRIMULA MEGASEEFOIA, Boissier.

This fine Primrose, figured in *Gardeners' Chronicle*, April 6, 1901, is now, at the end of January, in full flower in my garden in a cold frame. It was given to me last year by Miss Willmott, about the time of the April show in the Drill Hall, where it was exhibited for the first time. It has somewhat the habit and stature of *P. rosca*, but the flat leaves are rounder, the flowers are larger, and have more red in their colouring. In E. Boissier's *Flora Orientalis* (vol. iv., p. 26) only one habitat is mentioned, "moist, shady gorges near Rhizch (a maritime town, about halfway between Trebizond and Batum), at an elevation of 900 feet, flowering in May." The plant is now offered by the dozen by Carl Sprenger, of Naples, who tells us it is a native of Persia, and that it flowers "in winter and spring, and sometimes in autumn." It is just this uncertainty of season which may prove a drawback to its open-air cultivation in England. It will probably prove as hardy as *P. denticulata*, but, like that species, be liable to be

enticed into premature flowering when the early autumn is warm and wet, and so get its flowers spoilt by winter. In that case it will require some similar management to retard the autumn growth. The species is, however, well worth the attention of amateurs as a good late winter greenhouse plant, even if it cannot be persuaded to defer its flowering to what Boissier says is its proper season, May. *C. Wolley-Dod, Edge Hall, Malpas, Jan. 26.*

LILIES.

CULTURAL DIRECTIONS.—A good, medium soil, free from ground insects, is, as a rule, the most congenial soil for all Lilies. There are some species of Lilies which like more moisture than others. The soil at Mr. Arderne's is free, well drained, and the constant watering the Rhododendrons get makes the place an ideal one; and what can be more charming than to see rising from the midst of Rhododendrons such Lilies as the varieties of *L. pardalinum*, *L. auratum*, *L. excelsum*, and many others? The ground is shaded, the bulbs are kept cool, while absolute freedom for the tops and foliage is secured. Lilies should not be coddled, but planted where they are to flower. Should success attend the selection of the spot, a new pleasure is introduced into the garden; should there be a failure, this is no more than happens in one's daily routine—try again. A real gardener never gives up, but goes on till he succeeds.

On receiving Lily-bulbs, examine the base; if sound, all is well, but if the scales fall away from the base, you can have no success. There may, however, be some healthy parts on the scales; from these you have a chance of getting bulblets, by laying them on a compost of soil mostly clean sand, and covering over with the same material, placing the pot, box, or kerosene-tin in a shady place, and keeping the soil moist, but not wet. If you buy your bulbs, see that the outside scales are healthy and firm. If you import bulbs, caution the sender as to the degree of moisture in the moss surrounding the bulbs, as it often happens the sphagnum-moss used is too wet, and in consequence the bulbs are apt to rot. I have seen good consignments of Lily-bulbs packed in common sawdust of such wood as white deal. Avoid charcoal and cork sawdust; these absorb the goodness out of Lily-bulbs. A heavy soil may suit some of the moisture-loving Lilies, but a sour soil or a water-logged soil is bad. Drainage is indispensable for the successful culture of all Lilies; if a collection of Lilies be grown in the same bed, put the bed, if possible, on a sloping bank, those which love the dry soil highest up, and graduate down to the moisture-loving ones at the lower part of the bed. Lilies, such as the varieties of elegans and some others, like a rather dry ridge, and with deep planting, will stand a good deal of drought.

Give Lilies more or less shade from the midday sun, and shelter them as much as possible from severe winds. The great aim should be to keep the soil cool, and this may be best attained by a mulch of the preceding year's leaves of trees, rotted, or laying stones on the surface, there being no objection to plenty of sand-stones heaped on the beds. Under such conditions, moisture-loving Lilies may be grown to perfection, bearing in mind shade and watering. The Lilies which do well in a partially dry soil, will do better with than without stones on the surface. The stones ensure coolness, and conserve moisture. I am strongly in favour of blocks, large and small, of sand-stone amongst which Lilies should be grown, and I am almost sure this

mode of growing them would be attended with as much success as if planted amongst Rhododendrons. It must not, however, be forgotten that shade from the midday sun—indeed, the fierce rays at any hour of the day—should be avoided, and shade in Cape Town is as good as full exposure in Europe.

Lily-bulbs, when out of the ground, should never be exposed to the atmosphere, or the scales will become flabby, and this means a loss of vitality, and often the cause of failure; while some Lily-bulbs when much exposed to the atmosphere will make no top-growth the first year. They are not however, resting. If they are not dead, they will be found working underground, and will make a leaf-growth the following year. I saw some *L. auratum* in kerosene-tins the other day in a very crippled condition. On examination, I found this arose from the bulbs being partially uncovered; the result could not have been otherwise. Had the bulbs been a few inches below the surface, a very different state of things would have happened; no chance for the root-stalks, and the stem was drawing on the bulb-roots, a very unfair thing for the bulb. It was doing double duty, and this was not its nature. If a bulb, after a reasonable time, does not throw a shoot, scrape down carefully, and find whether dead or alive. Mr. Chalwin, of the Cape Town Botanic Garden, in my presence, dug up some *L. longiflorum* which had made no top-growth, notwithstanding which they had actually increased in number, both in large and small bulbs. There did not appear any reason for this freak of Nature, but here was a lesson not to judge hastily, and the same happens with many other bulbs. I remember a whole bed of *L. testaceum* serving me so, and I recollect also a bed of Angels'-tears Daffodils, which I had collected on an island in the Bay of Vigo, in Spain, serving me in like manner. In both cases, the bulbs when dug up were in splendid condition. There must have been a reason in both cases, as also in that of Mr. Chalwin's *L. longiflorum*, but why they should take a year in Mother Earth, without calling in the aid of the atmosphere, is one of those questions we may speculate upon, and not be much the wiser in the end.

All exporters of Lily bulbs are fully aware of the necessity of keeping the scales plump, hence their mode of packing. In the short run from England to the Cape there should be no difficulty in getting out the bulbs in prime condition.

There has been a good deal said and written on the subject of disease in Lilies; it comes on the foliage like Potato-rust, and in all such cases these leaves should be removed. The Bordeaux Mixture will stop it. This disease, I am informed, is not unknown amongst wild Lilies. It does not, however, appear to affect the bulb. Disease produced from manuring is quite another thing. I am told there is an insect which eats out the centre of a Lily stem, but in the cases submitted for examination, showed that the Lilies had not been properly treated.

Nearly all Lilies like a good, rich soil to grow in, but not a freshly-manured soil. It is a custom with some, when the Lily has no top growth (this we call being at rest, but I am doubtful if a Lily or any bulb is ever actually at rest) to mulch with cow-manure, dried and rubbed through a sieve, and leave the rain to wash the fertiliser down to the roots. The Japs at this time give a little liquid manure, made from night-soil, once a month, and stop as soon as the Lily-top appears above the ground. It is to be remembered that the Japs are all but vegetarians. The nearest, there-

fore, to their liquid manure will be that made from the droppings from the cowshed, and the liquor should never be darker than stout. The Lily bulb, as I have already said, is really nefer at rest, hence the Japs feed the young roots that they may the better earry the flower-stem and reproduce themselves. The Japs care nothing for Lilies beyond the money they can make from the sale of the bulbs, or as an article of diet. P. Barr, in "Cape Times."

In fine size and shape, it has some resemblance to *C. × Beckmanni*, but in point of fact there is nothing comparable with it. It is probably a second crossing, which has progressed and developed beauties not seen in the other members of the batch. The upper sepal is emerald green at the base, and white in the upper part, the middle and basal area bearing fine blackish-purple blotches, the middle space between the blotches and the white margin

France it was condemned as being useless by all the leading nurserymen. Yet at the present time it is recognised as being one of the most valuable flowering plants, and besides the large numbers grown in France, many plants are furnished by English growers. Its re-introduction to France is due to M. A. Truffaut, of Versailles, who when visiting England a few years ago told me that the plant was no good, but on seeing some well-grown plants, exclaimed that he had never seen it so beautiful before, and was induced to make another trial of it in France, with the result that he has built a range of glass-houses specially for its cultivation; and although he now cultivates large quantities, English growers receive extensive orders, both from France and Germany. It is now unnecessary to enlarge on the merits of this capital plant, but a few remarks on its cultivation may be of service.

In the first place, it is so persistent in flowering that cuttings are with difficulty obtained, and many cut off the flower stems with the idea of getting the plants to start from the base, with the result that they do start, and begin to flower again; whilst if allowed to flower from the original stems, the buds at the base will remain dormant till the flowering period is pretty well exhausted, and when they do start good cuttings are readily obtained. There is no difficulty in propagating the plant, as with ordinary care almost every cutting will make roots. The most important point is to pot them off as soon as they are fit, and keep them growing without a check. Although they do not fill the pots with roots like some varieties, they like pot-room, and a good rich compost. In the earlier stages of growth plenty of warmth may be applied, and later on a moderate temperature with plenty of light and fresh air; the plants must never be crowded together after they are well established in their flowering pots; manure-water may be used freely.

VARIETIES.

In addition to the original variety, we now have some distinct sports. The "Turnford Hall" variety, which has almost pure white flowers may be regarded as the best and most distinct of these. The flowers are almost pure white, having only a slight shade of pink on the under side of the petals; the flowers stand up well, and are as abundant as those of the original. The Gunnersbury variety, "Mrs. Leopold de Rothschild," has flowers of a paler shade of pink than the parent, and the racemes are closer, the flowers hold on more persistently, and with age they assume almost a leafy character instead of falling. The first white-flowered sport, Caledonia, is very distinct, and though not quite so vigorous as the type, it may improve; and to those who have not succeeded with it I should say, "try again." It may be noted that this variety produces more female flowers than any other variety referred to, but I have not yet found it to form mature seeds. A. Hemsley.

BILBERRIES AND THE LIKE. — Mr. MUNSON of the Maine Agricultural Station has published a bulletin relating to the genus *Vaccinium* in its horticultural aspects. After dealing with the literary history of the genus, the author proceeds to detail the methods of cultivation. In the State of Maine alone there are seven factories for canning Blueberries (*Vaccinium corymbosum*), whilst the Cranberries (*Vaccinium macrocarpon* and *V. Oxycoccos*), must be grown on a much larger scale if we may judge from the large quantities that come into our markets. A botanical description of the several species adds greatly to the value of this excellent monograph.

FIG. 28.—CYPRIPEDIUM × MRS. W. MOSTYN.

CYPRIPEDIUM × MRS. WM. MOSTYN.

THIS fine Cypripedium (fig. 28), which was pronounced one of the finest hybrids of its class, and awarded a First-class Certificate by the Orchid Committee of the Royal Horticultural Society on January 14, 1902, when it was exhibited by its fortunate owner, F. Wellesley, Esq., Westfield, near Woking (gr., Mr. J. Gilbert), has puzzled experts to decide what its parentage might be, for its features seem to convey the best qualities of several species and hybrids, and especially of *C. × Calypso* Oakwood variety, which may have been one of the parents.

being of a soft rose colour. The petals and lip have a yellow ground, spotted and tinged with chocolate-purple, the surface being very glossy.

BEGONIA GLOIRE DE LORRAINE.

THE cultural requirements of this beautiful winter-flowering plant are becoming better understood. It is pretty well known that it originated in France, M. Lemoine being the raiser, and after being sent to England and receiving a First-Class Certificate from the Royal Horticultural Society, it was taken up by many growers, most of whom failed to do any good with it; and in

The Week's Work.

FRUITS UNDER GLASS.

By JAMES WHYTOCK, Gardener to the DUKE OF
BUCCLEUCH, Dalkeith.

Melons.—The sowing of Melon-seed before the middle of January is attended with only partial success unless suitably constructed and well-heated Melon-houses exist in which to grow and fruit the plants. As a mode of sowing, drop two lumpy bits of moderately dry loam into 3-inch pots; put two seeds in each pot, and, without affording water, plunge the seed-pots in a bed having a bottom-heat of 80° or 85°, and as soon as they germinate, bring them near the glass to prevent the drawing of the plants, still withholding water—for the little plants at this season will thrive with comparatively little moisture—whereas, should the soil get wet and be kept in that condition they will do no good. It is not good practice to shift into a size larger pot to grow on, but leave the stronger of the two in the 3-inch pot until leaves and stem are stoutly developed; then plant in the fruiting quarter, which may either be a bed resting on bottom-heat of 85°, or in 12-inch pots plunged in bottom-heat. If planted on beds, do not make a big body of soil at this season, but rather put up a narrow ridge of moderately dry soil, mixed with little bits of lime-rubbish. Melons like a good heavy soil, and in the absence of that, use turfy loam mixed with an approved kind of artificial manure; make the ridge firm, and when the soil is warmed throughout plant on the top of the ridge at a distance of 2 feet apart, and apply no water after planting, at this season the moisture in soil being probably enough for the plants till they have made a fair start. The mean temperature of the air should be 70°, 10° to 15° higher in the day-time; and let the paths and all other surfaces be damped frequently, guarding against the drying effect of fire-heat, and keeping generally a moist growing atmosphere.

Cucumbers.—Plants raised from seed sown at the beginning of January, unlike Melons, may be shifted from the 3-inch pot to a 5-inch pot before planting them in the fruiting quarter, and one house if sufficiently long will suit both, if the Melons are placed at the warmer end, and are allowed to have plenty of sunshine. The portion of the border the Cucumbers are planted in should have 6 inches of drainage material on the bottom, sods (the grassy side downwards) being placed on this, and a small ridge of soil on the sods in which to plant. The soil for Cucumbers may consist of one half rough, turfy soil, and one half well-rotted manure well mixed together, this openness of material suiting the more copious waterings and syringings that the Cucumber plant needs.

Young Vines.—If young Vines are wanted either for pots or planting-out, now is the time to put in the eyes. There is no question that striking the eyes in turfy-loam is the best method. To do this, fill boxes measuring 24 inches by 18 inches by 3 inches with finely-chopped turfy-loam; put the Vine-eyes over the surface at 6 inches apart, and place in bottom-heat of 80°, the temperature of the house being 55° to 60°. When the eyes have grown 6 inches in length, cut out each "eye" in the centre of a square of 6 inches, when the young Vines will flag—but after two days the little squares may be potted if meant for pot Vines; and those meant for planting-out should be reboxed, say, two or three plants in the above-sized box, the soil used being fresh turfy-loam with some Vine-manure added. By the middle of May—the best time for planting—lift each Vine out as a solid sod, lay it on the surface of a new border where it will grow without feeling the removal, and the roots will keep near the surface. I had some Vine eyes inserted last February for planting in a newinery which was only finished towards the end of the month of June; at that time the young Vines were planted, and by the beginning of the

month of October, they had grown to a length of 25 feet, the house being a very high one. In preparing cut-backs or one-year-old Vines, steep them in a tank of water for forty-eight hours, then shake away all of the soil from the roots, half fill some boxes of the size given above with turfy-loam mixed with Vine-manure, spread the roots out carefully, one Vine in a box; cover with 1½ in. of the same kind of soil. This done early in February, they will lift out as a flat, solid sod in the middle of the month of May, and grow away without check. A crop of Grapes may be cut at the end of May, the Vines grubbed up, a small new border made, and Vines raised from eyes planted the same season, the rods going to the top of the house by October.

PLANTS UNDER GLASS.

By J. C. TALLACK, Gardener to E. MILLER MUNDY, Esq.,
Shipley Hall, Derby.

Yellow-spathed Richardias.—Of these *C. Elliotiana* seems to be the most popular, but as the cultural treatment of *C. Pentlandi* and *C. aurata* is identical, they are all included within the scope of these remarks. They differ in their needs from *R. africana* in that they require much more heat when growing, and a longer and more complete resting period, for unless the tubers are well baked in sunshine, no spathes need be expected. In order to have spathes during the latter half of April and throughout the month of May, which seems to be their natural flowering season, the tubers should now be potted, using rather large pots, as they make a considerable quantity of roots. The soil used should consist of equal parts of loam, leaf mould, silver sand, and a small quantity of dried cow-manure; the sand not being stinted, it appearing to be essential to good growth. They should be started in a light position in a house having a minimum temperature of about 60°. At the beginning no water, excepting what falls from the syringe, should be afforded, but when they are rooting strongly copious supplies are required until the growth of the plant is complete. Seeds of these plants sown at this season in heat germinate freely; the seeds should be sown far enough apart to allow of them growing for one season without removal from the seed-pots.

Ferns.—Many plants will be the better for being split up and repotted in new soil, others may perhaps go through another year with a top-dressing and a re-arrangement of the drainage materials. It should be borne in mind that all Ferns with rhizomatous stems do not like deep potting, or even deep pots. Most Ferns succeed in peaty soil, but soils containing a large proportion of pasture-loam suit *Adiantums* grown chiefly for cutting purposes. Take great care, when potting, of the young fronds now showing, as future success depends greatly on careful treatment at this date.

Alocasias, Marantas, and some other Store Foliage Plants should be examined, top-dressed, or repotted, while the sun's warmth is feeble, Marantas especially suffering from root disturbance. A very good mixture for most of these plants consists of peat, leaf mould, sand, and a small quantity of turfy loam. *Dieffenbachias* may be beheaded, the tops struck, and their stems cut up and treated like those of *Dracaenas*, if increase be desired. Young plants are, as a rule, more useful than old ones.

Bourvardias.—Plants that are passing out of flower should receive less water preparatory to pruning them later on for the production of shoots fit for propagating purposes. For my part, I like root-cuttings the best, but young stock may be raised by either method.

Plant-cleansing.—When opportunity offers, plants of all kinds infested by insect pests, not destroyed by fumigation or vaporisation, should be cleansed with a sponge and an insecticide. Mealy-bug and various scale insects are especially troublesome in warm plant-houses, and should be destroyed at this season, when breeding is at its lowest point.

THE KITCHEN GARDEN.

By T. TURTON, Gr. to J. K. D. WINGFIELD DIGBY, Esq.,
Sherborne Castle, Dorset.

Early Carrots.—Sow in drills in hot-bed frames the French Forcing, and for succession Sutton's Early Gem, the former at 8 inches apart, and the latter at 9 inches. Where a separate frame cannot be set apart for growing early Radishes, seed may be sown between the rows of Carrots, the latter being then sown in drills drawn 11 inches or 12 inches apart. Radishes germinate so quickly, and require to be so freely ventilated, that it is inadvisable to sow them together when the Carrots are required early. Avoid sowing either of them thickly.

Turnips.—Sow in a frame placed on a mild hot-bed seeds of the Early White Milan and Sutton's White Gem Turnips, in drills drawn at 1 ft. apart, and intercrop with Wood's Early Frame and French Breakfast Radishes, sowing thinly both Turnip and Radish seeds; and place Lettuce-leaves on the bed, in order to form baits for slugs, examining the leaves night and morning. A stack of good soil should always be available for frame purposes; and that in which Chrysanthemums, pot Strawberries, Melons, &c., have been grown, if it has been in stack for a time, will be found in every respect a very suitable one.

Spinach.—When the soil is in a condition to get upon, make a good sowing of a round-seeded variety, the Victoria by preference, and place the bed, if possible, on a south border. Autumn-sown Spinach in old kitchen gardens is apt to get gappy as time goes on, therefore the advisability of making a sowing at about this date. The seed-drills should be drawn at 18 inches apart; or they may find a place between the lines of early Peas. Spinach succeeds in freshly broken up land, as, for example, in fields that have been long under the plough, and is then heavily manured, and dug 1 to 2 spits deep.

Seakale.—Finish lifting the roots that are to be forced in warm, dark places. The best plan to adopt for getting a supply of Seakale late in the season is to grow some part of the crop in permanent beds, two rows in a bed, or in rows of small groups of three or four plants each. Where such beds exist, Seakale pots with movable covers should be placed over the clumps, and then a wall of strawy stable-litter should be built round the bed, and the centre filled up and well over the pots with last year's tree-leaves, trampling them firmly between the pots, and applying a covering of litter, so as to keep the leaves from being blown about. Seakale grown in this manner is superior to that produced by lifted roots, and its production entails very little labour, provided the beds are so placed as to be come-at-able with the garden cart.

Pea-sticks.—Procure the supply of these forthwith, and when received, lay them flat on a level piece of ground, and after forming them into a stack, lay some heavy pieces of timber on the top of the stack, till they can be trimmed and the butt ends sharpened. Treated in this fashion when green makes them flat, facilitates the work of sticking the rows, and makes more sightly rows. For early Peas I use the previous year's sticks, which should now be re-sharpened, and formed into bundles of a size convenient for a man to carry.

THE ORCHID HOUSES.

By W. P. BOUND, Gardener to J. COLMAN, Esq., Gatton
Park, Reigate.

General Remarks.—The various shadings and blinds belonging to the various Orchid-houses should be repaired and got in readiness for use. I favour the use of lath blinds, for apart from the fact that they are best for the plants in the summer, they are useful to lower over the roof on cold nights in winter, so as to minimise the use of fireheat, and if kept well painted they will last for many years. Blinds made of split Bamboos answer the same purpose, but for a gentleman's establishment, where the houses are in a prominent position,

they are not so neat as laths. Obtain a sufficient quantity of peat, sphagnum-moss, and leaf-soil, so there may be no delay in repotting the plants. All bottom ventilators in Orchid-houses should have a piece of perforated zinc fastened on the inside to keep slugs and other vermin out of the houses.

Cymbidiums.—Plants of *C. Traceyanum* and *C. giganteum* that flowered in the late autumn or early winter will now be making growth, and if any of them require to be repotted or divided, this is the proper season for these operations. Large specimens of *Cymbidiums* are very attractive, and I advise everyone who has sufficient house-room to cultivate a few of them. In order to maintain the plants in great vigour it becomes necessary to divide them after they have attained to the desired dimensions, and grow on the smaller pieces, so as to take their places as specimens. After a plant has filled as large a pot as it is possible to afford it, and the compost is exhausted, the deterioration of the plant will begin, unless it be divided and given a fresh start. A suitable compost consists of good turfy loam two-thirds, and leaf-soil one-third, together with a sprinkling of small crocks, the whole being well mixed together. A few large clean crocks will suffice for drainage, and over these some lumps of turfy loam should be placed. Pot rather firmly, and keep the base of the plant a little below the rim of the pot. After potting apply water very carefully till the plants have taken a good hold of the new compost: syringe freely between the pots and under the leaves, but overhead only on bright days.

C. Lowianum, *C. eburneum*, and the charming hybrids *Lowio-eburneum*, and the reverse cross, are now developing their flowers, and the plants will take water freely and without injury if the pots are well filled with roots. *Cymbidiums* do not require so much heat as is generally applied, and when grown cool the flowers and foliage are much finer than when the opposite course is followed, and there is little trouble in keeping them clear of insect pests. The same temperature as that advised for the *Odontoglossum*-house is quite high enough, plenty of fresh air being afforded.

Imported Orchids.—Much of the success in the establishing of imported Orchids is due to the sort of treatment afforded immediately on being received from the importers. Before being allowed to go into the houses thoroughly cleanse them of dirt and insects, then lay them on a stage in a somewhat cool, moist house till the potting can be attended to. Many of the leaves may be retained if they are placed in a cool-house and kept well shaded till they show signs of growing. An imported plant requires time to recover, and cool treatment affords that time; growth also is stronger and cleaner when it does start.

THE HARDY FRUIT GARDEN.

By J. MAYNE, Gardener to the Hon. MARK ROLLE, Bictou, East Budleigh, Devonshire.

Grass Orchards.—The established and older trees should receive an annual top-dressing at this season, and for this purpose road-scrappings mixed with farmyard manure form a good compost, and if not plentiful enough to spread over the entire orchard, it should be placed around each tree for a space of 6 feet in diameter. Many Devonshire farmers turn sheep or pigs into their orchards as soon as the fruit has been cleared from them, towards the end of November, and gratifying results are achieved thereby, the fruit swelling up to a much larger size than heretofore, especially where pigs were turned in. When these animals are taken out of an orchard, not a blade of grass can be seen, but as soon as the warm days come, it soon begins to grow again. These animals do not touch the trees, but they root up and devour all roots of nettles that come in their way; still, it is safer to put wire netting, branches of Holly or Furze around the stems of young trees in order to prevent the pigs rubbing themselves against them. Sheep have been known to

bark the trees badly when the latter are left unprotected. All newly-planted trees should be firmly staked and tied before animals are turned into an orchard. Liquid-manure, generally obtainable where there are large gardens, may be applied with advantage at this season to established trees only.

The Mulberry.—Outside of a nursery the Mulberry is seldom seen as a young tree, a matter for regret, seeing that the fruit is so generally liked in tarts, and as jelly. The Mulberry is generally found growing best in moist situations, though I have seen trees of great age in this county on a dry bank flourishing and fruiting abundantly in most years. The standard is the usual form of tree, and it should be planted on turf, so that the ripe fruit may fall thereon, and be fit for use. The wood of the Mulberry being very brittle, the tree should not be planted in exposed situations. In the less warm parts of the country, the Mulberry requires a warm wall to bring it to perfection.

The Quince and Medlar.—A few Quince and Medlar-trees should be found in every garden, for while the fruit of the former cannot be eaten in the raw state, it makes a delicious marmalade and an addition to Apples in tarts. It is best grown as a bush or a pyramid. The pruning is much the same as that afforded the Apple, removing all useless sprays each winter, affording a rather moist loamy soil, and full exposure to the sun. The varieties with Apple and Pear-shaped fruits are those mostly cultivated, and the flowers are very beautiful, so that the Quince is a capital plant for the shrubbery, or isolated on the lawn. The Medlar makes an excellent jelly when blotted, and many persons like them in the raw state. The tree requires but little pruning when once it begins to fruit, though any shoots that are inclined to cross each other, or run away unduly, should be removed betimes or cut back. It is generally grown as a standard, but forms a picturesque bush. Old trees should be assisted with manure in some form, or the fruit will be small. The Royal and the Nottingham are good varieties to plant. Trees may still be planted in open weather.

THE FLOWER GARDEN.

By R. DAVIDSON, Gardener to EARL CADOGAN, Culford Hall, Bury St. Edmunds.

Propagation.—Shoots fit for making cuttings of *Iresines*, *Alternantheras*, *Heliotropes*, *Abutilons*, &c., should now be taken off, and, after proper preparation, inserted in pots or pans filled with a mixture of finely sifted leaf-mould one-half, loam one-quarter, silver-sand one-quarter, with a $\frac{1}{2}$ -inch layer of sand on the surface; afford water sufficient in quantity to settle the sand about them, but no more, and plunge in bottom-heat of about 75° in a propagating-house or frame, and keep close and shaded from sunshine for about ten days, and then gradually inure to light and air. If possible, let the requisite number of each variety be struck at one time, in order that batches of equal-sized plants are obtained. If certain varieties of bedding *Pelargoniums* are scarce, cuttings may be obtained in quantity from plants which have been stored in pots or boxes, potting them singly in 60's in a light compost, placing them on the border in a Peach-house orinery that has been started, where they will strike readily and become useful plants. If *Lobelias* are required in large numbers, sow seeds of a good strain at this season, and again in a fortnight, using shallow pans, and affording tepid water to the soil before sowing the seed. When the surface of the soil becomes dry, place a square of glass over each pan, and shade with some light materials until the seeds germinate. Care must be taken not to apply water overhead before such time as the seedlings are well rooted into the soil; slightly immerse the seed-pans in tepid water, so that the water enters from below.

Toy-leaved Pelargoniums.—These plants are very desirable for outdoor gardening, either

as trailers, or specimens for covering trellises. Such of the plants as are intended for forming into specimens, which have wintered in 7-inch pots, may now be potted in 9 or 10-inch ones, making use of a compost consisting of turfy-loam, spent Mushroom-dung, and some road scrapings. Cuttings of these plants standing in boxes having commenced to grow should be potted off to the number of two in a 60-pot, in a less rich material.

Flowering Shrubs.—The pruning, tying, and nailing of climbing plants on walls with a warm aspect should now have attention. The system of spurring the laterals will suit all the summer-flowering varieties of *Lonicera*, such shoots only being retained of full length as may be required for extension. Species of *Clematis* will require little beyond removing the dead shoots. The shoots of some species die to the ground annually; but hybrids of the Jackman type, where the plants are robust, should have the weakest shoots thinned out, or the plants will soon exceed the available space. *C. Jackmani* and its hybrids may be cut down to the ground annually, as it flowers on the current season's growth, or the shoots may be simply shortened; *C. montana* (spring), *C. patens* (spring), *C. florida* (summer), flower on the one-year-old wood; *C. graveolens* (late summer), *C. lanuginosa* (successional), and *C. viticella* (successional), flower on the young growing summer shoots. Avoid the overcrowding of the shoots of *Jasminum officinale* by removing the superfluous growths. *Buddleia globosa*, *Choisya ternata*, *Thermopsis laburnifolia*, *Passiflora cœrulea*, and *P. Constance Elliott*, grow and flower best by allowing free extension, only unripened parts of shoots being removed. There are many kinds of *Roses* that may be closely spurred so far as regards the growth of the previous year, but reserving well ripened shoots that spring from the base of the plants; these being laid in, filling the place of exhausted shoots and branches. The flowers of *Maréchal Niel* and climbing *Niphetos* are borne on young, well ripened lateral shoots. Cut back old bare branches where practicable, and thus make room for strong vigorous growth that will produce flowers the coming summer.

RESOURCES OF THE STRAITS SETTLEMENTS.—According to a recent number of *Nature*, Mr. H. N. RIDLEY, Director of the Botanic Gardens, Singapore, delivered a lecture at the Imperial Institute recently, entitled "The Economic Resources of the Straits Settlements and the Malay Peninsula." He remarked that the forests, which originally covered the whole peninsula, contain many valuable products, such as timbers, wood-oil, benzoin, gutta-percha, and rattans. Owing to the felling of trees by the Malays, gutta-percha, so indispensable for electric work, has been nearly exterminated. Fortunately, however, the product can now be extracted from the leaves and twigs without injury to the trees, which are being planted by the Government. A very large area of the Federated States is under Coffee, but on account of the present glut of the market, and the consequent low prices, most of the planters are adding Para-rubber to their estates—a tree which thrives marvellously well, and produces a very satisfactory amount of rubber of the first quality. India-rubber from the *Ficus elastica* also promises well; but although it is being planted, its product is less highly valued. Accounts were given of the cultivation and preparation of Sago (Laere of the Sago-Palm gives as much nourishment as 163 acres of Wheat), *Tapioea*, *Gambia*, *Mangrove-Cutah*, *Pepper*, *Nutmegs*, *Cloves*, *Indigo*, and *Pineapples*. The greater part of the preserved Pines of commerce come from Singapore, where the price of the fruit varies from a farthing to a penny each; and the lecturer remembered a time when they had been as cheap as sixteen a penny! The mineral resources of the colony include gold and tin, the latter being found in great abundance."

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editor does not undertake to pay for any contributions, or to return the unused communications or illustrations, unless by special arrangement.

Illustrations.—The Editor will thankfully receive and select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.

Local News.—Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

SALES FOR THE WEEK.

MONDAY, FEB. 3.—Plants, Lilies, &c., by Protheroe & Morris, at 12.
WEDNESDAY, FEB. 5.—Palms and Decorative Plants, Fruit Trees, &c., at Stevens' Rooms, 12.30.—Azaleas, Palms, &c., by Protheroe & Morris, at 12.
FRIDAY, FEB. 7.—Roses, Ferns, &c., at 12; Orchids, by Protheroe & Morris, at 12.30.
(For further particulars see Advertisement columns.)

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three Years at Chiswick —39° 3'.

ACTUAL TEMPERATURES:—

LONDON.—January 29 (6 P.M.): Max. 39°; Min. 31°.

January 30.—Fine; slight frost.

PROVINCES.—January 29 (6 P.M.): Max. 42°, S.W. Ireland; Min. 27°, N.E. Scotland.

We are challenged by Mr. WARD to give chapter and verse for our statement in a recent number, that there is no "special" virtue in the use of nitrogenous manures for Peas. Perhaps, if we had used the word proportionate, our meaning would have been clearer. We did not intend to convey the impression that Peas were not at all benefited by manure of this kind—daily experience in the season would prove the contrary. But the benefit is not directly proportionate to the quantity of manure used. We based our statements on the well-known Rothamsted experiments, in particular on some which we had the opportunity of watching and noting for ourselves for some years in succession.

On a plot manured with dung, the total Leguminosæ actually diminished in comparison with what happened on the unmanured plot. Leguminous plants under the influence of dung and ammonia-salts were almost banished, and corresponding results were observable on each one of the many plots to which nitrogenous manure of any kind was applied. It must be remembered that these were not a few experiments on a small scale over a short term of years, but, on the contrary, they were very numerous, on a large scale, and extended over half a century, the records being kept with that minute accuracy which characterised all the Rothamsted experiments.* A summary statement of the facts is given

in Dr. MASTERS' *Plant Life*, p. 100, in the chapter on "The Battle of Life."

Leguminous plants are known to be in a degree independent of nitrogenous manure by virtue of the little nodules which are met with on their roots. These nodules result from the irritation and swelling caused by minute bacteria. But the irritation and swelling are not all detrimental to the plant. The bacteria they contain have the power, in some way or another, of collecting and furnishing to the plant the nitrogen it requires, possibly by converting insoluble compounds of nitrogen in the soil into those which can be assimilated. In any case, the apparent parasite confers a benefit on its host, and a state of what botanists call "symbiosis" is maintained, to the advantage of both. Percival's *Agricultural Botany* (1900) has an instructive chapter on this subject.

The whole subject is indeed complex and ill-understood, but enough is known to show that, provided a soil be fairly rich, no large amount of farmyard manure or of nitrogenous manures generally, is necessary in the culture of Peas and Beans. In this respect they are the antithesis of cereal plants.

One of the best artificial manures for leguminous plants, Peas and Beans, is muriate of potash afforded as top-dressings at tri-weekly intervals, and if possible in moist weather hoeing it into the ground. This should be applied just before the plants come into flower, and again during the bearing season. In the event of rain not falling, water must be applied on each side of the row for a space of 18 inches, the distance to which the dressing should extend. As manures furnishing potash and phosphates, there are the Norwegian fish-manures, especially that of cod and potash, the phosphates equalling 20 per cent., and potash 15 per cent., and the quantity advisable to use being from 2 to 4 cwt. per acre. As a means of treating the land in accordance with the needs of the Pea-crop, the intercropping method is the more suitable, the position of the rows of Peas being indicated by stakes, the breadth for single rows being 4 feet, and double rows 7 to 8 feet, according to the height of haulm. These strips could be left undug, and be trenched 2 to 3 spits deep; and the intermediate breadths should be manured in a manner suited to the various crops they are intended to carry, and dug or trenched as may seem desirable.

LINNEAN SOCIETY.—On the occasion of the evening meeting to be held on Thursday, February 6, 1902, at 8 P.M., the following papers will be read:—1. "On a Method of Investigating the Gravitational Sensitiveness of the Root-tip," by F. DARWIN, F.R.S., F.L.S.; 2. "An Extinct Family of Ferns," by Dr. D. H. SCOTT, F.R.S., F.L.S.

MY GARDEN DIARY.—MESSRS. SUTTON & SONS, of Reading, have again this year sent out an Almanac in a pretty cover, and containing useful cultural notes, and blank spaces for memoranda. The following appropriate quotations are appended to the booklet:—"Doing things in good time is the main secret of successful gardening," *The Garden that I Love*, by ALFRED AUSTIN. "I do hold it, in the royal ordering of gardens, there ought to be gardens for all the months in the year; in which, severally, things of beauty may be then in season," Lord BACON.

PRESENTATION TO MR. JOHN WRIGHT.—At the annual meeting of the Worshipful Company of Fruiterers, held on Friday, January 24, Mr. JOHN WRIGHT, V.M.H., was presented with the handsome Gold Medal of the Company upon the publication of the sixth edition of *Profitable Fruit Growing*. Mr. WRIGHT, who was for twenty-five years (ending at the close of 1900) on the staff of the *Journal of Horticulture*, thus becomes a triple Gold Medallist for distinguished services in horticulture.

MONMOUTH TECHNICAL INSTRUCTION COMMITTEE.—We have received the Report of the Organising Secretary to the Technical Instruction Committee (County of Monmouth) as regards agriculture, dairy and cheese schools, horticulture and arboriculture. Horticultural instruction has proved acceptable and profitable, and cider-making has also received attention, and the cider showed a marked improvement upon that made last year.

"AGENDA HORTICOLE."—Par L. HENRY (Paris: Librairie and Imprimerie Horticole, 84 bis, Rue de Grenelle). A useful handbook, including a calendar and much useful information, not merely about agricultural and horticultural arrangements for the current year and notes, but also weights and measures, postal information, money tables, and the usual accompaniments of an almanac, including a blank diary and pages for memoranda.

"INDEX KEWENSIS."—The first instalment of the Supplement to the *Index Kewensis*, prepared by M. DURAND, of the Brussels Botanic Garden, and Mr. B. DAYDON JACKSON, has just been issued. It comprises the names of plants published between 1886 and 1895 inclusive, and extends from "A" to "Cym." The first thing that strikes us is the overwhelming number of names for which Herr KUNTZE is responsible. To give one instance: under *Acinodendron* between seven and eight quarto columns of Kuntzean names are given for species which have been referred by all other authors to *Miconia*. Herr KUNTZE may be right or he may be wrong in his opinion, but by insisting on it, he is making systematic botany impossible. Nomenclature in itself is a means and not an end; pursued as an end it defeats its own object of facilitating study. The editors are probably technically correct in inserting all these names, but we should have been just as well pleased if they had been left in the author's *Revisio Generum Plantarum*, where they might have been found by those desirous of making the search. If these names had been the outcome of monographic research on the part of the author, they would, of course, have a clear right to be inserted in this Index. Ten years ago we discussed the matter in these columns, and need not more fully advert to it now unless it be to express our satisfaction that the names alluded to are treated as synonyms rather than as accepted names. The more frequent insertion in the Supplement of the date of publication is an improvement for which workers will be grateful. Even now, there are omissions in this particular, for while the dates are given in some genera, they are omitted in others. In some cases we find hybrids included, a circumstance which, in view of the activity of hybridists, we may well rejoice at. The spelling of the word *Alchimilla* is unfamiliar: LINNÆUS certainly wrote *Alchemilla*, but doubtless the editors had good reason, because, as we see in the *Philosophia Botanica*, TOURNEFORT wrote *Alchimilla*. If this is the reason, the change is of a rather Kuntzean character. A few misprints, wonderfully few,

* "Agricultural, Botanical, and Chemical Results of Experiments on the Mixed Herbage of Permanent Meadow, conducted for more than twenty years in succession on the same land." Part II. "The Botanical Results." By Sir J. B. LAWES, Bart., LL.D., &c.; J. H. GILBERT, Ph.D., F.R.S., &c.; and MAXWELL T. MASTERS, M.D., F.R.S. *Philosophical Transactions of the Royal Society*, vol. 173 (1883).

are apparent: "*lasciocarpa*" should be "*lasiocarpa*," and "*Im Thurn*" should be "*Im Thurn*;" *Aristolochia longe-caudata*, Mast., published in MARTIUS' *Flora Brasiliensis* in 1869, and figured in the *Gardeners' Chronicle*, November 1, 1890, is not mentioned either in the original text or in the Supplement, although SERENO WATSON's plant of the same name, but not published till 1887, is included. But these are very minor matters; the substantial fact is, that we have here the commencement of the record of all plant-names (except those of Cryptogams), published between 1886 (the date at which the original volumes cease) and 1895; and this is a boon for which all botanists and all those engaged in systematic research will hold the editors in grateful admiration.

A VICTORIA MEMORIAL TREE.—The KING has planted a tree at the Flemish Farm, Windsor Great Park, in memory of QUEEN VICTORIA. It is placed near that planted by the late QUEEN to the memory of the PRINCE CONSORT, to mark the spot where he fired his last shot when shooting in Windsor Park, where he caught a chill shortly before his death.

BOTANICAL BOOKS.—The books recently sold at STEVENS' Rooms in many cases sold at splendid prices: "Curtis's British Entomology" realised £19; a remarkably fine set of "Curtis's Botanical Magazine," £130; "Edwards' Botanical Register" realised £16; "Hooker's *Icones Plantarum*," £43 10s.; "Loddiges' Botanical Cabinet," £39; "Sowerby's English Botany," £15; "Parkinson's *Paradisi in Sole*, &c.," £20; "Andrews' Coloured Engravings of Heaths," £15 10s.; "Curtis's *Flora Londinensis*," £12 12s.; and "Blume's *Rumphia*" realised £13.

HOUBLON APPLE.—Messrs. HORNE & SONS, Cliffe, near Rochester, Kent, have purchased the entire stock of the new dessert Apple called Houblon from Mr. C. ROSS, Welford Park Gardens, Newbury, Berkshire. This is from the same cross as the famous Charles Ross Apple; in fact, it is from a pip out of the same fruit, but takes more of the character of one of its parents, Cox's Orange. It gained the 1st prize at the Palace Show, October 10 last. The same dish was shown at the Royal Horticultural meeting, December 17, when an Award of Merit was recommended for the novelty. The fruits were not larger than Cox's Orange Pippin, but were very highly coloured. The eye is open, and set in a moderate-sized basin; the quality of the flesh is good. The parent tree having a heavy crop of fruit last summer, made but little wood, so that the stock of trees the first year will be very limited.

THE MIDDLESEX COUNTY COUNCIL SCHOOL OF HORTICULTURE.—The Technical Education Committee of the Middlesex County Council having decided to establish a school of practical and scientific horticulture, has, by arrangement with the Edmonton District Council, acquired a large piece of land with six greenhouses at Pymmes Park, Edmonton, for the purpose of carrying out this idea. The main object in view is to give a thorough horticultural training to those who are anxious to take up gardening as a profession. Opportunity will also be afforded to school teachers to acquire a knowledge of horticulture by means of special Saturday morning lessons and demonstrations in the gardens. Only the best and most profitable kinds of fruits, flowers, and vegetables, will be grown; and trials and experiments of particular crops or varieties

will be carried out from time to time, as occasion may require. Scientific training will go hand in hand with the practical, and lectures and demonstrations on the theory and practice of horticulture, the examination and classification of plants, the use of the microscope, &c., will be freely given. Students will also have the privilege of attending the lectures on chemistry and other sciences at the Council's well appointed laboratories at the Tottenham Polytechnic. The County Council offers three scholarships of £20 to £30 per annum, according to the age of candidates. The work in the gardens will be carried out under the direction of the Council's Instructor in Horticulture, Mr. JOHN WEATHERS, F.R.H.S., author of *A Practical Guide to Garden Plants*. Prospectuses and further information relating to the School of Horticulture may be obtained from the Organising Secretary, The Guildhall, Westminster, S.W.

FLOWERS IN SEASON.—Some blooms of very excellent varieties of *Primula sinensis* were recently brought to our notice by Mr. W. BULL, the New Plant Establishment, King's Road, Chelsea, which brought out capitally the advances made in colour, form, and size, in this species. We remarked *marmorata*, *lilacea*, *Ruby Queen*, *Imperial Blue*, *Avalanche* (a fine dense white), and *Comet*, all single-flowered; *Blushing Beauty*, *Fulgens*, and *Prince Arthur*, among double-flowered varieties.

CHRYSANTHEMUMS.—Mr. H. CANNELL lately discoursed at Chislehurst on the history of the Chrysanthemum. Few persons are better able to speak with authority on this subject, as he has been an active participator in the work of improvement during the last 50 years. SALTER, whom Mr. CANNELL mentions, was not a Frenchman, but an Englishman who resided for some years at Versailles and afterwards returned to England, bringing with him many novelties among Chrysanthemums. He was also one of the first to take up the varieties imported by Fortune. Mr. CANNELL alludes to the value of the services of Mr. HARMAN PAYNE; and sketches the origin and progress of the Pompon, Japanese, hairy, early-flowering, and other varieties, and does not overlook the beauty of the single varieties.

TESTIMONIAL TO MR. RICHARD DEAN.—At a meeting of subscribers, held on January 14 at the Royal Aquarium, Westminster, it was resolved to entertain Mr. DEAN to dinner at the Aquarium on February 1, and to then present the testimonial. The testimonial will take the form of an address on vellum and a cheque. Application for dinner tickets should be made to Mr. H. J. JONES, Ryecroft, Lewisham, London.

"THE CULTURE OF VEGETABLES AND FLOWERS FROM SEEDS AND ROOTS."—By SUTTON & SONS, Reading. (London: SIMPKIN, MARSHALL, HAMILTON, KENT & Co., Ltd.) This is the tenth edition of a handbook valuable to any gardener, professional or amateur. It deals with a Year's Work in the Vegetable Garden, the Rotation of (Vegetable) Crops, the Chemistry of Crops, Culture of Flowers from Seeds and from Bulbs, Flowers all the Year Round, Lawns from Seeds, and Fungous and Insect Pests. The book is the work of experienced hands, and the present edition appears to be improved and enlarged. The index is a useful addition.

"BOTANIKER ADRESSBUCH."—This is a list of the names and addresses of living botanists in all countries. It is carefully executed, and indispensable to botanists and those who have to do with them. The latest change in

the Brussels Botanic Garden is not noted, probably because the book was already in type. It may be had from Herr DÖRFLER, Barichgasse 36, Vienna, III.

SNOWDROPS.—In a garden at Ealing exposed to the north, the first Snowdrop was picked on January 21, which is about the average date. The earliest date in the same garden was January 9, 1890, the latest date February 6, 1891.

FRUITS AND VEGETABLES FROM FRANCE.—It is interesting, for several reasons, to learn that the trade in Strawberries and vegetables between Brest and Plymouth is an increasing one, and very profitable to our friends across the Channel. In 1900 the sales here of French produce amounted to £50,000; last year they reached some £60,000; and it is believed that this year there will be a still further increase. In view of this, several steamers are being taken up here on six-week contracts to carry fruit and vegetables from Brest, &c., to Plymouth, on every day of the week excepting Saturday and Sunday.

THE NATIONAL CHRYSANTHEMUM SOCIETY'S annual general meeting, which has been already announced for Monday next, Feb. 3, will be held at Carr's Restaurant, 265, Strand, W.C., at 7 P.M., when Sir A. K. ROLLIT, M.P., the new President, is expected to take the Chair. In addition to the usual business, such as the presentation of the Committee's report and balance-sheet, election of Officers, &c., notices have been given of proposed amendments to Rules III. and XIV. A subscription-list has been opened for the purpose of establishing a memorial to the late President by the offering for competition each year of a large Gold Medal of the Society, such medal to be known as "The Sir Edwin Saunders Memorial Gold Medal."

"IN A MINSTER GARDEN."—A causerie by the Dean of ELY. (London: ELLIOT STOCK, 62, Paternoster Row, E.C.) The pictures first draw our attention, as they are from photographs of charming "bits" of Ely architecture. As to the garden, that is the setting for a love-story with a heroine endowed with beauty, book-learning, musical genius, and just a few other possessions. Dr. STUBBS is evidently enthusiastic about the history of Ely and the "Minster," and is most at home when writing of BRYHTNOTH the Ealdorman, JOHN of Crauden, and other local heroes, who are still far more interesting than the puppet-like characters that are supposed to be types of modern life. But we are not disposed to be severe on any part of a book "written," says the Dean, "to amuse myself during the enforced leisure of convalescence;" and avowedly "O et olla." This motto is a quotation from a list of expenditures of the thirteenth and fourteenth centuries: the "O" indicating one or other of the great pre-Christmas antiphons which began *O sapientia!* *O Adonai!* and so on. "The olla, or pot, was the homely synonym for the subsequent rejoicing at the refectory feast . . . under the titulus 'O et olla,' therefore, was evidently combined the thought of things both solemn and joyous, grave and gay, of prayer and worship in church, of comradely work and happy leisure in cloister and frater house." Besides the subjects already indicated, we read of the Prior's holiday in the New World, where his experiences were favourable but, probably, not unique, and so are given to us in a single chapter, and not spun out to form a whole book. This "Minster Garden" should be welcomed by transatlantic readers, for it

bears about it the atmosphere as it were of antiquity, half traditional, half historical, that makes our cathedral cities so charming. The book would make a welcome gift to anyone interested in Ely, as it is full of local "colour," yet quite unlike an ordinary guide-book.

RUMPHIUS.—The directors of the Colonial Museum at Haarlem intend to celebrate, on June 15, 1902, the bicentenary of the death of GEORG EBERHARD RUMPHIUS. This naturalist, who was born in 1627, died on the Island of Amboyna, after forty years of unremitting labour there. A medal is to be issued to commemorate the life and work of this distinguished scientific man in the Moluccas. The medal shows, on one side, the portrait of RUMPHIUS, and on the other, a view in Amboyna. The execution of the design has been entrusted to the firm of C. Y. BEGER, of Utrecht. Purchasers of the medal will be presented with a copy of the Rumphius Memorial Book, which will be published on June 15, 1902, at the Colonial Museum. Contributions may be sent to Herr W. P. GROENEVELDT, or to Herr M. GRESHOFF, director and secretary respectively of the Colonial Museum, Haarlem. The medal, which is about 2 inches across, costs about two guineas in silver, and eight shillings and sixpence in bronze.

"LINDENIA."—The December number of this important publication contains coloured illustrations and descriptions of the following Orchids:—

Vanda teres var. *candida*, tab. declvii.—A variety originally described by Reichenbach in our columns in 1875. The segments are white, the anterior lobe of the lip streaked with lilac, and the base marked with yellow.

Odontoglossum crispum La Veine, t. declviii.—A truly superb variety, with flat flowers, broad, ovate-acute, undulate segments, white, with a large central rosy-purple blotch. The lip is of similar form, with a large central purplish blotch, surrounded by a narrow white edge, and with a yellow disc. The name "la Veine" has reference to the fine "vein" of *Odontoglossums* which the collectors for the Moortebeke establishment have been so lucky as to exploit.

Catanthe : *Mylesii*, t. declix.—Probably a hybrid between *C. vestita* and *C. Veitchii*. The hybrid has the flowers entirely white. A list of the more important hybrids is given.

Cymbidium ligurium, t. declx.: *Bot. Mag.*, t. 5457. One of Mr. Parish's discoveries in the mountains of Tenuasserim. Flower segments greenish-yellow spotted with red, the lip white streaked with purple, its lateral lobes yellow streaked with reddish-brown. The terminal flowers are sometimes wholly red, and the column imperfectly developed, peculiarities which are not constant, as they are not shown in the plate.

ROYAL APPOINTMENT.—Messrs. THOMAS GREEN & SON, Limited, inform us that they received a warrant appointing them purveyors of mowing-machines to the KING in August last, and they were therefore among the first to receive His Majesty's commands. The firm held a similar appointment from her late Majesty Queen VICTORIA.

PUBLICATIONS RECEIVED.—*The Ninth Report of the New Zealand Department of Agriculture, 1901.* Contents: Sir John McKenzie, K.C.M.G. (obituary notice); Report of Secretary for Agriculture, Dairying, Stock, Poultry, Veterinary Science, New Zealand Hemp, Biology, Horticulture, &c.—*Annual Report of the Queensland Department of Agriculture for 1900-01.* "The greatest agricultural industry here at present is the sugar industry. About one-fifth of all our cultivated land is under Sugar-cane, and about three-fourths of the value of our agricultural exports must be credited to sugar. It is therefore not pleasant to have to record the heavy loss this great industry suffered, chiefly from drought, last year." Much more encouraging are last year's figures relating to Wheat, Maize and fruit-growing also were successful.

SANTA BARBARA.

[SEE SUPPLEMENTARY ILLUSTRATION.]

OUR illustration, furnished by Dr. Franceschi, shows the effect of an Agave when permitted to flower in the open air. The plant is named *A. recurvata*, a name not in Mr. Baker's list, but which may be a form of the common *A. americana*, the so-called century plant, though every gardener is aware of the inaccuracy of the popular notion that a century is required to ensure the production of flower. A considerable time may indeed lapse before the conditions are favourable. When once the plant has flowered it dies, but not before it has provided for its perpetuation by the production of offsets.

Santa Barbara, says Dr. Franceschi, is known all over the world as the place where the largest number of plants from widely different climates have congregated to live happily together, and will often thrive with more vigour than in their native countries. Mainly two factors have contributed to bring these results. The first is Nature, namely, the special topographic and climatic conditions of this spot. The local meteorological records for over 30 years, when carefully compared with other localities of Southern California, unquestionably show that Santa Barbara enjoys the privilege of higher rainfall, and of less variation between the different seasons of the year, consequently the growth of most plants is continuous, and they will attain here larger size and come into bearing much earlier than in other places. The other factor is man, who in this case has wonderfully co-operated with Nature. Ever since the first establishment of the Old Mission, more than a century ago, a much larger number of plants was introduced here from foreign countries than in other localities of California, and a smaller number of them have been lost, because they found here more congenial conditions. At the beginning of the new century, it is safe to say that there are grown in the open at Santa Barbara not fewer than 150 different species of Palms, about the same number of Conifers, 50 species of Bamboos, about 300 Vines or climbers, and something like 2,000 different species trees, shrubs, and perennials. They have been introduced here from the hottest and from the coldest regions of the globe, as well as from the temperate ones, and they combine to make a display of vegetation that have no rivals anywhere else.

As for Roses and the more familiar garden flowers, their profusion at all seasons of the year is fairly bewildering. Even more interesting to the botanist, or indeed to most genuine flower-lovers, are the native wild flowers which, in their season, carpet field and hill-side.

THE SALE OF POISONS FOR INDUSTRIAL PURPOSES.

WILL you kindly allow me to bring under the notice of your numerous readers the action that is being taken by and on behalf of a number of important traders who are interested in the sale of poisons for other than medicinal purposes? Agricultural agents, farmers, agriculturists, fruit-growers, seedsmen, ironmongers, drysalters, and many others are concerned, and to some of these the subject of this letter may not be unfamiliar, while to others, who have not had their attention directed specially to it, it may be both new and interesting, as well as important.

To put it briefly, the question at issue is, the right, and the desirability, of poisonous compounds required for trading and industrial purposes, being sold by other than dispensing chemists and druggists. The latter possess, under the Act of 1868, the monopoly of all such sales, and occasionally the Pharmaceutical Society, acting in their behalf, institutes prosecutions for the recovery of penalties, with the object of assert-

ing this monopoly; but as a matter of common practice, the law is not generally regarded as having the effect that the Pharmaceutical Society contends for, and many retail dealers habitually disregard its alleged intention—of course, at the risk of being proceeded against. It is for the purpose of relieving traders of this liability, and thereby meeting the convenience of the public at large, that an organisation entitled "The Traders in Poisons or Poisonous Compounds for Technical or Trade Purposes Protection Society" has been formed; and the action that this Society is now taking, in the interests of all such traders throughout the country (and not merely its members), is what I am anxious to disclose to your readers.

The Society to which I have the honour to be Secretary was formed in March, 1900, since which date it has been very successful in organising the various traders who are directly concerned in the sale of poisonous compounds for industrial purposes; upon the eve of the last General Election it communicated with most of the parliamentary candidates, and 90 per cent. of the replies received were favourable to the Society's objects. Briefly put, the object is to secure an amendment of the existing law. Those traders who are continuing the sale of the various articles in which they have been accustomed to deal will be gratified to learn that effectual and energetic steps are being taken to vindicate their position, and secure their immunity from prosecutions. This is largely due to the great and sustained interest taken in the Protection Society by its Treasurer (Mr. G. H. Richards), whose strenuous exertions have done much to inspire confidence in the classes of traders who are directly concerned in this subject, and who may confidently rely upon a continuance of energetic action in their behalf until the object is attained. There are many reasons why the Pharmacy Act of 1868, already alluded to, should be amended. In the first place, it is evident, from the preamble, that it was intended more particularly to ensure the safety of the public, by insisting that only competent persons, having practical knowledge of the properties of poisons, should have the dispensing of same. That is reasonable enough; but in the days when the measure became law there were not in existence the multitudinous packages and bottles of preparations, compounded by the manufacturer ready for immediate use, for horticultural, agricultural, and other trade purposes, which are now to be met with all over the country. As regards these, the ordinary chemist and druggist has no more practical knowledge than the man in the wood. The manufacturer tells him—and the public at large—by advertisement, that this or that mixture, or sheep dip, or powder, is an excellent remedy for this or that disorder, and the purchaser, like the chemist, takes it on trust for some specific purpose, the chemist being merely the channel through which the manufacturer reaches the customer. There is no skilled practical knowledge of poisons required to dispose of a sealed packet or vessel which the chemist receives from the manufacturer, who alone undertakes the responsibility of declaring that a compound of poisonous articles, of a certain strength, is effective for a certain purpose. The purchaser might just as well buy what he wants from any other tradesman so far as the skilled knowledge of the chemist is brought to bear upon the article disposed of. Indeed, in most cases it would be distinctly advantageous to the buyer if he went to some person who had practical experience of the preparation required. Take, for instance, the case of an insecticide (such as XL All) containing poison. Would not a seedsman or horticultural agent be more likely to give valuable advice to a purchaser based upon practical experience, than a chemist whose principal employment is the dispensing of drugs intended to cure all the ills that flesh is heir to? The one has probably used the poison himself, and is in a position to say how best to apply it; but the chemist would, from his different occupation, have had no opportunity of acquiring such knowledge.

The same argument applies to sheep dips, weed-killers, &c. If there is any risk to public safety involved in the proposed freer sale, it is not increased by disposal through a seedsman, nor minimised by being handed over a chemist's counter. Again, how few pharmacists have any but the most remote knowledge of the best means of destroying aphids, mealy bug, or mildew—so destructive to the fruit-grower—compared with the seedsman or agricultural agent? The new vaporisers and insecticides which have come into such general use in recent years have been invented by members of the horticultural trade, and people who are accustomed to their application are naturally the best advisers of purchasers—not chemists, who know nothing of them beyond the label on each packet. Indeed, the skilled knowledge of the pharmacist, which may be of the utmost service in making up a bottle of medicine for a human being, is not brought into use in the sale of a sealed packet or vessel; hence the very reasonable demand that the sale of poisonous compounds for purposes already indicated shall not be confined to chemists and druggists, but be legally extended to other tradesmen, who can then meet the convenience of the public without incurring risk of

prosecution. A measure such as is contemplated would also enable photographic requisites containing poison to be sold by others than chemists.

It is to the benefit of traders in all parts of the country that the Society to which I have referred is exerting itself, and I am glad to inform you that the reasonableness of its demand has been admitted by the Privy Council, who last year appointed a Poisons Committee to investigate the matter and report on the evidence submitted to them. Already that Committee has held three sittings, at which witnesses were heard on behalf of the Pharmaceutical Society on the one hand, and our Protection Society on the other, besides

seedsmen, oil and colourmen, ironmongers, hardware dealers, and the like, who would benefit by an amendment of the law which enabled them to sell, without fear of prosecution, many articles in great demand, in town and country alike. I therefore hope that this Trade Protection Society will receive their cordial support. It already has the sympathy, in a practical form, of the Ironmongers, the Tar Distillers, and the Photographic Societies, and it is hoped that the success which has attended its efforts so far in its attack upon the monopoly, will attract the continued and extended interest of all those who wish to see that monopoly broken down.

A VISIT TO THE NORTH.—XI.

(Concluded from p. 55.)

DALKEITH PALACE.

On the last of the very few days spent in Edinburgh, I determined to go to Dalkeith, and get a glimpse of those gardens that, together with the name of their late director, Malcolm Dunn, are known, by repute at least, to all readers of the *Gardeners' Chronicle*. Time was very short, for when I had travelled

FIG. 29.—VIEW OF THE GARDENER'S HOUSE AT DALKEITH, AND SHOWING SITE OF THE RIBBON BORDERS, REFERRED TO ON P. 82.

some independent skilled and Departmental witnesses; and there is good reason for believing that the Committee may recommend the adoption of a third schedule to the Pharmacy Act, which will provide, where poisonous compounds are sold in sealed packages for agricultural, horticultural, disinfecting, and other trade or technical purposes, by persons other than chemists, who shall be duly licensed, and being respectable and responsible individuals, they shall be lawfully entitled to sell such articles.

It must be understood, however, that this desired result can only be obtained by the traders concerned bestirring themselves and bringing pressure to bear upon the Members of Parliament in their respective districts, pointing out to them the desirability of the Government being urged to bring in an amendment Bill for the purposes above indicated.

For every fully qualified chemist, there must be a large number of agricultural agents, horticulturists,

In saying this, allow me to add that we in no sense advocate, or desire to bring about, the indiscriminate sale of poisons. We urge that all retailers of them should be registered and licensed, and that those who are not pharmacists should sell only in sealed packages or vessels, without breaking bulk. By these precautions being observed, we contend that the public safety would be safeguarded quite as much as it now is, while the public convenience would be vastly increased. If other information is desired on this important subject, it will be readily furnished by yours faithfully, Thos. G. Dobbs, Secretary, 24, Sansome Street, Worcester, January 28, 1902.

P.S.—Since writing the above, according to the *Chemist and Druggist* (the trade organ of the pharmacists) of the 25th inst., it is admitted, to use their own words, "that the report (of the Poisons Committee of the Privy Council) will be to some extent opposed to the Pharmacy Act view of the sale of poisons."

to Esk Bank Station on the North British Railway, and walked to the gardens, the afternoon's sun was low. But contrary to expectation, I was fortunate in finding the new gardener, Mr. James Whytock, in one of the vineries, and he very kindly did all in his power to assist his unexpected visitor to see as much as was possible of this celebrated place.

The approach to the estate is not of the best description. The borough of Dalkeith impresses the visitor unfavourably. The houses are blackened by smoke, and the dwellings are small and mean in appearance; whilst the number of bare-footed "bairns," and of even

older individuals, that are seen in the streets and at the doors of the houses may be accepted as proof that the inhabitants generally are not in too comfortable circumstances. Such are the conditions of the main thoroughfare, and they approach almost to the great gates leading to the park.

Once upon any part of the estate of Dalkeith Palace, which it may be scarcely necessary to say is one of the residences of the Duke of Buccleuch, and the contrast afforded to Dalkeith itself is very impressive. Here is everything upon a grand scale. The Palace is large, the park is extensive, and contains very old timber trees, and the gardens are provided with everything necessary for the maintenance of a princely establishment.

IN THE GLASSHOUSES.

I have stated already that I found Mr. Whytock in one of the vineries, and that being so, he directed my attention at once to some Vines of the Sprotboro Muscat. Some gardeners believe this variety to be synonymous with Muscat of Alexandria, but at Dalkeith the blossoms set freely in a lower temperature than is successful in the case of the variety more generally cultivated. There is little doubt but that the Vines at Dalkeith have needed to be renewed in the past few years, and the new gardener has applied himself to the work at once. Consequently, some of the houses now contain quite young canes, and after a few seasons it is confidently expected that the yield of Grapes will be much greater and the quality superior. The Duke has built a new vinery as an encouragement. This structure is 75 feet long and 20 feet wide. It has a $\frac{3}{4}$ span roof, and is 20 feet high. The builders were Messrs. McKenzie & Moncur, and like most of their houses, this one is constructed of teak wood. The length of the house is relieved by a porch with lantern roof in the centre. The young Vines planted in this house had been raised from eyes started in the month of February. Some of my readers may think the house inconveniently high, and it is certainly unusually lofty, but I believe the dimensions were chosen by the Duke, and his gardener will doubtless be able to manage it satisfactorily. There are at Dalkeith, including the new one, eight vineries, one of which is very large. Most varieties of Grapes are cultivated, and Mr. Whytock has a very good opinion of the comparatively new Lady Hutt. In some of these vineries the system of glazing provides that the panes of glass overlap each other a little at the end, and there is $\frac{1}{8}$ -inch space between them, the lower pane passing, of course, under the higher one. This system answers perfectly, for there is no drip in consequence, and the air thus admitted in small quantities from the top of the house is very beneficial, and prevents scorching.

There are numerous Peach and Nectarine-trees indoors. In one of the houses, young trees had been planted in 1900, and in addition to others there is a Peach-house 250 feet in length, and adjoining this a similar structure also 250 feet long containing Plum-trees. Late Peaches and Nectarines were very plentiful at the time of my visit (September 3), and the trees appeared in good condition. Figs are cultivated in two houses which contain trees in pots and in borders. The forcing of Strawberries is a large item, as 6,000 plants are thus used. Favourite varieties are Keen's Seedling, Scarlet Queen, John Ruskin, and Royal Sovereign; but Mr. Whytock said their very best early Strawberry ripening at the end of February is Stevens' Wonder. Melons and Tomatos are grown in abundance. Of the former, the varieties known as Earl's

Favourite and Holborn Favourite are much prized.

I was next shown a feature that unfortunately is very rare in modern gardens, namely, a fine collection of Pineapples. These were in a low, three-quarter span-roofed, sunken pit, 200 feet long, with a path through it. Many gardeners, I know, are glad to be relieved of the care of Pine-cultivation, and owners are equally willing to be spared the expense of the necessary firing. But one notes the disappearance of the Pine-stove from a garden regretfully. The cultivation of Pines calls forth all the care and skill of a gardener, and a first-class fruit produced under the best cultivation is incomparably superior to most imported ones, that too many noblemen now rely upon exclusively. It is all in their favour at Dalkeith that coal is purchased there at 11s. the ton! What a boon would this be for Londoners!

In the pinery mentioned there were fine plants in flower of *Pergularia odoratissima*, and *Stephanotis floribunda*, neither of which harboured a single mealy-bug! Of the rest of the houses I must write very briefly. There were plenty of moderately-sized ornamental plants, suitable for table adornment or for furnishing vases, and excellent plants of *Coelogyne cristata* were remarked, 2 feet or more across them, *Caladiums*, *Cannas*, *Carnations*, *Streptocarpus*, and *Begonias*. *Calanthes* were looking well, and have doubtless made a good show of flower. In the stove, which contained larger-sized ornamental plants, were three fine *Musas*, and there is a house filled with *Camellia* plants, also a greenhouse, &c.

A CONVENIENT "POTTING-SHED."

Before passing from the glass structures, attention may be drawn to a new "potting-shed" that has been built under Mr. Whytock's directions. It is 60 feet long and 21 feet wide, and the roof is partly of glass. How great the contrast between this spacious, light shed and the potting-sheds in half the gardens in the country, which are small, draughty, and insufficiently light for the convenient discharge of the work that has to be done in them! The stokehole, too, at Dalkeith that leads to the powerful steel Cornish boilers (12 feet by 5 feet) is a most convenient one.

EXTRAORDINARY COLLECTION OF FRUIT TREES.

Of the kitchen garden, 4 acres are contained inside the walls, and 8 acres outside. It is divided by good broad walks, covered with loose gravel, and there is an old-fashioned sun-dial in the centre. Everything is maintained in a neat condition, and it was a pleasure to inspect the fine crops of vegetables that were then so plentiful. Probably there is no private collection of hardy fruit-trees so rich in variety as that formed at Dalkeith by Dunn, who had always a love for experiment, and thirst for increased knowledge at first hand. It was these characteristics that led him to plant nearly 200 varieties of Plums, 700 of Apples, and 500 of Pears. In an experimental garden these trees would now be of great value, if only as a means for the identification of fruits from time to time by comparison with living specimens, but they gave Dunn very much more trouble than fifty varieties of each would have done, and possibly the yield of fruit would have been much greater from the lesser number of varieties. In pruning and training also, Dunn tried most of the known methods for his own satisfaction, but the greater number of trees in the orchard are tall standards, with but few pyramids. Near to the glasshouses, and upon

either side of a path which leads to Mr. Whytock's house (see fig. 29), were exceedingly gay ribbon and hardy flower borders. There was nothing unusual among the plants used in them, but they thrived and flowered so well, that one turned again and again to look at the effect, which although so gay was harmonious, and proved that the arrangement of the plants had been given consideration. A somewhat formal flower garden is contained on a small lawn near to the kitchen garden, and shut off from the park by a wall on the east side. The walks between the beds are covered with white shell.

The wall just mentioned affords on this west side some protection to a choice collection of flowering and other shrubs, some of which grow in the border and others against the wall. *Choisya ternata*, *Cytisus pallidus*, *Olearias*, *Daphne hybrida*, shrubby *Spiraeas*, hybrid *Weigelas*, *Eleagnus*, double-flowered *Bramble*, *Nanthoceras sorbifolia*, *Syringas*, &c. Had there been more time, a closer inspection of the collection would have been of very great interest, for in this instance, Dunn's work is affording results in respect to new or little-known shrubs that would be profitable to all planters in this district of Scotland. In the same border *Eucalyptus Globulus* was 25 feet high.

AN OLD ROSE-TRELLIS.

An old rose-covered trellised walk abuts on to the lawn already mentioned. It covers a length of path of 500 ft., and among the old Rose-trees there are some varieties that may be now very rare. In addition to the Roses, there are Honeysuckles, Peas, &c.; and Mr. Whytock states that nearly always during spring, summer, and autumn, there is some plant or other in flower. This Rose-trellis, with an arbour at either end, is nearly a century and a-half old, and was moved by Macintosh, sixty or seventy years ago, from the old garden to the new one he was then engaged in forming.

Another collection of Roses worthy remark is contained in a hedge planted early in the last century, probably by Macintosh, or earlier. The varieties are double-flowered Scots Roses, and though there are now only ninety-one existing, it is said that the collection originally included 150 varieties, which at the time they were selected were thought to be not only distinct from each other, but the choicest obtainable. This broad hedge is about 100 yards long, and the varieties maintain a show of bloom for more than a month each year. The labels have long been lost from the plants, but each variety has been numbered and described when in flower with a view to identifying them. Many of them are exceedingly beautiful and fragrant, and such a quantity of them must scent the air for a considerable distance. These Roses were described at some length in the *Gardeners' Chronicle*, July 16, 1898, p. 41.

Dalkeith Palace stands on a terrace overlooking a deep valley where the river Esk flows through the grounds. There is a fine massive stone bridge over the river, and a waterfall behind; and on the terrace several fine Cedars of Lebanon. The view from the Palace embracing these and the wide sweeps of excellently maintained lawns is very enjoyable.

Dalkeith grounds include some part of the original Caledonian forests, and Oaks which are said to be 800 years old. In the pleasure-grounds are very many trees and shrubs of interest that I have not mentioned, including a large *Cedrus Deodara*, *Taxus adpressa*, *Hollies* in great variety, *Buddleia globosa*, *Kolreuteria paniculata*, and *Sequoia gigantea*.

pendula 18 feet high, said to be one of the first plants of this variety distributed. Its apex is still erect, not drooping, as in the specimen illustrated in the *Gardeners' Chronicle*, December 29, 1900, p. 478.

Mr. Whytock, a Scotsman, who came to Dalkeith from Earl Fitzwilliam's garden at Coolattin in Ireland two years ago last October, and who is now writing each week in these pages upon "Fruits under Glass," may be depended upon to maintain the gardens in first-rate condition, and keep the establishment to the front of Scottish horticulture by the practice of good cultivation. Mr. Whytock was once foreman in Dalkeith Gardens under the late Mr. Thomson, and his present position is the third he has held as head-gardener.

I returned to Edinburgh from Dalkeith railway station, reaching the City rather late in the evening. On the following morning, Wednesday, I had travelled to Glasgow by 9 o'clock to attend the second show in the International Exhibition, that of fruits and vegetables (an account of which was published in these pages at the time), and on Thursday morning at 8 o'clock was again in London.

Thus was "A Visit to the North" terminated, and therefore these notes may now conclude also with a grateful acknowledgment of the courtesy and kindness shown me by very many sympathetic horticulturists "across the Tweed." R. H. P.

LAW NOTES.

THE RIGHTS OF MARKET GARDENERS.

CLAIMS FOR ORCHARDS AND GLASSHOUSES: IMPORTANT JUDGMENT.

AN important judgment has just been delivered in the High Court by Mr. Justice Cozens-Hardy in the case of *Mears v. Callender*. This action was brought by a landlord against the outgoing tenant of a farm in respect to fixtures put up for market gardening purposes, and the result will interest all the market gardeners in East Anglia.

His Lordship said: About twenty years ago Mr. Joseph Mears bought of Mr. Wiltshire a farm called Kingwood Farm, in Oxfordshire. It was a purely agricultural holding. For some few years he occupied the farm, but on August 17, 1887, he granted a lease of it to the defendant for 7, 14, or 21 years, from Michaelmas, 1887, at the yearly rental of £165. Shortly after the lease, the defendant converted part of the meadow surrounding the house into an orchard. There are now upwards of 1200 trees in the orchard—Apples, Pears, Plums, and Cherries—in good bearing condition. These trees, though not capable of removal, are worth several hundred pounds to anyone taking the farm. The defendant also erected ten glasshouses, in which Grapes, Peaches, Nectarines, Tomatoes, and Strawberries were grown. From these houses he supplied fruit to Reading, and also to Covent Garden, and I think it is clear that he carried on the trade of a market gardener on the premises with marked success, and with the full knowledge of the landlord. The defendant gave notice to quit the farm at Michaelmas, 1901, and he claimed the right to remove the houses and to have compensation for the orchard trees. He pulled down three houses before action was brought, and the question raised in this action is whether the plaintiff, who is the present reversioner, can take the benefit of the orchard trees and of the remaining houses without making any compensation or payment for the same. The plaintiff's allegation that the defendant threatened to cut down or remove the orchard trees is not proved. There is some conflict of evidence as to the structure of the glasshouses. Upon the whole, I conclude that, as to one of the houses, which has concrete sides, and which was erected in or shortly after 1893, under the superintendence of Mr. Baker, the glass span-roof is not attached in such a way as to constitute it part of the freehold. I think it substantially rests by its own weight upon the concrete wall, and that it could be lifted up and removed without in any way pulling to pieces or damaging the walls. As to the other houses, wooden piles were driven into the ground, on the top of which wide sills were placed which supported the

glass span-roofs, except in the case of the vinery, where there was a lean-to roof. The roofs were nailed to the sills or backings, which in turn were nailed to the posts. Under these circumstances questions of importance and difficulty arise for my consideration. It is contended on the part of the plaintiff that the defendant is bound to leave the orchard and all the houses without claiming compensation. On the other hand, the defendant claims, both at common law and under the Agricultural Holdings (England) Act, 1883, as enlarged by the Market Gardeners' Compensation Act, 1895, to be entitled to remove or to have compensation for all the glasshouses, and he claims under those Acts to be entitled to compensation for the orchard trees. It will be convenient to consider—first, what are the rights of the parties irrespective of the Acts of 1883 and 1895, and whether, and to what extent, their rights are modified or affected by those Acts. Now, at common law, it is plain that the defendant could not cut down or remove the orchard trees or claim compensation. But, as to the glasshouses, a much more difficult question arises. If erected for the mere purpose of pleasure and ornament, and not for the purpose of a trade, they would not be removable—"Buckland v. Butterfield" (2 Broderip and Bingham, 54) "Jenkins v. Gething" (2 Johnson and Hemming, 520). If, however, they were erected, as in the present case, by a market-gardener for the purposes of his trade, different considerations arise. In "Penton v. Robart" (2 East, 88) Lord Kenyon intimated a strong opinion in favour of the tenant. On the other hand Lord Ellenborough, in the leading case of "Elwes v. Maw" (3 East, 38), did not approve of Lord Kenyon's observations, at least in so far as they might be taken to apply to agriculture:—"He"—i.e., Lord Kenyon—"certainly seems, however, to have thought that buildings erected by tenants for the purpose of farming were, or rather, ought to be, governed by the same rules which had been so long judiciously holden to apply in the case of buildings for the purposes of trade. But the case of buildings for trade has been always put and recognised as a known allowed exception from the general rule which obtains as to other buildings." I am not satisfied that Lord Ellenborough dissented from Lord Kenyon's view, so far as market-gardeners were concerned. If, however, there be any difference between Lord Kenyon and Lord Ellenborough, I prefer the view that glasshouses erected by a nurseryman for the purpose of carrying on his trade may be removed. The dicta of Lord Bramwell in "Wake v. Hall" (8 App. Cas., p. 240), support this view. Moreover, the whole tendency of the Courts in recent years has been to enlarge the rights of tenants in respect of fixtures. Nor do I consider that there is anything in Vice-Chancellor Kindersley's judgment in "Whitehead v. Bennett" (27 L. J., Ch. 474) which ought to lead me to a contrary conclusion. Therefore I think the defendant is entitled to remove the glasshouses. The next question is as to the effect of the Acts of 1883 and 1895. His Lordship having summarised the provisions of those Acts, proceeded: I think Parliament deliberately enacted for the benefit of market gardeners that, where a landlord had acquiesced in improvements by the tenant, the tenant should have the same right in respect thereof as he would have had if they had been executed after the Act of 1895. If so, it follows that the defendant is entitled to compensation for the glasshouses and for the fruit-trees, such improvements being taken out of the first part and placed in the third part of the first schedule of the Act of 1883. If, however, I am wrong in holding that the defendant will be entitled to compensation for the houses and orchard, under the Act of 1895, I think he will be entitled to compensation for the orchard, though not for the houses, under the Act of 1883. The landlord's consent in writing to planting the orchard was given by the lease. A landlord cannot impose as a condition of his consent to the term that no compensation shall be paid. The Act prohibits this. The result is that, in my opinion, the plaintiff fails in his contentions, and the action must be dismissed, with costs.

HOME CORRESPONDENCE.

ORANGES.—I have just read the note on "Abnormal Oranges" in the *Gardeners' Chronicle*, January 25, 1902. I can add some information concerning the matter, being acquainted with a dozen or so Orange-trees in Cannes, Nice, and San Remo, whose Oranges are always double-encincts, so to say. These trees differ in no respect from normal Orange-trees, but their Oranges are always double, and one can always see that they are so without opening them, as the distal end of the fruit is somewhat distended, as if there were a small burrow inside. This is the case specifically when the enclosed Orange is very small

or incomplete, for it stays at the distal end, between the skin and the large Orange. When the enclosed is large, it is to be found in the middle of the large one, and then there is no swelling at the distal end. The seeds give normal trees; abnormal Orange-bearing trees can be obtained only by cuttings or grafts from the latter. If you could send me some information concerning the Ladoo Orange, and also the seedless varieties, I should feel much obliged. H. de Varigny, Sc.D., 18, Rue Lalo, Paris.

EARLY FLOWERS.—In reading in the last issue of the *Gardeners' Chronicle* the names of the plants in flower in Mr. Broome's garden on January 18, I was reminded that on Jan. 9 we gathered from about four clumps of *Iris stylosa* a dozen perfect flowers, and since that date we have not been without flowers. At the time of writing, a dozen more might have been seen, and numerous buds visible. The clumps mentioned are growing in a border having a southerly aspect. I think that by affording it shelter from cold winds, *Iris stylosa* may be successfully grown anywhere in the Midlands, and some plants of it should find a place in every garden. J. Platt.

THE DUNN MEMORIAL FUND.—Having subscribed to the above fund, I should be interested to know what progress has been made, and how our money has been spent. Beyond a postcard acknowledgment of my contribution, no other information of any description was sent me. At the end of twelve months I wrote to one of the members of the committee asking him to give me information regarding the memorial; the reply I received was that a stone had been erected in Dalkeith Churchyard, which had not given satisfaction, and that a meeting was about to be called to consider the matter, after which a full report would be published in the gardening press. A year has passed, and still no report. I should like to know if it is a usual thing for subscribers to be treated in this way; if so, all I can say is, that the promoters of memorials are not likely to meet with success. J. Fulton, Grims Dyke, Harrow Weald.

THE BACK-BULBS OF ORCHIDS.—The correspondence that has been appearing of late in this journal in reference to the back-bulbs of Orchids must have suggested many ideas to the cultivator of these plants. I may say that I have cultivated Orchids continuously for twenty-three years as a gardener, and I am convinced that of all plants with which a gardener has to do, Orchids seem capable of standing more rough usage than any other plants; but on the other hand, no other plants give better results for good cultivation. I could record some interesting results of propagation, pruning, &c., but I should like to add a suggestion with regard to the long pseudobulbs of *Cattleya intermedia*, *C. Leopoldi*, and the like, which surely every grower would treat differently to those of *C. labiata*. Many persons will remember the beautifully grown batch of *C. nobilior* which came into Stevens' rooms from a Belgian firm some years ago. The treatment of this species was not well understood, and *connoisseurs* pronounced it a milfy, and the result was that there was no sale for it, and the lot, upwards of 150 potfuls, were sold at something like sixpence apiece. They came under my care, and I noticed that their mode of growth was very distinct; one bulb had leaves, the next apparently was deformed, with no leaves perhaps, and of very small size, then the next growth larger, with good leaves, and so on all through the lot. The fact suggested two growths in one season, but that by others was considered an unreasonable suggestion. However, I have proved without doubt that several varieties will do this successfully, and at this moment I have a plant of *C. intermedia* which has been well cared for during four years, and proves my contention. I purchased a small piece, two imported and one home-grown bulb, unfloated—a promising piece for what I had in view. That was in the month of November.

I placed it in warmth of 60°, and moist surroundings, and it started at once, made a growth, but did not flower. In the following month of August I shook it right out and re-potted it in peat and moss (not leaf-soil), and cut the imported pseudo-bulb away. It started again, and during the winter it made a growth just twice the size of the preceding one, and early in March it gave four fine flowers. I have never rested or dried it off, and it has twice since that time given four flowers and made one summer bulb, unflowered—that made in the winter always doing this. Now it is throwing up the largest growth it has ever had, and it is also breaking from the base of the third pseudo-bulb, and old and new are rooting vigorously. Let but imported plants once start roots, I am sure they will be found to succeed if they are kept growing. I have flowered *C. Leopoldi* with seven flowers from one sheath; and *C. amethystoglossa* also, under similar treatment, has made pseudo-bulbs 2½ feet long, and flowered freely—and I should have no hesitation in treating importations in like manner if I had the opportunity of so doing. *W. Gostling, Bournemouth.*

STREPTOSOLEN JAMESONI.—While visiting the gardens of A. H. Harman, Esq., Lower Greyswood, Haslemere, I was much struck with a fine display of *Streptosolen Jamesoni* in one of the greenhouses. The plants were over 9 feet high, growing in 10-inch pots, and clothed from top to bottom with fine trusses of bloom. Mr. Harris, the head gardener, informed me that he struck cuttings of this plant each year in the spring, and grew them on without pinching. A batch of plants grown in this manner would prove extremely useful in any establishment, especially when lofty conservatories and greenhouses have to be furnished with plants in flower at the present season. *J. Murray, Lythe Hill, Haslemere.*

EARLY PEAS.—Apropos of your articles on early Peas. Have we done anything for the earliness of Peas during the last 250 years? are they even as early as they were in the seventeenth century? On May 22, 1664, Mr. Pepys records in his diary, "So a good supper of Pease, the first I eat this year." Now these Peas must have been grown within a mile or so of London, and most assuredly grown in the open air; even with a good deal of coddling we cannot get Peas here in the open by the end of the third week in May, nor for a good many days after. A little farther on in the same year, he writes, on June 13, "Thence having a gally down to Greenwich, and there saw the King's works, which are great adoin'g there, and so to the Cherry Garden, and so carried some Cherries home, and after supper to bed." The Cherry Garden was on the bankside at Rotherhithe. Cherries were imported to the neighbouring county of Kent by Henry VIII. It seems that both Peas and Cherries were somewhat earlier in the reign of the Merry Monarch than "in this thin-faced time of ours." *Robt. Peel Sheldon, The Rosery, Twyford by Winchester.*

NITROGENOUS MANURES FOR PEAS.—Three years ago I grew twenty rows (of 150 feet) of Sweet Peas for cutting for market. The seed was sown about the last week in September, and with them I sowed a mixture of three parts (by weight) of superphosphate, and one part kainit; towards the end of January I thought I would try the effect of nitrate of soda on a part, as they did not appear to me to be looking as well as I could wish. I marked off 50 feet of each row, and gave a slight strewing of nitrate of soda; the result was apparent almost at once, and the flowers were ready to gather nine days earlier than the untreated portions of the rows, and the effect was also very marked in the increased length of the stems. I consider the result to be the more marked, as the nitrated portion of each row was the furthest from the shelter of the hedge; but the flowers spotted very badly whenever the weather was only slightly damp. I consider for early Peas or Beans an application of

nitrate of soda beneficial. I have tried it with later crops, but do not see any very decided benefit. I am advocating the use of nitrate of soda for early Leguminous crops in North Devon this spring, and several to whom I have recommended its use have promised to give it a trial, and some interesting lessons should be the result; and for the benefit of your readers, some at least of the results shall be sent you if you wish. *Albert J. Manning, Horticultural Instructor, Devon County Council.* [We shall be glad to receive them. Ed.]

— In dry soils, when trenching for mid-season and late Peas, it is good practice to place a layer of manure in the bottom of the trench (see p. 33), the manure retaining moisture, which is just what Peas in hot and dry soils, especially in the south of England, require. The frequent moistening overhead of the haulm after warm and dry days is also beneficial. On scientific grounds, the manuring of Peas in this way may be considered wasteful, but that view hardly comes within the scope of the present discussion. Besides, in many gardens Peas must be produced at all cost. As the matter stands at present, it appears to be one of those cases in which practice and results have "the pull" over theory. A solution may be found in the rejoinder of the darkey, who, on being interrogated as to why the muck made the corn grow so fast, replied: "It was in such a hurry to get up out of the way of the stench, it just grew and grew." *James Baxter.*

CLEANING THE LEAVES OF ORCHIDS.—My correction in the issue of the *Gardeners' Chronicle* for January 18 was simply the changing of the word "month" for the word "year," making it read thus, "at least once a year"; surely that does not convey the impression that no plant wants cleaning oftener. I quite agree with your correspondent, Mr. Bowyer, that if a plant gets covered and discoloured with dirt, it would be most injurious, whether it is a Cabbage or an Orchid. I assume that your correspondent quite agreed with a monthly sponging. Well, there is certainly one thing to be said in favour of it, we should never hear of any gardeners being out of situations. So far I have never found time to thoroughly cleanse all Orchids more than once a year. If the houses are kept as they should be, clear of insect pests, proper ventilation afforded, and the plants kept in a healthy state, they should not get into a very dirty condition. If your correspondent is so situated that he can find time to sponge his Orchids every month or so, I am not going to say they will not be benefited if carefully done. With perhaps the exception of *Phalaenopsis*, I have never yet found the necessity for such frequent sponging. I have never grown Cattleyas in a house containing much moisture; no doubt much moisture in a Cattleya-house would entail more cleaning than if the plants were grown in a sweet, well-ventilated house. I am a strong believer in cleanliness, and as soon as a plant has any dirt on it, that plant should be cleaned by all means. *W. P. Bound, Gatton Park Gardens.*

RATS AND BAMBOOS.—In that interesting and useful book, *The Bamboo Garden*, Mr. Freeman-Mitford says:—"The worst living enemies of these plants (Bamboos), especially of the dwarf species, appear to be the rats and voles, which will burrow under the wire-netting and gnaw through the stems in order to carry away the leaves for linings to their nests. It is not easy to suggest any remedy for this nuisance." At Pencarrow, Cornwall, early last summer some fine clumps of *Arundinaria japonica* growing on the bank of a lake were badly disfigured by water-rats, which gnawed through the culms at a height of about 4 feet. These detestable depredators were, however, soon shot. I am unable to assign a reason for this kind of mischief, as they did not, as in Mr. Mitford's case, carry away the stems or leaves wherewith to line their nests, nor did they eat any portion. Various theories were advanced, and for a time it was put

down to "sheer cussedness," till at last my employer (Mrs. Ford) expressed the opinion that as the culms of the Bamboos were nice and hard, and there being nothing else more suitable for their purpose, the water-rats had merely "sharpened their teeth" at the expense of our *Métaké*. And it is notorious that the front teeth of these rodents elongate to such an extent, that unless well ground back they would overlap those of the lower jaw, and the animal would, in consequence, die of starvation; this explains the otherwise unmeaning gnawing of doors, beams, and posts by rats and mice. *A. C. Bartlett, Pencarrow Gardens.*

BEGONIA SOCOTRANA.—The superb plants of *Begonia socotrana* shown at the Drill Hall meeting on Jan. 14 by Mr. Jennings, showed the great value of this plant as a decorative subject. Other gardeners have realised its worth, but in a different manner, viz., by using it in the crossing of other kinds. In this way this species would appear a favourite and in demand. And while this is so, its own merit—which, by the way, is as great or even greater than its crosses—has been kept out of sight, more or less, of the gardening public. The glossy peltate leaves of the plant alone formed an attraction, the freedom with which it flowers, and the length of the flower-stems, show it to be a plant of the highest class. Furnished with stems 18 inches and more in length, it is no matter for wonder that it finds favour for cutting purposes. Moreover, the plant is self supporting, and needs not even a central stake. The true pink colour of the flowers leave nothing to be desired, and Mr. Jennings may well be congratulated on his good culture, as well as the fact that he risked so fine a lot from safe-quarters at home on the eve of a very sharp frost. *E. Jenkins.*

EARLY SINGING OF THE THRUSH.—It may interest you and your correspondents to know that I have a thrush (caged) that commenced to sing the first week in December, and has been in full song this last month. He is hung out in the garden every morning, and sings against another thrush whose voice he can hear not far away. It is certainly very early for them to be so forward, but no doubt it is owing to the remarkable open weather we are having for the time of year. *A. W. Brooks.*

A METHOD OF BURNING ANTHRACITE COAL.—I have many times addressed you upon the subject of anthracite coal, and I strongly recommended it for greenhouse fires when it was at a reasonable price. Now that the best quality has gone up to 32s. a ton for delivery anywhere near London, I shall be glad to recount my experience. A coal merchant with whom I deal assured me that he could supply me with some very good anthracite, the same as I had had previously, at 26s. I agreed to take a truck, and he sent it in. When I tried it I found that instead of burning like the previous lot he had sent me, some of which still remained, it would not burn at all, in fact, it put the fire out when it was put on with the other anthracite coal. I at once got the coal merchant to come and examine it, and we certainly found that it differed considerably in appearance, and we sent samples to Swansea. The experts whom the matter was referred to wrote back to say that they had no knowledge as to where such coal could have been found, and begged for information. As I was in a fix, and some of the papers gave as a forecast the probability of very cold weather, I experimented by adding 25 per cent. of South Yorkshire to this non-combustible coal, and I found that it burned fairly well, but this was a great price to pay. I then further experimented by getting some small siftings from the coal-heaps, which came at a very much lower price, and to make this stop in the furnace we hit upon the plan of mixing these two sorts of coal with some water, and then putting it on the top of the fire, and it answers admirably. I send you this information in case, owing to the famine prices of anthracite coal, some of your readers

may be caught in the same way I have been, and they will know how to order, also how to get out of the difficulty should any of this coal from Cardiff have been sent in to them. Thos. Christy.

Obituary.

ALFRED WILLIAM BENNETT.—We greatly regret to have to announce the sudden death of this gentleman on the 23rd inst., at his residence, Park Village East, Regent's Park. Mr. Bennett, who was in his sixty-ninth year, was well known in botanical circles, having been lecturer on Botany at St. Thomas' Hospital for many years, and for a long period connected with the Royal Microscopical Society, of whose publications he was part editor. He contributed largely to botanical literature, having furnished a monograph of Polygalaceæ to Martius' *Flora Brasiliensis*, and similar contributions to some of the colonial floras prepared at Kew. In conjunction with Mr., now Sir William Thiselton-Dyer, he translated Sachs' *Text-Book of Botany*, assisted Dr. Masters in the preparation of the fourth edition of Henfrey's *Elementary Course of Botany*; and in conjunction with Mr. George Murray, brought out an excellent *Handbook of Cryptogamic Botany* (1889). He published various works on Alpine plants, paid great attention to the fertilisation of flowers by the agency of insects, and devoted much attention to the study of Algae. These brief indications will suffice to show the extent and variety of his work. Those who were associated with him will mourn the loss of a consistent and valued friend. Mr. Bennett was a Fellow of the Linnean Society, and a member of the Scientific Committee of the Royal Horticultural Society. It was he who prepared the original manuscript catalogue of the Lindley Library soon after its purchase by the Trustees in 1867.

DAVID SYME.—Many of our readers will learn with regret of the death of Mr. David Syme, the Managing Director of the firm of Peter Lawson & Son, Limited, of Edinburgh, which took place at New York, Lincolnshire, suddenly on Saturday morning, Jan. 25.

SOCIETIES.

ROYAL HORTICULTURAL.

JANUARY 28.—An ordinary fortnightly meeting of the Committees of this Society was held on Tuesday last in the Drill Hall, Buckingham Gate, Westminster. The display of exhibits was of moderate extent, and little greater than was the case a fortnight previously.

Orchids were fairly numerous, and the ORCHID COMMITTEE again considered a large number of novelties worthy a special award, recommending five Awards of Merit, two First-class Certificates, and one Botanical Certificate.

The FLORAL COMMITTEE recommended a First-class Certificate to a magnificent *Hemantthus* from M. LINDEN, Brussels; and Awards of Merit to *Begonia alba grandiflora* from Mr. LANGE, nurseryman, Hampton, and to *Primula sinensis* var. *The Duchess*, shown by Messrs. SUTTON & SONS, Reading. The largest exhibit before this Committee was one of *Primulas* from Messrs. SUTTON & SONS, and in addition to various minor exhibits, there was a collection of Ferns from Messrs. J. HILL & SONS, Lower Edmonton, a group of spring flowers from Messrs. BARR & SONS, and a group of bulbous Irises from Messrs. WALLACE & Co., Colchester.

At a meeting in the afternoon there were fifty-one new Fellows elected to the privileges of the Society; and a LECTURE upon "Renovating Old Fruit Trees" was given by Mr. GEO. BUNYARD, V.M.H., Chairman of the Fruit Committee.

Floral Committee.

Present: Charles E. Shea, Chas. T. Druery, H. B. May, James Walker, R. Dean, G. Reuthe, J. F. McLeod, James Hudson, John Jennings, W. Howe, C. R. Fielder, Chas. Dixon, Charles Jeffries, George Gordon, Chas. E. Pearson, Herbert J. Cutbush, George Paul, W. J. James, F. Page Roberts (Rev.), H. J. Jones, W. P. Thomson, E. H. Jenkins, and Charles Blick.

Coleus thyrsoides was again shown by Messrs. JAS. VEITCH & SONS, Royal Exotic Nursery, King's Road,

Chelsea, who on this occasion showed the stock plants from which the plants exhibited at the last meeting were struck in May last. These stock plants had apparently been stopped once after the cuttings were taken from them, and therefore bloomed a little later. The plants do not like too much heat during the summer.

Messrs. WALLACE & Co., Kilnfield Gardens, Colchester, showed a very interesting group of early-flowering Irises in pots. The varieties were numerous, and included the new *I. Tauri*, *I. Heldreichi*, *I. alata*, *I. Histrio*, *I. histrioides*, *I. h. major*, *I. Bakeriana*, and the distinct little yellow-flowered *I. Danfordiae*. Most of these Irises have been illustrated in these pages. There were also *Colchicum hydropilum*, and *C. libanoticum*, *Adeus amurensis*, *Galanthus Elwesii*, *Ikarie*, and *Whittalli*, and the early-flowering form of *Sternbergia Fischeriana* (Bronze Banksian Medal).

Messrs. GEO. JACKMAN & SON, Woking Nursery, Surrey, showed some good strong plants in pans, of *Iris persica Tauri* and *I. Tubergeniana*. The former was certificated a fortnight ago, and the latter last season. *I. Tubergeniana* is very handsome, by reason of its large, bright, white-edged foliage, with glaucous under-surface, and it continues to throw up fresh spikes of its yellow flowers for a considerable time.

A plant of *Loropetalum chinense* in a pot was shown by the Earl of LICHETER, Holland House, Kensington (gr., Mr. W. Dixon) (Vote of Thanks). Figured in *Gardeners' Chronicle*, vol. xix., n.s., 1883.

Mr. THOS. S. WARE, Ltd., Feltham, exhibited a collection of spring flowering plants in bloom in pots. Among these were *Eranthis cilicicus*, *Saxifraga Burseriana*, *Galanthus Whittalli*, *Gentiana acaulis*, several bulbous Irises, *Primula Forbesii*, &c.

Messrs. BARR & SONS, King Street, Covent Garden, London, W.C., exhibited a few hardy plants in pots which were arranged in such a manner that the pots were hidden by moss. There were Irises *Heldreichi*, *Danfordiae*, *Histrio*, *histrioides*; also several good varieties of *Helleborus niger*, including one named *Scoticus* (Bronze Banksian Medal).

Messrs. J. HILL & SONS, Barrowfield Nurseries, Lower Edmonton, Middlesex, made an exhibit of Ferns in pots. The varieties were chiefly popular ones, but included also some choice varieties of *Gymnogrammas*, *Polypodiums*, *Aspleniums*, &c. *Asplenium inaequale*, with most proliferous fronds; *Pellaea rotundifolia*, and *Ficus radicans variegata* were interesting (Silver Flora Medal).

Messrs. SUTTON & SONS, Reading, quite filled one of the long central tables with a display of varieties of *Primula sinensis*. The plants were in 5-inch pots, and the first trusses of flowers were nicely open. The variety of most immediate interest is described under "Awards." There was also a double-flowered variety of the same type as "The Duchess," possessing the rose-coloured ring of the latter. But as yet there exists only one plant. Another new double form had reddish-rose flowers. Of the older types there were groups of such varieties as *Giant Terra Cotta*, *Giant White*, *Giant Pink*, and mixed *Giants*, also single ones, including *Snowdrift*, *The Sirdar*, *Reading Blue*, *Royal White*, *Crimson King*, *Pearl*, *Brilliant Rose*, &c. Double forms included varieties of white, pink, and scarlet flowers, &c. In addition to all these, there were varieties of the *Stellate Primulas*, with pink, white, blue, or purple, and carmine flowers, &c. (Silver Flora Medal).

Awards.

Begonia alba grandiflora.—From the appearance of this *Begonia*, it would seem to be a sport from *B. Gloire de Lorraine*, but we do not know positively that this is the case. The flowers are larger than those of the variety *Caledonia*, and would be pure white were it not for the faintest tint of pink. The plants are vigorous in growth, and of good habit. From Mr. LANGE, nurseryman, Hampton (Award of Merit).

Hemantthus imperialis.—This is an exceedingly handsome *Hemantthus*, from M. LINDEN, Brussels. The flower-segments are very much larger and broader than those of *H. mirabilis* (figured in our pages, May 25, 1901), the segments being half an inch across and more than 1 inch in length; the flower-spike was about 15 inches high, and the colour of the flowers salmon-red (First-class Certificate). A plant of *H. mirabilis* in bloom was likewise shown.

Primula sinensis var. *The Duchess*.—This is a handsome and distinct variety of the Chinese *Primrose*, and was illustrated in the *Gardeners' Chronicle*, February 3, 1900. It is remarkable for a rich reddish-rose-coloured zone around the greenish-yellow eye, and a white margin. The flowers are of considerable size, and excellent form. This is the first occasion that Messrs. SUTTON

have exhibited so many plants of this novelty, which apparently comes very true from seeds. It will be welcomed in gardens as affording a distinct effect from any *Primula* at present in cultivation. From Messrs. SUTTON & SONS (Award of Merit).

Orchid Committee.

Present: Harry J. Veitch, Esq., in the Chair; and Messrs. Jas. O'Brien (Hon. Sec.), De B. Crawshaw, J. Coleman, J. Gurney Fowler, J. Wilson Potter, H. M. Pollett, H. Ballantine, Norman C. Cookson, R. Brooman-White, J. Douglas, E. Hill, F. A. Rehder, H. T. Pitt-G. F. Moore, T. W. Bond, W. A. Binley, H. J. Chapman, W. Boxall, W. H. Young, and H. A. Tracey.

Sir FREDERICK WIGAN, Bart., Clare Lawn, East Sheen (gr., Mr. W. H. Young), was awarded a Silver Flora Medal for a group which consisted principally of well-flowered *Phalenopsis*, many of which had been in the collection for fifteen years. The most numerous were the *P. Schilleriana*, including one of the pure white *P. S. vestalis*, and with them were good specimens of *P. Aphrodite*, *P. amabilis*, *P. x casta*; *Laelia anceps Hillii*, *L. a. Williamsii*, and a fine *L. a. Sanderiana*, with six flowers on the spike; *Odontoglossum x Loochristyense*, two forms of *O. x crispum-Harryanum*, a very fine *Miltonia x Bleuana*, *Cattleya x porphyrophlebia*, *Laelio-Cattleya x Cappei*, with three spikes; *Trichopilia marginata*, *Dendrobium x Wiganiae*, the true *Laelia praestans*, &c.

J. COLMAN, Esq., Gatton Park (gr., Mr. W. P. Bonnd), secured a Silver Flora Medal for an excellent group, principally of varieties of *Laelia anceps*, hybrid *Dendrobiums*, *Calanthes*, &c. In two sections of the group were massed well-flowered specimens of *Calanthe x Bryan*, and *C. x William Murray*, two of the best and most free-flowering; beside them were fine specimens of the favourite old *Zygopetalum Mackaili*, *Laelia anceps Schroderiana*, *L. a. Stella*, *L. a. Sanderiana*, and some pretty-coloured *Laelia anceps*, good *Odontoglossum crispum*, and *O. Andersonianum*; *Dendrobium x Juno*, *D. x Curtisii*, *D. x Cybele giganteum*, *D. x Ainsworthii*, *Woodhatch variety*, *D. x Rainbow*, *D. x Owenianum*, *D. x Burfordiense*, *D. x splendidissimum*, *D. nobile Amesiae*, *D. n. nobilium*, and others.

Messrs. CHARLESWORTH & Co., Heaton, Bradford, staged a small, select group, for which a Silver Banksian Medal was awarded. The centre was of five plants of the showy reddish-orange and crimson *Laelio-Cattleya x Charlesworthi* (*C. aurea x L. cinnabarina*), one variety differing from the others in having bright golden-yellow sepals and petals. On each side were vases of cut spikes of *Oncidium splendens*; and other remarkable plants were *Lycaste x Ballia superba*, *L. lasioglossa*, with a number of flowers; varieties of *Lycaste Skinneri*, of which the charming *L. S. "Lady Gladys"* was the best; and a fine example of the noble *Cypripedium x aureum Hycanum*.

H. T. PITT, Esq., Rosslyn, Stamford Hill (gr., Mr. Thurgood), showed a finely blotched form of *Odontoglossum x Loochristyense*, closely resembling *O. x L. Kimberley*; a pretty variety of *O. x crispum-Harryanum*, and *O. pardunum*.

DE B. CRAWSHAW, Esq., Rosefield, Sevenoaks (gr., Mr. Stables), showed the purple spotted *Odontoglossum Pescatorei* *Rosefieldense*, the heavily blotched *O. x Andersonianum "Jupiter"*, *Laelia anceps Hollidayana*, *L. a. H. Crawshawana* (see Awards), and *Laelia x Nemesis* (*anceps x superbens*), a very interesting hybrid, which, although intermediate in character, presents the features and colour of *L. superbens* strongly.

F. WELLESLEY, Esq., Westfield, near Woking (gr., Mr. J. Gilbert), showed *Cypripedium x Hera superbum*, with a fine white upper sepal, greenish at the base, and densely blotched with dark purple; *C. x Celeus* (*insigne Chantini x villosum*), one of the finest of the *C. x nitens* class; *C. x Miss Castellani*, a distinct flower of *C. x Lecanum* section; *C. x Dr. Conway* (*exul x callosum*), a delicately-tinted flower with an emerald-green ground-colour, the upper part of the dorsal sepal being pale rose, changing to white towards the margin. The base of the upper sepal and inner parts of the petals were spotted with chocolate. Mr. WELLESLEY also showed *C. x rubescens "Ranjitsinghi"* (see Awards).

Messrs. HUGH LOW & Co. showed *Cattleya Trianae Roeblingiana*, a fine flower of the *C. T. Backhousiana* type; *C. T. Mrs. de B. Crawshaw*, large, and with an intense crimson crimped front to the lip, another good form of *C. Trianae*, and *Cypripedium x Thompsoni*.

W. P. BURKINSHAW, Esq., Hesse, Hull, showed *Laelio-Cattleya x luminosa* (*L. tenebrosa x C. aurea*), a pretty variety with bronzy-yellow sepals, and petals slightly speckled with rose, and a purplish-rose labellum with darker veining.

Frau IDA BRANDT, Riesbach, Zurich (gr., Mr. Schlecht), sent flowers of a natural hybrid *Lycaste* (? Skinneri \times lasioglousa), and a singular-looking green *Lycaste* sp., and *Maxillaria ochroleuca*.

Awards.

FIRST-CLASS CERTIFICATE.

Cypripedium \times *Yenus*, *Oakwood variety* (niveum \times insigne Sandere).—From NORMAN C. COOKSON, Esq., Oakwood, Wylam, Northumberland. A charming hybrid, large and distinct, and of most delicate tints. The flower is wax-like in texture, the petals long, broad, and curved downwards. The upper sepal was white, with a yellowish tint over the basal half, which was also dotted with minute purple spots. Petals cream coloured, undulate at the edge, and evenly dotted with purple; lip pale primrose, compressed laterally; staminode clear, pale yellow, with a green boss in the centre; foliage greyish, with dark green reticulation. A very worthy production, and by far the best of the *C. insigne* Sandere crosses, or of the crosses of *C. niveum* and *C. insigne*.

Lelia anceps *Hollidayana* *Crawshayana*, from DE B. CRAWSHAY, Esq., Rosefield, Sevenoaks.—Flower large, white, with chocolate-purple lines on the inside of the side lobes of the lip, and a pencilling of rose-colour on the front lobe; crest yellow.

AWARD OF MERIT.

Cypripedium \times *rubescens* "*Ranjitsinghi*" (ananthum superbum \times Boxalli), from FRANCIS WELLESLEY, Esq., Westfield, Woking.—A very striking flower. Dorsal sepal nearly black, with a heavy purplish tinge at the back, showing through to the broad white margin of the upper portion. Petals and lip Indian-yellow, with a dark chocolate-purple tinge.

Cypripedium insigne *Fowlertanum*.—From J. GURNEY FOWLER, Esq., Glebelands, South Woodford. A very finely-formed variety of a dark tint. Upper sepal evenly blotched over the greater part of its surface with dark purplish-brown blotches; upper portion white.

Dendrobium Wardianum *Fowlertanum*.—From J. GURNEY FOWLER, Esq. The flowers all exhibited that form of peloria known as tri-labellia, the lower sepals being slightly modified like the labellum, and each bearing a yellow patch, and dark purple marking resembling the lip.

Laelio-Cattleya \times *Cappei* (*L. cinnabarina* \times *C. Warsceviczii*), from Sir FREDERICK WIGAN, Bart., Clare Lawn, East Sheen.—Sepals and petals dark copper-yellow, lip crimson, with purple veining.

Lycaste Skinneri "*Lady Gladys*," from Messrs. CHARLES WORTH & Co., Heaton, Bradford.—This may be likened to the best form of *L. Skinneri* alba, with a delicate pale rose-pink freckling on the petals. A very chaste and beautiful flower.

ROBOTICAL CERTIFICATE.

Odontoglossum pardinum, from H. T. PITT, Esq., Rosslyn, Stamford Hill.—Flowers yellow, with brown markings; segments narrow, like *O. ramosissimum*.

CULTURAL COMMENDATION

To Mr. Quartermain, gr. to A. SETH SMITH, Esq., Silvermere, Cobham, for a very fine plant of *Angraecum sesquipedale*, with ten flowers.

To Mr. Stables, gr. to DE B. CRAWSHAY, Esq., Rosefield, Sevenoaks, for a grand plant of the purple-spotted *Odontoglossum Pescatorei* *Rosefieldense*, with a branched spike of thirty-six flowers.

Fruit and Vegetable Committee.

Present: Geo. Bunyard, Esq., Chairman; and Messrs. Henry Eslings, Jos. Cheal, S. Mortimer, Alex. Dean, C. Herin, M. Gleeson, H. Markham, Geo. Kelf, Edwin Beckett, G. Norman, J. Willard, Jas. H. Veitch, H. Balderson, E. Shaw Blaker, and W. Wilks (Rev.).

Lieut.-Col. VIVIAN, Road Ashton, Trowbridge (gr., Mr. W. Strugnal), showed twelve dishes of Apples, uncommonly fine, well-preserved specimens in almost every instance. We remarked King of Tomkins County, Hoary Morning, Dutch Mignonne, Calville St. Sauveur, a green fruit; Newtown Pippin, Annie Elizabeth, Reinette du Canada, Claygate Pearmain, Norfolk Stone Pippin, Court Pendu Plat, and Gooseberry Pippin (a Silver Banksian Medal).

A dish of Benrre Rance Pears were shown by the Earl of LICHETER, Holland House, Kensington (gr., Mr. W. Dixon); the fruits were clean, and of average size, and showed how well some fruits can still be grown in London (Cultural Commendation).

A dish of five fruits of Pear-President Barabe were shown by Lord SUFFIELD, Gunton Park, Norwich (gr., Mr. Allan); they were fine examples of the variety (Cultural Commendation).

Mr. J. HARRIS, Blackpill Nurseries, Swansea, showed

Potato "Sir John Llewelyn," grown in open field; also samples of the same garden-grown, the latter being much the finer-looking sample. The tuber is flat, kidney-shaped, and very regular in outline (a Cultural Commendation).

Renovating Old Fruit Trees.

In the afternoon Mr. GEO. BUNYARD delivered a short lecture on "The Renovation of Old Fruit Trees," gave many hints, gained by much personal experience, and opened up an exhaustive disquisition upon a subject which has already been discussed. He said that whilst Pears are particularly amenable to this treatment, most stone fruits are not. Plums, Peaches, and Nectarines that have become unfruitful from age or neglect are best destroyed, and young trees substituted for them. Stone fruits, as a rule, will not endure the severe pruning that is necessary in an attempt to restore them to a fruitful condition. Cherry-trees in orchards, however, are exceptions, and may be successfully treated. Mr. Bunyard advised that in such a case all the useless wood and branches should first be removed from the trees; also any that are broken or cracked, or that tend to crowd the centre of the trees. If the land be pasture, then mow the grass, and clear away everything in the nature of prunings, &c., afterwards applying 2 cwt. of salt to the acre. When the grass has grown again, turn sheep into the orchard and feed them with oilcake and other good food. The sheep will eat the grass so short that it resembles a Turkey-carpet, and their droppings will be of great value to the roots of the trees.

Mr. Bunyard gave some hints upon restoring Pear-trees against walls. One system is to cut out every other tier of branches, and encourage new ones in their places. Subsequently, the alternate branches may be also removed, and the tree will then be composed of new wood, with the exception of the main stem. A more radical method is to cut down the main stem itself to a point just above the lowest tier of branches, and get a new stem and branches. Mr. Bunyard has recently seen a very good illustration of success following such practice. If the Pear-trees are not of good varieties, the laterals may be grafted 1 foot from the stem, with one variety, or with as many varieties as there are branches, thus making the tree serve to test new or little-known sorts. A good mulching may be afforded the ground, when the trees have been treated as described.

Pears on the Quince, and Apples on the Paradise stock, and planted in the open, said Mr. Bunyard, may be treated more easily than trees on the free-stock. Dig out a trench around the tree, and cut away the loose, rough roots, afterwards filling in with fresh loam. The trees will be in excellent condition for removal the following year, and it is best to move all the old trees into a new plantation of themselves. They can thus be afforded fresh rooting medium, and there can be effected a renewal of the soil where the old trees stood previously. Further hints were given upon the renovation of pyramidal Apple and Pear-trees, cordons on walls, Fig trees, and Vines.

Strawberries, said Mr. Bunyard, are best renewed after two years, or if a "lazy" bed be wished for supplying fruits for preserving, then keep them for three years.

HEREFORDSHIRE FRUIT GROWERS' ASSOCIATION.

JANUARY 23.—The third annual meeting of the Herefordshire Fruit Growers' Association was held at Hereford on the above date, Mr. C. W. Radcliffe Cooke presiding. In resigning the Chairmanship, Mr. Cooke congratulated the Association on the fact that it had a membership of 262. Besides the Association operations, it advertised Herefordshire as one of the best fruit-growing districts in the world. He pointed out various ways in which the Association might make itself useful in the current year, in addition to its field meetings and discussions. They might press upon the Corporation to still further enlarge the wholesale fruit market, which was attended by dealers from the Midlands and Wales, and which had become too small; and they might see what could be done in regard to securing uniform weights and measures in the sale of the fruit. A Committee was appointed to wait upon the Corporation.

Mr. George Cresswell was elected President, Dr. Bernard Dyer (who had been making experiments in fruit fertilisers) was appointed Analyst in the place of Dr. Voelcker, and Mr. R. Newstead was appointed Entomologist.

Mr. Machen suggested the giving of prizes for the best-managed orchards. Mr. Dawes, Ledbury, was added to the Committee.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.

ANNUAL REPORT.

THE Committee have much pleasure in submitting their annual report and statement of accounts, as audited, for the year 1901, and in doing so congratulate the subscribers and friends of the institution on its continued prosperity and the success which has attended its efforts on behalf of the aged, disabled, and distressed people who have been obliged through misfortune and necessity, occasioned by no fault of their own, to seek its benefits, and the aid thus afforded, it is encouraging to know, is most gratefully appreciated by the recipients in their days of need.

At the beginning of the year 181 persons—98 men and 83 widows—were receiving life annuities of £20 and £16 respectively. Of this number, during the year thirteen had passed away—ten men and three widows—whilst two widows have been removed from the list, one having been sent to an asylum owing to her mental condition, and the other to an infirmary on account of advanced age and illness, and consequent inability to pay for the medical attendance and nursing she now requires. Of the men deceased, four left widows, and their circumstances being of a deserving and necessitous nature, the committee have been enabled under their rules to award them the widows' allowance of £16 a year. There were, therefore, at the close of the year, 170 recipients of permanent relief, and the committee, notwithstanding that they have eleven vacancies only, recommend an addition of twenty pensioners to be elected this day, making a total of 190 persons on the funds, being nine more than at the corresponding period of last year, and the largest number of beneficiaries receiving life annuities from the Institution in any year since its foundation. Whilst the committee are keenly alive to the increased liability thus entailed, they have been influenced in their action by the generous financial support hitherto accorded to the institution, which they are encouraged to hope will be continued and increased in the future, so that there will be no necessity for the work to be in any way curtailed.

The committee are much gratified to be able to report that the Anniversary festival dinner, which took place in May last, under the presidency of the Right Hon. Lord Llangatock, was most successful, a substantial amount being realised in aid of the funds. For this pleasing result the committee are deeply thankful, and desire to place on record their great indebtedness to Lord Llangatock for his kindness in presiding, his able and warm advocacy of the Institution's claims, and for his lordship's generous contribution to the funds. The committee take this opportunity of offering their sincere thanks to the stewards, collectors, donors of flowers, the horticultural Press, and to other helpers who contributed in any way to make the festival a success.

The Committee have much pleasure also in drawing attention to the continued progress of the valuable auxiliaries, from which the following amounts have been received during the past year: Bristol and Bath (hon. sec., Mr. G. Harris), £80 17s.; Devon and Exeter (hon. sec., Mr. W. Mackay), £30; Reading and District (hon. sec., Mr. H. G. Cox), £70 7s.; Wolverhampton (hon. sec., Mr. Richard Lowe), £20; Worcester (hon. sec., Mr. Percy G. White), £85. The hon. secretaries are most cordially thanked for their valued services so ungrudgingly given to the cause, as are also other friends in various parts of the country who, either by arranging concerts, opening of gardens, holding flower stalls, or in other ways so generously furthered the interests of the institution.

The Committee are glad to be able to state that the special funds have proved a source of incalculable benefit. From the "Victorian Era Fund" nearly £100 was distributed during the past year amongst the unsuccessful candidates at the last election who were formerly subscribers to the Institution, whilst a sum of £48 has been given from the "Good Samaritan Fund" as a temporary help to several cases of a particularly distressing nature. This latter fund has been augmented in the past year, and the Committee rejoice that the increased income from that source will enable them to respond favourably to more of the many pathetic appeals which so frequently come before them. They would, however, again point out that only the interest derived from this fund is available, and they therefore very earnestly commend its object to those friends who have it in their power to increase its usefulness.

The committee have to make the very gratifying announcement that his Royal Highness the Prince of Wales has graciously consented to succeed his Majesty the King (now Patron) as President of the Institution, for which mark of Royal favour and recognition they are deeply grateful, and they feel sure that every friend of the Institution will unite with them in tendering his Royal Highness their most humble and respectful thanks.

The committee congratulate the members on the alterations in the rules which have been this day decided upon at the special meeting, feeling convinced that they will very largely conduce to the still greater success and well-being of the Institution in the future.

The committee cannot conclude their report without referring with great regret to the many losses that have occurred through death in the past year amongst the valued friends and supporters of the Institution. These losses will be severely felt, and the committee therefore plead most earnestly for renewed effort to fill the places of those subscribers who have passed away, that the work may be not only maintained, but that further help may be forthcoming to such an extent as to warrant an enlargement of its beneficent agency on behalf of a class who in their day have done so much to brighten the lives and minister to the necessities of others.

Having audited the accounts, we certify the same correct, and the books in good order. We also certify that the securities of the invested funds are in the hands of the bankers, by whom the dividends are received on behalf of the Institution. *Thomas Manning, Thomas Swift, Jcs Ward.*

WARGRAVE GARDENERS'.

JANUARY 15.—The annual meeting of the Association took place on the above date, Mr. W. H. Scott presiding. Mr. W. H. Scott read his 1st prize essay on "How to keep the Flower Garden gay during the Year." He treated the subject in calendar form, giving the work of the gardener from month to month, beginning with October. Lists of flowers, shrubs, bulbs, &c., which could be used in any way, with brief cultural directions, were given. He was heartily congratulated on his treatment of the subject. *H. Coleby, Hon. Sec.*

LEICESTER CHRYSANTHEMUM.

JANUARY 23.—The annual meeting of this Society was held on the above date, Alderman G. COLLINS in the chair.

The Chairman moved the adoption of the report and balance-sheet, and said the Society had not made much money, but they were on the right side. The Society was not formed for the purpose of making money; their object was solely to encourage horticulture, and especially the cultivation of Chrysanthemums and fruit. The report was then adopted.

Officers were elected as follows:—President, Alderman Collins; Hon. Treasurer, Mr. John Whit; Hon. Secretary, Mr. S. Scattergood.

CARDIFF AND DISTRICT CHRYSANTHEMUM.

JANUARY 24.—On the above date a large gathering of members and friends attended the annual meeting of this Society. The chair was occupied by Mr. G. SHEWRING.

The meeting decided to hold their annual show on November 5 and 6. It is understood that an amalgamation of the Penarth Society with that of this Society is to take place.

Mr. Geo. W. Drake, of Cardiff, was presented with an illuminated address, in recognition of his having won single-headed the National Society's Trophy for the Cardiff Society. *H. Gillett, Secretary.*

WOOLTON HORTICULTURAL.

THE annual general meeting was held in the Mechanics' Institute on Friday evening, Mr. J. Stoney, gr. to F. H. Gossage, Esq., Camp Hill, presiding. The Secretary's report proved to be very satisfactory.

LIVERPOOL HORTICULTURAL ASSOCIATION.

THE Committee of this Association are to be highly congratulated on the improved financial position of the Association disclosed at the annual general meeting, held in the Secretary's Offices, Victoria Street, on Saturday evening last, the numerous attendance being presided over by Mr. Thomas Foster, Chairman of the Association.

To the Gardeners' Royal Benevolent, and the Royal Gardeners' Orphan Fund the sums of three and two guineas were respectively voted. *Orchid.*

GRAND YORKSHIRE GALA.

THE annual meeting of the guarantors and life members of the Grand Yorkshire Gala has just been held. Sir C. MILWARD presided, and there were present the Lord Mayor, the Sheriff, several Aldermen and Councillors, and other well-known gentlemen in York.

The Lord Mayor, in acknowledging his election, said that it was true that he had been associated with the Gala for a great many years—he did not know exactly whether it was twenty or twenty-five—and he had always taken a great interest in it. It was a pleasing circumstance that this year they had the Lord Mayor and the Sheriff as Chairmen of the two important committees, the Finance and the Entertainment Committees. He hoped that the forthcoming Coronation would not detract from the popularity and success of the Gala. He alluded to the satisfactory fact that they had on the Council some of the most prominent business men of the city, which was, he believed, a cause of the great success of the Gala.

Alderman Border moved the re-election of Alderman Sir Christopher Milward as Chairman, for it was to him that they looked as their natural head.

The Chairman said that he would retain the position with great pleasure. With regard to reducing the schedule, they could not materially do so without running the risk of losing some of the exhibitors.

Alderman Border was re-elected Vice-Chairman, and Alderman Sir J. Sykes Rymer as Treasurer.

Alderman Dale moved the re-election of Mr. C. W. Simmons as Secretary, speaking of his great business aptitude, and the esteem and respect in which he was held.

Mr. Taylor was elected Auditor for the ensuing year.

The Council and the various committees were re-elected, and the various amounts allocated for prizes, entertainments, music, and fireworks.

It was resolved to send votes of condolence to the families of Mr. Cypher, Mr. Jackson, and Mr. Brock.

ALLAMANDA WILLIAMSH: S. H. G. If you cannot afford the plant the fullest amount of sunshine, and train it not less than a foot distant from the roof-glass, it will not flower satisfactorily. In order to flower it early, a start should have been made early in January. Allamandas last five to six months in bloom. Young plants struck from cuttings last year cannot be expected to flower much this year, indeed it would be better to remove the flowers.

AN ASPHALT FLOOR IN A CONSERVATORY: A. F. This is another instance, if one were needed, of the folly of consulting the ordinary architect in matters horticultural. As no flowering plant will live in the house, your only course is to replace it with cement tiles, ornamental, or plain, or stone.

AZALEA INDICA CASTING ITS LEAVES: E. T. Azalea plants will cast their leaves in some quantity yearly, and it depends on treatment how many and when they are cast. Plants kept cool and moderately dry at the root, as they should be when not forced in the winter season, retain their leaves till growth begins, when some of them are sure to fall. It is not a disease, and there are no signs of thrips on the leaves sent.

BOOKS: *Botanical Works.* M. E. Orr. If you will kindly furnish us with your correct address, we will reply to your questions through the post, as our previous reply was returned. — *Ralph Landless. Monograph of British Coccidae of the British Isles.* The book is furnished only to Fellows of the Ray Society.

CARNATIONS DISEASED: *Carnations.* The plants sent are attacked by a fungus, *Helminthosporium cecidivatum*, for which, owing to its attacking the plants from inside, there is no cure. Burn the plants forthwith, and grow no more on the same spot.

CHRYSANTHEMUMS: *Amateur.* Your list of incurred varieties is a good one. If you add to this, you may obtain Queen of England and any of its sports; Topaze Orientale, Louisa Giles, Mrs. H. J. Jones, Annie C. Love, W. Howe, and Mrs. Gerald Williams. There have been few additions of late years to the old-fashioned reflexed blooms, which, though not large, possess a degree of refinement, sometimes greatly lacking in the larger Japanese flowers. Your list is sufficiently representative, if you obtain the additional varieties you have suggested. There are few exhibitors of this type, and if you grow them well there is every probability of your winning a prize. We have not space to describe times for stopping and "taking" the buds of each variety, but you may obtain trustworthy information upon such details in the catalogue of a reputable raiser or grower. We have not recommended you to get this season's novelties, because an amateur is more likely to succeed with better-tried sorts, but if you have the necessary conveniences to grow rather more plants than you expect to need, then the cultivation of the latest novelties has a fascination not easily resisted. All of the varieties which have been certificated this season by the National Chrysanthemum and Royal Horticultural Societies have been described in these pages during November and December, from the actual flowers exhibited.

CODLIN-MOTH AND GREASE OR TAR BANDS: W. W. To begin the cycle of existence of this most destructive insect, the better to understand the means to be adopted for

its destruction; it may be stated that the grub having fed first on the pulp and then on the pips of the Apple, comes to the ground with the fall of the fruit consequent on the destruction of the seeds, lies still for a day or two, then crawls up the Apple-tree stems, selects a crevice of the bark, in which, having made it smooth, it spins a silken case, in which after a few weeks, it becomes a chrysalis, and in this state remains till the following June. In that month it is on the wing, depositing one egg on each Apple visited, which is deposited near the eye, where the skin is thinnest. The grub, on hatching out, pierces the fruit diagonally, avoiding the core at this period, and confining itself to the pulp, and piercing the skin at its lowest point, thus finding an easy outlet for the pellets, and an inlet for the air. Within a few days of being full fed, it pierces the horny core case, and eats the pips. It will thus be seen that grease or tar bands are of use in arresting the grubs after they leave the fruit, say in July, and climb the trees, and the moths in June, when they assemble in the daytime on the stems of the Apple-trees. It is also a good practice to make smother fires of weeds under the trees in the middle of June, in order to drive away the moths. When grease or tar bands are used, there should be wider bands, say 8 in., of grease-proof paper, bound round the trees, to prevent the grease, &c., entering the bark. The horticultural sundriesmen and nurserymen sell special preparations for smearing the bands. The wingless winter-moth and its caterpillars are caught by the same sort of bands put on the trees about the middle of October.

"COPY." H. C. writes, "at this dull season perhaps you could insert the enclosed" (something like three columns of printed matter). If our correspondent could see the hopeless heaps of "copy" on our table, for which it is impossible to find room, even by an increased number of pages, he would not say it was the dull season, but he would compassionate us in our constant struggle against the exigencies of space.

CYPRIPEDIUMS AFTER FLOWERING: *An Old Subscriber*. The plants having no pseudobulbs or fleshy roots, must be afforded water according to their needs all the year round.

DRACENAS: *An Old Subscriber*. A few leaves, the oldest, fall each year; but the crowding together of the plants, with consequent lack of light and air, will cause the fall of more leaves than would otherwise be the case.

FERN IN THE DINING-ROOM WINDOW: *Tooting Bee*. The air of a living-room being too dry to suit Ferns, you can only do them justice in a glass case. If the plant is found not to be dead on turning it out of the pot, shake the outer layer of soil from it, and repot, doing this in March. No top-dressing will be of any avail before growth has commenced. Perhaps a top-dressing in March would suffice, if not many roots have been made, and the soil is sweet. Ferns do not require much larger pots than will accommodate the roots without cramping them, together with a moderate portion of peat, or peat and loam.

GARDENERS' ROYAL BENEVOLENT INSTITUTION: J. C., and L. C. T. Name of Secretary, Mr. G. J. Ingram, Office, 175, Victoria Street, London, S.W.

GARDENING APPOINTMENT IN SOUTH AFRICA: R. James. But small chance of obtaining a situation as gardener before the country settles down at the close of the war. We are unable to say how a post could then be obtained by anyone on this side, excepting through an advertisement in this or the Cape of Good Hope journals.

GRAFTING LILAC: B. Brown. Being provided with your wildlings or suckers, laid in the soil in late autumn, they can be taken into a cold-house or shed at this season, and grafted by any of the usual methods, whip, cleft, or tongue, and at once laid-in in a cold-pit or frame, and kept as quiet as possible by good

ventilation when there is no actual frost, till the middle of March, when they should be bedded out in close lines in the nursery or reserve-garden.

HOW TO BECOME A FELLOW OF THE ROYAL HORTICULTURAL SOCIETY: J. M. You should write to the Secretary, Rev. W. Wilks, at the office of the Society, 117, Victoria Street, London, S.W., who will gladly furnish you with the desired information.

INSECTS: *Anxious*. The insects you describe as being similar to the house-flea have certainly one characteristic possessed by that nimble insect. We are unable to find them.

INSECTS IN SOIL: G. Bethel. 1, the grubs of *Tipula oleracea*, Daddy Longlegs; 2, the grey, vermiform grubs are the larvae of a species of *Mycetophilæ*, belong to a family of small, active gnats, the grubs of which frequent damp situations amongst various plants, including also *Boleti* and other fungi. In the absence of natural food they might possibly attack cultivated plants; but they are not included among the recognised pests of the horticulturist.

LILACS: J. W. The plants were doubtless not well cultivated, or the wood insufficiently matured; the wood and buds being thin and lacking in size.

MANURE FOR SWEET PEAS: S. P. Muriate of potash at the rate of 2 oz. to the square yard, applied twice or thrice as a top-dressing in wet weather. The land should be deeply dug and in good heart; bone-meal is too slow in its action. Sow thinly, and keep the pods diligently picked off the plants, for you cannot have many flowers if seed be allowed to form. Do not allow the ground alongside the rows to become long impervious to the air, but stir it frequently.

MARGUERITES: J. B. Why address the publisher on such a matter? Your plants probably received a check from cold some weeks since.

MUSHROOM ABNORMAL: Alex. Innes. Not uncommon. The spawn has overrun the Mushroom. Similar specimens, even more remarkable, have been figured in our columns.

NAMES OF PLANTS: W. H. O. 1, *Cypripedium × selligerum*; 2, *Cypripedium × Ashburtoniæ*; 3, *Cypripedium × Harrisianum*; 4, *Oncidium excavatum*, often called *Oncidium aurosum* in gardens.—F. P. Probably a species of *Geum*. How can it be a cure for dropsy? Dropsy is not a disease itself, but the result of disease in the heart, kidneys, or liver. Cure them, and you cure the dropsy, not otherwise.—*Weekly Subscriber*: Yarmouth. 2, *Acalypha marginata*; 3, *Lilbonia floribunda*; 4, *Agatheca cœlestis*; 5, *Thuja occidentalis*; 6, *Epiphyllum*.—L. C. T. *Lavatera arborea variegata*.—S. H. 1, *Centropogon Lueyanus*; 2, *Begonia argyrostigma*; 3, *Begonia Dregei*, often called *B. parviflora*; 4, *Begonia metallica* of gardens; 5, *Selaginella cœsia*; 6, *Selaginella denticulata*.—S. & M., Kelso. Apparently a leaf from *Galax aphylla*.—J. M., Devon. *Helleborus subpunctatus* (white). The purple-flowered vars. are derived from various crosses of *H. colchicus*, *H. orientalis*, and others. The other flowers sent were very nice for the season, and much earlier than the same would be in most other parts of the country.

NOTICE TO QUIT SERVICE: G. S. In law the gardener is a domestic servant, and as such is entitled, in the absence of an agreement to the contrary, to a quarter's notice, although in practice it is found more agreeable to employer and servant to shorten this to one month. A gardener living rent free in a house on an estate, and enjoying various perquisites, if he has to leave at short notice, can obtain compensation for insufficient notice, for wages, rent, and perquisites due during the unexpired term.

POTATOS DISCOLOURED: F. N. An early stage of the Potato disease, *Phytophthora infestans*, figured in these pages Dec. 13, 1884, and March 21, 1891.

REMOVAL OF TREES AND ON THE TERMINATION OF A TENANCY: G. W. S. See "Law Notes" in present issue, p. 83, for the latest decision in the Courts.

ROSE ON A N.-W. ASPECT: *Tooting Bee*. The plant may grow fairly well on this rather sunless aspect, but we should doubt its capacity to flower in a satisfactory manner. Rather plant a *Clematis*, *Jasminum revolutum*, *J. nudiflorum*, *Berberis stenophylla*, *Kerria japonica*, or *Aristolochia Siphon*.

SAN JOSÉ SCALE: D. D. C. Our figure was derived from an original source. The two groups are nearly allied.

SEED SOWING, TIMES OF SOWING, TRANSPLANTING, &c.: *Interested*. The *Cottager's Calendar*, published at this office, is not too much advanced for the use of young children, but the information conveyed should be supplemented by oral instruction of an elementary kind, not found in that useful little work. The teacher must therefore have some knowledge of gardening, and have the gift of making the children interested in the various operations, which is not a difficult matter; for no book alone will succeed in doing that. No book will teach a child how to prepare a seed-bed, draw a seed-drill, or lift a young plant and transplant it to a nurse-bed, or how to repot a plant. The thing to be done must be demonstrated by the teacher, then the lesson is at once grasped by the children. As a general rule, fine seeds, such as those of Celery, Cauliflower, Lettuce, Cabbage, Radish, the seeds of herbs, and those of the size of dust-shot, may be broadcasted on the surface and raked in, or put into drills made $\frac{1}{4}$ -inch deep or less, the latter being the better method. This applies also to flower-seeds of small size. Peas and Beans need drills 3 inches deep in close soils, and 4 inches in light or sandy ones. Spinach, Carrots, Parsnips, Onions, may be sown in those drawn 1 inch or less deep. Seeds sown in flower-pots and seed-pans are sown at various depths; the finest, such as *Lobelia*, *Nicotiana*, *Calecolaria*, &c., must be scattered evenly on a smooth, level, firm surface an hour after the soil has received a good application of water. Such seeds must not be covered with soil or sand, but kept dark with a tile or bit of slate till germination has taken place. Seeds slightly larger may be covered with very fine mould to a thickness equal to their own, and so on. Lupins, *Ricinus* (Castor Oil), and the like should be put $\frac{3}{4}$ -inch under the surface.

SOIL FOR POTTING SOUVENIR DE LA MALMAISON CARNATIONS: S. P. As a means of lightening very adhesive loams, peat is useful, but not necessary; broken-up plaster, road grit, or sand, answering the same purpose.

VIOLETS DISEASED: Y. X. The plants are attacked by a fungus known as *Puccinia Viola*. If the condition is at all common in your stock, it will be best to burn it, and procure fresh plants. The disease spreads from one Violet plant to another, but will not be likely to attack other species of plants in the same frame.

WATER-GLASS: M. R. This is another name for soluble glass, a silicate of potassium, found in commerce as a white, glassy mass, a stony powder, or dissolved as a viscous liquid. It can be bought at some chemists' shop. An explicit pamphlet has been issued by the Leicestershire Egg Preserving Depot, price 4½d.

DECORATING THE DINNER-TABLE.

WE are apt to plume ourselves in this connection upon our artistic notions and our well-dressed tables are sometimes thought of as ample proof of a highly civilised state of existence. We can, however, hardly consider this custom of decking our feasts and banquets as exclusively a modern one. The blossom-decked festivals of ancient Rome and Pompeii have been frequently referred to by historians, and if the story painted upon sarcophagus and temple wall in Egypt is to be relied on, we may readily believe that a much older civilisation than either of these was in the habit not only of adorning its religious observances, but also the mundane functions of eating and drinking were not carried out without the beautifying influence and presence of flowers.

Apart from considerations of the ancient or modern use of flowers at table, there occurs the thought of a time in Britain, as in other lands, "when wild in woods the noble savage ran." One can imagine a

nobler specimen than the other savages noting and taking an interest in the beauty surrounding him, as he ate his handful of roots, or tore from the bone the flesh he may have been consuming. At any rate, it always appears to me a tribute to a really primitive state of being, this plan of having flowers or plants arranged with more or less effect upon the table at which our meals are partaken. It is the same influence, that prompts people to carry food a long distance that they may eat and drink as did their ancestors of long ago, untrammelled by the four walls of a room, and with nothing except perhaps a few branches between them and the sky above.

It is a far cry from the days of the aboriginal Briton to the present time, but a few remarks upon this subject of decoration may not be out of place; there is, I fear, room for improvement in our methods. A man may be the happy possessor of ingenuity in carrying out original ideas, and yet these qualities will perhaps be the means of leading him to the perpetration of a design both incongruous and inartistic. Ingenuity has provided miniature arches, bridges and certain appliances in which wire plays an important part. For each and all of these we may be grateful or not. It depends so much upon the size of table to be dealt with, its accessories, and the style of dinner to be served upon it.

The peripatetic waiter will gaze with anything but admiration upon a daintily appointed table, and will tell you with something approaching derision for the light and elegant effect, at which you have aimed. "If it only had a square of silk in the centre it would look all right." At which you are tempted to ask if he would not like a mirror with a few china ducks "swimming" upon it. Most likely he will tell you "they would look very pretty," and in despair you leave him. Having seen these pretty ducks swimming on looking-glasses, and having no love for them, or the much-vaunted coloured centre-pieces of silk, I can only say that nothing short of compulsion shall ever make me use either one or the other for table decoration. In the exhibition-tent there is a growing tendency to make a special feature of table decorations, and there is no question that they excite a great amount of interest, and in large exhibitions, where the work is fairly well done and competition keen, it is usually a matter of some difficulty, owing to the number of spectators, to get a sufficiently comprehensive view of any of the designs to form a proper judgment. Even here it is possible to see some peculiar ideas carried out by exhibitors, and I shall not readily forget a rather flagrant case in which a well-known gardener and myself awarded the first prize to a table simply and yet artistically adorned with autumn-tinted leaves and ripe berries, in preference to one upon which Orchids in profusion had been heaped. Cypripedium insigne muddled up with splendid Cattleyas; above all, a bright scarlet lampshade—and I bore the brunt of the language bestowed on us by the disappointed one. The decorator who works in the daylight of an ordinary show has opportunities denied the one, the result of whose work will only be shown by artificial light. Here blue is an almost impossible colour, but in the daytime some charming effects may be

obtained by the use of blue flowers. In the case of yellow, none but the richest and deepest ought to be used for night-time; yet the pale varieties of the Iceland Poppy are used in the daylight with delightful results.

Those who have had something more than a nodding acquaintance with the work of high-class London florists, will know that their designs are not made to fit in with the appointments of the table, but *vice versa*. Everything must give way for their concocted arrangements. But those who have frequently less material to work with, viz., those private individuals to whose lot falls the decoration of the dinner-table, must more often than not make their ideas and devices fit in with and be subservient to the "laying" of the table.

There is great difficulty in giving advice and stating general rules for guidance in this matter. I have seen a book filled with highly-coloured but impossible designs for the dinner-table. The combinations of cut flowers were, to speak mildly, remarkable, and such as I should never dare to use.

Tables not only differ in their appointments, they differ in size. It has fallen to my lot to dress them in several districts, and in one case I remember there was scarcely room for the smallest amount of tracing, owing to the narrow table used. In others there is greater width, and upon these the best and most telling effects can be produced.

I am not going to give more than a general outline of the various methods of procedure. Minute instructions are almost sure to mislead in this matter. A sense of proportion is a great requisite. Most people, if they had not seen, could imagine, the noble display likely to be produced by a combination of Arums and Poinsettias; yet this would be out of place upon a small table, though suitable enough where from twenty to thirty are dining together. The most frequently-used articles for tracery and festooning we find are Smilax, Lygodium scandens, Selaginella, and Asparagus and Fern fronds. These are, doubtless, all suitable enough so long as small or smallish flowers are used in conjunction. It is when we come to use larger flowers, such as Chrysanthemums, Camellias, and so on, that some heavier material must be looked for, and used in lesser quantity. Malmaison Carnations look well with foliage of the border varieties, or Pinks. Roses with their own foliage, than which nothing becomes them better. Rêve d'Or produces charming leaves and shoots for this purpose, as does also Aglaia. The blooms of the common monthly Rose are almost perfect for the table, being amply supplied with buds, and of a colour which comes out well under artificial light. Charming dancing Daffodils must not be forgotten, but eschew Polyanthus Narcissi, which are too strongly scented—a drawback this to which all flowers of heavy odour are subject. Scarcely any of the Lilies are suitable, for this reason.

Amongst Orchids, Cattleyas, Lælias, Dendrobiums, Odontoglossums, and Calanthes, especially the two last, are worthy of being set up, each of them making for lightness and elegance. Cattleyas should be sparingly used, and it is to be supposed there are not a very large number of places where they are likely to be used in great profusion.

In conclusion, let me offer a few words in favour of the many lovely things we are able to produce outside, which when carefully treated give a refined and artistic finish to any table. Poppies, Aquilegias, Clematis, Sweet Peas, Anemone japonica, both white and rose-coloured; many Roses, and numberless inhabitants of the hardy herbaceous and half-hardy world. The use of plants is, by the rules of latter-day fashion, allowable both in conjunction with cut flowers and alone. There is a vast wealth of material in this connection which it is scarcely necessary to enumerate individually, *Draenas*, *Crotons* (*Codiaeums*), *Panax*, *Jacarandas*; various rush-like plants such as *Carex* and *Cyperus alternifolius*, the *Pandanuses* and *Aralias*, besides *Asparagus*, and many Ferns. These are all valuable in some way or other, and may be used in carrying out various designs, heightening the effect, or giving lightness to the floral part of many an arrangement upon the dinner-table. *J. W.*

THE RAINFALL AT ROTHAMSTED IN 1901.

ACCORDING to the rain-gauge at the Rothamsted Experimental Station, which was constructed forty-nine years ago, and is 1-1000th of an acre in area, stands 2 feet above the surface of the ground, and is about 420 feet above the sea-level, we find that the rainfall for the year 1901, recently ended, amounted to 23 $\frac{1}{2}$ inches, which is about 5 $\frac{1}{2}$ inches below the average record for this district, extending over a period of forty years.

The following table shows the rainfall of each month for the past year at Rothamsted, Hertfordshire, with the average amount of rainfall for each month of the previous forty years, and the difference of 1901 above or below the average:—

Rainfall at Rothamsted for each Month of the Year 1901, and the Average and Total Yearly Rainfall.

| Months. | Rainfall, 1901. | Average Rainfall of Forty Years. | 1901. Above or Below the Average.* |
|------------------|-----------------|----------------------------------|------------------------------------|
| | Inches. | Inches. | Inches. |
| January | 1.18 | 2.46 | -1.28 |
| February | 1.26 | 1.74 | -0.48 |
| March... .. | 2.56 | 1.73 | +0.83 |
| April | 2.51 | 1.97 | +0.54 |
| May | 1.81 | 2.34 | -0.53 |
| June | 0.84 | 2.42 | -1.58 |
| July | 2.44 | 2.72 | -0.28 |
| August | 2.00 | 2.60 | -0.60 |
| September | 1.35 | 2.60 | -1.25 |
| October | 2.02 | 3.20 | -1.18 |
| November | 1.05 | 2.65 | -1.60 |
| December | 4.13 | 2.20 | +1.93 |
| Yearly total ... | 23.15 | 28.63 | -5.48 |

* The sign (—) signifies below the average, and the sign (+) above the average.

The above table shows that the yearly total of rain, with melted snow and frost, for the past year was 23.15 inches, against an average of 28.65 inches for the previous forty years, showing a deficiency in the twelve months of nearly 5 $\frac{1}{2}$ inches. There were but three months in the year—namely, March, April, and December—when the rainfall exceeded the average record, consequently there were nine months of deficiency. This is the smallest yearly rainfall since 1898, when 20 $\frac{1}{2}$ inches only were measured.

In order to understand what this deficiency of 5 $\frac{1}{2}$ inches of rain means to our natural springs of water and to vegetation, it may be

explained that this deficiency represents a total of 553 tons of water, equal to 124,432 galls. on each acre of land; accordingly our well-springs and other supplies of water show a falling-off which can easily be accounted for. A well at the Rothamsted Laboratory, from which no water is drawn, but which is measured month by month, to determine the rise or fall of the springs, in January of last year recorded a depth of 2 feet 11 inches of water; this gradually rose to a maximum depth of 3 feet 11 inches in April. Since that date the water has been decreasing, and at the beginning of December, 1901, there were but 11 $\frac{1}{2}$ inches of water in the well. The large rainfall of the month of December will probably cause another rise of the springs. *J. J. Willis, Harpenden.*

DENDROBIUM TAURINUM.

ORIGINALLY discovered by Cuming in the Philippine Islands, this singular-looking species was flowered for the first time under cultiva-

FIG. 30.—DENDROBIUM TAURINUM.

tion in Loddiges' nursery in 1842, and from that time until a few years ago the small importations made of it always came from the Philippines. But among the plants collected in Amboina by the late David Burke, for Messrs. Jas. Veitch & Sons, were a few specimens of a plant identical with the typical *D. taurinum* in most respects, though differing much in the appearance of its brown tinted yellow flowers, and which was named *D. taurinum amboinense*. Last year Messrs. Hugh Low & Co. still further added to the known area of geographical distribution of the species by flowering plants imported from New Guinea, the flowers of which were in every respect similar to the Philippine species, a circumstance all the more singular because the Amboina plant, a much nearer neighbour of it than the original Philippine form, is so dissimilar in colour, and some other details, as to entail a great deal of consideration, as to whether it might not better be considered a distinct species.

Our illustration (fig. 30) represents a flower of Messrs. Hugh Low & Co.'s New Guinea form. The sepals and petals were whitish, the petals tinted with rose colour; the lip pale rose, with purplish markings at the base.

All the forms of *D. taurinum* are tall-growing, the pseudo-bulbs sometimes being 9 feet in height. Messrs. Low's plants were about 3 ft., but probably the dwarfest were selected for sending to this country. The inflorescence is borne on upright spikes, and the flowers have sufficient resemblance to the head of a bull to warrant the name given to it. It should be grown with *Dendrobium Phalenopsis*, *D. superbiens*, and others of that class in a warm house, and should be rested with a restricted supply of water in the intermediate-house.

FOREIGN CORRESPONDENCE.

GARDENERS' PROSPECTS IN THE UNITED STATES OF AMERICA.

I NOTICE in your issue of January 11, 1902, a communication from A. Harding, Villa Nova, Pa., setting forth in rather glowing colours the opportunity British gardeners have in this country, as he sees it. Mr. Harding speaks from an experience of eight months, and is naturally enthusiastic when he compares his present condition with those that ordinarily obtain in the English gardens. For nearly twenty years I have been in daily contact with the gardeners of New England and New York, and seldom a day passes without one or more applying to me for positions, therefore I feel that my experience warrants me in speaking as to the facts. The British and German gardeners, because of the knowledge they possess through a more systematic training in the business than is readily obtainable in this country, usually have the preference when positions are offered. There are not many American gardeners. The wages Mr. Harding mentions are correct, and in some instances even more money is paid. The trouble, however, is that there are now more gardeners, head and working, in America than there are positions for. A call round at the leading seed stores in any of the principal cities will, I think, demonstrate this statement to be beyond question. The business with which I am associated makes, at a considerable expense, a specialty of supplying horticultural and agricultural help; and we have to-day on our books the names of more capable men seeking positions than we expect to be able to place this season; while there will, undoubtedly, be added to this already too big list the usual number of "floaters" that come to the top every spring when the season's work opens.

The nurseries in this country are run on an entirely different system from what they are on your side; and usually it is only for a couple of months in the spring and another in the fall that a gardener, out of regular employment, can hope to find work in them. The employing of Poles, mentioned by Mr. Harding, is not per force, but by preference, because of the fact that Poles and Italians will work for less remuneration than almost any nationality that seeks refuge in the United States. Their 5s. or 6s. a day may seem a large sum when compared to the nursery labourers who are working at home for 15s. to 18s. a week, but the English nursery labourer should remember that he has employment for twelve months of the year, and that his 2s. has as great a purchasing power as our dollar, so far as necessities are concerned; while the nursery-labourer in this country, north and west of Pennsylvania, rarely finds employment for more than eight months of the twelve.

While it is not my purpose to discourage honest, capable, and ambitious gardeners and

florists from coming to the United States, it may not be out of place for them to know that this is not exactly a land flowing with milk and honey, and that situations are not always to be had for the asking. Perhaps it is not too much to say that more scope is afforded here, and young men of ability have more consideration shown them than they usually receive from English employers. Nevertheless, they have in many things to serve a second apprenticeship, and during that time receive only "apprentices' pay." When he eventually applies for the higher position, he finds, as Mr. Harding puts it, "over a dozen established and capable applicants in compe-

Cypripedium niveum and *C. insigne* Sanderæ, and on flowering this year was shown at the Royal Horticultural Society's meeting on January 28, when it was unanimously voted a First-class Certificate. The upper sepal is white with a yellow tinge over the basal half, which is also dotted with minute purple spots. The petals are cream coloured, evenly dotted with purple; lip pale primrose; staminode pale yellow, with a small green boss in the centre. The foliage is broader than that of *C. insigne*, greyish-green with dark green reticulation.

It may be assumed that this cross has been made before, and the seeds proved non-

STANDARD TREES OF PEACHES AND NECTARINES.

My first ideas on the above subject were obtained in 1862. At that time I was employed in a garden not far from Sudbury Hall in Derbyshire, and occasionally I called there to see the gardens. The head gardener at that time was a Mr. Dick, a very gentlemanly, intelligent man. For some time previous to his taking charge, the gardens had been practically closed. Amongst the fruit-houses were two roomy lean-to Peach-houses. The trellises for training the trees upon were curvilinear at the front, and on the upper portion of the back wall. Most of your readers will recall houses of this description. The natural soil of the district was of a moist loamy character, and as the trees on the front trellises had free access to the outside borders they grew very freely. I was informed that a few years previous to the time mentioned the trees generally had grown nearly wild, not having been pruned or tied down for some two or three years. In the case of those on the front trellises it was decided not to attempt to let them down to the trellis again. The shoots were thinned out, leaving the stoutest and best-placed ones, which thus formed a series of small bushes growing upright from the main branches. The first year a nice crop of good fruit was secured, and when I saw them they were producing a capital crop. I left that district at the end of 1863, so cannot say how long they continued to do well.

My next observation bearing upon this subject was in the case of a span-roofed house, which had been used previously for the cultivation of *Ericas* and other hard-wooded greenhouse plants. The house in question ran from east to west, hence the fall of the roof-glass was to the north and south. For about two-thirds of the distance up each side a trellis was fixed some 14 inches from the glass. The side facing north was planted with dessert Plums, and the one facing south with Peaches and Nectarines. Along the centre some good-sized trees of the latter, hitherto grown in pots, were planted out. For a few years the whole continued to afford fairly good crops of useful fruit, but they had to be cleared out after a time, as the house was too narrow and low for them. I ought to say that in wet, sunless seasons the Plums did not prove satisfactory. This was a case like the former, where the gardener had to make the most of the means at hand for the time being.

THE STYLE OF HOUSE FOR THE PURPOSE.

Were I called upon to erect a house or houses for the supply of late summer and autumn Peaches, I should erect them on the lines of the one last described; but the houses would run from north to south, and the interior space would be more roomy. Seeing that it is nearly impossible to permanently fill an ordinary lean-to or span-roofed house with standard Peaches and Nectarines and get regular crops of good fruit, I should propose to combine trellis-trained trees and free-growing standards in the same house. My reason for doing this would not be a cultural fad, but a firm belief that it would be profitable in every way to do so. A house of the kind I mention should be 30 feet in width; its length would depend upon the needs and wishes of the builder; if for a private establishment, one, say 100 ft. long would supply abundance of good fruit for most, if not all, families, ripening, say from the beginning of August to the end of September, after which time, in northern districts especially, Peaches are not much valued on the dessert-table. Of

FIG. 31.—CYPRIPEDIUM × VENUS, OAKWOOD VARIETY.

tion," which actually reduces the conditions to those prevailing in your country, except perhaps in the matter of pay, and this, as above suggested, is to a material extent offset by the extra expense of living and temptations to spend money naturally incident to the country. Archibald Smith, Boston, Mass.

CYPRIPEDIUM × VENUS, OAKWOOD VARIETY.

THE subject of our illustration (fig. 31) must be added to the list of really beautiful and distinct hybrid Orchids raised by Norman C. Cookson, Esq., of Oakwood, Wylam-on-Tyne, in whose garden so many fine garden-hybrids have originated. It was obtained by crossing

effective; for it is recorded in the *Gardeners' Chronicle*, 1895, i., p. 200, though no raiser's name is given. Whatever may have been the outcome of that record, certainly nothing so beautiful in its way as that shown by Mr. Cookson has been exhibited. The cross between *C. niveum* and ordinary *C. insigne* is known as *C. × niveo-insigne*; and *C. × Muriel* Hollington was said to be of similar parentage, but doubts are expressed on that point.

Mr. Cookson's success in securing the best in its class out of *C. insigne* Sanderæ is all the more gratifying, as that fine yellow form of *C. insigne* does not generally produce good results. Probably its chaste beauty is nullified by crossing with coloured species, but the other parent in this case being white it is enhanced.

course, in late seasons one or two of the kinds named below would keep until the middle of October if required.

Beyond giving a few dimensions of the house I allude to, there is no need to go into further particulars. Any good horticultural builder would erect it. I mentioned 30 feet as the width, the height of the ridge should be 12 feet 6 inches from ground level, with 3 feet 3 inches for the eaves; 2 feet of the latter should consist of moveable lights, hung from their centres, so as to open inwards and outwards. By this method a current of fresh air is carried upwards in the space betwixt the glass and the trellis-trained trees. This is an important matter in late Peach-houses, especially now-a-days when the plane of their roofs is little better than a sheet of glass. On each side of the ridge there should be continuous moveable lights, say, not less than 2 feet 6 inches in width. If these were made in 9 feet lengths, and being so that they could be easily removed each year when the fruit was picked, and the wood properly ripened, it would be an advantage in several ways. One advantage would be, that it would prevent the house being converted into a general plant-store in the winter. Many so-called late Peach-houses are gradually turned into second early ones through being used for this purpose when the trees should be completely at rest. Instead of the usual door at each end under the ridge, I would have two doors at one end, if not at both. The object in this is to facilitate work when new soil is required, &c., by giving free access to wheelbarrows, garden-engines, and hand-barrows.

Owing to the standard trees being planted along the centre of the house, two small paths would be required. The doors suggested should be opposite the paths. It would be necessary to have not less than two lengths of 4-inch hot-water pipes up each side of the house to exclude frosts at night when the trees are in blossom; and also what is of equal effect, if not greater importance, in dull, sunless seasons, viz., dry the atmosphere sufficiently in the daytime to liberate the pollen-grains, and ensure a good set.

Beyond saying that the walls which carry the eaves should have well-arranged openings quite up to the ground-level so as to give free access outwards to the roots from the trellis-trained trees, I do not propose to go further to describe the details of border formation. These have been recently discussed in the *Gardeners' Chronicle* by fully competent men.

PLANTING THE TREES.

Beginning with standards, I would suggest that twelve trees be put in a house of the length named. This would give each tree about 8 feet 6 inches of space lengthways, and a little more crossways, in the space in centre of the house. Two parallel brick-on-edge walls running the whole length of the house, say from 3 to 4 feet from the centre, should be put down. These walls might be carried, say 1 foot below ground-level, and rise an equal height above it. Cross-walls of the same depth and height, and 8 feet 6 inches apart, would give a separate compartment for each standard tree. I am quite sure this extra expense would in the long run be amply repaid by the greater cultural advantages afforded. When planting, be sure and choose strong, healthy maiden trees on stout 5-foot stems. It will require fully as much care and attention to form the base of a good standard as that of a trellis-trained tree, though I would by no means suggest that much annual pruning is advisable. After the first year's growth, each tree would carry, say, two

dozen fair fruits. I know some gardeners speak of more fruits having been proportionately produced; but seeing that a Peach under, say, 5 ounces in weight is but an apology for a good fruit, I would dissuade growers from overcropping, at the outset at any rate. As is well known, it is the pulp that is eaten, not the stones, and it is impossible to have an undue quantity of the latter well clothed with the former. When fully grown, each standard would give not fewer than 100 Peaches, with perhaps 120 in the case of Nectarines. My selection of varieties of Peaches would be Barrington, Bellegarde, Violette Hâtive, Crimson Galande, Goshawk, Prince of Wales, Sea Eagle, and Walburton Admirable; and of Nectarines, Balgowan, Lord Napier, and Pineapple.

The trellises for training the trees upon along each side should run about 12 feet up the roofs from eaves, and be not less than 18 inches from the glass. Here I would plant six trees on each side, thus allowing a space of about 16 feet 6 inches for each tree. Nectarines should be kept to themselves.

My selection of varieties for trellis trees is Condor, A'bee, Grosse Mignonne, Nectarine Peach; Dymond, Violette Hâtive, Princess of Wales Peaches; and Early Rivers, Balgowan, Violette Hâtive, and Stanwick Elruge Nectarines.

Taking one fruit from each square foot of trellis would give 1,200 fruits from each side of the house, making with fruit from standards considerably over 3,000 fruits annually, which most practical fruit-growers will agree is a fair quantity. I need hardly mention that until the trees come into full bearing, the vacant space might be occupied with Tomatos, or some other crop. *H. J. C., Grimston Gardens, Tadcaster.*

CULTURAL MEMORANDUM.

DAPHNE ODORA.

SOME few individuals of this old and fragrant species which flowers about Christmas, should be found in every greenhouse. The plant is generally grafted on stocks of *D. laureola* in March, though I have been fairly successful in growing them on their own roots by putting in during September slips 3 ins. long, with a heel of older wood, in a mixture of sandy peat and loam, in thumb-pots. The slips should be placed against the side of the pot, afforded water, and put under a bell-glass in the greenhouse. They may take longer to form roots than in heat, but the plants are stronger, and not so liable to decay; moreover, the plants are longer-lived on their own roots than grafted plants. At Bieton the plant is used to cover a greenhouse back wall, where they succeed admirably, not being crowded with other plants; and for this purpose grafted plants are preferable, as they grow stronger. Nice little bushy specimens can be grown in 7-inch pots, in loam and peat in equal proportions, with enough silver-sand and a small quantity of powdered brick-bat as will give porosity, potting firmly. Frequent repotting should be avoided so long as a plant is healthy.

Water must be applied only when it is wanted, as ill-health quickly follows excess of moisture at the root; and manures should be avoided. In the month of July, plants in pots are the better for being placed outdoors, and gradually inured to full sunshine, plunged in a bed of coal-ashes. In Devon and Cornwall *Daphne odora* is hardy, and except in very severe winters, they flower freely from the

new year onwards. Out-of-doors, a S. or S.E. wall should be selected for the plants, and one fairly sheltered from cutting winds, and the drainage should be good; the same kind of soil as that used for *Daphnes* in pots, but in a more lumpy state. At Bieton, some litter or bracken is placed around the stems of the plants when severe frosts threaten, and put a mat over them if they are in flower. *J. Mayne, Bieton.* [Our correspondent kindly sent a few flower-heads, taken from plants that had been out-of-doors for five years, the variety being the pink-flowered one. This and the white-flowered variety are very sweet-scented. Ed.]

NITROGENOUS MANURES FOR PEAS.

IN such discussions as occurred in your last issue, it is well to take the entire horizon into consideration, when science and practice will always march hand in hand and pull together, and redress the balance over the assumption that "practice and results have the pull over theory," as stated by Mr. James Baxter. As the more important part of the problem, I prefer to consider Mr. Manning's point of view first, who tells us he sees no very decided benefit in supplying nitrate of soda to Peas, except the earlier ones. This is as it should be, for as nitrification in the soil sets up in proportion to the action of the sun's heat, summer and later crops obtaining the full spell of the power of our great orb, are well provided from natural nitrification in the soil. In this connection, I should like to offer another illustration bearing on the subject. In dry, warm seasons, we have observed that fruit crops do not colour so well as when a fair amount of rain falls. Rain reduces summer heat of the soil and diminishes nitrification. When this occurs fairly, fruit (especially Apples) will be highly coloured. When continuous drought occurs, the fruit will be green. Anyone wishing to experiment can do so for himself by intelligently assisting Nature, and copiously affording water, and syringing with water a portion of his trees in August and September, and comparing results with the other portion left to Nature unassisted.

Dry heat of the soil promotes nitrification, and thus continued growth of fruit occurs, instead of the maturity shown in the development of colour which is promoted by rain and its effects of cooling the soil. Thus, in general, the application of nitrate of soda has its most striking effects in spring on all kinds of crops, natural nitrification being yet little developed so early. The interesting lessons foreseen by Mr. Manning, and which, so says an editorial parenthesis, will be gladly received, will therefore be surely evolved on these lines from the various trials to be made by others as suggested by Mr. Manning. When we thus see results from joining theory to practice, we come to Mr. Baxter's case, who finds a layer of manure (presumably dung), placed at the bottom of a trench, very useful. Naturally so, in a dry season; but, of course, not for its manurial character, but as he says, for a moister bed for the roots, which he supplements by moistening the Pea-haulm overhead, being also found beneficial. When we shall have acquired the habit to irrigate, a goodly supply of water will not be considered any longer so unnecessary; but its sufficiency at the root of Peas will reduce the usefulness of manure at the bottom of trenches for Peas, as the latter thrive remarkably with water only for the later crops, and are quite independent of dung, as natural nitrification makes up for it in the case of all Leguminous plants.

Irrigation in agriculture dates from hoary antiquity, and at the present time one-seventh part of the entire population of our globe, or five times the population of these isles, subsist almost entirely by production, dependent upon

easy one, and thus proceed from the simple to more complex environment, so that a scientific system be evolved in time out of the learning of the A, B, C, to start from the present day. H. H. Ruschen, Sidcup, Kent.

by the Floral Committee. It is a perennial greenhouse shrub, of bushy habit, a foot or less in height as shown, growing in 6-inch and 7-inch pots. The leaves are sessile, ovate-lanceolate, deep green, rather glossy, $1\frac{1}{2}$ inch across at the base; flowers rather more than $\frac{1}{2}$ -inch across, produced in terminal racemes, purple, or violet-purple in colour, with prominent yellow anthers. The plants shown by Messrs. Veitch had been cultivated in a greenhouse, having an intermediate temperature. *E. affine* was illustrated in the *Gard. Chron.*, May 10, 1884, and *E. macranthum*, Mar. 17, 1894.

COLONIAL NOTES.

AN INTERESTING GATHERING AT BARBADOS.

THIS, the fourth meeting of the Agricultural Conference, has just taken place at Barbados, and we have returned to our respective homes after what may be looked upon as a most profitable and pleasant time. Among the representatives from the West Indian Colonies were nine Kew men, and our old friend, Mr. J. H. Hart, of the Botanical Department in the flourishing island of Trinidad. The Kew men present were:—Messrs. R. Ward, of British Guiana; H. Powell, of St. Vincent; J. Jones and D. Tannock, of Dominica; Wm. Lunt, from St. Kitts; W. N. Sands, of Antigua; A. J. Jordan, of Montserrat; H. Miller, of Tobago; and W. E. Broadway, of Grenada. We missed one colleague, Mr. J. C. Moore, the Curator of the Botanic Station at St. Lucia, who unfortunately was prevented from putting in an appearance on account of his island being under quarantine. Possibly this is the only part of the tropics where so many Kew men annually meet. Situated as we are thousands of miles away from home, and among, relatively, few of one's kinsfolk, it is difficult to describe how we appreciate the opportunity of meeting each other. We, who have been so long from the old country, hear and learn much from the newer men, as well as from those who have been privileged to visit Britain on their well-deserved holiday. The stay at Barbados extended beyond the usual time by some forty-eight hours, owing to the Royal Mail steamer *Elbe* from England being two days late, having experienced bad weather. These annual Conferences are held under the presidency of Dr. Morris, C.M.G., &c., the Imperial Commissioner of Agriculture for the West Indies, and it is through his invitation and influence that Kew men and others are enabled thus to foregather for business and pleasure. Barbados, an old British colony, is a strikingly busy place compared with Grenada. One of its characteristics is the delicious flying-fish, which, when alive, skim over the open sea and resemble a lot of birds flying together. There are also edible sea-urchins. W. E. Broadway, Grenada, January 10, 1902.

WEST INDIAN BULLETIN.

The last part received contains a full report of the proceedings at the West Indian Agricultural Conference, 1902, held at Barbados under the presidency of Dr. Morris. The zeal and energy of this gentleman appear to be having good results. Dr. Morris still holds out the hope that a Sugar-cane will be developed which will yield 40 to 50 per cent. more sugar than any now in cultivation. Remembering what was accomplished with the Sugar-beet by the late Henry de Vilmorin, and his father before him, there is good ground for the belief that similar results may accrue in the case of the Sugar-cane. The Presidential address is very suggestive and hopeful. Next year, perhaps, the Conference will be held in one of the other islands.

FIG. 32.—EXACUM FORBESII: GREENHOUSE SHRUB; FLOWERS PURPLE.

EXACUM FORBESII.

OUR illustration (fig. 32) of this new species from Socotra, was obtained from plants shown by Messrs. James Veitch & Sons, Royal Exotic Nursery, Chelsea, at a meeting of the Royal Horticultural Society on January 14, when the novelty was recommended an Award of Merit

systematic irrigation, not a few million lives being thus maintained in British India. It seems a good broad hint to this nation to apply irrigation at home, which modern habit of thought expects of intelligence. Especially should rain-water be stored individually, so to have a resource on the spot wherever physical configuration renders the problem an

The Week's Work.

THE ORCHID HOUSES.

By W. P. BOUND, Gardener to J. COLMAN, Esq., Gatton Park, Reigate.

The removal of the back pseudo-bulbs.—I would refer to the article on p. 409 in *Gardeners' Chronicle* for December 7 last, on the removal of the leading growth of Orchids. I consider this article gives us the one and only method of checking the great loss of plants that has been going on since Orchids have been imported. The species worthy of propagation can be found; but the others which have been allowed to remain in the same state as when imported, i.e., with all the old pseudo-bulbs to rob the leads of nutriment, are gone altogether in a great many cases, and others are following them. Nothing is more charming than a specimen Orchid, but it is not the number of pseudo-bulbs which a plant possesses, but rather the number of its leads. There is nothing to be gained by leaving a string of perhaps 8 to 12 pseudo-bulbs behind the lead, but if they are allowed to remain they make the lead weak continually and general decay sets in. My advice is to sever all the back pseudo-bulbs excepting three or four immediately behind the lead, especially in the case of *Laelias* and *Cattleyas*; then, when the plants are potted, the leads can be placed together in the case of specimens, and make a much neater plant, and generally improve the health of the plants.

Cypripediums.—The present is a suitable time to re-pot or divide plants of *C. insigne* and its many forms, *C. Charlesworthi*, *C. Spicerianum* and the crosses derived from them. Few if any Orchids are more generally useful in apartments than *C. insigne*, or that will succeed amongst and under specimen Orchids. At Gatton Park this *Cypripedium* is grown beneath plants of *Cymbidiums*, in which way they do not take up much valuable room, and they afford a lot of flowers. The importations of recent years, especially of the *C. Montana*, have given gardeners many charming varieties of this fine old species, and lovers of flowers—apart from Orchid cultivators—should grow, in addition to the old form, such varieties as *C. insigne Sanderæ*, *C. i. Sanderianum*, *C. i. Dorothy*, *C. i. Fowlerianum*, *C. i. Harfield Hall var.*, and others. Specimen-making should be the one aim with all of the *C. i.* section, with the reservation that, as previously stated, after they have attained the desired dimensions and the soil has become exhausted, they should be divided, and the divisions grown on to specimen size. If this practice be followed from year to year, dividing a few and potting others, a stock of specimens can be readily kept up. Sometimes specimens are observed that have been grown in the same flower-pot for a number of years and still flower well; but still, if the plant had been divided there would have been twice the number of flowers obtained.

Potting soil.—*C. insigne* and its varieties grow well in turfy peat two-fifths, good fibry loam two-fifths, leaf-soil one-fifth, knocking out the finer particles of the loam if it be heavy. The ingredients should be mixed together and the pot well drained, and both pots and crocks quite clean. Let the potting be done rather firmly, filling the pots nearly to the rim, and insert a few clumps of living sphagnum-moss on the surface. The same kind of compost suits *C. Charlesworthi*, *C. Spicerianum*, but in potting these varieties the base of the growths should be kept a little higher than the rim or more drainage afforded, but do not make the surface convex. Water should be afforded carefully till the roots have seized upon the new compost. Frequent moistening of the stage and the sides of the pots, and the foliage on bright days, is of benefit to the plants. Any plants that have been divided should be shaded from the sun till the roots make a new start. The species and hybrids named need a temperature of not

less than 50°, considerable humidity in the air, and the avoidance of all closeness. A suitable house is one in which exotic Ferns and Palms are grown, or a moist greenhouse.

THE FLOWER GARDEN.

By R. DAVIDSON, Gardener to EARL CADOGAN, Culford Hall, Bury St. Edmunds.

Humea elegans.—Plants that are being grown on for out-of-door decoration of any kind should now be shifted into 9-inch pots in a soil consisting of turfy-loam and decayed manure, and a small quantity of charcoal and silver-sand, with sufficient drainage material. When the plants have begun to seize upon the new soil, afford them full sunlight and plenty of air on all favourable occasions by day, and apply water carefully. Plants of *Grevillea robusta* and *Eucalyptus Globulus* growing in pots which have become too tall for the greenhouse may be shifted into larger pots, and beyond affording them water more freely, they may be treated like *Humeas*. They will form excellent subjects for planting in the shrubberies or large beds in June.

Bedding Pelargoniums.—Those which have been placed in warm houses will have begun to grow freely, and may be potted forthwith singly in 60's in a mixture of turfy-loam and spent Mushroom-dung passed through a $\frac{3}{4}$ -inch sieve, with a small quantity of sand added. The pots used should be new or well washed, and no crocks will be necessary if some pieces of turfy-loam be placed over the bottom of the pots. Recourse is sometimes had to the "mossing," and replacing the plants in boxes, but I have not found this method very satisfactory.

Marguerites.—Rooted cuttings should be repotted into 48's after treatment similar to that of the *Pelargoniums*, but they must be removed to cold frames at a much earlier date, in order to induce a desirable sturdiness of growth.

Gazania splendens.—Young plants may be transferred from the cutting-boxes, and put 4 inches apart in other boxes in a mixture of loam, peat, decayed manure, and sand.

Dahlias.—If an increase of the number of plants is desired, old roots should now be put upon a bed having a bottom-heat of 75°, covering them up to the collar with light soil; syringe them twice daily, and as soon as the shoots produced have grown two joints in length, remove them by slipping them off, insert singly in small pots filled with sand and leaf-soil, and plunge in a close warm frame. When rooted, gradually inure to light and air, and repot as may be required.

Seeds.—A sowing of East Lothian Stock seed should be made at this date thinly in shallow pans or boxes filled with light soil, and place in a vinery at work till germination takes place, then remove to a cool house. In about a fortnight the plants may be pricked off singly into large 60's, using a rich loamy soil, place them on the border of such house, and apply water sparingly until growth begins, after which admit air freely, and at no time allow them to become dry at the root. Sow seeds of *Salvia patens*, and afford ordinary treatment under glass until the month of May. It usually happens that some of the old seeds decay in the winter, hence the need to sow. Seeds of *Salvia Scarlet Queen* should also be sown, and when pricked off the plants should be grown on in a warm house till midsummer. This plant associates well with autumn-flowering *Chrysanthemums*, or it may be planted in the borders.

FRUITS UNDER GLASS.

By JAMES WHYTOCK, Gardener to the DUKE OF BUCCLEUCH, Dalkeith.

The Earliest Peach-house.—The fruit being well set and of the size of horse-beans, a certain amount of thinning should be carried out, but leaving plenty for later thinning, early forced trees not always swelling off the

fruit regularly. As the swelling proceeds more fruits can be removed, the final thinning taking place when stoning is over. Everything possible should be done at the present time to help the swelling of the fruits, keeping a mean temperature of 60°, and 10° or 15° higher in the day-time; syringing twice daily with tepid water, and sprinkling a quick-acting manure on the border, which should be washed-in with tepid water. The Peach does not like a stuffy atmosphere, but as much fresh air as may be prudently admitted, avoiding cold draughts, which chill the small fruit and arrest growth. Disbudding should now receive attention, taking care to leave the bud at the base of the shoot. At this stage greenfly is often troublesome, and the trees should be syringed with quassia-water; and if the small points are curled with greenfly, dust them with tobacco-powder.

Early Vinery.—If the Vines are in flower, keep a mean temperature in the vinery of 65°, rising to 80° or higher in the daytime with sun-heat, damping the paths and wall surfaces so as to secure a moist air in the house. Much watchfulness day and night will be required on the part of those in charge of the houses, changing the air of the vinery by admitting it in small quantity by the upper sashes or ventilators during the warmest hours of the day—cold air injuring both foliage and berries when admitted in quantity. Attend to the tying-down of the young shoots, and keep them away from the glass. Allow two or three buds beyond the bunch to grow, stopping laterals back to one bud; proceed with the thinning of the berries as soon as the fruit is properly set, and apply a light sprinkling of vine-manure to the border, washing it into the soil with tepid water.

Second Vinery.—The vines in this vinery are following close upon the heels of those started a month earlier, and are developing their flowers. Let there be no haste to disbud, but first see which bunches are likely to be the best before making a choice. One shoot to one spur is enough to leave. The mean temperature should not go below 60°, or 5° more than this if the weather is moderate, and 70° to 75° by day. Tie the shoots to the wires with a long strand of matting at the first, and bring them bit by bit on alternate days towards the trellis. If the weather is bright and the air in the vinery inclined to be dry, damp down frequently. Vines, in order to produce ripe Grapes in the months of July and August, should now be started. Unless the weather is very cold, but little fire-heat will be required at the first to maintain a night temperature of 50°, and by day of 55° to 60° when weather is bright. Syringe the Vines in the early morning and early in the afternoon, damping the paths occasionally. If the weather is dull, one syringing in the morning is usually enough. Before starting the vinery the inside border should be examined, and if found to be dry, it should be afforded warm water mixed weakly with cow-house drainings, and afterwards a moderate sprinkling of bone-meal and vine-manure put on the surface together with two inches of fresh, turfy loam finely chopped.

PLANTS UNDER GLASS.

By J. C. TALLACK, Gardener to E. MILLER MUNDY, Esq., Shipley Hall, Derby.

Palms generally will now require their annual inspection as regards repotting and retubbing. I would like to suggest, however, that these accommodating plants are often subjected to too much root disturbance, and that while they are doing well, and show no signs of lessened vigour, they should be let alone, as over-potting may lead to the souring of the soil, and given the requisite shade and syringing during the summer, the small amount of root-space that they require is surprising. *Kentias*, *Arecas*, and, in fact, almost all the more useful *Palms* grown under glass, appear to enjoy a certain amount of confinement at the root, if other conditions are right, and to the decorator this is a great advantage. When

potting is necessary, however, the greatest care should be taken to provide good tough turfy peat and loam that will not soon decay; and good, but not an excessive amount of drainage, carefully placed, and leaving as much space as possible for the roots without elevating the crowns of the root above the rim. No new soil should be placed above the root-level. I would rather leave some roots exposed than bury any portion of the stems. In potting-on young plants, the smallest shifts should be given. A new Palm that has pleased me very much is *Kentia Sanderiana*; this has an Areca-like appearance, and promises to stand rough usage better than that popular species, *Areca lutescens*.

Eucharis.—While these are doing well, they may be left alone. Probably the best plants now to be found have occupied their pots for many years together without disturbance, except to replace the surface-soil, which is sure to get washed away. If, on the other hand, the soil has got into a bad condition, the plants must be shaken out and repotted, placing as many bulbs as possible in a pot, and potting them deeply. Pots over 12 inches in diameter are unsuitable for *Eucharis*, as the large body of soil required soon gets sour. February is a suitable month in which to repot, as then the roots are fairly active, and the temperature may be kept equable, there being no great amount of sun-heat. To keep *Eucharis* healthy and free from the mite, I prefer a cooler, more airy, and somewhat drier treatment overhead than that generally given. A free use of sand in the potting mixture, good loam and peat, are the essentials, with, of course, sufficient, but not over-abundant drainage.

Fuchsias.—Autumn-struck *Fuchsias* should now be repotted, old plants brought to the light, and any that are wanted to produce shoots for propagating purposes, after being slightly cut back, should be placed in a vinery at work; while those intended for growing on as specimens may be pruned severely into shape, and kept cool for some time, no water being afforded for several days after pruning.

Herbaceous Calceolarias.—These may be placed in their flowering pots, using sandy loam, enriched with decayed cow-manure in a dry state. Pot them with a moderate degree of firmness, and place in a house where the general conditions are cool and moist, with plenty of light, and where they get very little direct sunshine.

THE KITCHEN GARDEN.

By T. TURTON, Gr. to J. K. D. WINGFIELD DIGBY, Esq., Sherborne Castle, Dorset.

Ridging Ground for Potatoes.—Land intended for the main crop of Potatoes, and now becoming vacant, if at all retentive, may be got into good condition before the time arrives for planting, if ridging is done at once. This will allow the ground to be exposed for several weeks to frosts and other pulverising agencies, and effect a great saving in labour. Ridge the land at the necessary distances for planting Potatoes, which may be 2 feet 6 inches, except in cases of very strong growers, which may require 3 feet from row to row. Having nicked out the land at these distances with a spade, dig deeply with a full-length, flat-tined digging-fork by preference, between the nicked-out lines, throwing the soil up roughly into a sharp ridge. When planting-time arrives, the frost will have pulverised the sides of the ridges; then take a digging-fork, and level up the trenches to the proper depth to receive the sets. The tubers can be planted by one man to a line, and another man should follow with a digging-fork to cover the tubers with soil from the ridges. The land between the rows may be forked over directly afterwards or left until a more convenient time. If extra fine and clean-skinned tubers are desired, or should the land require such a dressing, cover the sets in the trenches with decayed leaf-mould and charred garden-refuse. This has been my practice in respect to the main crop of Potatoes for many years.

Onion Ground.—If this has not already been well prepared by heavy manuring and trenching, no time must be lost. Land on which the main crop of Peas was grown last year, and which in most cases would be followed with Savoys and other early winter crops, will now be vacant. Place at the bottom of the trench all rubbish in the way of leaves from the Savoys, and other refuse from the crops; but pull up and burn all big stumps. After turning in the top spit, put on a layer of dung, and another layer under the finishing spit, which should be left roughly thrown up, and so exposed to the action of the weather till the time arrives for preparing the surface for sowing.

Mushroom-house.—Where much fire-heat has to be employed to maintain the required temperature, this will necessitate frequent sprinkling of the beds, walls, and path with water through a fine-rose water-pot or syringe. Judgment and experience, however, are the great factors in successful Mushroom-growing, and the covering of beds which are exposed to fluctuating temperatures or dry atmospheres with clean soft hay not only prevents moisture evaporating, but reserves the heat in the beds. Watering beds whilst the Mushrooms are small is often fatal to them, and the aim should be to afford a good watering to beds after a crop has been gathered, then re-cover with fresh hay, and unless the bed is exhausted, another crop will soon result. Maintain a temperature of 55° by fire-heat, and keep floors and surfaces near to hot-water pipes well damped. Collect droppings for another bed in the Mushroom-house, always avoiding, if possible, those voided by horses fed with Carrots; and upon no account use the dung from horses which have recently received physic.

THE HARDY FRUIT GARDEN.

By J. MAYNE, Gardener to the Hon. MARK ROLLE, Bietou, East Budleigh, Devonshire.

The Fig.—In this garden, near to the sea coast, we never find it necessary to protect Fig-trees, even in the most severe weather, and in localities where such protection is necessary, the covering should be used only during frosts. Do not permit the trees to accumulate too much wood. It is very essential that the sun and air should be able to penetrate freely among the branches, to thoroughly ripen the growths, and thus render the shoots less liable to be damaged by severe frost. Well ripened shoots of the Fig will withstand 12° to 16° of frost, but it is the continuance of hard frost for weeks together that does the mischief. Thinning of the shoots may be done in mild weather, and the remaining ones washed with a mixture of soft-soap and flowers-of-sulphur, made of the consistency of paint, which will kill any red-spider there may be upon them. Curtail the roofing space of the trees, and do not permit them to enter a rich, loose border, or they will make gross and unfruitful wood. Short-jointed wood is required, and for the production of this the border cannot well be too firm, as the best results are generally obtained from trees whose roots have worked under a road or garden path. Good loam, with about one-sixth of old mortar-rubble, well mixed together, is a good compost. Thorough drainage is necessary, and the planting is best done late in March. The old variety, Brown Turkey, is one of the hardiest, most reliable, and best-flavoured varieties for cultivation out-of-doors. If a wall is afforded the trees, it should be one facing south or south-west. In this county (Devon) standard and bush-trees of large dimensions are frequently seen laden with fruit during August and September, in warm positions sheltered from the north by buildings or evergreen hedges.

The Pear.—Any trees affected by the Mussel-scale, and that have been pruned, should be painted over with paraffin emulsion at once. We had two fan-trained trees on a west wall so badly infected that they made no growth. As a winter dressing, half-a-pint of paraffin

was put into a 4-gallon pail of nearly boiling water and thoroughly mixed together, and enough clay added as would make a thick paint. This was laid on over every part of the trees twice, after an interval of a week; the following season the trees grew away kindly, and have done so every year, no trace of scale having been noticed since. It is necessary to unfasten the trees before starting to paint, so that every part gets its share.

FRUIT CULTURE IN THE UNITED STATES.—

The subjoined figures and explanatory matter, from the Census Returns, refer to the State of

NEW HAMPSHIRE.

| Fruits. | Number of Trees. | | Bushels of Fruit. | |
|----------------------|------------------|-----------|-------------------|-----------|
| | 1900 | 1890 | 1899 | 1889 |
| Apples ... | 2,034,398 | 1,744,779 | 1,978,797 | 2,283,347 |
| Apriots ... | 141 | 191 | 2 | ... |
| Cherries ... | 6,700 | 7,164 | 1,183 | 504 |
| Peaches ... | 48,819 | 19,057 | 6,054 | 1,204 |
| Pears ... | 38,287 | 39,378 | 19,341 | 19,288 |
| Plums and Prunes ... | 18,137 | 10,151 | 4,942 | 842 |

The value of the fruit grown was 707,729 dols. In 1900, 94·8 per cent.; and in 1890, 95·8 per cent. of all the fruit trees in the State were Apple-trees. The increase in ten years was 16·6 per cent. Peaches flourish only in the south-eastern part of the State. The Cherry-trees decreased in the same period 6·5 per cent.; Pear-trees, 2·8 per cent.; while Plum and Prune-trees increased 78·7 per cent. As the quantity of fruit is determined largely by the nature of the season, which varies more or less from year to year in all the New England States, no valid comparisons can be made between the crops of 1889 and 1899. The former year was evidently more favourable to the Apple crop than was 1899, for although there was an increase in the number of trees, there was a decrease of 13·3 per cent. in the quantity of fruit reported. Cherry, Peach, Pear, and Plum trees, on the other hand, bore more abundantly in 1899 than in 1889. The area given over to small fruits in 1899 was 734 acres, and the value of the fruit grown was 116,830 dollars—an average of 159 dollars per acre. The acreage and production of berries were as follows:—Blackberries and Dewberries, 65 acres; Cranberries, 23; Currants, 27; Raspberries and Loganberries, 80; Strawberries, 307; Gooseberries, 5; and other small fruits, 227 acres, with a total produce of some 1,240,906 quarts. The produce was greatest with Strawberries, Raspberries, and Blackberries.

AGRICULTURAL STATISTICS, IRELAND.—A report has been published as a Government paper showing the extent in statute acres, and the amount of the crops grown in the several counties of Ireland in 1901. There is a decrease in acreage of over 20 per cent. in Wheat, of 0·5 in Oats, of 7·2 per cent. in Barley, and of 3·6 in Rye; in Potatoes of 2·9 per cent., in Turnips of 2·7 per cent. On the other hand, Mangel Wurzel, Flax, and Hay exhibit an increase. The amount of actual produce for Cereals and Potatoes shows an increase. Of the Potatoes grown over 66 per cent. are "Champions," and last season was very favourable, the produce per acre averaging 5·3 tons. A valuable diagram is given, showing the produce of Potatoes during each one of twenty years. It is very desirable that this should be correlated with similar tables showing the temperature, rainfall, and, if possible, the amount of sunshine.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Special Notice to Correspondents.—The Editor does not undertake to pay for any contributions, or to return the unused communications or illustrations, unless by special arrangement.

Illustrations.—The Editor will thankfully receive and select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.

APPOINTMENTS FOR THE ENSUING WEEK.

| | | |
|----------|----------|--|
| TUESDAY, | FEB. 11. | Royal Horticultural Society: Committees meet. Annual General Meeting of Fellows at 3 P.M. Horticultural Club at 5, Dinner at 6 P.M. |
| FRIDAY, | FEB. 14. | Annual Meeting of the Royal Gardeners' Orphan Fund. |

SALES FOR THE WEEK.

| | |
|----------------------|--|
| MONDAY, FEB. 10.— | Border Plants, Bulbs, &c., by Protheroe & Morris, at 12. |
| WEDNESDAY, FEB. 12.— | Azaleas, &c., by Protheroe & Morris, at 12.—Palms, &c., at Stevens' Rooms, 12.30.—Sale of Nursery, Bull Inn, Dartford, at 4, by Dann & Lucas. |
| THURSDAY, FEB. 13.— | Sale of Hollies and Rhododendrons, at the Eccleston Nurseries, Prescott, by Protheroe & Morris, at 12.30. |
| FRIDAY, FEB. 14.— | Sale of Hollies and Rhododendrons, at the Eccleston Nurseries, Prescott, at 12.30.—Roses, Plants, &c., at 12, and Orchids, at 12.30, by Protheroe & Morris. (For further particulars see Advertisement columns.) |

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three Years at Chiswick —39° 0'.

ACTUAL TEMPERATURES:—

LONDON.—February 5 (6 P.M.): Max. 38°; Min. 34°.
February 6.—Mild; dull.

PROVINCES.—February 5 (6 P.M.): Max. 41°, Scilly; Min. 33°, East Coast.

WELL in advance of the annual meeting on February 11, the Council of the Royal Horticultural Society has issued its annual report. It is in the main of a highly satisfactory character, financially and otherwise, but while, on the one hand, it contains little that the Fellows do not know already, on the other, it is silent upon the point of all others upon which the Fellows are most anxious to have information. We must possess our souls in patience till the annual meeting, when in all probability the President will be able to announce what has been done in the matter of obtaining a site for the erection of a Hall. We have not space to reprint the report in full, but we may comment on some of the more important of its contents. No fewer than 930 new Fellows have been elected in the past year, a fact which we can only characterise as "prodigious."

The net cost of maintaining Chiswick is put down at £1,576. The success of the Chiswick students in spite of the somewhat meagre opportunities afforded them is very gratifying. It is suggested that in future the examinations of pupils be held in February instead of in April, as being a more convenient season. In some quarters we hear complaints that the examination is not of a more directly practical character. If the candidates were closing their educational career instead of beginning it, there would be some force in this objection. Practical experience can only be obtained by practical work. To expect youths who have only been a short time in the garden to be expert practitioners is unreasonable. This points to the desirability of a preliminary examination to be held, say, at the end of the first or

second year of pupilage, and a final examination of a practical character two or three years later.

No fewer than 983 awards of some degree or other have been made during the year by the various committees. Of these no fewer than 408 were allotted by the Floral and 191 by the Orchid Committees. These figures, we think still, indicate an excessive liberality on the part of the censors, calculated to materially lower the value of the several awards. We are glad to see an attempt to meet this contingency by the promulgation of a new rule, that any proposal for an award "shall not be considered as carried unless the number of votes recorded for the proposal be at least double the number voting against it." We shall be glad to see this majority raised to a two-thirds majority in a committee of not fewer than twenty members.

It is a matter for satisfaction to find that several of the special societies have intimated their intention of holding their exhibitions in conjunction with the Society's meetings, and in future the show Tulips will be dealt with by the Narcissus Committee. We have always regretted the frittering away of means and energy occasioned by the special societies. They should, we think, be treated as sections of the parent Society, with a representative on the Council, and invested with Home Rule in all special matters. Extra prizes could be provided for as they are now. By some such means the minor societies would gain in dignity, and be less exposed to the charge of self-glorification of individuals.

The Fruit Show at the Crystal Palace is a most momentous matter as regards the promotion and improvement of fruit-culture. The Fellows do not appear to realise the importance of the subject as they should do. It is really a matter of national concern, which in other countries would be undertaken, or at least liberally helped by the Government.

Of the *Journal* we have lately spoken. The Fellows can but feel satisfied with the spirit with which this excellent publication is carried on.

One hundred and sixteen local societies have become affiliated to the Royal Horticultural Society during the year. This suggests that the Council might devise means for increasing the utility of provincial shows. They are very agreeable meetings, eagerly sought after by prize-winners, and even by commercial firms, but their influence in the promotion of horticulture is surely not proportionate to the efforts made. An annual meeting at which delegates from the local and special societies might be present to discuss matters of interest to them all is very desirable.

And this brings us to the matter not mentioned in the report, but which is uppermost in the minds of those actively concerned in the work of the Society. We mean the establishment of a horticultural Institute to serve as headquarters for the Society, and in which the gardening charities, the special societies, and all associations connected with horticulture, might find a home so far as it might be possible or expedient. Never was the Society in a better position to undertake such responsibilities, never were there greater chances of support than at present. What better way of celebrating the centenary of the Society

can be suggested? The Fellows await developments with eager interest. In the meantime, we believe negotiations of a satisfactory character are in progress, though not in a state to be formally divulged. In any case, they must be submitted to the Fellows for approval before any absolutely binding step is taken.

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the committees of this Society will take place on Tuesday, February 11, in the Drill Hall, Buckingham Gate, S.W. The annual general meeting of the Fellows of the Society will also be held in the Drill Hall at 3 P.M. on the same date.

—At a general meeting of the Royal Horticultural Society, held on Tuesday, Jan. 28, fifty-two new Fellows were elected—amongst them being the Countess of KENMARE, the Countess of SEFTON, and the Countess of ST. GERMAN—making a total of 123 elected since the beginning of the present year.

IRIS PERSICA.—Among Mr. WALLACE'S beautiful collection of spring-flowering Irises shown at the Drill Hall on the 28th ult., was a flower of *Iris persica* with six sepals (falls), six petals (standards), six stamens opposite to the sepals, and six petaloid styles. The natural supposition would be that this was a case of the union of two flowers, but against this view is the fact that the parts of the flower are perfect in number. In cases of fusion, some of the parts get squeezed out and obliterated, so that instead of twenty-four, as there were in this case, there might be twenty or some smaller number.

HORTICULTURAL CLUB.—The annual general meeting will be held in the Club Room, Hotel Windsor, on Tuesday, February 11, at 5 P.M.; and the annual dinner will be held in the same place at 6 P.M. We regret to see that the founder of this useful Institution, the Rev. H. H. D'OMBRAIN, has found it requisite to resign his post as Secretary.

ALLEGED CROSS BETWEEN A DWARF BEAN AND A PEA.—Mr. W. SMYTHE sends us two seeds of a dwarf Bean (*Phaseolus*), and one seed of an alleged cross between the Bean and a Pea (*Pisum*). We must not say that such a bi-generic cross is beyond the range of possibility, but the probabilities are that some oversight has occurred. In any case the supposed hybrid seed is very curious. The seeds of the Bean are about 12 mill. long, 8 mill. wide, compressed from side to side, oblong, obtuse at both ends, slightly kidney-shaped, chestnut-brown, shining, with a white, oblong, roundish scar or hilum, about 4 mill. long, partly surrounded by a blackish ring. The alleged hybrid seed is 11 mill. long, 9 mill. lat., greenish-yellow, oblong-ovoid, obtuse at each end, neither flattened nor kidney-shaped. The hilum is white, oblong, not surrounded by a deeper-coloured ring.

FORESTRY.—We hear that a Departmental Committee has been appointed to consider and report on forestry and woodlands in the United Kingdom.

"TRAITÉ DE CHIMIE AGRICOLE."—The first edition of the *Traité de Chimie Agricole* appeared ten years ago and was soon exhausted, and in the newly-published second edition, M. DEHÉRAIN has brought the work up to date by chronicling therein the discoveries made in the last ten years. Among the chapters that have been revised and enlarged may be mentioned those on germination, soluble manures, penetration and decomposition of carbonic acid in leaves, reduction

of nitrates and formation of albuminoids in the plant, growth, maturity, &c. There are also short monographs on Colza, Wheat, Oats, Beetroot, Potatoes, and the Vine. The author also records the results of scientific experiments relating to the circulation of water in the plant, enrichment of the soil, fermentations of arable land, calcareous applications, chemical manures and mixed manures. In fact, the treatise is thoroughly up to date, and should prove valuable to those for whose use it is intended. (Publishers, MASSON ET CIE., Paris.)

NATIONAL ROSE SOCIETY.—A meeting of the General Purposes Committee will be held at the rooms of the Horticultural Club, Hotel Windsor, Victoria Street, Westminster, on Tuesday, the 11th inst., at 2 P.M. A meeting of the Committee will be held on the same day at 3 P.M., H. HONYWOOD D'OMBRAIN, EDWARD MAWLEY, Hon. Secretaries.

THE CARE OF EPPING FOREST.—The annual report of the Epping Forest Committee details the necessary thinning carried out among the old trees during the past year, and the planting and due protection of young plants. The ponds have been cleaned and deepened; but for various reasons, drought being one of them, boating on the ponds has been less popular than usual. The committee has received the gift of a piece of freehold land and a cottage at Fairmead, Loughton, from Mr. GELLATLY, one of the verderers.

THE LAW.—An interesting case decided at the Tribunal of Commerce at Ghent is reported in the current number of the *Revue de l'Horticulture Belge*. The plaintiff purchaser sought damages from the defendant salesman, because the offsets had been taken off from some plants of *Draecena neo-caledonica* before they were delivered. The defendant pleaded the custom of the trade. The Court gave judgment for the plaintiff, saying, that if the defendant wished to retain the offshoots he should have made an express stipulation to that effect.

SEED LIST OF THE JARDIN DES PLANTES.—We have received the "Index seminum" from the Paris garden. It is a lengthy document, and is the first of its kind signed by the new Professor, M. J. COSTANTIN. Applications for exchange of seeds, &c., should be made to M. le Directeur du Muséum d'Histoire Naturelle (Service de la Culture), Rue Cuvier 57, Paris.

IRISH MIGRATORY LABOURERS.—In the official report published by the Department of Agriculture and Technical Instruction for Ireland, statistics are given of the number of Irish labourers migrant to Great Britain, and their condition. In absolute numbers, as well as considered in relation to the population, there has been a great decline during the last fifty years, partly owing to permanent emigration, to the curtailment of the cropped area of Great Britain, and to the use of agricultural machinery, and partly to the local development in Ireland of fishing and other industries. Strangely enough, one of the characteristics of Irish migrants is said to be "one of extreme thrift while in Great Britain, in order to save against the rainy day in the winter and early spring. A large Scotch employer of Irish labourers told of a lad working on his own farm who was brought to him one day in a faint. On enquiry, he found that the young fellow had not had a proper meal for several days, every penny he earned being immediately despatched to the old people in Mayo. These side-lights on the Irish labourer in Great Britain make one wish that an industry

and a self-sacrificing spirit of such a kind could find their opportunities on Irish soil." Certain it is that the Irish workman seems to do better anywhere than at home, exhibiting as a colonist or migrant qualities that are certainly not the usual characteristics of the nation. The development is often to be ascribed to physical benefits consequent on an improved climate and better food and clothing; but though these conditions may affect settled emigrants, they can have no influence on new-comers, who frequently, as in the case above mentioned, pass through a time of much privation.

"LES ROUTES FRUITIÈRES."—Par CHARLES BALTET, Horticulteur à Troyes (Paris: Librairie Agricole de la Maison Rustique, 26, Rue Jacob). M. BALTET here gives us a reprint from the *Journal d'Agriculture Pratique*, which we commend to the notice of all interested in fruit culture. He treats of the "but, origine, installation, produit, et choix des espèces à planter." The "but" is (translating freely), "to plant the borders of roads, streets, canals, and rivers, with fruit-trees; this is an act of humanity, foresight, and patriotism." We can but hope that the behaviour of the general public will justify this confidence if the scheme was universally adopted. "France includes more than 500,000 fruit-trees planted along her highways," and as these are appreciably and widely used, there seems every justification for adding yet further to the number.

THE SHASTA "DAISY."—This, like the Ox-eye "Daisy," from which it originated, is no true Daisy, but a variety raised by Mr. LUTHER BURBANK. The flower-heads, according to the figure, are 4 inches across, and of a glistening white. The plant is perennial, and is said to be the outcome of a cross between the American species with the European *C. Leucanthemum*. This was again crossed with the Japanese *C. nipponicum*, and rigid selection exercised till the present fine strain has been produced. Other varieties are promised in the future, some coloured, others "double."

THE SURVEYORS' INSTITUTION.—The next ordinary general meeting will be held in the Lecture Hall of the Institution, on Monday, February 10, when a discussion will take place on the papers read by Mr. A. DUDLEY CLARKE and Mr. G. S. MATHEWS, entitled "The Final Report of the Local Taxation Commission."

CAPE FRUIT.—The Castle Co.'s S.S. the *Kildonan Castle* has just brought home 406 packages of Plums, 34 of Apricots, 155 of Peaches, 1 of Nectarines, 6 of Pears, total 600 packages. The *Saxon* followed the above, bringing 744 packages of Plums, 52 of Apricots, and 259 of Peaches—in all, 1,055 packages of fruit.

MR. SHERWOOD.—One of the most pleasant features at the testimonial dinner to Mr. RICHARD DEAN was the announcement which was made by Mr. EDWARD SHERWOOD, to the effect that an improvement was manifest in the health of his father. Mr. SHERWOOD is so highly esteemed in horticultural circles that the news of his severe illness was felt as a personal matter, and the good news which his son was able to give was received with corresponding satisfaction.

THE DINNER TO MR. RICHARD DEAN.—Those who read our account of the presentation and dinner to Mr. RICHARD DEAN will feel no surprise at the enthusiastic nature of the proceedings. The narrative of his career of work during half a century is really astonishing. To it must be added what was only

slightly touched on at the meeting—his work as a journalist. How many reports of flower shows must he have written? How often have we had to avail ourselves of his services? In this connection we would specially allude to his review of horticulture and floriculture published at the time of our Jubilee, and also at the beginning of the century. No one had fuller knowledge of the subject, and no one could have treated it better from his point of view. We hope long to have the aid of our honoured friend.

THE NATIONAL SWEET PEA SOCIETY, at their Annual Meeting on the 28th ult., decided to hold its next exhibition on July 15 and 16, at the Royal Aquarium, Westminster.

BOOK SALES.—During Friday and Saturday last, Messrs. SOTHEY dispersed the libraries of the late Mr. W. MATHEWS and of the Rev. H. L. NELTHROPP, F.S.A. The MATHEWS collection included REICHENBACH'S *Icones Floræ*, 1850 to 1899, for £63 10s.; the *Alpine Journal*, 1863 to 1901, £29 10s.; COOK'S *British Fungi*, 1881 to 1891, £23; A. W. MOORE'S *The Alps in 1864*, £10 10s.; SOWERBY'S *British Botany*, 16 volumes, £33; and books like COLMAN'S *Scenes from the Snowfield*, 1859, for £6 10s.

THE BOTANICAL GARDENS, MANCHESTER.—The Royal Botanical and Horticultural Society of Manchester has again experienced ill-success. At the seventy-fourth annual meeting, recently held, the report stated that there had been a loss during 1901 of £639 18s. 4d., which increases the liabilities of the Society to £7,398 1s. 9d. Mr. W. FOGG, in supporting the resolution to adopt the report, said that for the last nine years there had been a continual loss, amounting in the aggregate, with allowing for one year's profit, to £739. He was prepared to suggest that the gardens should be handed over to the Corporation, under whose supervision the gardens would be much better carried on.

PINANGA KUHLLII, Blume.

[SUPPLEMENTARY ILLUSTRATION.]

THE Pinangas are Palms still too little valued by amateurs, but I cannot say what is the cause of this. They are rapid growers, forming strong plants attaining to a man's height in about four or five years; most of them form fine bushes by branching at the base, their leaves are charmingly varied as well as their general appearance, the sections often being by no means regular, as in their colour. In a short time they form a stem, and then they early begin to flower and to fruit. Their cultivation is without difficulty, if they have a regular temperature at the roots, and sufficient moisture. I have kept them for a long time in my room, with the pots embedded in moist sphagnum. This precaution enables many Palms to be cultivated indoors, which will not as a rule grow in the dry air of a living room. One of the hardiest species of Pinanga is *P. KuhlII*, Blume, a Palm 16 to 25 feet high, with annulate stems 2 inches in diameter, the younger nodes reddish. The fronds are terminal, have a long cylindrical base, a petiole 2 feet long, an elliptical pinatisect blade 4 feet long and 2½ feet broad, with sub-opposite segments, the lower ones 4 to 5 inches, the upper ones only 2 inches distant from each other; the uppermost 1 foot long, 2 inches broad at the apex, with bidentate teeth 4 to 5 inches long, 2 inches broad; the lateral segments falcate-lanceolate, 2 to 2½ inches broad, long acuminate, 1½ to 2½ feet long. This species is a native of the lower mountain woods of western Java. When the inflorescences appear beyond the leaves the

male flowers first develop, and after flowering fall off in a few days; then the female flowers appear. For pollination the male flowers must be collected and laid away in a dry place. For the photograph I am indebted to Prof. Treub of Buitenzorg, Udo Dummer, Gross Lichterfelde, Berlin.

PRESENTATION TO MR. RICHARD DEAN, V.M.H.

ABOUT fifty persons assembled at the Royal Aquarium, Westminster, on Tuesday evening last to entertain at dinner Mr. Richard Dean, and to present to him an illuminated address, accompanied with a cheque for £300. Mr. Dean attained his seventy-second birthday on the previous day.

Very much regret was expressed that Mr. N. N. Sherwood, who has been Treasurer to the Testimonial Fund, was prevented by illness from attending; and by further misfortune, Mr. W. Marshall, who was to have presided in Mr. Sherwood's absence, was also confined to his house by temporary indisposition. The senior Secretary to the Fund, Mr. M. Cuthbertson, of Rothsay, chief partner in the firm of Messrs. Dobbie & Co., in these circumstances discharged the duties of "The Chair" in excellent manner.

When the Royal toasts had been honoured, Mr. Cuthbertson in proposing that of Mr. Dean, said that it had been felt for some time that there should be some means taken to show an appreciation of the immense work Mr. Dean had done for horticulture during so many years. A few gentlemen, who should be nameless, agreed that a fitting opportunity for doing this was afforded by the fact that Mr. Dean was nearing the end of his seventy-second year. The chairman, being also joint secretary, had been particularly struck by the measure of spontaneity in the response, so many having subscribed who could only have known what was going on from the accounts in the horticultural papers. He referred to some of the principal work of Mr. Dean since the year 1857, and said that he was one of the founders of the Royal Gardeners' Orphan Fund, and remained upon its committee until the end of last year. Mr. Cuthbertson had known him for twenty years. He had been Mr. Dean's host, his guest, his equal (when judging florists' flowers at Wolverhampton and elsewhere), but never his superior. With a few further appropriate remarks, the chairman then made the presentation.

Mr. DEAN, in rising to respond, was for a minute quite overcome, but gaining mastery of his feelings, made a most interesting speech, which was practically the story of his life.

He was the son of a gardener, his father being foreman in a nursery near Southampton; but at thirteen years of age he was obliged to turn out and earn a living for himself. He was under-gardener to a gentleman who became Mayor of Southampton in 1859, when the under-gardener was made the Mayor's body-guard, and was brought into association with gentlemen and functions that stirred his imagination and inspired his ambition. In 1853 Dean entered the nursery of Charles Turner at Slough, earning 14s. a week. He was sent to various exhibitions with Turner's wonderful florist's flowers, and in many ways gained much experience. In 1857 he entered a large seed business in London, but it was not long before Mr. Turner informed Dean that a secretary was needed for the National Floricultural Society, in succession to John Edwards. Dean accepted this position. In 1858 the first great National Rose show was held, and he helped the present Dean of Rochester in the work on that occasion. In 1861 he joyfully received an invitation from Mr. Eyles to assist in judging at one of the great shows of the Royal Horticultural Society. In 1864, Mr. Dean succeeded John Edwards as secretary to the old Horticultural Club that met monthly at Anderson's Hotel, and where John Downie, William Paul, Dodds, Thomas Moore, and other well-remembered men gathered. In 1865, Dean went to Chester to take part in the business of F. A. Dickson & Co., but was not very comfortable there, and the late Dr. Hogg, hearing of this, invited him to return to London and become assistant-secretary to the great International Exhibition of May, 1866. At this marvellous exhibition there were 3½ acres of land covered over, and the total receipts amounted to £1618 4s. 7d. There were 110 judges. It was intended that the show should continue for four days, but at the end of that time it was found that the people of London were only awakening to the fact that a great international exhibition was taking place in their midst, and the exhibition was therefore maintained for five days longer. Financial disaster was thus averted, and as a result of that exhibition £1000 was given to the Gardeners' Royal Benevolent Institution, another sum was devoted to the purchase of the Lindley Library, and a considerable portion was spent in the preparation of a report of the proceedings, edited by Dr. Masters. The ground for the exhibition was laid out by a committee of Standish, Gibson, and Fortune, assisted by Mr. Eyles and others. At a dinner held at The Star and Garter, Richmond, sub-

sequent to the exhibition, there were twenty-one gentlemen present, all of whom had taken a conspicuous part in the work of the exhibition. After dinner the company was photographed, and of those twenty-one persons, only six are now alive, including Sir Daniel Cooper, Mr. Harry J. Veitch, Mr. W. Paul, Dr. M. T. Masters, Mr. W. Bull, and R. Dean.

In 1867 a series of provincial exhibitions was commenced by the Royal Horticultural Society, and Mr. Dean was engaged in some capacity or other at all of these excepting the last one, held at Preston, which he did not see. In 1870 and previously he was in Ireland, and visited many gardens on behalf of the *Irish Gardener*. He delivered a lecture upon spring flowers at the Rotunda, Dublin. Later he was associated with the late William Thomson in editing *The Gardener*, a Scottish horticultural journal. From 1873 to 1876 he had work in connection with City flower shows held in Finsbury Park, and with horticultural shows at Richmond. In 1889 the great fruit show was held in the Guildhall.

Mr. Dean was Secretary of two Hallsford Funds, one in 1876, when a storm visited North London, and £800 was obtained for relief purposes; and one in 1879, when a similar storm visited South London, and a sum of £750 was subscribed. He was Secretary also of the Postal Reform Union, a deputation from which waited upon the Rt. Hon. Wm. Monsell, Postmaster General, and which was instrumental in bringing about first the sample post, and next the parcel post, that is now so useful to the horticultural trade and others.

In 1890 Mr. Dean succeeded William Holmes as Secretary of the National Chrysanthemum Society, which position he still holds. In 1892 and 1893 Mr. Dean was employed in promoting a series of horticultural exhibitions at Earl's Court; and about the same time was engaged in carrying out exhibitions at the People's Palace in East London, and in giving horticultural lectures there. What has happened since that time, said Mr. Dean, was known to most of those present. He had done fifty years' honest horticultural work. He had been instrumental in connection with his brother Alexander in improving the Primula, and was among the first to get a break in P. Sieboldi. He had also done something with Potatoes, and in the way of improving the Viola. Mr. Dean said that he had attempted throughout to play the game of life fairly and squarely. He had doubtless made mistakes, but archbishops had done this also.

Mr. George Gordon, V.M.H., in proposing the toast of "Mr. N. Sherwood, Hon. Treasurer and Chairman of the Fund," referred feelingly to the cause of Mr. Sherwood's absence; and Mr. Ed. Sherwood replying, gave the welcome news that his father was much better, and that he had that day telephoned to his sons that he would have liked to have been present, but the doctor forbade.

Mr. T. Bevan proposed the toast of "The Testimonial Committee," and Mr. J. W. Wilkinson, responding, declared that he did not know which he most admired in Mr. Dean, his ability, his activity, or his audacity! "The Hon. Secretaries" was proposed by Mr. Robert Sydenham, and a response was made by Mr. H. J. Jones, who has shown extraordinary energy and tact in advancing the interests of the Testimonial. Mr. Jones read some amusing extracts from a large number of letters from gentlemen unable to be present. Mr. Owen Greening proposed "The Press" in a very felicitous speech, and it was responded to by Mr. C. H. Curtis, and Mr. R. Hooper Pearson.

ILLUMINATED ADDRESS.

The words upon the vellum were as follows:—"This address, with the accompanying purse containing £300, is presented to you on the occasion of your entering your seventy-third year, in grateful recognition of the many valuable services you have rendered to Horticulture during the past fifty years, and with the best wishes of all the subscribers." Then follow the names of the Secretaries, Treasurer, Committee, and of about 300 subscribers to the fund.

ENQUIRY.

A CORRESPONDENT, signing his communication "A. D. Berney," would be glad to be informed by some of our correspondents, acquainted with the railways of South Africa, what kinds of timber are used as sleepers on those lines.

PLANT PORTRAITS.

AZALEA INDICA MADAME EMMA ECKHAUTE.—Double rose-pink, edged with white. Described and figured by M. Charles Pynaert in the *Revue de l'Horticulture Belge* for February.

DELPHINIUM BICOLOR, Nuttall, *Meehans' Monthly*, January.

FICUS RADICANS VARIEGATA, *Revue de l'Horticulture Belge*, February.

LILAC HYBRID—Between *Syringa Bretschneideri* and *S. Josikoa*, raised by M. Henry in the Jardin des Plantes, *Revue Horticole*, January 16.

HÆMANTHUS IMPERIALIS.

A FINE flower-head of this handsome plant was shown by M. Linden, of Brussels, at the last meeting of the Royal Horticultural Society at the Drill Hall. The head of bloom was about 6 inches in diameter, poised on a stalk of about 15 inches in height, the colour being a pleasing shade of salmon-red. The flower-segments are longer (see fig. 33, p. 99), but more pointed than those of *H. mirabilis*, figured in *Gardeners' Chronicle*, May 25 last year, which had very superior flowers to the plant shown as *H. mirabilis* at the Drill Hall, with *H. imperialis*.

HOME CORRESPONDENCE.

NARCISSUS TAZETTA.—When in Boston, Mass., recently, I saw in Messrs. Farquhar's seed store an elegant mode of growing this pretty bulb. A shallow bowl was filled with pebbles about the size of a Hazel-nut, and a bulb was placed in the centre, and round the sides in thumb-pots were small plants of *Cyperus alternifolius*; the bowl was filled to the brim with water, and arranged in this manner the bowl formed a beautiful object in the conservatory at once. Another mode of making a bowl is to sow the top of the pebbles with seeds of Timothy-grass (*Phleum pratense*), and by the time the *Narcissus* is in bloom this will have formed quite a green carpet around it. *S. B. Dicks.*

CRINUM MOOREI AND C. POWELLI.—It may interest your correspondent "S. W. F." and others to know that these two majestic *Crinums* were produced over thirty years ago at Glasnevin Botanic Gardens by the late eminent Director, Dr. David Moore, and carefully developed under the care of his indoor foreman, Mr. Powell, to whom he dedicated one of the issues, known as *C. Powellii* ×. Both plants remained for many years in the border, stretching closely along the front of the long-glass-range, producing immense *Agapanthus*-like clumps, and displaying an unequalled stateliness of foliage and bloom unknown in the whole of the *Amaryllis* family. In some circular beds in the grass, not many yards distant, *Lilium giganteum* and *L. cordifolium* were to be seen growing in perfection; the former when in full bloom was usually 6 to 8 feet high. About 50 yards distant, and near the Director's house, stood the first Pampas Grass planted in the British Isles. By the way, Mr. John Orr, an eminent Scotch cryptogamic botanist and pupil of Sir W. Hooker, was then in charge of the fernery. He was over seventy years of age, and was highly esteemed by the late Dr. Moore as his valued aid in assisting in the study and discovery of many Irish mosses. *J. Murison.*

EARLY SNOWDROPS.—In a recent issue of the *Gardeners' Chronicle*, I note that the first Snowdrops were gathered at Ealing on January 21. Here the flowers have been gathered in quantity since January 16, and sent to my employer in London. Certainly, the Snowdrops here are not exposed to the north wind, but in many cases they are exposed on the south-east, where there is very little to protect them. Last year we were enabled to gather blossoms quite three weeks earlier. To-day, February 1, my son brought in a Daffodil bloom just starting to open. The Daffodils are well sheltered in all directions, being surrounded by large bushes of *Rhododendrons*. We are bounded on the south by the Solway Firth, which tempers the climate of the Isle. The Snowdrops cover some acres of ground, and about as much ground will soon be ablaze with Daffodils. *J. Jeffrey, The Gardens, St. Mary's Isle, Kirkcudbright.*

PEAS AND NITROGEN.—The editorial addendum to a recent paragraph on Peas and manures, because apparently so incomprehensible, seems to have proved a stumbling-block to some worthy and very practically-minded gardener-contributors, who are astounded to read that

"nitrogenous manure is not of any special value to Peas, if not actually injurious." Probably these readers have not followed closely scientific investigations, which have shown that members of the pulse tribe, or pod-bearing plants, have a capacity not common to other forms of plant-life, of being able to abstract from the air and to feed upon it, nitrogen, which constitutes so large an element in the atmosphere. It is found that Peas, for instance, possess this capacity just in proportion as the plant-roots have on them small swellings or nodules, and these small eruptions are present on the roots of all the Leguminosæ in greater or less quantity. Thus, the editorial observation is based on what is, without doubt, sound scientific facts, and is easily understood by those familiar with the

ties grown under absolutely similar conditions from which nitrogenous manures have been withheld. That serves to show that however apparently sound is the scientific theory, its weak feature is the fact that the free application of nitrogen as manure produces far better results. But then the question is, in what form for Peas, &c., is nitrogen as manure best supplied? I think ninety-nine out of every hundred growers would say, "In the form of good animal manure." I fear it is a case in which I can hardly be other than partial, as in all cases I have found that the effect on pulse of any application of good stable or other animal manure is to far exceed in growth and crop-production what can be obtained by the application of artificial manures even when those be liberally utilised.

LILY OF THE VALLEY.—I was very pleased to see one communication concerning the failure of the Lily of the Valley to flower satisfactorily, but at the same time your correspondent, writing under the signature "E.N., Chatham," does not give the cause of the failure, inasmuch as he says in the first place that the failure, by the description given, points to too much heat being employed, and then in the same breath he says, but he has others in Cocoa-nut fibre refuse, which did well. The cause of the trouble may be in the peat. He then gives a very good substitute for Cocoa-fibre refuse, which he says, with a steady temperature of 75°, gives no trouble. I may say that I never reach that temperature, preferring from 55° to 60°, which I find suits retarded Lily of the Valley admirably. I have noticed that whenever a question has been asked about retarded plants, it is very seldom there is much discussion on the subject, so that it makes one think that there are some secrets concerning the cultivation that those who grow them by the thousands do not wish to divulge for the benefit of others. I am sure a good article written and printed in these pages by one of the large growers who have shown us at different times what can be done with these retarded things, and the success they have gained, I am sure is not without experiments in the first instance, would not only be read with keen interest by us novices, but would give us heart to go in for these subjects more if we were sure we should not have all failures, and I also maintain it would open up the trade for them in not too busy a season of the year. *Midland.*

GAS-TAR AND CLAY DRESSING FOR VINES.—The above-named dressing seems to be much recommended as an antidote to mealy-bug on Grape-vines. No doubt it will destroy and check the pest, but at the same time it has a most curious effect on the Vines, and which I have no doubt has been observed by other practical gardeners, viz., that after the Vines have broken, and reached the tying-down stage, that the young shoots so dislike the tar that they grow themselves almost away from the parent stem; that tying down tar-dressed Vines is almost a fine art—so much so, that I should not like to give a young gardener the job; and for that reason I shall never use gas-tar dressing, after an experience some years since. Half a pint of Fir-tree oil to a gallon of clay puddle is safe, and equally effective, without the drawback of the tar effect at the time of tying down the Vine. Of course, whatever remedy is used, some of the insects will appear in the spring, and a sharp look-out should be kept, and as one of your correspondents observed, should be touched with methylated spirit; and all gardeners who are by circumstances compelled to make their vineries houses of general utility, stove, greenhouse, and vinery in turn, bug will continue to be a foe for a gardener to reckon with, in spite of all the remedies, ancient and modern. There is no remedy but cleanliness and hard work. If the common wren can find its way by broken pane or chink to any glass-house, it is very fond of the above noxious insects. *R. M., Newbury.*

SELECT VARIETIES OF SWEET PEAS.—That the selection of twenty-four varieties of Sweet Peas enumerated in the *Gardeners' Chronicle* of January 11 is fairly representative will be the opinion of many growers of this popular flower. Mr. Simpson evidently does not favour the striped varieties, but some of these are very attractive, notably Princess of Wales and America, the former striped mauve on a white ground, and the latter bright red striped, and very showy. In the dark maroon selfs, Black Knight would make an excellent companion to Othello, and has the merit of being exceptionally free flowering; Navy Blue will always hold its own amongst the dark blue varieties, of which Emily Eckford and Captain of the Blues are favourites. A distinct and beautiful variety which I have grown for two seasons is Captivation, a pleasing shade of magenta. Five of the

FIG. 33.—HEMANTHUS IMPERIALIS: FLOWERS SALMON-RED. (SEE P. 98.)

nodule theory. But gardening practice has shown, that so far from the application of nitrogenous manure to Peas, Beans, or others of the family being harmful, it is really beneficial. On the other hand, it does not seem yet to have been shown whether the free application of nitrogenous manures to the soil on which pod-bearing plants are grown, to some extent renders the natural abstraction of nitrogen from the air for the benefit of the crop inoperative, or partially so. Has anyone so far tested the nodule creation on roots of Pea plants that have from their inception been liberally fed with nitrogen as manure, as compared with the product on roots of plants that have not been so fed, and have had to obtain the essential nitrogen from the atmosphere? As a rule, it is found that Peas and Beans liberally fed with manure from the first produce the stoutest stems, the largest and most luxuriant leafage, and the finest as well as greatest abundance of pods, as compared with the plants and produce of the same varie-

Now, good animal manure contains free nitrogen in greater degree, probably, than it does either of phosphate or potash; yet when applied to ground on which pod-bearing crops are to be grown in the winter, there is no waste, and the nitrogen seems to be fully utilised. If that be so, why is it so commonly noticed that nitrate of soda, the favourite nitrogenous manure of the chemical compound apostles, is advised to be applied so late as after crops have made growth, lest it be washed out and wasted. If not wasted in the one case, why so in the other? No doubt, as experiments here and all over the kingdom have shown, that these chemical manures in dry seasons hardly become soluble, hence to a large extent, no doubt, their comparative ineffectiveness on crops. To test them fairly against animal manures, they want to be applied early in the year, and thus become thoroughly soluble. A. D. [The point is not whether nitrogenous manure is beneficial (we all know it is), but whether the benefit is proportionate to the expenditure. Ep.]

orange-pink varieties are given in Mr. Simpson's list, the best of these without doubt being Miss Willmott, probably the largest Sweet Pea yet raised, and grand in every way. All varieties of this particular colour are more or less scorched by the hot sun, and to present them in their true character it is advisable to shade them with some light material during the hottest part of the day. Amongst the so-called yellow Sweet Peas, the new Hon. Mrs. Kenyon is an advance, more in size, however, than in colour, made more apparent by its fine, erect standard. Blanche Burpee, the well-known white, also has this desirable feature, which doubtless accounts for its popularity over the later raised Sadie Burpee. Among rose-coloured varieties, Prince of Wales and Royal Rose are splendid, both being very vigorous growers, which frequently produce four flowers on a stem. Mrs. Dugdale, also of this shade, has a tendency to come streaky and splashed with a lighter colour. Light blue or lavender shades are well represented in Lady Grisel Hamilton and Countess of Radnor, still one of the best. No better pink could be grown than the variety called Lovely, worthy the name, although Mr. Robert Sydenham maintains that Prima Donna is slightly superior. The nearest approach to a scarlet is Prince Edward of York, a very desirable variety. In conclusion, I have proved the merits of the following dozen—Blanche Burpee, Black Knight, Lady Grisel Hamilton, Navy Blue, Miss Willmott, Prince of Wales, Captivation, Gorgeous, Lovely, Salopian, Prince Edward of York, Queen Victoria. T. H. B., Walthampton.

AN EARLY-HATCHED THRUSH.—On Wednesday, January 22, 1902, when out shooting pheasants, I found on the ground amongst the Ivy leaves a young fledged thrush, but not able to fly; it sat and opened its beak to be fed, just as it would in the nest. W. H. W., Belvoir Park, Belfast.

SALE OF HORTICULTURAL POISONS.—I am extremely pleased to gather from your columns of Feb. 1 that energetic steps are being taken to remedy the absurdity involved in the present regulation regarding the above. Taking the well-known XL-All fumigating materials as a popular example, I may cite my own case as illustrating the inconvenience and even damage involved. For years I had been in the habit of getting a supply from a well-known horticultural firm in London Wall, but on the last occasion when I went there, I was informed they were debarred from selling, and could give me no information as to how I could obtain it. Searching the advertising columns where it used to appear as obtainable anywhere, I found that even the advertisements were suspended; and finally, after some days' delay, during which my floral foes were getting well ahead, and laying their new season's eggs, which I aimed at preventing by their annihilation in time, I found the manufacturer's address, and made my way to Southwark. Even there, however, the ridiculous law blocked me, and all I could do was to get the address of a City chemist, who was apparently the sole agent. This involved another journey, which resulted in my getting what I wanted with a considerable expenditure of time and trouble, and a delay which led to the subsequent detriment of my plants by the advent of a fresh generation of foes. Furthermore the chemist naturally was absolutely devoid of practical experience as regarded the application of the remedy, while at my previous source of supply I had only to ask to obtain reliable advice, since the tradesmen were both nurserymen and salesmen. Hence I could not but feel that any such invasion of a qualified trade by an utterly unqualified one was not merely an anomaly, but a great wrong both to the rightful trade itself, and its legitimate customers, who very often required skilled advice as well as the materials with which to carry it out. What would the Pharmaceutical Society think if the horticultural trade claimed and obtained a monopoly of all vegetable ingredients, and the right to dis-

pense them without the ability to specify their particular uses and modes of application? Many garden plants, too, are very poisonous: Monkshood (*Aconitum*) to wit, has led to many deaths by being taken for Horseradish: far more fatalities have occurred in this way than can be laid to the charge of horticultural remedies. Why, then, does not the Pharmaceutical Society step in and claim the right of sale of all such plants, and keep a register to be signed by the purchasers? These suggestions are ridiculous on the face of them, but not more so than the unjustifiable attempt of one trade to draw a hard-and-fast frontier line which is clearly a long way within the boundaries of another, to the hindrance of business, and the detriment of the customer, to say nothing of the vested interests of the inventors and proprietors of extremely valuable articles, whose interests must have suffered severely by the trade being suspended for so long in mid-air, like Mahomet's coffin, while the nurserymen and pharmacutists fight out the battle. C. T. D.

MALCOLM DUNN MEMORIAL FUND.—I notice in your issue of 1st inst. a communication from Mr. J. Fulton on this matter. There has been considerable delay in issuing a report of this Fund, but as it would serve no good purpose to enter into the causes, I do not trouble you with them. I anticipate, however, that a report will be issued very shortly. P. Murray Thomson, Joint Secretary.

Obituary.

THE LATE MR. DAVID SYME, EDINBURGH.—The remains of Mr. David Syme, whose death was briefly announced in our last issue, were interred in Sighthill Cemetery, Glasgow, on Wednesday, Jan. 29. For over half a century, says the *Scotsman*, Mr. Syme was a prominent man in the seed trade. He began commercial life fifty-six years ago in Glasgow with the firm of J. & R. Thyne. After various changes he came to Edinburgh over forty years ago to undertake the management of the nurseries of Peter Lawson & Son, and when that firm was ultimately formed into a limited liability company he was appointed manager, and latterly managing director. During that long period he controlled the business, which is carried on in all parts of the United Kingdom and abroad, in an eminently satisfactory manner. He was a very genial man, and had friends in all parts of the country. Five or six years ago, when he completed his fiftieth year in the seed trade, a silver service was presented to him in London by representatives of seed firms in the United Kingdom, as well as abroad. When disputes arose between seed merchants in various parts of the country, Mr. Syme was frequently referred to to settle the matter. Mr. Syme was twice married, his second wife pre-deceasing him some years ago.

ED. AMOS PEAK.—We deeply regret having to record the removal by death, in his sixty-eighth year, on January 11, of the much-respected horticulturist, Edward Amos Peak, Parks' Superintendent to the Hull City Corporation for forty-two years.

Mr. Peak was born at Davenport, in Cheshire, in September, 1833, and before many years had elapsed he found himself in the gardens belonging to the late Earl Crewe, Crewe Hall, Cheshire. A few years later he was transferred to Brantinghamthorpe Gardens, in East Yorkshire, where he remained until an opening for him was found in the gardens at Hampton Court Palace. Here he remained, and finally acquired a good all-round experience as a practical gardener; but not feeling satisfied with that post, he secured an appointment under the late

Mr. Niven, the then Curator of the Hull Botanic Gardens, in Linneus Street. Shortly afterwards he was chosen to assist Mr. Niven in forming and laying out the now very beautiful Pearson Park. It was from this time, and until his death, that Mr. Peak proved himself to be the right man in the right place; whilst his botanical knowledge fitted him well for the position he was for so many years afterwards destined to fill.

For years Peak laboured assiduously in the hope that the great horticultural awakening would come, and his anticipations were realised in the formation, under his personal superintendence, of the extensive East and West Parks. He lived, not only to formulate and construct, but to foster and care for the great avenues of trees that line the streets of Hull. The extensive glass structures in the various Hull parks are crowded with evidences of Peak's ability as a plantsman; and the flower-beds are the admiration of all who have seen them.

At the many public functions in the city, Peak displayed marked decorative ability, and the fine Chrysanthemums, together with the artistic manner in which the groups were arranged for exhibition at the Hull Chrysanthemum Society's shows, earned for him general recognition as a decorative artist; but he was not allowed to enter into public competition. He did much planting at the crematorium, sanatorium, burial-grounds, and other public places. By his expressed wish, his body was taken to the crematorium to be consumed. To the trust reposed in him Mr. Peak was faithful to the end; and although a man of a retiring disposition, he was known to a very wide circle of horticultural friends. J. P. Leadbetter, Tranby Croft Gardens.

SOCIETIES.

ROYAL HORTICULTURAL. Scientific Committee.

JANUARY 24.

Present: H. J. Veitch, Esq., in the Chair, and Messrs Druery, Douglas, Holmes, Saunders, Shea, Michael, Bowles, Rev. W. Wilks, Drs. Müller, Cooke, and Masters.

Richardia corms and Cyclamens.—Mr. G. S. SAUNDERS reported on the corms sent to the last meeting: "The *Richardia* corms that I took away from the last meeting of the Scientific Committee are attacked by one of the 'bulb mites,' probably *Rhizoglyphus echinopus*; it is a very difficult pest to deal with. Water at a temperature of 115° Fahr. will kill them. I should add 4 oz. of sulphide of potassium to every quart of water, and allow the bulbs to remain in the mixture for ten minutes or a quarter of an hour. I do not imagine it would injure them in any way, the injury does not seem to have gone very far below the surface, so that it might be well to cut out the injured portion before putting them into the warm water. I should be very careful not to allow any of the earth in which these plants were grown to get upon the potting bench, or any uncontaminated soil.

"As to the *Cyclamens*, I must admit that I was unable to find any eel worms in the roots, but they are affected so exactly in the same manner as others in which I have found them, that I have no doubt but that the 'root-knot eel worm' (*Heterodera radicola*) is the cause. I cannot suggest any remedy, but to prevent the pest spreading the plants and the soil in which they are growing should be burnt, and on no account thrown on to a rubbish-heap, or any of the soil allowed to come in contact with non-infested soil."

Mrs. BATTEN POOL since the previous meeting sent specimens of the *Richardia* in growth to supplement the corms above alluded to. On examining the plants, the older roots were found to be decaying, but an attempt was made to form new roots. The appearances were thought by the Committee to be due to a check caused by cold.

Pteris serrulata.—A firm of nurserymen sent fronds partially destroyed by some insect supposed to be a black-fly. The condition is very common, but the

cause is not perfectly ascertained. The senders were requested to forward specimens of the fly for determination.

Pelargonium Leaves.—With reference to Dr. COOKE's report on these leaves, Mr. FRASER writes:—"I should like to say a word in reply to the suggestions made: (1) As to faulty cultivation. I can plead that I have been an amateur plantsman for over forty years, during fifteen of which, in my younger days, I, single-handed, grew stove and greenhouse plants for exhibition with good success. I always use the best materials I can buy for compost, and have never yet put a plant into a dirty pot. (2) The wash I used was sulphide of potassium and soft-soap, applied both by spraying and liberal ablution, and as fungus and sulphur do not agree, the former may have got the worst of it. (3) My greenhouse has the sun on it sixteen hours a day in the long days, and a fair share in the short ones. It is glazed with glass 16 inches wide, between rafters 1 inch thick, and the glass is washed when necessary, so the plants enjoy all the light it is possible to give them in London. We have had little fog so far. In all my experience I have never seen Pelargonium-leaves decay in the same way before, and to me the cause is still obscure. I now intend to try nitrate of soda, to induce leaf-growth, and later on will report the result."

Soil.—A sample of soil was sent by a firm of seedsmen, but the committee desired to see specimens of plants stated to be injured by it.

Chrysanthemum Rust.—Dr. COOKE made the following communication on this subject:—

"**Chrysanthemum and Cornflower Rust.**—Recently, when I reported to the committee upon these rusts, I applied a scientific name to the fungus doubtfully, and with a mental reservation that in each case they were the Uredo form of Puccinia Hieracii, and this was precisely what the book-makers led me to do.

"I am since informed that in spite of all the efforts and experiments of the heterocismists, they are unable to claim the Uredo of the Chrysanthemum as the Uredo form of Puccinia Hieracii, or of any other Puccinia, which I believed in my own heart all along. Nowadays we are not permitted to trust our eyes, but must have faith in experiments. Hence the poor Chrysanthemum rust is an orphan, or worse, even illegitimate, and must remain as Uredo Chrysanthemi.

"As to the other rust, it awaits the result of experiment; but I am more disposed to call it the Uredo of Puccinia Centauree, which has been united or mixed up with Puccinia Hieracii. I may be permitted to observe that no fewer than fourteen of the old species of Puccinia date before the Reformation! and I know not how many species of Uredo are all bundled together into the latter-day species called Puccinia Hieracii, amongst these being the Puccinia Centauree of Martius, and still nearer to our tramping Uredo, the Puccinia Cyani of Passerini. Let us hope that this also will find rest at last. I should recommend horticulturists to call it Uredo Centauree, and they will not be very far from the truth."

Bulbiform Seed of Crinum.—Mr. Drury showed on behalf of Mr. Roupell a fine example of this curious condition. The seed was of the size of a small Apple, green and fleshy.

Leaf Galls, &c.—Mr. E. M. Holmes brought specimens which will be reported on later.

Red Spot on Leaves of Imantophyllum.—Mr. Saunders brought specimens showing red spots. It was stated that these spots sometimes followed on the attacks of the bulb-mite, and that they were connected with the presence of a yeast fungus (Saccharomyces).

Fasciation in Valeriana arizonica.—"In March last," writes Mr. Worthington Smith, "I received by post from Dr. Masters a specimen of Valeriana arizonica for illustration. The example was received in a flat and semi-dried state, and it had previously been received also by post from Mr. Henkel of Darmstadt, so the specimen may be truly said to have passed through some vicissitudes before I received it. The illustration is printed in the *Gardeners' Chronicle* for March 30, 1901. I planted the damaged and cut root-stock in very poor earth in a pot, and placed it under glass without heat, with the result that the old root-stock has now produced two new growths, both twice the size of the original plant, with leaves twice the normal length, all the parts fasciated in a remarkable manner and with flowers from two to three months in advance of the parent. Fasciation is sometimes put down to over-rich living and comfortable surroundings, but in this instance it seems to have been brought about by serious difficulties."

Cucumber Leaves.—From Mrs. BATTEN POOL came

specimens with the familiar signs of the presence of red-spider.

Grub in Roots of Peony.—Mr. CANNINGTON LEY, of Farleigh, sent, through Mr. Bunyard, Peony-roots eaten by the larva of some moth, which was pronounced to be a Swift-moth, *Hepialus*.

Cypripedium insigne variety.—Mr. TRACY, Amyand Park Road, Twickenham, sent a specimen which may be described as a dwarf or stunted flower, in which all the parts of the flower are normal, but much reduced in size. The plant produced flowers of the same character last year also. No information was given as to whether the whole plant was dwarfed, or only the flower.

Cypripedium insigne variety.—In this specimen, from Mr. PARR, Trent Park, New Barnet, there were two flowers, the topmost flower expanding first, the second flower developing from the axil of the bract which was developed as a perfect leaf. The parts of the flower were normal. M. T. M.

LINNEAN.

JANUARY 16.—Prof. S. H. VINES, F.R.S., President, in the Chair.

Mr. ALFRED O. WALKER, F.L.S., exhibited some branches of Cherry affected with a fungus disease caused by *Gnomonia erythrostoma*, and made the following remarks:—"In the autumn of 1900 certain varieties of Cherry were noticed in Kent to retain their leaves in a withered state at the time of the normal leaf-fall. They were examined by Mr. G. Massee, and the fungus causing the mischief was ascertained to be *Gnomonia erythrostoma*, Auerswald. The Royal Agricultural Society investigated the evil, and recommended that all the affected leaves should be stripped off and burned, to avoid future mischief. Although few growers did this, the crop of 1901 was exceedingly good. The immunity of the Cherry orchards from the menaced calamity was ascribed by the exhibitor to the comparatively equable temperatures and the small rainfall of the latter year, whilst the outbreak in 1900 was attributed to the extreme low temperatures in May, following abnormally high temperatures in April.

Mr. J. E. HARTING, F.L.S., exhibited some heads of wild sheep, together with photographs and lantern-slides, to illustrate a recent suggestion by Dr. George Wherry, of Cambridge, as to the use and value of spiral horns in feral species.

Dr. WHERRY pointed out that while the horns were enormous, the ears were remarkably short, situated exactly in the axis of the spiral, and, as it were, at the apex of a hollow cone formed by the great spiral horn. This he regarded as a provision of Nature to enable the animal to hear better, and to determine the direction of sounds when there is a mist or fog.

Mr. HARTING pointed out that the remarkably large spiral horns were peculiar to the male sex, and that if they were to be regarded as of use for the preservation of the species, the ewes, which required the most protection, would be in that respect defenceless. This would be especially the case with *Ovis nivicola*, the sexes of which, according to Dr. Guillemard (*Voyage of the "Marchesa,"* vol. i., p. 214), lived apart in small herds for some portion of the year. It was a significant fact, also, that wild sheep, like other wild animals, posted sentries whilst feeding to prevent being surprised by their enemies, and it was the experience of those who hunted them that when approached, the alarm was generally given by a ewe.

Rev. J. GERARD quoted a letter received from his brother, Lieut.-Gen. Sir Montagu Gerard, H.M. Commissioner for delimitation of the Pamir boundary with Russia, to the effect that he had seen skeletons of *Ovis Poli* which showed that the horns of two big rams had become interlocked whilst fighting, and that both animals had perished from their inability to disengage themselves.

Messrs. H. and J. GROVES read a paper on "The Use of Linnean Specific Names." They showed that great diversity of practice existed in dealing with these names, and pointed out the necessity of arriving at some agreement as to their use as a first step towards uniformity in nomenclature.

A paper by Messrs. W. B. HEMSLEY, F.R.S., F.L.S., and H. H. W. PEARSON, M.A., F.L.S., was read, entitled "The Flora of Tibet or High Asia, being a consolidated account of the various Tibetan Botanical Collections in the Herbarium of the Royal Gardens, Kew."

THE HIGHGATE AND DISTRICT CHRYSANTHEMUM.

JANUARY 22.—The annual general meeting of this Society was held on the above date, the President, Mr. C. F. Cory-Wright, J.P., D.L., presiding, and was supported by a good attendance of members. The Treasurer (Mr. J. McKerchar) submitted the financial statement for 1901, which showed the Society in a solvent condition. The election of officers then took place, and resulted as follows:—President, the Rt. Hon. the Earl of Mansfield, proposed by Mr. Cory-Wright, who stated that Lord Mansfield had intimated his

intention of attending the Alexandra Palace on Oct. 29 to open the Society's exhibition, and preside at the annual dinner of the Society to be held there the same evening; he would also give £20 towards the prize fund.

JANUARY 30.—At a committee meeting held on the above date fifty-three new members were elected. The committee agreed to insert three classes, open to growers all over the country, to be called Special Coronation Classes, one to be for twelve vases of Japanese blooms, five blooms in each, prizes to consist of a silver cup, money, and medals; another to be for six vases of incurved blooms, five blooms in each; and the other, which is to be made a leading feature of the exhibition, that of a floral display of Chrysanthemums, which must include Japanese, incurved, reflexed, and Pompons, to be exhibited in pots or bottles, with Ferns, grasses and other foliage, in an oval space of 20 ft. by 14 ft. Prizes: 1st prize, £10 10s. and silver-gilt medal; 2nd, £7 7s. and silver medal; 3rd, £1 4s. and bronze medal; 4th, £2 2s. and bronze medal. Nothing in this exhibit to exceed 4 ft. in height.

CHISWICK GARDENERS' MUTUAL IMPROVEMENT.

JANUARY 23.—A very good attendance of members assembled on the above date to hear Mr. OSBORN, of Kew Gardens, read an interesting and instructive paper on "Ferns, their General Cultivation and known Genera." The paper was well thought out, and based on thorough practical experience, and traced Ferns from remote geological times, the introduction of exotic species by Tradescant in 1628, to those now in general cultivation. Suitable soils were noted, and special attention drawn to the fact that experience now shows that more light and less heat, with proper ventilation, suit this class of plants better than the closer, darker conditions prevalent a few decades since, when the subject was not so well understood.

Methods of reproduction noticed were by spores, division of root-stocks, rhizomes, and bulbils; and it was recommended that spores should be started as soon as dry after being gathered, for keeping generally proves unsatisfactory as regards subsequent germination.

After mentioning many interesting species worth cultivating of the various genera, a discussion was opened by Mr. M. T. Dawe, who divided his remarks into two heads, (1) botanical, (2) horticultural, and spoke for some length on both, and gave some interesting experiences of their cultivation. Messrs. Mallinson, Sillitoe, Ball, and Prince also spoke. Mr. T. Humphreys occupied the chair. C. H. Buck, Hon. Sec.

READING & DISTRICT GARDENERS' MUTUAL IMPROVEMENT.

JANUARY 27.—During the past month three meetings have been held in connection with the above association. The annual meeting took place on the above date, when the Report and Balance-sheet presented to the members proved that the Association during 1901 had experienced a flourishing year in regard to the attendance, the number of members, and also financially. The first ordinary meeting of the new year took place on the 27th, when Mr. E. Fry, gr., Greenlands, Reading, read a paper called "A Chat on the Kitchen Garden."

DEVON AND EXETER GARDENERS'.

"The Chrysanthemum as a Cottager's Plant" was the subject of a suggestive paper read before the Association by Mr. G. C. CHABUE, Prospect Park, Exeter, a well-known amateur member of the Association.

The essayist introduced his subject by saying that what he meant by treating the favourite autumn flower as a cottager's plant, was that as a class it required less care in its cultivation, less expense in growing, and which was so hardy that it could be grown to comparative perfection without the aid of glass or artificial protection. It was quite practicable to strike the cuttings in the open by placing some light, sandy soil in a sunny border, placing the framework of a grocer's box upon it, after having knocked the bottom out of the box, covering with loose squares of glass, and protecting with a bit of canvas or sacking of any kind.

The cuttings should be dibbled in about 3 inches apart. After about three days (?) the cuttings should have calloused, when light should gradually be given and in about three weeks give more and more air by removing the glass bit by bit, always taking care to exclude frost or excessive damp at night. A dusting of flowers-of-sulphur will keep away mildew, and a mulching of dung round the sides of the box will engender sufficient warmth. A southern, south-western, or south-eastern aspect is best, and one that is not overshadowed by a tall hedge, or anything of that nature.

A light soil is essential in raising the cuttings. When large enough to be put out, each plant, 4 feet apart, should have a little pit to itself, about 12 inches deep,

with 4 inches of broken crocks in the bottom. Oyster-shells would serve the same purpose. Place prepared compost on the top of them, and set your plants in that. A piece of wire netting 3 ft. 6 ins. wide, stood on end, cylinder fashion, makes a good support; and if sticks be preferred, let them be natural ones, with their bark on. Stopping should never be continued after Lady-day. (Several members demurred at this date, saying it was altogether too early, the consensus of opinion of the members present being that May was the better time to make the final stopping.)

Mr. Crabbe then dealt with feeding by liquid-manure, and the various remedies against insects. He recommended careful disbudding to get some of the flowers larger, especially picking off the crown bloom-bud as soon as it is fairly developed. When the plants have finished flowering, do not be in a hurry to cut down the old stems, but give a mulching of stable-manure or ashes, to induce the sending up of suckers for flowering the following year. The essayist then gave a selection of twenty-four sorts which he could recommend, giving their height and time of flowering.

A bunch of blooms, cut from the open ground near Exeter on January 29, was placed on the table by a member, the variety being Earl Canning. A. H.

NATIONAL CHRYSANTHEMUM.

(ANNUAL MEETING.)

FEBRUARY 3.—The annual General Meeting of this Society took place on Monday evening last, at Carr's Restaurant, Strand. The new President, Sir ALBERT K. ROLLITT, M.P., presided, and there were about eighty members present.

REPORT OF THE EXECUTIVE COMMITTEE.

Sir ALBERT ROLLITT in moving the adoption of the Report, associated himself with the sentiments of the opening paragraph, which expresses the Society's "deep sense of loss" through the death of Sir Edwin Saunders in March last. The report goes on to say that in memory of the late President, it has been decided to institute a Sir Edwin Saunders Memorial Gold Medal. The members are congratulated upon the quality of the exhibitions held in 1901, and are assured by the committee that "there are no indications that the Chrysanthemum has ceased to be in any degree a popular exhibition flower." During the past season the Floral Committee has awarded twenty-three First-class Certificates of Merit and four Awards of Merit to new varieties of Chrysanthemums, and the Classification Committee has continued its work of classifying doubtful varieties. The schedules of prizes have been modified a little, but no increase has been made in the sum of money offered. Reference is made to the annual outing of the Society, when a visit was made to the interesting garden of Mr. Alfred Tate, near Leatherhead, and incidentally to the gardens at Cherley Court. A contract has been made to hold the Society's exhibitions at the Royal Aquarium for the next three years. The present number of societies affiliated is 139, and the number of members 708. "The Society has had to experience during the past two years a somewhat serious loss of members, as also of affiliated societies." The report concludes with an expression of thanks to the donors of special prizes, including Sir Albert Rollitt, who has consented to continue the special 1st prize of £15 given by the late President in 1901. After Sir Albert Rollitt had referred to some of the items in the report, and to the services rendered by Mr. R. Dean, he formally moved that the report be adopted, and this was seconded by Mr. Thos. Bevan; and excepting an incident in respect to the privileges of delegates, which will be referred to presently, the report was accepted unanimously, and without discussion.

THE BALANCE SHEET.

The principal items in the receipts were annual subscriptions, £230 9s.; donations and special prizes, £127 9s. 6d.; from the Royal Aquarium Company, £375; rent of space, £31 3s. 6d.; affiliation fees, £58 5s. 6d.; and medals, &c., affiliated societies, £36 1s.—the total receipts were £1,111 5s. 2d. On the expenditure side, £497 was given in prizes, £56 13s. 3d. expended upon printing and stationery, £189 12s. 9d. upon medals and engraving, £69 18s. 6d. upon show expenses, £100 Secretary's salary, and £31 15s. 9d. upon postage and registration. There is a balance at the bank of £41 12s. 4d., and if this be subtracted from £87 7s. 4d. brought forward from the preceding year, a loss of over £40 during 1901 is shown. The balance-sheet was, however, accepted without discussion, if we except Mr. Bevan's question in respect to the carrying out of suggestions made by the auditors, one of which was that the Chairman of the Finance Committee should be required to sign all accounts.

ELECTION OF OFFICERS.

Sir Albert K. Rollitt, M.P., was unanimously elected President for the coming year; Mr. J. W. Moorman was re-elected Treasurer, Mr. Thos. Bevan Chairman of the Executive Committee, Mr. Witty Vice-Chairman, Mr. C. Harman Payne Foreign Corresponding Secretary, and Mr. R. Dean General Secretary. One of the Auditors, Mr. W. Seward, having served two years, has been succeeded by Mr. G. J. Ingram. From various reasons the following gentlemen have ceased to serve upon the Executive Committee: Messrs. C. Blick, W. Davey, E. Dove, C. Gibson, Geo. Cuthbert, W. Logan, T. G. Swales, and W. Owen. Eight of the retiring members were re-elected, and the following new ones: George Prickett, James Tyler, A. E. Stubbs, Geo. Little, C. H. Curtis, J. Jones, — Tapper, and — Hawes.

AMENDMENTS TO RULES.

Mr. Young, a delegate from an affiliated society, said that he had given notice to the General Secretary of an amendment to a rule governing the privileges of delegates, but it had not been put upon the Agenda. The Secretary explained that this was not done because he, the General Secretary, thought that delegates had not power to move such amendments. The President, however, after considering Rules IV., IX., and XIX., ruled that they have, and regretted that Mr. Young's intended amendment could not be proposed that evening because notice had not been given by the Secretary in the Agenda.

Mr. R. Dean moved that in Rule III.—

After "the management of the Society shall be vested in the Officers of the Society, viz., a President, Vice-Presidents, Treasurer, Chairman, and Vice-Chairman of the Executive Committee," add "General Secretary and;" also line 6 after "the President, Treasurer, Chairman, Vice-Chairman," add "General Secretary."

Mr. Dean, who described his position in the Society as equivalent to that of a "managing director," has evidently resented the deprivation three years ago of his privilege to vote upon the committees. He made an earnest appeal to the members to restore to him the privileges of a member, albeit he is paid a salary by the Society. The resolution was carried unanimously.

Mr. J. McKerchar then proposed, and Mr. J. T. Simpson seconded, that the following addition be made to Rule XIV., that:—"The officers of the Society and the elected members of the committee are disqualified for nomination or election as judges."

Mr. McKerchar was supported by Mr. W. Mease, Mr. Lake, Mr. Dean, and others, but was opposed by several speakers, most of them members of the committee. In the end, this desirable amendment was rejected by a majority of about two to one.

IRISH GARDENERS' ASSOCIATION.

ADDRESS BY THE PRESIDENT.

A MEETING of the members of the Irish Gardeners' Association and Benevolent Society was held on Jan. 28, 1902, in the N. L. Café, Grafton Street. Mr. F. W. BRUNNICE, M.A., President of the Association, occupied the chair, and there was a large attendance.

The Chairman, in the course of an interesting address, referred to the condition of gardeners generally, and contrasted the difference between gardeners who were employed close to large cities, and those who resided in the country districts. Passing on to speak of the different classes of employers, he said the ideal employer was a gentleman or lady who knew something of gardening themselves. There were others who did not in the least know what they wanted, but were determined to have it. They were uncertain themselves, and worried their gardeners in many ways. No one garden could have everything of the finest and best. Then there was often a plurality of employers, and a gardener who got amongst people at cross-purposes required a good deal of balance and backbone, and a good temper to boot. Some gardeners that he knew did their duty under irritating conditions of this kind so well, that they were really worthy of promotion into the diplomatic service of their country. The fact was, that many gardeners showed quite as much tact and ability in managing discordant people as they did in the culture of good fruit and flowers (applause). He was a great admirer and sympathiser with the present and the future lady gardener, but he pitied them when he looked round and saw what multifarious duties many "mere men" gardeners had to perform. Managing a garden and the things it contained was often a mere fraction of what the so-called gardener had to do. He was often a bailiff, at times a forester, had to keep an eye on the river and deter poachers from lifting the salmon; he must be a cattle doctor, and an engineer at times, levelling, drawing, taking out quantities, and calculating the cost of work. He (the Chairman) knew at least two most able gardeners near Dublin, who not only managed good gardens and the home farms, but also ran the electric light plant. So the lady gardener would have to learn a good deal more than mere garden craft, or work amongst the flowers, if she were to

succeed, for a gardener's work was practically unlimited. A gardener had to learn many things, but of all things he should know something of logic, or the science of clear and accurate thought. He especially recommended to the rising race of young gardeners the study of Prof. Jevon's *Primer of Logic*, and his companion volume on *Political Economy*, both of which were invaluable to a young man. To these should be added Mr. John Wright's *Primer of Horticulture*, which dealt with the first principles of gardening in a clear and efficient manner. Every gardener should also learn to draw anything to scale, and to make a sketch of anything he wished to remember. To be able to show things by means of a rough sketch or by a working drawing was often a great gain. Every gardener should have some speciality of his own. He should take up some plant, or group of plants, something preferably not attempted before, and try to improve it either for food, or for that delightful mental food called beauty. He should select, cross fertilise, or hybridise it, and so do his best to improve it in every possible way. Look what Burpee and Eckford had done for the Sweet Pea, or Engleheart and others for the Narcissus, and Laxton, father and son, for the culinary Pea and for the Strawberry. To come nearer home, let them look at what Mr. Campbell, of St. Ann's had done for the Chinese Primrose, the Japanese Anemone, the Persian Cyclamen, or the Carnation. Only want something, then work for it, and in the end they would gain their heart's desire. The successful gardener, like the successful doctor, was he who was best able to apply to his own business the discoveries that were being made by the great army of accurate observers, who were labouring on his behalf. The only secret in successful gardening was close observation and practical experience. Some gardeners spent the greater part of their lifetime out of a place, while others were rarely out of a situation. He would suggest that a registry for duly accredited gardeners should be kept and worked by the Association for all men who were well recommended, but especially, of course, for their own members. The organisation and registration of labour was especially necessary for gardeners, as so many of them were isolated. He did not propose anything like a trades union, but merely a central combination and a system of co-operation for their mutual good (applause). It would well repay the gardeners of Ireland to combine and join this Association, and subscribe sufficient to pay a registration secretary, who would devote his time and ability to look after their best interests in every possible way. But, after all was said and done, the gardener had really much to be thankful for. Every good gardener took a great and just pride in his work, and in most cases he ought to feel grateful that his work was carried on in pleasant places, and amid healthy and beautiful surroundings. His work was his very own, and he was right to feel proud of it. Now that they had an Agricultural and Technical Department in Ireland, he hoped that amongst other things, it would do much to avoid too much centralisation of industries in towns, and to revive local and village industries, and that the old-time emulation in good work would be re-established on or in connection with the land in this country. The revival of village industries and the cheapening of railway and other transit charges for raw materials and finished products might, he believed, not only relieve the congestion of half or totally unemployed labourers in towns, but it would restrict the exodus from this beautiful and fertile land of the best and strongest of their population, who at present became downhearted, and left them in desperation for the United States of America, or for other and often far less hospitable and kindly shores.

Afterwards a lecture on "Nitrate in the Garden" was delivered by Mr. John Simpson. The lecture, which was illustrated by a number of limelight views described in detail the results of the experiments carried out by the Permanent Nitrate Committee, and the lecturer claimed that in nitrate of soda, science had provided the gardener with nitrogen in the exact form adapted to the wants of the plant, whether in the orchard, the kitchen garden, the flower-bed, or the greenhouse. *The Daily Express, Dublin, January 29, 1902.*

CHESTER PAXTON.

CHESHIRE ORCHARDS.

THIS was the subject dealt with at the usual fortnightly meeting of the Paxton Society, held on Saturday last, under the chairmanship of Mr. Robt. Wakefield. Mr. John Taylor, of Hoole, gave a carefully prepared paper, and afforded some valuable hints, the outcome of long experience and careful observation. Mr. Taylor assured his audience that the County of Chester was as capable of producing good fruit as any other part of England; and this statement was fully borne out by the excellent examples of local-grown Apples and Pears exhibited at the meeting. An animated discussion followed the reading of the paper, in which the President (Mr. John Weaver) and others took part.

PUBLICATIONS RECEIVED.—*Journal of the Department of Agriculture of Western Australia*. December, 1901. Includes: Talks on Manures, Prevalent Blights, Red-Pear Mite, Importation of Indian Oranges, Lime and its Application to the Soil, &c.,—*Santa Barbara*, by C. A. Moody (illustrated). Reprinted from November, 1901, "Land of Sunshine," Los Angeles, Cal.—From the University of California. College of Agriculture, Agricultural Experiment Station. E. W. Hilgard, Director: Bulletins No. 131, *Phylloxera of the Vine*, by F. T. Bioletti; No. 133, *Tolerance of Alkali by various Cultures*, by R. H. Loughridge; No. 134, *Report on Condition of Vineyards in Portions of Santa Clara Valley*, by F. T. Bioletti and E. H. Twight; No. 135, *The Potato-worm in California*, by Warren T. Twight.—From the Blue Hill Nurseries, South Braintree, Mass., U.S.A.: *Price List of Hardy Herbaceous Perennials and Alpine Plants*, grown by Julius Hentlin.—*Hobbies Garden Guide*. 1902 (Dereham, Norfolk). A catalogue containing much useful information.—*Le Mots Scientifiques*. Janvier (Librairie J. B. Ballière et Fils, 19, Rue Hautefeuille, Paris.—*The Irish Gardener*, 11, Fleet Street, Dublin), January 11 and January 18.—*Annual Report on Government Gardens and Parks in Mysore*, for the year 1900—1901, with the Government Review thereon:—"Government have read Mr. Cameron's report with much interest, and are gratified at the increasing popularity and usefulness of the gardens under his charge. It is satisfactory to note that attention is being paid to the cultivation of *Paspalum dilatatum* (new fodder grass), Florida Velvet Bean, Rubber-trees, and other plants yielding useful products."

MARKETS.

COVENT GARDEN, FEBRUARY 6.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Thursday, by the kindness of several of the principal salesmen, who revise the list, and who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but often several times in one day. Ed.]

CUT FLOWERS, &c.—AVERAGE WHOLESALE PRICES.

| s.d. s.d. | s.d. s.d. |

SEEDS.

LONDON: February 5.—Messrs. John Shaw & Sons, Seed Merchants, of Great Maze Pond, Borough, London, S.E., report to-day's market thusly attended. There is now a fair seasonable all-round inquiry for field seeds. Choice samples of white Clover seed have become exceedingly scarce, and for these the late unprecedented rise is well sustained. Red seed is, however, rather quiet, and low, and even medium qualities are not readily placed. Full prices meantime are asked for Alsikes, Trefoils, and Rye-grasses. Lucerne and Timothy continue in short supply, and command high rates. There is this week no quotable variation in either Mustard, Rape, or Linseed. Tares are in improved request at currencies favourable to sellers. Bird seeds are just now neglected. For Peas, Haricots, and Lentils, the sale is small, at former figures. The low terms on which Scarlet and White Runners are now obtainable attract attention.

CORN.

AVERAGE PRICES of British Corn (per imperial qr.), for the week ending February 1, 1902, and for the corresponding period of 1901, together with the difference in the quotations. These figures are based on the Official Weekly Return:—

| Description. | 1901. | 1902. | Difference. |
|---------------|------------|------------|-------------|
| Wheat | s. d. 26 7 | s. d. 27 4 | + 0 9 |
| Barley | 25 7 | 26 7 | + 1 0 |
| Oats | 17 8 | 20 2 | + 2 6 |

FRUITS AND VEGETABLES.

GLASGOW, February 5.—The following are the averages of the prices during the past week:—Apples, Californian, 8s. 6d. to 1s. 6d. per case; Oregon, 12s. to 13s. 6d.; Nova Scotia Baldwins, 22s. to 24s. per barrel; Maine, 20s. to 24s. 6d.; Canadian, 23s. to 26s. 6d.; Oranges, Valencia, ordinary, 42s. 6d. to 4s. per box; do., large 42s. 6d. to 10s. 6d.; extra large do., 10s. 6d. to 12s. 6d. do.; large 74s. 6d. to 8s. 6d. do.; Jaffa, 12s. to 13s. 6d.; Grapes, 1s. to 2s. 6d. per lb.; Mushrooms, 1s. do.; Onions, Valencia, 5s. 9d. to 10s. per case; do., Globe do., 8s. 6d. do.; Dutch 6s. 6d. do.

LIVERPOOL: February 5.—*Wholesale Vegetable Market*.—Potatoes, per cwt.: Up-to-Date, 2s. 3d. to 2s. 9d.; Main Crop, 3s. to 4s.; Lynn Grays, 2s. to 2s. 6d.; Bruce, 2s. 3d. to 2s. 9d.; Turnips, 8d. to 1s. per 12 bunches; Swedes, 1s. 4d. to 1s. 6d. per cwt.; Carrots, 3s. to 4s. do.; Onions, foreign, 5s. 6d. to 6s. 6d. per cwt.; Cauliflowers, 1s. to 2s. 6d. per dozen; Cabbages, 8d. to 1s. 9d. do.; Celery, 8d. to 1s. 6d. do. *St. Johns*: Potatoes, 1s. to 1s. 2d. per peck; do., new, 6d. per lb.; Grapes, English, 2s. to 2s. 6d. per lb.; do., foreign, 1d. to 6d. do.; Apples, 2d. to 4d. per lb.; Tomatoes, 6d. do.; Asparagus, 1s. per bundle; Mushrooms, 1s. 4d. per lb. *Birkenhead*: Potatoes, 10d. to 1s. per peck; Grapes, English, 1s. 6d. to 3s. 6d. per lb.; do., foreign, 4d. to 8d. do.; Mushrooms, 1s. to 1s. 6d. per lb.

THE WEATHER.

Remarks.—The weather continued dull and very cold. There were heavy gales of wind from the north-east at the end of the week.

GENERAL OBSERVATIONS.

THE FOLLOWING SUMMARY RECORD of the weather throughout the British Islands, for the week ending Feb. 1, is furnished from the Meteorological Office:—

"The weather was unsettled during the early part of the week, with snow in the north, and cold rain, sleet, or snow elsewhere. Later on, however, the conditions improved greatly, and clear skies became general, and the air very dry and keen.

"The temperature was below the mean in all parts of the Kingdom; over England and Ireland the deficit ranged from 3° to 5°, and in the Channel Islands it was only 2°, but in Scotland it was unusually large, varying from 9° in the west to as much as 12° in the north. The highest of the maxima occurred during the earlier days of the week in the English and Irish districts, but towards its close in Scotland. They ranged from 51° in England, S., the Channel Islands; and Ireland, S., to 41° in Scotland, E. At several Scotch stations the daily maxima were sometimes below 32°, and at For. William on Thursday the thermometer did not exceed 22°. The absolute minima, which were mostly registered during the latter half of the week, were as low as 2° in Scotland, N. and E., and 15° in Scotland, W.; elsewhere they ranged from 16° in England, N.W., and 17° in England, N.E., to 20° in Ireland, N., 25° in England, E. and S., and to 32° in the Channel Islands.

"The rainfall was less than the mean in nearly all districts, but just equalled it in England, S.W., and slightly exceeded it in the Channel Islands.

"The bright sunshine was (after the first few days) very prevalent, and greatly exceeded the normal amount. The percentage of the possible duration ranged from 49 in England, E., 48 in England, S.W., and 47 in England, S., to 41 in the Midland Counties, 38 in Scotland, W., and 32 in Scotland, E."

THE WEATHER IN WEST HERTS.

A cold and sunny week, with searching northerly winds and some snow. On the coldest day the temperature in the screen at no time rose more than 1° above the freezing-point, but on the coldest night the exposed thermometer only registered 11° of frost. The ground at 2 feet deep is at the present time 2° colder, and at 1 foot deep 3° colder than is seasonable. On these days snow fell, and on the morning of the 4th the ground was covered to the depth of 3-inch. Throughout the evening of the 2nd, and also afterwards during the night, there occurred a fall of very fine sleet and rain, which froze on reaching the ground, thus causing a thin coating of ice to be formed upon it, and making the roads and pathways extremely slippery. This phenomenon, which is of comparatively rare occurrence, is known as a "glazed frost" or "silver thaw." There has been no measurable percolation through either of the soil gauges since the month began. On the first five days of the week the sun shone on an average for nearly five hours a day, but since then there has been no record of sunshine.

During the four days ending the 2nd, the mean velocity of the wind was 9 miles an hour, and the direction some point between north and east. Throughout the greater part of the week, the small amount of moisture in the air has been a noteworthy feature. Iris *Holstro* came first into flower on the 11th, which is a fortnight later than last year.

JANUARY.

This was a very warm January, and the fifth warm one in succession. At no time was there any exceptional heat or cold. The lowest reading indicated by the exposed thermometer was 17° of frost. Very little rain fell, indeed, less than one-third the average quantity for the month. Snow fell on two days, but on no occasion was there sufficient to cover the ground. The sun shone on an average for 1½ hours a day, which is a remarkably good record for January. The winds were, as a rule, high, and came principally from some westerly point of the compass. The atmosphere remained exceptionally dry, in fact, drier than in any January of which I have here any record.

THE RAINFALL FOR THE LAST FOUR MONTHS.

The total rainfall since the winter half of the drainage year began in October, comes short of the average for the same four months in the last forty-six years by 2½ inches, which is equivalent to a loss of over 12 gallons of rain-water on each square yard of surface in this district.—E. M., *Berkhamsted*, Feb. 4, 1902.

ANSWERS TO CORRESPONDENTS.

ADVERTISING FOR SITUATIONS IN GARDENING PAPERS IN CANADA AND U. S. A.: W. B. Had you read your *Gardeners' Chronicle* with due attention, your question would have been superfluous. See issue for Jan. 25 this year, p. 68.

AZALEA INDICA AND VIOLETS: J. W. B. The first have been infested by thrips, which have sucked the juices of the leaves, and caused their fall from the shoots; and the last were infested by red-spider whilst out-of-doors last year, with the result that the plants have been checked in growth, and they are not likely to flower satisfactorily. Azaleas should be frequently fumigated whilst under glass, and dipped in an insecticide once or twice whilst they remain out-of-doors in late summer and autumn, and occasionally be turned on their side and heavily syringed, more especially directing the water against the under-sides of the leaves. Violets should be placed in half-shady situations, the ground kept moist, and the under-sides of the foliage wetted frequently with an elbowed nozzle of a syringe.

CAMELLIA SCALE: H. R. M. *Aspidiotus Camelliae*. Remove by sponging and brushing with Gishurst Compound Soap used at the rate of 2 oz. to one gallon of water, spreading a cloth on the soil under the plants so as to capture all insects that may fall from the leaves, and putting them into the fire.

CAUSTIC SODA DRESSING: *Ignoramus*. This might do harm to vegetable crops growing beneath the trees.

CLUBBING IN BRASSICAS: W. W. The best cure is a total change of crop for at the least seven years, and dressings of lime and potash; the fungus *Plasmodiophora brassicae* is favoured by acids and checked by alkalis, and farmyard manures should not be applied, more especially if oxen have been fed on infected Turnips and Swedes.

CREOSOTED WOODEN STAGING: W. J. S. G. If your plants are certainly being injured by the fumes, you cannot do better than remove the staging, or leave the glasshouse unoccupied for a few months. Doubtless less injury will result to the plants when more air can be afforded than is possible at the winter season.

"DUST" ON CABBAGE-LEAVES, &c.: G. H. M. The spores of a fungus—*Puccinia* sps.

EMPLOYMENT IN KEW GARDENS: *Barnsley*. By making application to the Director, who will furnish you with a form to be filled up.

LABOURER'S NOTICE: E. R. No notice would be required if the man was engaged as a day labourer. The matter turns upon the terms of the engagement.

MAIDEN APPLE AND PLUM-TREES: N. T. P. The better method is not to cut back all of the lateral shoots on stems, but to leave four to six at full length, and remove the others entirely, leaving no snags. The few that are left for a year or two will strengthen the stems, and their removal will result in but few scars. At 6 feet, or a greater height if desired, the stems should be stopped, and half a dozen good shoots secured for forming the basis of a crown. The method of pruning differs if the bush form of tree is desired. The plants set out this season should be allowed to stand for the entire period till October unpruned, when the stems should be cut back to within 6 to 8 inches of the graft; and when they break in the spring following, the shoots should be reduced to four to six of the strongest. No other shoots should be allowed to form the first year.

MARKET TERMS: H. L. H. Per dozen bunches must be taken literally, although the number of roots in a bunch may differ considerably according to the kind of vegetable, root, &c. Seakale punnets measure 8 inches in diameter at the top, and 7½ inches at the bottom, and 2 inches deep. The number of Seakale heads going in a punnet will depend upon the size of the heads. A "tally" is not a measure of a weight, but of number, viz., 60.

MULBERRY-TREE FLOWERING BUT NOT FRUITING: M. H. If the site is low, and liable to be scourged by late frosts, this may account for the absence of fruit; or the plant being unisexual, with male and female catkins growing near each other in the axils of the leaves, may, in the case of your plant, be provided with flowers of one sex only. If these are of the female sex, the planting alongside of a fresh normal tree obtained from a nursery may effect a change.

MUSSEL SCALE ON APPLE-TREES: J. B. A very bad case. It would be well to cut away shoots infested to the degree of those received here. To destroy this scale when present in moderate quantities, follow the recommendation contained in our Hardy Fruit Garden article on p. 95 of present issue.

NAMES OF PLANTS: A Subscriber. *Cymbidium eburneum*.—J. F. A. *Cypripedium Sanderianum* has the reputation of being rather difficult to grow, but we have seen it luxuriating in a close warm house similar to a forcing-house, where an even temperature is ensured. The spotting might arise from a sudden fall in the temperature of the house. When your *Cypripedium Calypso* have finished their next growth, place them in a cooler and drier house for a few weeks, and probably it will induce them to flower.—A Reader. 1, A form of *Adiantum cuneatum*; 2, *Adiantum gracillimum*; 3, *Cyperus alternifolius*; 4, *Pteris cretica*.—*Frant*. 1, *Cypripedium venustum*; 2, *Cypripedium Spicerianum*; 3, *Cypripedium insignis*; 4, *Cypripedium nitens*.—*Heliotrope*. *Cymbidium eburneum*. Some varieties have no purple spots on the lip; yours is a showily spotted form.—H. S. S. *Lycaste cruenta*, and *Cypripedium* × *Ashburtoniae* variety.—F. B. 1, *Nephrolepis davallioides*; 2, *Pteris Adiantoides*; 3 and 7, forms of *Adiantum cuneatum*; 4, *Adiantum concinnum*; 5, *Adiantum hispidulum*; 6, *Adiantum tenerum*.—A. E. 1, *Quercus Ilex*, *Evergreen Oak*; 2, *Prunus lusitanica*, *Portugal Laurel*; 3, *Juniperus recurva*; 4, a Cedar, probably C. Libani; *Pinus silvestris*; 6, *Thuja occidentalis*. As some of the labels were detached, the numbers may in some cases be incorrect.

NITRATE OF SODA AND TARTARIC ACID MIXED: H. L. H. The action of these substances when mixed together on plants is unknown to us. Nitrate of soda is a well-known manure, employed largely when an increase

in the yield of fodder plants, grasses, &c., and leafage generally is desired. The ordinary dressing is from 3 to 5 cwt. per acre. Some crude tartaric acids contain salts of potassium.

NURSERY WORK AND ROUTINE: E. R. These are best learnt by taking service in good general nurseries for some years. It is a large subject; and it would be wise if you decided to what branch to devote yourself, indoors, fruit, or trees and shrubs.

PEARS AT THE TOP OF SOME TREES, SMALL AND DEFORMED: M. H. The trees being aged, may also be decrepit. Can you send specimens of the fruit?

RICHARDIA WITH DOUBLE SPATHE, ONE LEAFY: P. J. C. Not uncommon in very vigorous plants.

ROSES IN POTS FAILING WHEN FORCED: H. N. H. Roses will not force well unless well established in pots a year in advance. Roses received from a nursery in November, potted and pruned immediately, might flower unforced in early summer, but are not fit plants to force early, unless the entire ball of soil and roots is shifted with but little disturbance, beyond loosening a few of the outer roots. Dwarf-budded or grafted Roses should be buried so deep at the first or second potting as to bring the point of union under the soil.

SICK BOTHY MAN: *Enquirer*. The head gardener is not morally justified in stopping the under-gardener's pay, when, owing to illness, he cannot attend to his duties for one day; on the contrary, he would do well to obtain medical advice at the employer's expense, and make no deduction whatever, but this is a matter of humanity and good feeling.

TO SKELETONISE LEAVES: *Carnation*. Place the leaves in a pan of soft water, and leave them therein for a few days; then drain off the water, and replace it with fresh, containing a few drops of muriatic acid, and allow the leaves to remain in this for a few hours. Then try if the leaves are ready for skinning, and if so, take them out of the pan and place in a saucer, and gently rub off the pulp with a soft brush, to do which requires a good deal of patience and care. Then dry them, and put in the sun to bleach.

VINES IN A BAD STATE: A. L. The bad state of the Vines has been brought about during recent years by careless cultivation. Some parts of the borders received scarcely any water, others were deluged with strong manure-water. The rods were denuded of their bark to too great a depth, and then dressed with gas-tar (strength not given) and clay, innocent of harm if of the proper proportions. The general condition of the Vines being bad, you must set about their renovation, and that of the border forthwith; removing the apparently dead Vines, making an entirely new border of small width if new canes are planted, and of a suitable width if some of the old Vines are retained. All should be replanted. Let only good pasture loam be employed, mixing with it charcoal, lime-rubble, crushed bones, and Thomson's Vine Manure; the loam forming four-sixths of the whole. Make no use of farmyard or stable manure, and let the after-treatment be of a kind likely to maintain the soil in a healthy state for as long a period as possible. Pay great attention to the drainage of the borders.

INTERESTING RESEARCHES.

MR. CECIL WARBURTON, Zoologist to the Royal Agricultural Society, reports in the new volume of the Society's *Journal* the results of observations upon the Black Currant Gall-mite, carried out during the past year—by far the most complete and persistent of any hitherto attempted. In introducing them, Mr. Warburton remarks that, although the mite has been a recognised pest in England for more than thirty years [the first notice and figure were published in these columns in 1869, p. 841, by the late Professor Westwood, Ed.], and it is generally allowed that the first condition for the successful treatment of a pest is an accurate knowledge of its life-history, our acquaintance with the habits of this most destructive little creature has been very imperfect. The accounts of the few observers who have endeavoured to trace its life-history have differed in important points, and the method of its migration has been a mere matter of conjecture. It has followed that suggestions of treatment have been almost entirely empirical, and that different periods of the year have been named as those most suitable to the

application of dressings that may possibly prove effective. This unsatisfactory state of affairs, it is explained, was not due to a want of diligence upon the part of investigators, so much as to the difficulty of observing a mite only one-hundredth of an inch in length, and only a sixth or an eighth of that measurement in breadth. It is true that the mites within a bud can be seen by means of a good microscope; but when it comes to tracing their methods of migration, and keeping wandering individuals under observation for hours at a time, the difficulties are obviously very great.

On a former occasion Mr. Warburton published the results of some observations and experiments upon the mite, but they were chiefly of a negative character; and last year he determined to undertake the task in a thorough manner. As it was necessary to keep infested bushes under daily observation during the whole period of research, lest some important point should be missed, a second observer was almost a necessity, and the assistance of Miss Alice L. Embleton, B.Sc., was therefore obtained. With her help, the research was carried on without intermission from the middle of May throughout the summer and autumn.

From his earlier investigations Mr. Warburton found that there was no month in the year, with the possible exception of December, when the mature mites were not accompanied by eggs and young ones; and this tremendous fertility led him to the assumption that a large proportion of them perished annually without having time to do any damage. This assumption has now been fully confirmed. Some of the mites survive the winter in diseased buds, and as these are the parents of all subsequent broods, it was particularly desirable to observe what became of them. In this connection an important point comes into prominence. The mites are constrained to change their quarters by two causes. Buds that are only slightly infested are able to put out leaves, and the mites within them are then turned out to face the inclemency of an English spring. These are the mites that have been noticed wandering about Black Currant bushes early in the spring, and in Mr. Warburton's opinion, nearly all of them perish, because at that time no new buds have been formed, and he has not found any sheltered under the bark of a bush, or in the soil under it. Indeed, he has had mites on the ground under observation until they were dead. The conclusion is, then, that there is no need to apply dressings for the purpose of killing these early migrants, as they will be killed by the lack of food or the weather.

With respect to the other cause of the migration of mites, the case is entirely different. Where the infestation is sufficient to prevent the buds from developing leaves, the mites are provided with food and shelter until the buds have become withered and sapless, and before that time new buds for the next year's leafage have been partially developed. During February, March, and April the mites within the abortive buds multiply rapidly. About the middle of May some of the buds may be observed to be cracked, and mites can be seen on the out-sides of them. For three or four weeks after this, when the buds are gradually drying up and becoming unfit for habitation,

a constant migration of mites is taking place, and it was to this movement that the observations obviously needed to be chiefly directed.

Some curious and interesting results rewarded the assiduity of Mr. Warburton and his colleague when keeping these summer migrants under notice. Many of them were seen crawling about as quickly as four short legs near the head could drag a long and inert body. By desperate exertions, a mite can cover an inch in about ten minutes. This, it might be supposed, would be an ample rate of progress to enable a mite to travel from an old and withered bud to the nearest new and sappy one. It was found, however, that steady progress was seldom attempted, the crawling motion having been interrupted by curious performances. The mite possesses at the hinder end of its body a muscular disc, surmounted by two rather stiff and curved bristles. Upon such tail-discs mites were observed at frequent intervals to rear themselves, feebly waving their legs in the air, standing up, it is stated "like so many skittles."

At first these curious antics were puzzling, but experiments soon led to an explanation. It was found that mites, when in the upright attitude, if touched with a needle-point or a camel-hair brush, at once adhered to it, and let go their hold upon the Currant bud or stem. But, as Mr. Warburton remarks, it was obvious that needles and camel-hair brushes were not precisely the objects likely to present themselves to the mites in the ordinary course of Nature, and consequently not the objects of their rearing motion. Conjecturing that it was some insect, as a carrier, that was sought by the blind instinct of the mites, spiders, mites (other than the gall-mites), and ants were induced to run over the infested buds, while flying insects that had been seen to alight on the buds were caught and subjected to microscopical examination. Here we have the most important result of the research. In almost every case mites were found clinging to the hairs, legs, or bodies of the insects. "We can hardly doubt, therefore," Mr. Warburton remarks, "that this habit of rearing themselves upright, and waving their legs in the air, has been acquired for the definite purpose of obtaining the aid of passing insects in the accomplishment of journeys far beyond the reach of their own limited powers of locomotion."

But, a reader may object, the mites would do much better by crawling to the nearest new bud than by taking a precarious journey in the air. No doubt, if there are plenty of new buds on the bush. But it is to be borne in mind that there are few new buds on a bush half killed, and none on one entirely withered through the agency of the mites; also, that an infested bush seldom grows rapidly enough to provide food for a constantly and tremendously increasing number of mites. Hence the need of a better means of migration than that of crawling very slowly to the ground, along its surface, and up the stem of another bush, possibly distant, and not improbably sufficiently occupied by other mites. Here, however, we have one of the numerous examples of the apparent provision of Nature for the perpetuation and extension of the race, regardless of the fate of the individual. As any passing creature, Mr. Warburton observes, is seized indiscriminately, it is a mere accident

if the mite reaches a destination of the slightest use to it, and myriads that are borne away must be carried far from their food-plant, and perish of starvation. The latter part of this statement is probably true; but as the majority of insects that alight on Black Currant bushes may be supposed to do so for some special purpose, and to travel from one bush of the kind to another, it seems an exaggeration to say that it is a mere accident if a mite is carried to a desirable destination. Winged Currant aphides were observed to be particularly useful as carriers of the mites, which were found clinging to the antennae of many of them.

Another method of speedy locomotion on the part of mites was observed, that of projecting themselves endways from their standing position to a lower part of the bush or on to the ground. This they appear to do in desperation, after waiting vainly for a passing insect. But in this case again, the method of migration is precarious, as the mites which fall to the ground soon perish if they do not find a fresh bush and crawl up its stem. At least, the most careful observations failed to discover anything but more or less speedy death among mites on the ground. Hence, Mr. Warburton concludes, that there is no basis for the supposition that the ground under infested Black Currant bushes becomes contaminated with mites. This is comforting to growers who desire to make new plantations on the same ground as that occupied by old ones.

Another comforting piece of negative evidence is to be found in the failure of Mr. Warburton to find any mites under loose bark, in cracks on the stem, or on the roots of bushes. On the other hand, he observed mites wriggling their way into young buds, and he even found some attacking Red Currant bushes—which, however, are never seriously injured by mites.

Eggs were first found in young buds in the last week of June. After that time multiplication is very rapid. Mr. Warburton looked in vain for a second general migration, only rare cases of mites outside buds being discovered in the autumn.

If washing be tried, from the middle of May to the middle of June is the time to catch migrants; but that is just when the blossom might be injured, and, on the whole, washing is pronounced of doubtful value. Unfortunately, the only methods of checking the pest which Mr. Warburton at present can recommend are the old one of picking off the diseased buds in winter, and the removal of all wood bearing next year's buds, which, as he observes, would almost entirely destroy the crop of that season. It is to be hoped, however, that the last word upon the destruction of the Black Currant-mite has not yet been written. H. E. B.

NEW OR NOTEWORTHY PLANTS.

CRASSULA CONJUNCTA, N. E. BROWN
(N. SP.).

This species is nearly allied to *C. perforata*, Thunberg, and in the absence of flowers might be mistaken for that species, unless critically examined. The distinguishing points are as follows:—The leaves are always concave above, never flat or convex, nor recurved as they frequently are in *C. perforata*; they are of a rather lighter glaucous-green, and the ciliation on their margins is rather longer and

denser. The inflorescence is narrower and much more compact, the cymes of which it is composed having much shorter stalks, and the flowers are larger and pure white, not dull yellow as in *C. perforata*. The plant was sent to Kew by Professor MacOwan from South Africa in 1896, and is now in flower in the succulent-house at Kew.

Stems erect, often decumbent at the base, $1\frac{1}{2}$ lin. thick, somewhat woody in the lower part, glabrous, brown. Leaves $\frac{1}{4}$ to $\frac{3}{8}$ in. distant, fleshy, broadly connate-perfoliate, as if threaded on the stem, $\frac{1}{2}$ to $\frac{3}{4}$ in. long and as much in breadth, about 2 lin. thick, broadly ovate, shortly and somewhat obtusely pointed; very spreading but not recurved, slightly concave above, convex beneath, glabrous, rigidly ciliate with very short cartilaginous hairs, pale glaucous-green, tinted with red along the margins. Inflorescence a terminal thyrsus 2 to 3 inches long, $\frac{3}{4}$ inch in diameter, composed of six to eight (or more?) pairs of small, rather crowded, four to ten-flowered cymes. Bracts like very reduced leaves, 1 to 2 lin. long, $\frac{3}{4}$ to $1\frac{1}{2}$ lin. broad, connate, ovate, acute, erect, not ciliate. Peduncles of the cymes $1\frac{1}{2}$ to $1\frac{3}{4}$ lin. long, glabrous. Bracteoles like the bracts, but smaller. Pedicels $\frac{1}{2}$ to $\frac{3}{4}$ lin. long, glabrous. Sepals $\frac{1}{2}$ lin. long, ovate-lanceolate, acute, glabrous, not ciliate. Corolla $2\frac{1}{4}$ to $2\frac{1}{2}$ lin. in diameter, pure white; petals $1\frac{1}{2}$ lin. long, $\frac{3}{4}$ lin. broad, oblong, lanceolate, subacute, very shortly connate, and also adnate to the stamens at the base, spreading, recurved at the tips, glabrous. Stamens five, filaments $\frac{3}{4}$ lin. long, shortly adnate to the corolla at their base, gradually tapering upwards, glabrous, white; anthers $\frac{1}{2}$ lin. long, reddish. Hypogynous glands minute, about $\frac{1}{4}$ lin. long, quadrate, yellowish. Carpels five, about 1 lin. long, narrowly ovoid, tapering into a short style, pale yellowish-green, glabrous. N. E. Brown.

ANÆCTOCHILI.

I HAVE pleasure in sending you the following note about these gems of the vegetable kingdom—the most beautiful plants on earth, considered collectively—Anæctochili.

These small Orchids are found in both the eastern and western hemispheres, but the kinds or varieties which have the most lovely and richest leaf-colouring come from Java. Professor Treub told me a few years ago they do not grow so well in the forest under natural conditions as they do under cultivation at Utrecht.

Generally, these "jewels" are found difficult to keep alive; for some time they continue to put out two or three leaves, but soon become unhealthy and die off. Often and often I have sent a couple of healthy plants to my colleague, Mr. A. Fiet, Curator of the Botanic Garden at Groningen. For a few months they have been all right in the north of our damp country, but notwithstanding careful attention, sooner or later they died.

Three years ago, again I sent him two nice little plants, which arrived in perfect order. Perhaps he remembered on which side of the house they have a place at Utrecht, that is, on the north side. He gave his plants the same aspect at Groningen, and since then he has grown them just as well as I do.

We have, in one of our stoves, a small case on the north side, which is the home of our Anæctochili. Each plant is in a thumb-pot, filled with good peat and living sphagnum-moss, mixed with small broken pieces of charcoal and some sand. Twice a year, in March and October, they are repotted into clean pots, a work for which I use

my own hands and care. From most of them I take off young plants, an operation which every propagator understands, and keep the plants growing; when it is done they look so happy and so grateful. I am sure that if they could speak they would say, "You have done a good work; to be sure, we will make new growth and beautiful leaves." In summertime we give them plenty of water, but at this time of the year less, without letting them get quite dry. Whenever they show signs of flowering, we at once cut the bloom-spikes out, as soon as they can be got at.

Let me finish by telling your readers that everybody may have a look on these pearls except "Monsieur le Soleil," whose beams are not good for these lovely creatures. J. K. Budde, Utrecht.

COLONIAL NOTES.

FERNS IN QUEENSLAND.

WE have not many species of Ferns in the immediate neighbourhood, *Alsophila australis* is the finest. I have seen them 20 feet high, and with quite as much spread of fronds. Farther north *Angiopteris* and *Marrattia* grow very fine. Six months ago I had spores of twenty-six species sent me from England, and most of them have germinated, but several of them are British, so it is doubtful if they will live in this heat and dry air. Mr. Drury's articles in the *Gardeners' Chronicle* on Ferns are always very interesting to me, also the reports of the scientific committee. The last nine years of my life in England was spent as gardener and general manager with the late Sir W. Siemens at Tunbridge Wells, where I suggested to him the application of electric light to vegetation; it was soon put in practice, and Dr. Masters was one of the many visitors who came to see it. At Sir William's death I came out here. I was for ten years manager of the State Nursery here, but left it two years ago. The nursery was established for the purpose of collecting fruit-trees, &c., from all the tropical world, and testing their suitability for cultivation in Queensland. The chief crop is Sugar-cane, as it is really the only farm-crop grown, and great uneasiness prevails just now among the farmers and manufacturers with regard to the Kanaka Bill now before the Federal Parliament, for if it passes in its present form, and Polynesian labourers are done away with, then the Sugar industry will decline, for white men will not [or cannot] do field work in this climate. The Orange grows very well, but there is no market for it. The Mango is the king of fruits, but for that also there is no market, and tons rot on the ground. I feed my cows on Mangos, but that does not use up the crop. I have to read a paper on the life-history of the Fern at our next horticultural society's meeting, and shall draw largely on Mr. Drury's Fern lore. D. Buchanan, Kaliguil House, Mackay, Queensland.

IPOMŒA REPANDA, Jacq.

There are few prettier native climbing plants in Grenada than this *Ipomœa*. It is found in the parish of St. David's, where, among the trees and bush growth, the magenta-coloured flowers may be readily seen by persons passing along the main roads. The root of *I. repanda* is large, and not unlike some forms of Sweet Potato (*I. Batatas*), so extensively cultivated for food purposes. During many weeks now we have had it flowering on a wire support imported from England. The flowers are borne in large numbers. The leaves differ widely in their shape, some being simple, others three-lobed, others yet

again finely fingered, and between these are noticeable diverse and irregular cuttings. *Ipomoea repanda* is undoubtedly a desirable garden plant. That under cultivation in the Grenada Botanic Station was presented by Mrs. Branch on February 15, 1899, whose husband, by the way, the Rev. G. W. Branch, is a keen agriculturist, and a sympathetic gentleman in anything that tends to further and advance the interests of this Station and local agriculture generally.

LAGETTA LINTEARIA, Lam. (JAMAICA LACE BARK).

From the Botanical Gardens of Trinidad in 1898 we received a small plant of the West Indian Lace Bark-tree; subsequently it was planted out on Section N in the Botanic Station of this colony, where it has made fair progress. There are times of the year when the plant becomes divested of foliage, and then it appears as a bare, twiggy object; to-day—December 14, 1901—it is in full flower. Its height is 6 feet. The pure white and very fragrant inflorescences are a little like those of the Lily of the Valley, as seen produced upon this Lagetta. Of a delicate green colouring are the leaves when the tree breaks into blossom. We found difficulty in obtaining the species until Mr. J. H. Hart was good enough to send it from Trinidad. The lace-like inner bark is taken advantage of in some parts, and worked up into many kinds of fancy articles, doilies being among the number. W. E. Broadway, Grenada.

NEW GUINEA.

Mr. F. Manson Bailey, the colonial botanist of Queensland, publishes as reprints from the *Queensland Agricultural Journal* figures and descriptions of New Guinea plants, among which may be mentioned *Selaginella Palupalu*, a native name; *Cassia Bartonii*, and *Nepenthes Cholmondeleyi*. *Gomphocarpus brasiliensis*, an introduced plant to Queensland, is likely to be poisonous to stock. These and various other plants are described in the seventh and ninth volumes of the *Queensland Agricultural Journal*.

FLOWERS WHICH CHANGE COLOUR.

EVERYONE has heard of the blushing Rose. I need not therefore take up time with an account of such a well known phenomenon. There are other flowers of which it may be said that they are "born to blush unseen," except by those who are always on the alert for unconsidered trifles in the plant realm. And truly, when we come to study this curious tendency on the part of many of our native plants (as well as those of foreign lands) to change colour, the matter is full of wonder. What end can there be to gain, what result to achieve? Can the plant itself be benefited by the action, or is there some altruistic principle at work? We must try and discover the answer. The phenomenon is by no means so rare as one might suppose. Everyone who has noticed the *Celandine* of early spring will have observed how liable its petals are to get blanchet, and assume a washed-out appearance. When we come to think of it, we recall the fact that many garden flowers not only fade in the ordinary sense of the word, that is, droop and die, but they also fade as a carpet or ribbon will do when exposed to the sun, or as a dress material or wall paper are apt to do after having been for a while in use. It may be we have thought it was the same in both cases—that the flower, like the dress, had grown pale before the blanching sun. That may sometimes be the case, but we want to examine quite a different set of conditions.

Let us begin with a group of plants which contain some of the best known English flowers, and at the same time several of the most striking illustrations of colour change. I refer to that group which contains the Forget-me-Not, Bugloss, Borage, Comfrey, and Hound's-tongue. If you open any botanical work you will find a number of statements respecting these flowers, such as the following:—"The flowers are at first yellow, then blue;" or, "The blossoms are red on first opening, after which they change to bright blue or purple." You will also find that such names as *versicolor* (or that which changes colour), and *mutabilis* (i.e., mutable or changeable), are employed in connection with such plants, showing that when they were originally described and named by the botanical authorities, this peculiarity struck them as one of the most notable features. Thus we find one of the Forget-me-Nots (*Myosotis versicolor*) described as having flowers which are "concave, yellow, then dull blue;" or as another puts it, "at first pale yellow, afterwards blue. On plants inhabiting damp places, the flowers are at first white." Another has flowers which are pale pink in the bud, but very bright blue when expanded.

I was cycling the other day over the Sussex Downs, and came across an enormous quantity of the beautiful Viper's bugloss (*Echium vulgare*). The bulk of the flowers were of a rich blue colour, but among them it was easy to detect some which were decidedly red. You look up your botany, and find it recorded that the flowers are at first reddish, afterwards bright blue. I like to turn to that quaint old observer of Nature, Gerard, and see what he has to say about these things. He tells us that there is a kind of Viper's bugloss "that hath rough and hairy leaves; the stalk also is rough, charged full of little branches, which are laden on every side with divers small narrow leaves, among which leaves grow flowers, each of a sad blue or purple colour at the first, but when they are open they show to be of an azure colour, long and hollow, having certain small blue threads in the middle." And as I turn over the pages of his wonderful *Herbal*, I find under the Lungwort (*Pulmonaria*), or Cowslips of Jerusalem, this very accurate note: "Cowslips of Jerusalem, or the true and right Lungwort, both stalks a span long, bearing at the top many fine flowers, growing together in bunches like the flowers of Cowslips, saving that they be at the first red, or purple, and sometimes blue, and oftentimes all these colours at once." How little did old Gerard dream that in the days to come such facts as these would prove of surpassing interest, and throw a wonderful light on the problems relating to the cross-fertilisation of plants! Thus far, we have seen that flowers may be white, yellow, pink, red, or purple, and eventually change to blue. In each instance, up to the present, blue has been the last or highest colour. The flowers belonging to this group of plants, under normal conditions, never reverse the order. They do not begin with blue and end with pink, red, yellow, or white. Evidently, then, there is method and order in the variations, and the changes take place on a definite plan.

Before we enquire into the cause of this remarkable change, let us ask if it exists elsewhere in the plant world. It does, and to a very great extent, though the change is not always along the same line, or with the same colours. We find, for example, that some flowers only change colour when they are fading away, after having fulfilled all the duties of life, just as the blushing maiden may

change into the pallid or sorrow dame. Thus, we frequently find the White Hawthorn becoming pink, and I remember once in Cumberland observing with great surprise how a hedgerow which a week before had been one mass of snowy blossoms, was now quite of a ruddy hue. The Hawthorn had changed colour, and in so doing had progressed a stage from white to pink. Similarly, as every cottager knows, the modest little Virginia Stock, which on opening is of a yellowish tint, changes to pink, then progresses to a bright red colour, and finally appears as a mauve or blue flower.

I suppose few cultivated flowers show this peculiarity more strikingly than the Hydrangea. Several of the species are white in their early stages; but the one which flourishes best in our English borders, and grows with amazing profusion out-of-doors in Devonshire, starts life with pink blossoms; these change according to a regular law, gradually ascending from one colour stage to another until the series is complete. Those who are interested in the subject would find it alike pleasant and profitable to note down the changes.

Sometimes we see this law of change illustrated, not in a single flower, but by comparing the closely related species. For example, we have in England quite a number of wild Geraniums. Some of these have very small petals, and are fertilised by insignificant insects, or depend upon themselves for setting their seeds. The blossoms of these species are white, pink, light red, flesh-coloured, rising to blue and purple. As the flowers become larger, and cross-fertilisation is effected by the more advanced insects, such as bees, the colours become more intense; and so we proceed from rose colour to light-purple, purple, blue-purple, till we reach the dusky Geranium (*G. phaeum*), in which the blossoms are purplish-black—one of the deepest colours found in our flora. This parallel in a group of closely-related flowers, with the changes which take place in the Forget-me-Not, Lungwort, or Virginia Stock, is sufficiently curious to arouse attention and enquiry. The Mallows might be studied in the same way. One of these, a foreign plant, known as the Mutable Rose (*Hibiscus mutabilis*), resembles the Hydrangea in its colour-changes. It begins with white, then becomes flesh-coloured, and ends with being of a rich red hue. Our Sweet Peas often reveal similar changes. A *Sussex Naturalist*.

(To be continued.)

FLORISTS' FLOWERS.

PROPAGATING TREE CARNATIONS.

ALTHOUGH there is no definite time for taking cuttings, the months of February and March form the best season for striking cuttings of these plants, and cuttings struck then will make good plants for flowering the following winter. It is very important to get short-jointed side shoots for cuttings. These succeed best, and also branch out and make better plants than the long, thin growths. Success depends mainly on attending to small details. In the first place, care should be taken that the stock plants are free from insect pests, and that previous to taking cuttings they are fairly moist at the roots. I like to take the cuttings early in the morning, when they are fresh and stiff. They will then snap off at a joint and require no trimming at the base, and these always root better than if cut off. I usually cut the tips of the leaves off, and put twenty cuttings in a 5-inch pot, using loam, peat, and sand in equal parts, with a little

extra sand on the surface. The pots should be prepared beforehand, so that the cuttings can be put in as soon as taken off, or if anything should happen to delay, and they get withered, they should be put in water for a time. They root more quickly if they are kept quite close, with a good bottom-heat, and a surface warmth of 10° to 15° less. The frame should be opened every morning, but only left for a short time, for if once the cuttings get withered failure is sure to follow. They may be frequently sprinkled overhead, otherwise no water is needed. Provided the fine, thread-like fungus (which is the cause of what is called "damping") does not make its appearance, almost every cutting will root if reasonable care is taken, but a little neglect may result in losing a whole batch of cuttings. Nothing is more disastrous than letting them get withered, or exposing them too much before they have begun to make roots. To ensure short, sturdy plants, they must be removed from the close frame as soon as rooted, and gradually hardened off, by which time they will be ready for potting-off singly, which should always be done before the pots get too full of roots. *A. Hemsley.*

WINTER-FLOWERING CARNATIONS.

Having read Mr. Slade's excellent article on winter-flowering Carnations in the *Gardeners' Chronicle* of February 1, I must beg to differ with him concerning the variety Mrs. Leopold de Rothschild. Mr. Slade admits that it is a capital variety, but not a good bloomer in the winter. Having grown about 1,000 each year, since it was introduced, I do not hesitate to say that it is the very best variety I have yet seen for the above purpose. We strike the cuttings about the first week in February, and then as soon as they are fit, pot them off into thumbs, 60's being, I think, too big for the first potting; and finally shift them into a 72-size pot. But at what season the plants are to flower depends more upon the time the growths are stopped than anything else. The first stopping is done just as they are getting established into 4½-inch pots, or whatever size they are put into. That stopping is generally sufficient for most varieties, but Mrs. Leopold de Rothschild being such a quick and strong grower requires a second stopping about the first week in August if they are required to flower after November. By stopping the second time we get larger plants, and of course, a larger quantity of bloom. Willis' Manure is a capital stimulant, but I find soot-water and Clay's Fertiliser also good manures for them. I cultivate most of the varieties mentioned by Mr. Slade, viz., America, Glacier, Mrs. J. T. Brookes, Mrs. Lawson, &c.; but the Carnation has yet to be introduced that will compare with such a fine variety as Mrs. Leopold de Rothschild. *J. Jennings, Ascott Gardens.*

THE FOLIAGE OF ROSES.

THIS is a subject of some importance with reference to garden ornamentation; for there are many beautiful varieties of Roses which would be artistic in effect (especially when their growth begins on the confines of summer, and their tender buds appear), even though they did not produce thereafter a single flower. This is especially true of the Tea Roses, which have a delicacy of aspect, a gracefulness of manner—if I may so express it which their stronger brothers, the so-called Hybrid Perpetuals, do not equally possess; though it must be admitted by the impartial cultivator that they make ample amends for

this inferiority to their fairer sisters by their vigorous development, their massive foliage of a lustrous green, and the deep radiance of their flowers. But it may expressively be affirmed of the Hybrid Teas that, in this new race of pre-eminently beautiful Roses, the noblest attributes of the refined and graceful Teas, and of the stronger-growing Hybrid Perpetuals, are grandly combined. The finest foliaged Rose in my extensive collection of 180 distinct varieties is one which I find included in very few of the leading catalogues, I mean Madame Joseph Combet, which Mr. Wm. Paul includes among the Hybrid Perpetuals; mainly, I presume, because he does not devote a separate department to the Hybrid Teas. The foliage of this exceedingly strong-growing and even aspiring Rose is uniquely lovely, especially about the middle of June. At that leafy and luxurious period it is an object of great admiration to all beholders, growing as it does very conspicuously in the centre of my garden. Few, if any, of its contemporaries approach it in artistic effect; though one of its companions, Madame Lauretti Messimy, has also flower-shoots of marvellous hue. The latter is the finest of all the China Roses, whether as regards the production of graceful leaves or tenderly fragrant flowers.

Several of the Hybrid Perpetual Roses, while not so richly coloured, have very fine foliage, especially such varieties as A. K. Williams, whose opening shoots have a unique, characteristic, carmine shade, shining through the green; Madame Gabrielle Luizet, Crown Prince (whose virginal colours in early summer are notably fine), Cléo, Spenser, and Margaret Dickson. Of the Tea and Noisette Roses, some of the most impressive are Madame Pierre Cochet, which many rosarians regard as superior to William Allen Richardson, and whose foliage is quite as attractive as its deep orange flowers; L'Idéal, Catherine Mermet, Comtesse de Nadaillac, Safrano, Hon. Edith Gifford, Cleopatra, Sunrise, Enchantress, Bonquet d'Or, and Climbing Perle des Jardins. These, and many other kindred varieties that cannot here be enumerated or described, combine flowers of the noblest beauty with foliage of the loveliest artistic effect.

Many of the hybrid Tea Roses, whose splendid endowments I have already indicated, are equally effective, rivalling the Noisettes in their far-shining hues. Supreme among these are the invincible La France, which invariably generates magnificent shoots; Duchess of Albany, and Caroline Testout, which have similar characteristics; Papa Gentier, a rose of rare beauty; and Madame Pernet Ducher, two of the most precious of modern introductions; Marquis Litta, Clara Watson, a variety whose capabilities have been somewhat under estimated; Viscountess Folkestone, a supreme favourite with rosarians; Killarney, a charming semi-climbing Newtownards Rose; Gustave Regis, Marquis of Salisbury, and Mrs. W. J. Grant. All of those fragrant floral treasures of the garden are of great decorative value, not less for their distinctive foliage than for their odorous and luminous flowers.

When Wordsworth wrote, in a moment of inspiration:—

"It is my faith that every flower
Enjoys the air it breathes,"

he was expressing, consciously or otherwise, a scientific truth. For it is an unquestionable fact, that plants of every description breathe vitality through their leaves, and unless these are in a pure and health-giving condition they

do not realise the deep blessing of strong and vigorous existence. Life to them, under such conditions, can only be described as a living death. If, on the other hand, the leaves are fresh, and bright, and beautiful, unconscious of the influence of noxious insects, and other subtle enemies of vegetative life, they absolutely seem, as Wordsworth has told us, to enjoy their gracious activities, and rejoice in their strength.

While, therefore, the foliage of our fairest Roses is exquisite, it serves a higher purpose than this; it not only ministers to our instinct for beauty, but generates the healthful energy, and conserves the vital essence, so mysterious to us, and yet so realisable, of the life of those plants by which our natures live.

"Nature is but a name for an effect,
Whose cause is God."

David R. Williamson.

PEAS FOR SUCCESSION.

THE note I sent some time ago for publication in the *Gardeners' Chronicle* on the subject of Peas, brought some interesting communications which were published; and some persons asked why certain varieties were omitted, and others suggested different varieties. I agree with the remarks made by the several writers, but my note mostly concerned those varieties which I had found the most generally satisfactory. I intended to point out that diverse soils, methods of cultivation, and localities, account for great differences in Peas, and that which may succeed in one district or garden may fail in others. I indicated varieties that succeed in the cooler north, but failed at Syon. My present object in writing is to reply to the note (p. 33) from a correspondent, "C. B., Cambs.," and I gladly do as "C. B." suggests; and I would also thank Mr. H. W. Ward for his kind remarks concerning my note in the previous volume (p. 388). I try to get Peas for the table as early as possible, and employ glass protection at the start; but I am not sure that "C. B." can afford Peas this protection—still, it is one well worth trying, and which greatly aids early cropping. Briefly, it may be stated that there is great variety in Peas, and gardeners have their favourites. For first crop I sow early in December in 5-inch pots in good loamy soil, not too light, but porous, seven to ten seeds in a pot, thinning if necessary when the seedlings are large enough to handle, to about half the number, for nothing is gained by crowding the plants.

It may be asked why sow early in December? Because only cold frame treatment is adopted, and when the plants are well above the soil, air is admitted freely in suitable weather, and the plants are never coddled. I admit that Peas sown, say, six weeks later will, if sown in heat, be as large; but such Peas are less satisfactory than those grown in a cold frame from the start, the latter, if planted properly, not suffering. It is a waste of time to grow the plants for some time and then lose them. The east and north-east winds in March are trying for plants raised in heat, and if you do not plant out in March, pods cannot be gathered in May. My methods are very simple. The rows usually occupy a south border, which has a wall at the back or north side, and the soil is well enriched; the drills are made rather deep, and protection is given by sticking in branches of Yew or common Spruce, and the soil is made firm about the roots. The produce of these rows will be ready in the last week in May or first

week in June, according to the sort of weather that has prevailed. I need scarcely add that I am not wedded to the pot cultivation of Peas, and other means may be adopted in raising the plants, viz., sowing on strips of turf, in boxes or drain tiles; the 5-inch pot is handy, but the roots are much cramped in it. I have sown Peas in larger pots, and to the number of eight to ten seeds in a pot, and have been obliged to cover the plants when in bloom on frosty nights.

I now come to the important point, viz., the varieties to sow, and there is a fine choice. In pots I sow three varieties, Chelsea Gem, Gradus, and Daisy. The first-named is the earliest; the others give larger pods; and though these are 3-feet Peas, if staked in pots they rarely exceed 2 feet, and if they show any inclination to run higher, the bine is stopped at 2 feet. My earliest Peas in the open are Bountiful, Early Giant, and May Queen. I place Bountiful first on account of its hardiness, as it may be sown earlier than the others, and it has grand cropping qualities. The seed is sown as early in February as the ground can be worked; indeed, in the light soil at Sion I have sown in January, and the crop has been ready from June 10 to 20. This sowing succeeds the pot plants, and is also grown on a sheltered border; and as regards gathering, the seasons vary, so that I have given a good margin, though we have had pods earlier than the dates given. The next sowing is made in a less warm situation, and the same varieties are sown about the middle of the present month, the crop turning-in a little later than the last-named. For this sowing, the grower will find such varieties as Strata-gem, Acme, Excelsior, and Thomas Laxton—all splendid croppers—the best to sow. Acme is a new Pea, similar to, but larger than Chelsea Gem. From the middle of February sowings are made at tri-weekly intervals, and in the open quarter; and for March sowings I prefer Duke of Albany, a fine variety, whose failing is that it turns in quickly, and nearly all at once. Others well worth "C. B.'s" notice are Main Crop (Veitch), Telephone, Alderman, Criterion (Veitch), and Eureka. Any of these varieties, sown in April and May, will be reliable, and give the July and August supply.

Now comes the more critical season for Peas, viz., September and October. Indeed, on thin or gravelly soils the plants at times fail in August, and where this is the case I would advise sowing in trenches, using a liberal amount of decayed manure, and sowing thinly. Indeed, this latter advice is applicable to all sowings from the middle of March, as many failures occur when the seedlings crowd each other.

For late April and May sowings, any of the Ne Plus Ultra type may be sown. One of our best early autumn Peas is undoubtedly Veitch's Autoerat of Ne Plus Ultra type, which if sown in May and early June affords a grand crop if the soil is made good. Goldfinder is another splendid variety; and one your correspondent named Chelsonian, a very fine Pea of the Ne Plus Ultra type, as are Windsor Castle, Prodigy, Carter's Michaelmas, Sutton's Late Queen, and Latest-of-All, as autumn Peas. When these varieties fail, I have sown the first early Peas for October crops, but they need much attention in the matter of moisture at the roots, and it is well to sow them in a cool border in rich soil, and take means to keep down thrips and avert mildew attacks. Many of the tall varieties I have noticed above, I have found not to suffer from mildew late in the year. G. Wythes.

CROSSING AMONG CABBAGES.

WE extract from the columns of the *Standard* the following account of some experiments made under the direction of Mr. Arthur Sutton, which abundantly confirm the opinions generally held as to the facility of intercrossing among the members of the genus *Brassica*, and the imperative necessity of growing particular stocks apart from their near allies:—

"About two years ago Mr. Sutton was surprised to see in a public print statements by an agricultural authority who had had some experience in seed-growing, to the effect that all the trouble he had taken to isolate various cruciferous seed crops in the past was probably unnecessary, because it now appeared that they would not cross-fertilise naturally. Apparently, he based this conclusion upon the statements of some experimenters in artificial crossing, to which he was referring. Mr. Sutton knew that cruciferous plants would be particularly liable to cross, and to spoil each other, if the care thus pronounced unnecessary ceased to be taken, and therefore he determined to carry out a demonstration, not to satisfy himself, but to prove to doubters that plants of the Cabbage tribe would cross naturally with the utmost freedom when grown for seed side by side. Accordingly, at the beginning of 1900, he planted in a seed-bed one plant each of dwarf green curled Kale, Brussels Sprouts, Broccoli, red variegated Kale, purple curled Kale, thousand-head Kale, Couve Tronchuda (or Portugal Cabbage), Giant Drumhead Cabbage, Sutton's Favourite Cabbage, dwarf Blood-red Cabbage, and Drumhead Savoy. The Broccoli, Drumhead Cabbage, Blood-red Cabbage, and Savoy plants were either killed by the winter or so much damaged that they did not mature any seed, although the Red Cabbage, at least, appears to have grown to the flowering stage. The seed of each of the other plants was saved separately, and carefully sown in the spring of 1901.

From the plants thus raised two transplantings were made, each of about forty plants. In one transplanting the plants were taken without any selection; while in the other as many diverse forms as could be picked out from the appearance of the leaves were chosen. The results, now that the plants are mature, are so remarkable that they could hardly be imagined by anyone who has not seen them. It is no exaggeration to say that the crossing among these several varieties of cruciferous plants, by natural agency, has been as profuse and intricate as it could have been rendered by the most ingenious human manipulation. The results of the interesting experiments are still to be seen in Messrs. Sutton's trial-grounds within a mile of Reading.

On one side of a path a specimen of each of the types of seed-bearing parent-plants is growing, and opposite to it there are four rows of plants produced from the seed of the similar plant subjected to the trial. As has been intimated, the demonstration is duplicated, one set of plots containing plants taken at random, and the other plants selected for variety in appearance when they were small seedlings. There is very little difference between the two sets of plots in degree of variation from the parent stocks, now that the plants are mature. The plants which appear to have exhibited the greatest potency in the infection of other varieties are Brussels Sprouts and red variegated and green Kale, possibly in part because they, or the first at least, were flowering and producing pollen for a longer time than the other plants. In the case of Brussels Sprouts, it is reasonable to suppose that the numerous flower-heads which they throw up would mature by instalments, just as the top and the stem sprouts do when they are grown for cooking. In less degree this might have been expected, also, in the case of Thousand-head Kale; but the inoculative potency of this variety has proved in the trial smaller than that of some other kinds, though greater than that of the Close-hearted Cabbage.

Among about forty plants grown from the seed of a dwarf green and curled Kale, taken at random, there is not one true to type. There are two purple Kales, several of a coarse type of Kale, not properly curled and partly of Brussels Sprouts character, and one semi-Cabbage. In the companion plot of selected plants from the same seed, there is one Kale nearly true to type, and seven are dwarf purple Kales, while one is like a Thousand-head, the rest being coarse green Kales.

In neither of the Brussels Sprouts plots is there a single plant with "buttons" on its stem, as there would be in one of true type. Instead, there are the most curious specimens of loose Sprouts—some quite purple, some variegated red, and some with Kale leaves; while one has a top and stem Sprouts showing the peculiar light green and white-veined foliage of the Couve Tronchuda. It is not impossible that this Sprouts-Couve cross, alone among all the "sports," may prove worth perpetuation as a fresh culinary acquisition. The variegated Sprouts present a pretty appearance, but are of no value for cooking.

The red variegated Kale plants in both their plots show more signs of Cabbage inoculation than any

others. In each plot there are four plants of distinct Cabbage character, half of them being red and half variegated. Other plants are bastard types of the Kale, some red variegated and some green, while five in the unselected plot are sufficiently true to type to pass. Several of the plants are of Brussels Sprouts character, with Kale leaves.

Among the progeny of the dwarf purple Kale there are several plants of curious foliage, almost like the leaves of Parsnips in shape, and apparently, the result of the crossing of thousand-head and purple Kale. Other Kales have very large leaves, while some have curiously twisted foliage, unlike that of any cultivated plant. There are five dwarf purple Kales in one plot and ten in the other, but only two are as densely curled as the seed-bearing parent stock, and nearly all are much deteriorated in colour.

There is not a single plant of true type in the unselected plot of thousand-head Kale. Several are obvious crosses between that stock and Brussels Sprouts, a few of which show markings of the red variegated Kale, while others are semi-Couve Tronchudas. In the selected plot there are five plants of nearly true type, four more like Couve Tronchuda, and one a thousand-head Couve, others being nondescript purple or green Kales of degenerate forms.

Four distinct Cabbages are to be found in the two Couve Tronchuda plots; other plants are apparently crosses between Couve and thousand-head Kale, or Couve and Brussels Sprouts; and there are several like Drumhead Kales, but heartless, as the Couve is. In the selected plot are to be seen four plants similar to the seed-bearing parent, but not true to type, while there are none as nearly true in the other plot.

Perhaps of all the seven plants which produced seed, the Cabbage has been least spoilt by exposure to chance crossing. There are six true to type in the two plots, with three semi-red Cabbages, but still the great majority of the plants are of mixed character. There is one distinct Cabbage-Couve cross, and another plant appears to be a combination of Cabbage and thousand-head Kale, besides which are to be found two Cabbage-headed Brussels Sprouts, and several Kales of coarse type, probably Cabbage-Kales. Perhaps the most curious plant in either of the Cabbage plots in one of combined Couve Tronchuda and Brussels Sprouts character, the Sprouts on the stem being stained by the red variegated Kale.

NOTICES OF BOOKS.

INSECT LIFE: *Souvenirs of a Naturalist*, J. H. Fabre, Docteur des Sciences. "That inimitable observer," Charles Darwin. Translated from the French by the author of *Mademoiselle Mori*. With a preface by David Sharp, M.A., F.R.S., and edited by F. Merrifield; with illustrations by M. Prendergast Parker. (London: Macmillan & Co., Ltd.; New York: The Macmillan Company.)

A NUMBER of hands seem to have worked in the formation of this book, but a second reading of the somewhat lengthy title-page renders clearer the amount of credit due to each. First, much sympathy is elicited for the patient naturalist who, with a minuteness suggestive of that of Alphonse Karr, entered into the study of insect life. We are introduced to the Scarabeus, and his near relation *Gymnopleuris pilularius*, a scavenger beetle, whose behaviour is watched and experimented upon with results much to the credit of the creature's nerve-power and physical capacity for work. Then we pass on to the *Cerceris*, a burrowing hymenopteron; the yellow-winged *Sphex*, and many another creature, and we almost seem to share our author's eagerness in studying these, not as mere "specimens," but as wonderful beings instinct with life, and with a mission in the world. Here is an extract relating to the *Ammophila*:—

"That a wasp should return to the nest and a bee to the hive does not surprise me; these are permanent abodes, and the ways back are known by long practice; but the *Ammophila*, who has to return after a long absence, has no aid from acquaintance with the locality. Her shaft is in a place which she visited yesterday, perhaps for the first time, and must find again to-day when quite beyond her bearings, and moreover when she is encumbered by heavy

prey. Yet this exploit of topographical memory is accomplished, and sometimes with a precision which left me amazed. The insect made straight for the burrow as if long used to every path in the neighbourhood; but at other times there would be long visitation and repeated researches. If the difficulty became serious, the prey, which is an embarrassing load in a hurried exploration, is laid in some obvious place on a tuft of Thyme or grass where it can be easily seen when wanted. Freed from this burden, the *Ammophila* resumes an active search. As she hunted about I have traced with a pencil the track made by her. The result was a labyrinth of lines . . . a maze, showing how perplexed and astray was the insect. The shaft found, and the stone (that sealed it) lifted, she must return to the prey, not without some uncertainty when comings and goings have been too many. Although it was left in a place obvious enough, the *Ammophila* often seems at a loss when the time comes to drag it home; at least, if there be a very long search for the burrow, one sees her suddenly stop and go back to the caterpillar, feel it and give it a little bite, as if to make sure that it is her very own game and property, hurrying back to seek for the burrow, but returning a second time if needful, or even a third, to visit her prey. I incline to think that these repeated visits are made to refresh her memory as to where she left it."

This extract shows the style of the translator, as well as that of M. Fabre.

As regards this accomplished Frenchman, we hear that it was from poverty that he rose to his position as naturalist and writer, originality and freshness being peculiar to his work. "His philosophical position," says Mr. Sharp in the preface, "may be briefly stated to be a determined refusal to recognise evolution as a definite idea. In this we may think him wrong; but it must be admitted that his views form a valuable antithesis to those of the many evolutionists who take the position that all that remains for the naturalist to do is to repeat the words Natural Selection and Variation, and declare that thereby we understand the Cosmos."

M. Fabre's dissent from Darwinism seems nevertheless founded, as with other opponents, on an imperfect understanding of certain branches of the theory.

In concluding this notice of a learned book, charmingly written, we must praise the illustrations for being so life-like. To sketch insects at work so as to get a good portrait and get some idea of environment, is always difficult.

BRITISH VEGETABLE GALLS.—An introduction to their study, by Edward T. Connold. (Hutchinson & Co.) Large 8vo, pp. 312; tabb. 130.

THE author of this handsome volume has broached a fascinating subject, and has accumulated a vast mass of information which will be most helpful to the student. The photographic reproductions are numerous and excellent. There are numerous appendices, and a good index. In succeeding chapters the author deals with the nature and appearances of galls, their collection, and method of preservation. As to classification, the author groups these productions under four headings, according as the insects or nematodes affect the roots, stems, leaves, or flowers. The creatures which are instrumental in producing these excrescences are fungi, nematode worms (eel-worms), some beetles, flies, aphides, moths, and wasps.

In view of the great interest of the subject, it would seem as if the life-history of the

creatures, especially of the gall-flies, was scarcely treated with sufficient fulness; but as we are promised a companion volume on the galls of the Oak, the wonderful history of the gall-flies may fitly be included in that volume. In the present volume most of the more conspicuous galls, except those of the Oak, are described, the name of the insect given, the manner and time of growth of the gall, and the time when the perfect insect emerges. We think it is unfortunate that the author has not consulted the volumes of the *Gardeners' Chronicle*, for he would have found several original descriptions and figures by Curtis, Westwood, and others, long antecedent in some cases to those he has quoted. Mr. Connold has done good service by collecting within the covers of one volume details scattered over many books and periodicals, and must assuredly excite interest in a subject of the highest interest.

The Week's Work.

THE HARDY FRUIT GARDEN.

By J. MAYNE, Gardener to the Hon. MARK ROLLE, Bicton, East Budleigh, Devonshire.

The Apricot.—Pruning and training, as in the case of the Peach, are usually undertaken in the present month, and as this season in Devonshire gardens the trees will soon be in flower, the necessary work should not be longer delayed. Providing the right kind of treatment was adopted last summer, pruning will scarcely be necessary. Avoid as much as possible the removal of large branches, unless these are dead, as no other stone fruit suffers so much from the use of the saw. Apricot trees are less liable to insect pests than other stone fruit out of doors, which is partly accounted for by the treatment afforded the trees during the summer; be this as it may, the trees at this place have had no insecticide or dressing applied for eleven years, nor has the crop of fruit ever failed. Whilst encouraging the formation of fruit spurs, as it is from these that most of the fruit is obtained, it should be the gardener's aim to keep these as short as practicable, in order that they may receive the benefit of sunheat; do not crowd the spurs or shoots over-much. Well ripened last year's shoots should be laid in entire if not more than 18 inches long, and if it is necessary to shorten them let it be done just in front of a prominent wood-hud. The fruit on these shoots is much finer than on the spurs. In training, as with the Peach, endeavour to regulate the branches so as to equalise the flow of sap on either side of the tree. Good friable loam, with a fair amount of old plaster or lime rubbish incorporated in it if the soil is heavy, light loam receiving less. It is now late for transplanting, but I have carried out the operation when the flowers were on the eve of expanding, as also with the Peach, with excellent results, but I do not advocate late performance of such work.

Strawberries.—If new plantations are to be made in the spring, the land should be heavily manured and deeply dug, burying the manure between the first and second spits. Early in March, in suitable weather, set out the plants 12 inches apart, in rows at 2 feet asunder, making the soil about each plant firm, and mulching between them with strawy manure. A full crop cannot be expected till next year, when every other plant after fruiting should be removed. During the ensuing summer a row of Onions or Lettuces may be grown in alternate rows with the Strawberry plants. The period August and September is the most suitable for making new beds, as then, with strong plants, a fair crop may be reckoned upon the following summer. After giving both methods a trial, I prefer utilising the forced plants, setting out these in May and June 2 feet apart each way, getting a full crop the next season, and after the third crop has been taken, the plants are destroyed, and an equal number put out on a new piece of ground to take their place.

FRUITS UNDER GLASS.

By JAMES WHYTOCK, Gardener to the DUKE OF BUCKLEUCH, Dalkeith.

Vineries.—The Muscat and Gros Colman Vines should be got ready for starting, affording tepid water mixed with manure-water from the cow-house or other source, and then proceed to top-dress the border. If the roots are near the surface in large numbers, the merest scraping with a blunt instrument will suffice; and having removed thus much of the soil, sprinkle bone-meal and Vine-manure over it, and apply finely-chopped turfy-loam 2 inches thick, and on the top of all a mulch of short stable-dung. The cleansing of the house in the usual manner should follow. The night temperature should be 50° when the buds begin to swell, increasing it to 55° in mild weather. Strong fire-heat should be avoided, and lower temperatures rule in very cold weather. These Vines need a 10° higher mean temperature than others. Muscats when in flower to set them successfully need a mean of 73°.

Late Vineries.—Where Grapes are still hanging on the Vines these should now be cut with long pieces of the shoots and kept in bottles of water in the Grape-room. Take care that the bunches hang clear of the bottles and the rack, and that there is a bit of charcoal in each bottle. The Vines being cleared of Grapes may be pruned forthwith. Let all cuts be dressed with styptic, and proceed as with the earlier Vines, removing all loose bark, but not scraping the rods too much, washing them with soap and water, and if necessary, on account of thrips or bugs, painting them with a strong insecticide. Thoroughly cleanse wood-work, look to walls and pipes, and afford water to and top-dress inside borders. If the roots of late vines are not in good condition let the inside border be looked to at once, removing the soil, but carefully preserving the roots, covering them with damp mats. Ascertain the state of the drainage, making it good where faulty, and return the old soil to the extent of $\frac{3}{4}$, mixing with it $\frac{1}{2}$ -inch bones and bone-meal; the top of the border for 1 foot in depth should consist of turfy loam evenly chopped, and mixed with lime-rubbish, bone-meal, and Thomson's or other vine-manure, the whole being well compacted after spreading out the roots evenly—a mulch of horse-droppings may be placed over all. Outside and inside borders should not be disturbed the same year. Follow the same method with outside borders, choosing dry weather for the job, or it may not be successful.

Fig-house.—The Fig-trees in this house are exhibiting fruit and leaves, and the night temperature may be increased to 60°, with a rise of 10° by day, with a moist, growing atmosphere, syringing twice daily. If thrips are visible on the foliage, spray with XL-All insecticide. The roots of the Fig should be confined to a certain limited space; and if the soil is poor, afford frequent top-dressings of a quick-acting, artificial manure, washing in the same with tepid water, so as to encourage surface rooting, fine fruit, and foliage. Another Fig-house may be started, with a temperature of 50° at night and 60° by day, syringing the trees and damping down as the weather may render necessary.

Succession Peach-house.—If the trees are in flower or nearly so, little fire-heat will be needed in mild weather, and 55° in the daytime being enough with air admitted at the top of the house night and day. If the weather is dull and rainy, use fire-heat so as to increase the warmth 5°, or with sun-heat 15°. Use a camel's-hair pencil to distribute the pollen from trees on which it is plentiful to others upon which it is scarce. Damp down the paths, &c., occasionally. The pruning and cleansing of the trees of scale, thrips, or red-spider in the later houses should be finished before the buds become prominent, and the trees dressed with XL-All; also the woodwork and walls cleansed with a strong soft-soap and petroleum wash.

THE FLOWER GARDEN.

By R. DAVIDSON, Gardener to EARL CADOGAN, Culford Hall, Bury St. Edmunds.

Lawns.—Lawn-tennis courts, croquet and bowling-greens should have all coarse weeds extirpated, and a dressing of bone-meal applied at the rate of 3 cwt. per acre, and over this some finely-sifted rich loamy soil half-inch in depth. Should the grasses on some portions be thin, sow early in March fine lawn mixtures at the rate of 1 bushel per acre, making the seed into the turf and covering it with some sifted loam, rolling it frequently. A bowling-green should be frequently top-dressed thinly with fine river-sand, and be swept thoroughly in order to maintain an even surface, rolling being an almost daily necessity. The ordinary lawn should be freed from weeds and coarse grasses, very bad places being returned. Where there are subsidences, strip off the turf, fill in with loam, make level, and replace the turf, beating and rolling it when it is not in a frozen state. Turf under trees that is weak may be top-dressed with rich soil; and in March grass-seeds of strong-growing kinds may be sown. A net will probably be needed to protect such patches from birds, and treated in the manner described above. If labour and expense are of no consequence, relay with new turf. Lawns which contain much moss should be well scratched with a close toothed-iron rake or a patent moss-grubber, the moss collected and wheeled away, and a top-dressing of superphosphate of lime one-half, kainit one-quarter, nitrate of soda one-quarter, applied to the amount of 3 cwt. per acre, and over this strew loam to the depth of half an inch. Sow seeds if necessary. Grass slopes and banks with a S. and S.W. aspect which have suffered from last year's drought may either be sown or turfed; if the latter, the spaces between the turf must be filled with fine soil, and the turf-beater vigorously used. Grass verges may be relaid, but the cutting of the edges should be deferred till April.

THE KITCHEN GARDEN.

By T. TURTON, Gr. to J. K. D. WINGFIELD DIGBY, Esq., Sherborne Castle, Dorset.

Peas.—As soon as the state of the ground will admit of being trodden upon, sow second early varieties in quantity according to the demand, including that excellent early but somewhat delicate variety Exonian. Of second early marrowfat Peas, it will be difficult to excel Duke of Albany, Criterion, and Webb's Senator, the last-named being apparently but little known. It must be quite ten years since I first grew this variety, and yet I have looked in vain in other catalogues than Messrs. Webb & Son's for the variety; but considering its good cropping properties, it is a wonder that the price of the seed should keep at so high a figure. The drills for Peas growing to a height of 5 feet should be at the least 6 feet apart. Let them be taken out with the spade, and when the seeds are covered at this date, the drills should not be quite filled, and they should be kept deeper as the season advances, so as to facilitate the application of water at the root, and generally to avert the necessity for it. I still adhere to the practice of sowing over the Celery-trenches, which were dug out at 5 feet apart, and to sowing the dwarf varieties alternately with the taller ones. If mice attack these early sowings, set traps forthwith, or much damage may be done. One or two good cats kept in a kitchen garden save the gardener much worry and loss of seed by these pests.

Spring Cabbage.—Set out plants from the sowings made in August. In these gardens, land that was occupied by Beetroots and other root crops was bastard-trenched and well manured early in the winter, and the more forward plants set out, and others as they become fit will be planted. These plots adjoin those planted at the end of the month of September, and will form a succession to them, and the crop will be cleared off in time for planting Brussels Sprouts, which are grown in

quantity here. The ground will receive no further preparation for these last beyond cleaning and drawing deep drills with the hoe in which to plant. The Cabbages now planted may stand 21 ins. apart from row to row, and 15 ins. in the rows. In districts where the Turnip-flea is troublesome, Cabbages planted now from the late autumn sowings are more satisfactory than those from spring sowings: hence a separate border or piece of ground should be planted, where they can stand for supplying heads during the summer, and a crop of greens from the stumps during the autumn and early winter months.

Shallots and Garlic.—As soon as the ground is in a fit state, plant these bulbs without delay in well-prepared ground and open position. Give the ground a light dressing over of soot, and unless the soil is very light, a heavy dressing of charred garden refuse as well. Plant in beds 4 feet 6 inches wide good-sized cloves, at 9 inches apart, pressing them sufficiently deep to prevent disturbance by worms or when roots form.

General work.—Lift Salsafy, Parsnips, and Carrots which have been left in the ground. The Salsafy and Parsnips must be replanted close together on a border facing the north, so as to keep them in good condition as long as they are likely to be in request. The Carrots may be banked up against a wall in sand or light soil, preferably in an open shed facing north, or in the coolest place available, and stored in this manner they will keep till late in the spring.

THE ORCHID HOUSES.

By W. P. BOUND, Gardener to J. COLMAN, Esq., Gatton Park, Reigate.

Repotting and Potting.—In potting imported plants they should be made shapely by removing some of the back pseudo-bulbs, and the size of the pot or pan should correspond not so much with the number of pseudo-bulbs, as with the number of the leads. When potted make the plant secure by fastening the pseudo-bulbs to sticks, which, if the crocks are placed upright in the pot, can be made quite steady. The potting being finished, very little water should be applied till new roots have seized upon the compost, and the air should be kept moist, and damping down frequently done between the pots.

Brassavola nodosa grandiflora.—This plant is developing its flowers, and will require a fair amount of water at the root. The Cattleya-house is generally suitable for Brassavolas, and they should be so arranged that they may receive more sun than most Cattleyas will endure.

Brassavola Digbyana.—This plant is showing signs of growth, and any plant that requires repotting or top-dressing should be taken in hand. A suitable kind of compost consists of turfy peat two-thirds; chopped-up sphagnum-moss one-third, mixing these ingredients together. The drainage should be ample. At Gatton the Brassavolas grow best if suspended near the glass. While the plant is growing it will take a fair quantity of water, but the compost should be decidedly dry before water is afforded. On sunny days an occasional syringing is of benefit to the plant.

Zygopetalums.—The species Mackayi, crinitum, and intermedium, having passed out of flower may need repotting, and the potting mixture may consist of turfy-loam two-thirds, leaf-mould one-third, and crocks broken small should be added if the loam is heavy. Pot the plants firmly, and keep the base of the plant just below the rim. The drainage should be ample, so as to allow of the rapid passage of the large quantity of water which has to be applied when the plants are growing. All of the old leafless pseudo-bulbs should be removed, with the exception of those on plants which have got into a bad state of health, and perhaps have only leaves on the last pseudo-bulb, upon which it is prudent to leave two more pseudo-bulbs. Zygopetalums are pro-

perly inmates of the intermediate-house, and stand in need of a fair amount of light and sunshine. After being repotted, no more water is required than will just keep the materials slightly moist, but when there is more sunshine water may be freely applied. The black spot frequently seen on these plants arises, I believe, from affording the plants too much shade, and too close an atmosphere. It may be stated that no disturbance of the plants should take place unless it is actually required, although it is good practice to divide a few very large plants annually. The Zygopetalums, of which Z. Mackayi is a type, are very desirable for winter display, and the flowers make good material for cutting.

Epiphronitis Veitchi ×.—A pretty hybrid between Sophronitis grandiflora and E. radicans is now in flower here. The plant requires to be placed at the cooler part of the Cattleya-house, and during bright weather it should be kept well syringed. This variety, like E. radicans, is seldom out of flower, so it is advisable if the plants are not growing freely to remove the flower-spikes sometimes. Potting may be performed at almost any season when a plant requires it, in a compost of sphagnum-moss two-thirds, and peat-fibre one-third. They can be propagated in the same way as E. radicans.

PLANTS UNDER GLASS.

By J. C. TALLACK, Gardener to E. MILLER MUNDY, Esq., Shipley Hall, Derby.

Gloxinias and Achimenes.—The tubers should now be shaken out of the soil, and the first-named repotted at once, no water being applied until growth begins; and the second covered with sand and allowed to make 2 inches of stem-growth before being potted or put into baskets. Gloxinias do best in stove-heat from the start, but Achimenes will succeed in a vinery or other fruit-forcing house in the early stages of forcing.

Hydrangea.—The stems of H. paniculata should be cut down to the base, and only a limited number of shoots allowed to form, the fewer the shoots the finer being the flower-heads. H. Hortensia should, on the other hand, be only deprived of its weakest shoots, which should be cut back to the basal buds; last year's strong but flowerless shoots being retained for this year's flowering.

Zonal Pelargoniums.—Although for use in a cut state the zonal Pelargoniums are not very suitable, they are of value for winter flowering, and their brilliance of colour is hardly matched by that of any other plant. In order to obtain plants for winter flowering an early start is necessary, and cuttings should now be inserted singly in 3-inch pots, and placed on a sunny shelf near the glass in an intermediate-house. The cuttings should consist of shoots taken from plants that have been occupying a similar position, and not from attenuated specimens from the conservatory, the shoots of which have become soft and drawn. When choosing varieties, let them be those that have the character of flowering well in the winter, summer flowerers being not as a rule good at that season.

Pot Roses.—Where but a limited number of pot Roses can be forced, the season of forcing must be governed by one's special needs. H. P.'s take from eight to ten weeks to come to perfection when not hard forced; Teas a little less, and on these lines calculations should be based, bearing in mind that the harder the forcing the poorer the flowers. H. P.'s may be fairly hard-pruned, Teas rather less so, but in each case all growth too weak for flowering should be removed. A gentle-hot-bed made of tree-leaves and stable-dung is very useful, affording a moist heat, and the slight amount of top warmth needed at the first, which should not exceed 50° as a maximum. The chief enemy of pot Roses is mildew, and the most rational method of fighting which is to observe great care in not giving an excess of ventilation, indeed during the earlier stages it is wise not to ventilate much, if at all.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.
Special Notice to Correspondents.—The Editor does not undertake to pay for any contributions, or to return the unused communications or illustrations, unless by special arrangement.

APPOINTMENTS FOR THE ENSUING WEEK.

WEDNESDAY, FEB. 19. { Royal Botanic Society's Meeting.
 at 12.
 { Linnean Society's Meeting.
 THURSDAY, FEB. 20. { West of England Chrysanthemum Society's Annual General Meeting at Plymouth.

SALES FOR THE WEEK.

MONDAY, FEB. 17.—Hardy Border Plants, &c., by Protheroe & Morris, at 12.
 WEDNESDAY, FEB. 19.—Consignment of Japanese Lilies, Plants, &c., by Protheroe & Morris, at 12 and 5.
 THURSDAY, FEB. 20.—Rose-Trees, Azaleas, Begonias, Irish Ivies, Lilliums, Ferns &c., at Pollexfen & Co.'s Rooms, at 12.30.
 FRIDAY, FEB. 21.—Plants, Bulbs, &c., at 12, and Orchids, at 12.30, by Protheroe & Morris.

(For further particulars see Advertisement columns.)

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three Years at Chiswick—39° 3'.

ACTUAL TEMPERATURES:—

LONDON.—February 12 (6 P.M.): Max. 30°; Min. 21°.
 February 13.—Fine; cold. Wind N.N.E.
 PROVINCES.—February 12 (6 P.M.): Max. 41°, Scilly
 Min. 24°, Cambridge.

THE annual meeting on Tuesday last passed off satisfactorily. The proceedings followed very closely the forecast we were able to make last week. Sir TREVOR LAWRENCE's speech is reported in full in another column.

The question of a site for a new exhibition-hall, with offices for the Society and other horticultural bodies, was alluded to, but was not gone into in detail, as the negotiations are not in a sufficiently forward state to be made public. It is hoped that, provided no legal or other difficulties arise at the last moment, the arrangements proposed will be as satisfactory as circumstances will permit. In the meantime, there is really no reason why more might not be done in the present Hall at little cost and trouble for the comfort of the lecturer and audience than is at present the case.

LINNEAN SOCIETY.—On the occasion of the evening meeting to be held on Thursday, February 20, 1902, at 8 P.M., the following papers will be read:—I. (A.) "On some Gasteropoda (Limnætrochus and Chitra)," from Lake Tanganyika, with the description of a new genus. (B.) "On the Nyassa vivipara, and its Relationship to Neothauma," by Miss L. DIGBY. 2. "On the Fruit of *Melocanna bambusoides*, an Exalbuminous Grass," by Dr. A. STAPP, F.L.S. 3. "On a West Indian Sea Anemone, *Bunodeopsis globulifera*," by Dr. J. E. DUERDEN.

NATIONAL ROSE SOCIETY.—At the meeting held on the 11th inst., the retirement of the Rev. H. H. D'OMBRAIN from ill-health was announced. Mr. D'OMBRAIN was the founder of the Society, and his retirement will be felt as a severe personal loss by the members of the Society.

NATIONAL DAHLIA SOCIETY.—The annual general meeting of the Society will be held, by permission of the Horticultural Club,

in their Rooms, at the Hotel Windsor, Victoria Street, Westminster, S.W., on Tuesday, February 25, at 3 P.M. Agenda:—Report and balance-sheet for 1901; election of officers; other business. J. F. HUDSON, Hon. Sec. The committee will meet at 2.30 P.M. on the same date to prepare the Report for submission to the annual meeting, and to transact other business.

HORTICULTURAL CLUB.—At the annual meeting of this useful Institution, which may be described as the social centre of almost all the metropolitan horticultural societies, the resignation from ill-health of the secretary and founder, the Rev. H. H. D'OMBRAIN, was received with great regret. It was agreed that in future the subscription be reduced from £2 to £1 1s. Mr. E. T. COOK was unanimously appointed secretary, as from next July. Mr. H. J. VERTCH was appointed treasurer, and kindly consented to carry on the duties of secretary until Mr. Cook took up his appointment. The President, Sir JOHN LLEWELYN, Bart., was chairman at the annual dinner.

"BOTANICAL MAGAZINE."—The plants figured in the February number are:—

Moutrichardia aculeata, Cruger, tab. 7817.—A noble west tropical Aroid, with erect stem, stalked hastate leaves a foot long, and a white open spathe, about 8 inches long, encircling a thick cylindric white spadix. Kew.

Plectranthus Mahonii, N. E. Brown, tab. 7818.—A perennial labiate herb from Mt. Zomba, lat. 15½ S. The leaves are stalked, ovate, the numerous violet flowers in terminal racemes. Kew.

Minkelsia biflora, Hemsley, tab. 7819.—A Mexican Leguminous plant, allied to *Phaseolus*, but with longer calyx-lobes and more elongated petals. The plant is of climbing habit, with trifoliate leaves, the leaflets ovate. The flowers are on long stalks, and are remarkable for their large orbicular violet side-petals or wings, which exceed in size the standard. The genus is named in compliment to Dr. Minkels, of the University of Louvain. Kew.

Calathea crocata, E. Morren, tab. 7820.—See *Gardeners' Chronicle*, 1900, vol. ii., p. 113, f. 29.

Solanum Xanti, A. Gray, tab. 7821.—A native of S. California, remarkable for the variability of the foliage, though this feature is not remarkable in the specimen figured. The flowers are in terminal clusters, of a light violet colour. Cambridge Botanic Garden.

"THE COUNTRY."—A new illustrated monthly journal is to be published under this title. Mr. HARRY ROBERTS is the editor, and J. M. DENT & Co. the publishers. Descriptions of famous gardens are to constitute a feature.

UGANDA.—In Mr. WHYTE's opinion, this country will form an excellent Coffee and Tea-growing district, and most European crops will do well. Rubber from species of *Landolphia* and *Strobilanthes* (?) may be obtained with facility. *Tropical Agriculturist*.

ROYAL SEEDSMEN.—Messrs. DANIELS, BROTHERS, seedsmen and nurserymen, Norwich, have been appointed seed growers to His Majesty the KING.

KING EDWARD'S TREE.—In the New York Central Park, we are informed, there is an Oak tree which was planted by King EDWARD. It is small and very crooked, and was planted over forty years ago, on the occasion of the KING's (then Prince of WALES) first and only visit to the United States.

CAMBRIDGE BOTANIC GARDEN.—We have received a copy of the *Exchange List of Seeds* issued from the Botanic Garden of the University. It is an extensive list, and as it is signed by Mr. R. IRWIN LYNCH, the correctness of the nomenclature may be depended upon.

IRISES.—Mr. LYNCH, the Curator of the Botanic Garden, Cambridge, desires to make a special study of the genus *Iris*. He would, therefore, be extremely grateful for any flowers, not of the quite commoner kinds, which might be sent him. He would be happy to name them if required.

SALE OF POISONS.—At the Council meeting of the Royal Agricultural Society, held on Feb. 5, the question of the sale of poisonous substances used for agricultural or horticultural purposes was brought forward by Mr. BOWEN-JONES:—

"The Chemical Committee of the Royal Agricultural Society were of opinion that it was necessary (a) That Schedule A. of the Act of 1868 should be more strictly defined than at present; for example, the first item, 'Arsenic and its preparations,' might be held at present to cover sheep-dips, weed-killers, Paris green—for fruit-trees—arsenical soaps, and other articles used in agricultural operations, which were totally unconnected with pharmacy, and were not required to be dispensed, being already prepared in the form in which they are used by the public. Such articles should either be excluded from Schedule A. or otherwise excepted from the provisions of Section 15 of the Act. (b) That the power at present given under Section 2 of the Act to the Council of the Pharmaceutical Society to declare by resolution that 'any article in such resolution named ought to be deemed a poison within the meaning of the Act of 1868,' should, as regards agricultural and horticultural articles, be only exercised with the previous approval of the Board of Agriculture. With regard to the second reference to the Poisons Committee, 'to consider whether a third subdivision might not be added to the schedule, containing substances which, whether sold by pharmaceutical chemists or not, should be labelled or otherwise distinguished,' the Chemical Committee thought it would be reasonable that any vendor of what for convenience might be called 'agricultural and horticultural poisons' should be allowed to do so, provided he sold the article in the condition in which he received it from the manufacturers, the packet, bottle, or other receptacle being kept intact and unopened, and marked outside with an indication of its contents, and of the poisonous nature of the substance. The specific articles to be included in this third subdivision should be clearly stated in the schedule. In the case of the more virulently poisonous of such preparations, the same precautions as defined in Section 17 of the Act of 1868, as to a register of sales, &c., might also be prescribed; but otherwise there should be no restrictions or monopoly in the sale of poisonous substances used in agricultural or horticultural operations."

Whatever may be done, it should be made imperative in the general interest that the articles in question be sold in carefully sealed packages, and the poisonous nature of the contents should be clearly denoted on the package. At present this is not done, at least not in all cases. The same or similar restrictions as are now imposed on chemists who sell these substances should be imposed on vendors generally.

"BEES."—This is the title of a "journal devoted to up-to-date bee-keeping," the first number of which was published in January. Enthusiasts in the industry should read all available literature relating to it, this publication included. We note that the Editor invites correspondence from readers on all subjects connected with bee-keeping, and these should be addressed to Mr. E. A. GEARY, 26, Oxford Road, Upper Norwood, S.E. *Bees* is illustrated, and is planned to be issued monthly, at the price of 2d. a copy.

EELWORMS IN CHRYSANTHEMUMS.—In the *Comptes Rendus* of the Académie des Sciences, January 20, is a note by M. CHIFFLOT on the disease in Chrysanthemum foliage, caused by nematode worms of the genus *Aphelenchus*. The remedies suggested are: to burn the affected foliage; to prevent contaminating the soil used in repotting by taking care not

to throw on it infected leaves, &c.; as far as possible to sterilise the soil; to make use of artificial rather than of natural manures; and to take cuttings only from healthy plants.

DUST.—In a recent communication to the Society of Arts, dealing with observations made in a balloon at high altitudes, the Rev. M. I. BACON thus alludes to the subject of dust:—

"I commenced with collecting samples of dust from air which had passed over a large tract of sea. For this purpose I chose the Scilly Isles, where never mind whence the wind might blow it was easy to find a rocky rampart, which caught the first blast off the ocean. Keeping these as standard results labelled according to the directions of those winds which had given them, I next compared them with results similarly obtained inland on open commons, in different quarters of London, and so on, finally transferring the experiments to the car of the balloon. As may be supposed, the sample freest from matter in suspension was gathered in the Scilly Islands. It is likewise true that the most dust-laden sample was also collected from the opposite cliff of the same island (St. Mary's), the explanation of which when discovered was instructive. The island of St. Agnes lay a mile to windward, but its whole area was so small that I had regarded it as negligible. On visiting the island, however, I found it entirely carpeted with flowers grown for market, and then in full bloom, whose pollen, borne on a fresh breeze, had not only loaded but stained the spirit in the test-bottle.

"One of the clearest samples in the whole series was secured at the open end of the Aldersgate platform of the Metropolitan Railway, the explanation presumably being attributable to the passing trains attended with volumes of steam which emitted under the roof would entrap and cleanse out the dust. But another state of things was found aloft. On a still afternoon on May 1, at 2,000 feet above Kingston, the air was found far more heavily charged with dust than that of the London streets the next day. So again at half a mile above the City in August last the dust, though somewhat less in quantity, was far more abundant than on the ground within the enclosure of Stamford Bridge in the forenoon of the following day."

NEW PUBLIC RECREATION GROUND AT GILLINGHAM, KENT.—In a public competition for the best design for laying-out the above, Messrs. WILLIAM BARRON & SON, landscape gardeners, of Elvaston Nurseries, Borrowash, were awarded the first prize.

NATURE-KNOWLEDGE.—Nowadays there is a marked tendency to teach children less by books and more by object-lessons. The seed that Prof. HENSLOW sowed half a century ago at Hitcham is bearing fruit in places widely remote from that Suffolk village. Some papers reprinted by Mr. WILFRED and Miss ETHEL WEBB from *The Record of Technical and Secondary Education*, 1901 (MACMILLAN & Co.), are very interesting as showing what may be done to interest children, and stimulate and guide that faculty of curiosity which almost all children have, but which is too often disparaged rather than encouraged.

PRUMNOPITYS ELEGANS.

[SEE SUPPLEMENTARY ILLUSTRATION.]

THE demon of synonymy at once arises in the case of this plant. A beautiful illustration was sent to us from Penjerriek under the name *Podocarpus andina*. Those who consider the plant to be a *Podocarpus* will continue to use this name, but there are many of a different opinion, and who call the plant, some *Stachycarpus*, some *Prumnopitys*. In the list of Conifers published in the Report of the Conifer Conference, which is the fullest authoritative list of cultivated Conifers that we have, the name of *Prumnopitys elegans* of Philippi is adopted, as it was by Lindley, *Gardeners' Chronicle*, 1863, p. 6; Carrière, Veitch, and the compiler of the *Kew Hand-List*. The *Kew Index*, however, calls our plant *Podocarpus affinis*, which is probably a mistake, for *P. affinis* is a Pijian plant, described by Seemann.

In the Conifer Conference list the differences between our plant and *Podocarpus* are shown to consist in the fruits being placed on a loose, slender woody spike, instead of solitary on a fleshy stalk; whilst the anatomical structure of the root is, according to Van Tieghem,* different from that of its near allies. In the last edition of Veitch's *Manual*, p. 155, fig. 54, is given an illustration of a fruiting branch, which shows how different the plant is from the true *Podocarpus*.

Prumnopitys elegans inhabits the Andes of Southern Chile, and was introduced thence by Pearce on behalf of Messrs. Veitch. It is hardly over the greater part of Great Britain, but, says Mr. Kent in Veitch's *Manual*, it grows most freely in the south-western counties of England and in Ireland. Its foliage is Yew-like, dark green above, slightly silvery beneath, the individual leaves linear, oblong, acute, with a midrib prominent on both surfaces. The berries are about 1 cent. long, oblong, ovoid, rounded, with a fleshy red or purplish aril nearly covering the hard, bony seed. We believe the shrub to be quite hardy, and, as far as we have seen, it is not very particular as to soil; but it is so attractive a plant that it is worth a little special attention. It makes a good plant for a window or outside balcony, which is a pretty good proof that its requirements are not very exacting.

Lindley, quoting Philippi, describes the fruits as yellowish-green, but those we have seen have been reddish or purplish. The berries are edible—perhaps by those who can get nothing better.

A similar tree occurs in the same district, viz., *Podocarpus nubigena* (fig. 34), also introduced by Messrs. Veitch from Valdivia, by Mr. W. Lobb. It is a true *Podocarpus*, with linear, very pointed leaves, about 4 cent. long. Mr. Acton, of Kilmacurragh, Rathdrum, Ireland, furnished us in 1891 with specimens bearing male flowers, which up to that time had not been described (see *Gardeners' Chronicle*, August 8, 1891). The same native name, "Maniu," is said to be given to both plants. M. T. M.

CRINUM MOOREI AND C. POWELLI.

MR. GUMBLETON writes:—"I have read with considerable amazement the statements on p. 98 of your last issue, made by your correspondent Mr. J. Murison, as to the origin of these fine plants, which he asserts were both raised by my old friend the late Dr. David Moore, the Director of our Irish Kew at Glasnevin. I do not think that these statements are at all in accordance with facts, as I do not believe that he raised either of them. I have always heard that *Crinum Moorei* was sent to Dr. Moore from Natal as an unnamed species, which he was asked by the sender to allow to bear his name, as the first to bloom it in Europe. *Crinum Powellii* × was raised some twenty or more years ago by my friend Mr. C. B. Powell, of The Old Hall, Southborough, Tonbridge, by crossing the tender *C. Moorei* with the hardy *C. capense*, or longiflorum, and was distributed for him in three colours, named respectively *C. Powellii*, deep rose colour; *C. P. intermedium*, pale pink; and *C. P. album*, pure white, by Messrs. Henderson & Son, of Wellington Road, St. John's Wood, the site of whose nursery now forms a part of Lord's Cricket-ground. My memory of all these facts is so clear, from having grown all these plants since their introduction most successfully, that I hope my friend, the present Director of

Glasnevin Gardens, will bear me out in their correctness when he sees my letter in your columns. W. E. Gumbleton, Queenstown."

— In the *Gardeners' Chronicle* of the 8th inst., a correspondent gives us some special information about the above two varieties of very useful bulbs, which he says were "produced" over thirty years ago by Dr. David Moore. I saw *C. Moorei* at Glasnevin thirty-five years ago, growing out-of-doors, and in splendid health and condition, as nearly all the plants generally were in that pretty garden whilst Dr. Moore had it in his charge. Now, if your correspondent can give us the history of the "production" of *C. Moorei*, I am in the position of being able to do so in the case of *C. Powellii*. Not that this is necessary with readers of the *Gardeners' Chronicle*, for since 1881 it must have been repeated five or six times, and likewise by Mr. Burbidge in No. 949 of *The Garden*, in 1890, where a coloured illustration of it is given. The seeds of *C. capense*, crossed by the pollen of *C. Moorei*, were sown about 1875 in Bury St. Edmunds, and the young plants the following year were at once pricked out in a row out-of-doors, where they remained till I left Suffolk in 1880. They were sent up to London to Messrs. E. G. Henderson & Son, of The Pine-apple Place nursery, who began to dispose of them in the following year. Whilst in Bury, all the bulbs had not bloomed, for the white variety flowered first at Pine-apple Place. Seeds were saved from both "*C. capense album*," and the ordinary pink kind, but strange to say, the deeper-coloured varieties of *C. Powellii* were produced by the seedlings of the white variety. I would hardly have troubled you with these details, only that any accurate information about matters connected with the Cape cannot be too often repeated. C. B. Powell, Southboro'.

— Your correspondent has fallen into error about the history of *Crinum Powellii* ×. *Crinum Moorei* was first raised and flowered at Glasnevin, and is from Natal. *Crinum Powellii* × was raised in England by crossing *Crinum Moorei* with *C. capense*, the raiser of this fine plant being Mr. Powell, after whom it is called, and not after a foreman at Glasnevin, your correspondent evidently confusing the names Powell and Pope. There are varieties of both *Crinum Moorei* and *Crinum Powellii* ×, ranging from pure white to deep rose, each variety having its distinctive charm, and all being attractive. These *Crinums* are perfectly hardy, provided only that they are deeply planted; the whole neck of the bulb should be underground, so that sometimes it is from 2 to 3 feet from the surface of ground to base of bulb. F. W. Moore, Glasnevin.

[Other correspondents have addressed us to the same effect, which induces us to repeat the history of these plants in question. *C. Moorei* was described first by Sir Joseph Hooker in the *Botanical Magazine*, t. 6113, from a specimen sent by Dr. Moore, of Glasnevin, after whom it was named. It was also figured in the *Gardeners' Chronicle*, 1887, ii., fig. 101. It was first made known by a sketch made in Natal by the late Bishop Colenso. It is comprised under the same name by Mr. Baker in his *Handbook of the Amaryllidaceae* (1888), p. 93, and in the *Flora Capensis*, vi., 200. A coloured figure was also given in the *Garden* for 1881. *Crinum Powellii* × is a hybrid between *C. longifolium* alias *capense* and *C. Moorei*, botanically described in Baker's *Handbook*, p. 95, and also in the *Flora Capensis*, vi., 202. A notice of the plant is also given in the *Florist and Pomologist*, 1884, p. 155. Ed.]

* Bull. Soc. Bot. France, 1891, p. 163.

HOME CORRESPONDENCE.

PINANGA VEITCHI, WENDLAND.—I was very much struck by the beautiful picture of *Pinanga Kuhlji*, Blume, as it grows at Buitenzorg, in the *Gardeners' Chronicle*, February 8, and by Herr Udo Dammer's remarks at p. 97 on *Pinangas* generally. I wish all the species were as free-growing and as vigorous and satisfactory as he therein declares them to be. There is at least one exception in the genus which has so far, I believe, defied the best efforts of good cultivators to keep it alive in our hot-houses here in England, viz., *P. Veitchi*, a very handsome dwarf species with beautifully coloured foliage, which I introduced from Borneo for Messrs. Veitch, of Chelsea, about twenty-four years ago. As growing in Borneo, on the forest floor in reflected light amongst steel-blue Ferns and *Selaginellas*, it formed one of the most beautiful dwarf-growing Palms I ever saw; but it defied all efforts to develop its beauty in English gardens. I presume Herr Dammer has not had any experience of this species? *F. W. Burbidge, Dublin.*

KERRIA JAPONICA AS BACHELOR'S BUTTON.—On reading the article "What is the Bachelor's Button?" in your issue of the 1st inst., I was much struck by the omission of *Kerria japonica*, which I have from my youth known as Bachelor's Button. This may be due, perhaps, to its comparatively recent introduction, and therefore no allusion to it is made in the older works. *Charles Dennis, Hopedene, Holmby St. Mary.*

HYBRID ALPINE IRISES.—Quite recently considerable prominence was given to what was described at the time a "new race of hybrid alpine Irises" (see *Gardeners' Chronicle*, November 30, p. 397). Judged by the text, and by the excellent illustration, the reader had every reason to believe that there was a new and greatly-improved race of these hardiest of hardy plants. On Tuesday last at the Drill Hall, what I imagine to be representatives of this new race were placed before the Floral Committee in the most deplorable condition. All that was before the committee was the merest handful of flowers, crushed and bruised almost beyond recognition, and as far as is known, with not an atom of information to guide even those closely interested in such things. It is simply impossible for the above committee to know anything concerning new hybrid races of plants, unless it be given direct information. In a case such as this, the Irises should be shown in the growing state in pans or pots, so that the natural growth and other characteristics may be seen. *E. F. Jenkins, Hampton Hill.*

PEAR PRESIDENT BARABE.—In your report of a recent Royal Horticultural Society meeting at the Drill Hall, you allude to a small exhibit of the above variety as having been awarded a Cultural Commendation. This reminds me that I have very lately been enabled to partake of some fruits of this grand winter Pear, as grown by Mr. Allan; and I have no hesitation in saying that, taking all points into consideration, it is the best-grown Pear of its season in this country. The flavour is rich, the texture of the flesh melting, above middle size, and handsome in appearance. There is just the slightest tendency to grittiness towards the core in an occasional fruit, but this is scarcely worth mentioning. A great point is, that the flesh is sound at the core even when the skin has the appearance of decay, so that the gardener need have no fear when dishing up the fruits for dessert. I am not writing from one trial only, as I have had the opportunity of testing it for three seasons at the least. The best fruits Mr. Allan grows are obtained from shoots grafted on the free-growing and good *Conseiller de la Cour*, and this offers a method to those who may wish to try the variety, and can obtain shoots fit for grafting. I would suggest that it be worked on the wilding Pear stock, or on

some strong-growing Pear, and not largely on the Quince until its capabilities have been tested. On a strong-growing stock it will grow strongly and become fruitful at an early age. *J. C. Tallack.*

CANNA ITALIA.—Your correspondent "W. T. G." cannot have had the true *Canna Italia*, which he says has given him seeds. This hybrid, as well as all the other hybrids (about thirty) of the Orchid-flowering Cannas raised by Mr. Sprenger, at Naples, has, in spite of all efforts, remained perfectly sterile. The ovaries swell, but they continue to be hollow. The same has been observed in Spain, Portugal, and the south of France, while there has never appeared anything about production of seeds in the horticultural papers; and so in the seed trade, you will never find them offering these Orchid-flowering Cannas. If this is the case, how could it be possible that this *Canna* has produced seeds in England, where the climate is by no means so favourable as in the above-named countries? I am afraid one

FIG. 34.—*FODOCARPUS NUBIGENA*: SHOWING MALE CATKINS.
Separate anther, magn. 10 diam.; pollen grains magn. 240 diam. (See p. 113.)

must leave the decision of this question to a microscopical examination, which will prove that the pistil is crippled and unable to fulfil its function. *William Müller.*

PRIMULA MEGASEÆFOLIA.—In the Rev. C. Wolley-Dod's interesting note on the above plant, he refers to the uncertainty in its season of flowering as being a drawback to its open-air cultivation in England. I have it flowering well in a cold frame, and also out in the open, and of the two, the plants on the rock garden look the better. They have withstood 18° of frost uninjured, and are now looking thoroughly at home. Carl Sprenger gives the flowering season as being winter, autumn, and May. I can speak for its winter-flowering, but it remains to be seen if it will flower in May and autumn. The plant, for which I was given a R.H.S. award last April, sets its seeds well, and is a strong plant, in full flower now. *E. Willmott, Warley Place.*

CATERPILLAR OF THE GHOST-MOTH.—At the last meeting of the Scientific Committee of the Royal Horticultural Society a caterpillar was exhibited, found on the roots of a *Præony*, and said to belong to the genus *Hepialus*. These caterpillars are a nuisance in my garden, injuring, and even destroying some of my

Michaelmas Daisies, by eating the young fibres of the roots. They lodge in or just beneath the woody root-stalk, and under its shelter they move about feeding on the incipient growth. If I dig up a dozen pieces of Michaelmas Daisies probably half of them contain two or three or more of these soft and colourless semi-transparent and ill-looking vermin, more like the larva of a beetle than the caterpillar of a moth. I refer them to *Hepialus humuli*, the Ghost-moth, well known to all observers of Nature, the male being white above and brown beneath, alternately visible and invisible as it flits from side to side like a phantom in the dusk. These moths, of which there are several native kinds in the same genus, are known collectively as "Swifts," and rank next to the *Sphinxes* in classification. A smaller kind, equally common with the Ghost-moth, is named *H. lupulinus*, and is said to have a similar caterpillar, and the same root-eating habit. From their lodgment under a hard roof of root no insecticide can reach these caterpillars, so they complete their growth and transformations in security. *C. Wolley-Dod, Edge Hall, Malpas.*

A FINE SPECIMEN OF CEDAR OF LEBANON.—At Eden Hall, Cumberland, on November 13, 1901, a remarkably fine specimen of *Cedrus Libani* was blown down. It was one of a pair whose size and symmetry had earned for them a local fame. It measured 75 feet in height, and from the base to where the trunk divided into seven large branches it contained 100 cubic feet of wood. The whole tree being computed to contain over 800 cubic feet of wood, the market value of which was no doubt much lessened by its being slightly decayed in the centre. The spread of its branches was about 96 feet, and its age is supposed to be more than 200 years. The soil in which it grew was that covering the old red sandstone. Unlike *Cedrus Deodara* the wood has a very large grain similar to pitch Pine, and is of a much lighter colour. *J. W. Mallinson, Eden Hall, Cumberland.*

ORANGES.—Ladoo is described on p. 209 of my book, *Gardening in India*. The seedless Orange is a form of the Valencia Orange, described in the supplement to the book I send (supplement to p. 210). Out of a dozen Oranges served to me in a shop without selection, four proved entirely without seed. The fruit was from Aleira, and the trademark a scythe. At Poona, India, there is a very fine seedless variety of the Punalu (*Citrus decumana*) in cultivation, and no difficulty is found in its propagation by budding. *G. Marshall Woodrow.*

THE INSECTICIDE XL-ALL AS A WINTER DRESSING FOR GRAPE-VINES.—I have given Richards' XL-All a fair trial for all kinds of insects that infest plants under glass and out-of-doors; and as a winter dressing against mealy-bug on the Grape-vine, I have found it to be the best remedy of any I have used, and quite safe. I need hardly say that it must be used according to the directions given on the bottle. I have used it rather stronger, i.e., one part insecticide to ten of water, for Vines, and at that strength it destroys all the mealy-bugs which are touched by it; but "H. H." must not expect that it will thoroughly eradicate the pest, as there will be many of the insects that the insecticide will not reach, and he will have to keep a sharp look-out for them all through the summer season. For scale on *Codiaeums* and Palms, I use it at the rate of one part to twenty of water as a dip, and about three weeks afterwards I have the plants sponged with it, and the first-named plants do not lose their lower leaves afterwards. For green and black fly, one part to thirty-eight of water is quite effectual, and as a dip for the tips of the young shoots of Peach and Nectarine-trees it is excellent. I have used it as a dip and for syringing forced Roses, Carnations, Chrysanthemums, Cinerarias, Calceolarias, Lilliums, and various other plants. It is more effectual when mixed with warm rain-water. *J. Miskin, Runnymede, Old Windsor.*

"BARE-FOOTED BAIRNS" IN SCOTLAND.—One has read with so much pleasure "R. H. P.'s" interesting articles on a "Visit to the North," that I am rather unwilling to criticise anything. I think however that, like a good many Englishmen who come across the border, he has assumed too readily that the presence of bare-footed children, or even of bare-footed adults, is to be taken as a sign of poverty. I know little about Dalkeith, so am not concerned about its reputation, but would point out that throughout the greater part of Scotland, apart from the larger towns where the naked foot runs many risks, children whose parents are in what may be called comfortable circumstances go bare-footed in summer; while in country districts even the children of the parish ministers may be seen enjoying their freedom from foot-gear. This is for pure pleasure, and is a practice which, apart from economy, has much to commend it, as anyone will see who studies the free and lithe movements of bare-footed children, and contrast them with those of any who wear clogs, which generally give their wearers a slouching gait, or even those who wear shoes. I know well how difficult it is to induce children who have enjoyed the freedom of bare feet during the summer to put on their shoes and stockings when cold weather comes. The impression that the absence of shoes or other attire for the feet is a sign of Scottish poverty is an old one, as will be seen from the works of those who visited our northern land more than 100 years ago. *S. Arnott, Carsethorn, by Dumfries, N.B.* [So far as the above remarks relate to the naked foot in country districts, Mr. Arnott may be correct, but he is wrong in "thinking" that I "assumed" too readily that the practice of running bare-footed in the large towns is associated with more or less poverty, or thriftlessness. Instead of "assuming," I enquired of responsible Scotsmen having to do with the city government in Glasgow and Edinburgh, and the answers given me in both cases agreed with my own observations in the streets. Dalkeith is a borough, and not a country village, and the "bare-footed bairns" there, just as in the mining district of Bailleston, near Glasgow, belong to its least prosperous or least thrifty inhabitants. The custom may be a good one or not, but I heard everywhere, from Scotsmen, that in large towns at least, it is not practised to-day by the middle or upper classes to an appreciable extent. *R. H. P.*].

Obituary.

LEONARD KELWAY.—The *Langport and Somerton Herald* announces the death on February 5, at the early age of twenty-one, of Mr. Leonard Kelway, second son of Mr. William Kelway, of Brooklands. Leonard Kelway was born at Riverslea, Langport, in 1880. He was educated at Sherborne School (Wilson's House), which he entered in 1894, and left in 1898 to join the firm of Messrs. Jas. Kelway & Son.

MR. F. W. FLIGHT.—We regret to record the death of this gentleman, which occurred recently at his residence, Cornstiles, Twyford, Winchester. He was an enthusiastic horticulturist, exhibiting at most of the county shows with great success. The deceased was a member of the National Rose Society, and an exhibitor at times at the metropolitan shows of that society.

MR. F. J. GRAHAM.—The death of this once popular fruit-grower at a great age a few days ago at his residence, Cranford, Middlesex, was recently announced in the daily papers. Mr. Graham had lived in retirement so long, and had reached such a patriarchal age, that he had outlived most of his contemporaries. He was an active member of the British Pomological Society, and on the formation of the *Fruit and Vegetable Committee of the Royal*

Horticultural Society, he was one of its earlier Vice-Chairmen; and was a foremost figure at fruit exhibitions. One of the Apples he grew largely at Cranford for Covent Garden Market was Ronald's Gooseberry Pippin. Dr. Hogg, in his *Fruit Manual*, mentions it as a "very rare fruit," and he "doubted much if it is to be had true in an ordinary way." Mr. Graham's name is associated with his Yellow Perfection Wallflower, of which there is a coloured illustration in the number of the *Florist and Pomologist* for July, 1864. This variety was the result of careful seeding and selecting through many generations; the object sought to be obtained being the production of a variety in which the flowers should be of a pure yellow colour, of large size, good form, and highly fragrant. This fine variety is still to be found in some seed lists, and such present-day yellow Wallflowers as Cloth of Gold and Carter's Old Gold were no doubt derived from it. *R. D.*

MRS. R. BRIGGS-BURY.—It is with great regret that we announce the death of the above lady, at her residence, Bank House, Accrington, Lancs., on the morning of Friday last, February 7, at the age of sixty-two years. The loss, so unexpectedly we might say, of such a generous and enthusiastic horticulturist will be keenly felt throughout the county, for only upon the day previous to her death she was an exhibitor at the meeting of the Manchester and North of England Orchid Society, and expressed her feelings of pleasure at the success she had attained. The chief delight of the deceased lay in her Orchids, which were very successfully cultivated. At her funeral, which took place at Accrington on the 11th inst. amid tokens of sorrow on every hand, representatives of many of the horticultural firms and societies with which the deceased lady was connected, were present.

SOCIETIES.

ROYAL HORTICULTURAL.

FEBRUARY 11.—The meeting of the committees of the Royal Horticultural Society, in the Drill Hall, Buckingham Gate, Westminster, on Tuesday last, was the commencement of the Society's official year 1902-03. The personnel of the several committees was slightly altered, and all round a fresh start was made. A large number of Fellows visited the Hall during the day, and there was a good attendance at the annual general meeting, which was held at 3 p.m., in the Drill Hall, where occasionally the noise was so great the President could not make himself heard; and where little or no provision is made for the comfort of either audience or speaker, a good deal more might be done even at the Drill Hall.

The display of exhibits would have been larger had the weather been less severe, for several exhibits of Orchids and other tender plants were not brought to the Hall for this reason. The ORCHID COMMITTEE alone granted any awards to novelties, and possibly, now that a two-thirds majority is required in every such case, there will be fewer awards than there have hitherto been.

A remarkable exhibit of Apples from Messrs. GEORGE BUNYARD & CO., Maidstone, was honoured by an award of a Gold Medal.

Floral Committee.

Present: Chas. E. Shea (in the Chair); and Messrs. Chas. T. Drury, H. B. May, R. Dean, J. H. Fitt, John Jennings, Jas. Hudson, W. Howe, J. A. Nix, C. R. Fielder, Charles Dixon, Charles Jeffries, R. C. Notcutt, J. H. Barr, W. P. Thomson, E. H. Jenkins, R. Wilson Ker, H. J. Cutbush, W. J. James, H. Turner, Geo. Paul, Ed. Mawley, Chas. Blick, and H. J. Jones.

Clematis indivisa and its variety *lobata* were again shown by Messrs. W. PAUL & SON, Waltham Cross Nurseries, Herts, in a most attractive manner. There were about seventy plants in 5-inch and 6-inch pots, each plant about 3 feet high from the pot, and profusely

furnished with their pretty white flowers and pink anthers from the top of the plants to within a short distance of the base. The growths were tied to a single stake, and doubled back from the top (*Silver Flora Medal*).

Messrs. H. CANNELL & SONS, Swailey, Kent, made an imposing display with Chinese Primulas, more than sufficient to fill one side of a long table. The colours of the flowers were remarkably good, and in size and form, too, they were capital. Some of the best of the florist's varieties were *Swanley Blue*, *The Queen*, white or blush-pink; *Cannell's Pink*, certainly the best of this colour, with large, much-fimbriated petals; *The Sirdar*, rich carmine; *Dr. Nansen*, rich crimson; *Myra*, delicate mauve colour; *Surprise*, purplish-crimson; *Swanley Giant Improved*; *My Favourite*, very free, flowers rather small, rich pink colour, and much fimbriated; *H. Cannell*, one of the most brilliant of the crimson-flowered varieties; *Fern-leaf Blue*; *Snowdon*, large, white; and *Mrs. Kennard* (new), silver and rose coloured, very pretty, and of large size. In "The Lady" strain there were many degrees of crossing exhibited, some of the plants having the pure notched petal of the natural form, and others possessing very slightly fimbriated petals, and larger-sized flowers, but in company with much of the free-flowering habit of the "unimproved" strain. Some of these of note were *Mrs. R. Cannell*, *Queen of Holland*, *Queen Alexandra*, *Fairest of the Fair*, *Red Lady*, *Magenta King*, *Salmon Beauty*, &c. (*Silver Flora Medal*).

Messrs. WM. CUTBUSH & SON, Highgate Nurseries, N., and Barnet, Herts, showed a dozen plants of *Rhododendron Jacksoni* in flower in pots. The plants were full of bloom, and the flowers are pink-coloured, with deeper colour in the centre of each petal.

Coleus thyrsoides was again shown by Messrs. JAS. VEITCH & SONS, Royal Exotic Nursery, Chelsea, who brought the same plants that were shown in flower on January 14. They were fast passing when seen on Tuesday, but the exhibit served to show that the species will bloom continuously for a considerable period.

Messrs. VEITCH had also *Rhododendron Early Gem*, very profusely in flower, colour mauve; *Amygdalus persica magnifica*, crimson flowered; *A. Davidiana alba*, exceedingly pretty; and *Loropetalum chinense*, which was shown well by Lord ILCHESTER at the last meeting.

Cyclamens from Messrs. HUGH LOW & CO., Bush Hill Park Nurseries, Enfield, were very good, and exhibited a strain with large flowers, with great variation in colour.

Messrs. JOHN LAING & SONS, Forest Hill Nurseries, London, S.E., exhibited a group of miscellaneous plants, including *Rhododendron indicum* varieties, *Cordylines*, *Codiaeums*, *Palms*, &c.

Messrs. BARR & SONS, King Street, Covent Garden, London, exhibited in a moss-covered mound a number of pots containing hardy bulbous plants in flower, including the newer giant *Snowdrops*, *Narcissus cyclamineus*, *Iris persica*, *I. Heldreichii*, *Muscari*, &c. There were cut flowers of varieties of *Helleborus*, *Anemone tuberosa*, &c. (*Bronze Banksian Medal*).

Messrs. GRO. JACKMAN & SON, Woking Nursery, Surrey, exhibited a few rock-plants in flower, made up in a box to simulate natural conditions. There were *Saxifraga Burseriana*, *Primula Forbesii*, *Cyclamen repandum*, *Polygala chamaebuxus*, *Saxifraga oppositifolia*, *Primroses*, *Iris*, &c., including some nice ones in a pot of *I. mardensis*, which were lifted from the open ground. The colour of *I. mardensis* is silvery-grey, acquiring a purple tint, with a yellow mark along the falls, and a purple blotch at tip (*Bronze Banksian Medal*).

Orchid Committee.

Present: Harry J. Veitch, Esq., in the chair; and Messrs. Jas. O'Brien (hon. sec.), J. Gurney Fowler, De B. Crawshaw, H. T. Pitt, H. M. Pollett, H. A. Tracy, W. A. Bilney, F. A. Rehder, F. J. Thorne, J. W. Odell, H. J. Chapman, W. H. Young, W. Boxall, J. Douglas, E. Hill, and H. Ballantine.

Messrs. JAS. VEITCH & SONS, Chelsea, were awarded a *Silver Flora Medal* for a very good group of hybrid Orchids, in which their endeavours to produce good yellow-flowering winter-blooming hybrids was well shown in the bright yellow *Dendrobium* x *Ophir* (aurum x signatum), and the floriferous pale yellow *D. x Imogene* (signatum x enosium lencepterum). Sir TREVOR LAWRENCE's yellow *D. Wiganian* x *anthoclitum* was also shown, and *D. x Wardiano-japonicum*; *D. x Cordelia*; *Phalenopsis* x *Hebe* (rosea x *Sauderiana*), *P. x Ariadne* x *Stuartiana* x *Aplrodite*, a fine bunch

of the dark [scarlet form of *Epidendrum* × *O'Brienianum*, *Lælia* × *Edissa* (anceps × *purpurata*), a fine lemon-coloured form of *L.* × *Mrs. M. Gratrix*, *L.-C.* × *Doris* (*L. harpophylla* × *C. Trianaei*), *L.-C.* × *Myra*, *Cattleya* × *Miranda* (*amethystoglossa* × *Trianaei*), and two fine new hybrids enumerated in the list of Awards.

Messrs. CHARLESWORTH & Co., Heaton, Bradford, staged a very effective group for which a Silver Flora Medal was awarded. The centre was made of good varieties of *Lælia* *Mrs. M. Gratrix* of different tints of yellow, and *Lælio-Cattleya* × *Charlesworthi*, with orange sepals and petals and crimson lip. At the end were stands of eut spikes of *Odontoglossum cirrosum* and *Oncidium splendens*; and arranged with them were the handsome spotted *Odontoglossum crispum* "Etoile du Congo"; *O. c. Chestertoni*; *O. x Loochristyense* var. *nobilior*, a fine yellow variety, blotched with brown, the ground colour of the labellum being white; *O. x crispum* *Hallii* *Heatonense*; *Cymbidium grandiflorum*; *Houlletia odoratissima*, the red-brown typical form; and *H. o. flarescens*, a clear yellow variety.

J. COLMAN, Esq., Gatton Park (gr., Mr. W. P. Bound), showed *Dendrobium nobile* *Colmanianum*, a fine large, pure white variety, with sulphur-yellow disc to the lip; *D. x euosmum* "Eleanor" (*x endochlaris* × *nobile nobilius*), a pretty white flower, with rose tips to the segments; *D. nobile albiflorum*, white, with purple centre to the lip; and *D. x Ainsworthi* *Gatton Park* variety, near [*D. x A. intertextum*, but with larger primrose tinted flowers.

LEOPOLD DE ROTHSCHILD, Esq., Gunnersbury House, Acton (gr., Mr. Hudson), showed four fine flowers of *Cattleya Trianaei* "Mariee," a beautiful, large, and perfectly-shaped variety, with silvery-white sepals and petals, delicately tinged and veined with pink, and large labellum, the front of which was of a magenta-crimson tint, the disc yellow, a maroon coloured band extending between it and the front.

The Rev. F. PAYNTER, Stoke Hill, Guildford (gr., Mr. Cooke), showed a pretty hybrid *Cypripedium*, near to *C. x tessellatum* *porphyreum*, with flowers uniformly tinted with reddish-rose, the upper sepal bearing dark purplish lines.

Messrs. HUGH LOW & Co., Bush Hill Park, showed *Dendrobium nobile* *virginale* *Low's* variety, a true *D. nobile*, with large, pure white flowers, having a sulphur-yellow disc to the lip; a free grower and profuse bloomer. Also *Cypripedium* × *insigne* × *bellatulum*.

E. C. BLISS, Esq., Tulse Hill (gr., Mr. Parker), showed a compact specimen of [*Celogyne cristata* with a large number of flower-spikes.

H. T. PITT, Esq., Rosslyn, Stamford Hill (gr., Mr. Thurgood), showed the singular-looking *Cirrhopetalum appendiculatum*, a Sikkim species, illustrated in the *Gardeners' Chronicle*, December 10, 1898, p. 415; and a pale green species of *Eulophia*.

W. M. LOW, Esq., Wellesbourne, Warwick (gr., Mr. H. Liney), sent *Odontoglossum* × *loochristyense*, "Wellesbourne House" variety. Flower of good form, yellow, heavily blotched with brown.

Messrs. D. DOWEL, horticultural sundriesmen, Ravenscourt Avenue, Hammersmith, showed a varied assortment of Orchid-pans, some of the very small ones being well adapted for seedling Orchids; also potting materials, &c., of good quality.

Awards.

FIRST-CLASS CERTIFICATE.

Lælio-Cattleya × *Queen Alexandra* (*L.-C.* × *bella* × *C. Trianaei*), from Messrs. JAS. VEITCH & SONS, Chelsea.—A magnificent hybrid, surpassing in size, form, and fine colour of its flowers *L.-C.* × *bella* (*L. purpurata* × *C. labiata*), and others of that showy class; the flower being enlarged and broadened by the influence of *C. Trianaei*, the petals especially being very broad and well displayed. The sepals and petals are of a light rosy-lilac, the lip intense ruby-purple, with an orange-coloured disc, behind which are some reddish markings extending to the base; the whole of the front and edges of the side lobes having a very narrow lavender-coloured margin.

AWARD OF MERIT.

Cymbidium × *Lowio-grandiflorum* (*Lowianum* × *grandiflorum*), from Messrs. JAS. VEITCH & SONS, Chelsea.—A very fine hybrid, embodying all the stately characters of *C. grandiflorum* (*Hookerianum*), especially in its broad, emerald-green, wax-like sepals and petals, and apparently the free-flowering habit of *C. Lowianum*. The large flowers had emerald-green sepals and petals, and whitish lip marked with dark red, after the manner of the best form of *C. Lowianum*, but the lip is much larger than in that species, and bears nearer resemblance to *C. grandiflorum* in the crest. It was

said to be a founding, the seeds not coming up where they were sown, but this one, and [one or two more, presumably the same cross, came up on the moist wall of the house.

Odontoglossum × *Hallio-crispum* *Heatonense* (*Hallii* × *crispum*), from Messrs. CHARLESWORTH & Co., Heaton, Bradford.—Flower large and broad in all the segments, the large shield-shaped labellum being especially conspicuous. Sepals yellow, with red-brown blotches over the minor two-thirds, the tips yellow; petals fringed, yellow, with red-brown blotches on the inner halves; lip crimped at the edge, pale yellow, with a few reddish spots.

Cymbidium × *Lowio-Mastersianum* (*Lowianum* × *Mastersianum*).—A very interesting and pretty hybrid, whose advent merges the section honoured by botanists with the distinct generic name *Cyperorchis*, and which includes *Cyperorchis Mastersiana* and *Cymbidium* proper. The plant promises to be of elegant habit, and floriferous. The specimen, flowering for the first time, bore a raceme of four flowers, nearly as large as those of *C. x Lowio-eburneum* when first exhibited, and of similar formation. Sepals and petals white, slightly tinged with green; lip white, with purple markings.

CULTURAL COMMENDATION.

To Mr. DOWNES, gr. to J. T. BENNETT-POE, Esq., Holmewood, Cheshunt, for a well-grown Plant of *Ipsa speciosa*, with six spikes of large yellow flowers. The plant is referred to *Pachystoma senilis*, under which *Fortunei* and other yellow species are also placed in *Index Kewensis*.

Fruit and Vegetable Committee.

Present: Geo. Bunyard, Esq., in the Chair, and Messrs. Jos. Cheal, G. T. Miles, W. Bates, S. Mortimer, Alex. Dean, H. J. Wright, Geo. Kelf, Geo. Woodward, H. Markham, Jas. Smith, F. Q. Lane, J. Jaques, G. Reynolds, W. Wyfe, Ed. Beckett, A. Ward, J. Willard, Jas. H. Veitch, P. C. M. Veitch, A. H. Pearson, and C. G. Nix.

A dish of nice fruits of Pear *Bergamotte* *Esperen* was shown by the Earl of ILCHESTER, Holland House, Kensington (gr., Mr. Dixon), (Vote of Thanks).

Messrs. R. HARTLAND & SON, Cork, showed intensely-coloured fruits of an Apple described as *Ballinora Pippin*.

A fine bunch of forced *Asparagus* blanched to the very tip, was shown by the Duke of NORTHUMBERLAND, Syon House, Brentford (gr., Mr. Geo. Wythes), (Vote of Thanks).

Seakale from Messrs. JAS. VEITCH & SONS, Royal Exotic Nursery, Chelsea, attracted considerable attention. They showed a large quantity of the purple variety, and of *Lilywhite*, and of a new one called *Beddard's Seakale*, a cross from the purple and white varieties. It was said that the varieties were planted for forcing on Jan. 18, the varieties *Lily-White* and *Beddard's* being fit to cut in 23 days, and the purple variety five days earlier. The new one is undoubtedly a strong growing, attractive *Seakale* (Vote of Thanks).

Messrs. GEO. BUNYARD & Co., Royal Nurseries, Maidstone, were awarded a Gold Medal for a very handsome exhibit of Apples, which furnished one side of one of the long tables. The 100 dishes or so of fruits were of large size, excellent in colour, and as fresh-looking as in October. There were culinary and dessert varieties, and it is invidious to mention any when all were so good. The following varieties, however, were exceptionally attractive in appearance: *Gaseigne's Scarlet* Seedling, *King of the Pippins*, *Calville Rouge*, *Golden Noble*, *Annie Elizabeth*, *Twenty Ounce*, *Farmer's Seedling*, *Bismarck*, *Mrs. Phillimore*, *Belle Pointoise*, *Hoary Morning*, *Cox's Orange Pippin*, *Newton Wonder*, *Calville Malingre*, *Baumann's Winter Reinette*, *Winter Queening*, *Swedish Reineette*, *King of Tomkins* County, *Tower of Glamis*, *Peasgood's Nonsuch*, *Ribston Pippin*, &c. There were excellent fruits of the following Pears:—*Ramilies*, *Catillac*, and *Uvedale's St. Germain*.

Messrs. JAS. CHEAL & SONS, Lowfield Nurseries, Crawley, exhibited seventy-five baskets and dishes of Apples. We noticed very good specimens of *Cox's Orange Pippin*, *Newton Wonder*, *Jubilee*, *Beauty of Stoke*, *Paroquet* (new), *Lane's Prince Albert*, *Fearn's Pippin*, *Lord Derby*, *Mabbot's Pearmain*, and *Crawley Reinette*, a new one, said to be a very late one, in season in March, a late bloomer, and a very free cropper and easy "doer." It is a little similar to *Blenheim Orange* in appearance and size (Silver Knighting Medal).

Messrs. JOHN LAING & SONS, Forest Hill Nurseries, London, S.E., had a small collection of Apples, in which *Tom Putt*, *Gloria Mundi*, *Beauty of Kent*, *Dumelow's*

Seedling, and *Lane's Prince Albert*, showed to advantage.

Messrs. H. CANNELL & SONS, Swanley, exhibited some big Onions in several varieties.

Annual Meeting.

The annual general meeting of the Royal Horticultural Society was held at the Drill Hall, Buckingham Gate, Westminster, on Tuesday, February 11; Sir TREVOR LAWRENCE, Bart., the President, occupied the chair, and the attendance in the draughty Drill Hall was numerous.

The PRESIDENT, in opening the meeting, said:—Ladies and Gentlemen, I think we owe you some apology for the fact that we have to meet in this Hall to-day. It is not a very convenient place; but I hope that in the course of a few years we may be sufficiently fortunate to have a hall of our own.

Fifty-eight new Fellows were nominated for election at the meeting.

Mr. GEO. PAUL next moved a vote heartily thanking Sir JOHN LLEWELYN for his past services on the Council, and expressing the great regret of the Council that Sir John found it impossible, owing to the distance he lived from London, to attend the meetings of that body. Mr. Paul said they were losing a man who possessed great knowledge of horticulture, and his loss would be a very severe one to the Society.

Sir JOHN LLEWELYN, in returning thanks, assured the meeting that he left the Council with very great regret. He had always taken a pleasure in this work, which had been to him a work of love. It was a wholesome rule of the Society that members of Council should attend regularly, and this he found impossible, owing to living 200 miles from London. Of course, they did not want to make the Society a merely London Society, but they wished that its ramifications should extend far and wide. He was therefore glad to find that a countryman had been elected to fill his place. He should, however, at all times, do all he could to promote the welfare of the Royal Horticultural Society, and he was glad to see the proud position it was now holding in this country.

The PRESIDENT then said:—The next business is for me to move the adoption of the Annual report. I think there are very few people who are interested in the Royal Horticultural Society who will not agree with me, when I say that the Council are presenting a very satisfactory report to the Fellows.

NEW FELLOWS.

The numerical gains the Society has made are really remarkable. I find that 930 new Fellows were elected during the first year of the new century. That is, I say, remarkable, when I remember that in 1888—which, after all, is but a few years ago—there were only 552 paying members of the Society all told. It must not be supposed that this is in any way due to fashion. Unfortunately fashion, charming as it is, is perhaps the most fickle thing in the whole world, and if we were congratulating ourselves on the number of new Fellows to join a fashionable Society, I should not have the same satisfaction as I feel at the present moment. Nor must it be supposed that the recruiting-ground of the Society is in any way becoming exhausted; because, notwithstanding the fact that nearly 1,000 new Fellows joined the Society last year, we have already thus early in the year elected 180 new Fellows. The names of the Fellows occupy 126 closely printed pages of the Report. I have not counted them, but I am told that the total is, roughly speaking, 5500.

THE ROYAL BOTANIC.

I dare say some of you have seen in the newspapers some paragraphs associating the name of this Society with the Royal Botanic Society. We received a most courteous letter from that Society, suggesting that they should place their gardens at the disposal of this Society. Unfortunately, this Society had already made all its arrangements, not only for the present year, but I may say for practically a considerable time to come, and we were unable to meet the advances which were made to us.

THE TEMPLE SHOW.

I think you will agree with me that so long as the Benchers of the Honourable Society of the Inner Temple are so kind as to lend us their gardens, there is no better place in the City of London in which to hold our great shows. Perhaps I ought to take advantage of that remark, and say how very grateful we are to the Benchers of the Inner Temple, who have extended to us such enduring hospitality. Although the gardens are not quite as large as the Benchers might like, and certainly not so large as we could desire, still they

occupy a central position in the City of London, easily accessible from all parts, and that is a great advantage.

THE REPORT.

As to the report, I think you will agree with me that it is somewhat detailed. I do not wish to go unnecessarily into the matters dealt with; but in Paragraph 3 stress is laid on the value of the lists of awards by the various Committees of this Society. I think nobody who is occupied in the cultivation of a garden can do at all well without a copy of the lists of awards. They have been published by the Society, and we are very greatly indebted to several of our Fellows for the valuable assistance they have given us in that matter. In this connection I must mention Mr. Gurney Fowler, who has taken a great deal of trouble in making these lists correct, and I believe they have been so revised that there is scarcely a mistake to be found, if indeed there is one.

THE AWARDS.

The total awards by the various Committees during the year number 983. I venture to think that number is far too many. If the awards are multiplied with any degree of generosity, of course they lose their value in proportion to their multiplication. I think the new provision is a good one which lays it down that no award is to be given except by a vote of a two-thirds majority. Formerly the awards were decided by an absolute majority.

THE SCIENTIFIC COMMITTEE.

Then the report speaks of the value of the services of the Scientific Committee. Upon that committee are gentlemen of the highest scientific eminence in the horticultural world, and their services are very great indeed. There is no doubt whatever that the future belongs to science, and that applies to horticulture as it does to everything else. When we remember how science has absolutely altered the face of the globe, it will be seen what a prominent position is filled by the scientific horticulturist.

THE SPECIAL SOCIETIES.

It is a real satisfaction to this Society to find that several of the kindred societies, which no doubt were originally started by some members of this Society, are showing an increasing inclination to come home to roost under the auspices and guardianship of this Society. There is the Tulip Society, the Dahlia Society, the Auricula and Primula Society, and others. At this point noise was made by some workmen in the gallery, which led the President to point out the need for a Hall of their own—a remark which was again applauded. Continuing he said, these societies are now holding their shows under the auspices of the Royal Horticultural Society, and all we can say is, the more these kindred societies gather under the wings of the parent Society, the better the parent Society will be pleased.

THE AMERICAN CONFERENCE ON HYBRIDS.

With regard to paragraph 14, I should mention, in addition to Mr. Nicholson and Mr. Bateson, that we have, owing to a request coming from America, asked Captain Hurst, who is well known as a hybridiser of plants, especially Orchids, to go with those gentlemen to America for the Conference on Hybridisation to be held in New York in the autumn.

"THE JOURNAL."

There is one matter which I hope you will admit I am entitled to refer to with feelings of congratulation, and that is the *Journal*. I think there is nobody who is acquainted with the *Journal* who does not recognise the value of that publication now. Within the last year or two it has been enormously improved; and it is impossible to avoid mentioning in this connection the name of the gentleman who edits it. I refer, of course, to our invaluable Secretary, Mr. Wilks. I consider that the *Journal* for a Society of this sort has very nearly reached perfection. The cost of printing it is £1506. We have to deduct the amount we get from advertisements—£523, and from sale of copies, £88; that is a reduction of £591, leaving the net cost of producing the *Journal* £915—money, I venture to think, very well spent indeed. I must also ask you to bear in mind your obligation and gratitude to the gentlemen who are responsible for the abstracts and notes which now form a prominent feature of the *Journal*. These gentlemen occupy very prominent positions in connection with horticultural and botanical sciences, and the obligations of the Society to them are very great.

One Fellow asked whether the *Journal* could not be printed on unglazed paper; and another suggested that the edges might be cut.

The President said glazed paper was necessary for the proper production of the "blocks;" and anyone who loved books would regard the cutting of the edges as barbarous.

RECTIFICATIONS.

I should like to say in passing, that the expression "three years," in paragraph 5 of the Report, should read, "during the last five years." Then there is one rectification to make in paragraph 18 of the Report where it is stated that it is proposed to hold examinations of young men for Certificates in the month of February, instead of in April. It has been pointed out to the Council that that would be an exceedingly inconvenient time, and that it would absolutely deprive us of a considerable number of candidates, and the Council thought it best to revert to the original month of April.

ROSE CONFERENCE.

In another paragraph of the Report, you will see that, owing to the kindness of the Earl and Countess of Ilchester, a Rose Conference is to be held in the grounds of Holland House towards the end of June. I need hardly say that there could be no better place to hold such a Conference, for not only are the gardens very celebrated, but an historic interest pertains to the mansion, which would attract people to visit them, even if they did not care for the queen of flowers, the Rose. I do not think there is the slightest difficulty in entertaining the hope that the Conference which is to take place on June 24, may be continued on June 25. At one time there was considerable doubt, owing to the Coronation, but the date of that event has now been settled.

THE PROPOSED HALL.

There is only one other matter to which I ought to refer. It will be within the memory of all present that a considerable discussion has taken place as to the best way of celebrating the centenary of the Society, which will take place in 1904. It will also be within the memory of a great many present that we had a meeting in this building last year, when a proposal to purchase a site for a new garden did not, under the circumstances, recommend itself to the Fellows. At that time promises of pecuniary assistance were made to a very considerable amount by gentlemen who were present, provided the Society ultimately decided to adopt an alternative proposal for having a Horticultural Hall with offices instead of a new garden, as the best method of celebrating the centenary of the Society. Not that a hall, with offices, were to shut out the provision of a new garden when the Society has to leave Chiswick. It was felt by a great many people present that while there were always sites available for a new garden, the sites which would be suitable for a new hall would daily, and even hourly, become fewer. However that may be, it was decided by the meeting that the idea of a new garden, at all events in the manner in which it was placed before the Fellows, could not be entertained. It was largely at the instance of Baron Schröder, who has always been not only a very eminent horticulturist, but a very prominent and one of the best members of this Society, that a committee was formed to consider the sites which might be suggested for a hall for the Society. The committee consisted of Baron Schröder (as Chairman), Earl of Ilchester, Mr. Sherwood, Dr. Masters, Mr. May, Mr. Harry Veitch, and myself, with the Rev. Mr. Wilks as Secretary. Five different sites have been brought before the committee. It is not necessary, and I presume nobody would desire that I should delay this meeting by going into the details of these various sites; but during the last few weeks a site has been suggested which has been very carefully considered, and in regard to which negotiations are now going on. We were especially cautioned by the gentleman who was acting for the Society in regard to this site that we should not talk about it. Perhaps you will think that I am doing the very thing we were expressly cautioned against doing, but I am not going to mention the exact nature of the site. I believe you will trust the committee at all events not to do anything foolish, and I have the authority of every member of this Council to assure the Fellows that nothing will be done without the whole circumstances being placed fully before them, and receiving their consent. As the negotiation is now proceeding it would be not only not advantageous, but it would be absolutely disadvantageous if anything were said about it beyond what I have already stated—that the negotiation is now proceeding. As soon as it arrives at such a state that it can properly be placed before the members of this Society, the Council will summon a special general meeting and place before the Fellows the

whole of the facts. I should mention that no great delay can occur in regard to that. The matter must be settled within a reasonable time, and therefore my anticipation is that we shall be in a position to call a meeting before very long. I thought it would be wiser on the whole to make this statement rather than to say anything in reply to questions asked by the Fellows. Of course, I am well aware that the Fellows of the Society must feel very great anxiety on this subject, and if there is any question that any Fellow desires to ask, I shall be most willing to answer him if I can do so without in any way risking the success of the negotiations. I beg to thank you most sincerely for listening to my remarks. I hope you will agree that the Report is satisfactory. I should like in conclusion to say that we owe a very great debt of gratitude to everybody who has done what they possibly could to promote the interests of this Society. We owe it to the amateur and professional horticulturists of this kingdom who have done their best to maintain the Society; who have supported its shows, and put themselves to expense and personal inconvenience to promote the welfare of the Society; and we owe it to the men of science who have given us their assistance and their papers in our *Journal*. We also owe a great debt of gratitude to our Committees, which embrace most of the prominent horticulturists of the Kingdom, for their great services. Our Secretary's services to the Society are practically invaluable. He has lately been overworked, and you see how the Society has grown, and may judge what a very heavy burden of work falls upon him. We have endeavoured to relieve him of some of his work, and I am quite sure that whatever we do in that direction will receive the hearty support of the Fellows of this Society. We have a most excellent staff in our offices, and to them also our thanks are greatly due. I beg now to move the adoption of the report, and Dr. Masters will be kind enough to second the motion.

Dr. Masters said that, as a member of the Committee to which the President had alluded, he had the greatest pleasure in seconding the motion that the report be received and adopted.

CENTENARY CELEBRATION.

Mr. A. DEAN asked whether the Hall would be ready for the celebration of the Society's centenary? He also suggested that it would be a very proper way to celebrate the event by a great international horticultural exhibition for that year.

The PRESIDENT: That matter has not been overlooked. There has been considerable discussion in Council as to the desirability at some time of holding an international exhibition. But if there is one thing in the history of the Society—one caution which it conveys more than another—it is, not to be too impatient. We spent our money like water in times past. We left £80,000 at South Kensington, and what we should now do is to husband our resources with the greatest possible care, and devote them to the best means of securing an enduring prosperity for the Society, and not to run any unnecessary risks. Our hope is that when we find it possible to carry out the proposals which are being considered, the hall will certainly be ready by 1904.

The report was adopted unanimously.

THE COUNCIL.

As the provisions of the Charter require that three members of the Council shall resign every year, the Council have decided that the three vacancies shall be created by the resignation of Sir John Dillwyn Llewelyn, Bart., the Rev. Hugh A. Berners, M.A., and Harry J. Veitch, Esq. The following gentlemen have been duly nominated to fill the vacancies, viz.:—Arthur L. Wigan, Esq., Rev. Hugh A. Berners, M.A., Harry J. Veitch, Esq.

The following have been nominated for election as Vice-Presidents, viz.:—The Right Hon. Joseph Chamberlain, M.P.; the Right Hon. The Earl of Ducie; the Right Hon. Lord Rothschild; Baron Sir Henry Schroder Bart.; Sir John Dillwyn Llewelyn, Bart.; Sir Frederick Wigan, Bart.

The following have been nominated for election as officers, viz.:—Sir Trevor Lawrence, (Bart.), (V.M.), President; J. Gurney Fowler, Esq., Treasurer; Rev. W. Wilks, M.A., Secretary; Alfred C. Harper, Esq., Auditor.

The whole of these were elected without a vote being taken, as there were no other nominations.

Mr. ARTHUR SUTTON proposed: "That this meeting is glad to hear from the President that steps are being taken to secure a site for a hall, and pledges itself to

give its most favourable consideration to any proposal which the Council shall in due time lay before it." He said he was quite sure they were all indebted to the Council for work that they had been doing for many months past in trying to obtain a suitable and permanent home for the Royal Horticultural Society. He did not think that their having a hall need exclude their possessing a garden. But their experience in that building that afternoon proved to them the absolute necessity of having a home of their own.

Surgeon-Major INCE seconded the motion, which was carried with three dissentients.

The meeting then ended.

DULWICH CHRYSANTHEMUM.

FEBRUARY 4.—The eighth annual meeting of the Dulwich Chrysanthemum Society was held on the above date, and was signalled by a large attendance of the members. The balance-sheet shows a balance in hand of £10 18s. The receipts from all sources increased by £25 during the year, while the expenditure was not quite £11 more than in 1900. When it is remembered that the National Chrysanthemum Society has lost about £40 on the year's working, and many local societies have had a disappointing year, it is clear that the Dulwich Society receives a large and increasing amount of support, and great credit is due to the whole of the executive for its prosperous condition.

The Society intend to hold a three days' show instead of two days as heretofore, the dates fixed being November 11, 12, and 13.

CROYDON AND DISTRICT HORTICULTURAL.

FEBRUARY 4.—A well-attended meeting of the Croydon and District Horticultural Mutual Improvement Society was held at the "Sunflower" on the above date, Mr. W. J. SIMPSON in the chair.

Mr. A. MASLEN, gr., Bramley Hill House, read a paper on the Seasonable treatment of Vines. An interesting discussion followed.

WARGRAVE GARDENERS.

FEBRUARY 5.—The members met on the above date to hear Mr. W. J. FULLER'S 1st prize essay for assistant gardeners on "Chrysanthemum Culture." He dealt most fully with every phase of the subject, from the cutting to the exhibition stage. A long discussion took place, in which many joined. The dreaded "rust" gave rise to the expression of conflicting opinions by various gardeners.

There were some good exhibits. Six new members were elected. *H. Coleby, Hon. Sec.*

NORTH PECKHAM AMATEUR CHRYSANTHEMUM.

FEBRUARY 6.—The annual dinner of the above society took place at the Trafalgar Hotel, Peckham, on the above date, C. H. TAGG, Esq., Town Clerk of Camberwell, in the chair. He spoke highly of the horticultural Press, and in particular of the *Gardeners' Chronicle*, in the dissemination of instruction and information in regard to Chrysanthemums, as well as the support afforded to the various local authorities in London in their endeavour to provide open spaces for the "classes."

The monetary condition of the Society is very satisfactory, the balance at the bank being £35, after paying various sums to the local charities. A mutual instruction class has been started.

CHISWICK GARDENERS' MUTUAL IMPROVEMENT.

FEBRUARY 6.—At a meeting held on the above date, Mr. MILLER, of Ealing, read an interesting paper on "Plant Life," before a good attendance of members. Mr. Miller briefly traced vegetation from bacteria, viz., fungi algae, the bryophytes or liverworts, vascular cryptogams, and the phanerogams or flowering plants, and discoursed for a short time on the tissues which become more and more complex as the scale is ascended. Methods of reproduction in the various types were noted, and the phenomenon of symbiosis, as in the lichens, was discussed. The whole paper resolved itself into a brief treatise on some of the various phases of protoplasm, and as such was of immense interest, largely because so little is definitely known regarding the principles which govern its laws. *C. H. Buck, Hon. Sec.*

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

FEBRUARY 10.—At the monthly meeting held on the above date, twelve new members were elected. The death of Mr. James Clarke of Taunton was reported, and

a cheque for £61 18s. 2d. was drawn in favour of the widow, that being the amount standing to the late member's credit in the ledger. A member having received his full amount of sick pay was granted 5s. per week from the benevolent fund.

Ten members were reported on the sick fund, the amount paid out for the month being £18 2s. The Treasurer reported a balance in hand of £713 16s. 1d., and was empowered to invest £550 in the best available Trustee Stock. The annual meeting will be held at the Caledonian Hotel, Adelphi Terrace, Strand, on Monday, March 10, at 8 p.m.

NATIONAL CHRYSANTHEMUM.

FEBRUARY 10.—A meeting of the Executive Committee was held on the above date, on which occasion there was a full attendance. After an animated debate over the election of Mr. W. Mease as a judge at the October and December shows, the election was confirmed. The Secretary presented an interim financial statement, and announced that a considerable portion of the arrears of members' subscriptions had been paid. Some matters arising out of the report of the auditors were dealt with as directed by the annual meeting, and the subscriptions to the fund for establishing a memorial to the late President, Sir E. Saunders, were announced. The Secretary reported that the building [Carr's Restaurant] in which they held their meeting had been scheduled under the London County Council scheme of improvement to come down. Negotiations had been opened in several quarters in order to make provision for a future meeting-place, and with the consent of the Directors of the Royal Aquarium, Messrs. Bertram & Co. had made an offer of accommodation at the Aquarium at a nominal charge. This offer was accepted.

The date of the annual outing to Paddockhurst, Crawley, was fixed for July 23. An election to the Floral Committee was made, to fill the vacancies caused by members retiring by rotation, and most of the outgoing ones were re-elected. The Classification and Catalogue Committee, the Schedule Revision, Finance, Show, and Arbitration Committees were re-appointed with a few alterations; and a number of candidates for election were accepted.

PRESCOT HORTICULTURAL.

This is one of the more popular suburbs of Liverpool which can lay claim to a flower-show that always commands considerable attention from lovers of horticulture. In the report just issued by the Society, it is to be regretted that the year's working does not show a substantial balance, notwithstanding the fact that two social evenings have been given during the present season. However, the financial state is on the right side, and the committee, through their energetic Secretary, Mr. W. Case, have again announced an annual show, to be held, by kind permission of Lord Derby, in Knowsley Park, on July 31. *Orchid.*

HORTICULTURAL MEETING AT GHENT.

At the last meeting early in February of the *Chambre Syndicale des Horticulteurs Belges et Société Royale d'Agriculture et de Botanique*, at Ghent, the following awards were made:—Certificates of Merit: For a group of five *Odontoglossums*, from M. TH. PAUWELS; for *Cypripedium* *hyb. villosum* × *Leeanum*, from M. FL. STEPMAN, of Brussels; for *C. Hoogendyckeanum* *Leeanum* × *villosum*, for C. Vanden Bulcke *sup. x insigne coloratum*, both from M. STEPMAN; and for *Miltoniopsis Bleuana* and *Laelia anceps* var. *Hollidayana*, both from M. E. PRAET.

A Certificate of Flowering was allotted for *Lycaste Skinneri* var., from M. TH. PAUWELS.

The following awards were also made:—For *Cypripedium Spicerianum* × *insigne sylhetense*, from M. PYNNAERT VAN GEERT; *Ficus radicans* variegata, from M. LOUIS DE SNET; *Cypripedium* *hyb. Spicerianum* × *sylhetense*, and *C. Spic. x sylhetense*, both from M. L. DRAPS-DOM, of Brussels; and for cut flowers of *Cypripedium*, from MM. JANSSENS and PUTZEYS, of Merxem, Antwerp.

A Certificate of Flowering was awarded for *Cymbidium Hookerianum*, from M. L. DE SNET DUVIVIER.

Honourable Mention was accorded for: *Cypripedium* *hyb. Boxalli x barbatum*, from M. PYNNAERT VAN GEERT; for C. *Godseffianum*, from the same exhibitor; for *C. Spicerianum* × *barbatum purpuratum*, from M. L. DRAPS-DOM; and for *C. hirsutissimum* × *barbatum illustre*, from the same exhibitor.

SCILLY ISLES NARCISSUS.—The largest consignment—14 tons—of Narcissus grown this season in the Scilly Isles arrived at Penzance yesterday for the English market. *Westminster Gazette, February 12, 1902.*

SEASONABLE NOTES ON CHRYSANTHEMUMS.

PLANTS raised from cuttings put in during the month of December under frames, hand-glasses, &c., and properly attended to, are making good progress. When it is seen that growth is taking place, gradually expose them by admitting air, and a few days later the plants may be placed upon a shelf suspended from the rafters in the same house. When the young plants have moderately filled the pots with roots, they must be at once removed to others 3½ ins. in diameter. They will subsequently be removed into pots 5½ ins. in diameter, and later into the pots in which they will flower.

For the present potting use a compost of two parts loam, one of leaf-mould or half-decayed horse-manure, with sand added. To every bushel of such compost add 1 lb. of Thomson's Vine and Plant Manure, or other good plant stimulant. Many fail in cultivating Chrysanthemums because they start their plants too weakly. The plants cannot be grown too strongly at this period.

For the greater convenience in potting, pass the compost through a coarse sieve, rubbing the fibrous parts through also, not rejecting this. Use clean pots, and provide them with good drainage material, which should be protected by a covering with some of the rougher parts of the compost. Pot firmly. Let the soil be moist at the time it is used, and do not afford water for a day or two at least. During the early months of the year young Chrysanthemum plants may be severely checked by over-watering, and every care should be taken to avoid this, remembering also that the leaves should never be permitted to flag from lack of moisture.

After potting, return the plants to their former position on the shelf, until the roots run through the soil to the sides of the pots; then place a neat stake to each, and transfer them to a cold frame or pit, standing them upon ashes near to the glass. Keep the atmosphere of the frame rather close for a day or two, after which admit air as abundantly as the state of the weather will permit, and on very fine days remove the lights altogether during the warmest hours. A sufficient covering should be provided over the glass at night to protect the plants from frost. A Chrysanthemum plant should never be allowed to suffer a check of any kind, from the time the cutting is inserted until the blooms are developed. *E. Molyneux.*

MARKETS.

COVENT GARDEN, FEBRUARY 13.

(We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Thursday, by the kindness of several of the principal salesmen, who revise the list, and who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but often several times in one day. Ed.)

FRUITS AND VEGETABLES.

GLASGOW, February 12.—The following are the averages of the prices during the past week:—Apples, Newtown Californian, 8s. 6d. to 10s. 6d. per case; Oregon, 12s. to 13s. 6d.; Nova Scotia Baldwins, 22s. to 24s. per barrel; Maine, 20s. to 24s. do.; Canadian, 23s. to 26s. do.; Grapes, 1s. to 2s. 6d. per lb.; Oranges, Valencias, ordinary, 420s. 7s. to 8s. per box; do., large 420s. 9s. 6d. to 10s. do.; extra large do., 8s. 6d. to 12s. 6d. do.; large 714s. 9s. to 9s. 6d. do.; Jaffa, 12s. to 13s. do.; Mushrooms, 1s. to 1s. 3d. per lb.; Onions, Valencias, 5s. 9s. 6d. to 10s. per box; do., Globe 8s. 6d. do.; do. Dutch 6s. 6d. do.

LIVERPOOL: February 12.—Wholesale Vegetable Market.

—Potatoes, per cwt.: Up-to-Date, 2s. 3d. to 3s. 3d.; Main Crop, 3s. 3d. to 4s. 3d.; Lyon Grays, 2s. to 2s. 6d.; Bruce, 2s. 3d. to 3s. 3d.; Turnips, 10d. to 1s. 2d. per 12 bunches; Swedes, 1s. 6d. to 1s. 9d. per cwt.; Carrots, 3s. 6d. to 4s. do.; Onions, foreign, 5s. 6d. to 6s. 6d. per cwt.; Parsley, 10d. to 1s. 2d. per dozen bunches; Cauliflowers, 1s. to 2s. 6d. per dozen; Cabbages, 10d. to 2s. per dozen; Celery, 8d. to 1s. 6d. do. St. Johns: Potatoes, 1s. per peck; Cucumbers, 1s. each; Grapes, English, 1s. 6d.

to 2s. 6d. per lb.; do., foreign, 6d. to 8d. do.; Pines, foreign, 3s. 6d. to 6s. each; Mushrooms, 1s. per lb.; Filberts, 1s. do. Birkenhead: Potatoes, 1s. to 1s. 2d. per peck; Grapes, English, 1s. 6d. to 3s. 6d. per lb.; do., foreign, 4d. to 8d. do.; Mushrooms, 1s. to 1s. 6d. per lb.

SEEDS.

LONDON: February 12.—Messrs. John Shaw & Sons, Seed Merchants, of Great Maze Pond, Borough, London, S.E., report to-day's market thinly attended, with a quiet business passing. The article which still meets with most favour is Alsike, and a further advance therein has to be noted. With regard to White Clover-seed, although the excitement has spent itself, no lower prices are accepted, and its firmness appears fully justified by its real scarcity. Red Clover-seed, meantime, keeps dull, and favours buyers; but full rates are demanded for Trefoil, Timothy, and Cocksfoot. Linseed has risen 1s. per quarter; but Mustard is cheaper. There is, however, no change in Rape-seed. Tares are in active request, on fully former terms. Bird-seeds move just now in narrow limits. The severe weather naturally increases the consumption of Blue Peas and Haricot Beans. The Board of Trade returns give the imports into the United Kingdom of Clover and grass-seeds for the past month as 43,709 cwt., value £319,131; as against 37,701 cwt., value £244,603, for January, 1901.

CORN.

AVERAGE PRICES OF British Corn (per Imperial qr.), for the week ending February 8, 1902, and for the corresponding period of 1901, together with the difference in the quotations. These figures are based on the Official Weekly Return:—

| Description. | 1901. | 1902. | Difference. |
|--------------|-------|-------|-------------|
| | s. d. | s. d. | s. d. |
| Wheat ... | 28 8 | 27 2 | + 0 6 |
| Barley ... | 25 7 | 26 9 | + 1 2 |
| Oats ... | 17 7 | 20 3 | + 2 8 |

METEOROLOGICAL OBSERVATIONS taken in the Royal Horticultural Society's Gardens at Chiswick, London, for the period February 2 to February 8, 1902. Height above sea-level 24 feet.

Remarks.—Dull, cold weather has prevailed during the past week, with strong wind, slight rains, and snow at intervals.

GENERAL OBSERVATIONS.

THE FOLLOWING SUMMARY RECORD of the weather throughout the British Islands, for the week ending Feb. 8, is furnished from the Meteorological Office:—

The weather was fair in most parts of the Kingdom during the earlier half of the week, but subsequently became less settled, until by Saturday snow had become very general in all the northern districts, and sleet or cold rain in the south. The snowfall in some of the

northern districts of Great Britain and Ireland was very heavy.

The temperature was again below the mean, the deficit ranging from 3° in England, N.E., and 4° in Ireland, N., to 6° in the Midland Counties, England, S., the Channel Islands, and Scotland, N., and to 7° in England, S.W. The highest of the maxima were recorded on rather irregular dates. They varied from 48° in England, S.W. and the Channel Islands, to 42° in England, N.E. and N.W. At many northern, central, and eastern stations the daily maxima were frequently below 36°. The lowest of the minima were registered either at the beginning or end of the period. They varied from 8° in Scotland, E. and 10° in Scotland, N. (at Nairn and Wick on Sunday), to 20° in England, S.W., 28° in Ireland, S., and 31° in the Channel Islands.

The rainfall was less than the mean in all districts. Some of the amounts yielded by the snow were large—especially in the north of Ireland. At Edeniel there was as much as 0.92 inch, and at Armagh 1.02 inch.

The bright sunshine was much less than the normal over the Kingdom as a whole, but exceeded it in Scotland, N., and Ireland, S. The percentage of the possible duration ranged from 24 in the latter district, and 23 in the former, to 9 in England, S. and N.W., and in Ireland, N., and to 6 in England, E.

THE WEATHER IN WEST HERTS.

The present cold spell has now lasted exactly a fortnight, during which the temperature in the screen has at no time risen more than 8° above the freezing point. On the coldest night of the past week a thermometer exposed on the surface of the snow registered 18° of frost. The ground has been gradually getting colder, and is now 3° colder at 2 feet deep, and 4° colder at 1 foot deep, than is seasonable. Snow fell on the morning of the 8th to the mean depth of an inch, and the ground is still about half covered by this fall. No measurable quantity of water has as yet come through either of the percolation gauges this month. The sun shone on an average for one and a half hours a day during the week, which is a small record for February. The air has been throughout very calm, the mean rate of movement at 30 feet above the ground being only one and a half miles an hour. The atmosphere has again proved dry for the time of year. E. M., Berkhamstead, February 11, 1902.

TRADE NOTICE.

MR. F. SANDER, of St. Albans, and of Bruges, Belgium, requests us to make known that he has taken into partnership his three sons, Conrad Fearnley Sander, Frederick Kropp Sander, and Lewis Lohmann Sander, who have been engaged in the business for several years. The style of the firm will henceforth be Sander and Sons. Mr. Godseff remains as manager.

APPLE SHOOT BORED: W. Noble. The work of the Wood Leopard moth-caterpillar, *Zeuzera aesculi*. When coarse wood-dust is noticed at the foot of a tree or beneath the branches, suspect this creature as the originator, and look for the entrance to the gallery, up which thrust a wire and kill the caterpillar.

BOOKS: F. W. C. The most modern and the best for your purpose is *The Book of the Rose*, by the Rev. A. Foster-Melliar, published by Messrs. Macmillan & Co., St. Martin's Street, London, W.C. The publications of the National Rose Society can be obtained from Mr. E. Mawley, Rosebank, Great Berkhamstead.

CYCLAMEN: N. Y. Z. The production of two flower-stalks where one only normally occurs is not a very rare occurrence. In your case the two flower-stalks are fused together. On making a cross-cut, the vascular bundles are found arranged, not in a circle, but in an ellipse. The stalks are united all the way up, but the flowers themselves are not joined.

DISTANCE OF EARTH FROM THE SUN: B. G. S. The earth's path or orbit is not strictly

circular, but an ellipse in one of the foci of which is the sun. The earth is nearest the sun or in perihelion at the beginning of the year, or when it is winter in the northern hemisphere; and at its greatest distance, aphelion, at midsummer in that hemisphere. The least distance of the sun from the earth is 94,000,000, and the greatest 96,000,000 of miles.

EVERLASTING PEAS: *W. G. L.* The roots and tops of these reaching to considerable length, the plants in nursery lines should certainly not be planted at a less distance apart than 2 feet. If they are grown in 8 to 10-inch pots sunk in the soil, and that, perhaps, is the better way, 15 inches would afford enough space for top growth to develop.

FOREIGN BASKET-MAKERS: *G. Bradwell.* We are unable to recommend traders. You should consult *Letts' London Directory*, under Foreign.

GARDENER IN ILL-HEALTH: *Bouvard.* See reply to a similar question in our "Enquiry" column last week.

HARDY RED, WHITE, AND BLUE COLOURED PLANTS FOR A DEVICE: *Inquirer.* Red: *Ajuga reptans*; white: *Centaurea ragusina*, *Cineraria maritima*, or *Cerastium tomentosum*; blue: *Plumbago Larpetæ*. Much depends upon the season of the year for which the design is intended.

HYACINTHS FAILING: *G. F.* The bulbs may have been lifted in an immature condition, and are unfitted for forcing, although capable of producing flowers at their natural season. Many such instances of the slow-rooting of Hyacinths and Tulips have reached us this season.

LACK OF NOTICE: *E. R.* We think that you were there on trial. It would be unwise to take the matter into a Court.

LAPAGERIA: *Bouvard.* Loam of a rough, turfy kind, two-thirds; peat, one-third; and enough sharp sand as will make the soil porous.

LILY OF THE VALLEY: *Ignoramus.* So long as the plant is at rest it may be planted; and if you can determine those parts of the plant, i.e., buds, or, in garden parlance, crowns, which are three years old, and plant only these, you may get flowers next June as desired. That is the chief point, as crowns older than three years have already flowered, and will not again flower; and those of one and two years are too young for flowering. Three-year-old crowns are obtainable from the Lily of the Valley specialists. See our advertisement columns.

MONOGRAPH OF THE COCCIDÆ OF THE BRITISH ISLES: *A. L.* As was stated in last week's *Gardeners' Chronicle*, it is a publication of the Ray Society, and only obtainable by the members of that society.

NAMES OF FRUITS: *Novice.* 1, Winter Majetin; 2, Minchull Crab; 3, Ribston Pearmain.—*G. C.* 1, Besi Vact; 2, Due de Nemours; 3, Moccas; 4, Notaire Minot.—*B. B.* Irish Reinette.—*F. W.* 1, Jean de Witte; 2, L'Inconnue; 3, Leopold I.—*P. M., Malpas.* 1, Easter Bourré; 2, Glout Moreau; 3, Bourré Sterekmans.—*J. J.* Cassante de Mars.—*C. G. M.* 1, Winter Quoining; 2, Gascoyne's Scarlet Seedling; 3, Royal Russet; 4, Rosemary Russet; 5, Fearn's Pippin; 6, Cockle's Pippin.—*M. A. R.* The Apple is Red Ingestre, one of Knight's seedlings, which originated from the same cross as Yellow Ingestre, and the seed was obtained from the same fruit as the latter variety, which is however much more generally known.—*G. O. R.* The Apples are as follows: green, Winter Greening; bronze, not recognisable, a very poor specimen; red streak, Keeping Red Streak, it is not much grown now, but it was at one time in the Royal Horticultural Society's collection; russet, Pitmaston Nonpareil; lemon, Golden Spire.

NAMES OF PLANTS: *S.* The seed-pods of *Colutea arborescens* (Bladder Senna).—*F. Felix.* *Sericographis* (Jacobinia) *Ghiesbrechtiana*.—*W. C. & Sons.* 1, *Gesnera splendens*; 2, *Billbergia nutans*, figured in the *Botanical Magazine*, t. 6423.—*J. P.* *Ansellia gigantea lutea*.—*W. P. J.* *Dendrobium speciosum*, growing well in a sunny conservatory.—*Crassinode.* The Orchid seems to be *Sophranitis cernua*. It will grow on rafts or blocks suspended in a moderately cool house, and kept moist.—*W. P.* *Areostaphylos Uva-ursi*.—*J. B.* Probably a species of *Panax*, but we cannot be sure from the specimens sent.

PASSIFLORA: *Heliotrope.* The disfigurement upon the leaves may be due to drippings of cold water upon them. It is likely the flowers will set better when the days are a little longer, and warmer.

PEACH SHOOTS DEAD: *W. J. P.* There is nothing observable about the shoots sent to indicate the probable cause of their death. The shoots seem of fair strength, and they are well set with flower and wood-buds. We should attribute the loss to something applied to the soil or to the tree as a wash, or to the grubs of *Scolytus Pruni* or *S. rugulosus*, whose footless larvæ make perpendicular galleries or tunnels between bark and wood, from which in all directions smaller galleries branch out. You should examine the older wood and stem for traces of the borings. There are several other species of borers affecting the Peach. The soil sent appears to be of good quality, and quite suitable for the Peach.

PEACHES AND VINES: *Bouvard.* At the strength of 2 to 3 oz. of Gishurst Soap to the gallon of warm water; no harm will be done whilst the buds remain closed.

RAISER OF THE POTATO SIR JOHN LLEWELYN: *Solanum.* Probably the exhibitor, Mr. J. Harris, Blackpill Nurseries, Swansea. Why do you not write to them for information regarding the novelty?

STREPTOCARPUS: *Bouvard.* Petroleum; a wine-glassful in a gallon of soap-suds, keeping the same well agitated whilst being used. Dipping head downwards in a vessel containing the insecticide is better than syringing the plants. It must be repeated till the mealy bugs are destroyed.

SWEET WILLIAMS INJURED: *T. H. C.* The injury is caused by weevils, for which pay a visit to the plants after dark, providing yourself with a dark-lantern, and having turned on the light suddenly, the creatures will be observed to scamper away in all directions, when you must catch them.

THE NURSERYMEN, MARKET GARDENERS', AND GENERAL HAILSTORM INSURANCE CORPORATION, LTD.: *G. Bradwell.* The above is the full title of the Co., and its offices are at 41 and 42, King Street, Covent Garden, London, W.C.

TOMATOS: *J. W. N.* The young plants are attacked by some fungus, and you cannot do better than use sulphide of potassium (liver of sulphur), at the rate of $\frac{1}{2}$ oz. to one gallon of water; or continue the use of the Bordeaux Mixture or the Wye Mixture, which you have been using hitherto. The early winter-raising of Tomato plants on such an enormous scale is sure sooner or later to lead to a catastrophe, seeing that the conditions of cultivation weaken the plants, rendering them extremely liable to infection. The plant which had been syringed with the Wye Mixture showed the fungus killed or greatly checked. Both plants had evidently been raised in a warm, steamy house, with but little ventilation afforded, as would be the case at this season. We should question the advisability of sowing Tomato-seed at so early a date.

WISTARIAS: *D. K.* The white-flowered *W. chinensis macrobotrys*, and *W. japonica*, also white, are of equal hardness.

GARDENING APPOINTMENTS.

Mr. F. FOLWELL, for the past four and a half years Foreman in the gardens at Foxbury, Chislehurst, as Gardener to CHAS. MORLEY, Esq., M.P., Shockerwick House, Bath; entered upon his duties, February 10.

Mr. GEORGE FORD CHISLETT, for two years and a half Head Gardener at The Manor House, Ringwood, Hants, as Head Gardener to H. EMMONS, Esq., at his new place, Hamble, Southampton.

Mr. JOSEPH SANGSTER, for the last four years Steward and Gardener at Burton Hall, Stillorgan, County Dublin, as Head Gardener and Steward to CHAS. R. HAMILTON, Esq., of Hamwood, Dunboyne, Co. Meath.

Mr. CHAS. BRENNAN, lately Foreman in the Gardens, Kenure Park, Rush, Co. Dublin, as Head Gardener to GEO. F. BROOKE, Esq., D.L., Summertown, Castleknock, Co. Dublin.

Mr. R. Towse, late of Gisburn Park Gardens, Clitheroe, as Gardener to Mrs. Thwaites, Troy, Blackburn.

CALOCHORTUS PLUMMERAE (HORT. WALLACE): COLOUR LILAC.

CALOCHORTUS.

THERE are few if any, flowers that surpass in beauty those of this genus; and there are few, if any, botanists more capable of dealing with them in a satisfactory way than Mr. CARL PURDY. That gentleman has lately issued a revision of the genus *Calochortus* in the *Proceedings of the California Academy of Sciences*. The plants extend from British North-west America to

Mexico, and as far east as Nebraska. This vast area entails considerable variation in soil, climate, and altitude; and a corresponding variation in the plants which grow in it.

It is only in the garden, writes Mr. PURDY, where plants from different localities can be grown under identical conditions, that the relationship between apparently different forms can be satisfactorily determined. Mr. PURDY has had nearly every

known species under cultivation for some years, and the garden has proved the identity of forms apparently different; here also the variations attributed to environment are shown to be constant. In the garden, too, strains which from a botanist's standpoint seem scarcely distinguishable, showed marked differences in vigour, flowering time, or immunity from disease.

Hundreds and thousands of Liliaceous

CALOCHORTUS LEICHTLINI: COLOUR OF FLOWERS
WHITE WITH PURPLE SPOT.

CALOCHORTUS MADRENSIS (A NORTH MEXICAN SPECIES):
COLOUR OF PETALS ORANGE-YELLOW.

CALOCHORTUS PURDYI: COLOUR OF FLOWERS SILVERY-WHITE WITH PURPLISH HAZE.

CALOCHORTUS LUTEUS VAR. WEEDI: FLOWERS RICH YELLOW.

CALOCHORTUS ELEGANS VAR. ANGENA: COLOUR OF FLOWERS LILAC.

plants may in one locality be picked showing little or no variation. In another locality the variation is very observable. The difference may be slight, but the "variant" once noted is found to be constant. The difference is generally such as that which florists denote by the term strain, not that which constitutes a species or variety. Mr. PURDY tells us he has seen places where hundreds of flowers of *C. venustus* could have been selected, each differing in colour and markings from the rest. Why a species that remains so true to a type in some localities should vary so remarkably in others, is a circumstance not easy of explanation. Hybridisation will account for it in some but not in all instances.

In cultivation, a very slight variability in strain is often accompanied by a marked

constitutional difference. In two adjacent beds of *Calochortus venustus* coming from different localities, the differences may be too slight for the botanist's eye to detect. Nevertheless, in the one bed two-thirds of the leaves may be destroyed by mildew (*Botrytis*), whilst in the other not a leaf is affected. The extreme types on which species are founded are easily distinguishable, but a perfect chain of variations links them closely together; thus, there is no doubt that *C. Weedii*, *C. Plummerae*, and *C. obispoensis* are variations from one species. Absolute differences of size, dependent as they are on differences of environment, are of little value as points of distinction, but proportionate differences are of more value. Mr. PURDY describes forty species in two sections, each section divided into a number of groups. An ana-

lytical key will facilitate the identification of any particular species, a process still further aided by a full description of each species, with appropriate bibliographical references and explanatory notes. Figures of *C. Purdyi*, *longibarbus*, *luteus*, *Weedii*, and *macrocarpus* are given. The author, supported no doubt by competent authority, adopts the objectionable practice of spelling personal names with a small initial letter instead of a capital, a proceeding which we are glad to see is not followed in the new Supplement to the *Index Kewensis*. But this is a small matter. Of much greater moment is the fact that Mr. PURDY has laid gardeners, and especially garden-botanists, under great obligations by this publication, which will, we trust, be reprinted in some more easily accessible form than the *Proceedings of the California Academy*.

EARLY TREATISES ON HEATING.

THE subject of heating is obviously one of great importance to all who have greenhouses, and it forms a very considerable part in the economy of the garden. To-day the whole question has become reduced into very narrow proportions, and it is scarcely likely that the many existing "best" methods now employed will undergo any very radical change in the future. Those who have interested themselves in old garden literature will have been struck with the great number of books, dealing with the subject of heating, which appeared at the latter part of the 18th and during the earlier years of the 19th century. Each writer had a new system to demonstrate, the chief qualifications of which were claimed to be efficiency and economy. In a general way, it may be said that these were just the two essential qualities which the old systems lacked.

The number and variety of systems must have been exceedingly embarrassing to amateur gardeners of small means. The discussion passed from beyond the limits of the gardening world, and the *Quarterly*

Review, in *Tan Article* on "Horticulture," some eighty years ago, took up the topic. The writer was probably only attempting to be amusing when he charged Sir George S. Mackenzie, a distinguished and enthusiastic writer on horticulture, with inventing an economical hot-house in which it is proposed to ripen Peaches in the dark! Sir George repudiated the soft impeachment in his pleasant "Gleanings" in the *Memoirs of the Caledonian Horticultural Society*, 1821. There were doubtless scores of other jokes and witticisms at the expense of the advocates and inventors of the various rival systems, but these may be passed over.

I have been fortunate enough to pick up a good many old books which deal wholly or partially with the all-important subject of heating. These books can hardly be described as "light reading," for the authors are all in deadly earnest. One of the earliest books of this class in my collection is by an author whose writings on agricultural and cognate subjects enjoyed a great popularity in their day, Dr. James Anderson, the title of his book being *A Description of a Patent Hot-House, which operates chiefly by the Heat of the Sun, without the aid of Flues, Tan Bark or Steam, &c.*, and is dated 1803. Anderson, who had written many books, chiefly on agricultural subjects, and was a member of many societies, was the son of a Scotch farmer, and himself appears to have had a good deal of experience of rural life in his earlier years, although the attraction of a literary career proved irresistible. A highly appreciative notice of him appeared in *Public Characters*, 1800-1801; but there is a suspicion that Anderson himself, as in the case of the other persons "biographed" in this publication, had a hand in the article.

In regard to Anderson's "Patent Hot-House," the author was clearly a man of theory rather than one of practice. The "mode of applying the principles" in connection with this patent hot-house are: "first, the management of the heat produced by the sun alone, and the modifications of which it is susceptible, with a view to produce the desired effect without the aid of culinary fire; and, second, the management of culinary fires so as to make them produce the greatest effect possible with the smallest expenditure of fuel, and the less expense in other respects." As to the form and construction of the house, Dr. Anderson says:—"Instead of making the roof of the hot-house sloped, as usual, let it be made flat, or nearly horizontal, like the ceiling of a room, and all the joinings of the glasses closed with the utmost accuracy; and the sashes which contain them screwed fast down, and joined close, so as to be airtight." Instead of a flue, "or other contrivance of that sort," "all of which are expensive," the Doctor selected an Argand lamp. The whole of the house is to be surrounded with glass, with as little woodwork as possible, and no brickwork of any sort is allowed. I need not, perhaps, go more fully into details, into which the author enters with an amazing passion for minuteness. He gives a plate of diagrams which appear to be perfectly simple in theory. It is perhaps of more interest now to point out that the inventor conveyed the right of his patent to George Byfield, the architect; Samuel Butler, hot-house builder, of Chelsea; and David Stewart, gardener and hot-house

builder, of Woodlands, Blackheath; and they unanimously declared themselves perfectly satisfied of the efficacy of the plan proposed, "but Mr. Byfield expressed a doubt if the expense of construction would not be greater than the inventor imagined." Dr. Anderson, however, determined to put his theory to the test, directed Butler to erect a house according to his design, and this, after a year's trial, and "notwithstanding those unavoidable blunders in the workmanship which are always experienced on a first undertaking," he "has found that it not only came up to his wishes, but greatly exceeded his highest expectations." The invention appears to have made little or no headway, and the Doctor himself died soon after—in 1808—at West Ham, Essex, at the age of sixty-nine.

The second book on the subject of heating in my collection is by an Irishman, John Cushing, and its title is *The Exotic Gardener*, in which the management of the hot-house, greenhouse, and conservatory is fully and clearly delineated according to modern practice. It was first published at Dublin, in 1811, and ran into a third edition, which was issued in London in 1826. Cushing was an Irishman, and was for many years foreman of the forcing department in the nurseries of Lee & Kennedy, at Hammersmith. G. W. Johnson states that he died in 1819 or 1820. He appears to have left Lee & Kennedy and settled in Ireland, as nearly all of the subscribers, of whom a list is appended to his work, are Irish. He has no new invention to describe, but gives plain, matter-of-fact particulars of his own system of culture—a system which, with some few reservations, was at that time generally followed in good gardens.

One of the earliest mentions of hothouses was communicated to the *Philosophical Transactions* for 1694, by Sir Dudley Cullum, and the paper is described as "a new invented stove, for preserving plants in the greenhouse in winter;" but little progress was made for many years, for even in 1721, when John Mortimer published his *Whole Art of Husbandry* (5th ed.), it would seem that glass was not employed in the construction of greenhouses—perhaps on account of its great cost, and artificial heat seems to have been obtained by open fires in holes sunk in various parts of the floor.* Evelyn, however, mentions the greenhouse and hot-house in the Chelsea Gardens, and observes: "What was very ingenious, was the subterranean heat conveyed by means of a stove under the conservatory, all vaulted with bricks, so that Watts, the gardener, has the doors and windows open in the hardest frosts, excluding only the snow." At about this period also, or a little later, we read in *Switzer* of Bishop Compton's greenhouses at Fulham Palace.

* Apropos of this, I find I have preserved a cutting from one of our daily papers, which is worth reproducing here, but "without prejudice":—

"A curious illustration is given of the way in which one of the houses in the Botanic Garden, Oxford, was heated in the early days of the past century. It was simply a brazier on wheels, and the duty of the gardener was to move this primitive furnace from one spot in the house to another, so as to ensure that the freezing-point should not be attained."

[Our correspondent has not read his *Gardeners' Chronicle* well, or the daily paper was unprofessional enough to quote without giving references, for the paragraph was taken from the *Gardeners' Chronicle*: Many years ago we saw that brazier at Oxford, and obtained our information about it from the veteran botanist William Baxter, the elder. Ed.]

So far as I have been able to find, Anderson's book, which I referred to at the commencement of this article, is the first independent treatise on hothouse building and management. The subject was much discussed at that period, more particularly in the transactions of horticultural societies, as well as in books on gardening generally. In the *Memoirs of the Caledonian Horticultural Society* for 1821, there is an interesting paper "On the Application of Steam to the Heating of Forcing-houses and other kinds of Hothouses and Frames," by John Hay, Planner, Edinburgh. He there gives the results of his experiments, along with a design for a steam valve. From his remarks it is interesting to learn that "the use of steam for the heating of hothouses in general has of late years been much attended to in the neighbourhood of London, particularly by Messrs. Loddiges & Sons, of Hackney." In 1812, George Todd, who described himself as a surveyor and hothouse builder, published a folio volume of plans, elevations, and sections of hothouses, greenhouses, &c.; and since that time the number of books on the subject of greenhouses and the best means of heating them has been, in the words of the local reporter, "too numerous to mention." W. Roberts.

NEW OR NOTEWORTHY PLANTS.

MOSCHOSMA RIPARIUM.*

This is a native of south tropical Africa, both eastern and western, and occurs also in Natal. It is a Labiate shrub, with hairy stems, stalked, ovate, cordate, crenate leaves, and very numerous small, cream-coloured flowers in erect panicles. Mr. Worthington Smith's sketch (fig. 35) gives a good idea of the general appearance of the plant as exhibited lately by Messrs. Veitch at the Royal Horticultural Society. The plant has also been in bloom for some time in No. 4 house at Kew, a circumstance which indicates that the plant is useful for the decoration of stove or warm greenhouses during the winter months.

ORCHID NOTES AND GLEANINGS.

CATTLEYA TRIANÆI.

MR. F. MASON, of Clevedon Court Gardens, Somerset, has sent us a peloriate flower having three sepals and two lateral petals normal, three lips perfect; one anterior in the usual position, two lateral; column normal. The column is generally considered to contain potentially six stamens, of which one only is usually developed. Supposing the column of the flower before us to be represented by A1, as in the Darwinian notation, then the two lateral lips would be the representatives of the two outer lateral stamens A2, A3.

CATTLEYA QUADRICOLOR ALBA.

A fine flower of this pure white Cattleya is kindly sent by Robert Tunstill, Esq., Monkholme, Brierfield, Burnley (gr., Mr. Balmforth). It is a white form of the plant known in gardens as *C. chocoensis*, and *C. Trianæi chocoensis*, but it is as well separated from *C. Trianæi* by its very broad petals, which are almost as broad as long, and by the peculiar arrangement of the segments of the flower, as any of the other forms of *C. labiata* are.

* *Moschosma riparium*, Hochstetter.—Baker, in *Flora Tropical Africa*, vol. v. (1900), pp. 351 and 523; *Basitium myristolachyum*, Hiern, in *Cat. Plant.*, Welwitsch, vol. i., p. 858.

FIG. 35.—*MOSCHOSMA RIPARIUM* (WINTER-FLOWERING SHRUB); FLOWERS CREAM-COLOURED.

Its identity with *Cattleya quadricolor* which appeared in the collection of the late Mr. Rucker in 1850, and which was published by Bateman in the *Gardeners' Chronicle*, 1861, p. 269, is well established. It is one of the most elegant of *Cattleyas*, its extraordinarily broad petals rendering it very attractive. The whole flower is pure white except the disc of the lip, which is yellow.

DENDROBIUM CAPILLIPES.

Pseudo-bulbs bearing flowers of this pretty little Burman species are sent by Mr. J. Cole, gr. to — Smallpage, Esq., Craigmoor, Little Orme's Head, Llandudno, where it is said to be flowering very effectively. The pseudo-bulbs, some 3 inches in length, are stout, and much resembling small ones of *D. albo-sanguineum*. The flowers, which are over an

named handsome form has flowered in the collection of Robert Tunstill, Esq., Monkholme, Brierfield, near Burnley (gr., Mr. Balmforth). It is a beautifully-formed flower, just over 3 inches across; and the sepals and petals, which are nearly equal in width, are 1½ in. wide; the plain-edged sepals are white, with clusters of three to four irregularly elongated, dark rose-red blotches in each; the fringed petals are pure white; the fringed lip white, with a yellow crest, beside which are several dark red spots, and in front one large reddish blotch. Distinct features about it are its fine shape, and the peculiar red-tinted colour of its markings.

ODONTOGLOSSUM TRIUMPHANS VARIETIES.

A large number of this fine *Odontoglossum* have already bloomed at Messrs. T. Rochford

The base of the lip is pure white, the middle portion brown, and the tip yellow. The lighter form more nearly approaches *O. triumphans*, but it has also an elongated apiculate labellum. The sepals and petals are yellow, closely marked with narrow, oblong, transverse, brownish-orange markings. Both are very singular and distinct. The lighter one has been proved to be constant, and the darker is now flowering for the first time from a small plant. It now bears but one flower, but with good cultivation the large size and peculiar features may be expected to be maintained on a large inflorescence.

LÆLIA ANCEPS HOLLIDAYANA CRAWSHAYANA.

In the *Gardeners' Chronicle*, February 10, 1891, the type of *Lælia anceps Hollidayana* was described by Mr. James O'Brien; and in the issue for January 27 of the same year, he described *L. a. Ashworthiana*, a figure of which was also given at p. 103 of the same date. Both were imported by Messrs. F. Sander & Co. from the Orizaba district, and the distinguishing features were the finely-formed flowers and the highly-developed, square-fronted labellum.

In the variety *Crawshayana* (fig. 36), for which De B. Crawshay, Esq., Rosefield, Sevenoaks (gr., Mr. Stables), was awarded a First-class Certificate at the Royal Horticultural Society on Jan. 28 this year, while the general characteristics of the type are closely adhered to, the variety is florally better in every respect than any of the section which have yet appeared. The flowers are of fine substance, white, with chocolate-purple lines on the inside of the side lobes of the lip; a yellow crest, and a delicate pencilling of rose-colour on the front lobe.

FLORISTS' FLOWERS.

WINTER-FLOWERING CARNATIONS.

In the interesting article on winter-flowering Carnations, p. 70, by Mr. T. H. Slade, there are one or two points which appear to me to invite criticism. First, as to the size of cutting used. Is not a cutting of 4 inches long far too large for the majority of varieties? Mrs. T. W. Lawson will strike freely, I know, at that size, but to produce the most prolific plants of the varieties mostly cultivated, small side-shoots from the flowering stems, and averaging perhaps less than 3 inches in length, are preferred, for they root more freely than stronger cuttings taken from the basal growths, which correspond with the layering shoots of our ordinary border varieties.

Secondly, as to the value of Mrs. Leo Rothschild, which I prefer to call by its original name of *Mlle. Thérèse Franco*. With me it is absolutely the most reliable of all, and may be flowered, and flowered freely, from September to May; and this is, I believe, the generally accepted opinion. I feel convinced that it is due in a great measure to the value of this variety that this class of Carnation is now so popular. I hope Mr. Slade will some day find cause to modify his opinion of its merits.

Mr. Slade does not mention Reginald Godfrey among his selected varieties. It is another of our best. The flowers are slightly paler than those of *Thérèse Franco*, but are very full, and the plant is a free grower. It is a true winter-flowering variety, in which it differs from many sent out as such. Flora

FIG. 36.—LÆLIA ANCEPS HOLLIDAYANA CRAWSHAYANA.

inch across, are borne on slender, upright stems either singly or in pairs; the large labellum and petals almost concealing the lesser sepals. The colour is bright yellow, the lip having an orange-coloured disc. It is a neat, dwarf, early spring-flowering species, and one which is by no means common.

Flowers of a fine variety of *Dendrobium crassinode*, and a *D. Wardianum* with rose-pink tips to the sepals and petals, instead of the usual purplish-rose colour, are also sent.

ODONTOGLOSSUM CRISPUM REEDLEYENSE.

Blotched varieties of *Odontoglossum crispum* have been first favourites for some years past, and during that time many fine forms have flowered out of the importations received. A marked peculiarity about them is that each variety is positively distinct from all others, and easily recognisable by some feature to those who study them. The above-

& Sons, Turnford Hall Nurseries, Broxbourne, and among them there is considerable variation of form and colour, though the typical characters of structure are in most cases maintained. Two forms, however, exhibit marked structural differences, which seem to indicate that they are natural hybrids of the *O. diceranophorum* class (*Lindleyanum* × *triumphans*): Reh. f., *Gardeners' Chronicle*, March 17, 1888, p. 330; although it is difficult to understand how such a combination should result in flowers with longer segments than those of *O. triumphans*. The darker flower has narrow segments, which measure from tip to tip of the sepals 6 inches. The colour of the sepals and petals is like that of a good *triumphans*, viz., bright yellow, with glossy chestnut-coloured blotches, and clear yellow tips. The lip is only about half as wide as that of typical *O. triumphans*, and nearly twice as long, the front being continued into an acute point.

Hill and Mary Godfrey are our two best whites; the former is not flimsy here, though perhaps its deeply fringed edge gives it a slight appearance of flimsiness—it is full, and very sweet-scented. Mrs. Moore, after many years' acquaintance, and Deutsche Brandt, a variety of very poor constitution, I am discarding. Mary Godfrey has smooth edges, and a shell-like petal; it is very chaste in appearance, though some of its later flowers are tinged with rose, which scarcely detracts from its appearance.

Firefly is an excellent scarlet of good constitution, which I prefer to Wm. Robinson, as it is not so tall. Both are, however, good varieties. Sir R. Buller is shy in flowering, and the shoots should not be stopped; but the qualities of the flower are so magnificent that it cannot be spared. Individual flowers last almost twice as long as those of any other variety we have. The work of selection is interesting. I am discarding this year about a score of varieties found wanting in some point or other, and am still retaining more than that number, including half a dozen of the latest American varieties for further trial, as their journey across the water prevented their developing perfectly. *J. C. Tallack.*

BULB GARDEN.

LILIUM GIGANTEUM.

IN his interesting papers on "Lilies and their Culture," Mr. G. B. Mallett writes that *L. giganteum* "cannot be cultivated with any measure of success in the open border." This statement from an authority on Lilies being calculated to dissuade amateurs from attempting the cultivation of this grand Lily because they are unable to provide it with "rather dense shade," I venture to reassure them by a few words on the fairly successful culture of *L. giganteum* in sites where little or no shade was available. It is a well-known fact that in its native habitat *L. giganteum* grows invariably in the shade thrown by forest trees, but, as in the cases of many plants that are capable of making tolerably satisfactory growth under conditions that do not obtain in their natural homes, this Lily, if its wants are well cared for in other matters, will often grow and flower well even in open situations. In a sheltered and moist valley in the neighbourhood of Torquay, I grew *L. giganteum* for several years, and many fine flower-spikes were thrown up from a bed that was shadeless from 10 A.M. to sunset. I believe that flower-spikes 13 feet in height have been recorded. My best spike fell short of this height by 3 feet 2 inches, but an average of 9 feet was not uncommon. A bed 3 feet in depth, consisting of three-parts leaf-mould and one of loam, was provided, and the plants were copiously watered while making growth, while weak liquid-manure was given when the flower-spike was being thrown up. In the winter the bed had a heavy mulch of decayed hot-bed manure. In the garden in question some thirty species of Lilies grew, and for the most part flourished. On the steep, dry slope of light soil where I am now living, successful Lily-culture, except perhaps in the case of *L. rubellum*, is out of the question. In other gardens I have seen flower-spikes of *L. giganteum* from 8 feet to 10 feet in height produced by plants growing in a sunny position. But the most striking instance of this Lily exhibiting vigorous health in an unshaded position was met with by me in a certain Cornish garden during the past summer; in this garden I witnessed a sight that I never expected to see,

either in England or elsewhere, namely, about seventy flower-spikes of *Lilium giganteum*, fifty of which were in one colony. It was early summer, and the rapidly-lengthening flower-stalks showed as yet no sign of buds, but all looked pictures of health and robustness, and no doubt attained the height usual in the species. All these Lilies were raised from seed, perhaps the most advisable method of propagation if one has patience to await the long-deferred blossoming. If bulbs instead of seeds are relied on, Mr. Mallett's recommendation that small and not first-sized ones should be planted must be followed, if fine flower-spikes are to be produced, since, although the season of waiting will be longer, the ultimate effect will be far more satisfactory, for fine spikes are never thrown up by recently-planted bulbs.

In conclusion, I would suggest to those who are anxious to grow *Lilium giganteum*, that if they have at their disposal a shady spot where the roots of the Lilies will not be encroached upon by those of surrounding trees, they should plant the bulbs there; but that if no such site be available, they need not despair of achieving success in an open and sunny site, provided they spare no pains in attending to the wants of the Lilies in other respects. *S. W. F., Kingswear, S. Devon.*

LILY OF THE VALLEY.

YOUR correspondent, "E. N., Chatham," notes a failure that is by no means an isolated instance. I believe at the present time more gardeners fail to flower retarded Lily of the Valley than those who succeed, and I think I may safely say that in nine cases out of every ten this is due to placing them in too much heat at first. The point to remember is this, that the energies of these plants or roots have been suppressed by keeping them in a very low temperature for months after their usual flowering season. Therefore, as soon as they are exposed to a temperature a few degrees above the freezing point, and away from keen draughts, they will commence growth and produce flowers. But if they are placed in a high temperature, such as your correspondent speaks of, viz., 75°, so surely will they fail.

I believe it was six or seven years since one of the large importers of Lilies called my attention to these retarded roots, at the same time sending me a few bundles for trial, with written instructions as to their management, which I carried out to the letter, and needless to say, proved satisfactory. Since that time I have flowered many thousands, and perhaps you will allow me a little of your space wherein to describe my treatment. There is not the least doubt in my mind that cool treatment for these retarded roots is the correct course, viz., a temperature of 45° is sufficient to start with. But supposing they were required in flower at a certain date, and there was any doubt about this, a rise of 5° will not do any harm, and will have the desired effect. Temperatures, however, are not all the requirements. They should be potted or boxed in rather heavy soil, very firmly indeed, and must be heavily shaded (kept nearly in the dark), and of course should receive a thorough application of water. They must never be allowed to become dry, or anything approaching dryness. Under this kind of treatment they will have made 6 inches of growth in about ten days, and may be exposed to a little more light; but the degree of moisture must be maintained, and no direct sunlight admitted, as to do this would prove disastrous, especially if the leaves and flower-spikes are well advanced. A considerable amount of

shade must be afforded till the flower-spikes are well open, fit indeed for cutting; in fact, spikes will not bear exposure to full sunlight at any time. I have in my mind those plants that are to flower during the Christmas season and January.

In the event of flowers being required in the summer or autumn months, a common garden-frame placed in a slightly shady part of the garden is an excellent place for them. I simply plant them out in rows, or rather spread the bundles out in shallow trenches, and made the soil thoroughly firm about them. The two matters to guard against are excess of heat and light, for either of these will prove fatal. Crowns treated in the manner described will flower in from twenty-one to twenty-four days after being taken from the refrigerator. I fear I have overstepped the limits of space, but should it seem desirable, I will deal with *Spiraeas*, *Liliums*, and other retarded plants at a later date. [Please, do so. Ed.] *Thomas Arnold.*

FLOWERS WHICH CHANGE COLOUR.

(Concluded from p. 107.)

BUT now we have to call attention to another fact, which has perhaps hardly been sufficiently observed. We have seen that individual flowers, like the Forget-me-Not, change from yellow or white to pink, red, and blue. Next we have seen that groups of plants, like the Geraniums, reveal a similar order. Now take the flowers of the seasons, and look at them broadly for a similar law. In the early spring, we have flowers which are green, greenish-yellow, and yellow, as the Moschatel, Ivy, Hellebore, Celandine, and Buttercups. Then come the white flowers, as Dead-nettle, Daisy and Oxeye, Campion, Bedstraws, Umbels; and when the summer is here, and insect life is fully developed, we find all our Clovers, Vetches, Heathers, Bluebells, highly coloured Composites, Roses, Mallows, Irises, Geraniums, and other red, purple, blue, and richly pigmented blossoms. The fact is too patent and conspicuous to be passed over unobserved, and its bearing is entirely in harmony with the conclusions which the study of the previous facts would suggest. But before we try to ascertain the moral, it will be necessary to meet some objections.

It will be remarked by some careful observer that there are several highly coloured flowers in spring. What are they? Our native flora yields few save the Violets. True, we may possibly find the Columbine, an early Furnitory, the Mezerion, and one or two other plants with coloured flowers; but they are the exceptions which prove the rule. Their study is full of instruction and suggestion, but they are to be regarded from another point of view if we would understand them fully.

Again, it will be said that it is no unusual thing to find white varieties of red, purple, and blue flowers, and that this shows the law to be unreliable. Here we have again to deal with a noteworthy exception. Bluebells, Milkwort, Thistles, and many other plants with highly-coloured flowers do vary considerably. The further north we go the more prevalent does the albino become. White heather, which is regarded as lucky, white Bluebells, albino bugles, and other forms abound in Scotland, Sweden and Norway, and it would be possible greatly to enlarge these notes if one were writing for those who are familiar with botanical terms and distant floras. There are, moreover, several books which the student can consult if he prefers reading about such subjects to going into field botany for him-

self. Climate, soil, disease, may account for many exceptions.

Let us now turn to the practical issue. Flowers tend to change colour. These colour changes are of various kinds, and are wrought out under the influence of definite laws. The first thing I want to notice is that fading flowers often assume a higher colour as they complete their life-work. What a beautiful fact if one were preaching a sermon. What a pity more preachers are not naturalists. The law has been well stated in the following words: "We may lay it down as a principle that the fading colours of less developed petals often answer to the normal colours of more developed." This law holds good also between the different species of a genus, or among the various members of an order. Thus we find many flowers in the Forget-me-Not group which are pink, flesh-coloured, or red, when perfectly developed. This colour corresponds with the early stages

addresses until that colour appeared." Bees and butterflies are quick at colour-reading, and they have their individual preferences. Here in my garden is a blue Speedwell, around which the bees are busy all the day. The Dandelion, and many other yellow flowers, will be found alive with beetles and flies, while the Scabious, Foxglove, Bluebell, Cornflower, Sage, Heather, and other red, purple, and blue flowers, are being visited by bees and butterflies. One further interesting fact must also be observed. The æsthetic taste of the bees correspond with our own. The colours and perfumes which please us gratify them as well. Thus, the stock of bright blossoms and fragrant flowers which we love, is perpetuated by their industry. If the case were otherwise, what pleasures should we lose! Who will account for this? Can anyone affirm that the matter is accidental? We prefer to believe it to be divinely arranged. *A Sussex Naturalist.*

FIG. 37.—DENDROBIUM WARDIANUM FOWLERI.

of other flowers which change to purple and blue in their ultimate stages. This general law again obtains in relation to the seasons, so that the blue and purple flowers predominate when the insects are fully developed.

It seems evident from these three converging lines, that we must arrive at the following conclusion: Colour has relation to insect life. The higher the colour, the higher the form of insect which is attracted. Yellow is the colour for beetles, blue for bees. This fact is capable of abundant demonstration. I give one or two illustrations in conclusion. In South America there exists a *Viburnum* which changes colour as its flowering advances. It is yellow on the first day, orange on the second, and purple on the third. Now Müller observed that various butterflies visited the tree, and he was struck by the fact that "each kind of butterfly which visited it stuck rigidly to its own favourite colour, waiting to pay its

DENDROBIUM WARDIANUM FOWLERI.

In this remarkable variety, which was exhibited at the Royal Horticultural Society, January 28, by J. Gurney Fowler, Esq., Glebelands, South Woodford (gr., Mr. J. Davis), we have an example of *peloria*, as it is called with flowers generally, but which among Orchidists is known as *tri-labellia*, and of which a familiar example is the now plentiful *Dendrobium nobile* (Cooksoni), which has steadily remained constant, and it is to be presumed the abnormal characters of *D. Wardianum Fowleri* will also be maintained. It will be seen by our illustration (fig. 37) that the two lateral sepals have yellow marking with a purple blotch, after the manner of the colour displayed in the labellum, the rest of the flower being white, with rose-purple tips, as in the normal form. The variety received an Award of Merit.

CULTURAL MEMORANDUM.

MELON GROWING IN POTS.

HAVING read the note from your correspondent on the above subject with much interest, may I be allowed to make a few remarks on this subject. Few gardeners of the present day practice the pot culture of Melons, thinking that the application of enough bottom-heat is impracticable. If fruits of middle size and fine flavour are desired, the seeds should be sown early in the month of March, then good results can be obtained.

Last year I made use of pots and secured a good crop (as reference to the *Gardeners' Chronicle* for September 21, 1901, will show), without bottom-heat, and from the time I planted them in the fruiting-pots no artificial top-heat, the thermometer in the house often falling to 48°, which may appear to some too low for success with Melons. My practice is to place a strong plant in a 12-inch pot, which is allowed to go on to its full limit before stopping it. The plant will make short joints (a thing greatly in favour of fruiting), and push out shoots at every joint, and nearly every one of these will show a fruit; but, it not being essential to set all the fruits at once that the plant is to carry, some of the blossoms are fertilised three weeks later, and this can be done with good results. All non-fruiting lateral shoots must be cut off close to the stem, and after the fruit has reached a safe stage, the plant may be fed to any extent; what I usually afford is manure-water, and maintain the feeding till the fruit showed signs of ripening, when it is discontinued.

By the use of pots the plants receive the full benefit of the manure. My plants showed no signs of canker, nor did the fruits split. *W. J. Cosham, gr., Hillside, Groombridge.*

NEW INVENTIONS.

A NEW KIND OF VAPORISER.

WE have recently received a vaporiser for use in glasshouses, now being manufactured and sold by Messrs. W. J. Bush & Co., Ltd., Ash Grove, Hackney, London, N.E. It consists of a black-tin cylinder 7 inches in height, and 1 inches in diameter, fitted with a door in the side, a portable dish of copper for holding the liquid, a glass lamp for holding methylated spirits, and a cotton wick, the whole being strongly made and well finished. The 3 oz. bottle of compound accompanying the apparatus is stated to be capable of fumigating a house or houses containing 4,000 cubic feet at the cost of 3s. 6d. As yet we are unable to certify as to the efficiency of the compound in destroying plant pests, but hope to test it shortly.

COOPER'S FLEXIBLE CARBON FIBRE.

Watching the articles pretty closely in the *Gardeners' Chronicle*, I was struck particularly with one a short time ago concerning leaf-mould as a medium in which to cultivate Orchids. I am pleased to say I quite agree with the writer in one thing especially, that is, artificial cultivation of Orchids require treatment somewhat different to what they obtain in their natural state. For one reason, we cannot hope to supply exactly all that they get in their wild state; and yet from my experience in some cases we are able even to improve them by intelligent aid, and I feel sure that much is to be done by those bold enough to try. I have ventured to send for the writer of the article two samples of what appears to fit in with his ideas, and wish par-

ticularly to be understood that I am simply writing as an inventor who, after patient experiments, believes in his invention. To be candid, I may say that I made a slight mistake in sending the fibre out in its pure state. I expected the majority would know what to do, but some, I am sorry to say, expected it to be entirely different to what it really is. You will see one canister is prepared ready for use for most plants, yet can be altered as found desirable. The other canister contains pure fibre unchopped, as a pad of it is useful to cover the crocks instead of sphagnum-moss, and for other purposes that will present themselves. I may say the patent has been completed, and that I am prepared to back it up with a thousand pounds if required to advertise it, but I find it is useless to bother with the trade for a start—they simply want to sell their plants, and do not care much for scientific research. *E. W. Cooper.* [Some well-known cultivators report favourably upon it, and we intend to have it tested still further. Ed.]

TREES AND SHRUBS.

HAMAMELIS MOLLIS.

MR. BURBIDGE tells us that this Chinese shrub is flowering in the gardens at Hamwood, Dunboyn, co. Meath. It is a fortnight earlier to bloom than *H. arborea* or *H. japonica*. It has thicker shoots, more softly tomentose, and the flowers are denser and more brightly coloured than in its allies. It was introduced from China by Messrs. Veitch, and is a most desirable addition to our winter-blooming hardy shrubs.

ROBINIA HISPIDA, AND OTHERS.

The so-called Rose Acacia is a shrub of large size, as distinct as it is handsome, producing great masses of flowers; in fact, its flowers are so numerous sometimes as to almost break down the bushes, and I have often been obliged to fasten them up to stakes. It is a plant well suited for growing in pleasure-grounds, large or small, and it generally does well in any kind of soil. At Compton Bassett they are planted in various positions, and they are unusually attractive. Another very pretty species is *R. pseudo-Acacia Decaisneana*, a shrub of more upright habit, with pink flowers, produced very freely. This species is of robust growth, and soon forms a fine tree. It should not be planted in exposed positions, or the wind will greatly damage it. The tree is not particular as to soil. *W. A. Cook.*

The Week's Work.

FRUITS UNDER GLASS.

By JAMES WHYTECK, Gardener to the DUKE OF BUCCLEUCH, Dalkeith.

Pineapples.—Fruiting Queens which have been rested, and are rather dry at the root, should now have the soil thoroughly moistened, and the bottom-heat maintained at 85° to 90°. the atmospheric heat being 65° at night and 80° with sun-heat by day. Let the air of the house be kept uniformly moist. Suckers of Queen Pines potted-up in the autumn into 6-inch pots should now be shifted into the fruiting-pots, that is, pots of 10 inches in diameter; and before the work is started, let fresh tan be got ready to mix with the old, fresh, turfy, and rather light and dry loam, and mix bone-meal with it; also see that the pots are well cleansed and properly drained. The suckers a few days previously should receive a thorough application of water. When the plants are turned out of the pots, remove the surface-soil and the crocks, slightly disentangle the roots, place the old

ball rather low down in the pot, fill in round it with small quantities of soil, making it moderately firm with a rammer, and afford no water for a fortnight. The newly-potted plants should be plunged in the freshened-up bark-bed at 2 feet apart, and afforded a bottom-heat of 85° to 90°, and top-heat at night of 60°, and 70° by day, and a little more when the sun shines. The house should be kept close for a week, and no effort made to force growth by higher temperatures than those I have given. If the plunging thermometer shows an excess on the above figures for bottom-heat, slightly elevate the plants by placing a little tan under the pots, replunging when the heat declines.

The Earliest Pot Vines.—The Vines should be top-dressed without loss of time, using turfy loam, mixed with Vine-manure. It is an advantage to have the pots placed on large turfs of fibrous loam, and on a solid base, and to sprinkle the turves with Vine-manure. A barrel of cowhouse drainings should be kept at hand, and as it is usually rather potent, only a very small quantity should be added to the clean tepid water used. It should be frequently employed. The gardener must carefully guard against the soil in the pots becoming soddened. Let growth be encouraged, restricting only the laterals on shoots which are carrying bunches. With bright days and cold weather ventilation must be carefully studied, reducing the amount of fire-heat in the midday hour when possible, and at the warmest part of the day, or when the house is 10° higher than in the early morning. Admit a small amount of air at the top of theinery, closing the ventilators early, and damping paths and surfaces frequently, using weak cowshed-water occasionally for damping purposes, the ammonia thereby given off being helpful to the foliage, and checking the spread of red-spider.

Early Vines in Borders having the fruit set, should have all of the bunches not required removed, and berries thinned on those that remain. Encourage the growth of foliage to the fullest extent of the space allowed, and what restriction is called for should be carried out at frequent intervals, it being bad practice to allow a lot of growth and then cutting it away. Maintain a night temperature on cold nights of 60°, or 5° more on mild nights, advancing to 80° or 85° in the daytime with sunshine; and during spells of cold winds the ventilation must be carried out, especially at the early stages, or the berries will be marked. Afford inside borders a sprinkling of Vine-manure, and wash it in with tepid water, or use water with weak liquid-manure; a mulch of rotten manure will now be a benefit on the border.

THE HARDY FRUIT GARDEN.

By J. MAYNE, Gardener to the Hon. MARK ROLLE, Bickton, East Budleigh, Devonshire.

Spraying Fruit Trees.—The latter half of the present month is considered the best time for this operation, first completing any arrears in the matter of pruning, so that the wash can be put on before the buds get prominent. Doubtless the caustic soda and potash solution repeatedly recommended in these pages is the most effective, but on account of its corrosive action on the skin and clothes, many hesitate to make use of it. For spraying large trees the Stott sprayer is a capital invention, and at the present time is being used by the tenants on this estate upon orchard trees. It is used on the farms for spraying Charlock among Barley, but is easily adapted for using on fruit-trees by the addition of a few yards of hose and a fine-spraying nozzle. A calm, dry day is necessary for the work, and every care must be taken that the mixture does not come in contact with the skin. Besides destroying the insects that it touches as well as their eggs, also lichen and moss, leaving the tree bright and clean. To make this preparation, dissolve 1 lb. of crude commercial potash, 1 lb. of caustic soda, in 10 to 12 gallons of hot water, say at 110°; a little common treacle added will

make it stick on better. Apples, Pears, and Plums will stand it at the above strength, but for Peaches and Apricots 3 to 4 gallons more of water should be added. Keep the mixture well agitated while spraying is going on, and at the temperature stated above; but this is not always convenient.

Raspberries.—Established canes should have their tops shortened down to a plump bud. The canes planted in the autumn or early in the year are the better for being cut down to within 18 inches of the soil about the present date, and thus concentrate the energy of the plant for the production of strong growths for fruiting next year in preference to taking a few fruits this year. Autumn-bearing varieties require to be cut to the ground level at the end of February each year, and receive a good mulching of rich manure over the roots, which may be lightly forked in later on.

Bush fruits.—Newly-planted bushes of Gooseberries and Currants may be pruned into shape a bit, though if but one year from the cutting, which usually have three or four shoots, they will merely require shortening to within three buds of the base of each shoot. Gooseberries of erect habit of growth should have all shoots cut to a left bud, facing outwards; spreading-habited ones to a bud looking inwards; and pendulous-habited bushes to an upward-formed bud. The frosty weather at this date is very acceptable in the W. and S.W., as it will retard the blossoming of Apricots, Peaches, and Pears, which in these gardens are too far advanced for the time of year. Though the frost may be severe, pruning may be carried on for several hours during the warmer parts of the day; and recently planted trees of the trio just mentioned should be afforded whatever pruning is required before the buds get prominent. As the Apricot is the first to expand its blossoms, protection should be got in readiness, the erection and use of which will be dealt with in my next contribution.

THE KITCHEN GARDEN.

By T. TURTON, Gr. to J. K. D. WINGFIELD DIGBY, Esq., Sherborne Castle, Dorset.

Rhubarb.—Owing to the generally short Apple crop of last season, Rhubarb is in more demand than usual this season, and the supply must be kept up by placing a good batch of roots in a Mushroom-house at intervals of a fortnight. From now onwards I prefer Myatt's Victoria Rhubarb, which yields plenty of fine stalks of a nice colour. Where the supply of roots is not large, the forced roots will do for replanting, if properly hardened off when taken from the Mushroom-house, &c. They may be placed against the side of a hot-bed, and covered with leaf-mould, with some long litter over the crowns. Deeply trench and heavily manure the ground intended for the new plantation, which should be planted during the present month. Rhubarb pays for deep cultivation, and is most productive on retentive soils. The earlier varieties are showing signs of renewal of growth, and Seakale-pots may be placed over a few of the earlier roots, and surrounded with some sweetened fermenting material. Lacking Seakale or large plant-pots, boxes measuring 18 inches square at the bottom, 1 foot at the top, and 2 feet high, made with a cover, will answer instead. When made of seasoned Elm, they endure for several years. Some larger boxes, or barrels with the ends knocked out, are suitable for placing over crowns of Myatt's Victoria when they begin to grow, and no further protection beyond covering the top afforded.

Asparagus.—Where much Asparagus is forced, a certain quantity of land should be sown with Asparagus each year; and although a few weeks hence will be early enough to sow, the land should be now well prepared in readiness for sowing. Asparagus prefers a light, deeply worked soil, and it should be well enriched with good stable manure if the soil be retentive. In addition to a heavy dressing of the kind of manure named, roadside

trimmings which have been in good sized heaps for at least twelve months, river sand, charred garden refuse, old hot-bed soil, and anything of that nature should be incorporated with the soil in the course of trenching it. These additions will raise the soil considerably; and should the position be very damp, and in consequence cold, the beds should be raised still more by throwing soil from the alleys on to the spaces where the beds will be. I prefer sowing, to planting one or two-year-old plants.

Celery.—The seeds of Celery required early in September should be sown thinly forthwith in a compost of two-thirds good loam, and one-third equal parts spent mushroom-bed dung and leaf-mould, with a dash of silver sand, putting the soil into shallow boxes, and placing these in a temperature of from 55° to 60°. The boxes should be covered with sheets of glass, which need not be raised till the seeds have germinated. Place the plants near the glass, and harden them off so that they will withstand being pricked off into cold frames on hard bottom during April. It is usual to grow white Celery only for the early crop, as it blanches more readily than the red varieties. It is, however, advisable to sow an early pink or red variety also at the same time.

Sowing of Various Seeds.—Where a suitable border with a south or westerly aspect exists, small sowings of the following seeds may be made in skeleton frames made with 11-inch boards, and covered with spare lights from pits or frames, viz., Brussels Sprouts, Autumn Giant Cauliflowers, Early White Milan Turnips, French forcing Carrot, Radishes (Turnip and long-rooted), Leeks, Commodore Nutt and White Cos Lettuces. All of the above except Lettuce Commodore Nutt, which should be sown thinly broadcast and left to turn in for use, should be sown in drills made 9 inches apart. Sown thus, seedlings do not get drawn as when grown in hot-bed frames, and in the case of Brussels Sprouts, &c., they do not receive the same check as when transplanted from hot-bed frames.

THE FLOWER GARDEN.

By R. DAVIDSON, Gardener to EARL CADOGAN, Culford Hall, Bury St. Edmunds.

Gladiolus.—The corms should be planted as soon as the ground becomes fit for working; and if, as is usually done, sunny positions are chosen for the beds, groups, &c., and the ground is heavily manured and deeply dug, it will be ready for planting in March. Where small groups are to be planted, let the soil at planting-time be shovelled out to the depth of 4 ins., put in wheelbarrows, and place the corms at distances varying from 2 to 7 inches, according to the size to which the variety grows. The corms being firmly set on the soil, fill in the holes evenly with the excavated soil, and make smooth. If planted in borders, line out these into beds of about 5 feet in width, with alleys 18 inches wide between them, and draw drills at 10 inches apart and 4 inches deep, planting and covering the corms as above. Hybrids of *G. gandavensis* planted amongst *Hydrangea paniculata grandiflora* flower at the same season as the latter, and make an effective display. *G. The Bride* is excellent for massing in the herbaceous border, or associated with early-flowering Pentstemons of brilliant colours.

Hyacinthus candicans.—This ornamental Liliaceous plant makes telling masses in the front parts of the shrubberies, and the plant is not over-fastidious as to soil, but if a small quantity of sandy peat is incorporated with the staple, its needs are suited exactly. Proceed as with *Gladiolus*, but put the bulbs 3 inches down in the soil and 7 inches apart. Sprinkle some sharp sand over the bulbs before covering with the soil. In the event of severe frosts, a covering of cocoa-fibre refuse or half-decayed tree-leaves will keep out frost. When planted irregularly in beds or borders of Tree Peonies that are not too tall, the effects are highly decorative, or they may be planted in beds in company with *Gladiolus Brenchleyensis*.

Montbretias.—The flowers of these are of much value for cutting and decoration generally, and no time should be lost in planting them. For this purpose plant only selected and thoroughly matured flowering bulbs, on a south or west border. The plant succeeds in a light, rich soil, and they may be planted in beds similarly to *Gladiolus*, i.e., in drills 7 inches apart, and not more than half an inch between the corms, covering the whole evenly 2½ inches deep. Plant also in unoccupied spaces towards the front of the herbaceous border, where they afford a pleasing diversity of colour throughout the autumn.

THE ORCHID HOUSES.

By W. P. BOUND, Gardener to J. COLMAN, Esq., Gatton Park, Reigate.

Epidendrums for Covering Walls, &c.—*E. radicans* and the hybrid *E. O'Brienianum* are two Orchids adapted for training on the glass or solid ends of Dendrobium-stove or Cattleya-house, being fastened to bamboo-rods, and carried up to wires stretched transversely. The plants treated in this manner have pleasing effects when there is not much else in flower. When ably grown, the species named, more especially *E. radicans*, are nearly always in flower, and the flowers are useful for buttonholes. A suitable compost for these *Epidendrums* consists of equal parts of turfy-peat and chopped sphagnum-moss, and they should have plenty of light, a fair proportion of sunshine, and frequent syringings. The plants are increased by means of the aerial growths, which should be cut off and potted.

Trichosma suavis.—This pretty winter-flowering plant is now growing freely, and if potting is necessary this season, attention should be at once given to it. The plant succeeds in a compost consisting of good turfy peat two-thirds, chopped sphagnum moss one-third; the drainage should be good, so that the plant can have copious supplies of water during the spring and summer months without risk of souring the compost. A place in the cooler part of an intermediate-house suits the plant. Its fragrance, and the fact that it flowers in the winter, should make the species a favourite.

Phalenopsis.—The plants should still be kept rather drier than wet if the atmosphere in the house be kept humid as it should be. In some gardens, *Phalenopsis* are very difficult plants to grow, and it is not easy to define the reason why this should be. I have known them to succeed capitally in one house, and go back when removed to another where the same conditions have been maintained. An old house is preferable, and one where a very moist air prevails during the season of growth. A propagating-house where the moisture arises from the cocoa-fibre refuse plunging material laying over the hot-water pipes which supply the bottom-heat, often makes a suitable house. If the plants are suspended, the flower-spikes should be kept tied down away from the glass; and in the case of any plant not in good health, it should not be allowed to produce flowers. *Phalenopsis* will often throw up flower-spikes, when it would be fatal to let them remain on the plant. The moss should be kept well away from the centre of the plants. The temperature advised for the stove Orchid-house should be maintained.

Calanthes.—Most of the deciduous species and varieties having passed out of flower, should be afforded a rest; and if space is no object, the plants may be left in the pots and kept quite dry. Otherwise, shake them out, secure the labels to the pseudo-bulbs, and place the latter in shallow boxes with sand, keeping the dormant bud above the level of the sand. A shelf in the Cattleya or intermediate-house forms a suitable place on which to set them, or any house where the air is dryish, and the temperature does not fall below 55°. On no account should they be stored where they are exposed to full sunlight.

PLANTS UNDER GLASS.

By J. C. TALLACK, Gardener to E. MILLER MUNDY, Esq., Shipley Hall, Derby.

Humeas.—The earliest plants should now be ready for placing in the flowering pots, and not allowed first to get pot-bound. A mixture of peat, loam, leaf-mould, in equal proportions, and sand, is suitable; more peat or leaf-mould being employed if the loam is very tenacious. To afford water soon after potting is not advisable, and if the balls are in a fairly moist condition beforehand, and the potting soil is moist enough to bind without becoming pasty, no water will be needed for some time. Keep the plants in the greenhouse, as they dislike fire-heat; and do not use the syringe on them.

Begonia Gloire de Lorraine.—This is undoubtedly the most popular of winter-flowering Begonias, and its decorative merits are such as to make it quite invaluable in any garden. Given an intermediate temperature only when flowering, its season of growth is extended beyond the time when plants intended for stock should be at rest, and it is possible to keep the same batch of plants in a presentable condition as late as April, a date that is too late to commence the resting period that is necessary before good sucker-like cuttings, which can be relied on to furnish good plants, are produced. A portion of the stock of plants should now be divested of their flowers, removed to a house or pit with a temperature of about 55°, and kept for about a fortnight or three weeks rather dry at the root; at the end of that period the old flowering growths may be shortened to half their length, and when the suckers, which show renewed activity of the roots, appear, the remaining portions of the old stems may be cut hard back. Cuttings, perhaps, may be showing on these old stems, but these should not be relied on for propagation, as they never grow away with vigour. Some growers shake out and repot the old stools, but I have not found this necessary unless the soil has been soured with manure-water. In addition to plants raised from cuttings, some may be raised from the finest leaves, which can now be found on the plants. These should be dibbled in, with some two inches of stem, in shallow boxes of cocoa-nut fibre or light soil and sand, the leaf itself standing clear of the soil. In a temperature of from 65° to 70° roots will soon form, and be followed by good growths, but the leaves should not be placed in a close propagating-case, damping-off occurring if they are kept close.

Tuberous-rooted Begonias.—Some of the tubers may be potted up forthwith for early flowering, though I like to keep most of the stock back, for though not perhaps so good in autumn as in summer, they are generally much more useful then. All Begonias like decayed cow-manure, and this should be provided in the potting soil, which should consist of good sandy loam. Start them in a temperature of about 55°, and apply no water for some weeks after potting, as, given a moist soil at that time, the usual humidity of the house suffices.

Cyclamens.—Autumn-raised seedlings which have made at the fewest two leaves may be potted singly in thumb-pots, or several together in a 5 or 6-inch pot, or even pricked off in pans for the time being, affording each plenty of space in which to develop. Where the conditions of the house are suitable, and they can be kept close to the glass, I prefer to pot them singly. A temperature of not lower than 50° to 55° is most suitable at this stage.

Lapagerias.—Just now strong young basal shoots may be looked for on specimens growing in borders, and as slugs and weevils often cause injury to these, their appearance should be noted, and a collar of cotton-wool placed round the base of each shoot. A little thinning of the weaker shoots may now be effected, and the plants cleaned.

SALES FOR THE WEEK.

MONDAY, FEB. 24.—
 Border Plants, Perennials, Bulbs, &c., by Protheroe
 & Morris, at 12.
WEDNESDAY, FEB. 26.—
 Plants from Holland: Lilies, &c., by Protheroe &
 Morris, at 12. Bulbs and Plants, by Stevens & Son.
THURSDAY, FEB. 27.—
 Roses, Begonias, &c., by Protheroe & Morris, at 12.
FRIDAY, FEB. 28.—
 Orchids in great variety, by Protheroe & Morris,
 at 12.30.
 (For further particulars see Advertisement columns.)

AVERAGE TEMPERATURE for the ensuing week, deduced
 from Observations of Forty-three Years at Chiswick
 —40° 2'.

ACTUAL TEMPERATURES:—
 LONDON.—February 19 (6 P.M.): Max. 38°; Min. 35°.
 February 20.—Raw; damp; dull.
 PROVINCES.—February 19 (6 P.M.): Max. 45°, S. W.
 Ireland; Min. 34°, E. England.

The Cultivation of Orchids in Leaf-mould. THE use of leaf-mould in the cultivation of Orchids is attracting so much attention that we gladly lay before our readers the following remarks by M. LUCIEN LINDEN, whose cultivation of these plants leaves nothing to be desired. "We trust Orchid-growers will make experiment for themselves, and give our readers the benefit of their experience:—

"I see that in the newspapers, and particularly in articles published in the *Gardeners' Chronicle* and the *Orchid Review*, the question of growing Orchids in leaf-mould is attracting some interest in England. The opinion of those who have long cultivated Orchids, and studied the growth of these plants under various conditions, should, I think, have some value in this discussion. My opinion is shared by my foreman, M. VAN CAUWENBERGHE, whose ideas with regard to cultivation are the same as my own (and we have for twenty-seven years studied the subject together), should, we think, be of value, and it is our duty to make them known.

In the Moortebeek houses, the Orchid-cultivation in which is often eulogised in your columns, we are not partisans of the new method, for a very simple reason: from our own experiments, and from those that we have seen tried elsewhere, we have not yet found a system superior in its results to those obtained by us under the old system. We do not believe that the material, the sustenance for the plant, is of primary importance in Orchid-culture. Aëration, the degree of moisture given at different stages of their growth, the resting period, and a proper temperature, are the chief factors of success.

Whether the plants are cultivated on blocks (Cattleyas), in pots, in green moss, live sphagnum, leaf-mould, or in the roots of Polypodium, is a very secondary matter.

Orchids need no manure, and we never give them any. Formerly, my father grew all his Orchids in living sphagnum, and his plants were as fine as ours are to-day.

We might almost say that if material for repotting is of great importance in gardening, it is living sphagnum that we should recommend before everything else. When a plant is not doing well, be it an *Odontoglossum*, a *Cypripedium*, or a *Cattleya*, it is in sphagnum that it regains vigour—green sphagnum that

restores it to life. Life only can call back life.

Lately, to complete our experiments, we have bought right and left from amateurs and horticulturists *Cypripediums* and other Orchids cultivated in leaf-mould. The only living roots that we found were in the sphagnum over the surface of the pots; in the earth they were usually rotten.

We certainly do not wish to condemn the new system of cultivation; but the best result obtainable by the new method is that it will relieve amateurs from their apprehension in growing Orchids. A plant that can be repotted like a *Fuchsia* or a *Pelargonium* cannot be alarming. Therefore, in England and elsewhere, cultivation in leaf-mould should be tried, but not [*mais pas avec emballément*] to the exclusion of the ordinary method. Experienced growers, naturally, will understand why I say that it will only be of service to those who do not know how to cultivate Orchids.

If a commission be sent into Belgium to study the new system, I cordially invite them to visit our houses at Moortebeek, and to make comparisons for themselves. L. LINDEN."

MR. F. W. FLIGHT.—It gives us the greatest concern to find that we, in common with several of our contemporaries, were misinformed as to the death of this gentleman. The intelligence was conveyed to us at the last meeting of the Royal Horticultural Society, and we can only express our deep regret at the pain which we must unwittingly have occasioned, and at the same time our gratification at learning that Mr. FLIGHT is in good health.

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the Floral and Vegetable Committees of the Royal Horticultural Society will be held on Tuesday, February 25, in the Drill Hall, Buckingham Gate, Westminster, 1 to 4 P.M. A lecture on "The Use and Value of Nicotine in Horticulture," will be given by Mr. G. E. WILLIAMS at 3 o'clock.

—At the annual general meeting of the Royal Horticultural Society held on Tuesday, February 11, sixty new Fellows were elected, amongst them being Lady BOSTON, Col. J. HEAP, GEORGE H. BAXTER, F.Z.S., and the Rev. H. M. WELLS, M.A., making a total of 183 elected since the beginning of the present year.

—**EXAMINATION IN HORTICULTURE.**—Candidates wishing to sit for the Royal Horticultural Society's examination in horticulture on Wednesday, April 23, are requested to send in their names, with that of their supervisor, as early as possible. Entry forms may be obtained on application to the Secretary, Royal Horticultural Society, 117, Victoria Street, London, S.W. Applicants should enclose a stamp. The Society will also in future continue to hold its examination in April, and not in February, as it was once intended.

THE CULTIVATION AND CURE OF VANILLA IN SEYCHELLES are referred to in an interesting report by Messrs. BROOKES & GREEN, of Mining Lane, who state that the vanilla industry has been most successful in the island, and that Seychelles vanilla is superior as regards quality and value to all except Mexican vanilla. The island possesses a magnificent harbour, and the climate is very healthy; but owners of vanilla gardens have anxious times, a prolonged drought interfering most seriously with successful flowering, while between that period and fructescence the plants are frequently damaged by gales of wind, so that plantations which gave early

promise of a good crop finally yield but a poor result. When ripe and ready for harvesting, the beans (pods) are in a green, damp condition, and the process of curing and preparing the vanilla for shipment to London requires much care and attention, any parcels packed too damp (immaturely cured) almost invariably contracting "mould" on the voyage, and the value being thus largely reduced. The crop for 1901, shipped during the months of August to December, totalled "fully double" the heaviest quantity exported from Seychelles in any previous season, and the present season's crop will probably reach the important quantity of about 80 tons. *Pharmaceutical Journal*.

GARDENERS' ROYAL BENEVOLENT INSTITUTION AT LIVERPOOL.—Those who are in sympathy with the work and aims of the Gardeners' Royal Benevolent Institution will be glad to learn that a representative committee has been in Liverpool, to arrange a smoking concert to be held in the City Hall, Eberle Street, on Wednesday, March 12. Professor R. J. HARVEY GIBSON, M.A., F.L.S., Professor of Botany, Liverpool University College; H. J. VEITCH, Esq., and Mr. GEO. J. INGRAM, secretary of the Institution, will deliver addresses. The chairman of the committee is Mr. C. A. YOUNG, of the Floral Nursery, West Derby; secretary, Mr. R. G. WATERMAN; and treasurer, Mr. CRIPPEN. Donations will be thankfully received.

PRESENTATION TO A GARDENER.—On the occasion of the annual supper of the West Derby Horticultural Society on the 12th inst., the Chairman, Mr. C. A. YOUNG, presented to Mr. JOHN MASSEY, gr. to Mrs. HIGNETT, of Bankfield, West Derby, a silver and Oak "Tantalus." Mr. MASSEY, in returning thanks for the gift, said that it was also his 71st birthday. The inscription read: "Presented to Mr. JOHN MASSEY by a few friends, on the completion of 40 years' service at Bankfield." Mr. MASSEY incidentally remarked that he had been gardener at Bankfield to nine employers, and that he had seen the estate for the third time put up by auction, quaintly remarking that he supposed he had been bought in.

CHINESE CONIFERS.—In a communication to the *Bulletin of the Italian Botanical Society*, October 13, 1901, Mr. BEISSNER describes the Conifers collected by Father J. GIRALDI in Shen Si. Among them are *Larix chinensis*, *Cephalotaxus Griffithii*, a Himalayan species; *Juniperus taxifolia recurva*, and *Ginkgo biloba*, the native country of which has not been known till lately.

FRUIT AND FARM PRODUCE BY RAIL.—The authorities of the Great Eastern Railway Co. inform us that during the half-year ending in December last, the number of farm produce boxes forwarded to their destinations was 65,000, showing for the first time a decrease, as compared with a similar period. The falling off was caused principally by the partial failure of the fruit crops in the eastern counties, and also to the long drought during the summer months, which adversely affected the eggs and poultry traffic.

POISON!—The *Staffordshire Sentinel* for January 30 reports that a firm which manufactures a nicotine insecticide for horticultural purposes appears to have sent it out to seeds-men and florists without any indication of its poisonous nature; consequently the retailers, knowing nothing whatever about the dangerous properties of the liquid, supplied it to a customer in an old brandy bottle without a proper label. As a result, a gardener mistook

the insecticide for some beer, which it closely resembled in appearance, and died shortly afterwards.

SPRAYING.—At a recent meeting of the Nova Scotia Fruit Growers' Association, Dr. FLETCHER remarked that the spraying of fruit-trees was suggested in Canada first before the Association sixteen years ago, and he had had the honour of bringing in the suggestion. Yet after all these years of discussion, many people did not yet understand how to spray. Drenching a tree is not spraying it. Throwing a mixture over it in patches is not spraying. Spraying means enveloping the tree in a spray or fog so that every part may be wet but not drenched. Some men have a habit of using the same remedy for any insect that may be on the trees without regard to what the insect is. We spray, he said, too often without an intelligent idea of what we are doing. We should remember that there are two kinds of insects, those that chew and those that suck. We should spray with arsenates for insects that chew, and use an oily coating for those that suck. Fungus diseases also need their special remedies.

GARDEN ANNUAL FOR BELGIUM.—There has recently been issued a useful "Annuaire de l'Horticulture, de l'Arboriculture fruitière et de la Culture Maraîchère en Belgique et des Industries qui s'y rattachent." The scope of this work may be understood from its long title; it forms a large octavo volume, and should be useful to those for whom it is intended. It may be obtained from the Administration, Coupure, 15, Ghent, Belgium.

BOTANIC GARDEN, BRUSSELS.—The *ad interim* appointment of M. DURAND as Director has now been made permanent.

THE GHENT QUINQUENNIAL.—Yes, positively! the next Exhibition will be held in April, 1903. If we had not the schedule before us, we should have said that the last meeting was held the year before last!

"CASSELL'S DICTIONARY OF GARDENING" is well got up, and well illustrated; the text is accurate and suitable for amateurs, who will find it very serviceable for their requirements.

"RELIQUIÆ DEWEVREANÆ."—This is a sumptuous publication, prepared by MM. EM. DE WILDEMAN and TH. DURAND, of the Brussels Botanic Garden, and devoted to the description of the plants discovered in the Independent Congo State by M. ALF. DEWEVRE. It is published under the auspices of the Government of the Congo State. The technical descriptions are accompanied by useful notes. Two new or recently-described species of *Hæmanthus* are mentioned, viz., *H. Eltveldeanus* and *H. Arnoldianus*.

"INDUSTRIAL AND COMMERCIAL JAPAN."—This publication, by DENNISON GRAY (printed by the Yokohama Bunsha, Yokohama, Japan), deals with modern Japan, the "commercial, shipping, manufacturing, industrial, and general business capabilities of the Empire." It is, in fact, an illustrated account of the buildings and wares of many of the principal business firms of Japan. It includes an account, with pictures, of the nurseries of L. BOEHMER & Co., of Nos. 5 and 28, Bluff, Yokohama.

STOCK-TAKING: JANUARY.—The year has opened with a very considerable increase in the matter of imports, i.e., £4,143,832, some of which is due to the "budget" anticipations of speculators—this especially under the headings of "articles of food dutiable," where sugar looms largely. The total value of im-

ports for last month is £50,131,348, as against £45,987,516 for January, 1901—hence the increase above recorded. The following is our usual extract from the "January" table:—

| IMPORTS. | 1901. | 1902. | Difference. |
|--|------------|------------|-------------|
| | £ | £ | £ |
| Total value ... | 45,987,516 | 50,131,348 | +4,143,832 |
| (A.) Articles of food and drink—duty free ... | 13,843,506 | 14,589,213 | +1,045,707 |
| (B.) Articles of food & drink—dutiable ... | 4,084,853 | 5,383,665 | +1,298,812 |
| Raw materials for textile manufactures ... | 9,218,659 | 10,892,272 | +1,673,613 |
| Raw materials for sundry industries and manufactures ... | 4,073,790 | 3,872,232 | —201,558 |
| (A.) Miscellaneous articles ... | 1,435,851 | 1,958,030 | +522,179 |
| (B.) Parcel Post ... | 87,462 | 94,305 | +6,843 |

This table is somewhat fuller than of yore, and this may not be considered quite an improvement; one item is so, however—the markings of differences by the signs plus and minus, whereby a column is saved. The usually interesting figures are to be found under fruits, roots, and vegetables, as under:—

| IMPORTS. | 1901. | 1902. | Difference. |
|---|---------|-----------|-------------|
| | Cwt. | Cwt. | Cwt. |
| Fruits, raw:— | | | |
| Apples ... | 288,151 | 186,989 | —101,162 |
| Apricots and Peaches ... | 19 | 16 | —3 |
| Bananas... bunches ... | 119,834 | 157,053 | +37,219 |
| Grapes ... | 4,610 | 1,002 | —3,608 |
| Lemons ... | 97,495 | 126,144 | +28,649 |
| Nuts—Almonds ... | 4,989 | 14,316 | +9,327 |
| Others, used as food ... | 42,691 | 36,363 | —6,328 |
| Oranges... .. | 833,341 | 1,032,064 | +198,723 |
| Pears ... | 1,237 | 557 | —680 |
| Plums ... | 4 | 38 | +34 |
| Unenumerated, raw... .. | 6,235 | 6,822 | +587 |
| Fruits, dried:— | | | |
| Currants, for home consumption ... | 39,315 | 82,927 | +43,612 |
| Raisins ... | 17,673 | 29,114 | +11,441 |
| Vegetables, raw:— | | | |
| Onions ... bush. ... | 490,774 | 576,180 | +85,406 |
| Potatoes ... cwt. ... | 451,055 | 285,001 | —166,054 |
| Tomatoes... .. | 37,768 | 17,814 | —19,954 |
| Vegetables, raw, unenumerated ... value | £27,680 | £32,719 | +£5,039 |

One feature of interest to all has yet to be added to the Returns of the Board of Trade, and this is a brief statement of all the canned fruits imported.

THE EXPORTS

for the month are valued at £24,254,574, as against £24,753,531—the resulting decrease being £498,957. Coal exports are to some extent responsible for this falling off; but for which an increase on last year's total would have occurred.

MR. G. C. CREELMAN has been appointed Secretary to the Ontario Fruit-Growers' Association, leaving Mr. WOOLVERTON to edit the *Canadian Horticulturist*. Mr. CREELMAN is a graduate in agriculture from the University of Toronto, has been Professor of Biology in the Agricultural College of Mississippi, and has had much experience in teaching.

COMING EXHIBITIONS.—We have received a number of schedules of forthcoming horticultural exhibitions, among which are the following:—

THE DURHAM, NORTHUMBERLAND AND NEWCASTLE BOTANICAL AND HORTICULTURAL SOCIETY will hold a spring show on April 1 and 2, and a summer show on July 23, 24, and 25, both at

Newcastle. At the former exhibition there will be as many as sixty-seven classes for plants in bloom and cut flowers; whilst the same number of classes at the summer exhibition will include plants, cut flowers, floral decorations, fruits, and vegetables. The summer show has been postponed for a fortnight since our Almanack was published. The Secretary is Mr. J. B. REID, Mosley Chambers, 30, Mosley Street, Newcastle.

THE GRAND YORKSHIRE GALA on June 11, 12, and 13, in the Beetham Field, York, is expected to prove as fine a horticultural exhibition as any of its predecessors. There are ninety-four classes in the schedule, and a sum of £750 will be offered in prizes. This sum will be divided as follows:—£300 for Orchids, stove and greenhouse plants; £200 for Pelargoniums, Carnations, Begonias, &c.; £150 for Roses, cut flowers, &c.; and £100 for fruits and vegetables. The Pelargoniums and Fuchsias staged at York are now-a-days much finer features than at most exhibitions. The Secretary is Mr. CHAS. SIMMONS, The York Hotel, York.

THE ANCIENT SOCIETY OF YORK FLORISTS, instituted, as the schedule says, in time immemorial, and re-established in 1760, will hold minor shows on April 16, May 21, July 16, and September 3. At these exhibitions members of the society only may take part. The twenty-sixth annual Chrysanthemum show, which will take place on November 12, 13, and 14, is of a different kind, and contains many open classes. Altogether there are 113 classes for Chrysanthemums, fruits, and vegetables, and the prizes offered are of a very liberal character. The Secretary is Mr. GEO. F. W. OMAN, 38, Petergate, York.

THE ROYAL HORTICULTURAL SOCIETY OF SOUTHAMPTON have arranged to hold exhibitions on July 1 and 2, and on Nov. 4 and 5. The summer show will be for general horticultural exhibits, including Roses; and the autumn exhibition for Chrysanthemums, fruits, and vegetables. The Secretary is Mr. C. S. FUDGE, 6, College Terrace, London Road, Southampton.

THE COUNTY-BOROUGH OF HANLEY HORTICULTURAL FÊTE becomes a more important exhibition each year, and being situate in almost the centre of the thickly populated district in North Staffordshire known as "The Potteries," there are plenty of visitors to make the shows financially successful. The committee has now a balance at the bank of £2,287 14s. 6d., and the income in 1901 was £4,396 3s. 5d., as compared with £3,632 5s. 10d. in 1900. We have an advance proof of the schedule, which shows that very liberal prizes are offered for a great variety of horticultural subjects. It will open on the same day as the show of the National Rose Society in the Temple Gardens (July 2), a circumstance which will prevent some from visiting Hanley who may otherwise have done so. The Secretary is Mr. J. KENT, Hanley Park, Staffordshire.

THE TORQUAY DISTRICT GARDENERS' ASSOCIATION will hold a spring show on March 26, and a Chrysanthemum show on November 5. This is one of those societies that holds meetings for the discussion of horticultural subjects, as well as promote exhibitions; and the society possesses a library containing 100 valuable books. The Secretary is Mr. G. LEE, The Lodge, Upton Leigh.

THE KENT COUNTY CHRYSANTHEMUM SOCIETY held their annual shows at The Rink, Blackheath, and the next one has been arranged for October 29 and 30. The Secretary is Mr. F. FOX, The Gardens, The Cedars, Lee.

THE SHROPSHIRE HORTICULTURAL SOCIETY will hold its spring show, on April 9, when prizes will be given for plants and cut flowers in twenty-seven classes. This early exhibition, however, is not so interesting to the majority of our readers as the great floral fête which will take place on August 20 and 21 in The Quarry, Shrewsbury, and at which a schedule just to hand declares there will be offered more than £1,000 in prize-money, besides a "Silver Challenge Vase for Grapes, value 50 guineas, five Silver Cups, Gold and Silver Medals, and other valuable prizes." Very great encouragement is again offered exhibitors of groups of plants arranged for effect, and for collections of specimen plants. In the cut flower section there are classes for all, or very nearly all, the principal species in season. In the two principal fruit classes alone a sum of £100 is offered, besides a 50-guinea Challenge Cup, &c.; there are excellent classes for vegetables also. The Shropshire Horticultural Society shows itself determined to maintain its exhibitions the best displays of horticultural produce in the provinces, and this, notwithstanding there are many others that are now conducted much upon the same lines. The Hon. Secs. are Messrs. ADNITT and Naunton, The Square, Shrewsbury.

THE SURVEYORS' INSTITUTION.—The next Ordinary General Meeting will be held in the Lecture Hall of the Institution, on Monday, February 24, when a Paper will be read by Mr. ROWLAND BERKELEY (Associate), entitled, "Electric Railways and Street compensations." The Chair will be taken at 8 o'clock.

ACREAGE UNDER FRUIT.—The following is a brief outline of the statistics relating to the fruit crops in 1901, as published in an agricultural return just issued by the Board of Agriculture. The total area under orchards in England was 228,580 acres; that under small fruits, 67,828 acres. Wales shows a total of 3,767 acres under orchards; and 1,092 acres under small fruit. Scotland has 2,313 acres under orchards, and 6,079 acres under small fruit. The Isle of Man has 307 acres in orchards, and 139 acres under small fruit. Jersey possesses 1,027 acres of orchards, and 117 acres under small fruit; whilst Guernsey and the other Channel Islands have 207 acres in orchard, and 343 acres in small fruit. In Ireland, in 1901, there were 4,877 acres under small fruit.

CAPE FRUIT.—The ship *Norman* has brought 662 boxes of Peaches, 248 of Plums, 151 of Nectarines, and 47 of Pears.

PRIOR PARK.

THE subject of our Supplementary illustration this week, is the charming Palladian-bridge in the grounds at Prior Park, near Bath. Prior Park Mansion was built during the eighteenth century for Ralph Allen, whose name was closely connected with postal reform, and who enjoyed the friendship of many of the learned men of his day. The lands were once the property of the Priors of Bath, and in this way doubtless its present name originated.

The building is situated on the crest of one of the hills that surround Bath, and from its terraces may be obtained an exquisite view of the fine old city. A nearer view from the terrace is one consisting of the grounds of Prior Park themselves, with the Palladian-bridge almost at their termination.

Looking directly from the centre of the mansion, the ground dips away steeply in a most beautiful ravine-like valley, whose banks on right and left also slope markedly from the

terrace, and are ornamented by handsome groups of fine trees. The lakes are terraces, and the delightful effect of the bridge, in the grand "setting" that the grounds afford it, can scarcely be described.

Our photograph, taken by Mr. W. Rossiter, of Bath, does not give much idea of the lovely grounds, but well depicts the bridge in very near perspective. It is a fine specimen of Georgian architecture, and was built in 1751, when its design was no doubt copied from the famous bridge at Wilton.

The Palladian mansion, with its two wings, is very remarkable for extent and for magnificent workmanship, and during the middle of the eighteenth century was the scene of a social life of the highest culture, it having been the haunt of poets, authors, and actors of repute. Gainsborough painted his celebrated portrait of Garrick here. The poet Pope had a favourite walk in the grounds, which has since been named after him. Pope did not like Bath, and was staying at Prior Park when he wrote: "I live out of the sulphurous pit, at the edge of the pit, at Mr. Allen's, for a month or so." Fielding, Quin, Bishop Warburton and many other well-remembered men frequented the place as the guests of Ralph Allen.

For very many years past the mansion has been used as a Roman Catholic school, but visitors to Bath who may desire to see the beautiful grounds can always obtain permission to do so. Our photograph was taken when the grounds were looking their best, and the trees were resplendent with foliage, but even on Monday last, when we were there, the winter scene was a beautiful one.

THE CULTURE OF ANÆTOCHILUS.

In the *Gardeners' Chronicle* of December 7, 1901, p. 410, Mr. James O'Brien, in an interesting article entitled "Imported Orchids," mentions the *Anætochilus* as being plants generally found difficult to cultivate, and his success with them some years ago by frequently propagating them, and growing them in a compost mainly of loam-fibre. The use of loam-fibre I consider of special significance, for in loamy soil they are always found growing, and never in the light Orchid-peat and moss in which they are often potted in gardens. I am very fond of these jewelled members of the Orchid tribe, and as I have seen, as you will readily believe, a good many in their native habitats, I will venture to make a few remarks, which I hope may interest your readers, and which perhaps may help to make the beautiful *Anætochilus* better understood.

Now I assert that *Anætochilus* are not at all so delicate as they are generally supposed to be! I am certain that the real fact of the matter is, that these plants are starved to death, or killed with kindness, and that they do not die much faster than is the case now; only proves their great natural vitality. Now as you well know, the *Anætochilus* are ground Orchids. They are found in forests growing in very rich loam. I have never seen one growing in moss in its native country. Yet what do I see at home? There, as a rule, they are planted in the old orthodox mixture of sphagnum, charcoal, and fibre rubbish, which may be suited very well for an Epiphyte, but hardly for a ground Orchid. Then they are generally put under a glass shade, so that the poor things cannot even get much sustenance from the air. The result, of course, is that the plant weakens, gets delicate, and ultimately dies; and the plant is blamed, and not the method of cultivation.

I am well aware how difficult and often impossible it is at home to give a plant the exact natural conditions it enjoys in its wild state, and modifications have to be considered, yet I am sure if growers would procure some nice surface-loam out of the forest, and place the plants just loosely on this lumpy material, mixed perhaps with a little silver sand to keep it well open, and always keep it damp, they would be surprised at the result.

To show how hardy the *Anætochilus* are, I will just relate the story of the introduction of *Anætochilus Sanderianus*. I found the plant in British New Guinea, where it grows at an elevation of between 1,000 and 2,000 ft. I collected a good number, but had to keep them about a month before I could get away. A white mycelium was very troublesome, several times destroying a whole boxful in a single day. At last I was fortunate enough to get a passage in the mission steamer *John Williams*, which brought me and my plants safely to Cooktown. I intended to go to Singapore *via* Batavia. When applying for a passage per Royal Mail S.S. *Queensland*, the answer I got was "First steamer full, second steamer full also." I offered £10 extra, but it was useless. There were no other steamers. To go *via* Sydney was impossible, on account of the winter, so there was no help for it but to wait. I was despairing of keeping my plants alive—nine weeks in Cooktown in the winter would kill anything, I felt sure. Cooktown is the windiest place I was ever in. In the hotel the only sheltered spot I could get was a tiny bit of a court-yard, half garden, just outside the billiard-room. But even there the wind used to sweep down in strong gusts continually, the rain was icy cold, and I am afraid occasionally the billiard players watered my plants in a manner not at all suited to such delicate things. But in spite of all this wind, rain, and cold—I used to feel cold under two blankets—my *Anætochilus* were flourishing, and even growing, though unluckily two grand *Impatiens*, a gorgeous *Didymocarpus* (?), and several other new things died.

After nine weeks I got away, and after twelve days arrived at Batavia. I waited four days there, in two more days I reached Singapore. When I arrived there, my plants looked almost as fresh as they did when I started from New Guinea, and I had not lost a single *Anætochilus* after leaving there. After some delay at Singapore, Mr. Fox, of the Botanic Gardens, who was going home on leave, was kind enough to take them home, and Messrs. Sander received them at St. Albans almost as fresh as they were when collected. I do not think any other kind of Orchid would stand such prolonged rough treatment half so well.

Then take the grandest of all *Anætochilus*, I mean *A. Leopoldi*, with leaves 6 inches long and 4 inches broad, and most wonderfully marked. When the plants arrived in Belgium they had been on the road over three months, yet they were so good that they were exhibited at the Ghent Quinquennial show, where I have no doubt you saw them.

In Singapore I have seen them in private gardens, just potted in ordinary soil, and treated by native gardeners just as they treat *Begonias*, *Caladiums*, and things of that sort, and they do very well.

But I think I have said enough to convey my impression, that if people would seek to understand the *Anætochilus*, and treat them rationally, and more like other plants, there is nothing in their nature which prevents them being easily grown. W. Nicholitz, *Bhamo*, January 12, 1902.

DERMATOBOTRYS SAUNDERSII.

I FEEL that I have done this plant a wrong, and hasten therefore to make reparation. It had not flowered very freely until this season, and I concluded that, although very interesting and suitable for a botanic garden, it was not ornamental. It is interesting as being the sole representative of its genus, one also not closely allied to any other; and it is interesting on account of the nonconformity of its structure with that of any Natural Order to which it can be referred. One authority has referred it with little hesitation to the Solanaceae; while another, on account of characters foreign to that Order, has referred it to the Scrophulariaceae, where no similar plant is found. It is somewhat distinct type, upon which certain questions might be raised. All this, indeed, I had recognised, but now I find

The accompanying illustration (fig. 38) has been prepared from a photograph kindly taken for me by my foreman of the plant-houses, Mr. E. Allard, who has succeeded in obtaining a very good representation. The plant was introduced to Kew in 1892, and is figured in the *Botanical Magazine* of 1891, t. 7369. It is there stated, on the authority of Miss Katherine Saunders, who sent seeds and living plants to Kew, that "the shrub is epiphytic, growing normally on trees, though also on the ground." It will be noticed that the branches are sometimes thicker above than below, a feature which does sometimes belong to epiphytic plants, and it recalls *Drymonia punctata* to my mind at this moment. *Dermatobotrys* we have only grown as a pot-plant, under which treatment it does perfectly well. It is a native of Natal and Zululand. R. Irwin Lynch, Botanic Gardens, Cambridge.

FIG. 38.—DERMATOBOTRYS SAUNDERSII: FLOWERS RED.

That apart from interest, nothing could be more quaintly ornamental for the conservatory. The plant has an irregular manner of branching, though all principal branches proceed from a round knob-like base—a kind of hub. In autumn they lose all their leaves, and after a short time burst into growth, the flowers then appearing just at the juncture of the old and new wood, and crowned as it were by a tuft of fresh green foliage. The flowers are $1\frac{1}{2}$ inch long, of coral-red colour, and curved in a graceful manner. There are sixty-five on the plant here illustrated. It has been grown in a cold greenhouse, and is at least three years old, though only a foot high. It gives evidence of being a very useful winter-flowering plant, not growing inconveniently large, and not requiring to be re-struck from cuttings every now and then to produce the best result; indeed, the only drawback it appears to have is, that it does not at once become fully floriferous.

WINTER FLOWERS AT NORTH MYMMS PARK, HERTS.

It may at once be stated that what is grown here is of the best. The winter-flowering Begonias are the newest which Messrs. Veitch & Sons, of Chelsea, have distributed, together with the less modern *B. Gloire de Lorraine* and *B. Gloire de Sceaux*. Of each of these there were many fine specimens, grown in the case of the last few months from the cutting to a height of 4 feet, and almost as much in diameter. The last-named winter-flowering variety is not seen so often as it might be, and grown in the manner as it is here. The plants of *B. Gloire de Lorraine* were equally fine, and models of form. This variety is grown chiefly in 6-inch pots, and the plants had attained a height of 28 inches and a diameter of 2 feet, free-branching pyramids, and with but half the tying usually seen. I observed a number of fine plants of *B. socotrana*, the leaves handsome and shining, with numerous sprays of pink

flowers. The specimens of *B. Ensign*, a variety which was ablaze with flowers, were handsome plants, about 2 feet high, and unique for richness of colour. The plant increases with age in the richness of colour and size of the flowers. *B. Turnford Hall* was here, too.

The display does not consist entirely of novelties, for Mr. Fielder, gr. to Mrs. Burns, grows quantities of plants of *Centropogon Lueyanus*, *Ruellia macrantha*, fine specimens in full flower. *Lilium speciosum*, which had been retarded, were among those observed. Carnations are grown in great numbers, especially *Souvenir de la Malmaison* for flowering later. An excellent variety that was in bloom was *America*, a large and handsome flower of a shade of scarlet. As here grown, with one flower on one stem, the latter about 15 inches high, it is really very fine, and with no apparent liability to burst the calyx; the variety is nicely scented. Houses of a large size are set apart for Roses, and gave evidence of a good display of flowers to come. J.

CYTISUS RACEMOSUS.

It shoots 3 inches long and furnished with a heel of the older wood be taken at this season, and stuck-in round the rims of small well-drained pots filled with a sandy loam, made firm by hand, afforded water, and set aside for a time before inserting the cuttings, they will root under bell-glasses in a warm house. With proper attention in regard to potting and applying water, these will make sturdy, flowering plants in one year. When rooted in the first pots, shift into 60's, and place in a warm greenhouse, syringing them repeatedly in bright weather. Their next shift should be into 48's, employing turfy loam, leaf mould, and road grit. In June stand them on coal-ashes in a cold frame, and later draw off the lights till cold nights set in. The plant must be well supplied with moisture at the roots, and over head in hot weather; and occasionally soot-water and mild liquid manure may be applied.

GARDENIA FLORIDA, RADICANS, &c.

If old plants after flowering are pruned, shaken out of the exhausted soil in pans, and repotted, they will flower well the next year. But in order to keep up a healthy lot of Gardenias, plants should be struck in the autumn and winter seasons annually. In the absence of a propagating-pit, the cuttings may be struck in any hotbed having a temperature of 70°, and bottom-heat of 80°, or they may be struck in pots plunged in boxes filled with leaf-mould, and stood on hot-water pipes. H. Markham, Wrotham Park, Barnet.

ENQUIRIES.

VIOLETS DROOPING AND SCENTLESS.—A correspondent ("J.") would be pleased if some of our readers would kindly explain why frame-grown Violets droop very shortly after being gathered and put in water. Sometimes they wither in a few hours. Warm water has been used in the glasses, and a few drops of ammonia have been placed in the water; also the flowers and stalks altogether plunged in a basin of water for several hours before arranging them, but with no result. The blooms are large and plentiful.

CRONARTIUM RUBICOLA.—A Belgian correspondent asks whether this fungus, which passes part of its life on *Pinus Strobus*, and part on the Black Currant, is seriously injurious to the latter. He has no Weymouth Pines in the immediate neighbourhood. We have not heard of any serious damage from this fungus, but shall be glad of information (see *Gardeners' Chronicle*, 1892, pp. 41 and 135).

HOME CORRESPONDENCE.

THE FLEUR-DE-LYS.—In the *Gardeners' Chronicle* of January 4, 1902, p. 8, it is stated, regarding the heraldic emblem, usually called the "Fleur-de-Lys," that "unfortunately for this contention (i.e., that this emblem had the Iris for its parentage), it is not yet settled whether the device is really intended to represent an Iris, a Lily, or a spear-head!" There is one thing that would appear to be settled, viz., that it cannot represent any known flower. All "Fleur-de-Lys" have from one to three ligatures, that is say, one to three turns of a string. This feature is fatal to any contention that would derive it from a flower. That ever present feature would point that it is composed of two or four things tied to something, for there is no flower that has ligatures round its waist! It may be quite true that Clovis obtained this device from Palestine during the Crusades, and that it was first seen on the shield or banner of some Saracen chief. The probability, however, is that its parentage may be referred to a vulgar superstition, and that it has nothing to do with any kind of flower. In Oriental countries the belief is universal that horns of animals have the power of averting the evil influences of the "evil eye" from anything they may be attached to, so they are stuck on houses, trees, &c. The "Fleur-de-Lys" is probably no other than a degraded form of two pairs of horns tied to a stick. This superstition is very prevalent in the south of Europe, and may have been introduced there from the East, by either the Saracens, or those remarkable sea-faring traders, the Phoenicians. Anyhow, the probable origin of the "Fleur-de-Lys" can be seen on a large scale on the Sacred Tree of the Assyrians in the British Museum. See discussion on this subject in the *Flora of the Assyrian Monuments*, p. 131. E. Bonavia, M.D.

GARDENERS IN THE U.S.A.—My remarks upon America as a land of promise to the overcrowded horticulturists of England have been read with more interest than I anticipated, and I am deluged with correspondence on the subject. I shall be glad to give a general reply through your columns, by your kind permission, as it would be impossible for me to reply individually. Many wish to "take advantage of my offer to get them positions." I did not make such an offer. I am not in a position to do so; nor would the law here allow of anyone engaging them. Everyone must come out, and get the position afterward, taking some risk. In saying gardeners are scarce, I do not mean that lucrative head places are actually waiting for someone to take them, but that the opportunities are better, and competition less keen. I have been favoured with a letter from a leading nurseryman in this country, and one most qualified to judge, in which, commenting upon my previous letter to the *Gardeners' Chronicle*, he says:—"There is, as you say, a good field here for gardeners of the better class, and for under gardeners." The law of the land makes it necessary for everyone to fight his own battle, and one must be prepared to take the rough with the smooth, as witness my own experience. Coming from a place where I had all the privileges (and may I say "soft snaps") appertaining to the position of a head man with thirteen assistants, I found myself during the first weeks of my American experience laying turf, grubbing and replanting hedges, making paths, &c. I mention this, that no one should be led to try it by my advice, thinking the country an Eldorado, where dollars can be picked up in the streets. There is good money for good work—all a reasonable man can ask. To the many who have questioned me upon the subject, I may say the best time to come out is the end of March, ready to begin business in April. Outdoor work, retarded by frost, has then to be pushed forward rapidly, and nurserymen, landscape gardeners, and others, are very busy. The cost of the voyage is £8 second cabin (South-

ampton to New York), £6 steerage. In addition, one must have not less than 30 dols. to land with. It is necessary, not only for one's personal convenience, but for the satisfaction of the authorities here. The climate, which many enquire about, is such that any Briton should thrive in it—greater extremes of heat and cold, but nothing unpleasant; no special outfit is necessary. Wages vary, of course, but the casual worker obtains 8, 9, and 10 dols. per week, according to ability, out of which 4 to 5 dols. go for board and lodging, according to what district one is located in. Wages are highest around New York, and there the stranger would do well to look first for business, as, if unsuccessful, which in spring would not be likely, he could then come further on to New Jersey, and into Pennsylvania. Those interested solely in fruit farming should go further afield into Maine, or even to California. Where I am, it is a country place, with few chances of profitable employment, as compared with other places. In conclusion (although as a result of this correspondence a few may hear of something which may perhaps be to their advantage), I regret my inability to assist all in a practical way. I further regret that many sent stamped envelopes and stamps, which are useless here. My opinions, as expressed in this and my previous letter, are such as I have formed from only a slight knowledge of this vast land, and I, not desiring any credit for the success of any who may be led to try it through me, likewise as little desire to be blamed for any failure. Alfred Harding, Villa Nova, Pennsylvania.

THE ROYAL HORTICULTURAL SOCIETY.—It scarcely seems quite fair to the Superintendent of the Royal Horticultural Society's Gardens to compare its cultural and climatic advantages or disadvantages with those of other gardens in its immediate neighbourhood. The superintendents mentioned in the *Gardeners' Chronicle*, p. 44, all of them, it may be said, are in absolute power as to what they may do in their respective departments to bring about some act of cultural skill, or to create some new feature in the garden; some alterations which, according to their ideas, would be an agreeable surprise to their employers, who might, in all probability, know nothing of it, until some day on their home-coming they happened to see it. Such happy feeling under these circumstances between employer and employed makes life, even to a gardener, worth living for. Not so, however, with the Superintendent of the Royal Horticultural Society's gardens. His position is that of a very much handicapped man. It is not left to him to conceive some happy idea, the success of which he himself could foresee, and to at once carry the work out whilst the idea was fresh upon him. I believe I am right in supposing that in the first place the Superintendent must go to the Secretary, and he in turn to the Council, before sanction can be obtained; in this sort of circumlocution many a grand idea gets smothered ere it is born. We are told that nicely-coloured Alicante Grapes have been grown within three miles of Charing Cross. So also as good and better might be grown at Chiswick; but to produce sensational bunches, the borders of the once famous vinery would have to be renewed with a mechanical mixture of soil up-to-date in regard to its constituents, and young Vines planted. The history of Grape-cultivation in this country goes to show that grand bunches of Grapes are produced only at places where new vineries have been erected, or old ones thoroughly renovated and replanted, which will do quite as well. Our exhibition-tables show what a shifting business the successful cultivation of the Grape-vine is. An old hero disappears, a new Patroclus takes his place, only to be run down by a Hector, who in turn is bowled over by another aspiring Achilles; and so the Grape war goes on, prizes now here, and now there. Few gardeners have fought the battle of Grapes more successfully or more continuously than those at Eastnor and Elvaston Castles. But back to our text. That

the fertility of the soil in the Chiswick gardens is greatly exhausted is, I believe, admitted by all; but its renewal by a heavy dressing of turfy-loam is only a matter of £ s. d. But under the present circumstances would it be wise to spend money on the renovation of an old, worn-out garden, which is drifting year by year into such unfavourable local conditions which threaten, in a few more years, to render successful and satisfactory cultivation almost an impossibility? Rather we would say, look out for fairer fields and pastures new, where the soil is virgin, and the condition of the surrounding air everything that could be desired—anyhow, so far as it can be got in this country. But a truce to going too fast. We are pleased to hear that the Society's exchequer is now well filled, and its affairs in a healthy condition; that the two things for which we have for years been longing are now within measurable distance of realisation. One is the new Exhibition Hall, which everybody seems to be agreed should come first, and after that the new garden laid out in a locality where it will satisfy everybody! Keep on the old gardens until the new one is secured, then it may be parted with after removing from it everything thought worthy of removal. Commence in the new garden with a clean slate, under the guidance of the present indefatigable secretary. Supported by a wise and well-appointed Council, with such equipment, we should have a Society, and an experimental garden second to none. W. Miller, Berkswell.

POPULAR AND STERLING VARIETIES OF PEAS.—Under the above heading, on p. 32 of your issue of January 11 last, I read with interest, and also with some astonishment, the system on which Mr. Ward grew Peas when he was at Longford Castle. To quote his own words, he states that he trenched the ground "between 2 and 3 feet deep, and three layers, 6 inches thick each, of well-decayed horse-dung were incorporated with the soil in the process of trenching." Now, three layers 6 inches each equals 18 inches in depth of dung, and as he states that he prepared the soil for his "second early, mid-season, and late Peas" in this manner, he must have had to dung a considerable amount of ground. Taking my own case, that of a moderate-sized garden, a break something like 30 yards square would be required for the period mentioned by Mr. Ward, and to manure the soil to the extent he states would take the enormous quantity of 450 cubic yards or loads of manure, a quantity I should be glad of to manure the whole garden for three or four years, or longer. I have tried to understand if it was possible that this quantity could have been used, or whether Mr. Ward had made a slip of the pen; but if that were the case, there has been time to correct it, and we may take it that he so meant it. I think there are few gardeners who will attempt to follow Mr. Ward in his methods of Pea-growing so far as manuring is concerned, unless it be for experimental purposes, it being in most gardens impossible to obtain so much manure, even were it advisable to make use of it. My own experience is that such a large quantity of rotten manure is not required by Peas, and that about one-twentieth of the quantity Mr. Ward recommends is what we use here, and even that is a heavy dressing. Added to this are a sprinkling of wood-ashes and old mortar-rubbish, and a thin dressing of dissolved bones, these being incorporated with the soil during the trenching, which is done as Mr. Ward recommends, from 2 to 3 feet deep. The dung is used with a view to helping to retain the moisture in the soil, which, being of a gravelly and chalky nature, is very light and porous. On heavier soil, where there is more moisture, the results have been equally satisfactory as when no dung was applied. I have tried making up trenches on a limited scale with manure from the stables, and have had fair results, but nothing like so satisfactory as with the method I now employ. It is not claimed that my crops of Peas are as good or better than were Mr.

Ward's at Longford Castle, but they have been very satisfactory both as to quantity and quality. Having carefully watched of late years the effect of, or rather the ineffectiveness of, nitrogenous manures on Peas, I have come to the conclusion, that if they are of any benefit at all, it is in the form of farmyard or stable-dung on light soils which prove of use in conserving the moisture in the soil, thereby benefiting the Pea crops in dry weather; but I should not recommend a thickness of 18 inches. *James Gibson, Danesfield Gardens, Marlow, Bucks.*

PRIMULA MEGASEÆFOLIA, Boissier, is really a very fine species, and one of the best Primroses for winter-flowering purposes in greenhouses, cold frames, and probably also in rooms near the glass, when sufficient light is given. It is no doubt one of the richest flowering specimens, and will become a favourite with amateurs and gardeners. My garden is situated at an elevation of about 800 feet. I cultivate this Primrose in the open ground at the base of a shady wall in peat, loam, and leaf-mould, mixed with much silver-sand; the surface is covered richly with moss or dry Chestnut-leaves. There it grows very well, is evergreen, and flowers from September to May continually; only disturbed occasionally when the north-eastern wind sometimes injures it. It is freely watered in spring and summer, and I have found that it likes a short period of rest in the autumn. It seeds freely with me in the open ground, and it the seeds are sown immediately will germinate before the second spring or winter. They must be sown in very humid peat and sand. I also cultivate it with success in pots under glass during the winter, which here is never severe, keeping these plants during the summer in a shady and damp place near a wall, and never under trees or shrubs. These plants in pots do not flower much earlier than the others in the open ground, only their stalks are longer and more elegant, and the flowers appear to be a little larger, but are less finely coloured than the others in the open ground. The flowers are in a loose umbel of from ten to fifteen or more, and are mostly in a single umbel, more rarely in two, and very seldom in three. They are of a very fine red-purple colour; later ones are paler, changing to lilac, and certainly capable of producing, under good cultivation, much better forms. I have two very fine varieties not yet multiplied. It is widely diffused from the Caucasus to Persia and Afghanistan, but is not easily discovered, and never common; but where it is found it grows profusely, as it spreads by means of small thready suckers. The rootstock is somewhat thick, and can be kept six months and more without earth in quite a dry state. In this state only was I able to introduce it from a locality in Persia some years ago. Boissier saw it only, as it seems, in a locality near Rizeh, and also from this locality I have received a good stock which is quite identical with my Persian plants. That is all we know so far of this lovely and sweet Primrose, which to-day is in my garden in its glory, together with the fine Iris Heldreichi or tauri, both sent me some years ago from Mersina by Mr. Siehe. The purple Primroses with golden eyes, and the bright blue Iris Heldreichi are very happy, and form a fine contrast. *W. Sprenger, Vomero, Naples.*

MUSSEL-SCALE ON APPLE-TREES.—I should like to add one other remedy to your correspondent in "The Hardy Fruit Garden," and it is a very simple but a most effectual one, viz., mix 1 oz. of paraffin-soap to each gallon of water—see that the soap is thoroughly dissolved, and syringe the trees affected on evenings when sharp frost is expected, or while it is freezing; the sharper the frost the more effective will the remedy prove. I have cleaned many trees, both of Apples and Pears, in this way of this destructive insect. When the trees are badly coated by this scale, it may be found necessary to repeat the syringing several times, but it will undoubtedly clean the trees. Not only is it a good way of freeing

trees of this scale, but from every kind of insect, and their eggs and larvae. Of course, the object is to envelop the insects, &c., in ice, which will be the case on sharp frosty nights. I have followed this practice for some time, and I am well satisfied with results; it thoroughly cleanses the bark of vegetable growth as well as insect life. Of course, no one would think of doing this after the buds show signs of bursting, and therefore the sooner it is done the better. *T. Arnold, gr., Cirencester House, Gloucestershire.*

THE SQUIRREL received a large amount of attention at the meeting of the Royal Scottish Arboricultural Society on January 31, and the statements of Mr. Speedy as noted in the *Gardeners' Chronicle* of January 25 were largely corroborated. Mr. McHattie, of the City Gardens, Edinburgh, was the only speaker who declared largely in its favour, thinking it had not increased of late years, and that it would be a pity to exterminate it. Mr. Clark, Haddo House, advised the employment of bands of boys to beat woods for the agile creatures, every one that could be found to be shot. Lord Mansfield no doubt was correct in

THE LATE DR. STUART.

attributing the difficulty of rooting out squirrels to the sentimental feelings of ladies for the agile little quadruped. If we are to credit Lightfoot, and he was a careful observer, squirrels were very scarce in Scotland in 1772, when he itinerated the country along with Pennant, Strathspey being the only district where they were plentiful. Fifty years ago they were somewhat of a curiosity in lowland Scotland, and in some districts in the south-west they are still uncommon. *R.*

BAMBOOS.—Re Mr. Freeman Mitford and the "hardy Bamboos," see p. 13 of that interesting book *The Bamboo Garden*, where it is stated that it is only from the two or three knots at the base of the stem that a new growth proceeds; this, however, fails to cover the whole ground. Experience has shown me that the bunches of shoots which are produced from the upper joints of the two-year culm, if taken off when ripe, and placed in a suitable moist and warm atmosphere, root from the base of the mass of young shoots, resulting in a few months in a stock of nice little bushes. I am speaking in particular of the true *Arundinaria falcata*, as defined by Mr. Freeman Mitford; also of *Thamnoclamus Faleoneri*. I should judge, from observation of these plants, that in a sufficiently moist climate the

tufts of small shoots, by the bending over of the culms, reach the soil, and there root, as is the case with a number of other plants known to the gardener. *E. Tidmarsh, Grahamstown.*

DISEASE IN TOMATOS AND CUCUMBERS.—I notice in your "Answers to Correspondents" on February 15, the one with reference to the disease in Tomato-plants, an enquiry that I suppose will frequently appear in the *Gardeners' Chronicle* throughout the season. I am of the opinion that a great deal might be accomplished by a more careful method of seed saving of Tomatos and Cucumbers. In many instances cultivators save seeds year after year, from plants grown in a high temperature and highly manured, which certainly must tend to weaken the constitution of the plants, and make them more susceptible to disease. If sufficient plants of each to provide seed for the next season were grown under cooler treatment, and not manured. If any extra nutriment was required it might take the form of top-dressing with good virgin soil, I think that plants raised from seed saved in this manner would be stronger, and better able to resist disease. A correspondence on this subject would no doubt be of great service to a good many of your readers, as a failure in either of these crops is a serious matter to market gardeners in these days of severe competition and low returns. *E. B., Worthing.*

Obituary.

DR. CHARLES STUART.—The death of Dr. Charles Stuart, Chirnside, Berwickshire, was announced in the daily papers of the 14th inst. By his death the North of England loses one of its oldest and most successful florists. Dr. Stuart's age was not mentioned, but seeing that he and Mr. James Dobbie, of Rothsay—who survives—were competitors at a Pansy Show held at Berwick-on-Tweed in 1846, Dr. Stuart must have reached an advanced age. The Pansy was at that time a very popular florists' flower both north and south, and not a few of the most successful florists of thirty years ago commenced the culture of flowers by taking the Pansy in hand. Nor were hardy flowers generally overlooked by Dr. Stuart: he devoted his time to the improvement of several, and to his enterprise we owe *Aquilegia Stuarti*, a beautiful dwarf blue-flowered form, but which is found somewhat difficult of cultivation. The Polyanthus was also one of his special favourites, and he was highly successful in improving the Gold-laced Polyanthus, naming two or three varieties of great merit, which it is to be hoped will not be lost to cultivation, as it is a section which greatly needs strengthening. While travelling in Ireland some years ago, he discovered at Ballinora, Connemara, a new variety of hardy heath, which was named *Erica Tetralix Stuarti* in his honour.

It was his valuable and far-reaching work in improving the Viola which most called for the admiration of contemporary florists. Mr. Wm. Cuthbertson, Rothsay, has kindly placed at my disposal a memorandum compiled by Dr. Stuart, in which he sets forth details of his preparatory work. In 1874 he commenced by taking pollen from a then popular bedding Pansy, Blue King, and with it fertilised *Viola cornuta*. He obtained one pod of seed which, when sown, produced twelve plants. They flowered the next season, and were, as might have been expected, all blue in colour, and each with a close, tufted habit of growth. The next step was to cross a pink-flowered Pansy on to the seedlings obtained from the first cross, but with limited success. Such plants as were raised afforded more variety in colour, and the same tufted habit of growth was continued. The

best of this cross were propagated, and some of them were sent to the Chiswick Gardens of the Royal Horticultural Society to afford a test in a southern climate. Dr. Stuart at the same time issuing an invitation to all who were then raising *Violas* to send their flowers, so that there might be as complete a trial as possible.

Dr. Stuart states that in "the autumn of 1875 I was informed that I had got six First-class Certificates, and was 1st in the competition, Messrs. Dickson & Co., Edinburgh (whose manager, Mr. James Grieve, had been at work some time previously in the same direction), being 2nd. I find, on referring to the record of awards made by the Floral Committee in 1875, that one Certificate only was awarded to Dr. Stuart, and that for a variety named Williams; but three or four in 1876. At this time it was suggested to Dr. Stuart that he should endeavour to obtain a variety without rays round the eye, and he set himself to work to accomplish this end; but it was ten years before he succeeded in finding a really rayless *Viola*. This was in the year of the Queen's Jubilee. The plant was propagated; the next season he had a little plantation of it; it was of compact, tufted growth, and the blossoms emitted a powerful fragrance. This was the origin of the variety *Violetta*: by crossing this on to a white self with few rays, *Sylvia* was obtained; and *Sylvia*, crossed with a Peacock Pansy produced *Border Witch*, "a singular flower which, in its best dress in moist weather, is very striking." Many disappointments with his crossings were experienced by Dr. Stuart, for he relates that though he had crossed specially with a view to the production of rayless varieties, out of 150 seedlings *Border Witch* was the only one without rays. From that time forth, Dr. Stuart raised many fine varieties which came into cultivation. He always aimed at refinement, a close, tufted habit of growth, freedom and constancy in bloom, and fragrance. In a letter written in 1898 Dr. Stuart remarks:—"In crossing any wild species or varieties of *Violas*, it is necessary that the pollen should be taken from the cultivated species and dusted over the pistil of the wild one. Pollen taken from *V. cornuta*, for instance, will, if put on to a common garden Pansy, only give seed which will produce bedding Pansies, and not the sturdy, tufted strain *Violetta* represents." R. D.

JAMES HILL.—We regret to record the death, at the age of eighty years, of Mr. James Hill, florist and nurseryman, of Barrowfield Nursery, Lower Edmonton, which took place on Sunday, February 16, after a long and painful illness. Mr. Hill established the Barrowfield Nursery in 1848, and the business was carried on in recent years under the title of James Hill & Son. The specialty of the firm is exotic Ferns, of which very well cultivated exhibits are occasionally to be seen at the meetings of the Royal Horticultural Society.

HENRY TATE.—Readers of this journal in Liverpool and the country generally will learn with regret of the death of Mr. Henry Tate, formerly of Allerton Beeches, Liverpool, at his residence, Bolney House, Ennismore Gardens, London, at the early age of forty-eight years. Whilst residing at Allerton Beeches, the deceased gentleman made Orchids his hobby. The collection was not extensive, but the cultivation of the plants was very superior; moreover, many choice varieties have originated there. The collection of seedling *Cypripediums* and *Cattleyas* disposed of at the Allerton Beeches' sale contained many fine crosses and hybrids.

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

FEBRUARY 11.—Present: H. J. Veitch, Esq., in the Chair; Messrs. Hooper, Gordon, O'Brien, Chapman, Holmes, Douglas, Worsdell, Saunders, Bowles; Rev. W. Wilks; Drs. Cooke, Rendle, and Masters were present.

Pony Roots.—The identification of the Caterpillar affecting these roots as that of the Swift moth (*Hepialus*) was confirmed.

Bananas in the Canary Islands.—A Fellow made enquiries as to the best kind of manure to be used for these plants at a reasonable price, the usual substances recommended being too costly for commercial purposes.

Pelargoniums in the Transvaal.—A correspondent sent leaves of *Pelargonium*, which were referred to Mr. Massee, who has since reported as follows:—

"The fungus on *Pelargonium* leaves is the African species of 'Geranium leaf-rust,' *Puccinia granularis*, K. and C. Diseased plants should be isolated, and the diseased leaves removed as quickly as the health of the plant will allow. Spraying with Condy's Fluid would prevent healthy plants from becoming infected. The fungus is not uncommon on wild species of *Pelargonium* in S. Africa, and has probably passed from such wild plants to the cultivated ones. The fungus is a very interesting species not previously known as attacking cultivated plants. Care will have to be taken that it is not imported into Europe."

Carnation Leaves.—Some diseased and distorted leaves, from a gentleman at Thames Ditton, were referred to Dr. Cooke for examination and report.

Potato Disease.—Some specimens of diseased Potatoes were sent from the Chippenham Horticultural Society. They presented in the interior of the tuber black spots, such as were investigated at Chiswick by Dr. Plowright and others several years ago, and figured in the *Gardeners' Chronicle*, Dec. 20, 1884, p. 788, fig. 135. The specimens were placed in the hands of Dr. Cooke for examination and report.

Unhealthy Fern.—Mr. GORDON showed, from a correspondent, fronds of a Fern in a sickly distorted condition, attributed by the Committee to defective cultivation.

"Buddha's Fingers."—Mr. HOLMES showed a specimen of a malformation in a Citron, consisting of a dissociation of the carpels, which thus resembled so many fingers.

Proliferation of a Rose.—Mr. WORSDELL showed a good illustration of this frequent malformation.

Anemone nemorosa.—Mr. WORSDELL also showed specimens of this plant, in which the radical leaves were as long as the bracts of the involucre.

Diseased Begonias.—From Mr. A. DEWAR came leaves of *Begonia Gloire de Lorraine* in a diseased condition. The leaves were infested with thrips and mites. Fumigation or spraying with tobacco-water was recommended.

Air-canals in the leaf and in the flower-stalks of Nymphaeas.—Dr. MASTERS showed impressions illustrative of the varying arrangements of the air-canals in the petioles and peduncles of several species and varieties of this genus—arrangements which are sufficiently varied and sufficiently distinct to allow of the grouping of the several species and varieties into certain well defined groups. The subject had attracted the attention of the speaker many years ago, but the recent introduction of M. Latour Marillac's hybrids suggested a further examination, which was confirmatory of previous observations, and the results of which are detailed in the communication now laid before the Society. For the opportunity of examining numerous specimens, Dr. Masters expressed his great obligations to Mr. Hudson, the expert cultivator of these beautiful plants at Gunnersbury House.

LINNEAN.

FEBRUARY 6.—Professor S. H. VINES, F.R.S., President, in the Chair.

Professor REYNOLDS GREEN, F.R.S., F.L.S., exhibited some Primroses which showed the not uncommon phenomenon of sepaloid of the petals. The corolla was green and the limbs of the petals were rugose, and of a texture almost comparable with that of the foliage-leaves. He also showed another specimen in which the calyx as well as the corolla was petaloid. Both

specimens were received from a garden in the north of England.

Messrs. H. and J. GROVES, F.L.S., exhibited a series of British hybrid *Batrachian Ranunculi*, including *R. peltatus* × *Lenormandi* (R. Hilltoni, H. & J. Groves), *R. Baudotii* × *Drouetii*, *R. Baudotii* × *heterophyllus*, and *R. peltatus* × *trichophyllus*, together with specimens of their supposed parents. They pointed out that the hybrids were usually characterised by (1) being intermediate in appearance between the two parents, having some of the distinctive characters of each, but with a more vigorous vegetative growth; and (2) by the fruit being mostly abortive, and the peduncles not becoming recurved.

Mr. FRANCIS DARWIN, F.R.S., F.L.S., read a paper on "A Method of investigating the Gravitational Sensitiveness of the Root-tip," showing the apparatus used, and lantern-slides of seedlings under experiment. Confining himself to the modern development of the question, the author remarked that the observations of Czapek and of Pfeffer having been contradicted by Wachtel, it had become desirable to confirm these observations by employing a different method. The apparatus used consisted of a counterbalanced lever 53 cm. long, able to turn in any direction by being mounted on a knife-edge. Seedlings of the Bean and the Pea were employed, and glass tubes, straws, and Dandelion-scapes were in turn used to contain the root-tip, and by the aid of certain mechanical appliances, to prevent the root slipping out of the tube. The tip being fixed, the remaining part of the root and the hypocotyl (caulicle) became curved in varying degrees, due to the stimulation of the root-tip. The result has been confirmation of the observations made both by Czapek and by Pfeffer.

Dr. D. H. SCOTT, F.R.S., F.L.S., gave an account (illustrated by lantern-slides) of "An extinct Family of Ferns"—the *Botryopteridae*, our knowledge of which is primarily due to the researches of M. Renault. The vegetative organs and sporangia of the type-genus *Botryopteris* were described, and two British Palaeozoic species, *B. hirsuta*, Will., and *B. ramosa*, Will., were added to the genus on the ground of their anatomical structure. The genus *Zygopteris*, also known with some degree of completeness, was next dealt with, and the structure of the British species *Z. Grayi*, Will., described in some detail. Reasons were given for including other genera, such as *Anachoropteris*, *Asterochlæna*, and *Tubicaulis* in the family, while a close connection with *Diplolabis* and *Coryopteris* was also regarded as probable. The affinities of the group were discussed in conclusion, points of agreement with *Hymenophyllaceæ*, *Osmundaceæ*, *Ophioglossaceæ*, and other families of Ferns being pointed out. Heterospory, believed by M. Renault to exist in *Botryopteris* and *Zygopteris*, was not regarded as established, and affinities were sought rather among homosporous Filices.

ROYAL GARDENERS' ORPHAN FUND.

ANNUAL MEETING.

FEBRUARY 14.—The annual General Meeting of the supporters of this charitable Fund was held on the above date in the Essex Hall, Essex Street, Strand, W.C. The attendance was only moderate, not more than thirty gentlemen being present.

Mr. H. B. MAY, chairman of the Executive Committee, presided.

THE ANNUAL REPORT.

"In presenting their fourteenth annual report, the Executive Committee once more congratulates the supporters of the Fund upon its continued prosperity and usefulness, as, although unfortunately, in common with many other charitable institutions, the total receipts for the year show a slight falling off, the Committee have been enabled to meet all claims upon the Fund, and to expend in regular allowances to orphans duly elected to receive the same, an increase on the disbursements of the previous year, as well as to expend a larger amount in the form of grants in aid, the total amount disbursed being £1,099 17s. 6d., or an excess of £66 5s. over any previous year.

The Committee has the greatest satisfaction in making the announcement that Her Most Gracious Majesty Queen Alexandra has kindly consented to continue to the Fund the patronage which Her Majesty previously accorded to it as Princess of Wales.

By the generosity of the subscribers attending the last annual general meeting, when, as in the previous year, all the candidates were elected, the Committee were placed in the gratifying position of being able to commence the new century, and the first year of the reign of His Majesty King Edward VII., without any candidates waiting election.

With regard to the grants in aid, the Committee feel certain that in this beneficent branch of the fund's operations, they will have the sympathetic support of all subscribers in the good work that is being done in helping to give a useful start in life to those poor orphans, who, by virtue of the age limit, cease to receive regular assistance, by helping to lengthen the period of schooling in some cases, and by the provision of

clothing and tools in others; while candidates awaiting election are frequently assisted by means of allowance of 2s. 6d. per week.

The number of orphans who have been elected to receive the benefits of the Fund during the past thirteen years is 143, and the total amount expended in allowances during the same period is £9,844 12s. 6d. The number now on the Fund is seventy-five, and twelve will be added this day.

The Committee still deplore the fact that there are many gardening centres in the country from which the Fund receives little or no support; while, on the other hand, the efforts made by good friends and fellow-workers in such districts as Altrincham, Bournemouth, Bradford, Bristol, Chesterfield, Chislehurst, Reigate, Richmond, Rugby, Sevenoaks, Wimbledon, &c. (who, by means of local collections, concerts, and the sale of surplus flowers at exhibitions, annually raise amounts which greatly assist the Fund), are gratefully acknowledged by the Committee.

The Annual Festival, held at the Hotel Cecil on May 7, under the presidency of the Hon. W. F. D. Smith, M.P., proved to be one of the most successful of the series, and the Committee has the gratifying fact to record that the earnest and sympathetic appeal made by the chairman on that occasion resulted in a subscription list amounting to £848 17s. 1d. Most gratefully do the Committee acknowledge the great service rendered to the Institution by the Hon. W. F. D. Smith, and they have the greatest pleasure in recommending that he be this day elected a Vice-President of the Fund.

It is with the liveliest satisfaction that the Committee make the announcement that Leopold de Rothschild, Esq., has most kindly consented to preside at the next Festival, which will take place at the Hotel Cecil on Thursday, May 8th, and they trust that all friends of the Charity will assist them in making the presidency of this princely patron of Horticulture, in Coronation Year, a memorable one in the annals of the Fund.

In the month of May, a favourable opportunity offering, your Committee made an addition to the invested funds by the purchase of £514 Great Indian Peninsular Railway guaranteed 3 per cent. stock, at a cost of £499 18s. 8d.

With deep regret the Committee has to record the death of Mr. Alfred H. Smee, who, on the establishment of the Fund, readily gave his consent to act as one of the Trustees, and subsequently not only assisted the Institution with generous financial support, but also most readily afforded the management the benefit of his ripe financial experience in dealing with the Fund's investments. In life warmly interested in the success of the Fund, Mr. Smee did not forget the poor orphans in death, having bequeathed to the Institution £250 free of legacy duty.

Other valued supporters have also passed away in the persons of Sir Edwin Saunders, one of the Vice-Presidents; Mr. Martin Hope Sutton, Mr. D. T. Fish, Mr. A. Henderson, and Mr. Thomas Rochford. In the early days of the Institution, Mr. Fish was most strenuous in his efforts to gain support for the Fund, and helped materially to establish it on a sound financial basis; while by the lamented death of Mr. Rochford, the Fund has lost the open-handed and most sympathetic support of one of the most kindly natured of men, and British horticulture one of its most enterprising and skilful exponents.

The Committee have pleasure in recommending that Mr. Leonard G. Sutton, of Reading, be elected a trustee in the place of the late Mr. Smee.

The members of the Committee who retire by rotation are Messrs. W. R. Alderson, A. F. Barron, G. Cuthbert, W. Howe, J. Lyne, C. E. Osman, W. Poupert, and J. Walker; and Messrs. Alderson, Cuthbert, Howe, Lyne, and Poupert, being eligible, offer themselves for re-election. Mr. George H. Barr, King Street, Covent Garden; Mr. T. W. Sanders, Lewisham; and Mr. G. Nicholson, Richmond, are nominated by the Committee for election to the seats vacated by the retirement of Messrs. Barron, Osman, and Walker.

By the retirement of Mr. Barron, on account of continued ill-health, which all who know him deeply deplore, the Committee desire not only to assure him of their warmest sympathy and best wishes for his restoration to health, but also to place on record their high appreciation of the invaluable services which he rendered to the Fund at its foundation, and subsequently as its Secretary, and their sense of the loss which it sustains by his retirement from active participation in its management.

The Committee, keenly sympathising with Mr. Sherwood in his recent severe illness, and heartily hoping that he may be speedily restored to health, again most warmly acknowledges the great personal interest which, as Treasurer, he has taken in the management of the Fund, and the munificent financial support which he has continued to accord to it. Mr. Sherwood's re-election this day, the Committee feels assured, will afford the highest gratification to all well-wishers of the Fund.

To the Auditors, Mr. Martin Rowan and Mr. P. Rudolph Barr, the Committee also tender hearty thanks for their valued services in auditing the accounts—a labour of love, most conscientiously carried out. Mr. Rowan is the retiring Auditor, and is nominated by the Committee for re-election.

STATEMENT OF ACCOUNTS.

The receipts from general and local secretaries subscriptions were £340 7s. 3d., and from donations £161 13s. 6d. The annual dinner receipts were £648 17s. 1d.; dividends on stock and interest on deposits £302 4s. 8d. The total receipts, including a balance in hand of £1,173 4s. 3d., were £2,683 10s. 5d. On the expenditure side, allowances to orphans amounted to £1,028 10s., Emma Sherwood Memorial £13, and grants in aid £58 7s. 6d. The expenses of the annual dinner were £162 17s. 4d. (there being thus nearly £500 profit upon the event). Secretary's salary £100, various other items show an expenditure of £92 2s. 2d.; the purchase of £514 of Stock cost £499 18s. 8d., and there are balances at bank, on deposit, and in hand of £2,683 10s. 5d.

PROCEEDINGS.

The Chairman, in moving the adoption of the report and balance-sheet, said the year had been a singularly uneventful one. He said that the falling off in receipts was more apparent than real, as subscribers were apt to forget dates, and some subscriptions that should have appeared in this year's account would do so in the next. After the Chairman had referred to other features of the report, Sir J. T. D. Llewelyn, Bart., seconded its adoption, saying that the Fund was doing better work than ever. He hoped the number of subscribers would be lengthened and strengthened. The report was adopted unanimously.

On the proposition of Mr. W. Bates, the Hon. W. F. D. Smith was elected a Vice-President. On the proposition of Dr. M. T. Masters, seconded by Mr. Harry J. Veitch, Mr. Leonard G. Sutton was elected a trustee in the place of the late Mr. Smee.

The personnel of the Committee was then altered as suggested in the above report, and the retiring members were thanked for the services they have rendered.

Mr. A. Dean thought that the least the Committee could have done was to have suggested that Mr. A. F. Barron be elected a Vice-President; however, as explained by the Chairman and Mr. Assbee, it was thought that the proposal should be made by the members rather than by the Committee. Mr. Barron was thereupon unanimously declared a Vice-President.

Mr. Brian Wynne was unanimously re-elected Secretary, and the Chairman testified to the efficient manner in which Mr. Wynne had discharged the duties of the office.

CHILDREN ELECTED TO THE FUND

Messrs. George Cuthbert, William Cuthbert, J. F. McLeod, and H. J. Jones, were appointed scrutineers of the Ballot. At half-past four the Chairman declared the result as follows:—Frederick John Nicholls, 284 votes; H. H. Orchard, 236; Edith Martha Bevis, 232; F. E. Tickner, 222; E. D. Seydewitz, 218; E. M. Seydewitz, 213; Hugh Allee, 208; J. A. C. Robertson, 205; H. R. Tickner, 204; J. A. Wakelin, 191; H. Robertson, 185; M. M. de Gruchy, 167; W. Gregg, 107; Williamina Hendry, 47; Lilian M. Francis, 35; and Evelyn P. Cherry, 30. The Chairman then declared the twelve children first-named duly elected.

THE FRIENDLY SUPPER

took place in the evening, at the Cannon Street Hotel, Mr. R. B. May presiding; Mr. J. F. McLeod and Mr. Assbee filled the Vice-Chairs.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

FEBRUARY 6.—W. THOMPSON, Esq., Stone (gr., Mr. Stevens), staged a few nice *Odontoglossums*, *O. crispum* var. Jubilee receiving a First-class Certificate and a Cultural Certificate. The group contained also a number of panfuls of well-grown *Sophranitis grandiflora*. A Bronze Medal was awarded.

From the garden of the late Mrs. BRIGGS-BURY, Accrington (gr., Mr. Wilkinson), came *Cypripedium aureum* var. *Pomona*—an Award of Merit; C. x *Lilian Greenwood*, a very fine form, received a First-class Certificate; C. x *Beeckmanni* came from the same collection.

O. O. WHIGLEY, Esq., Bury (gr., Mr. Rogers), staged a fine lot of *Cypripediums* again. A fine plant of *C. Lathamianum*, in a 6-inch pot, and bearing fourteen flowers, received a Cultural Certificate. A Silver Medal was awarded for the group.

Mrs. S. GRATRIX, Whalley Range (gr., Mr. Cypher), exhibited *Lycaste* x *Baller*, which has been previously certificated by the Society.

Messrs. CHARLESWORTH & Co., Bradford, sent a magnificent hybrid *Lycaste*, of a deep purplish-rose colour, with dark crimson lip, named *Lycaste* x *Charlesworthi*, undoubtedly the best variety yet observed in this genus. The committee were unanimous in awarding a First-class Certificate.

Mr. J. CYPHER, Cheltenham, staged a group of plants consisting of good forms of various *Dendrobiums*, all good examples of careful cultivation; *Dendrobium* x *Ainsworthi* "Cypher's var." was one noted amongst

them, the flowers of a rich shade of colour, and of large size; *Lycaste Skinneri* var. *alba* was also well shown (a Bronze Medal).

Messrs. F. SANDER & SONS, St. Albans, received a First-class Certificate for *Cattleya Trianci* "Our King," a fine, handsome, richly-coloured flower, with flaked petals and a rich lip; the spike bore four of these flowers. P. W.

EALING HORTICULTURAL.

FEBRUARY 17.—The thirty-seventh annual meeting of this Society was held on the above date in the Town Hall, Mr. R. Willey, one of the Vice-Presidents, presiding. The annual report of the Committee expressed regret that the summer show held in the new Walpole Park was not so financially successful as could have been desired, owing to the incidence of the weather. The exhibition was a good one, and the special prizes for table decorations was the means of bringing out some charming designs. There was an excellent show in November, but a small attendance, owing to the dense fog which prevailed. The financial statement showed a balance in favour of income over expenditure of £31. Leopold de Rothschild, Esq., was re-elected President; the Vice-Presidents were re-elected, with the addition of the Mayor; and the officers were re-elected. A motion that the show on July 9 next should be held in Corporation Walpole Park, was met by an amendment that the President be approached for permission to hold the show in Gunnersbury Park. This was carried by a considerable majority. It was resolved that an autumn show of *Chrysanthemums* be held in the Town Hall on Wednesday, November 12.

DEVON AND EXETER GARDENERS'.

"GARDENS and Gardening on the Continent, as compared with England," was the title of the paper read at the last meeting of the Association by Mr. Percy A. Meyer, who had spent five years in continental nurseries, and at the Horticultural College of Proskau, Silesia, and is now an assistant at Kew. The observations, remarked Mr. Meyer, did not apply to the Continent generally, but to Germany and Switzerland. In comparison as regards climate, with all its faults, the English climate was more kindly, and many of our common shrubs, like *Hollies*, *Laurels*, *Aucubas*, and *Rhododendrons*, could, in some districts, only be grown out-of-doors in sheltered positions in Germany, and generally required the protection of straw or fir branches in the winter months. Evergreen *Euonymus*, *Portugal* and common *Laurels*, &c., were generally grown in tubs, which were put under cover from the end of October to the end of February, and later. Roses and wall fruit-trees have to be carefully protected from the frosts which, as a rule, prevail during most of the winter, and at times are very severe. Rockwork plants are covered with leaves and fir-branches pegged down on the top of them, spring-flowering bulbs being similarly treated. *Clethra*, *Ceanothus*, *Genista*, *Deutzia*, Japanese *Maples*, and *Honeysuckles*, all require protection. At the end of April in Germany the season is no further advanced than at the beginning of that month in England, but things soon forge ahead after that; and when a few weeks have passed, vegetation is in a more forward state than in this country. The temperature in summer reaches and maintains a higher standard than with us, and as regards Germany, that is why the saving of flower-seeds is so successful in the Erfurt, Quedlinburg, and other districts where the leading seed-growers have their headquarters.

In the north of Germany the land is light and sandy, and the country very flat. In the south, the country is more hilly, and the soil heavier. In the valleys of Switzerland, fruit-crops are abundant, and fruit is cheap. The love of gardening is more general in Germany than in England, but there is the rather curious fact to be noted that while a German owner will spend less on the making or laying out of a garden, and do more afterwards to maintain and improve it, the English owner is often more lavish in his initial expenditure, and niggardly afterwards in keeping it up. In the public gardens and nurseries, and in large private gardens in Germany, a marked distinction is made between the professional gardener and the garden-labourer. A three years' apprenticeship is imperative before a young man is accepted as a gardener proper and to become a foreman it is incumbent upon him to have served a term at some horticultural college, of which there are plenty in the country. He must be theoretical as well as practical. Women are employed to a considerable extent in gardening at wages running from 1s. to 1s. 6d. per day. Male garden-labourers get 2s. to 3s. per day. Gardeners do not get much more than labourers, although head gardeners and foremen generally have free cottages and a monthly wage. Some of the nurseries are very extensive, one near Berlin covering about 600 acres devoted to the cultivation of ornamental trees, shrubs, and fruit-trees. A

curious feature in such a nursery is that the packers, numbering between twenty and thirty, are paid by piece-work. The entire staff numbers about 400, of which about 100 are women. The Germans are far behind the English in fruit-forcing, and Grapes, Peaches, and similar fruits grown under glass in Germany are much inferior to the same class of fruit as grown in England. Nor is the cultivation of flowers under glass, particularly Orchids, so well done in Germany as it is in England. The public gardens of Germany are, on the whole, more tastefully laid out and better looked after than corresponding gardens in England. Private gardens in Germany are neither so numerous, extensive, or so well equipped as those in England. The plan of laying-out is on the model of the public gardens in most cases. Nearly every large city in Germany has its botanic garden, those of Berlin, Hamburg, Dresden, and Karlsruhe being excellent. Mr. Meyer gave some interesting details of the practice in Germany of budding, grafting, and the various methods of propagation, as practised in that country. *A. Hope.*

READING & DISTRICT GARDENERS' MUTUAL IMPROVEMENT.

FEBRUARY 10.—The fortnightly meeting of the above Association, held in the Abbey Hall, on the above date, was presided over by Mr. Leonard Sutton, the President, and was attended by nearly 130 members, one of the largest attendances yet recorded. The subject for the evening was "Salient Points of Fruit Culture," and was introduced in an exceedingly practical manner by Mr. E. Molyneux, of Swanmore Park, Bishops Waltham, his demonstrations in the art of root and branch pruning, staking, &c., making his lecture easy to follow, even by the youngest members present.

The exhibits were of fine quality for the season of the year, consisting of Apples, from Mr. J. BISSEY, gr., Beenhall Grange; and Mr. F. FRY, gr., Greenlands, Reading.

MR. ROBERT NEWSTEAD. — A crowded audience filled the Lecture Theatre at the Grosvenor Museum, Chester, on the occasion of a presentation to Mr. R. NEWSTEAD, a fuller notice of which will be taken in our next issue.

ARUM CORNUTUM: *J. R.* We know of no such plant; but there is no difficulty about the cultivation of Arums, either tender or hardy, given a rich soil, and a rest without drying off completely, in the case of those grown in pots, when the foliage has died down.

ASPIDISTRA GETTING SPOTTED AND TURNING YELLOW: *Mrs. Swanton.* A fungus is the probable cause. Can you send a diseased leaf for examination? The plant should be rested during the winter by being set in a cool place, not necessarily in full daylight, and the soil kept slightly moist. The flowers rise only just through the surface of the soil, and being dull purple in colour, cannot be mistaken for new leaves. The plant should not begin to make new growth till April.

BOOKS: *F. H. P.* *The Forcing Garden*, by Samuel Wood. Published by Crosby Lockwood & Co., Stationers' Hall Court, Ludgate Hill, E.C.; or get some of the special manuals sold by Mr. Upcott Gill, 170, Strand, W.C. — *A. F.* *Select Ferns and Lycopods*, by B. S. Williams. Sold at the Victoria Nurseries, Upper Holloway, London, N. *The Dictionary of Gardening*, by G. Nicholson and others. Published by Upcott Gill, 170, Strand, London, W.C. — *D. B.* At the *Journal of Horticulture* Office, 12, Mitre Court Chambers, Fleet Street, London. Price 1s.

CATERPILLAR IN POPLAR-TREES: *E. G.* The larvæ of the Goat-moth. Kill them by thrusting a piece of wire into the holes made in the stems.

CUCUMBER DYING OFF IN THE FIRST ROUGH-LEAF STAGE: *H. Woodthorpe.* The soil sent is of a very unsuitable kind, is heavy and retentive, instead of being light, porous, and moderately rich. Young plants are very

liable to "go off" from any excess of moisture when planted in soil of the nature of that sent. The plant had the appearance of having been grown in a but little ventilated frame.

DENDROBIUM HILDEBRANDI: *M. R. M.* The species is considered easy to grow and flower when treated as *D. nobile*. Probably if you rest them in a cool, airyinery or greenhouse after the growths are fully completed, you will flower them more satisfactorily; or if you place some of them in Orchid-baskets, and suspend them, that may answer the purpose.

DRESSING FOR TREE STEMS AS A PROTECTION AGAINST RABBITS: *J. S. H.* Make a thick paint of clay, cowdung, and lime and water, and to this add spirits of tar, in the proportion of two wineglasses to an ordinary pailful. With this the stems may be smeared 4 feet high. N. Ahlborn, 21, St. Andrew Square, Edinburgh, sells a tree protective composition that is highly spoken of.

FELLOW OF ROYAL HORTICULTURAL SOCIETY: *A. F.* If you apply to the Secretary, Rev. W. Wilks, 117, Victoria Street, Westminster, the necessary information will be sent you.

GREENHEART: *Prof. C.* Apply to Messrs. J. Lenanton & Sons, 9, Gracechurch Street, London; or to Messrs. Denny, Mott & Dickson, 165, Fenchurch Street, London, E.C.

NAME OF FRUIT: *R. C.* Catillae, a stewing Pear.

NAMES OF PLANTS: *R. E.* 1, *Cattleya Percivaliana*; 2, *Odontoglossum gloriosum*, which some include in the forms of *O. odoratum*; 3, *Goodyera discolor*, figured as such in the *Botanical Magazine* 46, t. 2055, but now known as the typical *Hemaria discolor*. In cultivation it is classed with the *Anacochili*, respecting which articles have appeared in the *Gardeners' Chronicle*, and others will follow. — *R. C.* *Graptophyllum hortense*; more often called *G. pictum* in gardens. It is known as the Caricature-plant; by shutting off certain sections of the colouring on the midrib, the most singular faces can be made out. — *J. H.* *Cypripedium insignis*, *Polypodium aureum* (not an *Adiantum*), and *Carex variegata*. — *W. J. C.* *Asparagus tenuissimus*. — *L. H.* *Senecio grandifolius*; generally called *S. Ghiesbreghtii* in gardens. It is used in subtropical gardening for summer display outdoors. — *W. S. T.* The specimens are very poor; the withered leaf No. 3 cannot even be guessed: 1 appears to be *Codiaeum* (*Croton*) *Johannis*; 3, *Maranta Makoyana*; 4, *Cissus discolor*. — *Fairlawn.* 1, *Cyperus laxus*; 2, *C. alternifolius*; 3, better specimen required; 4, 5, 6, varying growths of *Ficus stipularis*, which is known in gardens as *F. repens*; the leaves are comparatively small until the plants are old, and vary according as the plant is grown against a wall or as a standard.

PEACH BLOOMING AT IRREGULAR TIMES: *C. C. C. G.* The buds were formed and matured at slightly different periods in the plant's growth.

PUNNETS: *J. B., Edmonton.* We cannot undertake to recommend trade houses. Could you not visit the great London markets, and ascertain the names and addresses of makers, &c.?

ROSE LEAVES HAVING BLACK SPECKS ON THE LOWER SURFACES: *J. J., Chertsey.* The excrements of minute insects—not fungus. Cleanse the leaves with soapy water, and then syringe them with clean water.

THE GLUT: *S. W. F.* You have overlooked the fact that your suggestion is already carried out as far as possible.

TIMBER AND ORNAMENTAL TREES ON A HEAVY CLAY SOIL: *G. P.* If the land is drained by deep, open grips (narrow ditches), or rubble drains, and trenched 2 feet deep, the following trees are likely to succeed, with shelter from the wind in the form of some quick-growing trees, as Poplar, Willow, and

Alder. For permanent trees, employ Oaks of all kinds, if ornamental planting is looked for; or the common British Oak if it is to be left for timber; also Hornbeam, Alders, Planes, American Walnuts, Sycamore especially, planting this last on the windward side, or every side except the south; common Ash, Silver Fir, Balm of Gilead Fir, common Spruce, Douglas Fir, and Weymouth Pine; 2 acres of land is a small area under timber, and it will not admit of a large miscellaneous collection being planted, without great loss in the cutting away or transplantation of trees when they begin to crowd each other. If it is to be all under one or two kinds, say Oak and Hornbeam, or Douglas and Silver Fir, or a mixture of the four, the deciduous species should be planted at 12 to 16 feet apart, and common Spruce used as nurse-plants, cutting these away as the trees approach each other. If all is to be under Douglas or Silver Fir, these may be planted at 3 ft. apart in quincunx fashion, and finally be thinned to double the distance; you will then obtain straight, clean boles, free from knots and big limbs. Ornamental species of Conifers might occur at prominent points, or at the sides of roads, and about the entrances; as *Abies amabilis*, *A. magnifica*, *A. pinsapo*, *A. nobilis*, *Sequoia sempervirens* (Redwood), *Thuja gigantea*, and *T. plicata*, all of which would grow well in the heavy land.

TREES AND SHRUBS FOR PLANTING AN ISLAND IN CONJUNCTION WITH POPLARS AND WILLOWS: *A. R. P.* If the flooding endures but for a brief period of time, *Hibiscus syriacus* = *Althea frutex*, *Bignonia* (Catalpa) *syringæfolia*, *B. Bungei*, and *B. speciosa*, *Rhododendrons*, *Kalmias*, *Andromedas*, *Pernettyas*, *Gaultherias*, the last five in peat, or light sandy loam and leaf soil; *Aralia Sieboldi*, *Lilacs*, *Quinces*, *Medlars*, *Gleditschias*, *Black Thorn*, and *Thorns*, *Crataegus* in variety; *Hippophae rhamnoides*, *Celtis orientalis*, *Ribes* of species, *Cornus sanguinea*, and others; *Benthamia fragifera*, and *Symphoricarpos racemosus*. Of Conifers plant any of the *Thuias*, *Juniperus virginiana*, *Pinus excelsa*, if the position is warm. *P. insignis* also; also *P. Strobus*, *Abies pectinata*, *A. balsamea*, *Pseudotsuga Douglasii*, *Tsuga canadensis*, and *Taxodium distichum*. Of deciduous trees choose *Juglans nigra*, *Carpinus betulus*, and most of the Oaks of the new and old world succeed in wet soils if the water be not stagnant. We know of no kind of bulbs that rats will not devour when hard pressed by hunger.

WATER-GLASS: *J. E. H. and G. W. C.* At the foot of the article we inserted three weeks ago is found the name of the writer, but the post town, Hineckley, was omitted. We have nothing to add to what was there stated. Doubtless we shall hear more about the undertaking shortly.

COMMUNICATIONS RECEIVED. — *W. G. G.*, specimen, with thanks. — *E. im T.*, Ceylon. — *S. W. F.*, *H. H. D'O.*, *W. W. & Co.*, *M. Durand*, Brussels. — *H. O. F.*, *W. M. W.*, *G. W. C.*, *J. A.*, *D. W.*, (Rev.), *W. P. W.*, *W. G. S.*, Leeds, many thanks. — *W. M. W.*, *W. G. S.*, Danstable, many thanks. — *J. M. H.*, *R. S.*, Birmingham. — *Adnit & Naughton*. — *R. H. P.*, *E. W. R.*, *R. E. M.*, *R. S.*, *Dr. W.*, *B. B.*, *J. J.*, *M. W.*, *A. D.*, *J. W.*, *J. G. W.*, *W. S.*, Expert. — *C. L. B.*, *J. A.*, *J. R. J.*, *R. P. B.*, A Horticultural Student. — *J. H. Maiden*. — *J. Whytock*. — *W. A. C.*, *W. H. C.*, *E. C. A.*, *H. J. W.*, *J. H. H.*, *H. S.*, Froggatt. — *J. W. P.*, Colocynth. — *Inquisitor*.

DIED. — On the 18th inst., in London, JANE ELIZABETH RASHLEIGH, aged sixty-six years, second wife of Jonathan Rashleigh, Esq., of Menabilly, Cornwall, and 3, Cumberland Terrace, Regent's Park, N.W., and only child of Arthur Pugh, Esq., of Lissadrome, Co. Mayo.

SCHOOL GARDENS.

OF the school gardens which we now more frequently hear about in this country than formerly, two kinds may easily be distinguished. There are, in the first place, those intended for the benefit of elementary school children; and, in the second, others of which older pupils may avail themselves, in connection with what are called continuation schools.

At present it is only the latter style of garden which county councils can legally bring into existence, and directly assist with the money given to them for Technical Instruction. The fact therefore that the conference on school gardens, arranged lately by the Berkshire Technical Education Committee, dealt almost entirely with gardens for elementary schools, is worthy of note. It may be taken as additional evidence of the indirect help which the county councils are anxious to give to the Board of Education, in the endeavour to introduce a proper system of rural education for children.

It is being recognised, only too slowly perhaps, that it is better to learn by seeing and doing than by merely reading books.

In advocating, therefore, the formation of school gardens, in connection with which object lessons in Nature-knowledge are to be given as part of the school work, the Government has shown that it appreciates the educational value of gardening.

Already many elementary school teachers have been trained in technical classes how to teach their pupils to learn from Nature, and have been similarly initiated into many of the mysteries of horticulture. If, however, school gardens are to be encouraged as they should be, and made a success, it remains to bring before the teachers concerned the objects to be sought, as well as the difficulties in the way which some of their fellows have successfully surmounted, and to demonstrate the best model to be chosen. There is no better way, perhaps, of doing all this than by holding conferences like the one to which we have alluded.

Mr. T. G. Rooper, who was the principal speaker, very rightly made it clear that work in the garden of elementary schools must be entirely educational, and the utilitarian idea absolutely removed. We might say further, that an excellent training is gained from observing the growth and habits of living things, and gardening moreover exercises the memory, and its operations strengthen the limbs. On the other hand, the mere suggestion of turning out gardeners is ridiculous; the failure upon the part of critics to see that this is not intended, has oftentimes served to hinder the introduction of out-door work into the curricula of schools.

A comparison of the school-gardens, common on the Continent, with those of England, which Mr. Rooper is so well qualified to make, shows that while the latter are less elaborate, and probably afford less general information to the pupils, they are a great deal more practical and serve their purpose better. Indeed, the Germans themselves are prepared to admit this. Much may be learned from beds in which are found blossoms of decorative value, the flowers useful to bees, fruit-trees, vegetables grown as farm or garden crops, pot herbs, and plants used in medicine, as well as those of economic value, such as Madder, Flax, and Hops. The fact, however, remains that nine-tenths of the labour falls to the lot of the schoolmaster. In England, however, where the aim is only to grow the best sorts of vegetables and fruits, the children do all the work. Mr. Rooper claimed that English school-gardens are the best in the world; and Mr. J. C. Medd was able to quote the same opinion, in regard at least to one of them, as expressed by the High Commissioner appointed by Canada to study the question.

The schemes of work at this garden and one or two others, are given in an interesting pamphlet which has just been published by the Board of Education. Plans of various plots are also shown, and details of courses on plants and Nature knowledge, which are carried out at schools in Kent and Essex respectively, are included. The simple physiological experiments devised for the latter scheme are particularly worthy of consideration.

It must be remembered that the success of the school-garden depends, in a great measure, upon the man who inspects it. Mr. Rooper happens to be one of the

Government inspectors who has made the subject of horticulture his own. He is, however, the exception, and we sympathise with Mr. Macan, the Secretary of the Surrey Technical Instruction Committee, in his vain appeal to the authorities to appoint at least one man in the district who knows something about gardening.

There is much interest attaching to the experiences of an elementary schoolmaster, who at the outset thought that the difficulties in the way of his founding a school-garden were too great to be overcome. He did not know enough about horticulture to enable him to teach; how was he to get land; who would buy the tools; and where were the funds with which to purchase the necessary seeds? and so on. However, the master and some of his fellows asked the Oxford County Council to hold classes, after attending which the teachers passed the examination of the Royal Horticultural Society. A piece of the garden attached to the school-house was given up, and it was decided to start garden work if the parents of the pupils would provide the tools, while the small Government grant was allocated later to the purchase of material. Upon the day appointed for the inauguration of the garden, all the boys concerned appeared with spades in their hands, and a good beginning was at last made.

In this connection may be mentioned the formation of a new association organised by Mr. J. C. Medd, with Sir John Cockburn as Chairman, which it is hoped will hold an exhibition in London in July, where the results of the Nature-study work of all the various kinds of school in England, and possibly elsewhere, will be displayed.

Quite recently the Berkshire Technical Education Committee approved a scheme for the conduct of school gardens in connection with continuation schools; and at the Conference later in the day, a short paper by the County Horticulturist, Mr. Wright, brought out very strongly the useful work already done by them.

NEW OR NOTEWORTHY PLANTS.

STAPELIA BELLA, A. Berger (sp. nov.).

THE origin of this Stapelia is unknown to me. Since its introduction into this garden, some years ago, it has always been cultivated under the name of *Stapelia glauca* (from which, however, it is quite distinct), and no trace can be found of its antecedents or where it came from. It flowers abundantly every autumn, and proved very hardy in the severe winter of 1901, when it withstood a cold of $-3\frac{1}{2}^{\circ}$ Cels.

The structure of the flower is somewhat curious; it closely resembles the description recently published of *Stapelia mirabilis*, N. E. Br. The trembling hairs on the margin move, as in the *Tromotriche*; nevertheless the plant belongs to the sub-genus *Stapletonia*. It possibly might be a hybrid between an *Orbea*, or *Tromotriche*, and a *Stapletonia*. Mr. N. E. Brown, to whom I submitted this plant, and to whom I am much indebted for his kindness in helping me to name it, is also of this opinion.

The stems are erect, 6 to 7 inches high and $\frac{3}{4}$ of an inch broad, quadrangular, with short, papillose hairs, and with short, patent teeth at the angles. The flowers rise in threes or fours from a short common peduncle at the base of the young shoots. Pedicels short, $\frac{1}{2}$ to

$\frac{3}{4}$ of an inch long, reddish, puberulous. Calyx-lobes triangular-lanceolate, acuminate. Buds broad and flat-topped. Corolla with a short tube, radiate, with very patent, finally revolute lobes, externally green, with five reddish nerves, inside deep purple or brown, about 2 ins. broad. The corolla is of a very fleshy consistency, especially near the centre, where it is thickened in such a manner as to form a flat wall, which includes a short, pentangular tube, the inside of which is paler, and furnished with some reddish hairs of different lengths. The corolla-lobes are deltoid-ovate, glabrous, and fringed at the margins with long, simple, dark purple, trembling, and very deciduous hairs. Ligule of the corona erecto-patent, black-brown, from a broad base acuminate, and faintly tridentate. The inner divisions of the inner corona long filiform recurved, the outer divisions much shorter, wing-like, patent, triangular. *Alvin Berger, La Mortola.*

CULTURE OF THE ANÆTOCHILUS.

It would have been still more interesting if Mr. Budde, of Utrecht, had appended to his useful note in the last issue of the *Gard. Chron.* a list of the species cultivated by him. In my reference to them, Dec. 7, 1901, p. 410, I mentioned them only incidentally, and therefore did not indicate the species I at one time or other had through my hands, and it may be well to enumerate some of the leading species, and endeavour to place them under their recognised names, for although most of these pretty-leaved terrestrial Orchids are called *Anætochilus* in gardens, or perhaps more correctly *Anætochilus*, they include several very distinct genera, and probably if their flowers were readily available for comparison there would be more changes in their nomenclature. Their leaves are the great attraction, although the flowers are very pretty, and would be seen more often than they are but in my younger days it was generally thought to bring about the death of the plant to allow it to flower, and some form of the same notion still prevails. Certainly, as at present managed, the flowering of the *Anætochili*, with the exception of the varieties of *Hemaria discolor* and one or two more, seems to be fraught with peril. The reason of that is, that we have not as yet quite mastered the method of treatment of the plants, or we should be able to grow and flower each species in the same manner as other stove and greenhouse plants, and to that end the articles of Mr. Budde and Mr. Micholitz will lend assistance. I think the use of fibrous loam in the compost in which they are potted, and observance of Mr. Budde's hint about keeping them on the shady side of the house, and which Mr. Micholitz indirectly suggests when he describes them as growing in forests, would make two good points to work on. My own experience is that the *Anætochili* like a good clear light, but are soon damaged by the direct rays of the sun.

The species I had, and which may perhaps be found here and there in gardens still, were *Anætochilus argyronceus*, and *A. Frederici Augusti*, which sometimes appeared as *A. xanthophyllus*; *A. regalis*, a Ceylon species; *A. concinnum*, an Assam ally of it; *A. setaceus*, and its variety; *A. cordatus*, *A. Reinwardti*, and *A. Roxburghi*, also known as *A. Lobbianus*. Among some of these species there is great variation in the tint and marking of the leaves, and garden names have been given them. Of a more slender and ascending habit are *Physurus argenteus*, *P. Orgiesii*, *P. pictus*, and *P. querceticola*, the first three with

silvery veined leaves, and the last of a bright green, with oblique silvery markings.

Macodes Petola, with its bright green leaves beautifully veined with silver, is one of the strongest and freest growing. It is not an uncommon thing to see a pan of it with several growths in a shady part of the stove-house, without a bell-glass.

Macodes Sanderiana, more often called *Anætochilus Sanderianus*, is the recent introduction referred to by Mr. Micholitz, Feb. 22,

FIG. 40.—STAPEFIA BELLA.

FIG. 41.—STAPEFIA BELLA: DIAGRAM.

A, Section through the flower.

B, C, Floral details.

(See p. 137.)

p. 130. It may be likened to a robust and still freer-growing form of *M. Petola*, though quite distinct.

Dossinia marmorata, or as it is generally called, *Anætochilus Lowii*, is another strong-growing species, with large olive-green leaves, beautifully veined; and it succeeds well with but little trouble if a suitable place to grow it—that is the most important factor in all the other cases—be found.

The noble species which Mr. Micholitz mentions of *Anætochilus Leopoldi* is doubtless *Dossinia Leopoldi*. I can fully bear out all his remarks about it, for I was fortunate enough to be President of the jury of the Orchid section at the great Ghent Quinquennial Show, April, 1898, and remember its beauty, although shown, I believe, in the battered and travel-stained case in which it made its long and rough journey.

The section known as *Goodyera*, and including forms of *Hemaria discolor*, are free to grow and flower, and I have used the flowers of them for cut blooms. The old variety is well known, and *H. d. Dawsoni*, with its velvety chocolate leaves veined with red, and the green form of it known as *H. d. Ordiana*, have leaves of great beauty and pretty spikes of white flowers.

Of hybrids we had *Anætochilus* × *Dominii* and *A.* × *Veitchi*, both crosses between *Anætochilus* and *Hemaria discolor*. Both received First-class Certificates at the Royal Horticultural Society in 1865 as *Goodyera*.

Other distinct things known as *Anætochilus* in gardens are *Goodyera Rollissoni*, since identified by Mr. Rolfe as a *Macodes*; *Zeuxine regia*, with its narrow olive-green leaves, bearing a rosy-silver band down the middle, and which is better known as *Anætochilus striatus*, and *Monochilus regius*, the last generic name being an awkward complication, for it had been previously used for a genus of *Verbenaceæ*. Then we have the pretty *Nephelaphyllum pulchrum*, a Malayan species of comparatively easy culture. These all go under the common denomination *Anætochili* in some gardens, and so far as I have been able to prove them, all require a warm plant-house, preferring the shady side of a plant-stove to an Orchid-house. But there are a few worthy to associate with *Anætochili* which I have grown well in a cool house. These are the North American *Goodyera repens*, and *G. pubescens*, with green and silver leaves; and the pretty bronzy-leaved Japanese *G. velutina*.

Reminiscences of times gone by are the reward of all who have studied plants for many years, for when special sections are thought about, old friends temporarily forgotten, again appear before the mind's eye. The name *Goodyera* recalls a plant which I have long since lost sight of, although I think it has been recently imported again, viz., *Goodyera macrantha*, brought from Japan by the late John Gould Veitch, and figured in the *Gardeners' Chronicle* in 1867. The plant had the habit and beauty of an *Anætochilus*, the leaves being olive-green, with emerald-green veining, the sides bordered with light yellow. I always thought it was a Japanese garden production, or variegated form of a type without the yellow border. The flowers borne close down to the leaves are very curious. It was also called *Georchis*. Another pretty species now probably lost is *Goodyera rubrovenia*. Many of these pretty things have been lost from keeping them too warm continually, and not lowering the heat and moisture when the growths have finished, I believe. But let it not be thought that I am posing as one who has at any time thoroughly grasped the successful culture of what are called *Anætochili*, for when I was generally more successful than most others, I never had them in thoroughly safe and satisfactory condition throughout. One or other was continually turning sulky, and to meet that I adopted the plan of propagating them frequently, and that method prevented actual loss, and gave the best results. Perhaps others may give their experience on this interesting subject. *James O'Brien.*

THE ROSARY.

ROSA LUCIDA.

THERE are many single-flowered species of Roses that are invaluable for grouping in the garden and pleasure grounds, and *R. lucida* is one of them. It is a very hardy species, and readily raised from seed for the purpose of naturalising or planting in large groups, say, from 20 feet to 25 feet across. The plant spreads underground, and grows to about 4 feet in height. The shoots are slender, the

growth is free, but not quite so strong as that of *R. rugosa*, or some of the other varieties, and the fruits are not so numerous or handsome. This is but of secondary importance, as the flowers are produced in great abundance, and perfume the air for some distance around, especially if there are many plants. For this reason a situation near a walk is appropriate. Varieties of *R. rugosa* grow freely, require no pruning, and generally speaking, but little attention. The foliage is fine and very distinct, and the ripe fruits are showy in the early autumn. *J. G.*

about the present date. As some thousands have passed through my hands, I claim to know something about them. Long, green, sappy growths are usually of one year's growth, and therefore unsatisfactory if left at full length; and I advise their being cut down for dwarfs, as the nearer the roots the better is the wood ripened. Black hide-bound stocks are not suitable, and they seldom afford satisfactory shoots for budding on, and sometimes they remain quite dormant. The sort of stocks I have found invariably to succeed are from two and three years' growth, with firm green and brown-veined bark, similar to a nearly ripe, nicely netted, green-fleshed Melon. The stock should be quite straight from the ground-line, and if ultimately to carry a good head, should not be less than $\frac{3}{4}$ -inch in diameter, and 3 feet or more in height on stem, without any with bends or crooks; clubbed roots should be thrown aside. Briar cuttings for making dwarf stocks can still be made, and can usually be found in the hedgerows. A cutting should measure 6 to 9 inches long from straight ripe shoots. Disbud from the butt end, and leave only three or four buds at the top. Do not choose shoots that are commencing to grow, these being useless for the purpose. *J. D. Godwin, 29, Cleveland Road, Southsea.*

FIG. 42.—SEED-VESSEL OF *ARAUJA GRAVEOLENS*.

A, Side of fruit; nat. size.

B, Back of fruit; nat. size.

C, Longitudinal section of fruit; nat. size.

D, Transverse section of fruit; nat. size.

E, Central axis with imbricated seeds; nat. size.

F, G, Front and side of seed showing appressed seed-hairs; $\times 2$.

H, The hygroscopic seed hairs expanding and pushing off the seed; $\times 2$.

When the fruit is cut, each tuft of hairs quickly opens like an umbrella, and pushes the imbricated seeds from the fleshy central axis. Each seed has a loosely-attached tuft of hairs at its base.

FRUIT OF *ARAUJA GRAVEOLENS*.

WE give this name with some hesitation, as there seems to be wild confusion in the nomenclature of these plants, a confusion it is not in our power to disentangle; all we can do for the moment is to avoid coining a new name to add to the embarrassing synonymy.

The fruits we now figure are similar to those of *Arauja albens*, which we have illustrated on various occasions; but they differ in their more elongated and slender form, and in the coarse tubercles by which they are beset. The plants are nearly allied to the *Stephanotis*. The seed-pods illustrated (fig. 42) were obligingly sent to us by Mr. W. H. Clarke, of the gardens, Aston Rowant, near Wallingford, under the name of *Schubertia grandiflora*. This is, we believe, synonymous with *Arauja graveolens*, Mast., in *Gardeners' Chronicle*, September 8, 1888. The action of the seed-hairs in detaching the seed as described by Mr. Worthington Smith in the note beneath the figure is very noteworthy.

BERLIN.

LATANIA VERSCHAFFELTI, Lem., &c.

AMONGST the fan-leaved Palms, all the species of the genus *Latania* are jewels. Two of them are frequently met with in the collections of the amateur, viz., *L. Commersoni*, Gmelin, better known under the name *L. rubra*, and *L. Loddigesii*, Martius, which is also distributed under the name *L. glaucophylla*. The former is a variable Palm, as I have seen from many seedlings, as the purple margins of the segments vary in width. The finest varieties are those in which the purple colour is spread over the whole lamina, but these are seldom seen. *L. Loddigesii* differs in the glaucous nature of the petioles, and also in the seeds; but the plants lose their seeds, and the glaucous tint often gets washed away, and then it is difficult to distinguish this species from the other. The next young leaf to appear will prove the identity. The seedlings of these two species are remarkable in that the first leaf is from the beginning fan-shaped with deep sections. I know no other fan

STANDARD AND DWARF BRIAR STOCKS FROM CUTTINGS.

It is rather late in the day to touch on the above, seeing that they are usually planted in early winter. Still, it will occasionally happen that through pressure of work planting is delayed, the stocks being heeled in. Personally, I have been as successful with spring as with autumn plantings by taking the precaution of heeling them in directly they are received, and mulching the ground heavily with short litter. The few hints on selection I am about to give would have been more appropriate to the matter in the autumn, at the same time they will apply to stocks planted at

ROSE BLANC DOUBLE DE COUBERT.

Where the varieties of *R. rugosa* are cultivated, this variety should be included. It is a double-flowered form of *rugosa alba*, and fairly well known considering the comparatively short time it has been in commerce, and being one of the best it may be confidently recommended to planters. The habit of

foliage is glossy, the red flowers are produced near the points of the shoots, and the ripe, globular fruits are attractive after the leaves have fallen. The bare stems are of a deep red colour, and are effective in the winter sunshine. *J. G.*

Palm which has this characteristic, for the famous *Lodoicea seychellarum*, the first leaf of which is also fan-shaped, is no true Fan Palm, but intermediate between Fan and Feather Palms. Whether the third species of *Latania*, *L. Verschaffelti*, Lemaire, also known under the name *L. aurea*, Duncan, has the first leaf fan-shaped, I cannot say, as I have not yet had seedlings of it. This rare Palm is not to be confounded with the yellowish-green *Livistona aurea*, which is, it seems, a form of *Livistona chinensis*. The true *Latania Verschaffelti*, a Palm 40 feet high, has petioles 5 to 8 feet long, densely tomentose with orange margins, which are spiny on young plants. The pale green blade is $4\frac{1}{2}$ to 5 feet in diameter, with divisions $2\frac{1}{2}$ feet long by 2 inches broad, acuminate, the entire margins and the veins beneath slightly tomentose. It grows abundantly over the island of Rodriguez. It is a curious fact that the Palms of the Mascarenes and the neighbouring Seychelles have so often coloured margins. Besides the above, I note the *Dictyosperma album*, with orange margins when young; *D. rubrum*, which is by no means a variety of the former, with purple margins; and *D. furfuraceum*, also with purple margins. Other colours than green on the leaves of Palms from that region are not scarce, i.e., *Chrysallidocarpus lutescens* (better known as *Hyophorbe lutescens*), which is, by the way, not identical, as often is said, with *Hyophorbe indica*, as *Chrysallidocarpus* forms many slender stems 2 to 3 inches in diameter, whilst those of *Hyophorbe indica* are about 6 inches thick and single; then *Hyophorbe amaricanilis*, with fine violet petioles; *Hyophorbe Verschaffelti*, and *Phœnicophorium seychellarum*. This is a curious coincidence. Our Supplementary Illustration shows a fine specimen of *Latania Verschaffelti* as grown in the famous Botanic Garden at Buitenzorg. I am very much obliged to Professor Treub for kindly sending me the photograph. Dr. Udo Dammer, Berlin.

THE PROPAGATION OF BOUVARDIAS.

In order to obtain good plants for flowering the following autumn and winter, the cuttings should be put in not later than the middle of March, and if earlier, then all the better, if the cuttings are good ones. Plants that have been dried-off and cut back break freely when put into heat and kept syringed, and but little water afforded at the roots until they are well started. The plants should not be cut back too closely, and old leaves may be removed entirely. Before starting, it is a good plan to dip the plants in some fairly strong insecticide.

The cuttings should consist of shoots that have made two pairs of good leaves, taking them off close to the old shoots. A cutting requires but little "making," and they root just as freely when cut between the joints as when severed at a joint, but short-jointed cuttings with buds at the base make the best plants, for they will usually break from the buds under the soil if stopped at an early date.

The cutting-pots should be filled with a compost consisting of equal parts of loam, peat, and sand, with a little extra sand on the surface. I like the surface-sand to be quite dry, so that it will run down when the dibber is taken out of the soil, and thus afford a good base for the cuttings. I should add that the soil in the pots should be made just sufficiently firm to hold the cuttings erect, the *Bouvardia* being an exception to most fine-rooted plants, rooting better in a loose, open compost, and making better growth. Do not let the cut-

tings wither, and place them in the warmest part of the propagating-pit on a good bottom-heat. When afforded insufficient heat, the cuttings get hard, and are a long time in starting into growth. I usually stop *Bouvardias* once in the cutting-pots, and pot them off as soon as they have made fresh shoots, but potting them singly. It is very necessary to keep the plants growing freely from the start, and it is only when they receive proper attention in the early stages of growth that their full value can be realised. Most of the varieties, if propagated at this season, will make good plants by the autumn, but *B. Humboldtii corymbiflora* requires to be two years old to flower it satisfactorily, and this variety should not be stopped so late in the season as those with the rough leaves, such as *B. Hogarthi*, or *B. President Cleveland* and *B. Vreelandi*.

I may add that *B. Humboldtii grandiflora* is an improvement on *B. H. corymbiflora*, and one of the best for affording cut flowers, as with good treatment it will furnish flowers from June till October. *Bouvardias* require no artificial heat from June till September, but full exposure to the sun, with plenty of air and careful attention to affording water, with liquid-manure freely applied after they begin to flower. A. Hemsley.

FRUIT-TREES BY ROADSIDES.

"FRANCE has over 500,000 of these, and is planting more every year." Surely this is an object-lesson to us all in Great Britain, and especially in Ireland, and the idea may meet with some favour from our agricultural or forestry societies, and the country, district, or urban councils. Hardy fruit-trees, Apples, Pears, Plums, or Cherries, are so handsome when in bloom, that they deserve planting for beauty alone, apart altogether from the prospects of a fruit crop.

In America, Cranberries are sometimes grown on sandy wastes on a communal plan, and there is no reason why fruit-bearing trees should not be planted beside the roads near to our villages and country towns, and the fruit sold publicly by auction, and devoted to the upkeeping of the roads, or to other public objects.

Some may naturally object, and say the fruit would be stolen. At first this may take place; but why is not the fruit stolen in France, Germany, and elsewhere, where fruit-trees by the roadsides is an old-established institution?

By planting tall standard trees, the danger of wholesale theft would be minimised, and no one would object to the thirsty wayfarer taking and eating the fruit that fell to the ground; even the few knocked off by sticks or stones would not much affect the total crops.

The best of cider Apples, often very handsome in flower and fruit, though almost inedible, might at least be grown. F.W. Burbidge.

A CENSUS OF GARDENERS, &C., IN THE ADMINISTRATIVE COUNTY OF LONDON ON MARCH 31, 1901.

UNLIKE the method adopted at previous censuses, when the occupations of the people of England and Wales were published in one volume, and at a late period after the taking of the census, the authorities have created a new departure this time by publishing the results of the census taken less than a year ago in County Sections. The first occupational results to appear are those relating to the Administrative County of London, which comprises the City of London, together with the

twenty-eight Metropolitan Boroughs constituted under the Local Government Act of 1899. The figures given showing the number of gardeners (not domestic), nurserymen, seedsmen, and florists, enumerated within this area at the recent census are as follows:—

Total numbers, males, 6,858; females, 1,260.

These totals are distributed under the following range of ages:—

| Ages. | Males. | Females. | Ages. | Males. | Females. |
|-------|--------|----------|----------------|--------|----------|
| 10 | 10 | 3 | 45 | 1,387 | 89 |
| 11 | 50 | 19 | 55 | 1,114 | 60 |
| 15 | 479 | 333 | 65 | 598 | 18 |
| 20 | 554 | 299 | 75 and upwards | 143 | 6 |
| 25 | 1,276 | 273 | | | |
| 35 | 1,247 | 155 | | | |
| | | | Totals | 6,858 | 1,260 |

Of the 6,858 males, 440 are described as "employers," 4,898 as "working for employers," 1,358 as "working on own account," and 162 as "others, or no statement."

Of the 1,260 females, 42 are described as "employers," 1,025 as "working for employers," 151 as "working on own account," and 39 as "others, or no statement."

The following table has been prepared, showing the localities in which the gardeners, &c., were enumerated:—

| | Males | Females |
|---------------------------------|-------|---------|
| City of London | 11 | 4 |
| Battersea, Metropolitan Borough | 167 | 45 |
| Bermondsey | 38 | 4 |
| Bethnal Green | 37 | 14 |
| Camberwell | 384 | 33 |
| Chelsea | 17 | 29 |
| Deptford | 130 | 21 |
| Finsbury | 26 | 52 |
| Fulham | 326 | 46 |
| Greenwich | 226 | 17 |
| Hackney | 307 | 40 |
| Hammersmith | 259 | 40 |
| Hampstead | 325 | 31 |
| Holborn | 58 | 66 |
| Islington | 403 | 110 |
| Kensington | 291 | 78 |
| Lambeth | 699 | 77 |
| Lewisham | 791 | 39 |
| Paddington | 103 | 72 |
| Poplar | 38 | 8 |
| St. Marylebone | 182 | 51 |
| St. Pancras | 313 | 75 |
| Shoreditch | 22 | 31 |
| Southwark | 103 | 28 |
| Stepney | 74 | 44 |
| Stoke Newington | 95 | 12 |
| Wandsworth | 840 | 65 |
| Westminster (City) | 133 | 113 |
| Woolwich | 160 | 12 |
| Totals | 6,858 | 1,260 |

A. R. Bellingham, 10, Brompton Square, S.W.,
February 15, 1902.

TREES AND SHRUBS.

POPULUS MONILIFERA AUREA (P. CANADENSIS AUREA).

IN gardens where the planting of groups of trees and shrubs is carried out for the effect produced by their foliage in summer, this golden Poplar is one of the best, because of its good colour. It is a tree that is somewhat pyramidal in outline, and if it grows too high, it can easily be reduced by removing the leader. Those from 15 feet to 20 feet high form effective contrasts with, amongst other shrubs, *Prunus pissardi* and the purple hazel. The bright yellow foliage of this Poplar is very telling at a distance throughout the summer. J. G., Batsford Park Gardens.

EUCALYPTI.

A few weeks since some notes appeared in the *Gardeners' Chronicle*, p. 456, in which *E. coccifera* is stated to be synonymous with *E. amygdalina*. I think an error must have crept in, and one of these names got printed in mistake. The two species are very distinct here in the young state (5 feet high), and correspond to the descriptions given in Nicholson's *Dictionary of Gardening*. [*E. coccifera* is considered to be a mountain form of *E. amygdalina*. Ed.] But my chief object in writing is to state that *E. coccifera* is the only species I can obtain at present that is likely to prove hardy here. I have tried eighteen

different species during the last eight years, and will let you have a full report of them later. Many persons will now be ordering their seeds, and some may like to try *E. coccifera*; it is a much neater growing species than *E. Globulus*, and has smaller and whiter stems and leaves during the first year; the whiteness disappears to a great extent when the leaves get older. *E. cordata* is next to the above in hardness in my collection, and its leaves put on some pretty purple tints in the winter. *E. resinifera* was sent me by my friend the late Mr. Ewbank, but has not proved so hardy here as he anticipated; he was misled by the description given him by the Italian monk. *E. ficifolia* I have not yet tried;

the 12° of frost experienced at Poltimore seems to have had no injurious effect on them, owing to the fact that the air at the time was very dry. [For an illustration and an interesting history of this species, see *Gardeners' Chronicle*, April 23, 1892. Ed.]

KEEVIL MANOR.

OUR illustration (fig. 43) shows a view in the garden attached to the Manor House, Keevil, a remote village in Wiltshire, seven miles or more from Trowbridge, and sixteen or eighteen miles from Bath. The house is an Elizabethan structure, and the residence of Colonel Sir J. W. Wallington, K.C.B. The

berths for first-class gardeners who are steady men. When in Adelaide, South Australia, a few months ago, Mr. Henry Sewell, the leading nurseryman there, was lamenting the great deficiency of trained gardeners, and said: "I want such in my nursery, and I could place a few in good situations if I had them on hand." I promised, on my return, to make his wants known, but my return is so uncertain, and as the question is before the craft, I avail myself of your valuable medium to deliver my promised message to the gardeners of Great Britain. Those desirous of leaving home should write to Mr. Henry Sewell, nurseryman, Adelaide, South Australia, and as he is a very polite man, with a good heart, I am

FIG. 43.—THE MANOR HOUSE, KEEVIL, WILTS.

can anyone tell me where to get seed of it? *E. Gunnii* is not hardy here. When travelling about Ireland last autumn I watched for any *Eucalyptus* that appeared to be hardy there, but very few were to be seen; the oldest plants were two of *E. Globulus* in a cottage garden near Arklow (these had evidently been cut back by frost), and an old plant of *E. coccifera* at Fota, which must have been growing there for many years. Perhaps the gardener, Mr. Osborne, late of Fota Gardens, if he sees this, may be able to give some particulars as to what species have been tried there. W. H. Divers, *Belvoir Castle Gardens, Grantham*.

PRUNUS DAVIDIANA.

This, one of the earliest of trees to flower, should, writes Mr. Slade, of Poltimore Park Gardens, find a place in every garden that can afford it a spot for full development. The long, slender shoots are crowded with the pretty white blossoms at the present time, and

view is interesting, as showing an exceedingly pronounced representation of the formal type of gardening, in a locality where there is no railway station for several miles, and which is so remarkable for old-world characteristics. Probably this extreme cultivation has been practised to afford distinctness to a garden surrounded by natural beauty and contrast on every side.

The photograph is one by Mr. W. Rossiter, Bath.

COLONIAL NOTES.

THE EMIGRATING GARDENER.

READING the *Gardeners' Chronicle* this morning, dated January 11, my eye fell upon Mr. A. Harding's invitation to gardeners to better themselves in the United States, where there are no doubt numerous chances. There also are in our colonies many advantages and good

sure he would answer all such letters. There are many places open in other parts of Australia, but it is only in Sydney where there is an organisation ready to give a helping hand to new arrivals of the craft, and as this may not be generally known, I advise all gardeners going to New South Wales to go at once to the Gardeners' Association Rooms, Queen's Hall, Pitt Street, Sydney, where there is generally a good gathering of gardeners, and a little flower show of things of special interest each Friday, from 8 to 10 P.M. Then there is Mr. Robbie, Superintendent, Hyde Park, Sydney, who generally knows of any situation for a gardener, and who could put young men in the way of finding some kind of employment. A reference to this notice, and your correspondent's name, would not be without its effect. In Melbourne, Mr. Purvis, manager of F. Hamilton Brunning's seed business, would be a useful man; also Mr. Cheesman, nurseryman, Melbourne; and my good

friend Mr. Beatson, of George Anderson & Co., seedsmen, George Street, Sydney; and fruitmen would find Mr. Carl B. Luffmann, Royal Horticultural Gardens, Burnley, Melbourne, very sympathetic.

ST. JOHN'S BREAD.

In the same article reference is made to a good hedge. The finest I have seen in my travels is one made of St. John's Bread (*Ceranton siliqua*)—pleasant to look upon, secure as a stone wall, and handsome throughout, with none of those blemishes so constantly seen in hedges of *Coniferae*. This beautiful hedge surrounds Mr. Henry Sewell's nursery, in which is one bed with upwards of 500 varieties of Roses, including all the newest from Europe. Mr. Henry Sewell's nursery, Adelaide, is the best ordered one I have seen in my travels, and I am glad to make this testimony. Mr. Sewell is an old country gardener, and a genuine lover of plants, greatly esteemed and appreciated by the amateurs around Adelaide, whose sound advice can always be relied upon. He is also a great encourager of park development around Adelaide, which is the most beautiful city of Australia, surrounded, as it is, with its delightful hills within a few miles of the town, and which forms a summer residence for the well-to-do, as it is cool on the hottest day, the town being the winter residence of the families who have a house on the hills. *Peter Barr, V.M.H.*

The Week's Work.

THE ORCHID HOUSES.

By W. P. BOUND, Gardener to J. COLMAN, Esq., Gatton Park, Reigate.

Cattleya labiata autumnalis variety.—This plant is now exhibiting signs of renewed activity, and if any plant seems to require dividing, the operation should be carried out in the manner advised previously. Others not calling for subdivision may be top-dressed after removing the surface-compost, remembering that a root saved is a root made. A suitable compost which is both nourishing, lasting, and porous, consists of fibre-peat three-fifths, chopped sphagnum-moss one-fifth, and leaf-soil one-fifth, well mixed together. Fair drainage should be afforded, using discretion as to the quantity required by the health of the plant, a vigorous plant not wanting so much as a sickly one; and I would advise the crocks to be used in an erect position. Plants that are in small pots and in good health will only require potting-on, not disturbing the ball unless the compost is in a bad condition. Others that have gone back should be reduced, removing the whole of the useless back pseudo-bulbs in order to give the new growth the advantage of the roots made. In potting, the bud should be kept just a little above the rim of the pot. Carefully insert the compost among the roots rather firmly, and finish off with a few clumps of good sphagnum-heads on the surface. The plants will require for the present water only when the compost is dry. Damp freely between the pots on bright days.

Trichopilia fragrans and *T. f. var. nobilis* are two lovely white flowering Orchids, well worthy of general cultivation. A suitable place for these plants is a shady part of the intermediate-house, but the materials should not be allowed to get very dry, and when growing the plants should be afforded water very freely. The plants at Gatton are growing fast at this season, and should any of them need potting the best time for the operation is when the young growths are about 2 inches high. The potting compost may consist of equal parts of turfy peat and chopped sphagnum-moss. In sunny weather generally, and all through the summer months, *Trichopilias* are much benefited by syringing them once or twice a day.

Aërides.—Plants not needing to be repotted should have much of the compost on the surface removed and be top-dressed. Clean, picked sphagnum-moss two-thirds, and turfy-peat (out of which the finer particles are shaken) one-third, pressing the whole firmly. When repotting is required, get the plant as low down in the new pot as the leaves will allow, and cut away as much as possible of the old stem. When a plant has got tall and lanky, and possesses no air roots on that part where severance would be desirable, the stem should be mossed over, and kept damp in order to encourage roots to form before severing it. A shady corner in a moist stove forms a suitable home for *Aërides falcatum*, *A. f. var. expansum*, *A. Lawrenceae*, *A. odoratum*, *A. Sanderianum*, *A. Savageanum*, and others. *A. Fieldingi* and *A. affine* should be grown under rather cooler conditions. Repotted plants should be frequently damped at the sides of the pots, and strong sunshine not be allowed to reach them. If the house is very humid, but little water will be wanted at first, and nothing more afforded than a damping of the surface of the compost, so that the sphagnum-moss may not die.

Shading.—During bright weather lower the blinds on Orchids requiring shade, and Orchids that have been divided or bought in as imported recently, and over all small seedling Orchids. But do not shade too freely the *Odontoglossum*, although it will very soon be necessary to shade these in the middle of the day when the sunshine is stronger; but as yet a little sunshine together with good ventilation gives strength and firmness to the growths which have been developing during the winter. Each man must use his own judgment as to the amount of sunshine his plants will stand without being injured.

THE KITCHEN GARDEN.

By T. TURTON, Gr. to J. K. D. WINGFIELD DIGBY, Esq., Sherborne Castle, Dorset.

Parsnips.—Assuming that the land for this crop has been deeply dug, after being trenched for a previous crop, take the first opportunity when the surface of the ground is dry enough to admit of it being trodden upon to roughly rake it over, and make the surface level. These proceedings, although not absolutely necessary for obtaining good roots, help to make a good tilth, and are in keeping with good workmanship. But it is always advisable to wait for fine weather, rather than to carry out the work when the weather and the land are alike in an unsuitable state. Let drills be drawn 18 inches apart and 1 inch deep, and sow the seeds singly 2 or 3 inches apart in the drills. This entails a little more time than scattering the seed in the usual manner, but it is of advantage when the thinning has to be done.

The Onion Quarter.—If the ground was trenched as advised in a previous Calendar, it will have become pulverised by frosts, and advantage should be taken of fine weather to break up the clods and loosen the soil to the depth of 9 inches; and after it has dried sufficiently, and been well trampled upon all over, afford a moderate dressing of fresh soot previous to raking it down. Stiff land should be afforded a good dressing of charred garden refuse, which will have the effect of preventing the soil running together and getting compacted when it is trodden upon. It is so important to have a well made seed-bed for the Onion-crop, that no labour should be considered too great to obtain this, and it is advisable to wait a week or longer rather than to sow when the ground is in an unfit state. Sow the seed thinly in drills at 15 inches apart, and draw them from the same end of the ground, when there will be less likelihood of the drills varying in width, as is the case when the drills are drawn from both ends.

Seakale Ground.—If not already done, the ground for this should be well prepared by deeply trenching it forthwith, affording a liberal dressing of rotten farmyard manure if

the soil be light; but if of the opposite nature, then three parts rotten stable manure will be more suitable. In either case place the manure at the bottom of the trenches, and thus induce the roots to strike downwards, as they will in search of the manure, and hence better crowns also straighter and better roots for making into sets.

Jerusalem Artichokes.—With the return to suitable weather, let tubers be planted as early as possible, choosing a bit of ground that is retentive and has been deeply worked, but not necessarily heavily manured. Planting in such land encourages early tuberizing without the need for affording water in dry weather, which is the case when planted in shallow cultivated soil. Where they must be grown on the same piece of ground year after year, and they are often employed in this way to hide something objectionable during the summer months, let the crop be lifted as soon as the state of the weather will admit. Then find the number of sets that will be required when planted at 2 feet apart each way to plant the piece of ground, and select clean tubers about the size of a hen's egg. Place the lifted crop of tubers in a heap in any cool place out-of-doors, and cover them with rough straw or bracken. Deeply trench the ground every alternate year, and when the opportunity offers for doing so exchange some of the soil.

THE FLOWER GARDEN.

By R. DAVIDSON, Gardener to EARL CADOGAN, Culford Hall, Bury St. Edmunds.

Seeds.—Seeds of bedding Petunias may be sown at about this date, preferably the single-flowered varieties, than which, when the strain is a good one, nothing can be prettier. The plants succeed in almost any position in the garden, and flower profusely for a long time. Sow also seeds of *Dianthus Heddewigi* and *D. chinensis*, very excellent annuals for filling small beds; *Ageratum* and *Nemesia strumosa* Suttoni, a pretty, floriferous little plant, useful for planting in beds and border or in conjunction with other plants. Sweet Peas and *Mignonette* may now be sown out-of-doors in well-manured and deeply-dug soil. For affording flowers for cutting, a sowing of each should be made once a fortnight until the end of the month of July.

Propagation.—Many kinds and varieties of bedding plants now claim the gardener's attention; and cuttings that were inserted in the propagating-frames and house at the beginning of last month being well-rooted, should be forthwith put into pots or boxes. *Iresines*, *Heliotropes*, and *Abutilons* should all be potted singly in 60's in a light, rich compost. *Alternantheras* may be placed in shallow boxes at 3 inches distant from plant to plant, and if a little wood-ashes or even coal-ashes be added to the soil, the colouring of the foliage will be much enhanced. Cuttings of *Nasturtiums*, *Sweet Alyssum*, and *Mesembryanthemum cordifolium variegatum* may be put closely into boxes, the soil for the last-named consisting of loam, decayed manure, and sand in equal proportions, about one-sixth of the whole of lime-rubbish.

Edgings.—If the various kinds of live edgings employed for the margins of large beds, &c., be lifted at this date, and the ground well dug, if necessary a small quantity of fresh soil added, and the plants afterwards divided, re-arranged, and planted at regular distances apart, they will give little trouble for the remainder of the year. Among the plants used in this manner are *Vinea major elegantissima*, *Stachys lanata*, and various grasses, variegated and other. Where the pretty *Lonicera flexuosa aurea reticulata* is employed as a margin to large beds of flowering shrubs, the shoots must be regulated and pegged down close to the soil. Should the relaying and mending of the Box-edgings be found necessary, let the work be carried on without delay.

Flowering Shrubs.—The lateral shoots of *Jasminum nudiflorum* as they pass out of flower

should be cut back to the second or third basal bud, and the strong growths necessary for covering unfurnished spaces reserved at almost full length, nailing or tying them. *Chimonanthus fragrans* may be similarly treated, but leaving the shoots with at the most two buds. Sprinkling of an artificial manure on the surface of the ground per square yard at the rate of 2 to 3 ounces, and a mulch of half-decayed stable litter, will stimulate growth in these plants. Trees of *Prunus*, *Pyrus*, *Viburnum*, &c., recently planted, may now have their shoots cut hard back, in order to induce an even break, and the trees afterwards allowed to grow at will, unless symmetrical specimens are thought desirable.

THE HARDY FRUIT GARDEN.

By J. MAYNE, Gardener to the Hon. MARK ROLLE, Bicton, East Budleigh, Devonshire.

The Protection of Blossoms.—As soon as the colour of the petals on Apricots and Peaches is observed, some kind of protection is absolutely necessary, if good crops are to be looked for with any degree of certainty, more especially in low situations. The flowers, when kept dry, will withstand several degrees of frost with impunity; but when wet, and frost follows, loss more or less is sure to occur. The young growth, which appears soon after the flowers expand, also stands in need of protection. In some gardens no protection whatever is afforded these trees, but I consider the best policy is to look ahead, as if the foliage, especially that of the Peach, gets badly blistered later on, the young wood is crippled to such an extent that a full crop of fruit is a rare thing. It is not every Apricot and Peach-wall that is furnished, like that at Bicton, with a portable glass coping. The panes of glass in this protector are 2 feet long and 18 inches wide, and are secured in an iron frame having a fall of 9 inches from the top of the wall to the front, and on to this trebled fish-netting is hung, and reaches nearly half-way up the wall, and is secured to stakes placed 4 feet from the foot of the wall. Failing a glass coping of this sort, boards about 18 inches in width may be fixed to brackets. Scrim-canvas, Haythorn's hexagon netting, and similar materials are used; but with all of these the trees have to be uncovered on fine days and when it is not frosty; but in the case of fish-netting, it can remain in position until all danger from frost is at an end.

Pruning.—Stone and other fruit-trees planted in the autumn of 1901 should be pruned early this month. Shoots of standards, pyramids, and bush-trees should, if much growth was made last year, be shortened back to within 6 or 8 inches of the last operation, and shoots not required for extension cut back to a couple of buds. Maiden trees of last year should have the shoot or stem cut back to within four or six buds from the base, and thus lay the foundation of the future crown. Trees planted this year should be left untouched till the autumn. Where Gooseberries and Currants were left unpruned for fear the birds might take the buds, they should be pruned forthwith. All planting operations should be brought to a close as speedily as possible, for should a dry spring and early summer set in, the trees would have little chance of laying hold of the soil, unless much attention was paid them in the matter of affording water, and even then it is seldom that the growth made is satisfactory.

PLANTS UNDER GLASS.

By J. C. TALLACK, Gardener to E. MILLER MUNDY, Esq., Shipley Hall, Derby.

Chrysanthemums.—Many of the early-struck cuttings will now be ready for potting into large 60's, or 3½-inch pots. Previous to this, however, such varieties as require early stopping to induce breaks should be dealt with. Several of the finest varieties require this attention, in order to get them in good form at the exhibition season, and their names are to be found in almost all good catalogues. Turfy loam two-thirds, with decayed horse-

droppings one-third, and some sand, make a suitable mixture for these plants. Pot with a moderate degree of firmness, and place the plants in a light position near the glass in a frame from which frost is excluded, affording no water at the roots for a day or two, but syringing once or twice a day if flagging occurs.

Liliums.—To succeed with *L. longiflorum* var. *Harrisii*, and to provide for any deficiencies in that somewhat erratic variety, the earliest plants of this variety may be brought into an intermediate temperature. Growth should, however, have started before this is done, as any attempt to hurry the bulbs at this date will defeat the object in view. The house in which these Lilies are grown should be well exposed to light, as they do not like shade during the early part of their growing season.

Forced Plants.—The earliest-forced plants are of no use for growing on, but those which flower from now onward are worth keeping if they are afforded shelter under glass till April. A season's rest will bring *Azalea mollis*, *Lilacs*, *Guelldres Rose*, *Staphylea*, &c., round again, so that they may be again forced with good results. Daffodils, and in fact *Narcissi* of all types except perhaps the *Scilly* or *Paper-white*, may be saved for planting under trees, and there are many other such plants that pay for care after forcing.

Seed-sowing.—One need not enumerate the many kinds of plants grown from seeds that should be sown about this time, as the directions printed on seed packets will be quite sufficient to work on; and a little licence may be allowed in accordance with the time in which the various plants so raised are expected to flower, or, in the case of foliage plants, to be at their best for the decorative purposes they are to fill. Personally, I have generally found it best to delay a little beyond the dates as given, i.e., if February and March are given, the first week of the latter month will be quite soon enough, and it is well to remember that seeds germinate stronger and more freely as we emerge from the winter. Large bodies of soil turn sour more quickly than do smaller quantities, so it is not advisable to be too generous in this matter; and another point that should not be forgotten is, that most seeds germinate best in the dark, but must not remain under such conditions after the plants have pushed through the soil, and careful watching is necessary in all the early stages if good results are to be obtained.

Pricking off Seedlings.—Earlier raised seedlings of *Begonias*, *Streptocarpus*, &c., should be pricked off before the soil in the seed-pots gets sour. I advise pricking-off into shallow pans rather than potting-off singly, as the plants do not then require water so frequently, nor are they subject to the sudden changes to which plants in very small pots are liable. It is not necessary to wait until the plants may be easily separated from each other before attending to pricking off; indeed, some appear to do much better when lifted and replanted three or four in a clump. The great thing is to see that the seedlings are quickly transferred from one receptacle to the other, so that there shall be no chance of their becoming withered.

FRUITS UNDER GLASS.

By JAMES WRYTOCK, Gardener to the DUKE OF BUCKLEUCH, Dalkeith.

The Orchard-house.—The woodwork of this house should be thoroughly cleansed with soap and water, and all wall surfaces either painted or lime-washed. The kinds of fruits grown in orchard-houses, particularly in cold districts, are Cherries, Gage Plums, and Pears, which are liable to be infested with scale, and in order to destroy these the following dressing should be applied: in a large vessel of soapy water pour in a half pint of petroleum, and keep the mixture constantly stirred whilst syringing the trees, doing this forthwith, the buds being dormant. In very bad cases the branches may be dressed with XL-All liquid insecticide, using a painter's brush for the purpose. The

repotting of pot-trees requiring more rooting space, should have been carried out in September and October, but when no repotting is called for, let inert surface-soil be renewed, and a top-dressing of turfy loam, mixed with bone-meal and Vine-manure, be applied. The borders should also have the surface-soil removed, and be top-dressed in like manner, so as to induce the formation of numerous surface roots.

Early Muscats.—These Vines, if started at the beginning of the first month of the year, will be now in flower, and it will be necessary to keep the temperature at night at 72°, and by day with sunshine at 90°, but lower in dull weather. There should be just the least possible amount of air afforded, and the viney should be kept slightly moist. When in flower, distribute the pollen with the hand or camel's-hair brush, and if pollen of any other variety is available, convey it to the flowers of the Muscats. The foliage is tender, and more readily injured and scorched than that of other varieties; and when the fruit is set and has begun to swell, more air may be given in favourable weather. Guard against cold cutting winds entering the house, and causing rusting of the berries. The border for early Muscat Vines being inside, should now be afforded a sprinkling of Vine-manure, and a mulch of rotten manure; and if the drainage is all right, water may be applied copiously.

Fig House.—If the early varieties *Pingo de Mel* and *St. John's* are grown, the fruits will now be of a fair size, and the night temperature may be raised to 60°, and 10° higher in the daytime. Keep the air of the house moist, and as the days lengthen and more sunshine obtains, syringe the trees morning and afternoon; and if growing in pots, do not let them get dry at the roots, or the fruit will drop. Those planted out in a border may be afforded water copiously, and occasionally an artificial manure, or weak diluted manure-water from the cowshed. Squeeze the growths with the finger and thumb at the fifth joint to stop them.

THE APIARY.

By EXPERT.

The severe weather will induce the careful bee-master to ascertain the condition of his bees, especially the weak stocks. When his calendar, on referring to it, tells him that number one, two, and four are strong, and have plenty of stores, more harm than good will be done by interfering with them; but as to number three, which is weak, he should raise the corner of the quilt and slip a cake of candy underneath as gently and quietly as possible, and see that the quilt is put again in place—but in no case for the present must the bees be encouraged to breed. A cursory glance might be given to all hives on a bright day to see if the bees have any stores left, but do not disturb them. Wet or mouldy quilts must be replaced with dry ones, and a small quantity of naphthaline put on the quilt and at the back of the hive. The bee-keeper should take as his maxim for a month the old saying, "leave well alone."

To make Bee Candy.—Place a clean pan on the fire, put half a pint of clean water and three pounds of crystallised cane sugar, and stir it till the sugar is dissolved, not allowing it to burn. Boil it for a few seconds, and then cease stirring and let a drop or two fall on a plate, and if this "sets" at once, so that the surface does not stick to the finger when pressed, it is sufficiently boiled; but if sticky, it contains too much water, and either more sugar must be added, or the boiling continued. The right condition being reached, remove it from the fire, and set the pan in cold water to hasten cooling of the mixture, stirring briskly all the while until the mixture begins to turn white or granulate, and become rather stiff, when it may be poured into a mould suitable for the purpose, and lined with paper for easy removal, and to prevent it sticking to the quilts. The candy so made will, when cold, be of such consistency as to become quite soft and buttery when scraped with the finger-nail.

APPOINTMENTS FOR THE MONTH OF MARCH.

| | |
|--------------------|--|
| SATURDAY, MARCH 1 | Royal Botanical Society, Meeting. |
| SUNDAY, MARCH 2 | Chambre Syndicale des Horticulteurs Belges, Meeting at Ghent. |
| TUESDAY, MARCH 4 | Scottish Horticultural Association, Meeting. |
| THURSDAY, MARCH 6 | Linnean Society, Meeting. |
| TUESDAY, MAR. 11 | Royal Horticultural Society, Committees Meeting. |
| WEDNESDAY, MAR. 19 | Torquay Gardeners' Society, Spring Show. Royal Botanical Society, Meeting. |
| THURSDAY, MAR. 21 | Linnean Society, Meeting. |
| FRIDAY, MAR. 21 | Horticultural Show in Manchester Free Trade Hall. |
| TUESDAY, MAR. 25 | Royal Horticultural Society, Committees Meeting. |
| FRIDAY, MAR. 23 | Good Friday. |
| MONDAY, MAR. 31 | Bank Holiday. Jersey Agricultural and Horticultural Society, Exhibition opens. |

SALES FOR THE WEEK.

- MONDAY, MARCH 3.—Azaleas, Begonias, Carnations, Roses, &c., at Protheroe & Morris.
- TUESDAY, MARCH 4.—Sale of the Tixall Collection of Established Orchids, by order of the Exors. of the late E. Bostock, Esq., at Tixall Lodge, Tixall, near Stafford, by Protheroe & Morris, at 12.30.
- WEDNESDAY, MAR. 5.—Important Sale of 750 cases of Japanese Lilies, Davallias, Peonies, Acers, &c., at Protheroe & Morris' Rooms, at 5 o'clock. Continental Plants, Tuberoses, Roses, Greenhouse Plants, &c. at 12.—Ferns and Flowering Plants, Palms and Decorative Plants, Perennials, Lilies, Azaleas, Rhododendrons &c., at Stevens' Rooms, at 12.30.
- FRIDAY, MARCH 7.—Sale of Shrubs and other Stock at The Nurseries, Feltham, by order of Messrs. C. Lee & Son, by Protheroe & Morris, at 12.—Perennials, Carnations, Roses, Hardy Border Plants and Bulbs, at Protheroe & Morris' Rooms.—Imported and Established Orchids, at Protheroe & Morris' Rooms.

TENDER.

Grardians of the Parish of Lameth, Brook Street, Kennington Road—Up-keep of Garden at Norwood. Tenders to be sent in before March 11.

(For further particulars see Advertisement columns.)

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three Years at Chiswick —41°.

ACTUAL TEMPERATURES:—

LONDON.—February 26 (6 P.M.): Max. 47°; Min. 38°.

February 27.—mild; dull; rainy.

PROVINCES.—February 26 (6 P.M.): Max. 47°, Scilly; Min. 37°, E. Counties.

Use of the Electric Light and of Ether in Forcing Plants. PRACTICAL gardeners have rarely the opportunity of making scientific experiments, and commercial men, in spite of the all-importance of the subject to them, are even less inclined to step beyond the path marked out by routine, unless some immediate benefit is likely to be forthcoming. Experiment stations, then, become more and more necessary, and they should be supported by those who will ultimately benefit from them. Such a one we might have at Chiswick. We do not think there would be any insurmountable difficulty as to funds, or as to a scientific director competent to devise, carry out, and publish the results of experiments likely to benefit practical horticulture. How is it, for instance, that no one in this country has taken up the question of the use of the electric light, or for the matter of that, of artificial light of any kind, for forcing purposes in our dull winters? The evidence obtained some twenty years ago by the late Sir WILLIAM SIEMENS was simply astounding (see *Gard. Chron.*, 1880, April 3, p. 432). Mr. BUCHANAN, the gardener, now in Queensland, was allowed a free hand, and the results in the case of forced Strawberries, Wheat, and other crops

were almost beyond belief, more especially as regards the hastening of the ripening process.

Of course this was an experiment on a limited scale, and the question of expense did not enter into consideration. The houses were there, the apparatus was installed, the extra cost of utilising the light was not material. The results were, however, so extraordinary, that it is a matter for astonishment that no one in this country has continued the experiments, and shown what modifications are necessary to make the use of the electric light, or the incandescent gas light, in forcing a commercial success. The subject is not even mentioned in the recently published gardening manuals to which we have referred. In France more has been done, and still more in America, where the use of the electric light has been proved under certain circumstances commercially advantageous in the case of Lettuce-growing. Prof. BAILEY, in the *Cyclopædia of American Horticulture*, sums up the results that have been obtained in the United States by saying that "the application of the electric light to the growing of plants is a special matter to be used when the climate is abnormally cloudy, or when it is desired to hasten the maturity of crops for a particular date." Now these are just the very conditions which obtain in an ordinary British winter. Prof. BAILEY goes on to say that, "Only in the case of Lettuce has it been proved to be of general commercial importance, and even with Lettuce it is doubtful if it will pay for its cost in climates which are abundantly sunny."

Professor BAILEY writes, under the sunny skies of the States, of the electric light only, and from a commercial standpoint alone. The conditions of British horticulture differ widely, and in many places gas would be cheaper and more efficient than the electric light.

Another means of facilitating forcing operations has lately been made known by one of the professors at a Danish Agricultural School, and which consists in subjecting the plants to the fumes of ether. The plants so exposed shed their leaves, as though they had been subjected to frost. The best results with Lilacs are obtained in late summer. The ether then stops vegetative growth, and a moderate temperature being supplied, the flower-buds quickly expand, so that Lilacs may be had in bloom in the first half of September. M. FRASZ LEDIEX, of the Dresden Botanic Garden, has been experimenting in the same direction, and the results he has obtained are summarised in recent numbers of *Le Jardin*, from which we glean the following particulars:—

For early forcing, says Herr LEDIEX, the action of ether is so important that none who practice forcing on a large scale can afford to dispense with it. Flowers obtained by early forcing naturally command a high price. It should further be considered that fuel is saved by this method (whether the forcing be at a high or a low temperature), and that this economy more than balances the cost of etherisation. The cost per plant works out at rather more than one penny (12 cents.).

1. The varieties of Lilac usually forced in Germany: Marie Legraye, Charles X., and Léon Simon, were in full bloom twenty-eight days after having been brought into the house; Marie Legraye was even earlier in flowering.

2. Various flowering shrubs may be bloomed in much less time than by the usual process. Plants of the same variety not etherised have not bloomed, or have bloomed badly, in the comparative trials, or perhaps some opened their flowers in eight or ten days (according to the variety) after those that were treated with the ether.

3. Etherised plants can be forced at a lower temperature than that which is essential for the blooming of those not etherised.

Besides Lilacs, Herr LEDIEX also made experiments with *Viburnum tomentosum* syn. *plieatum*, *Azalea mollis*, *Prunus triloba*, *Deutzia gracilis*, Lily of the Valley, *Ilyacinth*, Rose, and cut branches of ornamental spring-flowering shrubs. *Azalea mollis* and *Viburnum* did well; *Prunus triloba* was less amenable to the action of the ether; *Deutzia gracilis* failed altogether. Lilies of the Valley etherised and placed in heat on November 21 flowered in the proportion of 40 per cent. on the twenty-first day, while of those not etherised only 2 per cent. flowered, and these in a temperature of 23° C. For late forcing of Lily of the Valley the ether had but little effect, so that it seemed better in that case to keep the plants in the refrigerating apparatus or in cool chambers. For Roses the results were not altogether decisive, although a very marked advance was reported.

Branches of *Azalea mollis* cut and etherised expanded their flowers in twenty-three days, while the buds on branches not treated did not open until twelve days after. The greatest success was with Lilacs, *Viburnum*, and *Azaleas*. *Viburnum plieatum*, though slow to bloom, placed in heat on December 2, was in full bloom about December 14; while those plants not etherised yielded only poor flowers at a much later date.

Azalea mollis submitted to ether on Nov. 26, and brought indoors on the 28th, was covered with flowers on December 20, although the cheek plants only bloomed partially in the beginning of January. The more nearly the normal season of the flowering of the shrubs is approached, the less vigorous is the effect of the ether. The value of etherisation, then, is for early forcing in November and December, when the flowering can be hastened by some two or three weeks.

Plants lifted from the borders without preliminary attention during the summer, flower as normally as if forced in January or February. This, it must be confessed, is an immense advance in the forcing industry.

The application of the treatment is not without certain inconveniences and difficulties at the commencement. The vapour of the ether is inflammable, so that no light must be brought into places where plants are etherised until the vapour has been thoroughly dispersed by ventilation; no fire or light must be allowed anywhere in the neighbourhood of the ether.

There is still some difficulty in administering the ether to ensure perfect volatilisation. The plants should remain plunged in the vapour for a certain time, about forty-eight hours, and this must be in an absolutely air-tight place, to prevent the escape of the vapour. The larger the area, the more precautions should be taken both to concentrate the vapour during the period of etherisation, and to ensure its rapid dispersal after the operation.

For forcing on a large scale, cemented buildings with a door and several ventilators, the interstices of which are hermetically sealed so as to prevent the escape of any ether, are most convenient. The interior arrangement should be such that every corner can be filled with plants, so as not to waste the ether unnecessarily.

Now here, to revert to our plea for an experiment station, is an experiment which could readily be tried at little cost at Chiswick, and if the facts as recorded by our Danish and Saxon friends can be confirmed at Chiswick, that establishment would confer a benefit on horticulture of more permanent value than it does by the present necessarily inadequate trials.

ROYAL GARDENERS' ORPHAN FUND.—In our account on p. 135 of the very satisfactory meeting of the supporters of this Fund, we were compelled to summarise the statement of accounts owing to pressure upon our space. In that summary it is stated that there are balances in hand, on deposit, and at bank of £2,683 10s. 5d., which is really the amount of expenditure for the year, including balances £728 15s. 9d.

LINNEAN SOCIETY.—On the occasion of the evening meeting to be held on Thursday, March 6, 1902, at 8 P.M., the following papers will be read:—1. "On some new Species of Lepididæ in the British Museum (Nat. Hist.)," by Prof. A. GRUVEL. 2. "On the Morphology of the Brain in the Mammalia, with special reference to the Lemurs, recent and extinct," by Dr. G. ELLIOT SMITH.

MR. SELFE LEONARD.—We greatly regret to have to announce the death, on the 21st inst., of Mr. SELFE LEONARD under very distressing circumstances. He was staying at an hotel in Rome and fell down the staircase, sustaining injuries from the effects of which he shortly succumbed. Mr. SELFE LEONARD was an enthusiast in the collection and cultivation of hardy plants, and his garden near Guildford is one of the most noteworthy in this respect in the country.

PRESENTATION.—On Friday, 21st inst., Mr. JAMES NEIGHBOUR, head gardener at Copped Hall, Epping, was the recipient of a handsome marble clock, presented to him on his retirement from his post by the garden staff, and other employes and friends on the Copped Hall estate. Mr. NEIGHBOUR has given faithful service to E. J. WYTHES, Esq., and family, for upwards of forty years, and was much respected by his employer. The presentation was made by Mr. J. FEATHERSTONE, foreman in the gardens at Copped Hall, in the presence of the garden staff and others.

BOSKOOP.—To lovers of hardy trees and shrubs, and of those adapted for forcing purposes, it will be interesting to know that an exhibition of such subjects is to take place at Boskoop, Mar. 22 to 25. When one remembers the profusion of *Mollis Azaleas*, and other flowering plants, which might be collected at Boskoop, one can but anticipate a show of extraordinary beauty. Mr. G. J. DE VINK is the Secretary.

NATIONAL ROSE SOCIETY.—A meeting of the General Purposes Committee will be held at the Rooms of the Horticultural Club, Hotel Windsor, Victoria Street, Westminster, on Wednesday, March 5, at 11.30 A.M. *Edward Mawley, Hon. Sec.*

PRESENTATION TO MR. R. NEWSTEAD.—A crowded audience, representative of all classes of citizens of Chester, filled the Lecture Theatre at the Grosvenor Museum on Wednesday evening, February 5, being attracted thither by two objects: the first, to take part in a presentation to Mr. R. NEWSTEAD, the distinguished and popular curator of the museum, of a handsome timepiece, and a purse of gold, containing £144, spontaneously subscribed for by many admirers as a token of

appreciation of his scientific work; the second, to hear from Mr. NEWSTEAD an interesting lecture, entitled "My Natural History Work." The timepiece bore the following engraved inscription: "Presented to ROBERT NEWSTEAD, A.L.S., F.E.S., and Hon. F.R.H.S., with a purse of guineas, by members of the Chester Society of Natural Science, Literature and Art. February 5, 1902." The chair was taken by Mr. J. D. SIDDALL, who was supported by the Mayor of Chester (Mr. JAMES FROST, who attended specially to make the presentation on behalf of the subscribers). The chairman (Mr. SIDDALL), after a few words of welcome to the Mayor, said Mr. NEWSTEAD's work for the Society was so well known as to hardly need any explanation from him. He was appointed curator when they came into that building. This presentation to Mr. NEWSTEAD came out on the publication by the Ray Society of a monograph by Mr. NEWSTEAD on the scale insects. The question treated in that work was one of very great economic and national importance, and the very fact of Mr. NEWSTEAD's work being chosen for publication by the Ray Society as their annual volume was in itself proof of the importance of the subject, and of the admirable way in which the subject had been treated by Mr. NEWSTEAD. Since the date of that publication, Mr. NEWSTEAD had had the great honour done him by being elected one of the Associates of the Linnean Society. These things, together with Mr. NEWSTEAD's continued kindly work for the museum, had suggested to them the desirability of choosing the present time for making to him some acknowledgment of their indebtedness for his manifold works.

THE LATE SIR HENRY GILBERT.—We learn from *Nature* that, according to the will of Sir HENRY, his portrait, painted by his brother JOSIAH GILBERT, is to be placed in the library of the Sibthorpe Professor of Rural Economy at Oxford. Sir HENRY occupied the Professorship from 1884 to 1899. Dr. DAUBENY held the Professorship for many years, and in more recent times Professor WARINGTON.

SYDNEY BOTANIC GARDENS.—During the month of March the garden was visited by immense numbers of flying-foxes. There must have been many thousands of them, and some of the large trees were quite black with them. Several local sportsmen shot large numbers, and the destructive animals were all killed or flew away in about a week from the first appearance of the swarm. It is many years since the gardens were visited by a plague of these animals.

"CULTURE FORCÉE DES OIGNONS À FLEURS," par JULES RUDOLPH; and **"L'ART DE BOUTURER,"** par ADOLPHE VANDEN HEDE (Librairie and Imprimerie Horticole, 64 bis, Rue de Grenelle, Paris). These two books may be mentioned together, as additions to the library of practical gardening books. Forced bulbs (to use a general term for them) are now so important an industry that any information on the subject is useful. As to the second book, the propagation of plants is also a valuable and interesting subject. The two Manuals are clearly illustrated, and the flowers are not exaggerated, as is too often the case in illustrations of them.

LOTUS ARABICUS.—Messrs. W. R. DUNSTAN and T. H. HENRY contribute to the *Philosophical Transactions*, vol. xciv., p. 515, a paper on the poisonous substance contained in this plant. The Arabs are aware that in the early stages of growth the plant is very poisonous,

though when mature it is used as fodder for cattle. The two investigators above-named found that in the unripe plant a considerable proportion of hydrocyanic acid is developed. In the mature plant no poisonous substance is formed.

"THE FAVOURITE FLOWERS OF JAPAN."—This is a publication from Messrs. L. BOEHMER & Co. (ALFRED UNGER, Proprietor), exporters and nurserymen, 5 and 28, Bluff, Yokohama, Japan. The firm claims to have the only European nursery in Japan, and this book is written by Mrs. UNGER for English readers. It is an account of many of the favourite flowers of the country, interspersed with cultural hints. The book is wonderfully light in weight, bound in Japanese fashion, and printed on native paper. Last, but not least, we must mention the charming and characteristic coloured pictures of Peach-blossoms, Cherry-blossoms, Pæonies, Iris, and other flowers, and the delightful and suggestive little landscapes.

THE CHUSAN PALM.—A correspondent in North Wales sends us some interesting particulars of the life-history of this Palm. The plant was at first grown in a Fern-house attached to the residence of the late N. B. WARD, of Fern-case fame, at Clapham. As it appeared strong and healthy, it was sunk in its pot in the garden during the summer, and taken under shelter in the winter. As it still did well, its next home was in a greenhouse, where it remained for some two or three years, being carefully protected in winter. Finally, its owner moved to Wales, and the plant was transferred to Penmaenmawr, where it found a home in the garden, in a corner where the only protection afforded is that of the surrounding shrubs. It has lived there for years, and is still quite hardy and healthy, and has bloomed in four successive years. The Palm has grown to a height of 10 feet, and continues to flourish in this favoured locality, where, as our correspondent remarks, except for the winds, plants from almost any temperate quarter of the globe would grow.

APPLES FROM THE ANTIPODES.—Respecting the arrivals of fruit cargoes from Australia during the present season, the officials of the Peninsula and Oriental Royal Mail Steamship Company write:—Sailing from Sydney, New South Wales, the *Areudia* sails on the 19th inst., expected in London on April 6; *India* sails March 5, due in London on April 20; the *Oceana* sails March 19, due in London on May 4; *Britannic* sails April 2, due in London on May 20; *Australia* sails April 16, due June 3. The traffic manager of the Orient Royal Mail Steamship Company inform us respecting the arrival in the port of London of their fruit ships that the *Austral* is due to arrive on March 29, the *Ophir* on April 12, the *Omrak* on April 26, the *Oratava* on May 10, and the *Orizaba* on May 26. The manager adds, that should the requirements of the season so demand, there may be an additional steamer or two put on.

CORNISH WINTERS.—The following note appeared in a recent number of the *Western Morning News*, kindly forwarded to us by Mr. FOX:—

"It may interest some of your readers to know that on Sunday last the following plants were flowering in the open air in Falmouth gardens:—*Abutilon vexillarium* variegatum, *Acacia dealbata* and *Iopanthia*, *Anemones*, *Arabis grandiflora*, *Arbutus Unedo*, *Aucuba* male, *Azalea amena*, *Berberis Darwini*, *Beall*, and *japonica*; *Borago officinalis*, *Camellia* white, *Campanula pyramidalis*, *Chimonanthus fragrans*, *Choisya ternata*, *Chrysanthemum segetum* and Japanese in variety; *Cistus*, rose-coloured; *Citron* Madras, *Clematis balearica* and *cirrheosa*; *Cornus mas*, *Correa*,

Coronilla glauca and *viminalis*; *Crocus*, *Cyclamen* *Comm.*, *ibericum*, and *persicum*; *Colletia horrida*, *Cytisus*, *Daphne Laureola* and *Mezereum*; *Eranthis hyemalis*, *Erica carnea* and *mediterranea*; *Escallonia macrantha*, *Eryngium pandanifolium*, *Eupatorium Weinmannianum*, *Euphorbia* *giant*, *Forsythia suspensa*, *Fragaria indica*, *Fuchsia* "Little Dot," &c.; *Garrya elliptica*, *Genista*, *Grevillea rosmarinifolia*, *Pelargonium*, *Helleborus colchicus*, *niger*, *maximus*, *orientalis*, *rubra*, *punctatus*, *trifolius*, and *fetidus*; *Hyacinth Roman*, *Hydrangea hortensis*, *Iberis semper-virens*, *Iris stylosa*, *Jasminum nudiflorum*, *Kerria japonica*, *Kniphofia*, *Lavender*, *Leptospermum scoparium*, *Lithospermum prostratum*, *Lunaria biennis*, *Mandragora officinalis*, *Marguerites*, *Cape Marigold*, *Mediantum* *major*, 10 feet high; *Narcissus minor* *Grand Monarque*, *Henry Irving*, *Paper White*, *Soleil d'Or*, &c.; *Olearia Gunniana*; *Pansies*; *Phlox fruticosa*; *Pittosporum Tobira*; *Polyanthus* in variety; *Primroses*; *Pyrus japonica*, red and white; *Rhododendrons*; *Roses* *Devoniensis*, *Bardon Job*, *Gloire de Dijon*, monthly, &c.; *Ribes fuchsoides*; *Ruscus aculeatus*; *Schizotylis coccinea*; *Saxifraga crassifolia*; *Scabiosa*; *Senecio petasites*; *Snowdrops*; *Stocks*; *Spirea hypericifolia*; *Tussilago fragrans*; *Veronica* in variety; *Viburnum lucidum* and *Tinus*; *Vinca major* and *variegata*; *Violets*; *Virginian Stock*; *Wallflowers*, &c.

"The list is less extensive to-day, but the scarlet berries of *Asparagus deflexus*, *Aucuba japonica*, *Skimmia japonica* and *longifolia*, and seeds of *Magnolia Yulans* *Lennei*, are in brilliant contrast to the snow. H. F., February 12."

"GARDEN NOTES FOR THE COLONIES AND ABROAD."—This publication, by Messrs. JAMES CARTER & Co., High Holborn, would be useful to all emigrants and colonists. It contains an alphabetical list of possessions and countries, with notes on the soil, climate, and suitable crops of each. Indian gardening receives special attention, the pages devoted to monthly work in the hills being particularly valuable. Following this portion of the handbook is a section, also alphabetically arranged, on Vegetables for Abroad, then one on Flowers for Abroad, and on Specialties for Abroad; all calculated to serve as useful guides to those who take with them to foreign lands their love of gardening, and are in entire ignorance as to how to continue their pursuit under the altered circumstances.

THE AGE OF TREES.—The estimation of the age of trees by means of the number of rings visible in the wood is well known to be subject to many exceptions. In a recent number of the *Revue Horticole* it is pointed out that by pinching, or pruning or grafting, a second layer of wood may be formed in one year in a shoot. The explanation given by M. GEIGUARD is that the pinching or other operation brings about a state of rest, less sap is directed to the wound. But when the adjacent buds begin to grow, the afflux of sap is increased, and a fresh zone of wood is the result.

PODOCARPUS CHILINA.—In a supplement to a recent number, that for February 15, we gave a reproduction of a photograph, which was sent to us as representing *Podocarpus andina*. Unfortunately, no specimen was sent with the photograph, so that we were unable to verify the name. *Podocarpus andina* is, as we pointed out, a synonym for *Prumnopitys elegans*. Now, we have before us a specimen from the tree at Penjerriek, and recognise that it is really *Podocarpus chilina*. Of this we have dried specimens from Kew and from the Royal Botanic Garden, Edinburgh. In the latter garden the plant is (or was in 1891) called *P. andina*, so that no doubt the plant is cultivated elsewhere under this wrong name. Looked at in detail, *P. chilina* is very different from *Prumnopitys*, a native of the same country, and the habit is also different. *P. chilina*, the plant represented in our Supplementary illustration, has leaves 8 to 9 cent. long, 6 mill. wide, linear lanceolate, acute, falcate, deep shining green above, paler beneath, tapering at the base into a very short stalk. Beneath the epiderm is a layer of stereome or strengthening cells, and,

in the substance of the leaf, beneath the central bundle, is one large resin canal. The hemistele, or central strand of tissue, is defined by a well-marked bundle-sheath or "endoderm," and is transversely oval in shape. In spite of the deep green colour of the leaf, the central cells of the cortex are destitute of chlorophyll or mesophyll. It is a native of the Andes of Chile, and is hardy in the south of England and Ireland. In VEITCH'S *Manual of the Coniferae*, prepared by Mr. A. H. KENT, in addition to the tree at Penjerriek, fine specimens are noted at Kilma-curragh, co. Wicklow, and at Fota Island, near Cork. M. T. M.

MR. GEORGE WOODWARD.—Many of our readers will share our sympathy with the popular and skilful fruit grower at Barham Court Estate, Maidstone, who has just suffered the loss of a little daughter, aged eleven years, from pneumonia.

THE NATIONAL DAHLIA.—The annual meeting of this society was held in the rooms of the Horticultural Club on Tuesday last, E. Mawley, Esq., in the Chair. The President, officers, and members of committee were re-elected, with the addition of Mr. W. Tulloch and of Mr. Bennett-Poë as a Vice-President. Owing to the unsatisfactory relations with the Crystal Palace Company, the society has, as we have previously announced, determined to hold their show next September in the Drill Hall, under the auspices of the Royal Horticultural Society. The financial statement showed that the society had a credit balance of £1 13s. 2d., but this pleasing result had been obtained by the liberality of some members of the trade who renounced the greater portion of the prize-money due to them. In this way the loss occasioned by the action of the Crystal Palace Company was made good. It was suggested that Lord Ilchester should be asked to become a patron. The report, proposed by Mr. Mawley and seconded by Mr. Jones, was adopted.

THE POPLARS, AVENUE ROAD, REGENT'S PARK.

OUR illustration in the present issue (fig. 44) affords a view of a portion of the Rockery, situated at the end of the pretty garden of Ludwig Mond, Esq., which, for a suburban garden, is most interesting by reason of the successful culture of the Orchids and other plants, and Grapes, attained by his gardener, Mr. J. O. Clarke, and which have been often noted in the *Gardeners' Chronicle*. The garden has some fine trees, and a good stretch of well-kept lawn, which is not cut up in flower-beds, in the manner too often found in suburban gardens. A good view of the general garden was given in the supplement of our issue of April 20, 1901.

The Rockery is thickly planted with old-fashioned flowers, among which a very large number of those mentioned by Shakespeare find a place, and render the arrangement doubly interesting. At the back are rambling Roses, Lilies, and flowering shrubs, all of which lend their part to the floral display in their seasons.

NURSERY NOTES.

MESSRS. R. & G. CUTHBERT.

MORE than a century ago, in the year 1797, James Cuthbert, of Berwick-on-Tweed, established a nursery business at Southgate, in Middlesex. It was a small beginning, but we believe the business has been carried on uninterruptedly until the present time. Less than a year since, there were four generations of George Cuthbert's living at Southgate, but the decease of the great-grandfather, the last surviving son of James Cuthbert, was recorded in the *Gardeners' Chronicle* for August 3 last, in the eighty-sixth year of his age. Since the veteran's death, the little house he

occupied in the nursery has been utilised for enlarging the offices and seed-shop, which has given to the frontage of the premises an increased dignity of appearance.

Camellias have been grown at this nursery for a large number of years. There are now seven houses containing planted-out specimens, some of which are of remarkable size, whilst all are in an excellent and healthy condition. Most of the plants are of the old variety *Alba Plena*, and have been planted sixty or more years. One large specimen, said to be over one hundred years old, measures 16 feet in height and 30 feet through, or 90 feet in circumference; it is well furnished with growths and foliage to the base, and appears covered with buds. No manure other than soot is given to these trees, but a liberal dressing of soot is applied after the flowering stage.

Large specimen plants of *Rhododendron* (*Azalea*) *indicum* varieties, including *Fielder's White*, are cultivated for supplying flowers for cutting; also thousands of Roman *Hya-cinths*, *Narcissus*, *Tulips*, *Ivy-leaf* and other *Pelargoniums*, *Roses*, &c. The old *Primula sinensis alba plena* is largely grown, and a white, single-flowered variety, named *The Bride*, is cultivated for seed purposes, its habit being unusually free-flowering. Altogether, there are about a score of glass-houses, some of which are very old, and roofed with tiny panes of glass, but others have been rebuilt.

The out-of-door stock is contained on about six or seven acres of land in the district, and comprises *Aucuba*, *Laurels*, *Cupressus*, *Cedars*, and other evergreen and deciduous trees and shrubs, especially *Limes*, of which there is a good stock; also flowering trees and shrubs of the species most commonly planted. Another 5 acres has been acquired recently, upon the top of the hill, near to the entrance to Trent Park, and this will be planted with nursery stock.

FORCED TREES AND SHRUBS.

During the last few years this Southgate firm, which now consists of George Cuthbert and his two sons, G. H. Cuthbert and R. J. Cuthbert, has come prominently before the horticultural public, by reason of the exceedingly fine exhibits of forced *Rhododendrons* (*Azaleas*) of the types known in gardens as *mollis*, *sinensis*, *Ghent*, *rustica*, &c., at the Drill Hall and the Temple shows; a photograph of the collection staged at the last Temple show being reproduced as a supplement to this journal on August 17. The public in this country has probably never seen these types of *Rhododendron* shown better than in the glorious and richly coloured groups exhibited by Messrs. Cuthbert, and the firm has thus helped very largely to direct attention to new and most desirable varieties for forcing, and for planting on southern slopes in the garden.

Being informed that the firm intended to exhibit a very large and interesting group of forced plants at the Drill Hall on February 25, we welcomed an opportunity of inspecting them a few days earlier in the glasshouses, this being the primary object of our visit on the 21st inst.

The weather during the last six weeks has not been very helpful in the matter of forcing, whether flowering plants or Vines, but notwithstanding this, by very great care in pushing along this species, and delaying that one, a very representative display of forced shrubs has been obtained for the closing days of February. Every day now marks an advance, there is more daylight, and the possibilities of

FIG. 44.—VIEW IN THE GARDEN OF LUDWIG MOND, ESQ., REGENT'S PARK, LONDON. (SEE P. 146.)

a little sunshine are better, so that before another fortnight has passed the Lilaes and other species that seemed hardly likely to be ready for Tuesday, will be in full flower. Among Rhododendrons that were sufficiently forward were the following: *Mollis* section, *Comte de Quincey*, yellow, shaded with orange; *Comte de Papadopoli*, rosy-red colour, shaded and spotted with orange; *Queen Sophia*, rose; *Chevalier de Reali*, creamy white, spotted orange; *Dr. Reichenbach*, a newer variety, of very pleasing colour, with shades of rose, salmon, and orange; *Elizabeth*, claret-coloured, with silvery sheen; the beautiful variety *Anthony Koster*, and others.

A very large plant of *Daviesii*, a most handsome variety of the Ghent or American section, in a pot 20 inches, in diameter, was just opening its flowers; these are white, with yellow blotch on the upper petal. Seedlings of *R. occidentale* in full flower were very beautiful; the flowers are white, with just a suspicion of pink, and with yellow blotch. They vary considerably in these characteristics, but all are deliciously scented.

Of shrubs there was considerable variety in bloom, and none were handsomer than the standard and bush plants of *Wistaria sinensis*. The standards averaged about 4 feet high, and the bush plants 2½ feet. On one of the latter plants there were fifteen trusses of flowers of delightful colour and fragrance. Gardeners do not force *Wistarias* so commonly as the effective qualities of the plants warrant. It may be that they are known to be difficult, but Messrs. Cuthbert succeed with them well enough even so early. The main consideration is to start them very slowly indeed, refraining from pushing them until the flower-buds show. In default of this the plants hurry along into growth, and produce few flowers or none at all.

Another very desirable plant for forcing is *Cytisus purpureus incarnatus*. The plants we saw were quite dwarf, consisting only of arching sprays a foot or more long, with flowers from all the leaf axils. Naturally, the flowers are purple coloured, but forced ones are only palely tinted.

Then there were the double-flowered *Prunus sinensis* in red and white varieties, *P. triloba*, *Malus floribunda*, and the variety *atrosanguinea*; *Laburnum*, *Magnolia conspicua*, *Deutzia gracilis*, *Erica melanthera*, double-flowering *Cherries*, *Genista Andreana*, *G. fragrans*, and *G. præcox alba*; *Kalmia latifolia*, *Ribes atrosanguineum* (which can be forced into bloom in about a week), the double-flowered *Thorn*, *Staphylea colchica*, *Daphne Genkwa*, with pale lavender-coloured flowers on very slender growths; and *Forsythia suspensa*; also *Pyrus Scheideckeri*, *P. Maulci*, and the much better *P. M. superba*; *P. japonica*, rose, alba, and rubra. There were also five or six varieties of flowering *Peaches* (*Prunus persica*), including *rosæflora*, *sanguinea*, and *alba plena*. All of these are very beautiful, and the snow-white blossoms of that last-named are useful for a variety of purposes. Many of the above-named species are forced as standards as well as bushes, and with a few Japanese Maples which have also been forced into leaf, a very pretty exhibit is likely to be made at the Drill Hall meeting.

SELECTED VARIETIES OF SWEET PEAS.

My attention has been drawn to the selection of Sweet Peas given by Mr. Simpson in your issue of January 11, p. 27. The list there is undoubtedly a very good one, but with your permission I will make an exception to a few of them, and tell your readers why I make the exception.

Captain of the Blues is hardly wanted with *Emily Eckford*; it is a very good variety, rather darker in colour, but I should certainly give the preference to *Navy Blue*. As the best substitute in place of *Chancellor*, I should undoubtedly select *coccinea*, one of the new varieties which went out last season for the first time, and which is undoubtedly the nearest approach to a scarlet that we have yet got. *Chancellor* is in my opinion too near *Lady Mary Currie* to be wanted in a stand of twenty-four distinct varieties; and I should even prefer *Oriental*, as somewhat a darker shade of colour, if *coccinea* were not used. *Duchess of Westminster*, according to all my trials and observations of the last season or two, has been so varied in its character, its markings, and its size, that I should much prefer *Countess of Lathom*, which is somewhat in the same way, but a much more reliable, and in my idea a better flower. *Colonist* I should leave out, for the reason that it is one of the most unreliable flowers I have ever grown, not so much in the size of its blooms as in the variety of its shades of colour, for I think if anyone would grow fifty seeds of *Colonist*, they might without any difficulty select five or six distinct shades of colour from the row when in bloom. I should much prefer the newer variety, *Lord Kenyon*, which in my opinion is the best of this shade of colour after *Prince of Wales*. *Mrs. Dugdale* I hardly think is wanted with *Royal Rose*, and it has an unfortunate habit of becoming very deformed at times in the lower part of the wings. For *Lady Ormesby Gore* I should substitute *Mrs. Eckford*, which, although perhaps not quite so bright in colour, is undoubtedly one of the best Peas in existence as a pale primrose self. *Lady Ormesby Gore* has a tendency to "hood," and is dumpy in the shape, and is certainly not wanted with the *Hon. Mrs. Kenyon*. For *Othello* I should substitute *Black Knight*; the former I look upon as a dull colour as compared to the latter, which is always one of the most telling dark varieties that is exhibited in a stand of twelve, eighteen, or twenty-four, and that was shown pretty well in the Sweet Pea Centenary at the Crystal Palace, for there I find *Othello* was only exhibited thirty-five times, whereas *Black Knight* was exhibited sixty-three. *Black Knight* was in the 1st prize stands on seven different occasions, and *Othello* was only represented in three. *Black Knight* was exhibited in twenty-eight different stands in other provincial shows during that season, as compared to seven of *Othello*.

Your correspondent of February 8 alludes to the fact that I still favour *Prima Donna* before *Lovely*, and I am still of that opinion. *Lovely* has such a tendency to become streaky in the centre of the standard, which in my opinion is a very great defect, whereas *Prima Donna* is a much more constant flower right through, although I find, on referring to the number of exhibits at the Centenary, *Lovely* was certainly shown on more occasions, it being represented in seventy-five stands as against fifty-four; in the provincial shows there was not so much difference, one being shown forty-three times and the other thirty-seven.

As another instance of Mr. Simpson's list, I am rather surprised he has left out *Sadie*

Barpee and put in *Emily Henderson*. There has always been a very great diversity of opinion amongst growers generally as to whether *Sadie Barpee* or *Blanche Barpee* is the better flower, but it has hardly ever been questioned or compared with *Emily Henderson*. *Blanche Barpee*, in my opinion, is the finest white in existence, with its bold, upright standard. *Sadie Barpee* is a very good flower, but unfortunately "saddles" in the standard too much to please me; whereas *Emily Henderson* is a smaller flower in every way, and has a split or heart-shaped standard, which is quite a standard of the past as compared to the flowers which are now looked upon as a standard of what a Sweet Pea ought to be. I find *Sadie Barpee* was exhibited at the Centenary show sixty times, and in the provincial shows thirty-seven times; whereas *Emily Henderson* only appeared thirty-three times at the Centenary and nineteen times in the provincial exhibitions. This, I think, will speak for itself as to its popularity. *R. Sydenham, Birmingham.*

LAW NOTES.

BANKRUPTCY OF WM. JNO. BATHO.

THE first meeting of the creditors interested under the failure of William John Batho, nurseryman, Finchley, was held at the London Bankruptcy Court on Friday last. The statement of affairs filed by the debtor disclosed gross liabilities amounting to £93,155, of which £21,574 15s. 2d. was due to unsecured creditors, the total liabilities expected to rank amounting to £36,390 19s. The assets are estimated to produce £20,456, including the estimated surplus from securities in the hands of fully secured creditors amounting to £18,077 11s. 11d. The net assets after deducting the claims of preferential creditors payable in full amounting to £196 19s. 11d., are returned at £20,259 0s. 1d., thus showing a deficiency of £16,131 18s. 11d.

It appears from the official receiver's report that the debtor has been adjudged bankrupt. The debtor commenced business in December, 1895, and purchased a nursery from Mr. Phippen for £2,500, and taking over a mortgage of about £1,300. It appears that he obtained the purchase-money by way of a gift from an aunt. He is possessed of about 37 acres of freehold land, with water-tower, and of various houses, situate at Finchley. The causes of insolvency are stated to be "insufficiency of capital, and the Vines not being sufficiently developed to permit of their fruiting, and the depression in trade caused by the war and the Queen's death; interest on borrowed money, and heavy insurance premiums." The debtor has been requested to furnish further particulars of the "Loss by speculation in mining shares." The debtor stated on his preliminary examination that he had taken out two life policies in the London Life Association, Ltd., for the sum of £2,500 each, which are mortgaged to Lord Forester and Mrs. Vernon, and further charged to Sir Henry A. White. It appears, however, that there are two further life policies taken out on the same Association, and the Company claims to have a first charge on each policy.

As the debtor was unable to make any offer of composition, Mr. Oscar Berry, chartered accountant, of Monument House, E.C., was appointed trustee of the estate, and to act with a committee of inspection also appointed.

PLANT PORTRAITS.

AQUILEGIA HELENÆ (flabellata × cærulea).—Sepals bluish-violet; broad petals, white, with a deep blue spot at the base. *Gartencell, February 1.*
VITIS VOINIERIANA.—Evergreen climber. *Revue Horticole, February 1.*

PUBLICATIONS RECEIVED.—*Agricultural Bulletin of the Straits and Federated Malay States*, December, 1901. Contents: Timbers of the Malay Peninsula (continued), Para Rubber in the State of Amazonas, Transport of Tropical Fruit, The World's Tea and Coffee Consumption, &c.—*Journal de la Société d'Horticulture du Japon*, December 20, 1901, containing articles (in Japanese) on Narcissus Culture, by S. Taketa; Culture of the Japanese Carrot, by M. Hayashi, &c.

HOME CORRESPONDENCE.

GRAFTING FRUIT-TREES.—As grafting will soon begin, I wish to mention two modes of grafting which I found very successful last year. One requires the stock and graft to be of about the same size; both are cut very sloping, like a fish-splice of a fishing-rod, and made to fit together; a small tie is made in the centre of the cuts, and india-rubber tape, well stretched first, such as is used by engineers for making electrical joints, is wound round the graft and stock, commencing at the bottom, and secured at the upper end with india-rubber solution. As the sun may rot the india-rubber before the union is firm, it is well to fasten bast round the india-rubber loosely. The india-rubber stretches as the graft grows, and when the matting gives way the graft is firm. *Capt. H. Rogers, Hartley, Plymouth.*

FLOWERS WHICH CHANGE COLOUR.—In a recent issue of the *Gardeners' Chronicle*, p. 124, bottom of third column, your contributor, "A Sussex Naturalist," in his interesting notes respecting "Flowers which change colour," says, "There are, moreover, several books which the student can consult." I, and probably many more of your readers, would be much indebted to him if he would kindly, in some future issue of the *Gardeners' Chronicle*, name the books in question. The subject he deals with is a most interesting one, and I should much like to know more about it. *R. B., Wimbledon.*

HARDY PLANTS FOR FORMING DEVICES.—It would appear from an enquiry by "Inquirer" (see p. 120 of the *Gardeners' Chronicle*), that advice is sought concerning device-planting; but it is not easy to suggest plants unless the season for which such things are required is clearly stated. This much is stated in the reply to "Inquirer," who appears to possess an idea for the patriotic "red, white, and blue." Even with the many hardy plants in cultivation, we are still without plants that would be effective in the particular shades of colour required, assuming that it is a floral device that is desired. There are hosts of good hardy plants, many in the colours named, although few that can endure to be pinched and pegged down as in carpet bedding. The very revival of hardy plants years ago was a sort of protest against this method of employing plants. There are hardy plants that may be introduced into any style of gardening, without robbing the plants of their beauty. Among flowering plants none can compare as a bedder with the blue *Lobelia* for dwarf habit or profuse flowering; therefore, where blue is needed, *Lobelia* will have to be used. The blues we find in *Veronica*, in *Campanula*, or the *Gentian*, but plants of spreading habit are, by their habit and free growth, unsuited for the making of devices. There are, however, hardy plants which are of service in general bedding arrangements, and I will give a few of the more prominent. It is, perhaps, in the silver-leaved plants that hardy subjects will shine best, for here we find, in addition to that very old and tried plant, *Cerastium tomentosum*, such things as *Achillea umbellata*, with silver foliage and white flowers; *A. ageratoides* = *Anthemis aizoon*, with white, Daisy-like flowers; *A. Clavennæ*, white-flowered, while the leafage in each is quite distinct. The first and last are readily dealt with in quantity, but *A. ageratoides* is less so. Another fine plant in the same category is *Teucrium Polium*, also known as *T. aureum* from the yellow flower-heads; the leafage of this is very fine, and the plant easily propagated. In this connection I do not forget *Leucophytum Browni*, a useful plant, but not absolutely hardy; and not least among white-leaved subjects is the well known *Antennaria candida*, whose dense, spreading tufts adapt it specially for devices on a small scale. To these may be added *Santolina incana*, a perfectly hardy sub-shrub. In green-leaved subjects, *Achillea tomentosa* and *A. aurea* are

rather alike, but distinct in their flowers; then there are *Veronica repens*, *Mazus pumilio*, *Mentha Pulegium gibraltarium* (not hardy), *Ajuga reptans*, and several "mossy" *Saxifragas*, as, e.g., *S. hypnoides*, and its variety *elegans*, *S. Stansfieldi*, *S. Sternbergi*, and others. Of *Sedums*, a pair of perfect bedding subjects may be found in *S. hispanicum* and its variety *S. h. glaucum*; and still another good plant in *Herniaria aurea*, which has also given a golden sport. In variegated subjects the Golden Thyme, the variegated forms of *Arabis lucida* and *mollis*, the golden-leaved *Stellaria graminea*, the variegated *Veronica gentianoides*, are some of the best. Besides these, there are such well marked plants as *Dactylis elegantissima*, *Chamaepeuce diacantha*, *Centaurea ragnsina* and *compacta*, *Cineraria maritima*, the purple-leaved form of *Ajuga reptans*; and for a large bed or in a damp locality, *Scrophularia nodosa* fol. var. This last will bear pegging down, and the points should be pinched to keep it from flowering. In this way the silver leafage is very fine. A good flowering plant is *Verbena venosa*. In the springtime there is an abundance of flowers on dwarf, verdant carpets; the *Anbrietias*, alpine and setacea varieties of *Phloxes*; *Gentiana acaulis*, *White Arabis*, *Asperula odorata*, and others; but none of these by their natural bearing suggest a more useful sphere by trimming them into well defined or rigid lines. They are far more beautiful naturally grown, and each in turn covered with its wealth of floral beauty. *E. J.* [Our correspondent has given the names of a large number of very useful plants, but "Inquirer" required only red, white, and blue. *Ed.*]

SEVERE WEATHER BY THE SOLWAY.—Not for seven years has there been in this district such a severe storm of frost and snow as the one just gone. The frost of 1895 cut down many tender plants that grow and flourish well along the shores of the Solway. *Buddleias*, *Fuchsias*, *Veronicas* were cut down to within a few inches of the ground. How they may fare this season, as well as others that have since been planted, such as *Hydrangeas*, *Phloxes*, *Eucalyptus*, *Choisyas*, &c., remains to be seen; but till the present month we have escaped the severe weather that prevailed, both north and south of this locality. Between the evening of February 7 and the morning of the 8th, 6 inches of snow fell, and frosts occurred on the 10th, 18°; 11th, 22°; 12th, 21°; 13th, 23°; 14th, 23°; 15th, 16°. As long as the sun allowed the snow to remain on the bushes they were doubtless safe. The *Eucalyptuses* were slightly protected by some branches of Sweet Bay, and except that the tips of their upright growths are a little damaged, they do not seem to have suffered much. It is to be hoped that the others mentioned may not have fared worse, as when the sun had melted the snow they were entirely unprotected. *J. Jeffrey, Kirkcudbright, N.B.*

THE ROYAL HORTICULTURAL SOCIETY.—The announcement of the president at the annual general meeting reported in the *Gardeners' Chronicle*, p. 117, has doubtless given great satisfaction to all the Fellows, especially to those who remember the Society in the bad old times; and the members of the Council are to be congratulated on the wise and straightforward course they have taken. All who are interested in horticulture should give loyal support to the policy that is now being pursued, and every effort should be centred upon the main object, viz., a Central Hall and suitable offices. The question of a new garden can wait, and nothing can be said upon the subject in more appropriate terms than those expressed by the president in his address. In the meantime it is noticeable that the old garden at Chiswick has recently asserted its capabilities in a remarkable way. Let anyone turn to the Report of the Council issued in December, 1901, and a most interesting and valuable paper on Plums will be found. Nothing comparable to it, or so free from trade bias, can be found elsewhere, and the only regret one feels disposed to express is that

the report on Plums was not issued in a separate form. This fruit is second in importance only to the Apple, and the result of the Chiswick trials will be a safe guide to planters throughout Great Britain. Very few varieties failed to fruit, and "good crop," "very good," and "extraordinary crop," are expressions of frequent occurrence in the report. Mr. Wright, the superintendent, and his staff, are entitled to great credit for the successful fruiting of so many varieties of Plums in the old garden under ordinary conditions. *W. Roupell.*

DALKEITH, AND OTHER MATTERS.—The account given of Dalkeith Gardens by "R. H. P.," p. 81, was to me very interesting reading, especially the allusion to the ribbon flower borders along the sides of the broad walk fronting the gardener's house. I think I am not very far wrong if I venture to say that the introduction of the striped-ribbon system of planting a flower-border was first initiated at Trentham, by the late Mr. Fleming, near upon sixty years ago. Be that as it may, I recollect how delighted I was when first I saw it there forty-nine years ago; and more than once have I helped to plant it. I well remember sending a sketch of the border, accompanied by a list of the various things with which it was planted, to the late Mr. Laing, who was then gardener to the Earl of Rosslyn, at Dysart House. Mr. Laing tried a short length of it, which so pleased the Earl that he desired a long border in the kitchen garden to be prepared, so that he could enjoy the effect of it on a more extensive scale. It is refreshing to find that ribbon-borders are not yet altogether written out of existence by the newer school of garden-writers, who must fill their often rather uninteresting books with something. When at Combe I had an opportunity of forming a very fine ribbon-border, longer than the one at Trentham, a portion of which was even carpet-bedded, and well did it look! When the late Mr. Stevens, of Trentham, saw my border, and found it to be longer than his, he went home and took an early opportunity of turning his down. The gardener's house at Dalkeith is a decent enough looking structure, but why should its walls be so completely naked of any representation of plant life? No *Wistaria*, no *Eseallonia*, no *Roses*; not even *Tropæolum speciosum*, which grows so freely, and is so much admired by southern visitors to Scotland. Part of the house too is obscured by what appears to be an ivy-clad brick wall; whilst on the other side there is a naked palisade, also without the semblance of plant-life upon it. Then, as to the glasshouses. From what we have heard from time to time of the grandeur at Dalkeith, we would have expected to have found a very different representation of them. Fig. 29 shows five houses, all of which are in different lengths, widths, and heights; of the person who directed their construction it certainly could not be said of him that he was a man of one idea only. I believe at one time a range of glass was considered to be more pleasingly effective by having a number of breaks in the lengths of its elevation or façade, the fallacy of which is now pretty well exploded, and we are pleased to note the erection of a new vinery, 75 feet long by 20 feet wide. This is encouraging for the new gardener; of the success of which we will hope to be favoured with an account by and by. "R. H. P." gives it as his opinion that an "English-grown Pine-apple is far superior in flavour to some of the imported ones." One often hears this remark, though the truth of it is difficult to appreciate, seeing that the Azore Islands (from which I believe the bulk of our Pine-apples come) are situate something like 1,000 miles further south than we are, enjoy a fair summer, and of course warmer climate; therefore, we would naturally conclude that Pine-apples with such advantages would be superior in flavour—as they are in size—to those grown in this country. It would be interesting to put the matter to proof, by selecting a first-class specimen of home and imported growth, and have their flavour tested by the Fruit Committee of the Royal Horticultural Society, followed by a

short lecture as to how and where the advantages or disadvantages of flavour comes in, in the culture of the fruits respectively of each country. W. Miller, Berkswell, February 10.

PALMS.—I have read with much interest the notes about Santa Barbara, California, and especially that 150 different Palms are grown there in the open. Would Dr. Franceschi give the list of these 150 species, and thereby greatly oblige all interested in cultivating Palms in semi-tropical climates? I have, after years of trial, been able to bring about 100 different (or supposed) species of Palms together growing here in the open. About as many others which I have tried have succumbed, but not always from climatic causes, so that if I could procure such species again I should go on trying them. Very many species may, *a priori*, be supposed to be as hardy as those which prove so here, but I have not been able to obtain them. Dr. U. Dammer thinks that about 300 different species of Palms would live here, and as the climate of Santa Barbara is about the same as this, it would obviously be of great interest to know which are the 150 species already found to be hardy there, and which may be supposed hardy in many other countries with a similar climate. *Ipomoea chrysanthra*, which has not flowered at Santa Barbara, has flowered here, producing middle-sized, pale yellow, rather inconspicuous flowers. I had planted this with many other climbers against my old, not very large house, but after two or three years the growth of *Ipomoea chrysanthra*, and of some others, whose habit of growth was unknown to me, as, for instance, *Coccinia Dinteri* (Naudin), which latter was described and figured by E. André in the *Revue Horticole*, 1900, p. 268, had become so enormous that I was obliged to take them away. In fact, these climbers had to be trimmed every few weeks to prevent them from burying the house altogether with their verdure, which lay in thick masses across the roof. Besides this very luxuriant growth, suitable only over immense buildings or large trees, the creepers had the quality of sucking up all moisture from the soil for a considerable distance around. When a stem was cut, the sap would flow out in a quantity enough to fill a drinking glass. The effect of this great absorption of moisture, and, of course, of that of other elements of food, was to prevent the growth, nay, the very life of any other plant for several yards distance around where they were growing. I should advise everybody to avoid planting such voracious plants near slow-growing or valuable specimens. A. Robertson-Proschowsky, *Parc les Tropiques, Chemin des Grottes, St. Hélène, Nice, Alpes-Maritimes, France*.

EARLINESS OF SNOWDROPS.—I find that a great many plants grow and flower here outside that would not do so in Oxfordshire, among such being Veronicas, Fuchsias, and even the Gum Cistus, which are doing here nicely. They have been planted nearly two years, and have been without any sort of protection. I selected a dry subsoil and well sheltered situation. The great drawback is that everything keeps growing up to Christmas, and then we get a cold time, with wind from the east in March. Fortunately, the garden is well sheltered from that quarter. J. Jeffrey, *St. Mary's Isle, Kirkcudbright*.

WINTER-FLOWERING CARNATIONS.—I am sorry so good a cultivator of Carnations as Mr. Jennings differs from me on the merits of Carnation Mrs. Leopold Rothschild as a winter-flowering variety; and in writing of winter, I will say the months of December and January as being about the worst time for flowering the plants. By having several batches of plants, with timely stopping, flowers come in succession; but there are doubtless many persons who grow but a tenth of the number Mr. Jennings does, and consequently they would not be able to gather so large a quantity of flowers daily in mid-winter. When writing of winter-flowering Carnations, I had

in my mind those varieties that I have found to be constant bloomers, which open their flowers freely in mid-winter, without any system of stopping the plants. The variety Mrs. L. Rothschild forms abundance of side shoots on the flowering stems, a good quality when increase of stock is desired, but if the plants produced a few less of these and more flowers, the value of this fine Carnation would be enhanced. Are there two varieties of Mrs. L. Rothschild? I have grown it with "Franco," but failed to see any difference in them. T. H. Slade, *Devon*.

CRINUM MOOREI AND C. POWELLI ×. — I have been much interested and instructed with your able correspondent's critical remarks on the origin of these plants. By some temporary forgetfulness, I associated Dr. Moore's foreman, Pope, with Mr. Powell, the raiser of *C. Powellii*. I beg to apologise to that gentleman for the inadvertency. I am indebted also to Mr. Gumbleton and Mr. Moore for their lucid information, as well as to the Editor for his historical references, and shall take the earliest opportunity of gratifying myself with a perusal of the articles referred to, and which I had missed reading during absence at various times from England. *C. Moorei*, with its numerous aliases and variations, *Colensoi*, *natalense*, *Makeni*, *Makoyanum*, *ornatum*, *Schmidtii*, &c., as well as the various dates usually given of their introduction, are very misleading. I believe the *Dictionary of Gardening* says introduced in 1874. Mr. Powell saw the plant at Glasnevin thirty-five years ago; I saw it thirty years ago, when a privileged student, in favour of the eminent Director from 1872 till 1877, and at the lectures on "Crossing species and Varieties, &c.," I heard Dr. Moore compliment his foreman by name in connection with raising *C. Moorei* at Glasnevin. Evidently he alluded to raising it from seed, but I understood it to mean a garden hybrid, and by that oversight subsequently associated Mr. Pope with the product of crossing *C. Moorei* and *C. longiflorum*. Perhaps Mr. Moore could say if Mr. Pope was in any way instrumental in procuring the seeds of *C. Moorei* originally, and if he remembers if that foreman had a brother in the Government service in Natal who sent the seeds home; or if its first appearance at Glasnevin preceded the receipt of the sketch made by Bishop Colenso? J. Murison.

TOMATO-DISEASE.—Referring to a note on Tomato-seed in the *Gardeners' Chronicle* of Feb. 22, I should say our gardening friend is quite correct about the selection of Tomato-seed, and to save it from plants grown under cool conditions. I may say that I grow Tomatos all the year round, and I hardly know what it is to have the disease, or any plants go wrong. I simply grow a few plants outdoors, and save just the medium-sized fruits for seed. The most important point is to examine every seed with a lens, and save only those seeds which are free from a black spot which is to be seen on some seeds when taken out of the pulp, which, although it is a tedious job, pays in the end. I once saw a crop of Tomatos, grown from seed saved in this way, a perfect sight, that will never go out of my memory. A. C.

THE CLEANSING OF ORCHIDS.—Mr. Bound seems quite surprised at my calling in question his method of cleansing of Orchids, asserting that I gave a wrong impression to his words. I adhere to my statement that Orchids require a thorough cleaning oftener than at least once a year. No doubt in the pure air of Reigate they do not get so dirty as in the suburbs of large towns; but what would a collection of Orchids look like at the end of a year if they did not get overhauled, the pots, stages, and glass washed, especially the side-lights of the houses, oftener than once a year? and they would certainly do no credit to the man who had charge of them. Mr. Bound assumes that I agree with a monthly sponging; not so, but I would rather advise once a month than a yearly one, where

circumstances allow of its being performed. My contention is, that as soon as plants require cleansing they should be cleansed, even if it is once a month. Mr. Bound emphasises the value of ventilation to Orchids, and it certainly is an excellent thing, but there are times when it cannot be afforded, especially in localities where town fogs abound, carrying with them all sorts of impurities. I agree that Cattleyas do not require so much moisture as the East Indian Orchids, but a certain amount must be afforded in order to keep the air moist, and the air-roots of the plants in a healthy active state. B. Bowyer, *Morton Hall Gardens, Swinderby, Lincs.*

SOCIETIES.

ROYAL HORTICULTURAL.

FEBRUARY 25.—A very interesting display of exhibits was made at a meeting of the committees on Tuesday last at the Drill Hall, Buckingham Gate, Westminster.

THE FLORAL COMMITTEE recommended a First-class Certificate to *Acacia cultriformis*, which was shown as *A. harpophylla*. It is a very pretty species, with peculiar, hatchet-shaped phyllodia. There were groups of forced flowering plants, of Primulas, Cyclamens, hardy plants, &c., to which eleven Medals were awarded.

Orchids were more numerous than on recent occasions, and the ORCHID COMMITTEE recommended First-class Certificates and Awards of Merit.

THE FRUIT AND VEGETABLE COMMITTEE had but little work to get through, and only awarded a few Cultural Commendations to some fine Onions, Seakale, and Asparagus.

In the afternoon, at a meeting presided over by Sir J. T. D. LLEWELYN, Bt., there were about seventy new Fellows elected to the Society, and a LECTURE upon the uses of Nicotine in Horticulture was given by Mr. WILLIAMS.

Floral Committee.

Present: Chas. E. Shea, Esq., in the chair; and Messrs. Chas. T. Drury, H. B. May, George Nicholson, James Walker, R. Dean, J. F. McLeod, John Jennings, J. Hudson, W. Howe, C. R. Fielder, Chas. Dixon, J. Fraser, C. Jeffries, J. A. Nix, Geo. Gordon, R. W. Wallace, E. H. Jenkins, R. C. Notcutt, C. Blick, Geo. Paul, and Ed. Mawley.

Messrs. R. & G. CUTHBERT, Southgate Nurseries, London, N., were awarded a Silver-gilt Flora Medal for a very exhaustive collection of forced flowering trees and shrubs, which, being described upon p. 146, need not be referred to in detail here.

A group of *Lachenalias* in bloom in baskets and pots was shown by Mr. ALLEN CHANDLER, Bunch Lane, Haslemere. The varieties were seedlings, most of them deep yellow-coloured, with little red about them. One in particular had very large flowers of much substance.

Primula obconica was shown in a group from Messrs. J. PEEN & SON, Norwood Road, West Norwood. The seedlings varied in the colour of the flowers, some being of rich pink colour, and others almost white (Bronze Banksian Medal).

MESSRS. WM. CUTHBERT & SON, Highgate, London, N., and Barnet, Herts, had a nice group of *Ericas* and other such plants in full flower. There were *Erica melanthera*, *E. Wilmoreana*, *Epacris* in red, white, and pink varieties; *Boronia megastigma*, and *B. heterophylla*; *Acacia Drummondii*, so useful as small plants in 5-inch pots, &c. (Silver Banksian Medal).

MR. GEORGE MOUNT, of Canterbury, has commenced to exhibit his forced Roses a fortnight earlier than usual, having on Tuesday last the varieties *La France*, *Mrs. Jno. Laing*, *Mrs. Sharman Crawford*, *Madame Gabrielle Luizet*, and *Capt. Hayward* (Silver Banksian Medal).

A variety of *Asparagus*, under the name of *A. plumosus Blampiedi*, was shown by Messrs. BLAMPIED & TAUDÉVIN, La Fosse, St. Marten's, Guernsey. Four plants in 10 inch pots were shown. The variety was obtained from seeds from South Africa, and is said to require 10° less heat than the type, is much freer in growth, and is liked better in the market. The growths develop phyllodia earlier than does the type, and produce an unusual amount of spray, the growth it has made since Christmas being remarkable.

MESSRS. WM. WOOD & SON, LTD., Wood Green, London, exhibited some of their specialties, including a new form of garden syringe and other sprayers, &c.

Prunus (Amygdalus) persica magnifica was finely shown by Messrs. JAS. VEITCH & SONS, 544, King's Road, Chelsea. This is a crimson-flowered Peach, very effective when forced into flower, as Messrs. VEITCH'S plants were. There were forty-eight of them in 7-inch pots, and all were nicely covered with flowers (Silver Banksian Medal). Some fine plants of *Cupressus Lawsoniana* var. *Stewarti*, a very effective golden-leaved variety, as well as forced plants of *Forsythia suspensa*, came from the same source. Also a group of plants of *Cineraria Feltham Beauty*, a distinct variety, with pretty mauve-coloured flowers, having a pleasing branching habit.

The new Rose Mrs. Oliver Ames, a sport from Mrs. Pierrepont Morgan, itself a sport from Madame Cusin, described in these pages on December 28 last, was exhibited by Mr. JOHN MAY, nurseryman, Summit, New Jersey, U.S.A. The flowers had travelled from America, and had been cut from the plants fourteen days, but they were sufficient to show that the variety is a good one (Cultural Commendation, and Vote of Thanks).

Messrs. H. CANNELL & SONS, Swanley, Kent, made a large exhibit of *Primula sinensis* varieties, all of them belonging to "The Lady" strain. Some had dark and others light coloured foliage, and the flowers varied in size and in the degree of notching or fimbriation. Some of the best varieties were Lady Emily Dyke, white; Red Lady, Queen Alexandra, mauve, with white ring around yellow eye; The Lady, white; Salmon Beauty, Princess Eva, white, or very palely tinted; Crimson Beauty, Lady Whitehead, white; and Purple Lady. Messrs. CANNELL had also a group of plants in flower of *Echeveria retusa*, whose reddish-orange-coloured flowers made a very showy display. Messrs. CANNELL also exhibited a dozen large, well-flowered plants of *Cyclamen Snowdrift*, a white-flowered variety, and gathered flowers of their florist's strain of *Primula sinensis* (Silver Flora Medal).

Messrs. HUGH LOW & CO., Bush Hill Park Nurseries, Enfield, showed a group of miscellaneous plants in flower, including *Cyclamens*, *Epacris*, *Rhododendron* (Azalea) *indium* varieties, *Lilacs*, *Ericas*, &c. This exhibit made a very showy display. Messrs. Low also showed some large standard trees of *Acacia ricinifolia*, *A. longifolia*, and *Cytisus racemosus* (Silver Flora Medal).

Messrs. WM. PAUL & SON, Waltham Cross Nurseries, Herts, showed a fine lot of *Camellias* in pots, which were stood along the centre of the hall. They were in capital health, and freely flowered. Upwards of fifty varieties were represented, including the old *alba plena*, still the best white one; *Reine des Fleurs*, red; *Montironi vera*, white; *tricolor Augusta superba*, rich pink, &c. Some pretty seedling varieties with semi-double flowers were shown, of which section Lady McKinnon, scarlet, mottled with white, is one of the finest (Silver-gilt Flora Medal).

Messrs. GEO. JACKMAN & SON, Woking Nursery, Surrey, again exhibited some rock plants and others in boxes, built up to represent a more or less natural environment. *Anemone blanda* was in bloom, also *Puschkinia libanotica*, *Anemone apennina alba*, the pretty little *Saxifraga oppositifolia*, *Iris reticulata*, *Fritillaria aurea*, *F. Moggridgei*, *Tulipa Kauffmanni*, yellow *Polyanthus*, the slender growing *Androsace lactea*, *Primula villosa*, &c.; also larger plants like *Spiraea Thunbergi*, the double-flowered *Arabis*, *Ericas*, &c. (Silver Banksian Medal).

Messrs. BARR & SONS, King Street, Covent Garden, London, exhibited a number of species and varieties of *Snowdrops* in flower, also *Narcissus cyclamineus*, *N. Corbularia*, and forced flowers of *N. princeps*, *N. Horsfieldi*, *N. Golden Spur*, and other varieties, making a very interesting exhibit (Silver Banksian Medal).

Messrs. T. S. WARE, LTD., Hale Farm Nurseries, Feltham, Middlesex, also showed a collection of choice hardy plants in bloom, and were awarded a Silver Banksian Medal.

Messrs. WEEKS & SONS, Bromley, and Beckenham, Kent, showed the "Charteris" Seedling Protector. The contrivance is an adaptation of the well-known practise of using thread to scare birds from plants, and would be useful for the protection of *Crocuses*, *Primroses*, *Carnations*, &c., from the ubiquitous sparrow.

FIRST-CLASS CERTIFICATE.

Acacia cultiformis.—Some sprays of *Acacia*, shown by Mrs. DENISON, Little Gaddesden, Berkhamsted (gr. Mr. A. G. Gentle), under the name of *A. harpophylla*, proved to be *A. cultiformis*, and was awarded a First class Certificate. It is a very distinct and pretty species, having phyllodia resembling the blade of a chopper one-third of an inch long, ending in an acute

point or hook. The flowers are yellow, and are borne upon axillary or terminal racemes. We were informed that the plant had been cultivated in a pot for twenty years, but had not flowered until last year, due probably to the plant having been removed from the pot and planted out.

Orchid Committee.

Present: Norman C. Cookson, Esq., in the Chair; and Messrs. Jas. O'Brien (Hon. Sec.), De B. Crawshaw, R. Brooman-White, J. Charlesworth, J. Douglas, A. Hilslop, H. T. Pitt, H. J. Chapman, J. Cypher, W. Boxall, W. A. Birney, F. A. Rehder, H. A. Tracy, and W. H. White. The weather being mild, a fine display of Orchids was made, both groups and new and rare plants being well represented.

In the former class, Messrs. SANDER & SONS, St. Albans, secured the highest award, a Silver-gilt Flora Medal, for an exceptionally fine group in which the forms of *Lycaste Skinneri* were remarkable, no fewer than twelve fine plants of the best variety of *Lycaste Skinneri alba* being among them. *Lycaste Skinneri* "Baroness Schroder" is a finely-formed flower, white, with a delicate flush of pink, and light rose markings on the petals. Among new or rare Orchids represented were *Cymbidium* × *Wiganianum* (*eburneum* × *Tracyanum*), a cream-white flower marked with purple on the lip, which partook of the form of *C. Tracyanum*; *Miltania* × *Bleuana*, a good form; *Zygopetalum* × *cristato-Gautieri*, a pretty hybrid, the lip of which was white and violet; *Masdevallia Schroderiana*, with many flowers; a singularly-freckled *Mormodes* not yet determined; a fine *Laelia Jongheana*, and various other remarkable novelties, several of which are enumerated in the list of Awards.

Sir TREVOR LAWRENCE, Bart., Burford (gr. Mr. W. H. White), was awarded a Silver Banksian Medal for a select group of remarkably finely-grown rare Orchids. In the centre was a fine plant of the rare *Dendrobium Treacherianum*, bearing nine large rose and claret-coloured flowers on one spike; *Cypripedium* × *Miss Louisa Fowler*, Burford variety, a very strongly grown example; the delicately tinted *C. × hirsuto-Sallieri*, with several fine flowers; *C. × argo-Morganiae*; the singular *Maxillaria arachnites*, profusely bloomed; *Masdevallia burfordiense*, with fleshy claret-coloured flowers, closely lying on the surface of the moss; the rich Indian red *M. × Bocking* hybrid; *M. Gargantua*, with very large purple and yellow flowers; *Laelia anceps Veitchiana*; *Dendrobium nobile burfordiense*, with the lateral sepals bearing purple colour, as in the lip; *D. × xanthocentrum pallens*, a model flower; and the new *Cypripedium* × *Berkeleyanum* (*bellatulum* × *Boxalli*), a distinct novelty, in which both parents appear. The upper sepal was greenish-white, marked with dark chocolate; petals broad, curved forward, cream-white, spotted and veined with dark purple.

Captain HOLFORD, Westonbirt (Orchid grower, Mr. Alexander), staged a group in which were a singular primrose-yellow tinted *Odontoglossum crispum*, another with blotched sepals, *Cattleya Trianaei* Westonbirt variety, *C. T.* allied to "Eboracensis," and several other good *C. Trianaei*; *Cypripedium villosum* Westonbirt variety, *C. × Calypso*, and the richly-coloured *C. × C. Oakwood* variety; a cut inflorescence of a noble hybrid, a fine improvement on *C. × A. de Lairese* (*Curtisii* × *Rothschildianum*), *Dendrobium* × *Leechianum roseum*, &c. (Silver Banksian Medal).

J. COLMAN, Esq., Gatton Park, Reigate (gr. Mr. W. P. Bound), was awarded a Silver Flora Medal for a very effective group of well-grown and profusely-flowered showy Orchids, among which the *Dendrobiums* were prominent. The centre was a fine specimen of the light coloured *D. nobile* Gatton Park variety. Around it were *D. n. nobilius*, *D. n. Cooksoni*, *D. n. elegans*, *D. n. delicatum*, *D. × Cybele giganteum*, a fine plant of the yellow, fragrant *D. aureum*, *D. × Juno*, and other *Dendrobies*; *Phaius* × *Norman*, and another white and purple hybrid *Phaius*; the purple *Masdevallia cucullata*, the scarlet *Epiphronitis* × *Veitchi*, *Odontoglossum crispum* varieties, *Cattleya Trianaei alba*, a finely-grown *Phalenopsis Schilleriana*, with a strong spike, the old one of last year bearing a strong plant; *Cypripedium* × *Winnianum*, *Laelia anceps Stella*, *L. a. Sanderiana*, and the massive white *L. anceps Waddoniensis*, &c.

Mr. J. CYPER, Cheltenham, received a Silver Flora Medal for a very showy and well arranged group of fine *Dendrobiums*, grown and flowered in the excellent manner for which the firm has a reputation. In the group among others were *Dendrobium* × *Ainsworthi* Cypher's variety, *D. × A. roseum*, *D. × splendidissimum grandiflorum*, and the still finer *D. s. magnificum*, *D. × Leechianum*, *D. × Virgil*, and others of that fine type; *D. × Cybele*, *D. × Aurora*, *D. nobile nobilius*, *D. n.*

Cooksoni, *D. n. giganteum*, and a very pretty white form with a rose centre of the class of *D. n. Murraianum*.

Messrs. CHARLESWORTH & CO., staged a group in which were two fine pans of *Odontoglossum cirrosum*, with many spikes, plants which they grow to perfection. In the centre was a healthy plant of the still rare blush-tinted, fringed-lipped *Laelio-Cattleya* × *Digby-ao-Messie*, Heaton variety. The disc of the lip was of a peculiar greenish-yellow, and there were some red markings at the base of the lip, and one in front, which will probably develop as the plant gains strength. Another showy hybrid which previously gained an award was *Laelio-Cattleya* × *Sunray* (*L. cinabarina* × *C. superba*), now shown with six bright orange-red flowers with ruby-red lips; and a pan of *Laelia* × *Coronet* (*harpophylla* × *cinabarina*) showed the plant intermediate in character, but the flowers approached *L. harpophylla* very closely. Messrs. CHARLESWORTH also showed two good varieties of *Laelia* × *Mrs. M. Gratrix*.

H. F. SIMONDS, Esq., Woodthorpe, Beckenham (gr. Mr. Geo. Day), showed *Odontoglossum* × *Adrianæ* Mrs. Simonds, pale yellow, with a few dark spots.

GEO. SINGER, Esq., Coundon Court, Coventry (gr. Mr. Collier), showed *Cypripedium* × *Coundonensis* (*Leeanum* × ?), a massive flower, with strong indication of *C. × Lecanum*, but heavily spotted on the broad petals. W. C. WALKER, Esq., Winchmore Hill (gr. Mr. G. Cragg), showed *Odontoglossum crispum* Avicé, a rose-tinted flower of the best type.

FRED HARDY, Esq., Ashton-on-Mersey (gr. Mr. Stafford), showed flowers of three hybrid *Cypripediums*.

R. G. THWAITES, Esq., Streatham (gr. Mr. Black), sent *Dendrobium* × *Wiganianum album* (*nobile albidiflorum* × *Hildebrandi*), a pretty white form, very free flowering. D. M. GRIMSDALE, Esq., Uxbridge (gr. Mr. T. A. Hooker), sent *Cypripedium villosum*, Kent Lodge variety, a large bold flower. MALCOLM S. COOKE, Esq., Kingston Hill (gr. Mr. Buckell), sent *Odontoglossum Rossii* "Cooke's variety," a fine large flower.

R. I. MEASURES, Esq., Cambridge Lodge, Camberwell (gr. Mr. H. J. Chapman), sent *Cypripedium* × *Argo-Athurianum*, a finely spotted flower.

Awards.

FIRST-CLASS CERTIFICATE.

Zygo-Colax × *Wiganianus superbus* (*Z. intermedium* × *C. jugosus*), from Messrs. SANDER & SONS.—A magnificent hybrid, and a substantial advance on the original form, although the plant is still small. Flowers much larger than the original, broad in all its parts, and of thick substance. Sepals and petals pale green, closely marked with chocolate-purple, confluent blotches, forming bars across each segment. Lip broad, white heavily marked with violet-blue. A remarkable and attractive flower.

AWARDS OF MERIT.

Cypripedium × *A. Dinmock* (× *Godseffianum* × *Drurii*) from Messrs. SANDER & SONS, St. Albans.—A very distinct novelty, unlike any other in the now numerous group of *Cypripediums*, but nearest to *C. × Winnianum* (*villosum* × *Drurii*). The fine flower of wax like substance, the petals bent forward after the manner of *C. Drurii*; upper sepal green at the base, spotted with dark purple, a broad band of the nearly black hue running up the middle; central area of the dorsal sepal flushed with rose, the upper part white; petals and lip yellow, the former spotted, and the latter tinged with purple-brown.

Laelio-Cattleya × *Choleliana* (*Laelia superbiens* × *Cattleya Mossie*), from Messrs. SANDER & SONS, and Messrs. HUGH LOW & CO.—A fine cross, in which the raisers have succeeded in enlarging the flower of *Laelia superbiens* to *Cattleya*-like proportions, and reducing the ungainly length of the inflorescence. Flower as large as *Cattleya labiata*, but narrower in the segments. Sepals and petals light rosy-lilac. Lip dark rose, with yellow disc, and some dark lines on the inside of the side lobes.

Odontoglossum × *L. ochristense Enfieldense*, from Messrs. HUGH LOW & CO., Bush Hill Park.—A very finely-formed variety of the natural hybrid between *O. triumphans* and *O. crispum*. All the segments almost equally broad. Sepals and petals bright canary-yellow, the petals having the inner halves white, the sepals large, with reddish blotches.

Phaio-Calanthe × *Ruby* (*P. Sanderianus* × *Calanthe* × *Oakwood Ruby*), from NORMAN C. COOKSON, Esq., Oakwood, Wylam (gr. Mr. Wm. Murray).—A really showy *Phaio-Calanthe*, partaking much of the blood-red tint of the phenomenal *Calanthe* × *Oakwood Ruby*, one of Mr. Cookson's best. Spike with many flowers of good size; sepals and petals rosy-lilac,

whitish at the back; lip large and openly displayed, of a deep purple colour, with some darker lines on the crest.

Odontoglossum crispum "Mabel Whateley," from H. WHATELEY, Esq., Priory Lawn, Kenilworth (gr., Mr. Cook).—A blotched form of the best type, and considering the small size and poor condition of the plant, likely to develop into a remarkable variety. All the segments broad; the reverse of the sepals heavily blotched and tinged with purple, which shows through in some degree to the surface, which also bear several bright red-brown blotches. Petals white, with a large irregular red-brown blotch extending nearly across the middle; lip white, with yellow crest, and some dark blotches.

Cypripedium × *Felicity* (? *callosum* × *tonsum*), from H. T. PITT, Esq., Stamford Hill (gr., Mr. Thurgood).—A charming and delicately tinted flower. Upper sepal pale green at the base, with emerald-green lines running into the middle area of pale lilac; tip white. Petals and lip greenish, slightly tinged and veined with rose.

Cypripedium × *Dowlerianum* (*insigne punctatum* violaceum × *Godefroye leucophilum*), from W. M. APPLETON, Esq., Weston-super-Mare. Flower of the yellowish white of *C. G. leucophilum*, but larger and more rounded, and beautifully marked with dark purple.

CULTURAL COMMENDATION.

To Mr. Duncan, gr. to C. J. LUCAS, Esq., Warham Court, Harsham, for three well-flowered plants of *Odontoglossum coronarium brevifolium*.

To Mr. Seaman, gr. to G. TAYLOR, Esq., Margery Hall, Reigate, for a fine specimen of *Dendrobium speciosum* with ten spikes, each from 1 to 2 feet in length.

Fruit and Vegetable Committee.

Present: A. H. Pearson, Esq. (in the Chair); and Messrs. Jas. H. Veitch, W. Poupart, Geo. Wythes, J. Willard, J. Jaques, James Smith, C. G. Nix, Ed. Beckett, W. Pope, M. Gleeson, George Kelf, H. J. Wright, Alex. Dean, S. Mortimer, H. Eslinges, and Jos. Cheal.

Six very fine bulbs of Cranston's Excelsior Onion were shown by WYNDHAM PORTER, Esq., Malshanger Park, Basingstoke (gr., Mr. N. Kneller). A Cultural Commendation was recommended.

Messrs. W. POUPART & SONS, Twickenham, obtained two Cultural Commendations. One of these was for some first-rate forced Asparagus, and the other for equally good Seakale.

Varieties of Apples were submitted by Mr. W. SANDERSON, Kirkby Laythorpe, Sleaford; J. VALE, Esq., Cullis, Orleton, Hereford; the Duke of RICHMOND AND GORDON, Goodwood, Chichester; and Messrs. W. B. ROWE & SON, Worcester. None of them were thought to possess exceptional merit.

The Lecture.

NICOTINE IN HORTICULTURE.

The afternoon lecture was one by Mr. G. E. Williams upon "The Use and Value of Nicotine in Horticulture." The lecturer, after describing that nicotine was an alkaloid present in the Tobacco-plant, said that in boiling the leaf of the plant, unless this was done in a vacuum, the nicotine would become oxidised, and consequently another substance would be formed. Very great care was needed to prevent this oxidation taking place.

There were other substances that were equally destructive to insect life, such as carbolic acid, sulphate of copper, and weak solutions of mineral acids, but they were more or less injurious to plant life; quassia-liquor was doubtless of use in the destruction of some pests, but it did not answer perfectly in all cases.

Nicotine was the most perfect of all insecticides. It had been proved to be absolutely harmless to all forms of vegetable life, though a deadly poison to insect and animal life, whether red-spider, aphides, mealy bug, or scale. Experiments had been made to ascertain whether or not nicotine was of use as a disinfectant against microbes. Microbes (which the lecturer described as being organisms between the vegetable and animal worlds) of small-pox, anthrax, typhoid, &c., were cultivated in Agar (a gelatinous substance) in jars, and the vapour of pure nicotine was caused to pass through the jelly for forty-eight hours. It was afterwards found that the microbes were not merely alive, but that they possessed the power to reproduce themselves as before, finally proving that nicotine had no effect upon microbes. A good disinfectant was not necessarily an insecticide, nor vice versa.

There were three ways or methods in which nicotine might be applied to plants for the purpose of cleansing them from insect pests. The first and principal method was that of applying heat to the nicotine, and so

vaporising the atmosphere of the house in which the plants were contained; 2nd, by direct application of the nicotine to the plants themselves; and 3rd, by mixing nicotine with a fibrous material, and burning it in the house, or by burning the leaves themselves. Mr. Williams strongly deprecated this method, as inefficient, and dangerous to the plants. When nicotine was brought into direct contact with fire, it was destroyed, and another substance formed, that, unlike nicotine, affected vegetable life injuriously. He said he had seen the bad results of such a method in the Channel Islands, where Tobacco-leaf, being duty-free, was burned in the Tomato, Cucumber, and other houses.

In adopting the first-named and best method, that of vaporising, it was necessary to bear in mind—

(1) That the boiling-point of nicotine is 250° Cent., whilst that of water is only 100° Cent.

(2) That the less heat applied, the more potent would be the vapour.

(3) That it is necessary that the vapour be given off very rapidly.

To meet these difficulties the nicotine is mixed with alcohol, which, being exceedingly volatile, is given off upon the application of little heat, and in rising takes into the air a considerable amount of the slow-boiling nicotine with which it is incorporated. Such fumigating compounds as this had been manufactured for use by horticulturists, and 1 oz. was sufficient to vaporise 1,000 cubic feet of air.

In reference to the method No. 2, by which the nicotine is applied directly to the plant, Mr. Williams explained that it is usual to mix it with a substance that will help to make it stick to the leaves of the plants; it is then much diluted, and applied by a syringe or sprayer. This method was useful when individual plants required treatment, and it was not necessary to treat the whole house.

In conclusion, Mr. Williams protested against the action of the Pharmaceutical Society in restraining persons other than the manufacturer and chemists from selling poisonous compounds of this nature, declaring that the seedsman should be permitted to sell them if he kept a register of the persons who purchased quantities from him.

ENQUIRY.

BOOK ON LUPINS.—Will some of our readers kindly recommend "W. G. T." an inexpensive book on the culture of Lupins, and the name and address of the publishers?

ANSWERS TO CORRESPONDENTS.

ARUM: J. W. M. Will you kindly send us spathe and leaf when developed, for identification.

ASPIDISTRA: Mrs. Swanton. It is as we feared. The plants are grown too warm in late autumn and winter, with the result that the leaves are thin, and the stalks rather attenuated. The plants cannot grow all the year round and be healthy. The autumn and winter temperature ought not to exceed 45°, and they will grow all the more vigorously in the summer from this enforced rest in those seasons; in fact, the plants may be afforded bottom-heat of 75° to 80°, and top-heat 10° to 15° higher whilst making their growth in early summer, but it is not necessary. When resting but little water is needed.

BOOKS: F. Voules. Williams' *Select Ferns and Lycopods*, to be obtained of the publisher, Victoria and Paradise Nurseries, Upper Holloway.

BRIAR CUTTINGS: T. H. These can be inserted in sandy soil, pressed firmly about them, in the season October 1 to February 28. Make them about a foot long, from hard, well-ripened shoots, taken with a thin heel of the older wood. If you want only a few, layer the points of the shoots in the soil around the mother-plant.

CORRECTION: In the article on winter-flowering Carnations, p. 124, for Deutsche Brandt, read Deutsche Braut.—SPRAYING FRUIT-TREES: Mr. Mayne is desirous of explaining that it was owing to a slip of the pen he mentioned the name of Stott instead of Strawson; see his Calendar, p. 124, in the last issue.

CYCLAMEN, &c.: *Inquisitor*. The plants have been potted in the right kind of compost,

but the cultivation has been at fault. Presumably the house has been kept too warm, the ventilation has been insufficient, and the plants have suffered from being crowded together, and placed at a considerable distance from the roof-glass. It should not be difficult for you to alter all that this year. If the whole of the young Cyclamens are drawn in the leaf-stalk like the one sent, a rather cooler and more airy treatment on a shelf close to the glass in a low pit, and one or two small shifts afforded the plants whilst growth is most active, should result in a more stocky growth of leaves in the future, and a plentiful set of flower in late autumn. Guard carefully against crowding the plants together, or with others. If the tubers of the older Cyclamens are kept, it should be in cold frames, and they should be afforded a rest when the leaves begin to decay, not entirely withholding water from them; or you might plant them in beds of peat, or some prepared light soil in the open air, putting them into pots at the end of the month of August; and if properly treated, they would afford a quantity of bloom late in the winter. The *Richardia* plant is strong, but it is much drawn as if by warmth, and lack of air. The tubers will be all right another year.

GRUBS: *Trouble*. "Leather Jackets," the larvae of the Daddy Longlegs. If you could turn up the soil between the rows occasionally, and pen some fowls on the plantation, and hunt for the grubs in the soil close up to the plants, their numbers would be greatly reduced.

GUMMINESS AND DISCOLORATION OF THE LEAVES OF CAMELIAS: J. P. The gummy coating is due to the excrements of aphids; and the black spots to a superficial mould. The remedy in each case is soap and water applied with a bit of sponge.

IMPROVING GRASS LAND: A. H. Loam four-sixths, wood-ashes two-sixths, preferably those from young shoots and small branches, and bush prunings. Apply the dressing by spreading it with a shovel, and do not apply it deeper than ½-inch. An excess of wood-ashes is injurious.

NAMES OF PLANTS: *Constant Reader*. *Lachenalia luteola*.—W. P., Lancaster. *Cattleya labiata Trianaei*. The abnormal development of the lip is interesting, but such is not an uncommon occurrence.—*Froggatt*. *Liparis longipes*, a pretty little species often imported with other plants from India.—J. L. 1, *Odontoglossum blandum*; 2, *Odontoglossum Lindleyanum*; 3, *Odontoglossum Pescatorei*.—*Mendeli*. *Dendrobium nobile*, a good form. *Habenaria Susannae*. It is deciduous, and requires to be kept cooler and dry for a time after the leaves die off.—J. M., Clifton. Both varieties of *Cattleya Trianaei*; No. 1 a very good form of it.—W. C. S. *Laelia alba*.—J. T., Dartford. 1, *Laelia anceps Sanderiana*; 2, *Dendrobium speciosum*.—R. R. 1, 2, and 3, varieties of *Odontoglossum* × *lanceans*, commonly called *Andersonianum*, 5 inclining towards *O. crispum*, and 2 towards *O. gloriosum*; 3, *O. luteo-purpureum sepiatum*; 4, *O. odoratum*; 6, *O. crispum*.—C. Jones. 1, Common single-flowered Daffodil; 2, *Spiraea Thunbergii*.

RHUBARB ELFORD: T. H. Not known to us.

WATER-GLASS: E. P. Water-glass, silicate of potash, may be bought at most chemists' shops.

WORKMEN'S COMPENSATION ACT: J. H. H. If contributory negligence could be proved on the part of the employer, he would be liable, not otherwise.

THE SCILLY ISLANDS FLOWER HARVEST.

JUST at the entrance to the two channels, where the currents meet, and the sea runs highest, lie those forty tiny, storm-swept Scilly Islands, of which only five are inhabited. The remainder are resting-places for countless flocks of sea and land birds. Being right in the track of our principal shipping, this rock-bound archipelago forms a veritable death-trap to the unwary mariner, as the graveyards only too plainly show; and yet, withal, they are so mild of climate, that just when vegetation is at its lowest ebb in the other parts of Great Britain, the air is redolent with the delightful fragrance of plants and flowers, and the fields are full of lovely various-hued Narcissi. From Christmas until after Easter, practically the whole archipelago is converted into a huge flower garden; dazzling in its brilliancy, and producing an average of over 10 tons of flowers daily, for the first three or four months of the year. This is the more remarkable when it is remembered that in the five inhabited islands there are only about 3,000 acres of land, and that much of this is rocky and barren. The soil is, however, very fertile, and this combined with an exceptionally mild climate, enables the Scillonians to gather two crops of flowers per week from the same area. The great and varied genus of *Narcissus* supplies the

chief products; nearly 200 varieties are cultivated, some of which are said to be indigenous to the islands. These reach the London and other markets sooner than those from the South of France, and are consequently in better condition.

Every available man, woman, and child is pressed into service during the season, and though small their numbers (under 2,000 all told), they manage to cut, sort, pack, and despatch from twenty to thirty-five tons of flowers every alternate day. This shipping on alternate days prevents the overstocking of the markets, and better prices are the result. 200,000 packages, totalling about 1,000 tons, are as nearly as possible the season's shipments. They are taken from Scilly to Penzance, a distance of about forty-three miles, by steam-packet, thence by rail to the various markets (see fig. 46, p. 155).

The prevailing winds are south and south-west, frost and snow being practically unknown, but southerly gales are frequent, and are sometimes of such severity as to prevent the steamer from putting to sea for as long as a week; this of course seriously interrupts the trade. During exceptionally strong gales the sea has been known to rush into St. Mary's (the most important island) on one side and dashing through the streets of the little town find an exit on the other. But, in spite of these storms, the temperature is wonderfully uniform all the year round. In winter the influence of the Gulf Stream, which envelops these quaint little isles, is so strong that the temperature very rarely falls below 45°, whilst the splendid ocean breezes of the summer time prevents its rising above 60°. It is indubitably the most uniform in temperature of any place in the United Kingdom, and surpasses in equability many of the more popular continental spas and winter resorts. Practically winter is unknown, for mild autumnal weather is experienced until Christmas, when spring sets in, and flowers being to bloom in the open. On account of this, these interesting little islands, within a few hours journey of London, should prove an ideal abode for invalids and others desirous of escaping the cold and fog of our winter season. The mildness of the climate is indicated by the field culture of *Richardia* (see fig. 45, p. 154).

The islands are held under lease from the Crown, and the proprietor is little short of a king to the people. His residence at Treseo is a fine old abbey homestead, which is supposed to have originally belonged to the Benedictine monks of Tavistock, even prior to the Norman Conquest. The abbey gardens, which are open to visitors, afford a treat not to be missed; tropical and sub-tropical, and the most delicate hot-house plants are healthy and vigorous in the open air all the year round. These gardens are beautifully laid out in sections; one plot is known as "The Wilderness," this contains Ferns from all parts of the world, not excluding Australia and New Zealand. Another portion is called "Lower Australia"; another "Higher Australia," &c., each plot containing exotics indigenous to the different parts of the world which they represent. [Illustrations of these gardens, and of the vegetation of the islands, have been from time to time given in our columns.]

There are many foreign plants there which are noted as being the only ones of

their kind to flower out-of-doors in the British Isles. There are Palms, Ferns, Prickly Pears, Aloes, Fuchsias, Azaleas, and many others too numerous to specify, but all contrasting finely with the many varieties of the beautiful, sweet-smelling *Narcissus*. The air is laden with delightful fragrance, whilst the eye is charmed by the beauty of the scene.

There is, however, another story to be told in connection with Scilly; a sad and terrible tale of suffering and death, which began with the advent of navigation, and has continued right down through the centuries to the present time, for in spite of lighthouse, fog-signals, and an ever-vigilant coast-guard force, many terrible shipwrecks with great loss of life have occurred from time to time round these rocky coasts. Ample proof of this may be seen at the entrance to the Abbey Gardens in the shape of a garden-house, known as the "Hall of Departed Spirits." This curious building is decorated with a large number of figure-heads, anchors, and other relics of the many ill-fated vessels which have been wrecked in the vicinity. The ceiling and spaces between the figures are filled with innumerable shells of many kinds, which give the building a very pretty appearance.

It will be remembered that Sir Cloudesley Shovel and his fleet were wrecked on the Scillies after the capture of Gibraltar in 1707; and there is a legend in connection therewith which is worth recounting. One of the crew of the Admiral's ship, the *Association*, was a Cornishman, and knowing the coast well, ventured an opinion to the officer of his watch that the ship was steering straight for the rocks at Scilly, and advised the altering of her course; this was reported to the Admiral, who, having complete confidence in his officers, ignored the advice. The seaman, however, strongly held to his own opinion, and this so enraged the Admiral that, it is alleged, he ordered the man to be hanged from the yard-arm. Before being hanged he was permitted to read a psalm, and the one he chose was one calling for vengeance upon his persecutors. Shortly after the man was hanged, the *Association* struck in a fog and quickly sank, only one man being saved; the remainder of the fleet were soon in the same predicament, and the loss of life was enormous.

A few brief words about the lesser islands will no doubt prove interesting. Wrecking and smuggling were at one time very prevalent, and the church of St. Agnes is said to have been built from the proceeds of a wreck. There is a well on that island, into which people cast pins, and called upon their patron saint to send them wrecks.

A bell in the turret of St. Martin's Church once did duty on board a ship which ran ashore there.

Of the uninhabited islands, Samson is probably the most interesting. The ruin of former habitations may be seen there. These dwellings, ten in number, were sufficient for the whole of the population, who were originally about fifty in number. Their numbers gradually decreased, and about half a century ago they were so few, and were living in such a semi-barbaric state that the late Governor caused them to remove to the larger islands, where they might learn something of the ways of civilisation. T. H. Liddicoat.

ORCHID NOTES AND GLEANINGS.

NURSERY NOTES.

CYMBIDIUM × EBURNEO-LOWIANUM.

A REMARKABLY fine and distinct variety of this ornamental hybrid Cymbidium is sent by Mr. John M. Bell, gr. to the Rev. Canon Pretymann, Great Carlton Lodge, Louth, Lincolnshire. Mr. Bell writes:—"It comes of a cross between *C. eburneum* ♂, and *C. Lowianum* ♀, effected in 1891, and now flowering for the first time." The same cross flowered in 1889 with Messrs. Jas. Veitch & Sons—the first hybrid Cymbidium to flower in gardens. The

GEO. COOLING AND SONS, BATH.

THE middle of February is not the best time to visit a Rose-garden, but being then in the neighbourhood of Messrs. Cooling's nursery at Batheaston, about two miles from the Great Western Railway Station in the city of Bath, and one mile from the railway station at Bathampton, we were strongly disinclined to leave the district without making a call. We soon discovered that in the light, span-roofed houses the work of increasing the stock of

was *R. himalaica* Cooling's variety, which is described as having larger flowers than the type, and possessing deeper yellow-coloured anthers. Some of these varieties were grafted upon the Briar, and others upon the Manetti stock. Those upon the Briar are "kept up" in potting, so that the stock may have exposure to sun and air. This stock under such conditions will swell as the plant develops, but will fail to do so if the whole of it is buried in the soil. In the case of varieties grafted upon the Manetti stock, Rose cultivators adopt a quite opposite method of procedure when repotting their plants, and the point of union is

FIG. 45.—FIELD OF WHITE ARUM (*RICHARDIA*) IN THE SCILLY ISLANDS. (SEE P. 153.)

(Photograph by Gibson, Penzance)

variety now sent seems different from others in having more colour in the lip, and a distinctly rosy tint in the sepals and petals. Probably a very fine form of *C. Lowianum* was one of the parents, for the rich colour displayed on the lip of the hybrid much resembles the colouring on the lip of *C. Lowianum*. The leaves however are narrower than usual, being only as broad as those of *C. eburneum*. The flowers are $4\frac{1}{2}$ inches across; the sepals and petals of a creamy white, with a decided flush of rose-pink, and the veining, especially that at the back of the flower, is pale green. The lip is yellowish-white, the callus bright yellow, and the front lobe has rosy-purple markings; column yellowish, tipped with purple. It is a very fine variety, beautiful in flower, and ornamental in growth.

new Roses was proceeding apace. In the case of such novelties, time is far too valuable to permit of the propagating being performed exclusively in the out-of-door nursery. Plants had been worked indoors, and were then being shifted into 5-inch pots from smaller ones. These novelties included Queen Alexandra, the new companion to Crimson Rambler, staged by Messrs. Jas. Veitch & Sons at the last Temple Show. The flowers are produced in large erect clusters, and the colour is very similar to that of the red Thorn; also Lady Battersea, Milton, Liberty, Boadicea, Leuchtstern, Sunrise, &c., most of which were illustrated last season in the *Gardeners' Chronicle*. Some of the *R. Wichuriana* hybrids that have been so well shown by Messrs. W. Paul & Son and others, were also being increased in this fashion, as

placed below the surface of the soil, so that the grafted Rose may form roots of its own, and eventually become independent of the stock. These are details familiar to every Rose-grower, and they should be observed by young gardeners who have a desire to increase their stock of particular varieties of Roses by similar means.

In the propagating houses we remarked also the new red Jackmanni Clematis, known as Ville de Lyon, of which a stock is desired as quickly as possible, this type of Clematis being greatly appreciated at the present time. Out of doors Messrs. Cooling & Sons have about thirty acres of land, of which eight acres at least are used for cultivating Roses, and nine acres for fruit trees. The Rose nursery is a considerable distance from what is termed

the home nursery, where the glasshouses, fruit trees, and other nursery stock is contained; but the enthusiasm the firm has for the cultivation of "garden" Roses is reflected in two borders at the home nursery, in which there are 500 varieties, each distinctly labelled with what is believed to be its true name.

The term "garden" Rose is used to describe every section and variety that may not be called "exhibition" Roses, or that are not sufficiently good from the florist's point of view to be shown in competitive classes for Hybrid Perpetuals, Hybrid Teas, or Teas. It includes all the Sweet Briars, the Moss Roses, the single flowers, such as the beautiful R.

FORCING RETARDED PLANTS.

IN compliance with your request, I offer a few additional remarks to those of last week on forcing retarded plants (if the word forcing is necessary). In reality, however, very little forcing is necessary provided the plants or bulbs are placed in a suitable position, and given ample time to come on gradually.

SPIRÆAS

should be potted as soon as received, and not allowed to lie about and become dry, or in any way neglected. Unlike Lilies of the Valley, these make considerable root-growth, and a fair amount of pot-room is required. The soil, moreover, should be of a fairly retentive

I have found that the maximum temperature for Spiræas is 55°, and the time required to flower them depends on the season they are taken out of the refrigerator. Those started in July, August, and September will take from eight to ten weeks, and proportionally longer as the days shorten and light declines. T. Arnold.

(To be continued.)

VEGETABLES.

EARLY CAULIFLOWERS.

WHEN seed is sown in January, February, and March, in preference to early autumn, a

FIG. 46.—LOADING SPECIAL TRAIN WITH FLOWERS FROM THE SCILLY ISLANDS. (SEE P. 153.)

(Photograph by Gibson, Penzance.)

macrantha, China, Polyantha, Noisette, and the varieties of species of Rosa, &c. Such are the 500 varieties that, planted on either side of a walk in the home nursery, scramble up the supports afforded them, and in June produce a prodigality of bloom, such as no exhibition variety can emulate. Every new or rare variety of these old-fashioned Roses, as they are sometimes termed, is obtained for these borders as early as possible, and so the collection is maintained a thoroughly representative one.

The fruit trees are cultivated on a slope in very good soil, consisting of sandy loam, and the trees were clean in the bark and extremely good in appearance. The rest of the nursery stock includes hardy trees and shrubs, conifers, &c.

character, and of good quality, and the potting should be firm.

The plants may be placed in a common garden-frame or cool greenhouse, when they soon start into growth, and may be taken to a house which is kept a little warmer. They must be shaded heavily during the time they are in the cool temperature. When they have made a few inches of growth, less shading will be required, but they must not be exposed to full sunshine till the leaves are well developed, when the shading may be removed by degrees and the plants exposed to full light. But here let me give a word of caution: place each plant in a saucer filled with water, for retarded plants must not be allowed to become dry at any time, and they should receive ample ventilation and space in which to grow.

good succession of Cauliflowers is obtained in the summer months from May onwards, without much risk from buttoning, if ordinary care be taken; the later sowings coming in for out-of-door planting, and the earlier one for growing and forming heads under glass protection. The seed requires a temperature of 50° to 55° for its germination, and the young plants from the first must be kept near the roof-glass or light, and plenty of air afforded, so that legginess be avoided. When two pairs of true leaves form, pot them singly into 60's in a light rich soil, and still keep near the light. For a week or more after the potting is a critical time for the plants, for if the soil should be too moist, or it presses too closely round about the stem, damping off is to be feared. When the plants start into growth,

water must not be lacking at the root, as if this occur good heads are seldom formed. On sunny days a dewing overhead with a fine rose-pot refreshes them. Well established plants should receive a few applications of Clay's Manure in water. Do not let the plants remain long in pots, but plant them in cold frames in rows at 15 inches apart, and 1 foot from plant to plant. The planting should be done in shallow drills, in which superphosphate and a small quantity of nitrate of soda is sprinkled. As the planting proceeds the drills should be filled, and the manure covered. The manure acts immediately on the growth of the plants from the first, and till the heads are fit for consumption. The plants should be freely afforded water. On bright days the frames should be closed at 2.30 to 3 P.M., and the plants sprinkled. Ventilation should be afforded as early in the morning as the state of the weather allows, and protection from frost must be afforded at night. Cauliflowers should always be grown freely, and I am satisfied that it pays the gardener to make use of artificial manure. For early cutting, two excellent varieties are Veitch's Extra Early Foreing, and Sutton's First Crop. If cold frames are limited in number, a few of these varieties may be grown for the earliest crops out-of-doors. To follow these two varieties out-of-doors, Veitch's Midsummer Day, a dwarf compact plant that forms heads quickly, and these are of a good size; and for succeeding these, Magnum Bonum, Universal, and Early Giant, of Messrs. Sutton & Sons; and Messrs. Veitch & Sons' Pearl produce fine heads; and if the seeds are sown at tri-weekly or monthly intervals, Cauliflowers can be obtained till October, when the Large White, and the Autumn Giant become fit for use. I follow the practice of drawing drills and manuring the same at planting time at all seasons, and the land is frequently stirred between the plants, till they are of a size that no longer admits of a man working a hoe amongst them without breaking the leaves or loosening the plants in the soil. *T. H. Slade.*

ZYGO-COLAX × WIGANIANUS SUPERBUS (fig. 47).

THE original form of *Z. C. × Wiganianus* was shown by Sir Frederick Wigan, Bart., Clare Lawn, East Sheen (gr., Mr. W. H. Young), at the Royal Horticultural Society, January 9, 1900, when it was accorded an Award of Merit, the parentage being given as *Zygopetalum intermedium* × *Colax jugosus*, and the record was probably correct. But in regard to both parents there is a little confusion in gardens, the fine old *Zygopetalum Mackayi* often being named *Z. intermedium*, and *vice versa*. With respect to the *Colax*, botanists have placed that part of the genus which includes *C. jugosus* under *Lycaste*, and hence the name would be *Lycaste jugosa*.

Zygo-Colax × Wiganianus superbis, which was evidently derived from the finest forms of each species used in the crossing, was shown by Messrs. Sander & Sons, St. Albans, at the Royal Horticultural Society, February 25 last, and was unanimously accorded a First-class Certificate.

It is a very attractive flower, larger in all its parts than the original, and beautifully marked. The substance of the flower is fleshy, and the surface glossy. Sepals and petals light green, closely marked with chocolate-purple. Lip violet-blue, with the white ground colour showing through towards the margin. The plant shown was quite a small one, and the flowers were very large, compared with the size of the plant.

ROYAL VICTORIA PARK AND BOTANIC GARDEN, BATH.

[SEE SUPPLEMENTARY ILLUSTRATION.]

THE Victoria Park, situate rather less than half a mile from the centre of the fashionable city of Bath, was opened by Queen Victoria in 1830, seven years before her accession. It was created at the expense of some of the wealthier inhabitants of the city, who provided a sum of £4000 for this purpose. At the present time, the park and botanic garden, which is contained in the park, constitute an area of 49 acres.

The management of this delightful pleasure ground and botanic garden is of a kind that is nowadays very rare. Though belonging to the citizens, the park has never been officially taken over by the authorities; it is therefore managed by an elected committee, and is dependent upon voluntary contributions, and upon small sums that are charged for the privileges of cycling on the excellent roads,

of spring before bursting into leaf and flower. That splendid tree, *Prunus Davidiana*, had its flower-buds well developed; and upon the rockery, *Primula denticulata* in similar condition seemed impatient for the frost to lift. But the Snowdrops, the Winter Aconite, Eriacas, and several of those choice hardy Irises, that are as early to flower even as the Snowdrops, were the only plants actually in open flower.

The photograph reproduced in the Supplement to our present issue was taken during last summer, and represents a few flower-beds in a portion of the park near to the Royal Crescent. The trees in the background include a fine Beech-tree, a smaller copper-leaved Beech, and a Horse-Chestnut tree. These few flower-beds are nearly all of a similar kind there are in the park, the bedding-out system being but little practised there.

The Royal Crescent alluded to is a most handsome five-storied building of stone, that overlooks the park on the south-east side. It is considered to be one of the most noteworthy

FIG. 47. — ZYGO-COLAX × WIGANIANUS SUPERBUS.

Flower (real size) green, with purple spots; lip blue.

attending the band concerts, and so forth. That the exceedingly interesting collection of trees and shrubs and of alpine and other hardy plants contained therein is maintained with so much care and judgment, is an excellent testimony to the liberality and intelligence of those upon whom the task devolves, rather than a justification of the present system. Most cities and towns have awakened in late years to a sense of their responsibility in the matter of acquiring and maintaining such means of out-of-doors amusement, recreation, and instruction as are provided by public parks and botanic gardens, and by officially making themselves responsible for the future maintenance of such as they possess, have secured them against possible neglect which may result, if from any reason it is found impossible to raise the necessary sum that is each year necessary. Probably the authorities would make themselves responsible for the park if such a state of things actually occurred; but the pity of it is in many such cases, the plants are allowed to suffer irreparable injury in the meantime. We hope such a misfortune will never happen to Bath.

On February 17, when we had the pleasure of visiting the park, there was little sign of the vegetative life that awaited the influence

architectural features of the city, and is composed of private residences.

Mention has already been made of the collection of trees in Victoria Park, selected we believe by Loudon, and planted by the late W. H. Baxter, who at one time had charge of the Bath Garden. The following are some of the most conspicuous ones. In an avenue of Horse-Chestnuts upon one side, and Elms on the other, particular interest centres in the Elms, which are different from each other, and are neatly but legibly named. These trees, with others in different parts of the park, make a very good collection of Elms. Varieties of *Crataegus* are numerous, and some old standard trees (all of them grafted), distinctly named, are very interesting, as they exhibit differences in habit of growth. There is a very old specimen of the Glastonbury variety (*C. oxyacantha praeox*).

Among Oaks we noticed fine trees of *Quercus asplenifolia*, *Q. Ilex* (the evergreen Oak), *Q. Cerris variegata*, with a curious habit of growth, the branches being very flat, and the top of the tree almost like a table, but it is a tree having a very beautiful effect when in leaf; *Q. rubicunda*, *Q. robur*, planted on our present King's wedding day, &c. There is a

fine tree of *Pavia flava*, near to the Queen's Square entrance to the park, and other species of *Pavia* and *Aesculus* were noted. One of the species of *Aesculus* (*A. carnea* or *rubicunda*) was unusually interesting, as it was more or less covered with burrs, formed probably in consequence of the attack of a mite. These burrs varied in size from that of a hen's egg to 2 feet across, and they were studded over with buds upon small spur-like growths 2 or 3 inches long. At the flowering stage these burrs become almost covered with a mass of curiously developed flower-spikes. There were originally six specimens in the park, but only two now remain, four having been cut down from

Cedrus Libani; the double-flowered Chinese Cherry, with flat branches, covered at top with short spur-like growths; a number of very large *Ailanthus glandulosa*, which form a marked feature of the park; *Ulmus suberosa* (the Cork Bark tree); a fine specimen of the handsome-leaved *Acer macrophyllum*; *Juglans nigra*; *Trachycarpus excelsa*, 20 feet or more high, protected with mats, &c. Some Weeping Willows of considerable dimensions, and other weeping species, adorn the margins of a pond which was beautified years ago by Milner, who formed a small island and made the banks into a pleasing outline, and planted them. A group of Hollies is very effective on one of the

other presenting itself for comparison, viz., *C. × Winnianum* (*villosum × Drurii*).

The flowers of *C. × A. Dimmock* have a shining wax-like appearance. The upper sepal is green at the base, spotted with dark purple, a broad band of nearly black hue running up the middle; the area above the green base is of a rose tint, the upper part and margin white. Petals and lip yellow, spotted and tinged with purple-brown. The plant seems to be a very strong grower, and when thoroughly established it may develop still greater beauty.

THE DESTRUCTION OF NATIVE PLANTS.

THE wholesale destruction of native plants by collectors for trade purposes is a matter that is becoming serious in many parts of the country; the scouring of hedge-banks and lanes for Primroses to meet the demand in large towns for the commemoration of an eminent statesman, is a case in point. To prevent such spoliation, it would be well if the local authorities throughout the kingdom were to follow the example of the United Devon Association in their efforts to preserve the natural beauty of the county by the prevention of the illegal removal of Ferns and wild flowers. These words are extracted from a report in a recent issue of the *Devon and Exeter Gazette*, of the prosecution of two men for wilful damage at Kenn, near Haldon, by taking up and carrying away a large number of Ferns and Fern-roots. The circumstances were as follows:—On the 6th inst. both the men were seen in the plantation in the act of digging up the roots, and being ordered off, left, promising not to return; later on, however, they returned and resumed their work, and when they were again surprised, the ground was found for yards riddled with numberless holes from whence the plants had been dug. Further on, no fewer than ten sacks filled with Ferns, and covered lightly over with leaves, were found, and close by a large heap of Ferns ready for removal. A horse and trap appeared later on the scene to remove the spoils. When the men were taken into custody, and upon an examination of the fruits of their labour being made, it was found that the number of roots taken amounted to nearly 2,000. The value of the Ferns for the purposes of the prosecution was estimated at from £8 to £10. The solicitor who appeared for the prosecution asked that a heavy penalty might be inflicted, as such men as the defendants were in the employ of London dealers who paid all the fines incurred by the Fern-gatherers when the latter were convicted. It was also said with regard to the principal offender that there was no doubt of his having sent to London at various times large quantities of Ferns. On January 20 he sent bags of Ivy and ten bags of Ferns; on January 31 seven bags of Ferns; and in the first week of February two bags more, all of which were consigned to a dealer in Covent Garden Market. The principal defendant was sentenced to two months' imprisonment with hard labour, and the other man, who seemed to a certain extent to be the other's agent, to six weeks with hard labour; and in sentencing them, the Chairman said that the Bench were determined to put a stop to such depredations, which were ruining the beauty of the county of Devon.

The Devonshire magistrates will have the full sympathy and support of all who love the country for the sake of its natural beauties. *John R. Jackson, Claremont, Lympstone, Devon.*

FIG. 48.—*CYPRIPEDIUM × A. DIMMOCK*.

the same reason. All of the trees were grafted upon the common Chestnut at different heights. Only the scions have been affected, never the stock, and although there are growing in the park many fine trees of Chestnut and *Pavia*, Mr. John Milburn, the present superintendent, declares that none other have been so affected. It would be interesting to know if this species has suffered similarly in other parts of the country.

Other trees that are noteworthy include *Gleditsia sinensis*, *Arbutus hybrida*, with five great spreading limbs proceeding from the bole of the tree, which is much cracked by the action of frost; *A. Andrachne*, exceedingly pretty with its reddish-brown branches, but bright green under the peeling bark; *A. Unedo*, which unlike *A. Andrachne*, fruits freely in most seasons; *Cupressus macrocarpa*;

banks, some little distance from the water, and in a delightful corner near to the water-fall are grouped a selection of choice tinted shrubs.

(To be continued.)

CYPRIPEDIUM × A. DIMMOCK (*GODSEFFIANUM × DRURII*).

SOME of the sections of hybrid *Cypripediums* have become so crowded as to render the identification of those nearest alike very difficult. In the case of the one represented by our illustration (fig. 48), and for which Messrs. Sander & Sons received an Award of Merit at the Royal Horticultural Society on February 25 last, no complication of the kind presents itself, for it is quite distinct, and not likely to be confounded with the only

The Week's Work.

THE FLOWER GARDEN.

By R. DAVIDSON, Gardener to EARL CADOGAN, Culford Hall, Bury St. Edmunds.

Hints on Work in General.—In the mixed borders, groups of *Iris reticulata* and *I.* major are now developing their deliciously fragrant flowers, and a little protection should be afforded them against frost and cold winds by placing hand-lights over them; or in lack of these, some Fir-boughs stuck firmly in the soil, and reclining over the flowers, will do tolerably well, serving also as a shade from sunshine, and thus save the flowers for a much longer period of time. Where *Anemone fulgens* is grown for effect, the plants must be carefully guarded against the ravages of pheasants, it being well known that they injure the young foliage coming through the soil, and also the flower-buds as they open by their scratching. Wire-netting about 3 feet high, neatly fastened around the beds or groups, is the most effective means of preserving the plants. Crocuses also, especially the yellow-flowered variety, are much disturbed by pheasants if no protection be given. If these bulbs are planted as narrow bands at the margins of beds and borders, Pea-guards may be placed over them as soon as they appear through the soil, which will preserve them from injury by these birds and sparrows.

Propagation.—If the propagating-frame is becoming empty, it may be reoccupied with the main batch of *Lobelia*-cuttings, taken from last year's selected stock plants; and if these cuttings are made $1\frac{1}{2}$ inch in length, and inserted to one-half their depth, quite close together, in a thin layer of sharp sand mixed with leaf-soil, on a bed with a bottom-heat of 60° to 65° , and sufficient water afforded with a fine rose water-pot, and slightly shaded from strong sunshine, in a few days roots will form. By gradually inuring the young plants to light and air, in a fortnight or a little more they will have made sufficient roots to warrant their being placed in shallow boxes at a distance of $2\frac{1}{2}$ inches apart. The compost in the boxes should not be much enriched, and a temperate-house will be the best place for them for about a fortnight; then remove to cold frames.

Violets.—Plants grown to produce flowers in succession to those in garden frames may have all protecting material removed, and be freed from decayed foliage and rubbish, stimulating growth by means of a light dressing of charred garden rubbish or wood-ashes, worked carefully into the soil. If the plants grow at the foot of a west or south wall, in a light, dry soil, an application of weak soot-water will act beneficially on them.

THE ORCHID HOUSES.

By W. P. BOUND, Gardener to J. COLMAN, Esq., Gatton Park, Reigate.

Propagation of *Dendrobiums*.—The plants should be placed on bottom-heat, and failing that, a position should be found for them that is near to the hot-water pipes in the stove Orchid-house, on a frame of some kind, or a hand-glass, the latter being usually sufficiently large for the purpose. The ordinary propagating-case is too moist in which to start the plants, although after the growths have been potted it answers quite well. In the case of the hot-water pipes being used, plenty of crocks for drainage should be placed for them; and when a stage is used, crocks are equally needed, as nothing that will retain moisture should be beneath the cuttings. Over the crocks place a mixture of two-thirds chopped sphagnum and one-third coarse sand, to the depth of 1 inch. If the pseudo-bulbs intended to be propagated were removed and laid on a dry stage, as previously advised, some of the sap in them would be dissipated, and they would not be liable to decay when cut up, and would start into growth quickly. The pseudo-bulbs should be cut into lengths, each with a dormant bud, but all the joints which have borne flowers may be thrown

away. The propagating-bed should be divided into sections with sticks, each section being as large as will accommodate one species or variety. Each should be named correctly—a matter of importance in a collection of Orchids. The cutting should be lightly pressed into the materials of the bed, only just deep enough to hold them steadily, with the dormant bud facing the light. Keep the frame, &c., close in the daytime, but afford air at night; on bright days a slight damping of the cuttings with the syringe will help them, but the compost must be kept on the dry side. If not placed over bottom heat no water should be afforded. As soon as the cuttings have grown 1 inch in length, place them in very small pots in a mixture of two-thirds chopped sphagnum-moss, and one-third chopped peat fibre, and return them to the frame, &c. till the first small pseudo-bulb is made up, afterwards gradually harden them off. The cuttings which are the earliest started will often make a second pseudo-bulb the first year. A collection of *Dendrobiums* may thus be kept young and vigorous if a few are propagated annually.

General Remarks.—The days are gradually getting longer, and the sunlight stronger, therefore the houses should be damped more frequently; and some species of plants will require more water at the roots. We must take care that the sun does not burn or unduly shrivel any of the plants. It is desirable to admit as much sun as can be done with safety, especially in the early morning, and late in the afternoon. Although there have been some days with clear sunshine, the next six weeks will be a very critical period, and every attention will be necessary to keep the temperatures right. This is extremely difficult when there is strong sunshine all the afternoon, and it is followed by a sharp frost and cold winds, as before we can get the proper night temperature the warmth has fallen lower than the correct temperature for the early morning. The fires should be started early enough in the afternoon to prevent this occurring. The temperatures should gradually fall from 3 P.M. to 6 A.M. to get as near as possible to the ideal temperature; nothing is more harmful to plants than to have the temperature higher in the morning than at night.

***Odontoglossum*-house.**—During bright days the *Odontoglossums* will be greatly benefited by a good overhead syringing about mid-day, which will be sufficient for the present; but frequently damp the stage, &c.; and admit air freely whenever practicable. The side ventilators may be opened whenever the outside temperature is above 45° . The bottom ventilators should never be shut quite closely; ours have not been shut this winter. A small quantity of air may be admitted at the top of the house until the last thing at night.

THE KITCHEN GARDEN.

By T. TURTON, Gr. to J. K. D. WINGFIELD DIGBY, Esq., Sherborne Castle, Dorset.

French Beans.—Where convenience exists for so doing, the best results are obtained in hot-water pits filled with tree-leaves and short stable dung in equal parts, over which sound loam, such as is suitable for Melon growing, should be placed to the depth of 1 foot without further preparation. If the pits are at liberty, let the Beans be sown in boxes at 3 inches apart, and place the boxes in a forcing-house, to be planted in the pits when the heat has declined to about 80° . Beans raised in this manner can also be planted in any bed or border in heated houses which may commend itself as suitable. Continue to practice the directions given in previous Calendars for fruiting and successional crops in pots.

Cauliflowers.—Pot into 3-inch pots the strongest plants of Pearl Cauliflower, seeds of which I advised the sowing in heat in January. Harden off the smaller plants, and prick them out at 4 inches apart in a spent hot-bed frame. Prick out also at the same distance apart seedlings of Early Forcing sown at the same

time. When planting out those last named into the open ground in April, every alternate plant in alternate rows may be left to form heads in the frame. They afford nice heads during the month of May, and being more delicate in flavour than Broccoli, are much appreciated.

Autumn-sown Onions.—Take the earliest opportunity when the ground is in a good condition for doing so to transplant these into ground that has been well prepared by trenching and heavily manuring. My practice is to plant a few rows on the margins of the ground prepared for spring-sown Onions. Plant in rows 15 inches apart and 9 inches in the rows. Preserve the roots as much as possible, and plant them just deep enough to keep the Onions in an upright position.

Potatoes.—Look over stores of these, and if convenient to do so remove them to a fresh place, be it in bins or in heaps on the floor of a shed or cellar where they will be secure from frost. Rub off the growing shoots, and use special care in handling the tubers, as after this date rough handling easily blackens them. Upon the first fine day look carefully over those in clamps; taking away diseased tubers, rubbing off shoots from the others, and removing them to the Potato-cellar or frost-proof shed. If the seed-tubers of main crop sorts have been kept over the winter in clamps, after rubbing off all the shoots, spread the tubers out thinly on shelves or floors where they can be made secure from frost, yet kept cool.

Potatoes in Heated Pits.—On warm sunny days examine the earliest plantings, and should the soil be in a dry state, afford sufficient tepid water to moisten well the whole bed of soil. In succession pits, as soon as the tops are well through the soil, if there is sufficient depth of soil, draw it up to the Potato-stems; or top-dress with soil such as that in which French Beans have been grown, which has been kept in a warm shed; otherwise it must be warmed previous to using. Plant succession crops in frames on beds of tree-leaves, having first prepared the beds as advised in a former Calendar. After placing from 6 to 9 inches of rich loamy-soil in the frame, it being about the same distance from the glass, take out deep drills with a trowel at 15 inches apart, and plant the sets 9 inches apart. The sets should have been laid out in boxes to sprout, and all shoots except two or three of the strongest taken out with the point of a knife.

General work.—Clear away all the decaying leaves from Brussels Sprouts, Kales, and other winter greens and Broccoli. Do not, however, unduly expose the stems of Broccoli in view of the possibility of further severe frosts. Keep the manure-heaps turned regularly; and where tanks exist for catching the drainings from hot-beds or from stables or cow-houses, throw sufficient of this over the heaps to aid the rotting of the manure before the drying winds of March are upon us.

THE HARDY FRUIT GARDEN.

By J. MAYNE, Gardener to the Hon. MARK ROLLE, Bilton, East Budleigh, Devonshire.

Labelling.—Before it is too late to distinguish the names on the nurseryman's tickets, let all newly bought-in trees and fruit bushes be furnished with lasting labels of zinc, lead, or hard wood, doing this very necessary work without loss of time. The lead label of our forefathers has my preference, having the letters or numerals punched-in with dies and painted white; the pieces of sheet lead, one-eighth of an inch in thickness, being cut of various sizes, according to length of the name of the variety to be stamped on them. Two holes should be made to take the wire or nails, the latter for attaching to walls, the former for fastening to stakes or trellis. These labels are rather too heavy for hanging on standard or bush trees in the open if the full name is put on, and in their case pieces $1\frac{1}{2}$ inch square should be employed for stamping with numbers, which should correspond with the name written in a book. The Acme label is largely used, and has proved all the inventors claimed

for it, neat, simple, and durable. In fastening the wire on to the trees, plenty of space should be left for the expansion of the branch or stem, otherwise canker may be set up, a malady that should be avoided at all costs.

The Wineberry (Rubus phenicolasius).—A fruit of recent introduction, and deserving of extended cultivation, ripening as it does during August and September, has proved a useful culinary and dessert fruit, and one of which the birds are not over fond. The plant bears similarly to the Raspberry, and requires the same general kind treatment. It grows rampant at Bicton, and would make an excellent plant for covering arches, the crimson-coloured shoots adding to its beauty, even when not in fruit. The quickest way to multiply the stock of the plant is by pegging the points of the shoots down to the soil in early autumn, when they quickly form roots. Being later in starting into growth than the Raspberry, it may still be transplanted in dry weather. Late-planted canes should be well mulched forthwith.

The Blackberry.—Of the many varieties found in nurserymen's catalogues, the Parsley-leaved is the one most generally grown in gardens, it being a hardier plant than the American kinds, though the Wilson Junior is a very fine fruit; but it requires plenty of space and a very warm, sheltered position in this country to do it justice, in which respect it resembles the Wineberry. These Rubuses should be grown on strained wire fences, or over wire or rustic arches of wood, and the shoots pruned back to a plump bud early in the present month, the wood that has fruited in summer having been removed in the early autumn, as in the case of Raspberries.

FRUITS UNDER GLASS.

By JAMES WHYTECK, Gardener to the DUKE OF BUCKLEIGH, Dalkeith.

Tomatos.—These, if they have been growing all the winter in a Cucumber or other warm house, will have grown tall, and in order to prolong their season of fruitfulness till the plants raised from seed at the new year are fit to take their places, the stems may be laid horizontally, intercrossing each other, bending each top into the soil in the pots or boxes. Keep the young Tomato-plants near the glass in a warm house or pit; and sow seed for the general summer supply, sowing thinly in well-drained pans or pots, and pricking out quickly into boxes when the plants are fit to handle, and keeping them near the glass.

The Orchard-house.—The roots of young Plum-trees which are growing very strong should be examined, and some of the stronger roots shortened, and the rest raised towards the surface. See that the soil of the borders and that in the pots is in a thoroughly moist state; and the pruning having been performed before the cleaning was begun, all will be in readiness for a start.

Early Peach-house.—The foliage is now fully developed, and may be heavily syringed twice daily, a little weak insecticide being frequently used in the water. Until the stones are formed in the fruit, keep a rather lower temperature, say 55° at night, and admit air at the top of the house in quantity according to the weather in the daytime. See that the soil of the borders is moderately moist, and when the second swelling begins, that is, after stoning, the temperature on mild nights should be 65°, and 60° on cold nights; close the house early in the afternoon with a temperature of 80° or 85° from sunheat. During the second swelling the trees should receive manure-water in a weak state. The final thinning of the fruit should be carried out when the second swelling begins, leaving one fruit to a square of 9 inches, or in the case of the weaker trees, 12 inches. The trees of Peaches and Nectarines that were started in January having set their fruits, these may be thinned for the first time, and a slight disbudding carried out; and in the case of fruits at the base of the buds, let three leaves be left to aid in developing them. The

temperature at night may range from 55° to 60°, according to the state of the weather; and on bright days let it reach 80° or 85° at the closing time. Syringe the trees twice daily except in dull weather, when once a day will be enough. Let the air be buoyant yet not arid. The border should be afforded water plentifully, and if the trees are vigorous they will require no manure, but old ones and those in a feeble state should have artificial manure, or tepid, diluted manure-water. Peach-trees to carry ripe fruit in July and August should now be in flower, and as much heat kept in the hot-water pipes as will afford a buoyant warmth in the house. A small quantity of ventilation night and day may be afforded at the top, and a night temperature of about 50°, rising to 70° or 75°, by day with sunshine. Apply water to the border when starting the house, and no more till the fruit is set.

Strawberries.—The fruits of the earliest forced plants are now ripening, and will be the better for being placed on an airy shelf. The succession plants will have thrown up strong foliage and flower-spikes, and should have received a top-dressing of some kind of artificial manure when put into the forcing-house, no more manure being applied till the fruits are swelling. When in flower maintain a warmth at night of 50° to 55°, and when the fruit is set let the temperature by night be not higher than 65°, the day temperature being 10° higher. Syringe the foliage, and apply no manure after the first fruits change colour. Thin the fruit sufficiently, and grow all so as to be fit for dessert. When the fruit is picked, put the plants in cold frames to harden-off for planting-out. All vacant shelves and frame space should be kept filled with succession-plants, washing the pots and top-dressing the plants before bringing them in.

PLANTS UNDER GLASS.

By J. C. TALLACK, Gardener to E. MILLER MUNDY, Esq., Shipley Hall, Derby.

Hard-wooded Plants.—The general collection will, during the present month, require much attention, especially with regard to ventilation, as on one hand cold draughts must be avoided, which is the cause of mildew on Heaths; and on the other, so as not to stint the plants of air. Water at the roots is now more frequently needed, and it should be, if possible, rain or river water. Leschenaultias and Boronias are plants with delicate roots, which quickly succumb to excess or lack of water.

Epacris.—When the flowers fade generally, the shoots should be pruned back almost to the base, and very weak ones entirely removed. For a few weeks afterwards much water should not be afforded, neither should much air be admitted; and it is better to remove the plants from the greenhouse to another house where less ventilation is afforded. When the forwardest of the new shoots are about 1 inch long, the plants should be turned out and repotted in a mixture of hard turfy peat and sand, potting them firmly, and taking care that the rootstock is not buried in the soil more than from $\frac{1}{4}$ to $\frac{1}{2}$ inch; and the roots are not long exposed to the air while the potting is being carried out.

Ericas.—Winter-flowering varieties which were cut back and started into growth in an intermediate temperature as advised a few weeks ago, will now be in a fit condition for being shifted, and this should not be delayed, it not being advisable to keep the plants in this house any longer than is absolutely necessary to induce the roots to seize upon the new soil. The same kind of soil as that employed for Epacris is suitable for Heaths, also potting and crocking, both of which must be carefully performed. Late or summer-flowering Heaths should be kept cool and well ventilated, so that they may come into flower at their proper season. Watch the tips of the new shoots, and if these are observed to be of a much paler tint than the matured leaves, it is an indication that the house is not well ventilated.

Cytisus racemosus.—Plants in bud or in flower may be afforded occasionally clear soot-water, which will impart a deep green tint to the leaves, and check the spread of red-spider. After the plants have ceased to flower, let them rest for a few weeks in a cold frame.

Stove plants.—In the stove there will be many plants now in need of repotting, and it will be advisable, in the case of those of a shrubby nature, to reduce the balls slightly, and repot them in the mixture of soil most suitable to the various subjects, making sure that the materials used are of the best, and that they are warmed, and the drainage is well arranged and effective without being too bulky, a few well-placed crocks being better than a large quantity put in carelessly. Allamandas, Bougainvilleas, Clerodendrons, and the like, which may have been recently hard pruned, should be left untouched until they start into growth.

Gardenias, if furnished with flower-buds, may have a weak mixture of water and some artificial manure applied, and occasionally clear soot-water. The young shoots that show around the flower-buds should be pinched out before they become large, or the latter will be injured. A few plants should, however, be allowed to grow away without any pinching of the shoots or points, for affording cuttings.

THE APIARY.

By EXPERT.

In my last contribution on the subject of feeding bees, I mentioned a method of making Cake Candy, and I now describe that of Flour Candy. This is made exactly in the manner previously described, but directly the pan is removed from the fire for cooling the candy, carefully add $1\frac{1}{2}$ lb. of pea-flour to the 10 lbs. of sugar, and stir the whole briskly till the mixture begins to stiffen, then proceed as before. Its effect on the bees is most beneficial. When used with frame-hives, the attached paper should not be removed, as this, placed uppermost, will prevent the flour-cake from sticking to the quilt.

Honey on Hand.—All honey on hand should be looked over, and where the sections have become candied, they should be bruised and given back to the bees a little later on to clear. Sections of honey should be sold now, unless they are to be kept for show purposes; and the same remark applies to run honey. Where this has candied, care should be taken that it is not made too hot to enable it to run, as this spoils the flavour very considerably. All crates and frames should likewise be cleansed, and a few got ready with full sheets of foundation wired-in for insertion in the brood chamber. Remove the old ones, unless they contain a little honey, which should be bruised and placed right in the front or the back for the bees to clear. It is a great mistake to keep comb in the hives for too long a period, and it is always less expensive in the long run to replace it with full sheets to strong stocks, much valuable time being lost in comb-building when the bees should be breeding.

Honey Imports.—The value of honey imported into the United Kingdom during the month of December, 1901, was £1,039.

SPRING-TIME* IN LONDON.—The current number of the *Girls' Realm* (Norfolk House, Norfolk Street, W.C.), includes an illustrated article on "Spring-time at the Corner of the Street." This deals with a subject somewhat rare in popular literature, that is, the numbers and varieties of flower-sellers in the London streets, where spring is certainly, in one sense, more forward than in many a country place in England. The same publication describes "A Year's Practical Gardening," or how two girls did the work of a head gardener. The adventures of the inexperienced couple will no doubt interest young readers of the magazine and others who are fond of flowers and of gardening.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER. Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY, MAR. 10. { Annual Meeting of the United Hort. Benefit and Provident Association, at 8 P.M.
TUESDAY, MAR. 11. { Royal Horticultural Society Committee Meetings.

SALES FOR THE WEEK.

MONDAY, MARCH 10.—Plants, Bulbs, &c., by Protheroe & Morris at 12.0.—Roses, Fruit Trees, and miscellaneous plants, by Johnson, Dymond and Son, at 12.0; Japanese Maples at 3.0.
TUESDAY, MARCH 11.—Clearance Sale of Conifers and Evergreens at Joyning's Nurseries, Waltham Cross, by Protheroe & Morris, at 12 o'clock.
WEDNESDAY, MAR. 12.—Azaleas, Liliums, Bulbs, &c., by Protheroe & Morris at 12 o'clock.—Specimen Palms and other Plants, at Stevens' Rooms, at 12.30.
FRIDAY, MARCH 14.—Hardy Plants, Perennials, &c., by Protheroe & Morris at 12.0.—Orchids in variety, by Protheroe & Morris at 12.30.—Lilies and Miscellaneous Plants, by Rendell & Searle, at 12.30.

(For further particulars see our Advertisement columns.)

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three Years at Chiswick —42°1'.

ACTUAL TEMPERATURES:—

LONDON.—March 5 (6 P.M.): Max. 47°; Min. 35°.

March 6.—Wet fog.

PROVINCES.—March 5 (6 P.M.): Max. 48°, Scilly; Min. 41°, E. England.

Artificial Winter. OUR forefathers would truly have stood aghast at many things which we, their successors, take as a matter of course. Much of what we do they would have looked on as a presumptuous interference with the laws of Nature. We know, to speak of our own experience, that they, or some of them, objected to the raising of artificial hybrids. If they could have carried their objections into practice, they might have reduced us to the consumption of "berries harsh and crude," and to the utilisation, with little improvement, of roots such as formed the dietary of the noble savage when wild in woods he ran. Nowadays, in order to keep the milk sweet, we heat the fluid to kill one bacillus—a fact of which the antivivisectionists should surely take note, and we add another to enhance the flavour of the butter and the uniformity of its composition. We illuminate the opacity of our organisation by the employment of rays of light which penetrate what was before impermeable. The phrase to see through a brick wall no longer conveys the impression of something beyond the limits of possibility. As for poor Puck, and his boast of putting a girdle round about the earth in forty minutes, Signor MARCONI has put him hopelessly behind the age. Actual fact has transcended imagination. Imagination foreshadowed the possibility; science has more than secured its realisation. All these things have been brought about by intelligent observation, research, and experiment. The same holds good in gardening. If we are to progress we must be constant in observation and experiment. If we restrict ourselves, as many of us are obliged to do, to the daily routine of practice, we may become as good

gardeners as our fathers were before us, but we shall not push the machine forwards, or leave our art any better than we found it. Fortunately, competition and commercial interest combine to overcome the stagnation of practitioners, and lift us out of the rut of routine. We have been led to these reflections by the perusal of an article on the retardation of plant-life in the columns of *Cold Storage* (5, Great Queen Street), which is so suggestive that, while leaving to our contemporary the responsibility for his statements, we think it of sufficient interest to transfer the greater part of the article to our own columns:—

"In the vegetable kingdom, with a few exceptions, the work is done in the summer and rest is taken in winter. In hot-houses it is always summer, and in cold stores it is always winter. Given the facilities for these conditions, the gardener of to-day is practically master of the situation, and can make plants live or rest, flower or fruit, just as he pleases or just as they are wanted for the market.

The field of actual experience in this branch of cold storage is not as yet a wide one, but, as far as is known, the best design for a horticultural cold store consists of an insulated room, kept in perfect darkness, and at a temperature of somewhere about 22° Fahr. The room should be surrounded by wooden shelves, covered with a layer about 2 inches thick of fine dry washed sand. On this sand the more delicate bulbs and roots should be laid, as, thus placed, they would be more available for examination from time to time. In stores attached to nursery gardens, where a trade is done in the roots, and where they are generally imported in large quantities from abroad, the roots need not be moved from the packing-cases in which they arrive, but can be piled up on the floor in these until wanted. There is no occasion to use cold-air refrigerating machines, which are very expensive in fuel; the much more economical carbonic acid or ammonia machines, working with brine circulation or direct expansion, are much the best. With these machines the temperature of the cold store can be regulated to a nicety by valves in the ordinary way. The rooms can be piped on the ceiling or round the walls, but in order to save the expense of running the refrigerating machine too frequently, brine walls or direct expansion pipes and brine accumulators are to be preferred. With these, a run of a few hours a day will generally suffice, for it must be remembered that, unlike food stores, root stores are not required to be entered continuously, and that in consequence, provided the insulation is good, there is very little tendency for the temperature to alter much.

These small refrigerating stores are eminently suitable for use in connection with the gardens of country houses, and can also be used for preserving all sorts of fruit (Apples have been kept in cold storage in perfect condition for over two years), vegetables, food, butter, game, &c. They might also be combined with a small ice-making plant, sufficiently large to keep the mansion supplied with ice during the summer months. As ice is always expensive, and usually exceedingly difficult to obtain in the country, this would be a great boon. From £400 to £500 would easily cover the cost of a small cold storage and ice-making plant suitable for such a purpose, and the gain from every point of view is inestimable. Most country houses of any pretensions already have their own electric light installation, in which case the same driver could readily run all the machinery.

In any case, an intelligent gardener could easily manage it.

There appears to be no reason why practically any root plant should not be capable of having its growth retarded by cold storage. Its use is at present confined to retarding varieties of bulbs, but any perennial that naturally dies down or loses its leaves in the winter should be susceptible to the same treatment, and made to bloom at any season of the year. For evergreens, light is required, and in that case greenhouses should be made with double glass lights, but with as few of them as possible. Naturally, however, owing to the less perfect insulation, these would require rather more refrigerating power than the dark store.

When the roots or plants are wanted to flower, they are removed from the cold store. With evergreens the change of temperature should not be too sudden, and they should be kept for a few days in an intermediate room before being removed to the open air or to the hot-house, as the case may be. Roots can be taken straight out of the store, and, after they have thawed in the ordinary atmosphere, can be planted out in beds or pots in the usual way.

The influence of warmth and dampness rapidly stimulates the dormant vitality. Lily of the Valley crowns in the ordinary way take six weeks to flower. Retarded roots are much more rapid; in a few days the shoots are a few inches high, in a week the plants are vigorous, and in less than a month they are in full bloom. Some plants, of course, are naturally more vigorous than others, but the prolonged rest appears generally to have the effect of stimulating the growth when once it is started.

There would seem to be no occasion to limit retardation by cold storage to plants and flowers; by its aid Grapes, Strawberries, Raspberries, Figs, and all manner of glass-house fruit, might have their fruiting season retarded at the absolute will of the gardener.

Steam power is not necessary; any form of motive power, such as an oil-engine, gas-engine, or water-wheel, is suitable, and, so long as there is a suitable supply of water for condensing purposes, the store can quite well be built in any convenient position, or in the place where power already exists. About five horse-power is amply sufficient to work a small cold store, and a small oil-engine will, in country districts, be generally found most suitable and economical for the purpose."

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the Floral and Fruit Committees will be held on Tuesday, March 11, in the Drill Hall of the London Scottish Volunteers, Buckingham Gate, Westminster, from 1 to 4 P.M. A lecture on "The New Soil Science" will be given at 3 o'clock by Mr. R. HEDGER WALLACE.

—At a general meeting of the Royal Horticultural Society held on Tuesday, Feb. 25, seventy-two new Fellows were elected, amongst them being the Marchioness of Bath, Lady Ebury, Lady Lewis, Lady Peel, Lady Ridley, Hon. Mrs. Parker, Hon. John Wallop, Lieut.-Col. Jas. Campbell, Major W. D. Garnett-Botfield, Surg.-Gen. A. Eteson, Capt. B. J. St. George, and A. H. Lyell, M.A., F.S.A., making a total of 255 elected since the beginning of the present year.

—The prize schedule for the Crystal Palace Fruit Show will be issued by the Royal Horticultural Society on March 31, price (post free) one penny. Donations towards the prize fund will be gratefully received by the Secretary of the Royal Horticultural Society, 117, Victoria Street, London, S.W.

HORTICULTURAL CLUB.—The monthly dinner will take place on Tuesday, March 11, at 6 P.M., when the subject for discussion will be "Birds in their relation to Horticulture," to be opened by Mr. C. E. PEARSON. Should time permit, it is proposed also to have a short discussion on the future of the Club. Dr. HENRY, who has done so much to make known the Chinese flora, is to be the guest of the Club at an early date. Full particulars will be shortly announced.

THE "THOMAS ROCHFORD" MEMORIAL.—The members of the Turnford Hall Working Men's Institute, founded in 1896 by the late Mr. THOS. ROCHFORD, who died on October 12, 1901, have placed in their club-room a permanent memorial of their late beloved President. It is an oil painting, executed by Mr. FRY, of Camden Square, and bears the inscription:—"THOMAS ROCHFORD. Born 1849. Died 1901. Founder and first President of the Turnford Hall Nurseries Institute. Subscribed for and presented to the Institute by the members." The unveiling ceremony was performed on Thursday evening by Mr. JOSEPH ROCHFORD. Mr. H. KELSALL, general manager, presided, and Mr. T. P. TROUNCE, manager of the London and County Bank, delivered an interesting address on the life-work of the deceased gentleman, who, he said, was no ordinary man, but one endowed with exceptional attainments, and who seemed to be one of the favoured ones of the spirit of success. He was frank, and ever ready to assist by advice or otherwise those who came openly to him; but he disliked any who tried by subterfuge or deceit to secure his favour. His energy was not devoted to the accumulation of wealth alone, for he took in more land, and, as it were, scattered more seed, thus making more employment for reapers and gleaners. No man better deserved the fruits of his labour, and he was wont to mingle in the pastimes and the pleasures of his men, and his entire sympathy was with those who worked for him. Mr. E. B. BARNARD, Sawbridgeworth, who also addressed the meeting, described the late Mr. ROCHFORD as an idealist, who secured success in business and the esteem of all who knew him. Other gentlemen addressed the members, and an enlarged photograph by Mr. H. CLEMENTS, was gratefully accepted by the members, as were also one or two other gifts reminiscent of the deceased.

MR. C. HARMAN PAYNE.—We learn with much satisfaction that the sympathetic Foreign Secretary to the National Chrysanthemum Society, Mr. C. H. PAYNE, has received a fresh proof of the appreciation of his labours from the Government of the French Republic, which has appointed him Officer of the Order of the Merite Agricole. This distinction has been conferred upon him for his contribution to French literature on the Chrysanthemum, on the occasion of the last congress at Bordeaux, when he won the Silver-gilt Medal awarded to the best and most comprehensive report in the French language upon that interesting and extensive subject, the Chrysanthemum. But the French Government also, no doubt, wished to acknowledge the valuable aid which Mr. PAYNE rendered his French *confrères* in the formation, and later on in the organisation of their Society, which indeed is a very great success. We believe Mr. PAYNE is the first Englishman raised to the rank of Officer of an Order which is seldom bestowed upon foreigners of any nationality, and we congratulate him upon his good fortune, and much appreciate the kindly act of the French Government.

M. LOUIS GENTIL, who for three years filled the important post of Agronome et Surintendant des Plantations du Haut-Congo, and who last year was sent on a mission as Inspecteur Forestier de l'Etat Indépendant du Congo by the Belgian Government, has been appointed Chef des Serres et des Cultures Coloniales du Jardin Botanique de Bruxelles. After serving an apprenticeship in a Government school of horticulture, and staying for a time at the nursery of Messrs. J. VEITCH & SONS, Chelsea, Mr. GENTIL entered the Royal Gardens, Kew. During his stay in England, the Société Française d'Horticulture de Londres, of which institution he was a most active member, never had a more painstaking secretary.

THE SCOTTISH HORTICULTURAL ASSOCIATION proposes to celebrate its semi-jubilee by a dinner to be held on March 21, at 129, Princes Street, Edinburgh. We wish the event every success, and the society continued prosperity. The Convener of the Dinner Committee is Mr. A. CHALMERS, 24, Frederick Street, Edinburgh.

THE ANNUAL MEETING of the United Horticultural Benefit and Provident Society is to be held on Monday next, March 10, at 8 P.M., at the Caledonian Hotel, Adelphi Terrace, Strand. Mr. HERBERT J. CUTBUSH will preside.

THE SURVEYORS' INSTITUTE.—A paper was read by Mr. ROWLAND BERKELEY (Associate), entitled "Electric Railways and Street Compensation." A discussion followed, and was concluded, and a vote of thanks was unanimously passed to Mr. BERKELEY for his paper. The next ordinary general meeting will be held in the Lecture Hall of the Institution on Monday, March 10, when a paper will be read by Mr. C. H. BEDELLS (Fellow), entitled "Notes on the Insurance of Buildings against Fire." The chair will be taken at 8 o'clock.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—A large gathering of horticulturists will be held on Wednesday, Mar. 12, 1902, at the City Hall, Eberle Street, Dale Street, Liverpool, when R. J. HARVEY GIBSON, Esq., M.A., F.L.S., has kindly consented to preside. HARRY J. VEITCH, Esq., Treasurer, and GEORGE J. INGRAM, Esq., Secretary of the Institution, have promised to be present to give some account of the objects and advantages of this beneficent society. At the conclusion of the meeting, a smoking concert will be held, for which a large array of talented artistes have generously tendered their services. We confidently rely upon the united support of gardeners (private and market), seedsmen, nurserymen, and others interested in horticulture, so that the result may prove beneficial to the Institution, and creditable to the city of Liverpool and district. The officers and committee will gladly receive the names of intending life members, subscribers, and donors; and will supply admission tickets (1s. each), and any information required. *Charles Young, Chairman, West Derby; A. J. Crippin, Treasurer, Egremont; R. G. Waterman, Secretary, Woolton.*

COMING EXHIBITIONS.—Further schedules to hand include the following, viz., that of:—

THE ROYAL CALEDONIAN HORTICULTURAL SOCIETY, for their spring show, to be held on May 7 and 8, and their autumn show on September 10 and 11. At the spring show, in addition to 108 classes of the usual character, there is to be a very interesting competition among under-gardeners, as announced in our pages in August last. They are required to draw a plan to scale (40 feet to inch) for laying

out a piece of ground about twenty acres in extent (as shown on a sketch published in the schedule) for kitchen garden, flower garden, and pleasure grounds. The plans have to be returned to the secretary not later than April 1. We hope there will be a good number of competitors for the three prizes, £3, £2, and £1, that are offered. The great autumn exhibitions held in the Waverley Market, Edinburgh, are remarkable for the fine displays of fruit, vegetables, and cut flowers then shown, and the forthcoming event promises to be as good as previous ones. The schedule includes about 270 classes, and the prizes in the leading classes in each section are of a liberal character. We may refer to a special open competition, for which a sum of £10 is offered in three prizes by Mr. and Mrs. J. MARTIN WHITE, of Balruidery, Dundee. These are offered for the "best essay on the lasting qualities, the preservation and arrangement of different flowers, foliage, and plants in a cut state in water, in either town or country, and in the town distinct from the country, including a statement of the conditions of age, growth, weather, &c., for, and the methods of cutting such flowers, foliage, and plants, and their treatment afterwards, so as to last well; a description of the injurious effects of some on others when placed together in water, and suggestions as to their arrangement so as to show them to the best advantage, having regard both to economy and beauty." All essays must be in the hands of the secretary by August 1. If the first prize essay shows particular merit, the first prize may be increased. The secretary is Mr. P. MURRAY THOMSON, 5, York Place, Edinburgh.

THE CROYDON HORTICULTURAL SOCIETY will hold its annual show on July 22 in the grounds of Brickwood House. Roses are always a special feature at this show, and altogether there are 122 classes for these and for plants, fruits, and vegetables. The secretary is Mr. A. C. ROFFEY, 55, Church Road, Croydon.

THE WOKING HORTICULTURAL SOCIETY holds meetings on the second Thursday of each month for the reading of papers, and for competitions in a few classes arranged for subjects particularly in season. The syllabus of lectures to be given in the session commencing March 13 is an excellent one. The secretary is Mr. M. ROSE, Elm Villa, Woking Village, Woking.

ACACIA CULTRIFORMIS.—Mr. GENTLE, gr. to Mrs. DENISON, who exhibited sprays of this distinct and beautiful Acacia at the last meeting of the Royal Horticultural Society, informs us that the plant is ten or twelve years old, and that it is now in flower for the fourth time.

CORK INTERNATIONAL EXHIBITION.—From May till November of this year a great exhibition will be held in this thriving and progressive city. The attractions offered, both those of a business character as well as those of a recreative nature, are very numerous.

"BRITISH COCCIDÆ."—We have been kindly informed by a correspondent that this very useful work, from the pen of Mr. ROBERT NEWSTEAD, can be secured by sending one guinea to the Secretary of the Ray Society, Rev. Professor WILTSHIRE, 25, Granville Park, Lewisham, Kent.

EARLY FLOWERS IN ST. MARY'S ISLE, KIRK-CUDBRIGHT.—We have received from the head gardener to Captain J. HOPE, at St. Mary's Isle, a number of hardy flowers which have opened since the cold snap in early February. These include Arabis, Winter Aconite, He-

patiens, *Leucoium vernal*, double and single-flowered Snowdrops, *Crocus*, Primroses, *Polyanthus*, Blue Squills, *Jasminum nudiflorum*, *Laurustinus*, *Chimonanthus fragrans*, Violets, *Mahonia aquifolia*, Wallflowers, Heaths, Daisies, and *Helleborus roseus*. In the note sent by the gardener at St. Mary's Isle, Mr. J. JEFFREY, and inserted in last week's issue, p. 149, the word *Phloxes* should have been *Flaxes* (*Phormium*), much more tender plants.

BOTANY IN HUNGARY AND IN ROUMANIA.—We have become accustomed to the receipt of Japanese publications on horticulture, but Hungarian and Roumanian papers have not been so common. The first number of the *Magyar Botanikai Lapok* (*Ungarische Botanische Blätter*) is before us. The text is in Magyar, accompanied happily by a German translation. Amongst its contents we note a variety of the common Spruce, called *Abies* (syn. *Picea*) *ellipsocensis*, of BORBAS. The cone is represented as erect, but that is probably by mistake, and the branches are studded with small glands. Another variety is called var. *adenoclada*, BORBAS, who refers it, under the eccentric system of nomenclature adopted by some, as *Abies Abies* (L.). Certainly LINNÆUS never mentioned such a species. The other publication is entitled *Buletinul Erbarului Institutului Botanic din Bucuresti* (*Bulletin de l'Herbier de l'Institut Botanique de Bucarest*), edited by Prof. VLADESCO. The second language here made use of is French, and in some cases German.

VICTORIA TRICKERI, HORT.—This is now determined to be the *V. Cruziana* of D'ORBIGNY of Paraguay. It is much hardier than the Amazon species. The leaves are villous on the under surface. Seeds may be sown in water in February or the early part of March, in a temperature of 75°. The seedlings may be potted off in thumb-pots, and repotted when the first floating leaf appears, repotting at intervals till the season is sufficiently advanced to permit of their being planted in summer quarters. The water should have a temperature of 75° to 80°. Full details are given by Mr. TRICKER in the *American Florist* for December 21.

THE BEAUTIFICATION OF PARIS.—Paris will soon possess a large new park in the Champ de Mars. The Champ de Mars, known to those who have visited the Universal Exhibitions held there since 1867, is a rectangular area including nearly 11,000 acres situated to the east of Paris, and bounded on one side by the École Militaire, and on the other by the Seine, by the borders of which is the Eiffel tower. Until 1889 this large space served as an exercising ground for the troops of the Paris garrison. After the Exhibition of 1889, part of the buildings of that Exhibition (*Galerie des Machines*, *Palais des Arts Libéraux*, &c.), were preserved, and the Minister of War received as compensation some ground outside the fortifications of the city. The Champ de Mars remained partly unoccupied until 1900, when it was again covered with the Exhibition buildings. It seems now arranged by general consent not to have another Universal Exhibition, at least, not in the middle of Paris. It is therefore decided to use this large and often empty space as a park, and this, after long negotiations between the City of Paris and the State. The *Galerie des Machines* (*Galerie d'Alimentation* and *Salle des Fêtes* in 1900), and the other buildings are to be taken down, the ground cleared, and a park made with ornamental water, rock-work, plantations, &c., the whole forming a picturesque effect comparable to the *Buttes Chaumont* designed by ALPHAND. The

neighbouring land will be sold, and the purchasers required to erect handsome-looking houses. It is hoped thus to impart beauty to a quarter which hitherto has been dull, and even dangerous, owing to the low population attracted by the vicinity of the barracks and this deserted space. G. T. G.

DAWLISH.—The last addition to the *Home-land Handbooks* is devoted to Dawlish and the Estuary of the Exe, with notes on Chudleigh; by BEATRIX CRESSWELL, illustrated by GORDON HOME. This is the usual modern, chatty guide-book mentioning the objects of beauty and interest round the locality treated of. In an appendix will be found details of some of the screens preserved in the country churches, these Devonshire screens having for some time past been studied by the author. We are grateful, also, for accounts of some of the landed estates in the neighbourhood; these are, of course, not open to the public, though it is often possible to obtain permission to visit them. At Mamhead, according to the writer, "The first Ilex Oaks were grown, from Acorns brought over in 1696. I have been told that the avenue of Spanish Chestnuts, which leads up to the house on the Starecross side of the property, was grown from some Chestnuts brought home after the Peninsular War, but I cannot vouch for the accuracy of the assertion. The 'Lucombe Oak,' a hybrid of the Ilex, was first grown here by Mr. Lucombe, who was gardener at Mamhead, and since well known in the firm of Lucombe & Pince, whose beautiful gardens are near Exeter. . . . Here in 1775 Boswell came to stay; he mentions setting out 'on a visit to the Earl of Pembroke at Wilton, and my friend Mr. Temple at Mamhead, in Devonshire.' At that time Mamhead Park was in the possession of the first Earl of Lisburne. In Mamhead churchyard is an enormous Yew-tree, the most notable tree on the estate; its size and magnificence so impressed Boswell that he made a vow underneath it never to be drunk again." Of Powderham and Powderham Park we hear praise, and a brief notice that there are fine Oaks and Rhododendrons in the Park, but the chief plant wonder of the place is not mentioned at all. This is the giant *Eucalyptus coccifera*, already upwards of 40 feet high, and, we believe, still flourishing. We advise those who admire English scenery to visit for themselves the scenes commended in this book, whose charms are those of woodland, sea, and archaeology. This guide, and the others of the series, are published by The Homeland Association, Ltd., St. Bride's House, 24, Bride Lane, Fleet Street, E.C.

THE BRONVAUX MEDLAR.—M. JOUIN, in the number of the *Jardin* for January 20, gives some further details respecting this alleged graft hybrid. This Medlar is grafted on the Hawthorn. Immediately below the graft a branch (1) is developed which is neither that of a Medlar nor of a Hawthorn. Another branch (2) springs from the same point side by side with No. 1. A third branch (3) springs from the trunk of the tree on the opposite side to the two preceding branches. The lower part of this third branch presents the characters of the Hawthorn, but the upper portion differs from both the Hawthorn and the Medlar. Branch No. 1 has produced one shoot which in no wise differs from the Medlar, and also a forked branchlet, which has produced on one side an inflorescence of the Hawthorn, and on the other a corymb of eight Medlar flowers. These variations have been grafted in their turn, and remain constant. M. JOUIN describes in full some of these graft-hybrids,

together with illustrations. Thus this curious Medlar resembles the Adams' Laburnum, which excites so much surprise every spring. Since the discovery by Mr. WALTER GARDINER of the continuity of protoplasm, these cases have become a little more intelligible than they were before. At one time the cell was considered as a closed bag, so that the protoplasm of one cell had no direct communication with the contents of its neighbour. Now it has been proved that in very many cases there is direct continuity between the plasm of one cell and that of another, so that the whole plant may be looked on as one mass of plasm imperfectly separated into separate masses by cells with permeable walls.

"THE QUEENSLAND FLORA."—The fourth part of this useful publication, prepared by Mr. F. MANSON BAILEY, the Colonial Botanist, has just been issued. It is modelled on the same plan as the Colonial Floras, but differs from them in containing illustrations; thus in the present part we find representations of no fewer than eight species of *Nepenthes*, as *N. Kennedyana*, *Bernaysii*, *albo-lineata*, *Moorei*, *Jardinei*, *Rowanae*, *Aliae*, and *Cholmondeleyi*. How such a book could have been produced away from our large herbaria would be a matter of surprise if we had not recalled the fact that BENTHAM'S *Flora Australiensis* was at hand to guide the author. But in any case the production is a remarkable one, and confers the highest credit on Mr. BAILEY. The printers also deserve a meed of approbation, as the work is as well turned out as if it had been issued in London. The present part concludes the first volume, and is provided with a good index.

ROSE SHOWS IN 1902.—The following list of Rose show fixtures has been kindly forwarded by Mr. ED. MAWLEY:—June 11 (Wednesday), York (three days); June 24 (Tuesday), Holland Park, London, W., Rose Conference (R.H.S.) (two days); June 28 (Saturday), Maidstone and Windsor; June 30 (Monday), Canterbury; July 2 (Wednesday), Temple Gardens, London, E.C. (N.R.S.); Croydon, Hanley (two days), and Richmond (Surrey); July 3 (Thursday), Colchester and Norwich; July 4 (Friday), Exeter (N.R.S.); July 5 (Saturday), Sutton (Surrey); July 8 (Tuesday), Gloucester and Harrow; July 9 (Wednesday), Ealing, Farnham, Formby, Hereford, and Stevenage; July 10 (Thursday), Bath, Eltham, and Woodbridge; July 17 (Thursday), Helensburgh and Halifax; July 19 (Saturday), Manchester (N.R.S.); July 22 (Tuesday), Tibshelf; July 23 (Wednesday), Cardiff (two days). The above are all the dates that have as yet reached us of Rose shows and other horticultural exhibitions where Roses form a leading feature.

ARBOR-DAY IN BRITAIN.—An essay has reached us written by Mr. ELLIOTT TILL for the Society for the Protection of Birds (3, Hanover Square, W.) on the best means of establishing a "Bird and Arbor-Day" in the British Isles. The author, like another EVELYN, notes the depletion of the woodlands for ship and other building, and the waste of bird-life also. He pleads for the planting of souvenir and other trees, as well as for careful re-forestation to compensate for compulsory clearances. With regard to birds, Mr. TILL claims that they are valuable as insect-destroyers, as well as interesting for many other causes, and that the extirpation of at least the rarer sorts would be a real calamity. We cannot sympathise fully with the praise of clipped trees and vegetable

curiosities, but quite agree that children should be taught, by means of object-lessons, to study the uses both of birds and of trees, and to observe without destroying them. As regards the institution mentioned in the title the author says: "*Festina lente* is a good motto to bear in mind in the endeavour to advance Bird and Arbor-Day. Attempt it first in one or two counties. I suggest Surrey and Essex. The forces which operated to bring about Arbor-Days in America may perhaps be present in England, but in nothing like the same degree. The idea should grow gradually, not be forced; a natural growth will result if the idea be properly cultivated." The planting of fruit-trees by road-sides, as done on the continent, should also receive attention. In conclusion, we must mention the charming plates illustrative of trees and of a bird that are shown us in this pamphlet, whose aims command our sympathy.

FRUIT TO AUSTRALIA.—We learn from the *Liverpool Journal of Commerce* of February 24 that the Orient Pacific Company has issued a circular offering to take fruit and vegetables to Australia at a rate per box. The boxes are not to be larger than 2 feet 10 inches cubic measurement, and half-boxes are to be allowed if they do not exceed 1 foot 5 inches. The freight to Fremantle is to be 5s. per box, and 2s. 9d. per half-box; and to the other ports, 4s. 3d. and 2s. 3d. Arrangements will be made for the transhipment of boxes to such Australasian ports as the Company does not call at. It is quite likely that this may be the beginning of an important trade with the Colonies, for, though Australia produces a large amount of fruit on her own account, the seasons here and there are interchanged, and European fruit will come in when their trees are not in bearing.

AUSTRALIAN APPLES.—The following message has been received from Sydney, advising the following shipment of fruit from the Colonies:—By the Orient Co.'s SS. *Austral*, expected on 29th inst. in London, 16,000 boxes; by the P. & O. Co.'s SS. *Arcadia*, expected home about the 5th prox., 18,000 boxes.

FRUIT FROM THE CAPE.—It is pleasing to note the regular despatch of fruit from Cape Town. The last advices to hand state that, concerning the Union Castle Company's ship, *Dunvegan Castle*, which has brought 540 boxes of Plums, 520 of Peaches, 117 of Nectarines, 106 of Pears, 120 of Grapes, and 2 of Grenadillas; total, 1411 boxes.

FORESTRY.—The Right Hon. R. W. HANBURY, M.P., President of the Board of Agriculture, has appointed a departmental committee to enquire into and report as to the present position and future prospects of forestry, and the planting and management of woodlands in Great Britain, and to consider whether any measures might with advantage be taken, either by the provision of further educational facilities or otherwise, for their promotion and encouragement. The committee consists of the following gentlemen, viz.:—Mr. RONALD C. MUNRO-FERGUSON, M.P. (Chairman), Sir JOHN F. L. ROLLESTON, M.P., Mr. EDWARD STAFFORD HOWARD, C.B., a Commissioner of his Majesty's Woods, Forests, and Land Revenues; Professor W. SCHLICH, C.I.E., Ph.D., Professor of Forestry, Royal Indian Engineering College, Cooper's Hill; Colonel FREDERICK BAILEY, R.E., Lecturer on Forestry, Edinburgh University; Professor JOHN R. CAMPBELL, B.Sc., an Assistant Secretary to the Department of Agriculture and other Industries, and Technical Instruction for Ireland; Mr. JOHN HERBERT LEWIS, M.P., Mr.

GEORGE MARSHALL, and Dr. WILLIAM SOMERVILLE, an Assistant Secretary to the Board of Agriculture. Mr. REGINALD H. HOOKER, of the Board of Agriculture, is the Secretary to the committee.

HORTICULTURISTS AND THE SALE OF POISONS.—At the Newcastle-under-Lyme Police-court, on Monday, March 3, two florists and horticulturists, of Newcastle, were summoned at the instance of the Pharmaceutical Society, under Section 17 of the Pharmacy Act, 1868, for selling a poisonous vegetable alkaloid without a label being attached to the vessel in which it was supplied bearing the word poison, and the name and address of the seller. A pint of XI-All insecticide was supplied in an old brandy-bottle without any label except one relating to brandy. No warning was given. MORGAN used a little of the insecticide and placed the bottle on a bench in the potting-shed of his employer's garden. On January 23 a man named THOMAS BULLOCK was working in the garden, and some beer which he sent for was also put in the potting-shed. The beer was in a bottle very similar to that containing the insecticide, and BULLOCK in mistake drank some of the latter and died in a short time. After a long hearing, the Chairman said the Bench were unanimous that an offence had been proved, and fined the defendants £2 and costs. *Journal of Horticulture.*

CULTURAL MEMORANDUM.

PROPAGATING POINSETTIAS.

It is not an uncommon error to start this plant into growth at too early a date, with the result that it gets tall, and by the time it should begin to form its bracts, it has begun to lose vigour, and does not form as fine heads as a younger plant would do. If cuttings be put in during June, or even as late as July, they will produce fine heads of bracts, provided the treatment is good. An important point is good strong cuttings, which can only be obtained by giving early attention to the stock plants. If the stock of plants is limited, some cuttings may be put in early, and the tops taken off later on. The plants that have been dried off may be started at this season by placing them in a light, warm position, and syringing them regularly, but not affording much, if any, water at the roots until growth has begun. Some of the old soil may be replaced with fresh loamy material. The first growths are usually thin, and may be cut off, and when they start again the shoots may be thinned out, leaving from three to five on a plant. As stated above, if the stock of plants is short, the early growths may be used for cuttings. There is little difficulty in propagating Poinsettias if the accommodation is suitable, viz., a close garden-frame set on a dung-bed, having a bottom-heat of 80°; but I prefer an indoor propagating-pit, this being more under control in all weathers, for it is most essential that they should have careful attention.

The cuttings should be inserted singly in 3-inch pots filled with a compost consisting of loam and leaf-mould, with enough sharp sand as will make it porous. Cut the shoots close under a joint. Those stems that have made much growth will be hollow between the joints, but that is no detriment if they are carefully treated, for they will root as freely as others, cut close to the old wood. Some dry sand should be applied to the base of the cuttings as soon as they are taken off; this

stops bleeding. [It is good practice to bury the cuttings head downwards in fairly dry sand till all are ready for dibbling in the cutting-pots. Ed.] If put into the close propagating-pit before they get withered, and given a slight sprinkling, and more water after the base of the cuttings has dried up, they will root without losing a leaf. The advantage of having the strong cuttings is, that they will have large leaves down to the base of the plants. Any early-struck plants which have their tops taken off, if cut down to about 4 inches from the pots, will break with two or three shoots each, and make useful plants for growing in large pots. Care must be taken that the cuttings are removed from the close pit as soon as rooted, and after a few days they may be fully exposed to the sun. With careful attention to affording water, Poinsettias may be grown on through the summer without any shading, and when the sun gets less powerful, they should be kept up as near the glass as possible. They will require no artificial heat until the nights get cold; but care must be taken that they are not left in a cold-house too long, for though they may not appear to suffer at the time, they will lose their leaves as soon as given more warmth. A. Hemsley.

HOME CORRESPONDENCE.

PLANTING FRUIT-TREES ON THE SIDES OF ROADS.—I was glad to read Mr. F. W. Burbidge's note at p. 140, in the issue of the *Gardeners' Chronicle* for March 1, recommending the planting of fruit trees at the sides of public roads. I hope this matter will be taken up by landowners, and the practice more generally adopted. I have several times advocated this in the pages of the *Gardeners' Chronicle*, but I fear without result so far; but I would like to say again, that not only roadsides but hedgerows and divisions of fields everywhere in all parts of the country, where nothing profitable or beautiful is growing, might with advantage, and without any large outlay of money, be planted with standard trees of Apple, Pear, Plum, Cherry, Damson, and other fruits; the landscape would be beautified in a very short space of time, and profitable returns would come in due time. I am told that in some parts of France many miles on both sides of the roads are planted with Cherry-trees, which afford abundance of fruit, and have a beautiful effect when in bloom. I believe that with the exception of sparrows, the French are not troubled so much during the fruit season with birds as we in England. If this practice were common throughout the country, its aspect would be much improved, to say nothing of the profit accruing to the owner of the trees. *Bailey Wadds, Birdsall, York.*

WINTER-FLOWERING CARNATIONS.—Replying to Mr. Slade's query regarding Mrs. Leopold de Rothschild, I have met with only one variety under this name, and it is undoubtedly the same variety that is known as Madame Thérèse Franco. With regard to the merits of this Carnation, Mr. Slade is not alone in his opinion, for I have heard some trade growers make the complaint that it does not flower so freely as they could wish. On the other hand, I find that some consider it to be the best pink coloured variety yet raised. I myself should still give the preference to the old favourite Miss Joliffe; or rather the improved variety of it, for in this the side shoots follow on, and come into flower much sooner than do those of Mrs. L. de Rothschild. Mr. Slade refers to the number of side shoots that this produces, and if he would pot the plants on, all of these side shoots would come into flower in due time. The spring struck plants do not have sufficient time for these side shoots to flower until the following spring;

but those propagated in October and stopped the following May will, if potted on, make fine bushy plants, which should flower well the following winter. I have seen it grown and flowered in 7-inch pots most satisfactorily. While writing about Carnations, I should like to say a word in favour of C. Countess of Warwick, a variety which was raised from Winter Cheer, fertilised with pollen of a seedling, the result of an earlier cross with Winter Cheer and Uriah Pike. It is not quite so dwarf as the seed parent, but it is equally free-flowering, and the flowers are of a bright crimson colour, with broad petals and a perfect calyx. I have found Winter Cheer to seed freely, and have raised some good varieties from it; but although I have persevered, I have never succeeded in getting good seed from Miss Jolliffe, while in others which appeared less likely to seed have proved very prolific. A. Hemsley.

BEGONIA GLOIRE DE LORRAINE AS A TABLE PLANT.—I was interested in reading the article on p. 89 concerning table decorations, but I was surprised that the writer made no mention of so good a plant for this purpose as Begonia Gloire de Lorraine. This plant when in flower has a pretty effect either by daylight or artificial light. The plants should be grown in 6-inch pots to a height of 15 inches. Small sprays of flowers and leaves may also be placed in small vases, or used in tracery, no other blooms being used. C. L. Branson.

GLADIOLUS INJURED BY FUMIGATION.—I enclose a few leaves of forms of Gladiolus nanus, which, like those of Watsonia, I showed last year, have become damaged by a very slight fumigation. It is singular that these things should suffer when young fronds of Ferns growing in the same house are uninjured. It cannot, I think, be too widely known that these plants cannot stand fumigation with tobacco or preparations thereof without injury. Is there any peculiarity in the cuticle of the leaf that would account for this? The inner cellular tissues have quite collapsed. I have noted that many Cape plants—particularly *Gastronema sanguineum*—are similarly affected when fumigated. Geo. B. Mallett, Colchester.

THE WET v. STALE EGG.—Since the appearance of the "Wet v. Stale Egg" letter in your recent issue and other papers, I have received several hundreds of letters asking the nature of water-glass, and where it can be obtained. Water-glass is a silicate of soda, and is supplied by many wholesale as well as retail chemists, and is used for other trade purposes besides egg-preserving. I may say that a leaflet has been issued by the Irish Board of Agriculture, and also that a very explicit pamphlet has been printed by the Leicestershire Egg-preserving Depot, Hineckley, price 4½d., and this I shall be pleased to forward post-free to anyone who may desire detailed information. K. B. Baghot-De la Bere, Burbage Hall, Leicestershire.

ARTIFICIAL MANURES FOR SWEET PEAS.—Last season my Sweet Peas were doing very badly, which I attributed to the poor kind of manure at my disposal—peat-moss litter from the stables. The dry season, together with the dry state of the manure, prevented it decomposing in the ground, as was observed in the autumn, when it was turned up with the spade almost as dry as when it was dug in. Having some artificial manure by me, the same as I use for Pear-trees, consisting of one part muriate of potash and two parts mineral superphosphate of lime, I gave them a sprinkling with this every fortnight, which was well watered in. The result was very marked, for the plants grew vigorously, flowered profusely, and the blooms were of a much brighter colour than usual, and very large in size, on long stalks; but they lacked substance, and would not stand the bright sunshine without becoming discoloured; dampness likewise caused them to decay. The seed-pods were kept cut off as often as time would allow, excepting on one occasion, when they were left rather longer than usual; I noticed then every pod

was well filled with small seeds, which I think goes to prove it an excellent manure for culinary varieties. In another part of the garden I sowed some fifty varieties on a well-prepared border, for the purpose of a screen. Being anxious to get quick growth, and with the view of testing the efficacy of the different manures, I gave them water every fortnight with sulphate of ammonia in it, of a strength of 2 oz. to 4 gallons of water. The result was a much closer jointed and firmer growth, but they did not bloom so freely, neither were the blooms so large as those dressed with the muriate of potash; but the colour of the flowers was equally good, and I found that they lasted much longer when cut, and also when left on the haulm. I do not say these manures would produce the same results on all kinds of soil; it would be interesting to know the different effects on different soils. To understand the application of manures thoroughly, we should all know the chemical analysis of the soil, so as to be able to add those constituents in which it is deficient. A great many of us give indiscriminately the same manure to everything, but I am not a believer in the same salve for every sore. Here the soil in both cases was the same, that is, a rather heavy, chalky nature. I have not as yet tried here a mixture of two parts kainit and one part nitrate of soda, but did so some four years ago with Sweet Peas growing on a light sandy loam, sprinkling a little along the rows, not too close to the plants, for fear of injuring them, and applying water afterwards, repeating this application every ten days. The results in this case were good; there was no damping or scalding of the flowers, and they were of good size and colour. W. H. Clarke, Aston Rowant Gardens, Oxon.

FLORISTS' FLOWERS AT THE DRILL HALL.—It is exceedingly interesting to observe in the arrangements of the Royal Horticultural Society for the present year, how the various special societies are sheltering themselves under its wing. The National Auricula Society has stuck to the Drill Hall loyally; the National Tulip Society, hitherto holding its southern competitions at the Temple Show, where they were amidst the immense wealth of exhibits somewhat lost, now has them at the Drill Hall on May 20. The National Carnation Society, evidently not successful in its flirtations with the grand lady of Sydenham Hill, returns to its old love, the Royal Horticultural Society, on July 22, with a big schedule; and on September 2, the National Dahlia Society brings its great show of flowers from the Crystal Palace to the Drill Hall. What remarkable additions to the Fellows' privileges do these shows present? Whatever may be the deficiencies of the Drill Hall, at least flowers will keep fresh longer there than anywhere else. A. D.

THE FLEUR-DE-LYS.—Amongst the many interesting and beautiful buildings that abound in the city of Reims, none is more worthy of attention than the ancient Abbey Church of St. Remi, founded by Clovis and Clotilda in the first part of the sixth century. When visiting this church with some friends a few years since, we were impressed by the curious appearance of an old piece of tapestry, which hung on the wall of the sacristy. It was of extremely early date, and the scene represented on the arras was apparently intended to commemorate the triumphant return of some kingly warrior to his people. The hero was on horseback; close behind him rode a retainer bearing the royal shield, on which were displayed three emblems, which at the first casual glance we accepted as the orthodox badge of the Kings of France—the Fleur-de-Lys; but a closer inspection revealed the fact that these were no "Lilies of France," but three unmistakable toads, grouped heraldically, their eyes were clearly defined, and their limbs attached to their bodies. On reflection, one can perceive how the conventional Fleur-de-Lys can be the natural evolution of such a weird device. This can be tested by copying the Fleur-de-Lys in its most primitive form,

and then sketching the outline of a toad in as simple and conventional a manner as possible, adding the eyes; and then comparing the two drawings, when the likeness between them is very noticeable. The unusual interest we displayed in the old tapestry at Reims seemed to amuse our guide, the sacristan. He told us it was stated to be one of the most ancient specimens of the handicraft still preserved to France, and that the badge on the royal shield was certainly intended to represent three toads, which was the primitive cognizance of the Kings of France, until Clovis transformed the reptiles into the conventional Fleur-de-Lys. On consulting Murray's *Handbook of France* later in the day, we read therein but a brief description of the old tapestry, but what little account there was fully corroborated all the sacristan had related concerning the traditional evolution of the Fleur-de-Lys. I have often seen the origin of the Fleur-de-Lys ascribed to the Lily, and the Iris. Eliezer Edwards, in his dictionary of *Words, Facts and Phrases*, says of it: "Louis VII. adopted the Iris as his badge when he formed the crusade, which led to its being called Fleur-de-Louis. This in the course of time has been corrupted to Fleur-de-Lys, the name it still retains in France, and in the southern parts of England." The evolution of the Fleur-de-Lys from a flower appears to be the universal and accepted tradition, and never, except at Reims, have I heard it suggested that after all it may be an idealised representation of the humble toad. E. M. W.

RAINFALL IN 1901 IN CENTRAL IRELAND.—Some of your readers may like to know the amount of the rainfall during 1901 at Belvedere, West Meath, which is near the centre of Ireland:—

| Month. | Total Depth. | Greatest fall in 24 Hours. | Number of Days on which '01 or more fell. |
|---------------|--------------|----------------------------|---|
| | Inches. | Depth. | Date. |
| January ... | 3.70 | .87 | 18 |
| February ... | 1.81 | .35 | 1 |
| March ... | 3.48 | .56 | 29 |
| April ... | 2.24 | .80 | 2 |
| May ... | 1.89 | .37 | 7 |
| June ... | 2.74 | 1.30 | 22 |
| July ... | 0.91 | .56 | 1 |
| August ... | 2.71 | .58 | 9 |
| September ... | 5.48 | 1.20 | 17 |
| October ... | 3.44 | .65 | 29 |
| November ... | 3.41 | 2.05 | 11 |
| December ... | 3.70 | .65 | 7 |
| Total ... | 35.54 | ... | 197 |

C. Brinsley-Marley.

THE RAINFALL AT SHIPLEY HALL, DERBY, IN 1901.—January, 1.61 in.; February, 1.38 in.; March, 2.21 in.; April, 1.76 in.; May, 1.02 in.; June, 1.79 in.; July, 5.05 in.; August, 1.52 in.; September, 1.45 in.; October, 1.55 in.; November, 2.31 in.; December, 4.25 in. Total for the year, 25.90 in. This quantity of rain and snow is almost as much below the average as that of 1900 was above it. July, as will be seen, was the wettest month, usurping in this respect the position taken by August in the previous year. More than half the July total fell in two consecutive days, viz., the 25th and 26th, when the falls were respectively 1.15 and 1.54 in. Part of the December record was due to the extraordinary and disastrous snowstorm of the 13th, in which over 1 foot of snow fell in the course of a very few hours, the snow being in that condition when it sticks closely to anything on which it may fall. J. C. Tallack.

PEAS AND MANURE.—Whatever kind of manure be applied to Peas, it should be well decayed and thoroughly mixed with the soil, which should be double dug or trenched. A thick layer of manure beneath the roots of Peas if it cakes in dry weather does more harm than good, causing abundant mildew; but a mulch applied to the soil alongside the rows, and water applied in dry weather, is of great assistance. My experience in Pea-growing is not limited to one garden or kind of soil, and

I have been obliged to produce good Peas from the end of May till late in the season. The surest method by which Peas may be obtained in quantity is to treat the land in the manner stated, and not put the manure in layers. Many gardeners believe in the efficacy of layers of manure at the bottom of trenches in conserving moisture in the soil, but of this idea I am rather doubtful, and prefer to mix it with the whole body of soil. L.

RETARDED LILY OF THE VALLEY.—With regard to "Midlands" note on p. 99, the thought has occurred to me, do people carry out properly the directions given them before they begin to think there are trade secrets with regard to the successful cultivation of this or that plant? I think any good firm who sells retarded plants will, if asked, always give directions as to the subsequent treatment necessary, and do in some cases send out printed directions with the plants. In my own case, not having had any experience with retarded crowns of Lily of the Valley, and hearing quite diverse opinions from those of my friends who had, I asked the firm who supplied me if any special treatment was required, and the answer was, "Nothing beyond the directions printed in catalogue." As this batch was wanted for a special occasion, I was

plant-houses or for decorating ball-rooms, as well as for affording stems for cutting. In this method of cultivation, the plants must be supplied with liquid-manure at frequent intervals, or the foliage will become yellow and stunted. As a basket plant, or for training along the rafters of the conservatory or stove-house, this species is unrivalled. Another use for the plant is for bordering the plant-stages or hiding the hot-water pipes; and when associated with *Oplismenus Barmanni variegata* in the stove, it is very pleasing. H. T. Martin.

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

FEBRUARY 25.—*Present*: A. D. Michael, Esq., in the chair; Rev. W. Wilks, Messrs. Saunders, Douglas, Bennett-Poë, Odell, Chapman, Hooper, Holmes, Nicholson, Worsdell, Boulger, Bowles, Carruthers (visitor), Drs. Müller, Rendle, Cooke, and Masters.

Diseased Leaves of Odontoglossum.—Mr. CHAPMAN showed leaves showing discoloration and shrivelling of the leaf-tips, attributable to excessive moisture and unfavourable climatic conditions. There was no trace of fungus.

red-spider and thrips, for which the application of tobacco-water and soft-soap as a wash was recommended. (2) Leaves of bulbous plant from Burmah. These were marked by red streaks, and ultimately by the decay and shrivelling of the tip of the leaf. The appearances were such as are occasioned by thrip, for which fumigation with tobacco or X.L. All is very effectual. (3) *Pelargonium*-leaves discoloured and shrivelled. No insect or fungus could be found on these leaves, the condition of which was attributed to unfavourable conditions of light, temperature, moisture, or all combined.

Cyclamen Flowers, Synanthus in.—Mr. J. S. DAVIS sent flowers of *Cyclamen* more or less united one to another, and with leaves developed on the flower-stalk. Although the appearances are far from uncommon, it is not easy to assign a definite cause for their production.

Fasciated Holly.—Mrs. MORLEY, Southborough, sent a specimen of this malformation, due to excessive growth. It presented no special peculiarities.

The Wood Leopard Moth.—Mr. A. D. WEBSTER sent specimens from Greenwich Park, to show how severely the trees were suffering from the effects of this tunnelling caterpillar.

Bacteriosis in Carnations.—Dr. COOKE reported as follows on some specimens exhibited at the last meeting:—"The *Carnation*-leaves sent to the last meeting are undoubtedly affected by the disease described as *Bacteriosis*. The appearance of the leaves is strikingly like that figured in the *Bulletin of the U.S.A. Experiment Station, Purdue University*, May 1, 1896, p. 549, and the minute organisms, whatever they may be, are similar. The name given to the parasite is *Bacterium Dianthi*. The disease is said to enter the plants chiefly through the punctures made by aphides, and the suggestions made are that the plants may be kept essentially free from the disease by keeping the foliage dry, and preventing the presence of aphides. Overhead spraying should only be done occasionally on bright days, with water containing a small amount of ammoniacal copper carbonate."

Germination of the Seeds of Crinum and other Amaryllids.—Mr. WORSLEY contributed a paper accompanied by illustrations. Mr. WORSLEY contends that the structure usually considered a cotyledon is not truly so named, for it has no counterpart among dicotyledons, and it does not perform the functions of a cotyledon. Moreover, Mr. WORSLEY thinks that "in comparative anatomy, function is a safer guide than locality."

New Species of Hippeastrum.—Mr. WORSLEY showed a flower of this supposed new species, with the following note:—

"*Hippeastrum Kromeri.*—This unrecorded species was introduced by Mr. Kromer of the Roxanna Nurseries, W. Croydon, who both presented me with a bulb and sent flowers of other bulbs not showing any divergence. It was gathered in the highlands of Minas Geraes, Brazil, on the banks of the Upper Rio São Francisco. It holds an intermediate position between the *rutulum*-regime group, and the epiphytal group inhabiting the Organ Mountains. It seems nearest akin, geographically and generally, with *H. correiense* (Borg. *Hexand.*, 9)."

Air-canals in Nymphæas.—The arrangement of the air-canals here shown, fig. 49, formed the subject of a communication to the Scientific Committee at its previous meeting, and will be discussed in detail in a future number of the *Journal of the R.H.S.*

BOLTON HORTICULTURAL AND CHRYSANTHEMUM.

FEBRUARY 11.—The adjourned general meeting of this society was held on the above date. The statement of accounts for the past year was adopted, showing a nett loss of £25 0s. 9d. on the year's working. It was unanimously agreed that the retiring President (Thos. Walker, Esq.), be asked to accept the presidency for the ensuing year. Mr. Smith was re-elected Chairman; Mr. Shore was re-elected Treasurer; Mr. H. Makin was elected Secretary; Messrs. Mather and Hay the Auditors; half of the committee were also elected. It was also resolved that the secretary of this society be elected at its annual general meeting. The full address of the new secretary is 628, St. Helen's Road, Bolton.

BECKENHAM HORTICULTURAL.

FEBRUARY 11.—A. D. Hall, Esq., M.A., Principal of the South Eastern Agricultural College, Wye, delivered a lecture on "Soils, Cultivation, and Water Supply." The importance of good soil, and the reasons of the difference in their value, were briefly alluded to; after which the lecturer applied his remarks more particularly to the soils of the district.

FIG. 49.—AIR-CANALS OF NYMPHÆAS.

A, B, Plan of section of flower-stalks. 1, 2, 3, Plan of arrangement in leaf-stalks.

very particular that the treatment recommended was carried out in every detail, and the result was the finest lot of Lily of the Valley, with plenty of healthy foliage, I had ever had in mid-winter. I have determined to always use retarded crowns for early forcing. To my mind, success in plant growing, as in other things, is brought about by strict attention to little details, and by allowing nothing to be too much trouble, remembering what is worth doing is worth doing well. J. G. W., Bessborough Gardens, Ireland.

ASPARAGUS SPRENGERI.—There is no ever-green plant of a decumbent character that can be put to more varied uses than *Asparagus Sprengeri*, and there is no plant cultivated under glass that will thrive better under adverse conditions. It will grow in the stove or the cold greenhouse, provided plenty of water, a suitable soil, and good drainage are afforded. When market-gardeners take up the extensive cultivation of a certain plant, as is the case with this plant, we may know that there is a good demand for it, and that there is "money in it." Well grown plants produce sprays of light green, feathery foliage, of 4 to 5 feet in length. Liberal treatment is required in order to obtain these results. Where large quantities are required, it is advisable to provide boxes or confined borders in which to plant, where the fleshy, tuber-like roots may ramble in search of nutriment. The soil should largely consist of friable loam, sand, and mortar-rubble. The plant may also be cultivated in pots for the embellishment of

Alleged Hybrid between Pea and Dwarf Bean.—Dr. MASTERS showed, on behalf of Mr. SMYTHE, a Pea-like seed raised, as was stated, between a dwarf Bean and one of the culinary Peas. The seeds of the Bean-parent were shown, in the form of small, flattened, kidney-shaped seeds, of a shining chestnut-brown colour. The supposed hybrid seed resembled a smooth, round Pea in size, form, and colour. As there was only one seed available, no minute examination was made, but the seed was forwarded to Chiswick to be grown and reported on.

Narcissus poeticus var. ornatus.—Mr. JENKINS sent flowers of this variety to show the manner in which the coloured edge of the corona was eaten off by slugs, leaving the yellow cup untouched. Whether the slugs are attracted by the reddish colour or seductive flavour of the rim of the corona, or by some other inducement, is a matter for investigation.

Gnaw on Esculus sp.—From the Botanic Garden, Bath, came a globular woody excrescence crowded with buds and contracted shoots. The tree is reported to bear very numerous such growths, from some of which the flowers protrude, so that their appearance is at that period peculiar and attractive. It was suggested that these outgrowths might be the result of the irritation set up by mites or by fungus (*Exoascus*). [See p. 157 of our present issue.]

Gnaw on Allamanda.—A similar production on the branch of an *Allamanda* was shown from Mr. Bedford, Straffan Gardens, Kildare; but in this case there were no buds or shoots. It was suggested that the irritation occasioned by ants was competent to induce such growths.

Diseased Leaves.—Miss DRYDEN sent various leaves, as follows:—(1) Violet leaves. These were affected with

WEYBRIDGE GARDENERS' IMPROVEMENT.

FEBRUARY 14.—At the invitation of the committee of the above society, Mr. Richard Dean, V.M.H., delivered an address at the Public Hall on "Floriculture and Florists during the past Fifty Years." Mr. J. Bilney was in the chair, and the attendance a very large one.

WARGRAVE GARDENERS'.

FEBRUARY 19.—The meeting on the above date was largely attended. Mr. H. G. Cox, Hon. Sec. of the Reading Gardeners' Association, gave an interesting lecture upon "The Primula," illustrated with a series of forty-one lantern-slides.

He traced the evolution of this popular plant from its introduction into this country in 1819 to the present day. General directions for culture as practised at Messrs. Sutton's nursery were given, and short references made to *P. stellata*, *P. obconica*, *P. Sieboldi*, and *P. floribunda*.

Among the excellent exhibits was a group of Primulas, by Mr. BRODIE, gr. at Wargrave Hill, which was awarded the Society's Cultural Certificate. Four new members were elected.

BRIGHTON AND SUSSEX HORTICULTURAL.

FEBRUARY 20.—The monthly meeting of this society was held at the Imperial Hotel, Brighton, on the above date, and the subject before the members was entitled "A Talk on the Chrysanthemum," by Mr. H. J. Jones, of Ryecroft Nursery, Lewisham. There was a large gathering of members, and the Chair was filled by Mr. Miles.

Mr. Jones' discourse on the cultivation and exhibition of the Chrysanthemum covered more than two hours, and was greatly appreciated by his audience.

LINNEAN.

FEBRUARY 20.—The Rev. T. R. R. STEBBING, M.A., F.R.S., in the Chair.

On behalf of Mr. G. M. THOMSON, F.L.S., of Dunedin, N.Z., the Secretary exhibited a series of photographs of New Zealand flowers, including several species of "Mountain Daisy," *Celmisia coriacea*, *C. ramulosa*, and *C. Haastii*; *Olearia insignis*, *Veronica biformis*, and *Clematis indivisa*. The alpine flora of these islands included a number of beautiful plants, many of them, like the *Raoulia* (or Vegetable Sheep), producing white blossoms in such profusion as to be conspicuous at a considerable distance. One of the most noticeable was the great white Buttercup, *Ranunculus Lyallii*, commonly known as the Mount Cook Lily, of which two photographs were shown.

In connection with the plants, some observations were made on the birds which visit them, e.g., the Bell-bird or "Korimako," *Anthornis melanura*, the Grey Warbler, *Gerygone flavirostris*, the Pied Fantail, *Rhipidura flabellifera*, and the Yellow-breasted Tit, *Petrarca macrocephala*. Of these, the first-named was observed to assist in the fertilisation of the native *Fuchsia*s, on quitting which the feathers of the head were seen to be stained with the bright blue pollen of the flowers. A favourite nesting-site of the Tit, *Petrarca macrocephala* was said to be immediately under the head of the Ti-tree, *Cordyline australis*, a good photograph of which was likewise exhibited.

A paper was read by Dr. J. E. DUERDEN on "The Internal Structure and Histology of *Bunodeopsis globulifera*, Verrill, a West Indian Sea Anemone."

Mr. B. DAYTON JACKSON, Sec. L.S., in a "Report on the Botanical Publications of the United Kingdom as a part of the International Catalogue of Scientific Literature," gave the history of botanic bibliography from the time of Linnaeus, mentioning the admirable catalogue by Dryander of Sir Joseph Bank's library, and passing on to the Royal Society's *Catalogue of Scientific Papers*, at present consisting of eleven volumes, ranging from 1800-1883, the record of the last seventeen years being in course of compilation.

The genesis of the *International Catalogue of Scientific Literature* was then briefly described, and the means adopted for the collection and classification of titles given. The Linnean Society had contributed the titles of papers and books issued within the United Kingdom, amounting to about 2,300, and the first part of the volume devoted to botany for 1901 was now in the hands of the printers, for early publication.

A paper by Miss LETTICE DIGBY, of the Biological Laboratory, Royal College of Science, was read on her behalf by Mr. J. E. S. Moore, "On the Structure and Affinities of some Gastropoda from Lake Tanganyika belonging to the genera *Chytia* and *Limnotrochus*."

READING & DISTRICT GARDENERS'.

FEBRUARY 24.—A pleasing ceremony took place at the ordinary meeting of the members on the above date, Mr. H. G. Cox, the energetic Secretary, being the recipient of a handsome testimonial, as a token of the appreciation felt by the members of his valuable services to the Association, which have now extended

over a period of some years; Mrs. Cox also was presented with a handsome solid silver tea service in morocco case, while to Mr. Cox himself a valuable half-hunter gold watch was handed. The gifts were accompanied by a framed illuminated address, bearing the photographs and the names of all the working members of the Association. The presentation was made in the presence of a large gathering of members, Mr. Leonard Sutton presiding.

Mr. L. Sutton, speaking on behalf of the members, expressed their indebtedness to Mr. Cox for his work as Secretary, and his services since he had been a member of the Association. He assured Mr. Cox of the great appreciation they all felt for what he had done. He knew from Mr. Cox's work outside the Association what a difficult matter it must have been for him to find the time for the work in connection with the Association. He (the President) was glad that one of the presents was for Mrs. Cox. The inscription was as follows:—"We, the undersigned members of the Reading and District Gardeners' Mutual Improvement Association, wishing to express our appreciation of the services rendered by Mr. H. G. Cox as Secretary, have this day presented him and Mrs. Cox with a silver tea service and gold watch as a token of our esteem and regard." Then followed a list of the working members of the Association.

Mr. Stanton, being called upon to say a few words, remarked that Mr. Cox had done a great deal for the Association, and had, in fact, made it what it was, the first in the country, there being now over 200 members. Mr. Stanton spoke of the appropriateness of the two presents, and mentioned that the way in which the subscriptions had come in was very creditable to the society. Over 150 persons had contributed.

Mr. Cox responded on behalf of himself and wife. It might interest the members, he said, to be reminded that the first meeting of the Association was held on December 6, 1888, when fifty-four members were elected. There were now 229 names upon the books, and there were three new members to be elected that evening. He had no doubt that at the present time the Association was the strongest of its kind in the country.

The ordinary business of the evening was then proceeded with.

BRISTOL AND DISTRICT GARDENERS'.

FEBRUARY 27.—A good meeting was held at St. John's Rooms on the above date, when Mr. J. C. House, of Westbury-on-Trym, delivered a lecture on the "Violet." The Bristol amateurs were invited to attend, and received a cordial welcome from their professional brethren. Mr. House has made a special study of the sweet Violet. Many people, the lecturer remarked, were under the impression that there was a deep secret concerning the cultivation of Violets, which he admitted, but which he said was that of "pains-taking" in every detail, and in doing everything needful, well. A clear atmosphere, suitable soil, and a natural position were the essential conditions. He recommended propagation by runners, put in during the autumn in sandy soil, covered with a frame and partly shaded during the first few days, and if possible facing south; planting the roots out about the third week of April, firming the soil round them, and keeping them well watered during the summer months. The best time for gathering the blooms was in the early morning or late in the evening. The lecturer also described several of the insect pests and diseases which the Violet is subject to, and gave the means for their prevention and eradication.

GLOUCESTERSHIRE ROOT, FRUIT, AND CHRYSANTHEMUM.

MARCH 1.—The annual meeting of this Society was held in Gloucester on the above date. The balance-sheet showed total receipts £328 16s. 7d., and expenditure (which included £202 15s. paid away in prizes) £308 19s. 4d.; leaving a balance in the bank of £19 17s. 3d., the largest the Society has ever had. It was acknowledged that this was due to the energetic efforts of Mr. S. S. Starr, the secretary, who had completely resuscitated the Society since his appointment some few years ago.

The Chairman (Mr. William Friday) was re-elected to that office for the seventeenth time in succession, and all the other officers were re-elected.

In arranging the schedule of prizes, some correspondence was read by the Secretary from Messrs. Sutton & Sons, Reading, with reference to certain altered conditions on which they were prepared to offer their prizes, namely, "that no exhibitor could claim Messrs. Sutton's prize who also exhibited at the same show, or in connection with the same Society, roots or green crops which are the produce of seeds supplied by other seedsmen." The Secretary said that similar conditions were also imposed by Messrs. Webb & Sons in connection with their prizes. It was resolved by a large majority of those present that the prizes of these seedsmen be not accepted on those terms.

DEVON AND EXETER GARDENERS'.

"HYBRIDISATION: Its Bearing on Gardeners, Botanists, and the Commercial World," was the subject of the lecture by Mr. G. Lee, gr., Upton Leigh, at the last meeting of the Association. Science, said Mr. Lee, however profound or however skilfully applied, would never do away with the necessity for a practical knowledge of gardening, and the use of the spade and the knife. Although the actual demonstration of the sexuality of plants was of much more recent date, its existence had been surmised by Empedocles, B.C. 460.

Tracing the study of gardening science from Theophrastus and Pliny to Bacon, Hales, Bonnet, and DuRoi, when the physiology of plants received careful study, he carried his references up to the Conference on Hybridisation in 1899. He mentioned the enormous improvement in the Begonia as one of the results of hybridisation.

The extraordinary impetus given to the cultivation of Orchids by the rich discoveries of the plant collectors of the earlier half of the nineteenth century, was followed by the no less stimulating effect of the published researches of Darwin on the fertilisation of Orchids. The advent of new species has been to a certain extent discredited by the success of hybridists; and many of their productions have revealed some of the possibilities of hybridisation, which justify the expectation of even greater and more interesting results. Nor has hybridisation benefited the so-called flowering plants only, but it has extended to the improvement of culinary vegetables, agricultural plants, and fruits.

It has been roughly calculated that the improvements effected on the different varieties of Wheat grown in America has made an increase of about 4 bushels per acre in the yield, which, at a moderate valuation, represents an increased annual value in the Wheat-crop of £28,000,000 sterling! The value of hybridisation as a botanical science is undoubted, and not easily estimated, while the fascination of the work is engrossing and elevating in a high degree.

Mr. Andrew Hlope (hon. secretary) occupied the chair. At the close a hearty vote of thanks was awarded to the lecturer. Mr. Hlope gave a prescription he had received from the Board of Agriculture for the removal of moss, lichens, decaying bark, and fruit-destroying insects from orchard-trees, saying at the same time that the recipe was both cheap and effectual, viz., 1 lb. caustic soda and 1 lb. pearl-ash, separately dissolved, adding $\frac{1}{2}$ lb. agricultural treacle, or the same quantity of soft-soap, to 10 gallons of water, the wash to be applied in the month of February, if possible.

CHESTER PAXTON.

At the Grosvenor Museum on Saturday Mr. B. Moore, The Dale, read a carefully prepared paper, entitled "The Successful Culture of Calanthes." Mr. Moore has been a successful grower of these beautiful orchidaceous plants for a number of years, and he dealt with his subject in a practical manner. He placed a high estimate upon them for decorative purposes, and stated that with care the flowers would last from two to three weeks after being cut. He gave minute details as to potting soils and suitable manures, and other matters connected with the cultivation of the plants.

NATIONAL AURICULA & PRIMULA (Southern Section).

THE twenty-fifth annual report of this Society in its statement of accounts shows a balance in hand, after paying its liabilities in the year 1901, of £21 13s. 6d., a sum about £2 in excess of that of 1900. Eleven new members joined the Society during the year, but there have been several losses from death and other causes; and to ensure the prosperity of the Society, it now remains for the members to bring in recruits to fill these and other vacancies, which must inevitably occur. This annual show will be held in the Drill Hall of the London Scottish Volunteers, Buckingham Gate, Westminster, on Tuesday, April 22.

Mr. J. Douglas, of Great Bookham, Surrey, again generously offers to supply members with a packet of Alpine Auricula seed, saved from the best varieties, to such as will undertake to sow the seed and cultivate the plants, and on condition that they apply to Mr. T. E. Henwood, 16, Hamilton Road, Reading, before June 1.

MIDLAND CARNATION & PICOTEE.

THE Report for 1901 of this Society shows continued prosperity, although the committee have to regret a considerable diminution of the balance in hand, as compared with 1900. The eleventh annual show held at Edgbaston on August 1 was considered to be one of the best hitherto held, in spite of the Flakes, Bizarres, and white ground Picotees not being up to the exhibition standard. The attendance of the public and of members was larger than in any previous year, and

the entries much more numerous than usual, particularly in selfs, yellow-ground Picotees, Fancies, and "undressed" classes. The rule made two years ago requiring that all seedlings should be named, has had salutary results.

FLORISTS' FLOWERS.

CACTUS DAHLIAS.

No visitor to any of the flower shows in the autumn months can fail to be struck with the beauty of the modern Cactus Dahlias. These have become so numerous of late, and the flowers are so exceedingly attractive and good as cut flowers for indoor decoration, that a note on some that took my fancy at the Crystal Palace show in September of last year may serve a useful purpose at the present time when gardeners are contemplating the purchase of novelties: Loreley, delicate rose, white centre; Mrs. J. Goddard, in colour scarlet, extra fine; Night is a very dark coloured flower; Laverstock Beauty, vermilion; Regulus, a deep crimson; Starfish, of orange-scarlet tint and nice form; Charles Woodbridge, purple-crimson; Cheal's White; The Clown, red, tipped with white; Emperor, plum coloured, with yellow base; Uncle Tom, very dark; Mrs. J. J. Crowe, pale yellow; Bridesmaid, primrose; Britannia, soft pink; Alfred Vasey; Harry Stedwick, with long crimson petals. Of these I intend to add several to my stock of these varieties.

The tubers having been brought from the store in which they have remained since the autumn, should be placed in a gentle heat, covered lightly with soil, and the shoots slipped off, potted singly or otherwise in sandy leaf-mould and peat. Let each variety be carefully labelled, and placed in bottom-heat of 75° till rooted, when they must be removed to a frame having top-heat of 55°, shifting them when necessary into larger pots, and in April inuring them to outside conditions. H. Markham, Wrotham Park.

MARKETS.

COVENT GARDEN, MARCH 6.

PLANTS IN POTS.—AVERAGE WHOLESALE PRICES.

REMARKS.—The Cape Grapes now arriving are Honey-pots, both red and white; Strawberries are easier in price, as also are Onions. Apples remain at about the same price as last week. Sweet Potatoes fetch, per cwt., 16s. to 18s.; old Potatoes about the same as last week. Grape-fruits, per doz., 4s. Bitter (Seville) Oranges are coming in, and the present is the proper time for making marmalade and wine.

POTATOS.

Dunbar Main Crop, 90s.; Up-to-Date, 80s. to 85s.; Blacklands, 45s. to 50s.; various, 50s. to 80s. Seed in variety, prices on application. John Bath, 32 & 34, Wellington Street, Covent Garden.

SEEDS.

LONDON: March 5.—Messrs. John Shaw & Sons, Seed Merchants, of Great Maze Pond, Borough, London, S.E., write that there were but few buyers on to-day's seed market, with only a small business passing. The chief requirement just now to bring on the consumptive demand is a spell of favourable weather. Meanwhile, Clover-seeds all round show no important change in value, but no description can be written dearer. Ryegrasses continue dull. There is this week no alteration in Mustard or Rapeseed, but Linsced is firm. Canary-seed, with its moderate stocks quietly diminishing, is featureless; other kinds of Birdseeds call for no comment. For Spring Tares there has been a better request. Scarlet and White Runner Beans are now obtainable on unusually moderate terms. Blue Peas and Haricot Beans have moved off slowly.

FRUITS AND VEGETABLES.

GLASGOW, March 5.—The following are the averages of the prices during the past week:—Apples, Newtown Californian, 9s. 6d. to 10s. 6d. per case; Oregon 12s. to 13s. 6d.; Nova Scotia Baldwin, 22s. to 24s. per brl.; Maine, 20s. to 24s. 6d.; Canadian, 23s. to 26s. 6d.; Oranges, Valencia, ordinary, 420s. 7s. 6d. to 8s. per box; do., large 420s. 9s. 6d. to 10s. 6d.; extra large do., 10s. 6d. to 12s. 6d.; do., large 714s. 9s. 6d. to 9s. 6d.; Jaffa, 12s. to 13s. 6d.; Grapes, home, 1s. 6d. to 2s. 6d.

per lb.; Onions, Valencia, 5s. 9s. 6d. to 10s. per box; do., Globes, 8s. 6d. to 10s. 6d.; do., Dutch, 6s. 6d. to 10s. 6d.; Mushrooms, 1s. to 1s. 6d. per lb.

LIVERPOOL: March 5.—Wholesale Vegetable Market.—Potatoes, per cwt.: Up-to-Date, 2s. 2d. to 2s. 8d.; Main Crop, 3s. to 4s.; Lynn Grays, 2s. to 2s. 6d.; Bruce, 2s. 2d. to 2s. 8d.; Turnips, Swedes, 2s. to 2s. 3d. per cwt.; Carrots, 3s. 6d. to 4s. 6d. St. Johns: Potatoes, 1s. to 1s. 2d. per peck; new do., 6d. per lb.; Grapes, English, 3s. per lb.; do., foreign, 4d. to 6d. 6d.; Pines, English, 5s. each; Apples, 2d. to 4d. per lb.; Tomatoes, 4d. to 6d. ditto; Asparagus, 1s. per bundle; Cucumbers, 1s. each; Mushrooms, 1s. 6d. per lb. Birkenhead: Potatoes, 10d. to 1s. per peck; Grapes, English, 2s. to 4s. per lb.; do., foreign, 6d. to 8d. 6d.; Mushrooms, 1s. to 1s. 6d. per lb.; Filberts, 1s. 6d.

CORN.

AVERAGE PRICES of British Corn (per Imperial qr.), for the week ending March 1, 1902, and for the corresponding period of 1901, together with the difference in the quotations. These figures are based on the Official Weekly Return:—

| Description. | 1901. | 1902. | Difference. |
|---------------|-------|-------|-------------|
| | s. d. | s. d. | s. d. |
| Wheat | 25 11 | 27 1 | + 1 2 |
| Barley | 25 0 | 26 7 | + 1 7 |
| Oats | 17 9 | 20 5 | + 2 8 |

METEOROLOGICAL OBSERVATIONS taken in the Royal Horticultural Society's Gardens at Chiswick, London, for the period February 23 to March 1, 1902. Height above sea-level 24 feet.

| 1902. FEBRUARY 23 TO MARCH 1. | DIRECTION OF WIND. | TEMPERATURE OF THE AIR. | | | | TEMPERATURE OF THE SOIL AT 9 A.M. | | | |

Remarks.—A week of foggy mornings and dull days, with frequent showers.

GENERAL OBSERVATIONS.

THE FOLLOWING SUMMARY RECORD of the weather throughout the British Islands, for the week ending March 1, is furnished from the Meteorological Office:—
"The weather during this period was generally mild with very frequent, but not as a rule, heavy rain. Some fine, clear intervals were, however, experienced at times, especially in the more eastern and southern districts."

"The temperature was above the mean throughout the kingdom; in the east and north-east of Great Britain the excess was only 1° or 2°, but in most other districts it was as much as 4°, and in England, S.W. and Ireland, S., 5°. The highest of the maxima occurred on rather irregular dates, and ranged from 59° in England, N.W. (at Llandudno on Tuesday), and 57° in England, S. and the Channel Islands, to 54° in the extreme northern and north-eastern districts, and to 51° in Scotland, W. The lowest of the minima, which were mostly recorded either on Wednesday or Thursday, ranged from 27° in the Midland Counties, and 28° in Scotland, E. and England, N.E. and E., to 37° in

England, S. and S.W., 39° in the Channel Islands, and to 40° in Ireland, S.

"The rainfall was more than the mean in almost all parts of the kingdom; the excess was very considerable in most districts, but only slight in the extreme north-east and east. In Scotland, N. and the Channel Islands the fall was less than the mean, the deficit in the former region being large.

"The bright sunshine was deficient in all districts except the Channel Islands. The percentage of the possible duration ranged from 35 in the district just named, and from 25 in England, E., to 21 in England, S., 19 in England, N.E., 8 in Scotland, N. and E., and 3 in Scotland, W.

THE WEATHER IN WEST HERTS.

A WEEK of very warm and showery weather. On five days the shade temperature rose in the middle of the day above 50°, and on no night did the exposed thermometer show more than 4° of frost. Both at 1 and 2 feet deep the ground is at the present time about 1° warmer than is seasonable. Some rain fell on nearly every day, but to the total depth of only about three-quarters of an inch. This was rather a dull week, as the sun shone on an average for only about two hours a day. The winds were, as a rule, very light, and there was more than the usual amount of moisture in the air. The first fertile flower appeared on a selected bush of the wild Hazel on the 1st, which is nearly a fortnight later than its average date in the previous eleven years, but two days earlier than last year.

FEBRUARY.

This was a very cold and exceptionally calm February. On only four nights did the exposed thermometer fail to register a temperature below the freezing point, and on the coldest night showed 25° of frost. Throughout the first three weeks both the days and nights were all cold, but during the remaining week the weather remained as persistently warm. Rain or snow fell on thirteen days, to the total depth of nearly 1½ inch, which is about half an inch below the average for the month. Of the total quantity, however, less than a quarter of an inch was deposited during the first three weeks. About 5 gallons of rainwater came through the percolation-gauge covered with short grass during the last week of February, and about 6 gallons through the bare soil gauge, but previous to this there was no measurable percolation through either gauge. The sun shone on an average for about one and three-quarter hours a day, which is about half an hour a day short of the mean record for the month. The atmosphere remained remarkably calm, indeed calmer than in any previous February of which I have here any record. It was also more humid than in any February for sixteen years.

THE WINTER.

Taken as a whole, this was rather a mild winter, and the rainfall was about half an inch in defect of the average for the season. December proved excessively wet, but after this there was very little rain until the last week in February. In fact, during the seven weeks ending February 21, only about three quarters of an inch of rain fell, which is only about one-fifth of the average quantity for that period. The record of clear sunshine fell short of the mean for the quarter by about five minutes a day.

THE RAINFALL FOR THE PAST FIVE MONTHS.

Since the winter half of the drainage year began in October, the total rainfall has come short of the average for those five months by 3½ inches, which is equivalent to a loss on each square yard of surface in this district of 15 gallons of rain-water. *E. M., Berkhamsted, March 4, 1902.*

A GRAFTING-WAX: *E. T.* A wax that may be used either warm or cold is made by melting 1½ lb. of clear resin and ¼ lb. of white pitch. At the same time melt ¼ lb. of tallow. Pour the melted tallow into the first mixture, and stir vigorously; then before the stuff cools add slowly ¼ lb. of venetian red. Another recipe for a cold wax is: Melt six parts white resin with one part beeswax. Remove from, and partially cool by stirring, then add gradually with continual stirring enough methylated spirit to make the mixture

when cool of the consistency of porridge. It may be applied with a bit of wood or the finger.

ANALYSIS OF SOIL: *J. L.* If you, or your employer, is a Fellow of the R.H.S., you can get your soil analysed at a small expenditure. Apply to the Secretary, 117, Victoria Street, Westminster.

CALLA OR RICHARDIA BLOOM: *J. G. W.* A twin-flowered specimen, by no means uncommon.

CORRECTION: *Calanthes.* In our Orchid Calendar for Feb. 22 last, it was erroneously stated that the pseudo-bulbs of *Calanthes* should not be exposed to sunshine in order to mature them, when the contrary is the case.

CUCUMBER LEAVES: *C. B.* There is nothing in the leaves themselves to account for the disfigurement. They are rather thin, such as we should expect to find upon forced plants in weather that prevented the use of the ventilators. Keep your plants as sturdy as possible, and be very careful not to use excessive doses of the manures you name. There is no disease manifest in the leaves.

GRUB IN PEAS: *F. W. C.* The larvæ of the Pea-weevil, *Bruchus granarius*. Their presence does not always prevent germination, but the resulting plants are sure to be deficient in vigour. All respectable seed merchants have the seed-peas sorted by women and girls, and weevil-eaten seeds picked out before the order season arrives.

HIPPEASTRUM (AMARYLLIS): *Thomas Gibbs.* An exceedingly fine flower, of rich flame colour, almost scarlet. In size it is quite remarkable, and is not unlike some of the varieties that have been exhibited by Capt. Holford; but whether a name has been given to an exactly similar one we are unable to say.

MOSS-LITTER AS A MANURE FOR TOMATOS: *Whitney.* If the material is allowed to heat and be turned and thrown into heaps about once a week till it is freed of much of its ammonia, and decay has set in generally, it is useful as a manure, especially with heavy loam.

NAMES OF FRUITS: *T. W. L.* Apparently poor fruits of *Ne Plus Meuris*.

NAMES OF PLANTS: *G. A.* We cannot undertake to name varieties of *Camellia*. Send the flowers to some nurseryman who grows them largely.—*J. G.* *Eupatorium Weinmannianum*.—*J. M. B.* *Cymbidium* × *eburneolum* of excellent quality. We remark on it in a paragraph, p. 154.—*C. C.* *Pittosporum undulatum*.—*Froggatt.* *Odontoglossum* × *Andersonianum*, a small variety of it.—*Dr. C. Ludlow.* *Odontoglossum triumphans*, a very fine variety of it.—*T. Denny.* *Cypripedium Boxalli*; we shall have something to say about the flower *C. exul* in a future issue.

PEAR DISEASE: *Trevince.* The shoots sent are affected with a fungus, *Nectria ditissima*, causing the so-called carker. Dress affected parts with coal-tar, or cut out down to living bark, and destroy by burning all infected material. It is also advisable to remove down to living healthy tissue. The infection is brought about by the germination of spores on wounded parts, pruned shoots and spurs, bruised and abraded bark, &c.

PRIMROSE SEEDLINGS: *C. W. D.* The seedling *Primulas* are attacked by the fungus called *Ovularia primulina*. The disease is mostly confined to the seedling stage. If the soil is thoroughly disinfected by heat, and the seedlings sprayed with dilute potassium permanganate solution, the disease can be held in check. *G. Massee.*

STOPPING CHRYSANTHEMUMS SO AS TO HAVE THE PLANTS IN BLOOM NOV. 20: *Careful Reader.* To know when to stop any of the varieties, and also the time when to take the buds, consult a specialist's catalogue.

THEORETIC INSTRUCTION IN HORTICULTURE: *Anxious.* Certainly we would advise you to participate in a course of theoretical instruction, as you will then gain an insight of the "reason why" of numerous practices of the gardener's art, with the result that you will be better equipped as a gardener, and better enabled to direct the labours of others. Without it you cannot expect to surpass your predecessors. With it you may make an advance on what they could do.

VINE: *Grapes, Tewkesbury.* There is no Phylloxera on the specimen sent, but the cause of the death of the Vine is not discoverable, unless it be the exhaustion of the soil in the pot (?) of all plant food.

WIRE TRELLISING: *R. T. H.* If it be a wall that is to be furnished with wire to which fruit-trees will be fastened, let common iron wire be employed, securing it with cast-iron studs, which can be bought at about the same price as cast-iron wall-nails. It is prudent to have the terminal studs about 2 inches long, and the intermediate ones 1½ inch. These and the wire, which may be about the size of ordinary packing-twine, i.e., one-tenth of an inch in diameter, will last many years. The wires should be fixed vertically, there being then no sagging owing to the weight of the branches; and being of short lengths there is no movement as in horizontal wires to cause rubbing of the kind. The wire should be placed at 7 inches apart, ¼ inch distant from the face of the wall, and be stretched very taut. All ties should pass once completely round a wire, and in the case of the branches of more than one year old, it should be twisted twice afterwards, so as to form a pad between branch and wire, and avoid contact of the two. A tied tree has a neater appearance than one that is fastened with nails and shreds; and an expert man will tie a tree almost as quickly as a good nailer would nail it.

DAFFODILS.

OF all vernal flowers, these are the most fascinating. They have also the longest reign, extending, as it does, from the death of the Crocus till the re-appearance of the fragrant Narcissus ornatus, an early form of *N. poeticus*. We do not "weep" now-a-days, like the olden English poet, to see them "pass away so soon." Perhaps in his day he had only the early and familiar Narcissus pseudo-Narcissus and the great *Telamonius plenus*; whereas we, who live in the golden days of hybridisation, have Daffodils in glorious and continuous bloom from the confines of March till the middle of May. Most of them also are comparatively easy of culture; in many instances the noblest varieties, such as Emperor and Empress, will increase year by year, if only they are assigned a suitable position, in deep, moist loam, with adequate drainage; while others of a hardier character, and even more accommodating nature, will, without any difficulty, become naturalised on lawns. The earliest variety here, growing in grass under the venerable, over-arching trees, with charming effect during the month of March, is the "Scottish Garland Lily" (*Narcissus scoticus*), where it has been, I

believe, for the last fifty years. It is a much more perfect flower than the English Lent Lily, to which, under its botanical name, allusion has already been incidentally made, and it is exquisitely serrated. I would not describe its perianth as white (unless the variety we possess is a hybrid), rather as being very pale primrose. My supreme favourites for garden-cultivation are the beautiful white-winged, or bicolor forms, all of which are exquisite, while several, in their size and substance and splendour, are nobly impressive. Among the grandest of these are the famous Weardale Perfection, whose price, unless to the affluent cultivator, is quite prohibitive, but which is unquestionably one of the most striking Daffodils in existence; Victoria (which I first saw at the Long Ditton nurseries of the Messrs. Barr), with creamy-white perianth and golden trumpet, gracefully fringed; J. B. M. Camm, remarkable for its beauty of form; the venerable Horsfield, raised by a flower-loving Lancashire weaver; Empress and Grandis, rivalling in their endowments the boasted beauty of Weardale, though perhaps not quite so large. Exceedingly decorative to our garden borders are also the pure yellows, of which some of the finest are the almost invincible Emperor, which I never weary of contemplating, so lustrous is its aspect during the period of bloom; Ard Righ, an early-flowering Irish creation, requiring for effective culture a half-shady situation; Glory of Leiden, a grand variety; Countess of Annesley, Golden Spur, a Daffodil of rare beauty, worthy of its name; and the highly distinctive Queen of Spain. The variety last mentioned, discovered in Spain by Mr. Peter Barr, I have not found very reliable or enduring; but I greatly fear that it did not find in my garden congenial soil.

Extremely interesting also are the "chalice-cupped" Daffodils (*Narcissus incomparabilis*), especially such fine forms as C. J. Backhouse, of a luminous yellow hue, with orange-scarlet cup, which was awarded a First-class Certificate by the Royal Horticultural Society; the greatly-admired Gloria Mundi, which received a similar distinction; Princess Mary, Queen Sophia, and the richly-coloured, highly-artistic Frank Miles. A very effective hybrid is Barri conspicuus, which should be found in every garden. Most charming in their influence are the "Eucharis-flowered," silvery-white Daffodils, of which some of the choicest varieties are Duchess of Westminster, Mrs. Langtry, Beatrice, Grand Duchess, Duchess of Brabant, and Princess of Wales.

The fair and fragrant successors of these are *Narcissus ornatus* and *N. poeticus*, which keep our gardens beautiful and odorous till the advent of the Rose. *David R. Williamson*.

NEW OR NOTEWORTHY PLANTS.

HELICHRYSUM VOLKENSH.*

(See fig. 50, p. 170.)

THIS is another of the African species which Mr. Gumbleton has succeeded in flowering. To him we are indebted for the specimen now figured by Mr. Worthington Smith, and which

* *Helichrysum Volkensii*, O. Hoffmann, in *Engl. Pflanzenzenc. Ost.-Afrik.* (1895), p. 410.

has been identified for us by Dr. Rendle. Like its congeners that have been recently figured, it is a native of the Kilima-njaro mountain in German East Tropical Africa, where it grows in the "highest zone of vegetation." It is of shrubby habit, the stems and branches densely covered with white, shaggy hairs. The upper leaves are about 4 cent. long, 3 to 4 mill. wide; sessile, ascending, linear, mucronate, with recurved edges, and more or less studded (especially on the under surface near the midrib) with small-stalked, capitate glands. The flower-heads in the specimen before us are about 2 cent. long, 25 mill. across, in groups of three. Bracts of the involucre membranous, lanceolate; outermost shorter, bright rose-coloured; innermost longer, whitish.

The plant before us differs from the type, as pointed out to us by Dr. Rendle, in having fewer heads of flowers on shorter peduncles; but this may be due to cultivation.

PASSIFLORA AMBIGUA.

Our illustration in fig. 51, p. 171, is of a new Passion flower, published in the current number of the *Botanical Magazine*, from which journal we extract the following particulars:—"The description of *Passiflora ambigua* cited under tab. 7822 is taken almost wholly from one kindly lent me by Mr. Hemsley. It was drawn up by him from a specimen which was raised from seed received in 1896 from Mr. E. G. Sturridge, nurseryman, of Blewfields, in Nicaragua, which flowered in the Palm-house of the Royal Gardens, Kew, in May, 1901. Mr. Hemsley regards its affinity [to be] so close with *P. laurifolia*, Linn. (Jacquin, *Hortus Vindobonensis* ii., t. 162), and *P. maliformis*, Linn. (*Bot. Register*, t. 94), as to suggest the possibility of its being of hybrid origin. Premising that *P. ambigua* is a very much larger plant, with flowers more than double the size, and with a differently coloured perianth, it further differs from *P. laurifolia* in the petiole, being biglandular in the middle, not at the apex, in the bracteoles being eglandular, in the leaves not being cordate at the base, and in the long filaments of the corona having obtuse not subulate tips. From *P. maliformis* it differs in the same characters of the leaf-base, size of flower, and long filaments of the corona, and also in the stipules being linear, not ovate with subulate tips." *J. D. H.*, in *Botanical Magazine*.

THE FORCING OF RETARDED PLANTS.

(Concluded from p. 155.)

LILIUM LONGIFLORUM.—This plant has been the least satisfactory with me, and I believe this is a somewhat general experience. The bulbs must be potted as soon as received, the potting being similar to that afforded to *Spiræas*; and they should receive but a very moderate amount of water, in fact, I never afford any before the soil is filled with roots. It is better to use moderately moist soil for potting than to apply water, and plunge the pots in Cocoanut-fibre refuse or finely-sifted coal-ashes in a cold frame. The pots should be frequently sprinkled or syringed. When growth has begun, carefully shade the plants, and place them near the glass in a house where a temperature of 50° can be maintained; when flower-buds show, a warmth of 60° should be afforded, but not higher than this. The bulbs may be potted at any time during the summer and autumn; those potted before September require from fourteen to sixteen weeks to bring them into flower, and proportionately longer as the season advances. Green-fly must be kept in check, or deformed flowers

will be the result. *L. lancifolium* and the variety *album* require the same kind of treatment, but a period of three or four weeks longer is required to bring them into flower.

AZALEA MOLLIS.

These plants should be potted as soon as received, put in a cold frame or the greenhouse, lightly shaded in bright weather, and syringed frequently till the flower-buds begin to open, but no longer. *Azalea mollis* requires careful treatment, or the flowers will be very short-lived. They must not be kept in a dry atmosphere, or one that is very moist, and soil should be kept moist.

In conclusion, I may state that these plants are not so lasting in apartments as naturally-grown plants, more especially *Azalea mollis*. But a great deal depends upon the treatment afforded, for should any of the details here set forth be neglected they will flag, and there is an end of them for decorative purposes. I have not by any means exhausted the list of retarded plants now on the market, such as *Deutzias*, double and single-flowered *Cherries*, *Pyrus*, and other useful subjects. *T. Arnold*.

ORCHID NOTES AND GLEANINGS.

CATTLEYA TRIANÆI WITH THREE LIPS.

A SINGULAR and rather pretty case of *peloria* is shown in one of the two flowers of an inflorescence of *Cattleya labiata Trianæi*, kindly sent by Mr. Brown, gr. to Geo. C. Raphael, Esq., Castle Hill, Englefield Green. One of the flowers is of the normal shape, a good and well coloured variety; the other in the arrangement of its parts seems to imitate an *Iris*, the nearly straight column having three labellums arranged round it like the standards of an *Iris germanica*. In each the normal form of the lip is tolerably well retained, though they are scarcely so large as that of the perfect flower. The colour is the same, viz., pale lilac at the base, orange in the centre, and bright purple in front. The sepals and petals are white, tinted with rose; the petals slightly stalked at the base, and both sepals and petals arranged round the showy centre of bright coloured labellum.

ODONTOGLOSSUM × ADRIANÆ "LIEUT. T. G. GIBSON."

The pretty set of natural hybrids between *Odontoglossum crispum* and *O. Hunnewellianum* appear tolerably freely among importations from a certain locality, and there is great variation both in the size and the markings of the flowers of the different forms. First there are a good number with small flowers of a crumpled shape, which are not much valued; then there are the dark varieties with yellowish ground colour, spotted with chestnut-brown, and more nearly approaching *O. Hunnewellianum*; and lastly the forms approaching *O. crispum*, which are much prized and valued according to the nearness to which they approach the typical *O. crispum* in the size and arrangement of their flowers. The best of that finest type which we have seen is *O. × Adrianæ* "Lieut. T. G. Gibson," kindly sent us by Mr. James Riddell, gr. to T. G. Gibson, Esq., Lesbury House, Lesbury, Northumberland, who names it after his son, Lieut. Gibson, who has for the last three years been serving his country in South Africa. The flower, which is nearly 3 inches across, is almost as broad in the segments as *O. crispum*; in colour white, with a purple tint on the backs of the sepals, which shows through to the surface. The sepals have each a group of

small red-brown blotches near the base, and one large irregular one near the tops, which are margined with primrose-yellow. The fringed petals have the middle portions blotched with red-brown. The lip is white, with pale yellow crest, above which are many small purple lines, and in front several red-brown blotches, the margin being toothed. It is said to have two spikes of ten and twelve flowers.

THE FERNERY.

THE TREATMENT OF HARDY FERNS.

FOR those who possess collections of hardy native Ferns, or who contemplate giving some space to choice varieties in shady

or division, taking care not to over-pot, a pot an inch wider being usually ample for a shift except for very robust varieties. The drainage should be carefully seen to, and if the old ball shows any signs of sourness, it is best to shake the Fern quite out, remove the dead roots, and repot in fresh soil. The best general compost is a mixture of equal parts of friable yellow loam and leaf-mould, or brown fibrous-peat, adding a dash of coarse silver or road sand to assist in keeping it open. Ferns which have developed a number of side-shoots or offsets should have these removed—a single crown always makes a better specimen, and shows the varietal characters to more advantage than when a crowd is permitted to accumulate. These offsets can be usually pulled away or split off with a blunt trowel or piece

FIG. 50.—*HELICHRYSUM VOLKENSII*: BRACTS BRIGHT ROSE-COLOURED.
(SEE P. 169.)

situations in the open or in cold conservatories with a northern aspect, March is decidedly the best month in which to over-haul or instal the plants. The Ferns are only just commencing to awake from their long winter sleep, and are thus not only in a vigorous condition, and best fitted to withstand the shock of removal or transmission, but are also the least liable to suffer permanent damage since the new fronds are all to come, and the old ones if damaged imply no great loss by removal. It is, however, advisable to retain these old fronds of ever-green species until the plants are re-established, and the new ones well advanced, cutting off only the obviously dead portions, or such as may show evidence of insect infestation in the previous season, as such evidence is always accompanied by the presence of eggs, which mean a later brood if not destroyed. Pots should now be cleaned, and their tenants attended to as regards repotting

of wood, and as they are furnished with their own particular set of roots, they only require potting-up or transplanting to form independent specimens. These remarks refer to such Ferns as Lady Ferns, Male Ferns, and other Lastreas, and Shield Ferns, all of which form central crowns, round which a complete set of fronds form a circle like a shuttlecock. The rambling species with travelling root-stocks, like the several Polypodies, the common Polypody, and Oak, Beech, and Limestone Polypodies are best left alone to form clumps, as their fronds spring up singly, and arrange themselves in such a way that they look best when well established. Under glass this tribe is best grown in shallow pans, room being thus given for lateral extension. Such Ferns can be propagated easily by cutting the rhizomes or root-stocks here and there, and pulling them asunder, when each piece with a growing tip roots, and a frond or two will make a plant. The pans should stand on,

not in, smaller saucers, which will catch and retain surplus water, and should not be allowed to become empty. On the other hand, it is not wise to stand pots in saucers so that they are constantly saturated; none but remarkably vigorous plants in full growth will stand such saturation long, as the soil is

sourness results, and growth, as we have found, is greatly stimulated, while the trouble of watering is reduced. Fern-beds in the open may now be cleared of absolutely dead fronds, but it is well to mulch, not bury, the crowns lightly with old leaves, to protect the incipient growth from drying winds, to which

to their houses on the north or east, where the satisfactory growth of flowering plants is impracticable, we cannot too strongly suggest the installation of a few dozen fine varieties of our native hardy Ferns, such as any trade list will indicate. With a little care, a collection of such plants will prove intensely inte-

FIG. 51.—PASSIFLORA AMBIGUA. (SEE P. 169.)

apt to become sour, and air is as necessary to roots as water for healthy growth. We have tried, and cannot too strongly recommend, for Ferns Sankey's well-pots, which have a hole in the side a little way from the bottom, and an earthenware diaphragm fitted loosely inside the pot just above the orifice. The bottom of the pot retains the surplus water, but as there is a space between this and the diaphragm, no

they are subject at this time of year. In planting such as is necessitated by the removal of divisions from crowded plants, care should be taken to give ample room for subsequent growth; the fault of most collections is overcrowding, in consequence of which a large proportion of the natural beauty is sacrificed.

To those who have conservatories attached

resting, as well as extremely decorative; the shade which is so adverse to the flowering plants, is the congenial element for the Ferns, if not overdone. The plants are as hardy as grass, and their diversity of form really wonderful, while their variation in size from the giant to the dwarf, admits of their use under any space conditions whatever. Chas. T. Drury, F.L.S., V.M.H.

MARKET GARDENING.

THE SOIL MIXTURE FOR CUCUMBERS.

THERE can be no doubt that the best results in the cultivation of Cucumbers are obtained with turf that has been in stack for twelve months, kept free from all weeds whatever and under cover. This will seem easier to try than to do, which I fully admit; such turf, however, providing it is kept dry and free from herbage, will be entirely free from nematodes, worms, and insect pests. What to do the first year, when, of course, no such soil is available, is to mix newly-dug, turfy loam with fresh horse-dung, using enough of the latter to set up strong heat in the body of loam, and after a few days to turn the heap, putting the outside into the middle in re-forming the heap, and then leave it for a week or two, after which space of time, there will be no insect left alive, providing the work has been properly done. Another method when no horse-dung is available, is to employ lime and soot, mixing these with the soil, which, as I have proved by experience, frees the soil from the insects that are the bane of the Cucumber-grower. Another method is to bake the sods made up into a stack on the top of a garden boiler, which however cannot be put in practice where large quantities of soil are required.

If a certain amount of fresh stable-dung be employed in the mixture, and it is at once brought into the Cucumber-house, it will heat slightly for a short time, and much more so if warm water be applied to it. When turf cannot be obtained cheaply, the best of what there is has to be made, and an effort made to make it fit for the purpose. Cucumber soil usually contains a large percentage of manure, and the absence of fibre in the mould is of less importance. The materials should be in a rough, unsifted state that will let water pass freely away, and remain in that condition for a few months. Cucumbers will succeed in it; whatever other ingredient is lacking can be added afterwards.

The market-growers and private gardeners like to see strong growth of leaf and shoot, but it is possible to make the soil too rich for the plants by supplying too much nitrogen in the soil; and seeing that soil in the form of top-dressing has to be employed, artificial fertilisers beyond what the soil mixture contains should not be used at first unless the soil is known to be poor or not quite suitable.

A Cucumber plant in full bearing takes from the ground principally nitrogen, potash, and phosphoric acid, and if these in the proper quantities could be added to the soil, good results would follow; but if we were to add any of these elements in excess of the demands of the plants, bad results would ensue. With too much nitrogen in the soil, the plants form very gross shoots and foliage, and do not crop so freely as short-jointed, moderate-sized shoots and leaves will do, and the fruit will take longer in reaching a usable size. The grower should test his fruit now and again, and the flavour will tell him if any mistake has been made in the treatment of the plants. A well grown Cucumber freshly cut has a pleasant flavour. Too much phosphoric acid in the mixture might be a gain in quality, but the fruit would be classed as seconds (in size) only; yet nothing would sooner stop the production of fruit than lack of phosphoric acid in the soil. Again, if too much potash is used the plants will not last for any length of time, and they will not, as the gardener says,

"break freely." The Cucumber-plants will absorb large quantities of potash to their detriment, and the cultivator must cut back the bine considerably. It should be remembered that some kinds of soil contain an abundance of potash, and manure may also be present.

From all this it will be seen that the making of a suitable Cucumber-compost is not an easy matter. The gardener should find out in what elements his soil is lacking and supply these, which is true of all cultures; but particularly with that of Cucumbers. A capital fertiliser for mixing with Cucumber soil is charred garden refuse, which is rich in potash and mineral salts, and is useful in imparting porosity.

Lime in some form is another necessary addition to a Cucumber-compost if it be not naturally found in the soil, as in the case of loams from chalky districts. If we see young plants when still in the pots producing

from November to January, while the earliest Pseudo-Narcissus does not begin to flower till the end of February. But as I planted the bulbs of the first specimen (Paper-white) in December, it flowered here at the same time as the latter (Daffodil), and so their fecundation was somewhat easily effected.

The following is a description of the hybrid:—

Bulb globose, somewhat smaller than that of the mother, covered with thin, light brown tunics. Leaf linear, light green, not glaucous; 1 to 1½ ft. long about ½ to 1 in. broad. Peduncle shorter than the leaves, about a foot long, or a little longer, veined with two prominent edges; flowering from February to March. Pedicels irregular, shorter than the spathe. Flowers two or three, closely united, fragrant. Perianth milky-white, ascending, tube funnel-shaped, green on the base outwards; segments concave, acute, as long as the tube; corona cup-shaped, truncate, about half as long as the segments, milky-white on their base, sulphur-yellow on the upper part. Stamens and style variable, the latter much shorter than the stamens. Quite sterile, as I believe.

FIG. 52.—NARCISSUS MARGARITE "IOLANDA."

flowers, it might safely be taken that it does contain enough lime. A disadvantage in the use of lime is that it sets part of the ammonia free. If the soil is clayey, lime will form a very good addition [but it should take the form of quicklime, and be distributed throughout the soil whilst it is still in the heap, and before it is put on to the beds. ED.]. A. A. Fabius, Redlands Nursery, Emsworth.

HYBRID NARCISSI.

NARCISSUS × MARGARITE "IOLANDA" (NARCISSUS PAPYRACEUS × PSEUDO-NARCISSUS), (see fig. 52).

AMONGST my new hybrid Narcissus are some very fine and graceful specimens, flowering at the end of February, and to-day (March 4) in their full glory. It was somewhat difficult to hybridise the two different species, as *N. papyraceus*, known in gardens under the old name of "Paper-white Narcissus," flowers very early here

This very fine hybrid Narcissus flowers here in my garden near Saint Elmo luxuriantly, and will become, when more known, a favourite, if it prove hardy in English gardens; but that is doubtful. Ch. Sprenger.

NARCISSUS × SPRENGERI, Baker, in *Gardeners' Chronicle*, VAR. VOMERENSIS (*N. TENORII* × *PSEUDO-NARCISSUS*), (fig. 53.)

Bulb very large, ovoid. Leaves six or more, broad, linear, somewhat glaucous, erect, or ascending, flattish, much longer than the peduncle; this is about 1½ ft. long, striated, cylindrical, with two slightly prominent edges, flowering in February to March. Pedicels irregular, shorter than or as long as the spathe. Perianth spreading, or slightly ascending; tube large, funnel-shaped, longer than the segments. Segments ovate-oblong, acute, ascending, pale sulphur-yellow. Corona fine golden-yellow, as long as the segments, cylindrical, erect, sometimes plicate, undulate, irregular, crenate. Stamens and style very short. Stamens erect, much longer than the style, inserted low down the tube, but deeper than in the pseudo-Narcissus. Flowers mostly three on the stalk, very fine, fragrant.

As it seems, this hybrid is quite sterile. A very splendid garden hybrid, of great interest. It is in flower here now for the first time.

NARCISSUS × SPRENGERI, Baker, VAR. ELMENSIS (N. TENORII × PSEUDO-NARCISSUS VAR.), (fig. 51).

Bulb large, ovoid. Leaves four to six, linear, glaucous, erect, canaliculate. Peduncle shorter than the leaves, with two prominent edges; flowers produced from February to March. Pedicels irregular, shorter than the spathe. Perianth horizontal, not ascending; tube greenish-yellow, funnel-shaped, as long as the segments. Segments splendid lemon-yellow, spatulate, undulate-acute, longer than the corona. Corona golden-yellow, cylindrical, erect, plicate, irregularly inciso-crenate as is the case in the flowers of the male parent. Stamens and style much shorter than the corona. Stamens not erect. Style much longer than the stamens. Flowers very fragrant.

A magnificent new hybrid, flowering for the first time. *Ch. Sprenger, Naples.*

of seeing for themselves what is being done with Primulas and Cyclamens.

With double-flowered varieties of the first, great progress has been made, which renders the plants of this section more easy of cultivation as compared with the older method pursued with the ordinary double-flowering Primula. No fewer than six distinct varieties are now in commerce. Added to this, a double-flowered form of *The Duchess* has been obtained which cannot fail to become popular, possessing as it does the colour of that variety.

Much progress, too, has been made with the *Carnation flaked strain*, in which formerly there was so much more white than purple;

maintains its place for the purity of the white flowers, even the latest exhibit no tinge of any other colour, and it is quite the earliest to flower where early-flowering bright coloured Primulas are valued; the variety *Reading Scarlet* is indispensable. Very fine are the individual blooms of *Reading Blue* and *Cambridge Blue*, which have but few leaves, and the style of growth is very effective and the plants very dwarf, and of remarkable freedom in flowering. *Rosy Queen*, a Fern-leaved variety, is desirable, the habit good. The *Duchess* is still as fine as when introduced in 1900, and is perhaps the showiest Primula, the rosy-carmine centre being so telling a feature.

FIG. 51.—NARCISSUS SPRENGERI ELMENSIS.

NURSERY NOTES.

PRIMULAS AND CYCLAMENS AT MESSRS. SUTTON AND SONS'.

A CHARMING contrast to the weather outside was afforded by the houses on the occasion of a recent visit. The Primulas were in full flower, but the Cyclamens had been at their best shortly before.

It may be the last time that we shall see this yearly display in their present quarters. As happens in most well-conducted businesses, Messrs. Sutton have found the demands of their customers have outgrown the capabilities of the existing premises, and they contemplate removing the glasshouses to a much more commodious site.

A few lines on what came under notice may have an interest for many readers of these pages, who may not have had the opportunity

but now the flaking is much more decided. The flowers of this strain are especially telling by artificial light. The white-flowering forms with dark leaf-stems are also found more effective on the plants than these varieties having green leaves and stems. The deeply-fringed flowers come in compact trusses on short stems, and are freely produced. The improved double scarlet is now as rich in colour as *Crimson King*, which is one of the brightest of Primulas.

Among single-flowered forms there were many handsome types observed, but the one which struck me most was *Pearl*, a variety that still holds its own. Twenty-one years have elapsed since Sutton introduced this variety, and it is still a very popular variety. The plant is of robust growth, and the flowers come in large trusses, making it a very effective plant.

Royal White is another favourite; *Snowdrift*

The giant single-flowered forms, in a variety of colours, are a distinct gain; the magnificent flower-trusses and flowers, some of the latter 3 inches in diameter, render this type very valuable in decorative work. *Giant Pink*, *Giant Crimson*, and *Royal White* are desirable forms, the first being especially effective.

Star Primulas have a future before them, seeing what a great variety of colour has been obtained, and how useful they are for cutting. No fewer than seven distinct colours are offered. *White Queen* is especially free; *Mont Blanc*, with dark Fern-leaves, is become a very popular variety. A Primula having flowers white, splashed with purple flakes is attractive; pink and salmon colours are pleasing. *Giant White* produces flowers fully 1½ inch in diameter, remarkable for great substance in the segments. *Carmine* is, perhaps, the most desirable in the star sections under artificial

light. Taken as a whole, the star types of *Primulas* are sure to become popular.

Cyclamens.—Although somewhat past their best, it was easy to see that the plants, now carrying a full crop of seed-vessels, had been very floriferous, the Giant forms of almost all the popular colours having been especially showy. Salmon Queen is much improved since last season, as are the Giant forms of Vulcan and Giant White, which last is much improved. Butterfly still maintains its hold on the public by the quality of its flowers, and is distinctly the best of the latifolius type. E. M.

The Week's Work.

THE ORCHID HOUSES.

By W. P. BOUND, Gardener to J. COLMAN, Esq., Gatton Park, Reigate.

Vandas.—Most of these plants may be grown in the same house as the *Aërides*, and afforded the same kind of treatment, but if *V. coerulea* be placed in the stove during the growing season, it should be removed to the *Cattleya*-house during the resting season. At Gatton we leave the plants all the year round in the *Cattleya*-house, and keep them dry during the winter months. Imported plants may now be obtained cheaply. On receiving such plants, thoroughly cleanse them before putting them into the houses. When this has been done, suspend them head downwards in a cool shady house, and slightly spray them once or twice a day till they show signs of root action, then pot them up in the compost advised for *Aërides*. Make the pots two-thirds full of crocks, and in potting let the leaves be brought as near as possible to the level of the compost, cutting away a portion of the old stem, and letting a further portion go down amongst the crocks. Keep the plants well shaded, and syringe frequently between the pots; but until the roots have made a good start, the compost should be kept fairly dry.

Dendrobiums.—Many of the plants, having flowered, are throwing up the young growth, and when this has got about 3 inches in length is the proper time to repot. The wholesale repotting of *Dendrobiums* is not to be recommended, and only those that have reached a certain stage should be repotted. The compost may consist of turfy peat one-half, good leaf-soil one-quarter, and chopped sphagnum-moss one-quarter, all being mixed together. A fair amount of drainage is needed by plants standing on a stage, but the *Dendrobium* requires something more than crocks upon which to feed, and the amount of material must be in the discretion of the cultivator. In cases where water can be dispensed with care and judgment, but little drainage is necessary; on the other hand, if water has to be applied to batches of the plants, then give good drainage in the pots. Suspended plants in pans, &c., do not need much drainage material. Young, healthy plants simply requiring to be shifted should not have the ball of material disturbed beyond removing the compost at the top, unless it has become sour, or is worn out. Older plants, and especially such as have only leading growths near the rim of the pot, should be pulled to pieces and the older parts removed, not more than two pseudo-bulbs behind the leading bulb being retained, and the divided portions placed together. By this means the same number of leads are obtained, but in a smaller pot, and the health of the plant is maintained. *Dendrobiums* should be potted rather firmly, and the base of the leading growth kept a little below the rim of the pot. At the finish, insert three or four clumps of live sphagnum-moss on the surface, which are of assistance in the summer months by reason of the moisture thereby being retained. Repotted plants require scarcely any water at the root for some time, if the house be kept moist. The critical stage is when the roots begin to emerge from the new growth, and no water must be applied then unless the compost is thoroughly dry; and the right time for so doing is early morning.

PLANTS UNDER GLASS.

By J. C. TALLACK, Gardener to E. MILLER MUNDY, Esq., Shipley Hall, Derby.

Hippeastrums.—These, where they have been retarded, will now be pushing up their flower-shafts, and should be brought into a warmer house, and afforded one good application of water or manure-water, and no more till the leaves begin to develop.

Shading will soon be required, *Anthuriums* especially needing much attention in this particular.

Gloriosa superba.—Pot the bulbs in a mixture of peat, leaf-mould, and loam, and a large proportion of sand, and place a handful of it and some decayed cow-manure round each. The soil being moderately moist when used, no water will be required till growth is being made. The best sized pot is one of 10 inches in diameter, which does away with the necessity for repotting.

Winter-flowering Carnations.—Let all young stock be potted off singly when rooted, and be grown on rapidly in rich sandy loam, which is the best sort of soil for them in the early stages. Those plants which were potted earlier may remain for the present rather close to the glass, in a house having a temperature at night of about 60°, and be sprinkled lightly twice or thrice daily. Pot off later cuttings as they become rooted, using for them a mixture of loam, leaf-mould, some decayed manure well pulverised, and a considerable proportion of silver-sand. Let the potting be fairly firm, but do not ram the soil, it being advisable for the present to let the roots run freely in the soil. Earlier struck plants potted singly should be shifted as soon as the roots begin to coil round the sides of the pots, but not affording large shifts.

Souvenir de la Malmaison Carnations.—The best place for these varieties in the winter is a vinery shelf, but as Vines will soon be growing, this position will be no longer suitable for the plants, and they must be removed to another house, where a slight amount of shade may be afforded when the sun becomes powerful. Small and weak layers occupying 60's should be shifted into 5-inch pots, and grown on for flowering next year, it being unlikely that they will produce good blooms this year.

Hard-wooded Plants.—Continue the potting of such plants as have flowered, and are starting into fresh growth, as when caught in this condition they do not suffer from lack of movement at the root, or from having much new growth to support. *Azalea indica* which flowered early should be repotted if the pots are too small, but if they are large they will, if other conditions are right, grow and flower well for several years in the same pots; and if much bigger plants are not desirable, repotting is best left alone. Old plants, or those which may have got into an unhealthy state, may sometimes be restored to health by cutting back into the old wood, removing all weak shoots, placing the plants in a forcing-house, and syringing them frequently.

FRUITS UNDER GLASS.

By JAMES WHYTECK, Gardener to the DUKE OF BUCCLEUCH, Dalkeith.

Earliest Peach-house.—The severe weather and unusual absence of sunshine experienced in February caused the gardener to place his entire dependence upon artificial heat, which together with a lack of fresh air, has resulted in the Vines making slow progress. Patience must be exercised, and till stoning is finished and the second swelling begun, the temperature should not exceed 60° at night, and 70° to 75° by day, affording as much air as is safe, but not when the north or east winds prevail. Just sufficient young shoots should be left for next year's bearing wood, with plenty of shoots towards the centre of the tree; but do not crowd the shoots. Sometimes shoots must be removed which have fruits at their bases, in such cases shorten the shoots to three leaves.

The use of much fire-heat will have favoured the increase of red-spider, and heavy syringings morning and afternoon, with occasionally a weak mixture of soft-soap specially made for horticultural purposes, should be applied. I use Bentley's, which is also a good anti-mildew preparation.

The Peach-house started in January.—The trees in this house are nearly as forward as in that which was started one month earlier, and the same kind of treatment applies to it. The inside border is not likely to be dry, the constant syringings and mulch of dung on the surface having kept the soil moist; but where trees are not growing strongly, apply a Vine-manure, and then water copiously when water becomes necessary. This kind of treatment attracts the roots to the surface, and produces fruitful wood, as well as swells the fruit to a fine size, even in poor soils.

The Peach-house started at the beginning of February.—If the fruits have set very thickly, there will still be some that need removing at this the second thinning; but do not remove all, rather reserve some for another thinning in a week or ten days. The treatment is the same as for the earlier houses. If aphides infest the trees, syringe with quassia-water, fumigation being risky. With lengthening days and more sunshine, this Peach-house will progress more rapidly than the earlier ones. Maintain a night temperature of 60°, and close in the afternoon with sunheat at 80°. Syringe the trees twice a day, and keep a moist but not stuffy atmosphere; and help the swelling of the fruits with Vine-manure sprinkled on the soil, washing it in with tepid water, or employ weak manure-water from the cowhouse instead. The trees that are to provide ripe fruit in July and August should be kept at 60° by night, and be treated generally as directed for trees started a month earlier. The trees in the latest house should be kept back as much as possible with all the ventilators open, but when the flowers open, let the night temperature be 50° to 55°. Guard against frosty cutting winds; damp the paths occasionally, and afford air night and day.

THE HARDY FRUIT GARDEN.

By J. MAYNE, Gardener to the Hon. MARK ROLLE, Bleton, East Budleigh, Devonshire.

The Fig.—After this date it is safe, even in the colder districts, to remove protective materials from the trees. This done, remove the very thin and the more sappy, gross shoots; and in fastening the shoots to the wall or fence, do not crowd them together so much as to obstruct the sunlight, or the wood will be ill-ripened, and the fruit-crop the next year a poor one. A space of from 12 to 15 inches between the chief branches will allow of good space to lay in lateral shoots for next year's bearing.

The Pear.—In less favoured counties than Devon, Pears usually occupy warm walls, as in the case of Apriots and Peaches here. Where this is the case, and no provision exists for the protection of the blossom, spruce fir-boughs placed thinly over the earlier flowering varieties, which will soon be opening their flowers, will afford protection from hoar frost.

Grafting.—It is yet early to begin to graft, though much depends upon the season in regard to this kind of work, and not a little on the locality. In the south-west, grafting is fully three weeks in advance of the north; and, as a rule, no grafting should be done till the sap has begun to flow in the stock, that is, from the middle of March—the present month, and the operation may be carried on till the end of the month of April. Apples and Pears are the fruits which the private gardener mostly grafts, substituting good in place of inferior varieties on trees of moderate age that are healthy. Such trees usually bear fruits the second year, and the crop increases year by year if the seasons are favourable. The branches that are grafted should not be

more than 6 inches long, measured from the stem, and the ends should be made smooth with a chisel or knife before grafting begins. The scions should consist of mature one-year-old wood, and possess two to four wood-buds, according to the strength of the stock. The saddle-graft is most in vogue in the west, withstanding wind much better when in leaf than the side or whip-graft, though it requires support as growth increases. Crown-grafting is a very simple method, and is done by cutting the rind about 2 inches or so down the stock, and inserting the wedge-shaped scion, having a shoulder cut out so as to rest on the top of the stock; while for large trees, cleft-grafting is about the only means of tackling them, and often two scions are put in at one operation by splitting the stock with a chisel, and inserting two wedge-cut scions, one at each end of the cleft, and making sure that the barks of stock and scion coincide. Whip-grafting, too, is much in use, and when stock and scion are about of a size, it is a successful method. First remove a slip of wood and bark in an upward direction on the stock, and a similar one from the scion with a tongue to fit into a cleft made in the stock. The whip and the saddle-graft hold the scions better, but have no other merit. Tying-in the grafts needs to be done firmly, but not so as to cut into the bark; and raffia is as good as anything for the purpose. Claying a graft consists of forming an egg-shaped mass of clay and horse-dung round the point of union for the purpose of excluding moisture, and preventing the drying-up of the scion; but grafting-wax is much better than clay, and more easily applied.

THE KITCHEN GARDEN.

By T. TURTON, Gr. to J. K. D. WINGFIELD DICBY, Esq., Sherborne Castle, Dorset.

Small Seeds.—Good breadths of the seeds of the following vegetables may now be sown on warm borders, viz., Brussels Sprouts, for the main crop; Pearl and Autumn Giant Cauliflower, Earliest-of-All Cabbage, Winter Mammoth and Christmas White Broccolis, Early Horn Carrot, Sutton's White Gem and Early White Milan Turnips, Globe or Turnip-rooted Beet, for an early supply of roots; and long-rooted and olive-shaped Radishes. All of the above, excepting the Radishes, should be sown in drills made at 1 foot apart. The Radishes may either be sown in drills at 8 inches apart, or broadcasted in beds having a width of 4 feet in the case of the latter, raking the seed into the ground and afterwards patting it with the back of a spade. If small birds are troublesome, especially greenfinches and chaffinches, protect the seeds with nets as soon as sown. Stout sticks, about 3 feet long, placed along the back and front of the border, to which stout lacing wire to carry the nets is easily fixed, is the most effectual way of protecting the seed.

Lettuce.—Make a good sowing of Perfect Gem or Commodore Nutt broadcast, but very thinly, on a sunny border on a well enriched soil, and sow very thinly in drills drawn at 15 inches apart, seeds of the Paris White Cos. Where convenience does not exist for raising White Cos Lettuce-plants under glass, those raised from seed sown now and thinned early, grow away without check, and afford fine Lettuces in succession to those raised in the autumn. Plant out Brown Cos wintered in cold frames or from the seed-bed. If planted on a cool border they will succeed those planted out last autumn on warm borders.

Parsley.—Make a small sowing forthwith on firm soil in a warm position. This will succeed last year's old Parsley bed when the latter affords no more good pickings.

Peas.—Make sowings in quantity, according to the expected demand, from this date, at the least once a fortnight; and a good rule to observe in regard to Peas is to sow as soon as the last sowing is well through the soil. Peas of the Ne Plus Ultra type afford better returns

if sown during March, than at a later date. Sow at the same time Duke of Albany from a reliable stock. In regard to heavy cropping and superior flavour, these two Peas for second early and midseason supply are difficult to surpass. They grow well in most soils. From this date seed may be sown in shallow trenches taken out with spade; and after covering the seed about 1 inch, the soil in the trenches should be about 3 inches below the general level, and the depth should be increased as the season advances. Peas coming through the soil must be protected from sparrows with Pea-guards, or by running three rows of black thread over each row, making fast to sticks placed 6 yards apart, and 1 foot above the ground. Black thread is much more effectual than white, which the sparrows avoid. In northern parts of the country where early Peas are raised in pots or in other ways, these should now occupy cold pits or frames, and should be well hardened off. I have long since given up raising early Peas in this way, as from sowings made on a warm border as early as the state of the ground will admit in January, these come up on the first change to open weather in February and grow away; even after a month of continuous frost, our earliest Peas sown on January 13 on a warm border, and also in the open quarter, were well through the ground at the beginning of the present month.

THE FLOWER GARDEN.

By R. DAVIDSON, Gardener to EARL CADOGAN, Culford Hall, Bury St. Edmunds.

The Rosary.—A commencement with the pruning of the bushes, &c., may now be made, choosing first the hardiest Roses. Although the methods of cultivation adopted with these varieties is varied, and must in their nature differ, the end in view is the same, viz., the suppression of certain parts to promote the building up of others. Strong-growing varieties of H.P.'s and H.T.'s should have all unripened growths cut hard back, and the stout, well-ripened shoots retained at from 14 inches to 18 inches in length, and the wood of three and four years old cut out of the centres as far as may be practicable. Moderate-growing varieties may be left at from 8 inches to 12 inches, and weak-growing ones at about three buds from the base. If pegging down is desirable, let long shoots be retained, and bend down and peg them early next month. Roses which are grown for furnishing flowers for cutting require but little pruning beyond the cutting away of dead wood, and regulating the shoots. Some varieties of Teas and Noisettes will, in some localities, have suffered from frost, and stand in need of having the dead portions removed down to living wood. The plants that have thus suffered will lose much of their vitality, and the display of blossoms will be poor. Standards, than which no other form of training the Rose is more ornamental when the plants are well grown, may have the branches carefully pruned and regulated as to the distance they stand apart, and according to the habit and vigour of the variety. Test every stake, and put new ones where they are required, making all ligatures secure, and using neat pads of leather or cloth to preserve the bark from friction. Afford all beds, borders, and solitary plants a dressing of rotten cow-manure, forking it carefully into the soil.

Evergreen Shrubs.—Isolated specimens of Laurel, in order to maintain the desired character in form, may have the strong shoots neatly cut back, and the whole surface of the crowns made even with the knife. The common Laurel is a useful shrub for massing; and for covering slopes it should be cut quite low down. Where hollies are used for topiary work, the same kind of pruning may be carried out at the end of the present month. With the advance of spring, specimen plants growing in tubs must be afforded water copiously at the root, and occasionally some artificial manure and soot-water.

FRUIT REGISTER.

PLUM ANNA SPÄTH.

This variety is figured in the February number of the *Bulletin d'Arboriculture*, &c., and is described as a tree of vigorous growth, hardy, and fertile. The fruits are about 2½ inches long, oblong, a little flattened at both ends, purple, with a bluish "bloom"; flesh Apricot-coloured, juicy, and of good flavour. It flowers late, and ripens its fruit in October.

APRICOTS.

M. Mouillefert, in a recent number of *Le Jardin*, gives a description and a coloured figure of two varieties of Apricots, which he considers to be primitive forms of the Apricot. These varieties were found in Cyprus, where they bear freely, the fruits being largely used for culinary purposes. The varieties are reproduced from seed.

NURSERIES IN THE UNITED STATES.—We take the following figures from the *American Nurserymen*. They show some of the results of the late census, and indicate very strikingly the differences between the state of affairs in 1890 and in 1900. The figures give the number of nurseries in certain States, and the value of the products in dollars:—

| State. | 1890. | | 1900. | |
|---------------------|-------|------------|-------|------------|
| | No. | Value. | No. | Value. |
| Alabama | 15 | \$ 272,152 | 22 | \$ 179,300 |
| Arkansas | 68 | 80,410 | 47 | 101,455 |
| California | 166 | 4,158,851 | 141 | 1,725,945 |
| Colorado | 23 | 106,250 | 21 | 121,925 |
| Connecticut | 20 | 146,509 | 23 | 284,600 |
| Delaware | 35 | 111,805 | 11 | 49,900 |
| Idaho | 8 | 124,000 | 6 | 67,025 |
| Maine | 41 | 180,912 | 16 | 78,400 |
| Massachusetts | 120 | 1,393,666 | 49 | 314,600 |
| New Hampshire | 5 | 8,166 | 8 | 32,000 |
| New Jersey | 145 | 1,712,464 | 54 | 646,475 |
| New York | 530 | 10,609,806 | 237 | 3,607,107 |
| Pennsylvania | 311 | 3,134,780 | 95 | 944,790 |
| Rhode Island | 9 | 36,000 | 9 | 185,300 |
| Vermont | 17 | 35,000 | 4 | 28,500 |

A PLANT THAT CATCHES CHICKENS.—In the *Journal of the Department of Agriculture of Western Australia*, there lately appeared an account of a plant which is described as being a perfect death-trap for chickens. As they feed or play amongst it, it enmeshes them, lacing them round with its long tendrils as with so much twine, and holding them until they are released or die of starvation. Seven chickens about a fortnight old were rescued from the plant in one day. The matter being referred to the Government Botanist, he (Dr. MORRISON) replied:—"The plant is *Boerhaavia diffusa*, a native of all the Australian States and of Polynesia, and the warmer parts of Asia and Africa. It belongs to the natural order *Nyctaginaceae*, and probably like other species of the same family, possesses medicinal qualities. More commonly, the plant is not provided with hairs, but in the form sent it is covered all over with erect, jointed, rigid, or almost spiny hairs of varying length, and to these it owes its faculty as a chicken-catcher. The chicken is caught by these stiff hairs fixing themselves on its tender skin under the young feathers, and the more the bird struggles the more the flexible branches become wound round its body and its escape becomes more hopeless."

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

APPOINTMENTS FOR THE ENSUING WEEK.

| | |
|---------------------|---|
| WEDNESDAY, MAR. 19. | Torquay Gardeners' Society, Spring Show is postponed until 26th inst. |
| | Royal Botanical Society, Meet. |
| THURSDAY, MAR. 20. | Linnean Society, Meeting. Horticultural Show in Manchester Free Trade Hall. |
| FRIDAY, MAR. 21. | Special Meeting, Royal Hort. Society, at the Drill Hall, Buckingham Gate, at 3 p.m. |

SALES FOR THE WEEK.

| | |
|----------------------|---|
| MONDAY, MARCH 17.— | Lilies, &c., by Protheroe & Morris at 12.0. |
| TUESDAY, MAR. 18.— | Greenhouse Plants, &c., Aberdeen Park Nurseries, Highbury, by Protheroe & Morris, at 12.0.—Roses and other Plants, by Pollexfen & Co. |
| WEDNESDAY, MAR. 19.— | Roses and other Plants, at Stevens' Rooms.—Azaleas, Palms, &c., by Protheroe & Morris, at 12.0. Lilies, &c., at 5 p.m. |
| THURSDAY, MAR. 20.— | Roses and various Plants, by Pollexfen & Co.—Dwarf Japanese Plants, &c., by Knight, Frank & Rutley, 9, Conduit Street, W. |
| FRIDAY, MAR. 21.— | Lilies, &c., by Rendell & Searle, at 12.30.—Orchids, by Protheroe & Morris, at 12.30. |

(For further particulars see our Advertisement columns.)

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three Years at Chiswick —43° 0'.

ACTUAL TEMPERATURES:—

LONDON.—March 12 (6 P.M.): Max. 54°; Min. 43°.

March 13.—Fine.

PROVINCES.—March 12 (6 P.M.): Max. 53°, Scilly; Min. 39°, Orkneys.

THE PROPOSED HORTICULTURAL HALL.

WE have been requested to publish the following notices:—

ROYAL HORTICULTURAL SOCIETY,
117, Victoria Street, S.W.

Notice is hereby given, that a General Meeting of the Society will be held at 3 p.m., on Friday, March 21, at the Drill Hall (London Scottish), Buckingham Gate, S.W., to receive from the Council and, if approved, to adopt a report recommending a proposed site for a horticultural hall and offices.

Fellows are requested to show their tickets at the door. None but Fellows will be admitted.

By order of the Council, W. WILKS, Sec.

It is important that all Fellows should endeavour to attend this meeting.

REPORT

Presented to the Council of the Royal Horticultural Society by the New Hall Committee, February 25, 1902.

GENTLEMEN.—Your Committee was appointed on June 4, 1901. It consisted of Baron Sir Henry Schröder, Bart., Chairman; Sir Trevor Lawrence, Bart., V.M.H., Harry J. Veitch, Esq., F.L.S., Dr. Masters, F.R.S., N. N. Sherwood, Esq., V.M.H., Rev. W. Wilks, M.A., Secretary. It has since been enlarged by the addition of the Rt. Hon. the Earl of Ilchester, and Henry B. May, Esq.

The Committee was appointed "to consider the question of a Horticultural Hall, and to report thereupon to the Council.

Your Committee has held fourteen formal meetings, besides several informal, for the inspection of sites by various members of the Committee.

At the first meeting, Baron Schröder made a statement in regard to finance, concluding with the words, "The financial part of the question need not cause any insuperable difficulty." It was therefore decided that the first matter for the Committee to engage upon should be the finding of a suitable site.

Five different sites have been very carefully inspected and enquired into, with the result that four have been dismissed as unsuitable for one reason or another.

Your committee strongly advise the adoption of the fifth site, which they regard as suitable for the Society's purposes, all circumstances considered. They do not believe that any better site can be obtained which would not prove to be altogether beyond the financial resources likely to be available.

The first site investigated was that known as Niagara, covering an acre of land (about 40,000 square feet), and with a large circular building. The price of the freehold was fixed at a little over £100,000. Probably at least £5000 would have been required for adapting the building for the Society's purposes, and another £5000 or more for building suitable offices. The rates and taxes would also have been exceedingly heavy. Long and careful consideration was given to this site, but after the fullest enquiry with regard to borrowing upon the freehold, and the rate of interest required, Baron Schröder announced at the fourth formal meeting of the committee that the rate of interest required for borrowing on Niagara is so high that, considering the large initial outlay required, he had reluctantly but decidedly come to the conclusion that the property was too large and too costly to be further entertained.

The second site was one in the Buckingham Palace Road, containing 15,190 square feet. This site also received careful consideration, but was eventually dismissed, on the ground that a rent of £700 a year, coupled with an obligation to expend at least £20,000 on buildings, was too high a price for the Society to pay for a lease of eighty years only.

The third site was bounded by Vauxhall Bridge Road, Francis Street, and Carlisle Place, and included the fine building suitable for offices, &c., known as the Old Cardinal's House. The whole site proposed contained 22,500 square feet. This property commended itself strongly to the Committee, but it had the disadvantage of belonging to three different owners, and also of involving the necessity of obtaining certain permissions from the London County Council. As soon as definite negotiations were entered into with the various owners, it was apparent that an agreement as to price could not be arrived at, and this site was most regretfully dismissed.

The fourth site was in Francis Street, consisting of 15,000 square feet, but the rent asked, viz., £1,400 a year for a long lease, was considered to be beyond the Society's means.

The fifth site is in Vincent Square, at the corner of Bell Street. It has an area of 17,565 square feet, and the rent asked is £690 a year for a lease of 999 years. (The present Drill Hall contains 7,200 square feet.) Your Committee recommend the adoption of this site.

The Ecclesiastical Commissioners, the

owners of the land, stipulate that a sum of not less than £15,000 should be spent on a building and offices, and your Committee are advised that the rates would not exceed £400 a year, which with the rent would make an annual expenditure of £1,100; or after deducting the present cost of hall and offices, £320 a year, it would involve an increase of expenditure of £780 a year. The approaches to Vincent Square are not at present all that could be desired, but two new roads are already decided upon; one direct from Francis Street, starting from exactly opposite the New Cardinal's House; and the other from Horseferry Road, to the corner of the site in question in Bell Street.

In considering the extra annual cost, your Committee have not made any calculation of either the additional expense of caretaker, light, and fuel, nor for the possible income from letting part of the buildings to horticultural societies, or the great hall for meetings, &c. Your Committee believe that a sufficient sum to cover the erection of the necessary buildings may be raised by public subscription, towards which promises amounting to £8,000 have already been received. Signed on behalf of the Committee, TREVOR LAWRENCE.

MEMORANDUM by the COUNCIL.

The Council of the Royal Horticultural Society consider it desirable at the present juncture to make to the Fellows a general statement of the policy they intend to pursue.

The Council are fully aware that a considerable number of Fellows desire that a garden better situated than Chiswick should be secured as a memorial of the centenary of the Society.

It was also shown unmistakably at the late general meeting that a widely-felt desire exists that a better Hall and offices should be provided, which the Society would have completely under its own control.

The Council desire to carry both these objects to a successful issue, and looking at the history of the Society during recent years, they see no reason why this should not be done.

The practical question at the moment is, which of the two shall have precedence, as they certainly cannot both be proceeded with at the same time.

The policy of the existing Council is to endeavour to secure first a suitable Hall and offices near those now occupied at Westminster, and when that is done, to devote their attention at once to the acquisition of a site for a new garden.

The reasons which actuate the Council in adopting this order are many, and among the more important are the following:—

1. They consider it to be the more generally acceptable to those Fellows who take an active part in promoting the welfare of the Society.

2. They have already received promises of financial support to the extent of £8,000 towards the building, whereas no such support has at present been tendered towards securing a garden.

3. A site for a Hall, 400 yards from Victoria Street, and in a rapidly improving neighbourhood, as good as can ever be expected to be within the means of the Society, is at our disposal.

4. The Council are of opinion, and have

been professionally advised, that the rent asked is a moderate one, and is within the means of the Society. The proposed lease is for 999 years, which is equivalent to a freehold.

5. They are also of opinion that the provision of a good Hall and offices would in itself attract a large number of new Fellows, and would in that respect help the subsequent acquisition of a garden.

It should be noted that it has been found necessary to take the decision of the Fellows without any delay, owing to the obligation of terminating certain leases at Lady-day.

The Council confidently appeal to the Fellows, of whom they hope to see a full attendance at the Drill Hall on the 21st at 3 P.M., to support the policy briefly outlined in this memorandum. They trust that the Fellows will not allow the Society to be placed in the undignified position of doing nothing to celebrate so memorable an occasion as its Centenary, which would be the probable result of the rejection of this proposal.

The Council hope to be in a position to place preliminary plans and estimates before the Fellows on the 21st. Having regard to the unbroken continuance of large additions to the Fellowship roll, and to the ever-increasing interest taken throughout the Empire in every branch of horticulture, the Council feel that they will not appeal in vain for the funds necessary to provide a satisfactory Hall and Offices without serious encroachment on the invested funds of the Society. *W. Wilks, Secretary. By Order of the Council, March 11, 1902.*

Royal Horticultural Society. THE most pressing needs of the Royal Horticultural Society are the possession of a home and of a garden. When we speak of the Royal Horticultural Society in this connection, we consider it, not as a local society, but as the corporate representative of British horticulture. As such, no one will deny the necessity for a common meeting place, with accommodation for offices, library, lecture-room, exhibition-hall, and other requisites. To provide these will be a fitting method of celebrating the centenary.

As to the garden, that will be, rather than is, a necessity. We have a garden at our disposal for nearly twenty years. It is, no doubt, very desirable to have a new one of modest dimensions in a more suitable situation. The realisation of that desire can wait. Meanwhile, let us make the best of what we have.

Now, as to the Hall. It will be remembered that when the schemes for a garden or gardens in the country were laid before the Fellows, they were ultimately rejected by large majorities. After the letters of Sir WILLIAM THISELTON DYER, and the speeches and explanations of other prominent Fellows, no other course was possible consistently with commonsense. The lapse of time does but emphasise this conclusion. As a result, the Council was empowered to find a location for the erection of suitable premises. The Council delegated this work to a committee, consisting of some of its own members, together with some outside Fellows, and headed by Baron Sir H. SCHRÖDER.

Several sites were accordingly examined. All but one were found unsuitable, either

on the score of expense, shortness of tenure, or for some other reason. At length a plot of ground in Vincent Square, Westminster, an open space of some ten acres, has been found. It is not an ideal situation, but it is distinctly a good one, and in a few years there is no doubt that, owing to the improvements now in progress, it will be excellent. It is, as the map published in our present issue shows, within a few minutes' walk of the existing offices and Drill Hall, near to St. James's Park Station, not far from Victoria, close to the new Roman Catholic Cathedral, and in the immediate vicinity of a large residential upper and middle class community. Access to it is already better than in the case of the Drill Hall.

Now, as to the financial question, experts like Baron SCHRÖDER tell us it is not beyond the means of the Society, and need not entail burdens beyond what the Society may assume under existing circumstances, without undue risk.

Baron SCHRÖDER has shown his own confidence in the scheme by promising five thousand pounds towards its fulfilment. What is of even greater significance, he has actually become responsible for the ground-rent until the building is erected. Further than that, three gentlemen have already promised the sum of a thousand pounds each. So that before a single penny has been solicited from the Fellows, a sum of eight thousand pounds has been spontaneously promised, while nothing has as yet been promised for the garden scheme. The Society has ten or twelve thousand pounds in reserve, which can be utilised for purposes of paying interest. Its annual income is increasing rapidly. Since the beginning of the year more than a hundred new Fellows have been elected than during the corresponding period last year. The financial outlook was never so good. Circumstances were never so propitious. They are not likely ever to be more so. The Fellows, therefore, have now the opportunity for which they have been longing. It is for those gentlemen who are eager to secure a Hall to act up to their convictions, and transmute their words into acts. If they do not, they will create a lamentable dead-lock, and perpetuate those inconveniences which all are loud in decrying. It is the bounden duty of every Fellow to attend the Special Meeting of the Society which will be held in the Drill Hall, James Street, Westminster, on Friday, March 21, at 3 P.M. The proposal as explained in the lucid and straightforward Council Memorandum will then be presented for approval or rejection. Surely among those who use the Drill Hall and are familiar with the workings of the Society, there can be no possible doubt as to the result. As to the country Fellows, whilst a hall would be of the greatest convenience to them, a garden would be all but useless. An International Horticultural Exhibition could well be combined with the hall scheme. Who knows but that Vincent Square itself could be obtained for such a purpose, and then—the prospect is almost too brilliant for the imagination!

LINNEAN SOCIETY.—On the occasion of the evening meeting, to be held on Thursday, March 20, 1902, at 8 P.M., the following papers will be read:—1. Electric Response in ordinary plants under Mechanical Stimulus, by

Prof. J. C. BOSE. 2. On the Fruit of *Melocanna bambusoides*, Trinius, an Exalbuminous Grass, by Dr. O. STAFF, A.L.S., &c. 3. On *Malacostraca* from the Red Sea, collected by Dr. H. O. FORBES, by Messrs. ALFRED O. WALKER, F.L.S., and ANDREW SCOTT.

"BOTANICAL MAGAZINE."—The plants figured in the March number are:—

Passiflora ambigua, Hemsley, t. 7822, having flowers somewhat like those of *P. alata*, but with terete stems and elliptic leaves (see pp. 169 & 171 in the present issue).

Jasminum Maingayi, C. B. Clarke, t. 7823.—A climbing shrub, with stalked, ovate, entire acuminate leaves, and terminal tufts of white flowers, each flower with a corolla-limb of eight to ten segments. Native of Penang.

Masdevallia elephanticeps, Rehb. f., t. 7824.—A remarkable species; also mentioned by REICHENBACH in the *Gardeners' Chronicle*, 1876, ii., 516, under the name *M. gargantua*. The flowers are 8 to 9 cent. long, with a thick calycine tube about 2 to 3 cent. long, expanding into a 2-lobed limb, the upper segment solitary, free to the base, yellowish-green, oblong, with a long tail; the two lower ones united to the middle with a large crimson blotch in the centre, each ending in a long tail. It was discovered on the mountains of New Granada by WARSCWICZ at an elevation of 7,000 to 10,000 feet.

Aster Tradescanti, Linnæus, t. 7825.—The supposed original of the Michaelmas Daisy, introduced before 1633 by JOHN TRADESCANT, doubtless from Virginia.

Impatiens grandiflora, Hemsley; *Gardeners' Chronicle*, 1901, vol. i., p. 110, fig. 47.—The finest of the Balsams in cultivation, with rosylilac flowers, streaked and blotched with carmine. Introduced from Madagascar by Mr. WARPUR.

"THE COUNTRY."—We have pleasure in noticing the first number of a new periodical, entitled *The Country*, and edited by Mr. HARRY ROBERTS. The magazine is a sixpenny one, and is to be published monthly from Aldino House, 29 and 30, Bedford Street, W.C. The March number includes a portrait of the Very Rev. S. REYNOLDS HOLE, Dean of Rochester; country gossip by F. W. BURBIDGE, Canon ELLACOMBE, Hon. Mrs. EARLE, S. ARNOTT, and the Editor; and various articles, illustrated for the most part by photographs, on topics included in the scope of the paper. These subjects are all connected with the country, for the publication deals and will deal with: 1, drawings, by HERBERT RAILTON, of the moated houses of England; 2, study of wild life in Britain, illustrated by photographs of birds, beasts, and insects; 3, fishing, shooting, hunting, and other sports and games; 4, dogs, horses, cattle, poultry, bees, &c.; 5, the fishing rivers of Britain.

LYCHEES IN NATAL.—Looking at the favour with which the fruit is received in Natal, an extended planting of the tree is in contemplation, so at least we are informed; possibly the prices paid for imported fruit may have something to do with the report. London boys, and girls also, are not in love with the Lychee; they declare it a nut without meat in it. Certainly in many we have seen the contents had shrivelled into a dirty-looking bit of "something," as a small purchaser termed it; and the whole thing was fit only for playing ping-pong with!

SWEET PEA CUPID.—Mr. RÖMER, of Quedlinburg, tells us that seeds of this section ripened in America do not flower well in Germany. The plants do well, but drop their

buds. This is not the case with plants raised from German seeds. Mr. RÖMER has sent us seeds for trial, and some have been sent to Chiswick. We have ourselves noticed the tendency to drop the flower-buds before expansion in the case of plants grown from American seed, but we cannot say at present whether on the same soil English-grown seed does better.

NEW PARK AT ELTHAM.—An effort is being made to secure a large acreage for the formation of a public park in this Kentish suburb of the "Great Wen." The Woolwich folks promise largely, and soon the matter may be expected to take proper shape—much of the money necessary is already promised.

LAWNS.—In a suggestive green cover we have a pamphlet on garden lawns, tennis lawns, bowling greens, putting greens, and cricket grounds, by SUTTON & SONS, Reading. The subject-matter is good, and the advice given excellent, and we recommend the pages to anyone needing help with lawns at this, the gardeners' busy season. Publishers: SIMPKIN, MARSHALL, HAMILTON, KENT & Co., Ltd.

"CLAY'S SUCCESSFUL GARDENING."—This is the second edition of a small handbook of practical horticulture, issued by Messrs. CLAY & SON, Stratford, and E. W. ALLEN, 4, Ave Maria Lane, E.C., the former firm being the proprietors of Clay's Manures. The new edition has been revised, partly rewritten, and reduced in price, so is sure of favour from the public, for whom it is intended. Among the contributors we note the names of more or less well known professional, amateur, and market growers, whose articles are worth careful reading.

"IN A MINSTER GARDEN."—This book, by Dr. STUBBS, Dean of Ely, was lately favourably noticed in our columns. We welcome the second edition of the "Causerie," the appearance of which is proof of the appreciation with which it has met. We may mention again that the book is full of chatty information and illustrations of charming nooks in and about Ely and its minster, and that the publisher is Mr. ELLIOT STOCK, 62, Paternoster Row, E.C.

COLD STORAGE OF FRUIT.—Various experiments have been made in France as regards storing fruit, flowers, and vegetables, in ice chambers. M. LOISEAU, President of the Montreuil (Seine) Société d'Horticulture, showed at the autumn exhibition of the National Horticultural Society at Grand Palais some Peaches that had kept perfectly in a refrigerator built according to the plans of M. DOUANE, of Paris. The Peaches had been kept in the chamber fifty-three and fifty-eight days, and represented the varieties Mignonne, Bonouvrier, Belle Beauce, Impériale, Alexis Lepère, and Galande. A wholesale dealer offered four francs each for them. The experiments will be continued.

THE NATIONAL SWEET PEA SOCIETY'S schedule, just to hand, shows that the competitive classes arranged for the forthcoming show on July 14 and 15 next, are much the same as those of last year. There are not so many open classes, however, nurserymen and seedsmen being excluded from several in most of the sections.

STOCK-TAKING: FEBRUARY.—The Board of Trade Returns for the month of February show, to some extent, the effect of endeavouring to anticipate the modifying hand of the Chancellor of the Exchequer, in the matter of fettering instead of freeing the breakfast-table. Surely this latter was a consummation most devoutly to be wished; those whose duty it is to "make ends meet" do not appear to

think so now—hence the rise or fall in quantity of food imports. Really, then, figures do not at present count for much—they will after Easter. The value of last month's imports is just £41,691,591, against £39,714,439—or an increase of £1,977,152. Sugar, both refined and raw from Germany, bulks largely; cocoa went up, but tea and coffee gave way; but fruit figures well, as will be seen. Wines and brandy show a fear lest the hand of the Chancellor should lay hold of them. Here is our usual extract from the "summary table."

| IMPORTS. | 1901. | 1902. | Difference. |

There can no longer be any doubt that the Banana has come to stay with us; looking back, the truth of this will be found in our monthly table of fruit imports, which for February reads as follows:—

| IMPORTS. | 1901. | 1902. | Difference. |
|---|---------|---------|-------------|
| | Cwt. | Cwt. | Cwt. |
| Fruits, raw:— | | | |
| Apples ... | 166,577 | 123,651 | —42,926 |
| Apricots and Peaches ... | 164 | 104 | —60 |
| Bananas... bunches | 87,125 | 154,861 | +67,736 |
| Grapes ... | 606 | 1,089 | +483 |
| Lemons ... | 85,978 | 51,697 | —31,281 |

| Tomatoes... .. | 36,310 | 23,938 | —12,372 |
| Vegetables, raw, unenumerated ... value | £25,960 | £35,435 | +£9,475 |

By the way, some are of opinion that Lemons will give way in favour of Bananas; that, we would say, continues a moot point, and the Lemon—no fruit in fact—could be spared from our menu. The imports for the first two months of the year foot up £91,822,939, against £85,701,955 for the same period this year—showing an increase of £6,120,984; and one day of last month was given over to the obsequies for Her late Majesty, QUEEN VICTORIA.

THE EXPORTS

for last month were valued at £21,312,276 against £21,037,455 for the same period in 1901, or a gain of £274,821. The gain may be small—it is a welcome change to the dull monotony of "decrease," noted month by month of last year. Coal shipments show a heavy fall, but the exports of this raw material last year at this time were very high; looking once more at the action of the Exchequer officials. Ships built for export showed increased value, as did materials for textiles;

and here China shows what may once more be expected from her merchants, even with Japan as her next-door neighbour. The value of the exports for the first two months of the year are placed at £45,581,450, compared with £45,790,986 for the same period in 1901—a decrease of £209,536; a trifle surely to be made up in the Returns for March!

PLANTING FRUIT TREES ON FARMS.—Herefordshire fruit is famous, and a number of landlords and tenants of this fertile county assembled under the auspices of the Fruit Growers' Association at Hereford recently, for the purpose of discussing the best terms to be arranged upon as between landlord and tenant when planting fruit-trees. Mr. MANBY POWER, a large landowner and fruit-grower, near Ross, suggested that the landlord should let the tenant plant, and at the expiration of his tenancy allow him to have three-quarters of the value of the trees. Mr. JOHN WATKINS, another large fruit-grower, said his idea was that if a landlord wished to improve his estate by planting or fitting up orchards he should have full power to do so, if the tenancy was an annual one, on notice of twelve months. If the tenancy was on lease, the landlord should have no power to plant without the tenant's consent. If a tenant wishes to plant orchard-trees, he should have power to do so after giving twelve months' notice, and at the end of his tenancy claim full compensation for the cost of the trees, protecting, planting, and looking after them the first four years, with compound interest on the cost. The suggestions met with general approval, and a committee was appointed to report on the subject.

THE CORNWALL DAFFODIL AND SPRING FLOWER SOCIETY, writes Hon. JOHN BOSCAWEN, of Tregye, "had the honour of showing their loyalty to her Majesty (who is Patroness of the Society), during her visit to Cornish waters, by sending cut flowers to decorate the Royal cabins and other parts of their Majesties' yacht *Victoria and Albert*. The flowers were conveyed to the Royal yacht by me on Friday, March 7, before their Majesties' arrival, and the flowers were presented to her Majesty by the President, the Earl of MOUNT EDGECUMBE. The flowers and shrubs were all grown out-of-doors in Cornwall and the Scilly Islands, and consisted of Mimosa, Rhododendrons, Violets, Anemones, Primroses, Crocus, Iris, and Daffodils. A more beautiful collection of flowers could not have been produced, the Violets and Rhododendrons being especially of great beauty. The flowers filled twenty-six market boxes. Both the KING and Queen ALEXANDRA expressed their admiration at the beauty of the display and their gratification at receiving the floral tribute; and the QUEEN further honoured the Society by wearing some of the flowers in her dress on every occasion during her visit, and took some away with her in an open basket in the Royal train." When one hears so much of the immense quantities of flowers coming from abroad, it is only right for the public to know what their own country can produce at this time of year.

WOLVERHAMPTON FLORAL FETE.—The fourteenth annual show will be held in the West Park on July 8, 9, and 10, in association with the Wolverhampton Art and Industrial Exhibition. The schedule has just been issued, and shows that the value of the prizes has been largely increased, and that new classes have been provided for Begonias, Sweet Briar, Tea and Noisette Roses, hardy flowers, laced Pinks, Carnations, Gloxinias, and arrangements of cut flowers. Altogether a sum of nearly

£800 is offered in prizes, besides a Silver Challenge Trophy, Gold, Silver, and Bronze Medals. The beautiful West Park is an admirable place for the exhibition, and although the show has been increasingly successful ever since its establishment, there is little doubt but that in the present year, when so many people are likely to be attracted to Wolverhampton by the Art and Industrial Exhibition, the horticultural exhibition will be better than any previous one. There is never such a display of fruit at Wolverhampton as one sees at Shrewsbury, but the date of the exhibition which makes this impossible at Wolverhampton is also the reason why at the latter place there are always such fine shows of Roses, Pinks, Carnations, Pansies, Violas, &c., in addition to the collections of plants. The Secretary is Mr. W. E. BARNETT, SNOW Hill, Wolverhampton.

to remedy it by the underground watering of gardens by means of his Bamboo water-spears. These, briefly described, are hollow canes, to be thrust into the soil and filled (perchance with a funnel) from a can of water. We leave patient readers and gardeners to learn further details from the book, and also commend to their notice the chapters on the culture of Rose trees and the propagation of Rose trees, included in the volume.

"RUBBER CULTIVATION IN WEST AFRICA."

This handbook is by Mr. J. H. HOLLAND, Curator of the Botanic Gardens, Old Calabar, Southern Nigeria. It contains mention of six of the principal Rubbers of the world: Para, Ceara, African Vine, African Tree, Central American, and Assam, representing the three natural orders Euphorbiaceæ, Apocynaceæ, and Urticaceæ. Para rubber is not successful in West

London County Council has agreed to join hands concerning the projected improvements, which will therefore stand a good chance of being carried out.

DAFFODILS AND LILIES.—Mr. PETER BARR, the Daffodil King, for whom we shall have to invent a new epithet to indicate his feats as a traveller, has reprinted his lectures in Cape Town on the Lilies of the world, and on the cultivation of the Daffodil. The lectures were amply worth publishing in a more permanent form, and on the return of this modern Ulysses we may hope for a further publication.

FLOWERS IN SEASON reached us recently from Ard Cairn, Mr. BAYLOR HARTLAND'S nursery near Cork. They included very nice, well-developed flowers of Ard Righ, one of the earliest to open its flowers in the open air, and another equally good. Next probably to Scilly, Cork produces the greatest quantity of Narcissus in the three kingdoms, as also excellent bulbs.

BAILIFF OF THE ROYAL PARKS AND GARDENS.—The First Commissioner of Works has promoted Major WILLIAM CLIVE HUSSEY, late Royal Engineers, Assistant-Bailiff of the Royal Parks and Gardens, to be Bailiff of the Royal Parks and Gardens, in the room of Colonel MORETON JOHN WHEATLEY, C.B., late Royal Engineers, who has retired under the age limit.

THE HORTICULTURAL CLUB.—A pleasant evening was spent at the Club on Tuesday last, the occasion of the monthly dinner. In the absence of the Chairman, Sir J. T. D. LLEWELLYN, Bart., the chair was occupied by the vice-chairman, H. J. VEITCH, Esq. After dinner, a discussion was opened by Mr. CHAS. E. PEARSON, whose subject was "Bird Life in relation to Horticulture"—a bright and interesting paper. A vote of sympathy was passed with Mrs. SELFF-LEONARD in her recent sad bereavement. Dr. HENRY will be the guest of the Club at the next monthly dinner on April 8.

PUBLICATIONS RECEIVED.—From the Royal Gardens, Kew, *Bulletin of Miscellaneous Information, Appendix II.*, 1902. *Catalogue of the Library: Additions received during 1901.*—*Twenty-fifth Annual Report (for 1901) of the National Carnation and Picotee Society (Southern Section).* The annual exhibition was a very successful one. New flowers were not so much in evidence as on former occasions.—*Cassell's Dictionary of Gardening*, Part 10. From "Hydrocharis to Law," and with coloured Plate of Michaelmas Daisies.—*Eleventh Annual Report (for 1901) of the Society for the Protection of Birds.* Records good work done as regards the restriction of cruelty to birds and the preservation of rare species.—From the Yorkshire College, Leeds, and the East and West Ridings Joint Agricultural Council. *Report on a Test of Varieties of Potatoes at Garforth, 1900-1901.* The results of the test are tabulated according to the varieties employed and the circumstances of their environment.—*The Gardeners' Magazine (Calcutta)*, February. Contents: News and Notes, Notes and Replies, the Editor's Table, Cyclopædia of Indian Plants.—*Der Botanische Garten und das Botanische Museum der Universität Zürich, im Jahre, 1901.* Issued by the Director, Prof. Dr. Hans Schinz.

ROYAL VICTORIA PARK AND BOTANIC GARDEN, BATH.

(Concluded from p. 157.)

[SEE SUPPLEMENTARY ILLUSTRATION.]

"THE DELL" is the name given to a disused old quarry that, owing to the natural shelter it provided, was formed into a small pinetum many years ago. It is the most charming spot in the park to the lover of fine trees, and of conifers especially. There is a magnificent specimen of Wellingtonia (*Sequoia gigantea*), 50 ft. or more high; and the Redwood, *S. sempervirens*, is even a nobler and better specimen of 60 feet high; *Abies Smithiana*, *Taxus baccata* *Dovastonii* (Weeping Yew),

FIG. 55.—PART OF THE ROCKERY AT BOTANIC GARDEN, BATH.

Showing a very fine plant of *Astragalus Tragacantha*; also *Ozothamnus rosmarinifolius* = *Helichrysum diosmæfolium* in bloom, &c.

"UNDERGROUND WATERING OF PLANTS AND GARDENS."—To which are added chapters on the culture and propagation of Rose trees. By JOHN GRANT (London: WARD, LOCK & Co., Ltd., New York, and Melbourne). "Having been an enthusiastic gardener for some fifty years . . . I verily believe I have, in my old age, discovered a most important fact or principle which has hitherto escaped the notice of mankind . . . What I have observed is, that there exists, in very hot, dry weather, a zone of earth at or near the surface, and extending downwards to a depth of several inches, which presents an impassable barrier to the principle, or rather to the action of the principle, of capillary attraction, which I have observed is the great distributing power by which water falling, or collecting, upon the earth unequally, that is to say, in larger quantities at some spots than at others, is evenly distributed over adjoining spaces." This check to "capillary attraction" resulting in an absence of water where water is needed; that is to say, at the roots of plants Mr. GRANT proposes

Africa; Ceara grows in some districts, but is a failure as a rubber producer, as also is Central American. Assam, after ten years' trial, does not yield so well as when growing naturally. Landolphas, from their climbing habit, are not well adapted for cultivation. The native tree (*Funtumia elastica*) possesses many qualities to recommend it. The rubber is of good quality. The book before us includes five large and useful plates.

RARE CONIFERS.—M. OSCAR BIERBACH, of the Botanic Gardens, Belgrade, informs us that he has seeds for disposal of *Abies Apollinis*, *Pinus Penke*, *P. leucodermis*, *Picea omorica*, *Pinus pindica*, and other species not met with in commerce.

SPITALFIELDS MARKET.—There is at length a possibility of getting this popular market extended and renovated, also the surrounding streets widened, all the approaches in fact made suitable for a market with a future. The Stepney District Council and the City Corporation have come to an understanding, and the

presenting a front of about 15 yards long; *Cupressus Lawsoniana*, and several species of *Pinus*, are very well worth inspection. The handsome *Cephalotaxus Fortunei* and *C. drupacea* have not made large specimens, and probably the shade is now too dense for them to succeed.

At one of the entrances to the park is a fine obelisk, erected in 1837 in honour of Queen Victoria; and there are several large vases. The "Victoria" vase was erected in 1880 to celebrate the fiftieth year the park had been opened. The "Miller" or Batheaston vase, shown in our Supplementary Illustration, is said to have been found at Fraseati, near Cicero's villa, in 1759, and to have been subsequently in the garden of Lady Miller at Batheaston Villa.

Since our last issue was published we are informed that the Park in 1830 was laid out from plans of Mr. Ed. Davis, a Bath architect, and father of Mr. C. E. Davis, the present city architect.

THE BOTANIC GARDEN.

A little more than fifteen years ago a valuable collection of hardy plants was left by C. E. Broome, F.L.S., for the botanic garden, and Mr. John Milburn, the present Superintendent of the park and botanic garden, was engaged from the Royal Gardens, Kew, to go to Bath and plant the new collection, and take charge of the old one. A walk amongst the plants with that gentleman is sufficient to convince one that he has the greatest interest in and care for them. The honorary Curator at that time was the late J. W. Morris, F.L.S., and he was responsible for some of the plans followed by Mr. Milburn when laying out and planting the garden. The present honorary Curator is T. F. Inman, Esq.

Directly one enters the gateway, there are to be seen some rather tender and other choice plants growing very well in the grass. Such are *Choisya ternata*, *Olearia macrodonta* (quite hardy here), *Verbascum pannosum*, as a single plant on the turf, and Mr. Milburn says it is a glorious plant in such a position; *Abelia chinensis*, planted in similar circumstances; *Myrtle*, provided with slight temporary protection; *Xanthoceras sorbifolia*, and a seedling from Canon Ellacombe's plant of *Egle sepiaria* (*Citrus trifoliata*), which fruits at Bitton (see fig. in *Gardeners' Chronicle*, April 28, 1900, p. 269). Mr. Milburn hopes that he, too, will obtain fruits from his plant. *Polygonum baldschuanicum* is planted on an exposed portion of the rockery, and succeeds perfectly. Mr. Milburn says that the species is much less effective if growing amidst shelter. His plant grows very stocky, with short internodes. *Daphniphyllum* is the nearest ally to the *Rhododendron*, so far as superficial appearance goes, that is capable of cultivation here, the soil containing a quantity of lime; *Olearia stellata*, *Raphiolepis japonica*, 3 to 4 feet high, and 3 feet through; *Magnolia Soulangeana*, &c., were noticed.

A bog-garden is being formed, and some Bamboos have been planted near to this spot. These will be increased so far as space will permit. There are great banks of *Arabis*, *Phloxes*, *Ericas*, and a grand plant of *Euphorbia Wulfenii*; *Sophora* (*Edwardsia*) *tetraptera*, which has proved hardy here for ten years at least; *Carpenteria californica*, most vigorous plants of *Daphne Cneorum*, the dwarf Willow (*Salix reticulata*), fifty years old, but not more than 2½ inches high; *Shortia galacifolia* in a pocket on the top of the rockery; *Photinia serrulata*, the dwarf Almond which fruited here last season; and beds of *Iris*es, &c. We will not make the list more

tedious by enumerating other species, but there are many that would interest the hardy plantsman.

Our illustration at fig. 55, p. 179, represents a portion of the rockery as it appeared last summer, containing a very fine plant of *Astragalus Tragacantha*, *Ozothamnus rosmarinifolius*, *Pinks*, and other plants in flower, &c. A small collection of British plants is maintained, and a collection of choice British Ferns purchased from the collection of the late Colonel Jones of Clifton.

Sufficient proof is furnished by the plants in the Victoria Park of the genial climate enjoyed by the Bath district, and of the sheltered and favourable situation of Bath itself.

In conclusion, we may remind our readers that it was in the Victoria Park that the Bath exhibition of the Royal Horticultural Society was held in 1873, an event which formed the subject of notes in many issues of the *Gardeners' Chronicle* for that year.

HOME CORRESPONDENCE.

PROPAGATING POINSETTIAS.—May I supplement Mr. Hemsley's able article on p. 163? If very dwarf plants with large heads are required, these may be produced by employing the following method. During the first half of August stake the plants to their full length, and cut halfway through the stem at a joint about 4 inches from the top. For a few days keep the plants shaded during sunshine, and gently dew them with the syringe. In about a fortnight the incision will have callused; the remaining portion of the stem should then be cut, and the cuttings inserted as directed by Mr. Hemsley. These cuttings will quickly root and produce large heads slightly earlier than plants grown in the ordinary manner. If allowed to break and grow on, the plants from which the cuttings were taken will furnish two or three smaller but useful heads of bracts. I can endorse Mr. Hemsley's concluding remarks—as a rule, Poinsettias are "coddled" far too much, but as he says, they must not be left in the cool-house "too" long. In Devon and Cornwall these subjects summer well in cold pits, and the lights may be left off on mild and dry nights. A. C. B.

ADONIS DAVURICA.—In the *Index Kewensis* this plant is given as synonymous with *A. vernalis*, and certainly, so far as appearance is concerned, there is little or no difference between them; but from the garden point of view *A. davurica* has this notable distinction, that it is a long way the first herbaceous plant of the year, coming into flower before the winter Aconites. It can be bought at 6-50 dols. per 100 from the Yokohama Nursery Co. of Japan. Re winter Aconites, I wonder whether other people have had my experience, and found *Eranthis cilicica* a far more reliable bloomer than *E. hyemalis*. A. K. Bulley, Ness, Neston, Cheshire.

A YELLOW SNOWDROP.—Among the clumps of Snowdrops in a cottage garden in this neighbourhood, several flowers have appeared of a distinct yellow colour. The plants differ slightly from the ordinary type. They have the usual pair of leaves, but they are green, not glaucous. The three outer segments of the perianth are slightly narrower, more acute, and less concave; and there is a short tube above the ovary, which is a darker yellow than the rest of the flower. I have never heard of such a variety, nor can I find any record of such. Is it known to English gardeners? I have just gathered from my own garden a Snowdrop with two flowers on the same stalk, one about an inch below the other. It is a case of fasciation, but the union of the two stalks is scarcely visible, and the effect is very elegant. Could such fasciation be induced as a normal character? F. T. Mott, Leicester, February 8.

THE GARDEN AS A HOBBY.—The discussion raised by Mr. Mott's recommendation that old men who retire from business should take to a garden and do part of the actual gardening work themselves, has been an interesting one, but it is not possible to agree altogether with those who advocate either view of the question. However beneficial we who love gardening for itself find it, we must admit that there are many who take no interest whatever in it, and whose entering upon it as a hobby would neither tend to benefit them physically nor mentally. Yet it is probable that many who have not tried gardening as a hobby would benefit immensely, and they would find in the actual labour required a pleasure and both physical and mental advantage. I have known several instances of old men who have turned to gardening in the leisure of retirement, who have found in it true joy and a satisfying hobby at a time when they would have almost died of ennui had it not been for its occupation and engrossing interest. It may be replied that this interest had been fostered by, or had been a legacy from the teachings of a parent, or from seeing her or him busy among their flowers and plants. In many cases this is so, but there are many others in which no such influence can be traced; and we may only suppose that the taste arises from some innate love for gardening, which only awaited leisure to ensure its development. I have particularly one case in view in which it was difficult to see whence this business man derived the taste for gardening which made him one of the keenest of growers of a certain class of plants, not even plants beloved of the multitude, nor such as could be shown to visitors as rare flowers, costing so much money, and to be looked upon as the luxuries of a man who "had made his pile," and could afford to have them. I would go the length of saying that old men who retire from business ought to try gardening for a time to see if it suit their tastes. If it should do so, then they will have alighted on a well of happiness which will never fail them, even though increasing age render them incapable of the actual work required. One thing which always strikes me forcibly in connection with this subject is, the number of retired soldiers and sailors—principally sailors—who become enthusiastic and really good gardeners after their retirement from active work. It is not necessary always to be a disciple of their particular style of gardening to enable one to look upon their efforts with pleasure. Some gardens presided over by these men are often painfully stiff and formal; while some of our old sea-captains show a liking for decorating their gardens with old figure-heads and all kinds of curiosities. Yet they may be keen gardeners, and it is a pleasure to see them so interested in the ancient craft which brings so much health and happiness to those who can enter into it with zest, but which is a cruel bondage to those who have no taste for it. As for blunders in gardening, I fancy that as we know more about it and other things, we grow more painfully conscious of how much we have yet to learn; of how much we knew but have forgotten, and of the difficulty of arriving at the exact truth with regard to many plants. Mr. Fitzherbert has a very suggestive passage bearing on this subject on p. 17 of your issue of January 11; and because a man, however old, is unacquainted with scientific nomenclature, or even with the names or characteristics of the Natural Orders, he may not be debarred from growing his plants well, and may have from them a good deal of the enjoyment received by the one who has the names, habitats, botanical features, and such-like at his fingers' ends. Not that one despises these things; they are most valuable, and the man who has them has sources of pleasure denied to the other; but there is no reason why we should not persuade a man who does not know the difference between a Crucifer and a Composite to continue growing his Wallflowers and his Sunflowers, though ignorant wherein lies the differences of structure they show. Even the man who likes to work about his

garden walks, to tie up his flowers, to cut off faded blooms, and such-like common tasks, but leaves the other things to his gardener or the jobbing man who comes in at intervals, is surely spending his time better than in aimless lounging about the streets, passing his afternoons drowsily perusing the newspapers of which he has long before secured the salient features, or in worse ways passing the time Providence, aided perhaps by his own exertions, has left him to use as he pleases for the remainder of his days. If such a man has a taste for gardening in any of its aspects, by all means let him enter upon it. Those who love it, or come to care for it, will find that it is still not only "the purest," but the most satisfying of human pleasures. *S. Arnott, Dumfries.*

LILIUM GIGANTEUM.—I note that "S. W. F." takes exception to my remark that "Lilium giganteum cannot be grown with any measure of success in the open border;" and he further cites an instance of this Lily thriving in the

wall, and the only safe course open to me is a middle one, the climatic conditions of which may be clearly stated. Only recently a correspondent complained that I had not done *Crinum Moorei* justice, in declaring it "to be too tender to withstand our winters, save in the shelter of a heated wall." The instance he cited was that of a clump growing in a warm, sheltered position in South Devon, and a certain clump buried more than a foot deep, so that the tips of the bulbs (usually quite 2 feet long) were just above the ground. The first case cited explains itself, whilst I cannot conscientiously recommend the course followed in the latter, for I have in my records of the *Amaryllidaceæ* a note of experiments made in a celebrated garden, in the matter of planting *Crinums* deeply as a protection from frost. The bulbs, a fine, valuable lot, were planted 1 to 2 feet deep, according to their size, and have not been seen since. The method, I believe, was originally advocated by the late Dean Herbert, who was rather successful with *Crinums*. In that case, however, it was an

bone-dust as a dressing for summer flower-beds, particularly for *Pelargoniums* and *Calceolarias*, forking it into the surface of the soil just before the plants are planted. *H. Foster, The Lodge Gardens, Doncaster.*

BOOK NOTICE.

THE CULTURE OF GREENHOUSE ORCHIDS.
By Frederick Boyle. (Chapman & Hall).

YET another work on Orchids by Mr. Frederick Boyle, and this time of a more important character, for it is designed to assist the struggling amateur. As Mr. Boyle himself puts it, he considered that there was room for a book on Orchids written "by an amateur for amateurs," and on those lines he commenced it and carried it out. But as it was intended for a serious work, expected to be reliable on all points of cultural details, the amateur did a wise thing, and submitted his copy to Mr. Joseph Godseff, the well-known manager to Messrs. Sander & Sons, of St. Albans, and hence the work has the stamp of expert authority placed on the amateur effort. The book deals only with Orchids which may be grown successfully in a cold-house. That simple fact is much in its favour, for it enables the amateur with only cool-house accommodation to get readily at the things which are suitable for his case without having to separate them from plants which require more heat than he can give, the possession of which causes more small collections where accommodation is very limited, to look and be unsatisfactory, both as regards growth and flower, than anything else. The enumeration of all species available for culture in the greenhouse is likely to do good also in another way, for it will indicate many species, such as the highland Brazilian *Oncidium*s, which should be grown cool, but which are killed in large quantities by being kept in excessive heat, especially when at rest.

The book, which has for a frontispiece a coloured plate of "*Odontoglossum crispum* Alexandræ," the *Alexandræ* accidentally placed as a varietal instead of a synonymous name, has also a plate of *Lælia anceps* *Schroderiana* and *Oncidium macranthum*, and the descriptive matter is brightened by fifty illustrations of single flowers of standard cool-house Orchids, reproduced from photographs by Col. F. C. Taylor, one of which—*Odontoglossum crispum* "Lady Jane," a remarkable form, flowered by J. Wilson Potter, Esq., of Croydon—we, by the courtesy of the Publishers, are enabled to produce (fig. 56). The bulk of the work is taken up with the enumeration of the genera and species recommended for culture in the greenhouse, together with cultural instructions, and much other information regarding each of the subjects dealt with, and the whole is successfully and entertainingly treated, much that cannot fail to be of the greatest service to the amateur being set forth in a very plain and intelligible manner.

The opening chapter, "The Nature of Orchids," deals in a familiar way with the structure and mode of growth of Orchids, and in its course touches on the question of the use of artificial manures, but without any definite conclusion or recommendation being come to or given.

The second chapter is on "The Orchid House," most useful details, instructions, and a cross-section plan of a model house being given.

FIG. 56.—*ODONTOGLOSSUM CRISPUM* "LADY JANE."

open border, but "in a sheltered and moist valley in the neighbourhood of Torquay," a further reference being made to a clump in a Cornish garden. I would like to point out that the extreme south-west of England is exceptionally mild, and that records of the behaviour of *Lilium giganteum* in that part are of little use to those living elsewhere. I venture to assert that the plant would refuse to grow at all in some parts of England, and would not thrive so well under the best possible conditions found north of the Thames as it would do south of that boundary. Wherever there are late spring frosts to be feared, *Lilium giganteum* cannot be grown without being afforded a good deal of shelter. It may grow fairly satisfactorily until the spike appears, when, should cold winds or a frost occur, followed by warm sunshine at midday, the stem will split and crack in all directions. The early morning sun will destroy any spike of *L. giganteum* in this manner, after it has passed through a cold or frosty night. "S. W. F." should remember that the climate of south-west England is moist compared with the eastern side of England, and much milder. When writing of the degrees of hardiness of plants, it is necessary to remember that there are gardens in Caithness as well as in Corn-

expert who knew his plants well, and who was guided in all that he did by that knowledge. I have planted out a great many *Crinums* for the test of hardiness in a garden near London, and I should think quite sixty bulbs of *Moorei*, but none of the latter have thriven in the open under the best possible conditions. They existed, and probably exist still, but not as creditable specimens. *Geo. B. Mallett.*

ARTIFICIAL MANURES FOR SWEET PEAS.—I am of the same opinion as Mr. Clark, that one salve does not suit every sore. I have proved that artificial manures give better results than stable-manure. For the last five years I have grown four rows (50 feet long) of Sweet Peas in different parts of the kitchen garden at this place, the soil of which is light and sandy, using stable-manure, and that of pigs, and the plants have done fairly well; but the best results were obtained from bone-dust. The ground is dug deeply in the autumn, and as soon as the weather permits in February, having taken out a drill, into which I sprinkle bone-dust rather heavily, and cover the same with soil 3 or 4 inches deep, I sow the seed. In dry weather I apply manure and scot, and Thompson's or Standen's manure. I can strongly recommend

"Orchid Names" is the heading of the next chapter, and in it the matter savours more of the popular magazine than of a book seriously intended for workers. In the course of a rambling criticism on the scientific Orchid names, the author says: "Nineteen in twenty among genera and most species bear a Greek or Latin title, qualified only by bad grammar." Patient and clever men have worked on this question for centuries, and have done their best, and to them Mr. Boyle should be thankful that he is able to indicate the plants he writes about, and wishes his readers to identify. It is common for novices in our days to think they can leap into notoriety by assailing the best that science can place before them, and that, too, without even hinting at or attempting to suggest a better method. The names are intended as a means of classifying the genera and identifying the species wherever plants are studied or cultivated, and that means is accomplished in an admirable degree by our present system of nomenclature. Botanists themselves are always ready (perhaps too ready) to correct errors whenever any fresh light is thrown on the subject, but the system as it is must remain.

In his dealing with the names at his command, too, the author is not always accurate. Taking at random *Odontoglossum* × *Andersonianum*, it is said to be named after Dr. Anderson, botanist, instead of the late Mr. Anderson, gr. to T. Dawson, Esq.; and *Cymbidium Mastersii* after Mr. Masters, editor of the *Gardeners' Chronicle*, instead of Mr. Masters, then of the Calcutta Botanic Gardens.

In the chapter on "Potting Orchids," and in other parts of the work, Mr. Boyle writes enthusiastically of the Belgian culture of Orchids in Oak-leaf mould, or *terre de bruyère*; but in the cultural instructions under each genus he wisely places the well-tried British method of potting in peat-fibre and sphagnum-moss first, and sometimes refers to the other method as an alternative.

Recent communications in the *Gardeners' Chronicle* show that the leaf-soil culture is by no means generally accepted, even in Belgium, whilst in this country it is only on its trial; and although excellent plants may be found here, grown in leaf-soil, there are not wanting growers who pronounce against it after trial. Further cautious experiments in that direction are needed. Taking the work for what its author intended it to be, viz., a plain, sufficient, and trustworthy guide for amateurs of little experience, it may be said that he has accomplished this end to a remarkable degree, most matters, to which some might take exception, having little bearing on the vital question of good culture. The average prices of many of the things are also given.

SOCIETIES.

ROYAL HORTICULTURAL.

MARCH 11.—There was a very fine show of plants and flowers in the Drill Hall, Buckingham Gate, Westminster, on Tuesday last. The display was a larger one than has been made at any meeting since the commencement of last autumn, and quite as much as the present hall can conveniently contain. Throughout the day there was very little daylight in London, whilst in the hall itself it was impossible to see the exhibits perfectly. Before 3 P.M. it was necessary to light the building with gas, but this was at best very inefficiently done.

Orchids were shown numerously, and the ORCHID COMMITTEE considered a number of novelties to be worthy of awards.

The FLORAL COMMITTEE made only one such award, and this was to a variety of *Lachenalia*, from the Glasnevin Botanic Garden. Several very fine groups

of forced flowering trees and shrubs were shown, and a number of other groups of miscellaneous description, some *Cyclamens* being of exceptional cultural merit.

The NARCISSUS COMMITTEE met, but there being so little to do, did not formally "sit," so that the Floral Committee discharged the work.

The FRUIT AND VEGETABLE COMMITTEE had not many exhibits before it, but fruits of a reputed cross between an Apple and a Pear were very interesting.

In the afternoon a Lecture was given by Mr. R. Hedger Wallace, entitled "The New Soil Science." Mr. Harry J. Veitch, who presided, announced that during the present year 100 more new Fellows have been elected than during the corresponding period of last year.

Floral Committee.

Present: W. Marshall, Esq. (Chairman); and H. B. May, Geo. Nicholson, R. Dean, J. W. Barr, G. Renthe, J. F. McLeod, W. Howe, Chas. E. Pearson, J. Fraser, Chas. Dixon, H. J. Cutbush, C. J. Salter, Chas. Jeffries, Jno. A. Nix, Chas. E. Shea, R. W. Wallace, W. P. Thomson, E. H. Jenkins, W. J. James, H. Turner, Geo. Paul, Jas. Walker, E. T. Cook, R. C. Notcutt, and H. J. Jones.

Tea Rose Lady Roberts, exhibited by Messrs. FRANK CANT & Co., Baiswick Rose Gardens, Colechester, is a reddish apricot-coloured flower, previously given an Award of Merit by the Royal Horticultural Society.

Some very fine hybrid *Lachenalias* were shown by Mr. F. W. MOORE, from the Royal Botanic Gardens, Glasnevin, Phyllis Paul, Brightness, Kathleen Paul, Brilliant, and W. E. Gumbleton, were names attached to the varieties, which were more or less yellow in colour, and of large size and substance.

Several varieties of Violets in pots and as cut flowers were shown by exhibitors, one very purple in colour, being from Lady ANCASTER, Nornanton, Stamford.

That lovely Rose, Fortune's Yellow, was shown in very great profusion by Lady WANTAGE, Lockinge Park (gr., Mr. Fyfe), from whose garden we have seen many previous exhibits of the same old Rose. In this instance the blooms were made into a great pyramidal bouquet, such as is presented by a free flowered *Rhododendron* (*Azalea*).

Clivias (*Imantophyllums*) were splendidly shown by Messrs. JAS. VEITCH & SONS, Royal Exotic Nurseries, Chelsea, who had forty plants in 6-inch and 8-inch pots. Each plant bore a very strong spike of flowers, all of them of good type, and varying slightly in degree of colouring. *Loropetalum chinense* was grandly shown in small plants from the same establishment; they were in 5-inch pots, the plants being 1 foot or 1½ foot high, and very full of flower. The plant is evidently capable of becoming a good vase plant, perhaps even a "table" plant. *Rhododendron amenum* Illuminator and *Shortia galacifolia* were shown in flower from the same firm (Silver Flora Medal).

Messrs. JAS. VEITCH & SONS again exhibited plants of *Cineraria* Feltham Beauty, of rather dwarf and branching habit, the flowers being a distinct mauve colour. These plants were accompanied by another batch of a variety called *ramosa*, of taller and looser habit, with purple flowers.

Some extraordinary plants of *Cyclamen* were shown by Colonel ROGERS, Franklands, Burgess Hill, Sussex (gr., Mr. C. Murrell). The plants were in 8-inch pots, and were not only remarkable for excellent habit, but for unusual freedom of flowering, the blooms being large, and of great substance. Some of the plants were seven years or more old, and it was stated that one of the best specimens, with white flowers, had been shown in flower in November last at the Birmingham Chrysanthemum Show—an extraordinary instance of continued flowering. There were white, and mauve, and purple and crimson varieties, and from any point of view were deserving of praise. The plants came from a very small establishment (Silver Flora Medal).

Messrs. JNO. WATERER & SONS, Ltd., Bagshot, exhibited some choice varieties of Conifers in pots, the plants being almost perfect ones. Some of the forms represented were:—*Retinospora pisifera nana* variegata (excellent dwarf plant), *Cupressus versicolor*, *Juniperus virginiana aurea*, *Thuja occidentalis aurea*, *Cupressus Westermanni*, *Retinospora obtusa nana aurea*, *Retinospora filifera aurea*, *Juniperus japonica aurea*, *Buxus canadensis nova*. There were also numerous good plants of *Skimmia japonica* and *Audromeda japonica* in bloom (Bronze Banksian Medal).

Messrs. H. CANNELL & SONS, Swanley, Kent, again made a very gay exhibit of flowering plants, including a considerable batch of *Cinerarias* of a fine strain of the florists' type. *Cyclamens* were very good, and included some of the fimbriated varieties. A batch of plants of *Primula obconica* showed what an amount of

colour is now obtainable in the flowers of this species, which for hardness of constitution, and a free-flowering habit, is everything that could be wished (Silver Flora Medal).

Messrs. HUGH LOW & Co., Clapton, London, and Bush Hill Nurseries, Enfield, exhibited a pretty group of plants, containing *Acacia Drummondii*, *A. ovata*, *Cyclamens*, *Schizanthus Wisetonensis*, *Boronia megastigma*, *B. heterophylla*, &c.; Carnations, &c. Messrs. HUGH LOW & Co. also showed a corner group arranged on the floor, consisting of Palms, ranging from 6 to 10 ft. in height, healthy, and well furnished with leaves. In the front of the group stood a row of plants of *Crimson Rambler* Roses, and *Cytisus racemosus*, these being placed alternately (Silver Flora Medal).

Messrs. PAUL & SON, The Old Nurseries, Cheshunt, showed some first-class varieties of *Lachenalia*, one of the best of which was *L. aurea chrysanthia*; also some blooms of *Camellia alba plena*, plants of *Cœlogyne cristata alba*, &c. (Bronze Banksian Medal).

Seedling *Hippeastrums* from F. A. BEVAN, Esq., Trent Park, Barnet (gr., Mr. H. Parr), included some fine varieties, and were shown over a ground-work formed of varieties of *Primula stellata*.

Messrs. JNO. LAING & SONS, Forest Hill Nurseries, London, S.E., exhibited a group of choice stove and greenhouse plants.

HARDY PLANTS.

Messrs. R. WALLACE & Co., Kilnfield Gardens, Colchester, exhibited some choice hardy plants in pots. Several Irises were included, as the distinct *I. Sindjarensis*, *I. histrioides*, *I. reticulata*, *I. r. Krelagei*, and *I. Danfordie*; *Fritillaria aurea*, *Muscari azureum*, *Scilla sibirica alba*, several varieties of *Narcissus*, and of *Galanthus*, &c. (Silver Banksian Medal).

Messrs. T. S. WARE & Co., Ltd., Hale Farm Nurseries, Feltham, showed a large collection of hardy alpine and other plants in pots. *Hepatica triloba* in various colours, *Saxifraga Burseriana*, &c., in good batches, were effective. There were forced *Magnolias*, *Narcissus*, &c. (Bronze Banksian Medal).

Messrs. GEO. JACKMAN & SON, Woking Nurseries, Surrey, exhibited some hardy plants on a rockery. Amongst the numerous species in flower were *Lithospermum canescens*, a new *Fritillaria*, *F. Zagriga*, with slender growths, 3 or 4 inches high, and small brown and green flowers; *Polygala chamæbuxus purpurea*, *Primula verticillata*, *P. denticulata alba*, &c. (Silver Banksian Medal).

Messrs. BARR & SONS, King Street, Covent Garden, showed extensively various *Narcissus*, many *Hepaticas* of the small-flowered species, *Anemones*, *Helleborus*, species of hardy *Cyclamens*, *Clionodoxa*, several Irises, including *Orchidoideis*, *Bulboëdium monophyllum*. The chief features of the exhibit was the bank of named *Narcissus* blooms in good condition. A Silver-gilt Banksian Medal was awarded.

Messrs. W. CUTNISH & SON, Highgate, London, N., showed flat baskets filled with *Hepatica triloba rubra*, and the double-flowered of this variety; *H. t. cerulea*, and the double-flowered form of it; and *H. t. alba*.

Mr. ROBERT SYDENHAM, Birmingham, exhibited some *Narcissus*, *Hyacinthus*, Tulips, &c. growing in moss-fibre instead of soil. The fibre certainly suited them perfectly.

FORCED TREES AND SHRUBS.

Messrs. W. PAUL & SON, Waltham Cross Nurseries, Herts, had an exceedingly beautiful group of forced trees and shrubs, remarkable for the numerous varieties of Peach, Almond, and *Prunus* species. The double white and the double crimson Peach, also the Carnation-flowered (rich rosy-red), are very lovely. *Prunus triloba* was of capital colour, and like all the other species, was full of bloom. *Magnolia conspicua*, in several specimens; *Forsythia suspensa*, very freely bloomed, were among other good plants in the group. (Silver-gilt Flora Medal).

Messrs. R. & G. CUTHBERT, Southgate Nurseries, Middlesex, contented themselves with a smaller group of forced shrubs than was shown on the previous occasion. There were very large plants of *Rhododendron molle*, *Hortulanus Witte*, and *Isabelle Van Houtte*. Standard Lilacs of the varieties *Madame Lemoine* (double white), and *Charles X.*, also of *Viburnum Opulus*, double white and double pink Thorns, *Staphylea colehica*, &c. Among the dwarfier plants *Kalmia latifolia* was very pretty, and many varieties of Japanese *Acers* (Silver Banksian Medal).

Messrs. W. CUTNISH & SON, Highgate Nurseries, London, and Barnet, Herts, exhibited forced shrubs, in which standard trees of *Cytisus*, *Laburnum*, *Spiræa grandiflora*, double pink Thorn, Lilacs, Ribes, &c., were

included. Among the smaller plants were *Spiraea prunifolia* fl.-pl., with its little white, button-like flowers; *Staphylea colchica*, *Prunus triloba*, *Lilacs*, *Magnolia Soulangeana*, &c. (Silver Flora Medal).

AWARD OF MERIT.

Lachenalia W. E. Gumbleton.—A very fine variety, with large flowers wholly golden-yellow in colour, except in the bud state, when they are orange-red. From Mr. F. W. Moore, Royal Botanic Garden, Glasnevin.

Orchid Committee.

Present: Harry J. Veitch, Esq. (in the Chair); and Messrs. Jas. O'Brien (Hon. Sec.), De B. Crawshaw, H. M. Pollett, H. Ballantine, J. Douglas, J. Cypher, F. A. Rehder, W. A. Bilney, H. T. Pitt, W. H. Young, H. J. Chapman, F. W. Ashton, W. H. White, W. Boxall, T. W. Bond, W. Thompson, H. Little, H. A. Tracy, and J. W. Potter.

Sir Trevor Lawrence, Bart., Burford (gr., Mr. W. H. White), staged an effective group, in which the plants were splendidly grown, and profusely flowered throughout. The principal feature was the fine *Dendrobium*s, among which were two forms of the pretty *D. x burfordense*, the large and showy *D. x melanodiscus* Rainbow, *D. x Rolfeae*, *D. x Cybele*, *D. x Dominianum*, a charming specimen of *D. barbatulum*, with over thirty fine spikes of white flowers; the rare bluish-white *D. superbum* Burkei, *D. nobile* Ballianum, *D. x speciosio-Kingianum*, with many spikes; the bright yellow *Sophro-Lælia x Marriottiana* flavescens, *Masdevallia x Hinksiana*, *M. Jeontoglossa*, *M. triangularis*, and the pretty orange-coloured *M. x xanthino-Veitchiana* (Silver Flora Medal).

Messrs. Jas. Veitch & Sons, Chelsea, were awarded a Silver Flora Medal for a remarkable group, mainly consisting of rare hybrids, which, though fine, were eclipsed by the central plant, *Lælia x Digbyano-purpurata* Edward VII. (see Awards); with it were two others from the same batch, but with smaller whiter flowers, tinged and veined with rosy-lilac; sprays of the brilliant scarlet form of *Epidendrum x O'Brienianum*, *Lælio-Cattleya x Antimachus* Cænea, L.-C. x *Pallas*, varieties of L.-C. x *Myra*, with yellow flowers; *Cypripedium x Euryades* splendens, a magnificent and richly-coloured variety, far the best of its class; *C. x Leonidas*, *C. x eximium*, various *Dendrobium*s, &c.

Frank A. Rehder, Esq., Gipsy Hill (gr., Mr. Norris), was awarded a Silver Flora Medal for a neatly arranged group of *Dendrobium*s. The varieties of *D. nobile* ranged from the pure white *D. n. album* to the richly-coloured forms of the nobilium class. Of the hybrids the best was *D. x Magda* (nobile nobilium x *melanodiscus*), a grand flower, with the rich purple colouring of *D. nobile nobilium*, and the broad petals and fine substance of the other parent. Also very distinct were *D. x socius nobilior*, *D. x Sibyl*, *D. x splendidissimum* grandiflorum, *D. x xanthocentrum*, and other hybrids.

Messrs. F. Sander & Sons, St. Albans, were awarded a Silver Flora Medal for a very effective group, principally of varieties of *Phaius x Normani*, *P. x Marthæ*, and other hybrid *Phaius*, among which there was remarkable variation in colour. With them were good specimens of *Cymbidium eburneum*, *Lælio-Cattleya x Lucia superba* (C. Mendeli x L. cinnabarina), with clear yellow sepals and petals, and a crimson front and edges of the side lobes of the lip; and L.-C. x *Edwardi* (L. cinnabarina x C. Hardiana), with bronzy-orange flowers, the sepals and petals veined and tinged with dark red; the lip ruby-crimson.

G. Singer, Esq., Coundon Court, Coventry (gr., Mr. J. Collier), showed *Cattleya Trianaei* Coundonense, a very remarkable, broad-petalled variety of a uniform purplish-rose tint, the large disc of the lip orange, and the front ruby-crimson; C. T. Cassandra, a bluish-white flower, with purple front to the lip; C. T. alba Coundon Court variety, a fine pure white; C. T. Theodora, a very finely-shaped, light variety; *Cypripedium x Olivia*, *Phalænopsis intermedia* Portei, *P. i. Brymeri*, and *P. x Lady Rothschild*.

Mr. Jas. Cypher, Cheltenham, was accorded a Silver Flora Medal for a very fine group of magnificently-grown *Dendrobium*s, comprising *D. x Ainsworthi* Cypher's variety, *D. x Aspasia*, *D. x rubens* magnificum, *D. nobile nobilium*, *D. n. Statterianum*, *D. n. Fisheri*, *D. n. Murrianum*, and other *Dendrobium*s; a fine *Lælia Jongheana*, good *Odontoglossum Hallii*, varieties of *Cattleya Trianaei*, and hybrid *Cypripedium*s.

Messrs. Stanley, Ashton & Co., Southgate, staged an effective group, containing a great variety of species and hybrids. The centre was a fine *Cymbidium Lowianum*, with a large specimen of *C. x eburneo-Lowianum* on each side. With them were a good selection of varieties of *Lycaste Skinneri*, including the pure white

form; *Lælia harpophylla*, L. flava, *Odontoglossum*, *Cochlidoda Noezliana*; various *Dendrobium*s, including the pretty *D. x Ainsworthi*, *Osidge* variety, and *D. x Vannerianum*, &c.

H. T. Pitt, Esq., Rosslyn, Stamford Hill (gr., Mr. Thurgood), showed *Odontoglossum Hallii* leucoglossum, "Rosslyn variety," with large and finely-marked flowers; *O. x loochristyense*, Rosslyn variety, a very fine canary-yellow, handsomely-blotched flower, and a pretty form of *O. x asperum*.

Jeremiah Colman, Esq., Gattton Park (gr., Mr. W. P. Bound), sent *Dendrobium x Wiganiaum* Gattton Park variety.

Baron Sir H. Schroder, The Dell, Egham (gr., Mr. Ballantine), showed *Odontoglossum crispum* Truffautianum, a fine form with white flowers bearing irregular clusters of red-brown blotches on the middle of each of the segments.

A. Warrington, Esq., Vine House, Haslingden, showed the handsomely-blotched *Odontoglossum crispum* Lindeni.

J. Ebner, Esq., Beckenham (gr., Mr. Scutcher), sent *Odontoglossum mirandum*, *Cypripedium villosum*, and a distinct hybrid between *C. x Lathamianum* and *C. villosum*.

Mrs. Haywood, Woodhatch, Reigate (gr., Mr. C. J. Salter), showed *Dendrobium x Aspasia superbum*, and *D. x splendidissimum* grandiflorum Mrs. Haywood, both good floriferous hybrids.

F. Wellesley, Esq., Westfield, Woking (gr., Mr. Gilbert), showed *Lælio-Cattleya x Gattoiana* Westfield variety, a very distinct flower, with pale buff sepals, and petals veined and tinged with light purple, and a rich purple labellum.

Messrs. Hugh Low & Co. showed *Lælio-Cattleya x Lucasiana*.

Fred Hardy, Esq. (gr., Mr. T. Stafford), sent flowers of three singular but not showy hybrid *Cypripedium*s.

Awards.

FIRST-CLASS CERTIFICATE.

Lælia x Digbyano-purpurata "Edward VII." from Messrs. Jas. Veitch & Sons, Chelsea.—One of the most remarkable hybrids yet raised. The first of the parentage was flowered by Messrs. Jas. Veitch & Sons in 1898, but gave no promise of such a remarkable development as that seen in the present variety, "Edward VII." The labellum constitutes the greater part of the flower, the sepals and petals, which are white veined with rose, being gracefully arranged round it, contributing to the effectiveness of the labellum, which forms the chief attraction. The lip has much of the form of that of *Lælia Digbyana*, but is expanded and enlarged in a very remarkable degree. The base is of a primrose-yellow tint, in front of which is a white band, from which radiates rose-purple veining, extending into the rose-tinted front, which generally gets lighter in hue until at the beautifully fringed margin it is nearly white. Progression seems to have carried this remarkable hybrid almost out of touch with the others of its parentage.

AWARD OF MERIT.

Lælio-Cattleya x purpurata-Schilleriana Whateley.—From H. Whateley, Esq., Priory Lawn, Kenilworth (gr., Mr. Cook). A pretty hybrid, approaching nearest to *Cattleya Schilleriana*. The sepals and petals are tinged with light purple; lip front glowing ruby, disc yellow, with some dark lines, side lobes white with purple veining.

Dendrobium x Apollo album (nobile pulcherrimum x *splendidissimum* grandiflorum).—A very beautiful variety, with large, finely-formed, white flowers, with dark claret-purple disc to the lip.

BOTANICAL CERTIFICATE.

Masdevallia minuta, Lindl., from R. I. Measures, Esq., Camberwell (gr., Mr. H. J. Chapman).—A singular tufted dwarf species, with numerous white flowers from Guiana.

CULTURAL COMMENDATION.

To Mr. Stevens, gr. to W. Thompson, Esq., Walton Grange, for a fine specimen of *Odontoglossum pulchellum* majus, with sixteen spikes.

To Mr. Scutcher, gr. to J. Ebner, Esq., for *Odontoglossum mirandum*, Rehb. f.

Fruit and Vegetable Committee.

Present: Joseph Cheal, Esq., in the Chair; and Messrs. W. Bates, S. Mortimer, A. Dean, H. J. Wright, E. Beckett, W. Fyfe, H. Markham, J. Willard, Jas. H. Veitch, W. H. Divers, W. Poupard, M. Gleeson, and G. T. Miles.

Mr. Will Tayler, Osborn Nursery, Hampton, Middlesex, exhibited eighteen dishes of very well preserved Apples. Particularly good were Northern

Greening, Newton Wonder, Annie Elizabeth, Cox's Orange Pippin, Claygate Pearmain, and Blenheim Orange Pippin. Uvedale St. Germain Pear was shown well (Silver Knightian Medal).

From Lord Wantage's garden at Lockinge (gr., Mr. Fyfe), came some big Onions, including such varieties as Alls Craig, Cranston's Excelsior, Aristocrat, &c. (Silver Banksian Medal).

From the Duke of Rutland's garden at Belvoir, near Grantham (gr., Mr. W. H. Divers), were shown fruits of Apples Court Pendu Plat, and Scarlet Nonpareil; and Pear Ne Plus Meuris, all of them good.

Dr. B. Addy, Pembury Court, Kent, exhibited fruits of a reputed cross between an Apple and a Pear. The fruits were more or less Pear-shaped, but the flesh and flavour were those of an Apple. The wood and foliage of the tree were described as resembling a Pear-tree. It would be interesting to learn more of the circumstances.

The Lecture.

The lecture delivered by Mr. R. Hedger Wallace was, as far as we could hear it, an excellent summary of what is known of the action of bacteria in the soil. The conditions in the Drill Hall are so bad, and so little is done to improve them, or to add to the convenience either of the lecturer or of the audience, that we must await the publication of Mr. Wallace's paper in the *Journal* till we can do justice to it. The soil science, as the lecturer said, is in its infancy, but we know enough to realise that under ordinary conditions the soil teems with organisms of the minutest size, whose business it is, on the one hand, to break up the constituents of the soil into their component elements, and thus render them available in the nutrition of the plant; or, on the other, to effect the combination of elements and build up, rather than destroy. In either case, complex chemical and fermentative changes ensue, the nature of which is not yet fully determined. Most of these creatures are influenced unfavourably by light, but thrive in darkness, moisture, and a sufficiency of heat. To many of them air (oxygen) is essential, others thrive in the absence of that element. In the case of Leguminosæ, the bacteria or bacterioid bodies which are found in the little knobs on the root are able to supply a sufficiency of nitrogen which reduces (but does not annul) the necessity for the application of nitrogenous manures. The knobs themselves are supposed to be caused as a consequence of the irritation set up by the bacteria. It had been thought that by inoculating the soil with bacteria increased crops would result, and a substance known as nitrigen, and consisting of bacteria, had been used for this purpose, but the results at present were not satisfactory. That the Fellows will look forward to the publication of Mr. Wallace's lecture with great interest was testified by the brisk discussion that ensued.

KINGSTON CHRYSANTHEMUM.

MARCH 4.—The annual meeting was held on the above date, there being only a moderate attendance. The chair was occupied by Mr. W. J. Wells.

Mr. Hayward, secretary, presented a statement of accounts, which showed that the receipts for the year from all sources were £152 16s. 9d., and the expenses £170 1s. 9d., leaving an adverse balance of £17 5s., which was greatly due to the very bad weather on the days of the Society's show last year.

After discussion, it was decided to hold the next show on November 12 and 13, at St. James's Hall.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

ANNUAL MEETING.

MARCH 10.—The annual meeting was held under the presidency of Mr. Herbert J. Cutbush, at the offices of the Society, Caledonian Hotel, Adelphi Terrace Strand, W.C. The report for the past year was unanimously adopted, and it was decided to print 3,000 copies of same for distribution amongst the members and others. A perusal of the report shows a continued increase in membership—eighty-three new members having been elected during the year, whilst two only had died—the total membership is now over 900. Over £300 has been distributed in sick pay during the same period, whilst members, aged and otherwise, had been assisted to the amount of £107. The Convalescent Fund had not been drawn upon to a great extent. This fund is not sufficiently known we think to the members. Its object is to assist them by a change of air during convalescence. The entire working expenses, including the secretary's salary, printing, postages, auditor's fees, &c., amount to £143—being about 3s. 6d. per member. The treasurer reported having invested £1,600 during the year—the largest amount ever set

aside in an equal time. The total invested funds now stand at £19,000, with a balance in the treasurer's hands of £86 14s. 1d. The liabilities to members amount to £18,887 7s. 10d., leaving a balance of £199 6s. 3d. over and above all liabilities.

Mr. Cutbush strongly advocated the claims the Society has upon the whole body of gardeners, especially the younger ones now starting into life. In a concise and clear manner he laid the Society's benefits before the members, and urged them to renewed efforts to further extend its usefulness.

Thanks to the retiring members of the committee, who were again elected; to the secretary, who was also re-elected; to the trustees and treasurer, were all unanimously passed. As treasurer, Mr. Hudson has held office for twenty years consecutively, having invested in that time £16,593 in Trustees' Stocks for the sum of £17,011.

As showing the interest the officers and committee take in the business affairs of the Society it was stated that out of a possible attendance of fifteen, the average attendance was eleven. For reports and rules our readers are referred to the secretary, Mr. W. Collins, 9, Martindale Road, Balham, S.W.

TRADE NOTICE.

MR. FRED. SMITH, for the past three years gardener to Sir Shirley H. Salt, Bart., Crikhowell, has taken over the glasshouses and kitchen gardens at Waltham Grove, near Grimsby, where he will commence business as a fruiterer and florist.

Obituary.

JAMES TEGG.—The death, at the age of seventy years, of Mr. J. Tegg, who up to recently was head gardener and forester at Bearwood, Wokingham, is announced as having occurred on the 5th inst. Some two years or so ago, Mr. Tegg retired through ill-health, and resided at Wokingham, near the scene of the principal work of his life. Death came somewhat suddenly through heart failure, and he was buried in Bearwood churchyard, which is on the estate. He leaves a widow and grown-up family.

James Tegg was born at Midgham, in South Berkshire, on March 29, 1832, and began his gardening career in the then well-known nursery of Mr. Henry Groom, at Clapham Rise, Surrey. From thence he went to Driffield, in Yorkshire, and filled the position of foreman in a private garden. From thence he came south, and was next found as foreman at Messrs. Maudsley & Sons, at Norwood; and from there joined his father, who was then gardener at Dover House, Rochester, as his foreman. Then came the opportunity of his life—his appointment as head gardener to Baron Hambro', at Roehampton, where he soon became known as a successful cultivator and exhibitor of fruit at the exhibitions of the Royal Botanic Society in the Regent's Park, the Crystal Palace, and elsewhere, Grapes and Melons especially being staged by him. Here he remained for ten and a-half years, when he went to Clumber, Worksop, Notts, as head gardener to the late Duke of Newcastle, and while there he was an exhibitor in several classes at the International Horticultural Exhibition held at South Kensington in May, 1866. He remained at Clumber five years, and then came south to take charge of the gardens and woods of Bearwood, the estate of Mr. Walter—a post that he filled for the space of thirty-one years; and while here he carried out several extensive alterations and improvements, including the planting of the Wellingtonia avenue, the formation of a new kitchen-garden, an extensive rock-garden, &c. The building of the palatial mansion some years ago afforded an opportunity for extending the pleasure-grounds, and in subsequent years other improvements were made. Mr. Tegg always took a strong personal interest in his work. He was a man of remarkable energy and activity, and kept the gardens and houses in excellent order. One incident in his career was occasionally mentioned by him. He made up the first bouquet presented to her present Majesty the Queen, when as Princess Alexandra of Denmark she first came to England in 1863. The bouquet was made by order of Baron Hambro', and was presented to the Princess by the Danish Ambassador. R. D.

ANSWERS TO CORRESPONDENTS.

ASPIDISTRA: A. B. The present month is a good time for subdividing the plants. When this is done, the plants sooner recover when afforded bottom-heat of 75° to 80° in a frame for a month or two. Use a loamy soil, and good but not over-abundant drainage.

CATERPILLARS FOUND AMONG CABBAGES: J. S. At the stage of the grub sent it is very difficult to say for certain what the species is. It is not peculiar to Cabbages, and you had better feed some of them on the leaves and stems of Cabbages; allow them to pass through the chrysalis stage and form the perfect insect, and send that to us.

DAFFODIL SIR WATKIN: H. & B. St. Martin. The striping or deep channelling of the leaves is due to some sort of check to growth. The plants will doubtless grow out of it as the weather gets warmer.

GARDENING IN INDIA: Correspondent. In reply to your question, we would say that *Gardening in India*, by G. Marshall Woodrow, is the most suitable book for your purpose. The publishers are: Bombay, Thacker & Co., Ltd.; Calcutta, Thacker, Spink & Co.; Madras, Higginbotham & Co.

GARDENER'S HOUSE AND THE PAROCHIAL RATES: An Old Subscriber. If the house you occupy rent free is not on the home estate of the employer, but is a separate tenement, you must pay the rate, and make the best terms you can with him.

LANDSCAPE WORK, DRAWING, DESIGNING, &c.: A. B. C. Obtain Mr. H. E. Milner's *Landscape Gardening*.

LEAF-MINERS IN MARGUERITES: Maggot. Insecticides are of no avail. You must pinch the grubs under the thumb-nail when there are but few of them, or cut off the leaves and burn them if too numerous to destroy by the first method. When the insect is on the wing, the deposition of eggs may be prevented by the use of quassia-water. The same fly infests Chrysanthemums, Cinerarias, Senecios, &c.

NAMES OF FRUITS: C. P. Beauty of Kent.—J. H. 1, Normead Pearmain; 2, a small example of Hambleton Deux Ans.—*Colocynth*. Flanders Pippin.—W. D. 1, Cox's Orange Pippin; 2, Sturmer Pippin; 3, Christmas Pearmain.—G. R. A handsome form of Beauty of Kent.—D. C. H. 1, probably a local variety; 2, we believe this to be the true Melrose.—G. H. 1, Warner's King; 2, Cobham.—H. J. 1, Golden Reinette; 2, somewhat resembles Cluster Golden Pippin, hence, perhaps, it has obtained the local name of Cluster; this, with 3 and 6, are, no doubt, of local origin; 4, Fenouillet Jaune; 5, Norfolk Stone Pippin; 6, is not the true Ten Shillings, an old Apple, but resembles it in some points, and has thus probably been named locally.

NAMES OF PLANTS: C. S. You send three very small sprays of some Junipers without numbers by which we can identify the specimens. Please send better specimens properly numbered.—J. F. Brassavola glauca, Lindl., now generally called *Laelia glauca*. It generally has some slight purple markings at the base of the lip. See *Gardeners' Chronicle*, 1890, vol. vii., p. 356.—T. H. O. P. Cattleya Trianaei, a fairly good variety.—W. J. R. 1, Todea superba, a filmy Fern; 2, Adiantum cuneatum mundulum; 3, Polypodium aureum; 4, Adiantum hispidulum; 5, Platylema flexuosum, sometimes called *Pteris flexuosa*; 6, *Daphne Mezereum*.—J. C. B. 1, Cattleya Trianaei delicata; 2, Cattleya labiata, flowering late.—C. R. S. *Laelia Jongheana*, now rather plentiful, but very rare a few years ago.—D. E. T. 1, *Diosma* species, send in flower; 2, *Diosma ericoides*; 3, *Diosma capitata*; 4, send in flower—possibly a Privet; 5, *Polygala oppositifolia*; 6, *Polygala cordata*; 7, *Acacia pulchella*; 8, *Acacia eultriformis*. Please send better specimens in future, most of these are

without flowers.—W. P. *Dendrobium nobile* album.—A. B. 1, *Acalypha Macleania*; 2, *Acacia longifolia*; 3, *Acacia cyanophylla*, so far as we can judge by the specimens sent.—J. W., Coventry. A very fine variety of *Dendrobium nobile*, but without sufficient distinctness to warrant a special name.—R. E. The small African Orchid is *Eulophia tristis*; the fleshy flower *Stauroopsis gigantea*, more often called *Vanda gigantea*; the *Dendrobium nobile* is a very fine variety.—E. R. 1, *Habrothamnus*, or *Cestrum fasciculatum*; 2, *Cotyledon* sp., send when in flower; 3, *Abies Pinsapo*.—G. H. P. *Lonicera fragrantissima*.—Rosa. *Griselinia littoralis*, nat. order Cornaceae.—E. C. L. Leaves insufficient, send when in flower. Sent with an Apple, but No Name. 2, *Grevillea rosmarinifolia*; 3, *Diplopappus chrysophyllus*; 4, *Cupressus lusitanica*, probably; 5, *Cupressus*, perhaps *Goweniana*, but we cannot tell without cones; 6, *Veronica Traversii*.

NOTICE TO LEAVE EMPLOYMENT: D. Kimber. If you lose wages from being late in the morning, you do no work in the first quarter of the day, so that there is really no cause of complaint on your side, but rather on that of the employer. If oft repeated it might afford a reasonable cause for discharging you at a moment's notice. If you are a day labourer, no notice is required by an employer. If living in a bothy, a month or a week's notice is customarily required and given.

NOTICE TO QUIT SERVICE: A. A., Kent. Under the circumstances related, you are, as a gardener engaged at a yearly salary, entitled to at the least one month's notice, or in lieu thereof, payment in full for that length of time.

NURSERY: D. K. L. As you possess only an acre of land, and must transplant the young stuff after it has remained in the seed-beds two years, a very few pounds of Larch, Spruce, and Scots Pine will suffice—say 10 lb. of the larger and heavier seeds, and proportionately less of the small, light seeds. Prepare now beds 4 feet wide and of any desired length, by dressing them with leaf-mould or quite decayed stable-manure, and digging the soil deeply, but not necessarily trenching it; trample the soil firmly, rake it to a fine tilth, scatter the seed thinly broadcast, cover with soil out of the alleys from a quarter to half an inch deep, and roll lightly.

PELARGONIUM: J. C. The disfigurement upon the leaves of the variety *Raspail* is probably due to drip or damp. Afford more ventilation, and maintain as buoyant and pure air as possible.

PRIMULA OBCONICA: F. R. H. S. A few years ago the flowers you send would have been novel; but there have been many seedlings raised recently that produce blooms quite as large, and of equal colour to yours. Some very remarkable plants shown at the Drill Hall are referred to on p. 182.

STRAWBERRY PLANTS FAILING: Worcester. The plants have the appearance of having had the top growth forced up by a high temperature much in advance of any action at the root. The forcing needs to be very gentle in the early stages, and, if possible, bottom-heat should be applied by sinking the pots partly or wholly in a leaf-bed, and at the same time keeping the tops cool and ventilated.

VEGETABLE PRODUCTS IN MINCING LANE.

AT this time of year, when the British public generally is more or less interesting itself in the Chancellor of the Exchequer's Budget, our thoughts run over a wide range of commercial products, or likely sources of taxation that may possibly suggest themselves to the resourceful and fertile mind of the Chancellor, and that will not press too heavily on any class of the community in particular. In doing this we cannot help being struck with the prominent part the vegetable kingdom plays in the realisation of revenue. A glance even at the Customs Tariff of the United Kingdom which, of course, is a list of those articles which are already liable to duty, proves the truth of this statement, not only with regard to the number of vegetable products in comparison with those from other sources, but also to the absence of many other well-known substances of equal or even more importance, and which would probably yield large sums were a slight duty chargeable. Tobacco, Tea, and Sugar are, as everybody knows, fruitful sources of revenue which, though the rates upon each may be varied, will, like the income tax, probably never be surrendered. Probably, however, there are comparatively

few people who have any idea of the important position fruits and flowers under different forms hold in the Customs tariff, and the unequal manner under which they are taxed; thus, while dried Currants pay only two shillings per cwt., Raisins are charged seven shillings—very unequal rates for two varieties of the Grape, the presence or absence of “stones” or seeds in the fruit apparently making all the difference, and yet not entirely so, for the Sultana (a stoneless Grape) is classified as a Raisin, while some of the very large Currants now often seen in the market are sometimes a puzzle even to the Customs authorities, who have to decide whether they should be classified as Currants or Raisins. Figs and Fig-cake, Plums and Prunes, are chargeable with the same rate as Raisins; while canned and bottled fruits preserved in thin syrup pay one shilling per cwt., the same preserved in thick syrup have to pay two shillings more, or three shillings per cwt. Crystallised fruits are distinguished from others by a higher rate, namely 4s. 2d. per cwt. Ginger preserved in syrup or sugar is charged three shillings per cwt., while preserved Tamarinds pay only one shilling.

Flowers occur in the Customs tariff in one form only, and this not in a fresh or dried state, but in the condition of sweetmeat, namely, the crystallised flowers of the Violet, Rose, Orange, and which are charged at the same rate as crystallised fruits, namely, 4s. 2d. per cwt.

If the Chancellor of the Exchequer were to take a walk through the several brokers' show-rooms in Mincing Lane, he would, no doubt, become imbued with new ideas of taxation: at any rate, a glance down the reports of the London markets in that busy corner of the great city is a lesson of much interest and great educational value, for it is chiefly in these reports that we first find references to products new to commerce—things that are sent into market at first in small quantities to test their suitability as marketable articles, and their prospect of finding purchasers. Products of this kind of any real value seldom make their way with any flourish of trumpets, but become quietly established, the demand increasing as their properties become known.

The case is, perhaps, rather different with regard to medicinal products, any new discovery in this direction has of late years been made the cause of many much-advertised quack medicines, though some of them have proved of value, and have found a place in the *Pharmacopœia*, such as Coca (*Erythroxylon coca*), and Cascara sagrada (*Rhamnus Purshiana*), and others. In the Mincing Lane classification of products, it is sometimes difficult to find any special article; for instance, one unacquainted with the ways of product brokers, would scarcely expect to find Chillies classed with spices, but in such company they are always placed, though the principal use of the Chilly is as a condiment, either for making cayenne pepper or for mixing with pickles. Very large quantities of these pungent fruits now come into English commerce, and it is said that the increased demand is to some extent due to the use of much larger quantities than has hitherto been the case in the West of England pickle preserving trade: though there is also a fairly good demand for them in medicine.

The geographical range of commercial Chillies has of late years become much wider than formerly, for besides the regular source from India, we receive Chillies of good quality and very bright appearance from Nyassaland, Sierra Leone, and Zanzibar; and more recently from Japan. The botanical source of the African Chillies is attributed to *Capsicum minimum*, and though the general appearance of the Japanese form is very similar, it is usually somewhat larger, and has less pungency; and it has been suggested that it may be a small form of *C. annum*. The market value of Chillies varies from 38s. per cwt. for ordinary mixed Zanzibar, to 52s. for good red Nyassaland fruits, but these prices are affected by the ebb and flow of supply and demand.

Speaking of spices, one would rather expect to find Vanilla under this head, but so important is this valuable product in the Mincing Lane trade, that it is not only placed under a separate heading in the market reports, but the samples themselves are always shown in a separate show-room, and indeed in a distinct building.

The extension of the cultivation of Vanilla, not only in new plantations, but also in entirely new countries, is sufficient proof of its constant demand, and of its value as a profitable crop; and this notwithstanding the continued manufacture and use of artificial vanilline. The following facts on the present condition of the trade in Vanilla are gathered from our well-informed contemporary the *Chemist and Druggist*, who, in reporting on the Vanilla sales at the end of last month, say that the supply brought forward was the heaviest on record, and attracted a much larger attendance of buyers than usual. There was, however, a good demand, and practically the whole quantity offered, about 2,800 tons, was sold. Long lengths being scarce brought good prices, while medium lengths also sold well, pods from 8 to 8½ inches long, and of good chocolate colour, fetched 22s. 6d. per lb.; 7½ to 8 inches, 19s. 6d. to 21s. 6d.; and so on in proportion, for it must be remembered that Vanilla-pods are classified in the market and valued according to their lengths, plumpness, and colour. Thus, at the same sale the lowest grade of dry, brown pods realised only from 4s. to 11s. 6d. per lb.

Referring to the condition and prospects of Vanilla cultivation in the Seychelles, Messrs. Brookes & Green, the well-known brokers, state that the Seychelles crop for 1901 shipped from August to December totalled fully double the heaviest quantity exported from the island in any previous season, it being estimated at about 80 tons. The feature of this season's supply of Vanilla from Seychelles is the unprecedented large proportion of short beans. Medium to good size quality measure from 6 to 8 inches, but the consignments landed in London during the past three months have contained about 75 per cent. of very short beans, ranging from 3 to 5 inches. The result has been that whilst long-length quality has fairly maintained previous values, the short measurements show a reduction of about 50 per cent. To obtain good plump pods, it is incumbent for planters to see that early in the season the young shoots are thinned by picking out a quantity of surplus sprouts; in the present

case it would seem as though nearly all had been allowed to grow. This view is somewhat confirmed by recent reports from Seychelles, which advise that the flowering for the next crop is small—possibly due to the weakening of the vines last year;

ment, it may be stated that in November last one shipment from the Seychelles amounted to 21,267 kilos, of which 12,386 kilos went to Marseilles, and 8,881 kilos to London. The exports from Tahiti during 1900 amounted to 162,636 lb., of the value of

NEW OR NOTEWORTHY PLANTS.

ARISTOLOCHIA ARBOREA.

In the catalogue of M. Linden issued in 1858, this plant is mentioned as having been found in the forests of Chiapas, New Granada,

FIG. 57.—FRUIT AND SEED OF *ARISTOLOCHIA ARBOREA* FROM BOTANIC GARDEN, BATH. (SEE P. 187.)

indeed, some of the older plants are reported as seriously exhausted—a very natural result if the above surmise is true.

The warning here given, though not expressed in gardening terms, will be understood by those who cultivate the plant for profit, and who will, no doubt, benefit by the hints.

As an illustration of the quantity of Vanilla sometimes shipped in one consign-

£32,132—no small sum to be added to the finances of the island.

Chillies and Vanilla, to which we have referred, are only two items in the immense returns that flow into and are distributed from the great city markets included under the generic name of Mincing Lane. At another time I hope to refer to other products of equal value and interest. *John R. Jackson, Lympstone, Devon.*

by M. Ghiesbreght. Linden, it appears, sent it to Kew, where it flowered, and was figured and described by Sir William Hooker in the *Botanical Magazine* (1862), t. 5295. Since that time, so far as we can find, nothing has been heard of the plant till Captain Donnell Smith, of Baltimore, forwarded us specimens of an *Aristolochia* gathered by Herr von Turekheim in Guatemala at an altitude of 350 metres. On examination of the flower we had no difficulty

in at once referring the plant to the *A. arborea* of Linden. The plant is highly curious, as like its congener, *A. maxima*, it is not a climber, but a low, branching shrub, with numerous erect, slender branches, long, lan-

beneath the surface of the ground, about 2 inches in diameter, of a rich brown colour, the outer part of the corolla [perianth] on the lower end 3-lobed, middle lobe white (the white even extending over the side lobes), but the

junction between the distended tube and the expanded limb. This stalk is surmounted by a thick, oblong, cushion-like, fleshy cap, about 1 cent. in its longest diameter, aptly compared by von Turekheim to the pileus of a fungus.

The column placed, as usual, at the extreme base of the tube immediately above the ovary, is oblong, with a sub-orbicular, 2-lobed disc, differing from the ordinary 6-lobed style of most *Aristolochias*, but resembling that in the genus *Holostylis*. The flowers of *Aristolochias* have in many cases a fold or tube emerging from the throat of the perianth, and pointing downwards as if to facilitate the ingress of insects, and perhaps to obstruct their egress when once they have gained admission. This arrangement, like the curious process of *A. arborea*, is doubtless connected in some way with the fertilisation of the flower, but it would be rash to say in what way till we had the opportunity of seeing the insect, if insect it be, at work. We must have examined many scores of dried *Aristolochia* flowers, and many living ones, but we scarcely remember to have seen an insect in them on any occasion. Maxwell T. Masters.

HORSE-CHESTNUTS.

ÆSCULUS AND PAVIA.—Among trees of large size that are hardy in this country, the common Horse-Chestnut (*Æ. Hippocastanum*) is by far the most ornamental as regards its flowers. No tree that we can grow equals it in its combined grandeur of aspect and beauty as a flowering tree. There are, besides this, seven other species in cultivation, but none of these, in this country at any rate, is more than medium-sized, and two of them are usually of a shrubby character. All the species of *Æsculus* are noteworthy for their beauty of foliage, standing perhaps pre-eminently in this respect as a genus of hardy trees. It should be mentioned that "*Æsculus*," as now interpreted, includes what were formerly known as "*Pavias*." The *Pavias* were distinguished from *Æsculus* by their smooth fruits and four-petalled corollas; the true *Æsculus* having spiny fruits and five petals in the corolla. The discovery, however, of species in which these distinctions broke down caused the merging of the two groups under *Æsculus*.

All the species are gross feeders, and like a rich, moist soil. The greedy, far-reaching roots of the common Horse-Chestnut make it difficult to grow any choice plants near it. It is, in fact, only suitable for large gardens or parks.

The best method of propagating these trees is by seed, which should be sown as soon as ripe. Some of the varieties of garden origin have, of course, to be "worked," but it is unfortunate that the stock oftenest used for the smaller-growing ones should be the Horse-Chestnut. Its vigour and rapid growth make it quite unsuitable for them, and grotesque specimens, with the stock thrice the thickness of the scion, are frequently the result of using it. Seedlings of the species to which the variety belongs should, if possible, be used as stocks.

Æ. CALIFORNICA.

This tree, one of the rarest of the Horse-Chestnuts, is a native of the western slopes of the mountains of California. It has a low, rather spreading habit, and at its largest is only from 30 feet to 40 feet high; oftener it is a shrub one-third as high. In the southern parts of England, even at Kew, it is perfectly hardy, and it flowered in Messrs. Veitch's nursery at Exeter as long ago as 1858. During the summer of 1901 it flowered and fruited at

FIG. 58.—*ÆSCULUS TURBINATA* (= *Æ. CHINENSIS*, HORT.).

(SEE P. 188.)

ceolate leaves, and curious flowers emitted from the corky stem near the base.

The main peculiarity of the flower we shall allude to immediately, but in the meantime we may quote M. von Turekheim's description from the living plant. "A little tree or shrub about 8 to 10 feet high, with very rough bark [and], long, lanceolate leaves; flowers coming out on the main trunk in clusters, even from

most queer thing is that the place where the outer corolla goes into the tube is closed by a spongy excrescence of the shape of a fungus whose stalk is white, while the hat [pileus] is of the same dark brown as the corolla."

The coloration is not perceptible in the dried flowers, but the fungus-like excrescence is easily detected. Its broad, cylindrical stalk emerges from the throat of the perianth at the

the Bath Botanic Gardens, under the charge of Mr. J. Milburn, from whose specimen the accompanying illustration (fig. 57, p. 186) was made. Sargent describes it as the most beautiful of all the American species in its numerous flowers, which are borne on erect racemes, 6 inches or more long, and are white tinted with rose in colour. The leaflets vary in number from four to seven, but are usually five in each leaf, and are narrower and smaller than in the other species. Perhaps the climate of southern England may scarcely be sunny enough to suit the Californian Horse-Chestnut, but judging by its success at Bath, it seems deserving of more frequent trial.

Æ. CARNEA.

Nothing certain appears to be known of the origin of this Horse-Chestnut, but it is assumed to be a cross between the common Horse-Chestnut and *Æ. Pavia*. Its convenient size (25 feet to 30 feet in height) makes it a popular tree in gardens, and it is now almost as well known as *Æ. Hippocastanum*. It is the best of all the Chestnuts, with brightly coloured flowers, some of its improved forms—the best of which is called *Briotii*—being of a rich, deep red. Its neat, rounded habit makes it as well adapted for small gardens as the common Horse-Chestnut is for parks and avenues. It ripens seeds, and improved forms can be raised from them.

Æ. FLAVA.

None of the American species of *Æsculus* seems capable of attaining to great dimensions in this country, but this, the "Sweet Buckeye" of the United States, is the largest. It is described as often 90 feet high, growing wild on the slopes of the mountains of Carolina and Tennessee, but the finest specimen I have seen in Britain has been little more than one-third as high. It is, nevertheless, a very handsome tree, shapely, even rather formal in outline, and amply furnished with its beautiful foliage. Its racemes are 4 to 5 inches in length, and the flowers pale yellow. There is a variety of it which has reddish-purple flowers, and numerous forms (or perhaps hybrids between this and *Æ. Pavia*) exist in nurseries. Some of these, such as *discolor*, *Lyoni*, *neglecta*, *Whitleyi*, and *macrocarpa*, are amongst the handsomest of dwarf Horse-Chestnuts. They are, however, frequently short-lived, owing to the practice of budding them on the common Horse-Chestnut which has been alluded to.

Æ. GLABRA.

Although this species, like all the Horse-Chestnuts, is handsome as regards its foliage, it has no merit as a flowering-tree. The racemes are not large, nor are the flowers; and the latter are of an inconspicuous greenish-yellow. It is a North American species, and is most frequent in the Mississippi Valley, where it is rarely more than 30 feet high; it is now, however, a rare tree in a wild state. Its popular name is the "Ohio Buckeye."

Æ. HIPPOCASTANUM.

The common Horse-Chestnut, in spite of the species subsequently introduced, is still by far the best as a park or avenue-tree. In breadth and bulk, none of the other species approach it, at least in this country. Nor in its splendour as a flowering tree is it equalled by any other of similar size that can be grown in this country. For very long after its introduction to Western Europe, over three centuries ago, its native country could only be conjectured. It was known to have reached more western countries by way of Constantinople, and was believed to have come originally from Northern Asia. It has, however, been found to be a

native of the mountains of Northern Greece. Of several varieties of the Horse-Chestnut in commerce, the most noteworthy and useful is the double-flowered one. The flowers of this variety being very double, and the racemes of large size, give it a very striking appearance, and the blossoms remain longer in good condition than those of the single forms. Var. *Schirenoferi* is also double-flowered, but in what way it differs from the old I have not known it long enough to find out. The curious variety known as *laciniata*, or *asplenifolia*, has its leaves divided into narrow lobes. There are also variegated forms of no particular merit.

Æ. INDICA.

In its foliage this is one of the most striking of the Horse-Chestnuts. The leaflets are more numerous than in any other cultivated species, being usually seven, and frequently as many as nine, to each leaf. The leaflets are often 1 foot long, and the leaf-stalks a rich red colour. There are some small trees at Kew that have flowered occasionally, but they will probably flower with more frequency and freedom as they get older. The raceme is a very fine one, being 8 to 10 inches long, erect, and more slender than that of *Æ. Hippocastanum*; the flowers are white, the upper petal being marked with a yellow blotch, and the lower ones tinged with rose. At Kew, the Indian Horse-Chestnut has proved to be hardy, although there is no doubt it likes a sheltered spot. It comes from the Himalaya, and there reaches a height of 60 to 70 feet, equalling the common species in beauty when in flower. Apparently it almost equals it in bulk as well, for, according to Sir Joseph Hooker, it has a trunk 3 feet in diameter.

Æ. PARVIFLORA (= PAVIA MACROSTACHYA, Gard. Chron., 1877, ii., 657).

Whilst this species is usually seen in a shrubby state, it does occasionally become a small tree. Where space is limited, it is the best of the *Æsculus*, as it usually remains under 9 feet in height, and is of compact, bushy form. Single specimens are sometimes 15 feet or more in diameter. The foliage is of a fine dark green, and is handsome in form, rendering the species one of the most striking of deciduous shrubs. Flowering five or six weeks later than the common Horse-Chestnut, it is not until late July or August that it is at its best; its racemes are slender, erect, and numerous, furnished with pinkish-white flowers, a prominent feature of which are the long, thread-like, more deeply-tinted stamens. It is a native of Eastern North America, where it is found on the foot-hills of the Southern Alleghanies. (See fig. 59, p. 189; and fig. 60, p. ix.)

Æ. PAVIA (PAVIA RUBRA).

This species is often confounded with the red-flowered varieties of *Æ. flava*, with which, possibly, it has hybridised. The true plant is somewhat rare. It is a shrub, usually low and even straggling in habit, but it is perhaps the richest coloured of all the *Æsculus*. The flowers are not abundant on the racemes, but are each 2 to 3 inches long, narrow, and of a bright red. The leaves are small, and of a shining dark green. It is a native of the Southern United States, and is less hardy than most of the American species.

Æ. TURBINATA (= Æ. CHINENSIS HORT., NOT OF BUNGE).

Little can be said of this species as yet, for it is a comparatively recent introduction. It flowered in Messrs. Veitch's Coombe Wood nursery last year, but was, I believe, dis-

appointing. However, it may improve with age. It is perfectly hardy, as might indeed be expected, for it comes from the Island of Yezo (Japan). It is remarkable for its fruits, which are about 2 inches in diameter, and even more distinctly Pear-shaped than those of *Æ. californica* (fig. 58, p. 187).

The tree known in European gardens as *Æsculus chinensis* (or *sinensis*) is this Japanese Horse-Chestnut. The plant figured in *Gard. Chron.*, 1889, v., p. 116, is also *Æ. turbinata*. The true *Æ. chinensis* of Bunge has not, so far as I am aware, been introduced to Europe. It is quite distinct from *Æ. turbinata*, being much more nearly allied to *Æ. indica*. The accompanying figure was made from a specimen that flowered with Mr. Van Volxem thirteen years ago, under the erroneous name of *Æ. sinensis*. W. J. Bean, Kew.

HIPPEASTRUMS.

THEIR CULTURE.—Our earliest-potted bulbs, which were placed in an intermediate-house after they were potted, are pushing up their flower-shafts, and in the case of a collection being an extensive one, which is divided into two portions, the later portion of bulbs may now have their annual repotting, assuming that growth is dormant. Some gardeners repot only a portion of the bulbs annually; moreover, when many are grown, it is not convenient to repot the entire stock, those top-dressed last season being the only repotted ones. I prefer to repot annually, the plants growing the stronger for it. A good turfy loam which has been in stack for a year, two-thirds, some spent Mushroom-bed manure, one-third, and silver-sand, form the potting soil. The exhausted soil should be shaken from the roots, then crock clean pots, putting rough loam over the crocks, following this with a handful of the soil, and make this firm, then put in the bulb, spread out the roots, and let some of the compost trickle in amongst them; make firm and fill up the pot to within an inch of the rim, the shoulder of the bulb being visible. Plunge, if convenient, in a mild hot-bed, not far from the glass, and afford no water before some amount of growth has taken place, the water-syringe being sufficient at the first. When the flower-spikes are well up out of the bulb, afford enough water as will moisten the entire mass of soil, and after this stage keep the soil consistently moist.

If the pots are plunged in a hot-bed, only a moderate amount of water is required. It is customary to surface the hot-bed with tanners' bark or cocoa-fibre refuse. The plants may be grown satisfactorily without a hot-bed. After flowering, place the bulbs in an intermediate-house or a vinery, but not where the shade is dense; water in abundance should be applied during growth, withholding it gradually when the leaves show signs of ripening. At this stage, fully expose them to sunshine, and afford air freely; they must be kept safe from frost. A well-flowered *Hippeastrum* makes a useful vase plant, seldom failing to excite admiration, if of a good type. Bulbs may now be bought fairly cheap; but to those about to grow them, I would suggest the buying of a few good varieties. They cross readily, and produce seed freely, and the raising of seedlings is an interesting occupation. Seedlings flower when fully four years old, and sometimes when three years old if the treatment has been very good. Thrips are sometimes troublesome, but fumigating or sponging with some insecticide will eradicate these; while if grown with other plants troubled with scale, this parasite will attack them. [Bulbs started very early in the year by the

FIG. 59.—*ESCHULUS PARVIFLORA* (*PAVIA MACROSTACHYA*). (SEE P. 188.)

aid of hot-bed frames can be flowered in April, ripened off, rested, top-dressed, and flowered again within the space of twelve months. Such bulbs should not be started early the next year. Ed.] T. H. Slade.

ORCHID NOTES AND GLEANINGS.

CYPRIPEDIUM × EDMUND ROTHWELL.

THE issue of *American Gardening* for March 1 gives an illustration of this distinct hybrid, together with illustrations of the parents—C. Hookeræ and C. Sallieri Hycanum. The raiser, Mr. J. E. Rothwell, gives an account of the origin of the plant, which first flowered on January 3 this year, six years from the time the cross was made. He likewise gives the following description:—"Dorsal sepal primrose-yellow, darkest towards the base, with a white margin. Petals rich butter-yellow, with a strong suffusion of the purple of the pollen parent (Hookeræ) over the lower half, most intense at the extreme ends. Inferior sepal greenish, much the shape of Hookeræ. The staminode strongly resembles the seed parent, Sallieri, a strong yellow in colour. The pouch also resembles the seed parent in shape, and is of a dark yellow, suffused with a tawny colour. The spots of Sallieri have entirely disappeared from the dorsal, and the general appearance of the flower is a decided improvement over those of the parents, and yet it is quite intermediate."

A TWIN-FLOWERED LYCASTE SKINNERI.

ON several occasions the extraordinary vigour of the plants of *Lycaste Skinneri* in Mr. J. Broome's garden at Llandudno has been commented upon in this journal, and a fresh sending of fine blooms discloses the fact that the vigour of the plants has not decreased. The largest flower is supported by a stem 13 inches in height, and the former is 7 inches across. The others are nearly as large, and in the case of one of them two large flowers are growing on one spike, which present a strange appearance, one flower being arranged almost in front of the other on a foot-stalk 2 inches in length. Flowers of a superb variety of *Dendrobium nobile*, two distinct large forms of *Odontoglossum triumphans*, *O. Hallii xanthoglossum*, and a bright yellow *Lælia Cowani*, which seems to differ in the form of its lip from *L. flava*, are also sent.

LÆLIA JONGHEANA VARIETIES.

THIS fine species bears very large flowers, considering its dwarf habit, and some plants are now in bloom in many gardens. The plant thrives when it is suspended in a light position from the roof of a cool intermediate house. There is great variation in the colour of the flowers, for apart from the occasional albino, this ranges from blush-white to lilac and bright purple, the extraordinary orange-coloured, ridged crest being present in all, but varying also in some degree. Two fine flowers, each about 7 inches across, the one of a pale lilac tint, and the other tinged and veined with dark rose-purple, are kindly sent by J. Broome, Esq., Sunny Hill, Llandudno, exhibit structural differences in a marked degree. The darker flower has the wavy-edged, middle lobe of the lip gradually tapering to the apex, and continuous with the margins of the side lobes, with no perceptible cleft between them. The lighter flower has the middle lobe crimped and broadly ovate, and distinctly separated from the side lobes by a cleft $\frac{1}{2}$ inch in length on each side. Deviation in this respect in some degree is noticeable wherever there are several plants

of the species; but seeing the two extremes together, we perceive how untrustworthy even what many would consider botanical differences are, although distinct species have been made of plants with less clearly defined differences.

PLANT NOTES.

TORENIAS.

THE genus *Torenia* contains some very beautiful species of dwarf-growing greenhouse plants. They are of easy culture, and the plants when in flower are very decorative.

The two best all-round species are *T. asiatica* and *T. Fournieri*, both of which are robust in constitution and remarkable for flowering freely throughout the summer months.

There are two methods by which the required number of plants may be raised. First by sowing seed in the month of April, and when the young plants are sufficiently large, pricking them off singly, and growing them on quickly in a temperate-house; or secondly, by striking cuttings of the young shoots when procurable. If these be inserted in a light, sandy soil, and covered with a bell-glass, roots will very quickly be emitted. An essential point to bear in mind in growing these soft-wooded subjects is to give them every encouragement to grow away freely, without check of any kind. Maintain a genial atmosphere about them, and afford frequent syringings, especially on hot, dry days.

A compost I have found very suitable for *Torenia* is one consisting of one-third loam, one part of flaky leaf-soil (not sifted too finely), and the remaining part Mushroom-bed refuse and sand.

T. Fournieri is of more upright growth than *T. asiatica*, and is well adapted for growing in pots, though the species is sometimes cultivated in hanging baskets, and when well-grown, the *Torenia*s are excellent subjects for this purpose, provided copious supplies of water be afforded them in hot weather, by immersing them in a vessel of water. This method of watering will check the progress of insect pests to some extent.

Thrips and red-spider will sometimes attack *Torenia*s, but with slight fumigations, or syringings with weak insecticides before the flowering stage, they will not do much harm. When the flowers appear, keep the plants near to the light, and discontinue overhead syringings. At this period the plants may be removed to an airy structure that is shaded during the hottest part of the day. The *Torenia*s make very beautiful room-plants, and are not quickly injured by being placed in them. H. T. Martin, *Stonleigh Abbey Gardens, Kenilworth*.

The Week's Work.

THE KITCHEN GARDEN.

By T. TURTON, Gr. to J. K. D. WINGFIELD DIOBY, Esq., Sherborne Castle, Dorset.

Planting Potatoes.—The planting of early Potatoes is a matter which is just now occupying the attention of most gardeners. The earliest crop is obtained from south borders, sheltered on the north by a wall or high building; and on such sites skeleton frames can be fixed for supporting mats or other protecting material when frost threatens in May. Sufficient ground should now be planted to ensure a supply of tubers for the table till those that will be planted a month hence come into use. As an early variety to plant outside and under glass, I prefer Ringleader, which I grow exclusively for this purpose. Assuming that the

sets were all stood on end in shallow boxes as advised in a former Calendar, the shoots will be sturdy and strong, and should be reduced to two or three of the stronger, in the same way as were those planted in frames. The object with the earliest crop of Potatoes is the production of tubers of a goodly size for the table without wasting the energies of the plants in producing a host of very small tubers useless for consumption, which is the case when all the shoots are left. If the border was well prepared by trenching and manuring in early winter, it will be in fine condition for planting with a dibber, a method I prefer, as it economises labour, and avoids much disturbance of the soil. Heavy soils are the better for being thrown into ridges when dug, and these should be levelled, unless the ridges run north by south. The handiest way is to plant in the furrows. A Potato-dibber should be made about 15 inches long and about 3 inches thick. It should be made of hard wood, as Yew-tree branch or Boxwood, and should have a spur of a smaller branch on the top of it to fit between the thumb and forefinger. The sets should not be placed deeper than 4 inches.

Autumn-planted Cabbages.—When the surface is dry and the day fine, put the hoe through the Cabbage-beds, and pick up all the chick-weed and other weeds of any size. The hoeing will check the growth of weeds, and aerate the soil. If the land be of a light nature, make it firm about the plants by trampling round each, all Brassicas succeeding best in a firm soil, and more especially Cabbages.

Broad Beans.—Early Long-pod Beans, sown in boxes as advised in the month of January, should now be standing in cold frames; and after a few days of full exposure by having the lights removed, on the first spell of mild weather set out the plants in shallow trenches on a warm border, in double lines, the plants standing at 1 foot apart in the line, and the trenches drawn at 4 feet apart. Another sowing of a Long-pod variety may be made forthwith on a warm border, and at the same distances apart as those planted out, and also in shallow trenches. Failing an available border, sow in the open quarter.

THE ORCHID HOUSES.

By W. P. BOUND, Gardener to J. COLMAN, Esq., Gatton Park, Reigate.

Odontoglossum citrosimum.—These plants are pushing up their growths, and should be afforded a little more water than they have hitherto received since October, but let there be no forcing of growth till the flower-spikes appear. The good flowering of the plant depends on the treatment afforded in the rest season. At that season they should be exposed to full sunlight, and the ventilation should be ample till the flower-spikes appear; they should also have a large amount of sunshine, and water be gradually increased in quantity.

Potting.—After flowering is over is the best time to repot the plants should it be required, not disturbing them unless the materials are in a bad condition. The compost may consist of turfy peat two-thirds, and chopped sphagnum moss one-third. Pans are to be preferred to pots, as these can be easily suspended on account of the pendulous spikes, and hung close to the glass. The drainage should be good. At repotting, remove the back pseudobulbs with the exception of two behind the leading one. When growing freely after flowering, apply water abundantly, and syringe them overhead on bright days. If placed in an intermediate-house and afforded a good rest during the winter months, with sunshine, no difficulty will be experienced in flowering this species of *Odontoglossum*.

Compost and Drainage.—A compost of two-quarters fibre peat, one-quarter clean chopped sphagnum-moss, one-quarter good leaf soil, well mixed together, will prove a very suitable mixture. I do not advise the use of any crocks in potting *Odontoglossums*; the rhizomes from the peat make an ideal drainage. I am firmly

convinced the introduction of rhizomes in place of crocks for drainage, is one of the greatest advances ever made in the culture of *Odontoglossums*. The pots should be filled to the extent of one-third with chopped rhizomes; do not pot too firmly, and keep the base of the plant below the level of the rim of pot. Finish the operation by inserting two or three clumps of live sphagnum-moss. I do not believe in covering the whole of the surface with sphagnum. Newly-potted plants at any season require careful watering till the growth gets advanced; it is when the plant is growing fast, and the roots are very active, they require water freely.

Thunias.—It is advisable to shake out and repot these plants annually, using a compost of fibry loam one-half, peat one-quarter, leaf-soil one-quarter, with a sprinkling of coarse silver sand, and crocks broken small. The pots should be filled to about one-third their depth full with clean crocks, and over these put some of the rougher potting material. The proper time for repotting, as with most things, is when the young growths are becoming visible. Remove most of the old roots, leaving just enough to steady the plant; pot firmly and keep the surface of the compost below the rim of the pot, making the plant secure to a neat stake. The plants will require very little water until the young growths push forth roots, when the supply may be increased. *Thunias* should be grown quickly, and have plenty of sunshine, which will cause them to flower freely and will strengthen the growths. A place in the Dendrobium-house close to the glass will suit them. I have grown them successfully, hung up close to the glass, in a Croton-house, and if the plants are started without shade, and not allowed to become dry after plenty of roots have formed, no sunshine will injuriously affect them before the middle of April.

FRUITS UNDER GLASS.

By JAMES WHYLOCK, Gardener to the DUKE OF BUCKLEUCH, Dalkeith.

Melons planted at the beginning of this month in the warmest and sunniest part of a forcing house, will require no water at the roots nor any syringing for a time, moist atmosphere sufficing for them. Melons require a heavy soil mixed with lime-rubbish, not rotten dung. Earlier sown Melons, now at the fruiting stage, may be afforded a steady bottom-heat of 85°, and a drier atmosphere about them. Pollinate the female flowers with pollen during sunshine, after making sure there is the required number of female flowers upon the plant, that they may all swell alike when the crop is set. Afford a good application of manure-water, but leave a portion round the collar of the plant 6 inches wide not watered. Melon-plants will now be showing the roots on the surface of the soil, and a top-dressing should be applied, containing a little artificial-manure, and mulch with horse-droppings. Temperature by night 70°, by day 80° to 85°.

Muscat of Alexandria Vines started at the beginning of January, being now in flower, require a night temperature of 70°, and two or three degrees warmer if the weather be mild. During the day, with sun-heat, the temperature may run up to near 90°, and keep the air of the house moist. Fresh air should be admitted in small quantities evenly over the house. Distribute the pollen by gently tapping the trellis, or drawing the hand over the bunches of flowers. Do not thin the fruit so early as Hamburgs are done, but wait until it can be seen which berries will swell kindly. Muscats throw an abundance of bunches, but for all that avoid heavy cropping. Attend frequently to the stopping and regulating; do not permit the growths to be too numerous, and in removing them do this gradually. Keep all the main foliage clean and healthy. Syringing must be discontinued whilst the Vines are in flower, but throw plenty of water about the house, occasionally using manure-water for the purpose. If the roots are at the surface,

afford one or two sprinklings of Thomson's Vine-manure on the inside border after the fruit is set, and apply water afterwards. Want of proper nourishment induces red-spider quicker than anything. Muscats require a mean temperature of 70° to 75° all through. Muscat Vines now breaking into growth will require a temperature at night of 60° or 65°, according to the state of the weather, shutting up in the afternoons with sun-heat 80° or 85°. Syringe the Vines twice daily, and by damping the paths and other surfaces keep the air moist. Young Muscat Vines coming into bearing, if progressing, will have strong wood, and will require to be kept in a temperature as low as 50°, to induce the eyes to break equally. No attempt should be made to force such Vines, whether Muscats or other variety.

Late Vineries should now be started, so that the fruit may ripen by the end of September. If there is a considerable depth of surface-soil on the border, and no roots in it, remove this and top dress with finely-chopped turfy loam, adding a spadeful each of bone-meal and Thomson's Vine-manure to every wheelbarrowful of loam. Afford the inside border a thorough application of water before applying the top-dressing.

THE HARDY FRUIT GARDEN.

By J. MAYNE, Gardener to the Hon. MARK ROLLE, Bicton, East Budleigh, Devonshire.

Bush-fruit Quarters.—The dressing of the bushes that were pruned lately should be carried out with well-decayed pig or cow-dung, and the ground lightly dug with a fork before the wind carries its manurial properties away. I have the ground dug close up to the stems of the bushes, the continual trampling on the ground when gathering the fruit making the soil quite hard. The soil round about newly-planted bushes is not touched. Bushes that are top heavy should be provided with a stout stake about 2½ feet long, 1 foot of which should stand above the soil, and to this the stem should be fastened with willow twigs or tarred string. Bush quarters dug over at an earlier date should be stirred with the flat hoe in dry weather, as should also the Raspberry quarter. Where it is the custom to lightly dig the soil between Strawberries, in order to bury the dressing of manure, the work should be carried out forthwith; and as the plants are now making growth, any withered or decayed foliage should be removed before the digging is begun. At Bicton the plants have not suffered nearly so much as in some seasons, but up to the present we have had very little east wind.

The Fruit Room.—The stock of fruits should be examined weekly, and fruits removed that show any signs of decay—and though late varieties of Pears and Apples in general are keeping well this season, there are sure to be some that are rotting. As the re-grafting of worthless varieties with better will now be in full swing, it may not be amiss to enumerate some, the good keeping qualities of which have been proved for some years past. Among desert Apples, Blenheim Orange Pippin, Adams' Pearmain, Searlet Nonpareil, King of Tompkins County, Baumann's Red Reinette, Ribston Pippin, and Sturmer Pippin, are still plump; and of culinary Apples, Bramley's Seedling, Newton Wonder, Beauty of Kent, Rymer, Wadhurst Pippin, Alfriston, Annie Elizabeth, The Sandringham, Norfolk Beefing, Tower of Glamis, Betty Geeson, and Dumelow's Seedling, are still very good.

THE FLOWER GARDEN.

By R. DAVIDSON, Gardener to EARL CADOGAN, Culford Hall, Bury St. Edmunds.

Seeds.—Numerous seeds of annuals will have to be sown during the next six weeks, most of which may be raised in cold pits furnished with moveable sashes; the varieties that are quite hardy in beds or patches in the open, in well prepared soil, sowing when the weather is fine, and the soil in a fairly dry condition.

Salpiglossis, *Phlox Drummondii*, and *Zinnias*, should be sown at about this date on a mild hot-bed, having an even covering of finely sifted soil 2 inches deep, made smooth and thoroughly moistened. The seeds should be thinly broadcasted, and covered with finely sifted soil to the depth of ¼ inch, shading the soil till germination has taken place; and the seedlings should not be allowed to flag or even become dry. With regard to *Zinnias*, when the seedlings are large enough to be pricked off, they should be placed in moderately-rich soil, singly in 60's, or three in a 48-sized pot.

Violas struck from cuttings last autumn, if hardened off, may now be planted out-of-doors where they are to flower. The soil for *Violets* should receive a dressing of charred garden refuse, as in this substance the *Violet* roots freely, makes fine large clumps in a short space of time, and if a slightly shaded position can be afforded, the flowering will be much prolonged.

Calceolarias.—These plants, if well rooted, should be transplanted to cold frames at about 5 inches apart, the soil used being loam two-thirds, spent Mushroom-dung one-third, to which some sharp sand must be added. Keep the frames close for about a week after transplanting, then expose the plants gradually to the air, and do not stint them for water when growing. Only when frost threatens is there any need to cover the frames at night.

Bedding Hyacinths.—The flower-heads have just come through the soil, and will need some sort of protection against frost, such as would be afforded by spreading cocoa-nut fibre refuse 1 inch thick over the beds, which might remain till the flowering period is over. This layer preserves the flowers from being splashed by the rain, which spoils the white and light coloured varieties.

Helleborus plants gone out of flower should be mulched with rotten manure. *Hellebores* are impatient of removal, but if additional clumps are desired, some of the larger clumps may be dug up now and divided, and the divisions planted in trenched ground in a moist, partially shaded situation. If the soil is retentive, put in plenty of drainage materials below the plants. Hybrids of *H. orientalis* now in flower should be protected from rain by means of handlights or bell-glasses.

PLANTS UNDER GLASS.

By J. C. TALLACK, Gardener to E. MILLER MUNDY, Esq., Shipley Hall, Derby.

Eucharis.—Those plants potted as recommended some few weeks back now require to have water carefully afforded, as excess at this period would be injurious to any roots that are just beginning to seize upon the new soil; and it is this which makes the repotting of healthy *Eucharis* unpopular with gardeners. Atmospheric conditions should be watched, for the hot, steamy atmosphere that some gardeners maintain and advise is bad for the new leaves, which, under such conditions are thin, and endure but badly. Shade is necessary, but it should be accompanied by sufficient ventilation. The best plants of *Eucharis grandiflora* (amazonica) I have ever grown were kept in a healthy and vigorous condition under the shade of a fan-trained Fig-tree during the greater part of the year, the abundant moisture accompanied by free ventilation necessary for the Figs suiting the *Eucharis* admirably; and these plants remained in excellent condition without spot or blemish for many years under my charge. I mention this fact, here, as showing the exact conditions I would maintain for *Eucharis* generally, which will produce abundant leaves of a leathery texture, not likely to succumb to any fluctuations to which the plants may be exposed.

Deutzias which have flowered should have much of the old wood cut hard back, in some cases almost to the level of the soil, and be placed in a forcing-house. New shoots will soon form, which will flower much better, and be more useful than the usual thicket of old wood which the plant so often presents.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER.

Letters for Publication, as well as specimens and plants for naming, should be addressed to the EDITOR, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Newspapers.—Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.

Illustrations.—The Editor will thankfully receive and select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c.; but he cannot be responsible for loss or injury.

Special Notice to Correspondents.—The Editor does not undertake to pay for any contributions or illustrations, or to return the unused communications or illustrations, unless by special arrangement.

APPOINTMENTS FOR THE ENSUING WEEK.

| | | |
|------------|---------|--|
| SUNDAY, | MAR. 23 | Exhibition of Hardy Trees and Shrubs at Boskoop. |
| TUESDAY, | MAR. 25 | Royal Horticultural Society, Committees Meeting. |
| WEDNESDAY, | MAR. 26 | Torquay Gardeners' Society Spring Show. |
| FRIDAY, | MAR. 28 | Good Friday. |

SALES FOR THE WEEK.

| | |
|----------------------|--|
| MONDAY, MAR. 24.— | Roses, Hardy Plants, &c., by Protheroe & Morris, at 12.0. |
| TUESDAY, MAR. 25.— | Collection of Orchids, by the late E. Hopper. Esq., at 67, Cheapside, by Protheroe & Morris, at 12.30.—Roses and other Plants, by Pollexfen & Co. |
| WEDNESDAY, MAR. 26.— | Azaleas, Palms, &c., by Protheroe & Morris, at 12. Odontoglossum crispum, by Protheroe & Morris, at 12.30.—Palms, Decorative Plants, Roses, &c., by Mr. J. C. Stevens, at 12.30.—Palms, Roses, Carnations, Azaleas, Rhododendrons, &c., at Stevens Rooms, at 12.30.—Roses, Bays, Palms, &c., at Pollexfen & Co.'s Rooms, at 12.30. |

(For further particulars see our Advertisement columns.)

AVERAGE TEMPERATURE for the ensuing week, deduced from Observations of Forty-three Years at Chiswick —42°.

ACTUAL TEMPERATURES:—

LONDON.—March 19 (6 P.M.): Max. 59°; Min. 44°.
March 20.—Rainy, colder.

PROVINCES.—March 19 (6 P.M.): Max. 51°, S. Midlands; Min. 39°, Orkneys.

The Horticultural Hall. BEFORE this issue can reach the reader's hands, it is probable that the Horticultural Hall scheme—if associated with a great International Exhibition, so much the better—will have been accepted, rejected, or its consideration postponed. We have already laid before our readers the reasons why, in our opinion, it should be accepted. We have reason to know that the advisory committee, presided over by Baron SCHRÖDER, and comprising several members of the Council, was unanimous in its recommendation of the site in Vincent Square, as the most suitable locality for the erection of the proposed Hall. Postponement would be highly inconvenient—perhaps fatal; rejection seems to us, in the circumstances, scarcely possible.

The only alternative scheme, so far as we know, is the formation of a new garden. The very formidable objections to such garden-schemes as were formulated last year need not be repeated. They remain in full force.

A properly-equipped research-garden, or experimental-station, directed by a scientific investigator, such as may be counted by the score in the United States and Germany, is quite another matter. This need not interfere with the present garden operations. But it will be time to consider these matters when the question at present before the Fellows is settled. One thing at a time.

THE PROPOSED HALL.—As it is the unexpected that frequently happens, any scheme that be submitted by the Council should have the fullest discussion, even if more than one meeting be necessary. Moreover, Fellows resident some distance from London should have an opportunity of expressing their opinions. We as fully appreciate the importance of the Society having a suitable building in which to conduct its business, house the magnificent library under its charge, and hold its meetings and minor exhibitions, as the most strenuous advocate of a horticultural hall; but we are extremely anxious that the Society should not be crushed by bricks and mortar, or be so crippled as to be unable to maintain an experimental garden in a full state of efficiency. *Gardeners' Magazine*.

—We found the place without the slightest difficulty, and discovered that all that had been said in favour of the site was no elaboration, and that the place is, in the highest sense, eminently satisfactory. The corner of Bell Street proposed to be rented for the hall, seems to be at present a goodly sized garden belonging to a villa standing alone. Being walled-in, the space cannot be seen from the street. It is a most convenient position, however, and is exactly at the corner where Bell Street meets Vincent Square Road at right angles. Vincent Square, by the way, is really a ten acre green grass park or playing-field, used by the boys of Westminster School. Thus, right in front, there is ample freedom and a pleasant survey. Bell Street, at present, is composed of low-roofed houses, and tenanted by labouring people, but the whole neighbourhood is highly respectable even now, and is yearly being remodelled into one where handsome residential flats, churches, and such other buildings form the composition.

Fellows of the Society who desire to see the ground and its surroundings before voting at the meeting on the 21st, can do so by a three-minutes' walk from the present exhibition hall in Buckingham Gate. Cross into Artillery Row (which is exactly opposite Buckingham Gate), and at the bottom of the street bear round to the left behind the Army and Navy Stores, where there is a wide, open, paved space. Here take the right hand and cross into Greycoat Street, on the left, this leading into Bell Street, at the end of which the site lies. The whole distance is not more than 400 yards.

It is earnestly hoped that Fellows who support the proposed new Hall movement will be forward at the meeting in the Drill Hall at 3 o'clock, and that at last the Society will sign its intentions to take the necessary steps towards the erection of a suitable edifice for its floral exhibitions, its library, offices, lecture-hall, and council chamber. £5,000 have already been promised, and at least another £5,000 can be expected by an appeal to the 5,500 Fellows, without touching the standing funds of the Society at all. The expenditure of £750 a year extra on ground-rent for the proposed Hall is a mere bagatelle in face of the constant accession of Fellows, and also in view of the likely attractions of such a Hall. *Journal of Horticulture*.

THE ROYAL HORTICULTURAL SOCIETY'S COMMITTEES, will meet on Tuesday next, March 25, in the Drill Hall, Buckingham Gate, Westminster. A lecture on "The Defence of Plants," will be given by Professor CARR, at 3 p.m.
